Preface

Since the first EcoDesign International Symposium held in 1999, this symposium has led the research and practices of environmentally conscious design of products, services, manufacturing systems, supply chain, consumption, as well as economics and society. EcoDesign 2011 — the 7th International Symposium on Environmentally Conscious Design and Inverse Manufacturing — is successfully held in the Japanese old capital city of Kyoto, on November 30th - December 2nd, 2011. The subtitle of EcoDesign 2011 is set to “design for value innovation towards sustainable society.” This subtitle indicates that, in EcoDesign 2011, we discuss the way to achieve both drastic environmental consciousness and value innovation in order to realize a sustainable society.

Over 300 abstracts were submitted to EcoDesign 2011 from 30 countries and regions all over the world. It indicates the further increase of the demands and interests in the topics of this symposium. In recent years, it is more and more demanded for academia, industries and governments to act globally and internationally. We expect that EcoDesign2011 provides a distinguished occasion to discuss the topics with people from various backgrounds.

In EcoDesign 2011, we have papers on the latest topics of EcoDesign such as of social perspectives in EcoDesign, business aspects of EcoDesign, user behaviour studies, and so on. As plenary keynote speakers, we have distinguished speakers from AIST, an organizer research institute, and three global leading companies — Panasonic, Siemens, and Kone. It is our great pleasure and honor to have such great plenary presenters and paper presenters from all over the world.

We would like to express our sincere appreciation to all contributors to the proceedings. We also would like to extend our thanks to the members of the executive committee for their efforts to arranging the conference and this proceedings book available to the public.

Yasushi Umeda, Executive Committee Chair of EcoDesign2011

Panasonic's Environmental Vision and its Practices

Machiko Miyai
Panasonic Corporation

Abstract
There needs a shift of perspective on how businesses think about performance, which make us emphasize on environmental targets as much as conventional sales and profit. Panasonic has decided its corporate vision to be the 'No.1 Green Innovation Company in the Electronics Industry' in 2018. Where, aiming at 'integrating contributing to the environment and attaining business growth,' the group-wide initiatives with two major pillars of CO_2 reduction and resources recycling are promoted as a part of environmental management. Energy and material efficiencies are key strategies for a manufacturing industry, and we practice in pursuit of them throughout all our business activities.

Keywords:
Environmental vision, green innovation company, energy solution, resources recycling

1 INTRODUCTION

Going green is now a must for survival in general. In businesses, a serious consideration on the environment should take first-class priority at every activity including non-manufacturing processes. There needs a shift of perspective on how businesses think about performance, which make us emphasize on environmental targets as much as conventional sales and profit.

For Panasonic, it directly means reducing environmental impact like CO_2 emissions and improving productivity in all business activities such as designing products, production, sales, service, etc. At the same time, we must be encouraging resources recycling in the manufacturing system and a green culture amongst our employees.

This paper describes Panasonic's environmental vision for the 'No.1 Green Innovation Company in the Electronics Industry' in 2018 and its practices in particular two major initiatives of CO_2 reduction and resources recycling.

2 ENVIRONMENTAL VISION OF PANASONIC

2.1 To be the 'No.1 Green Innovation Company'

Panasonic was established in 1918 by the founder, Mr Kounosuke Matsushita, and reaches the 100th anniversary of its founding in 2018. Looking to this memorial year, we have decided our corporate vision to be the 'No.1 Green Innovation Company in the Electronics Industry.' The main concept is 'the more our business grows, the better the global environment becomes,' in other words, 'the integration of our contribution to the environment and business growth.' Therefore the vision toward the 100th anniversary of founding indivisibly incorporates a couple of environmental initiatives, and our environmental vision can be understood as the same as the corporate vision.

There are two criteria to manage the performances in pursuit of the vision. One is to 'Always meet Global Excellence Indexes,' which is related to financial aspects like sales and profit. And the other is the 'No.1 in Green Indexes,' which is on our environmental initiatives such as; contribution to CO_2 reduction and resources recycling, expansion of energy systems business, and increase in a percentage of sales for No.1 environmentally conscious products. As we simultaneously pursue such Indexes designated in both criteria, we aim to integrate our contribution to the environment and business growth throughout the entire company group.

With this ambitious concept Panasonic will make the 'environment' central to all of our business activities with a firm attitude which allows for no exceptions.

Table 1: Green Targets in GP2018

CO_2 Reduction	Make net CO_2 emissions peak and decline thereafter
Resources Recycling	Pursue recycling-oriented manufacturing to make the best use of resources
Water	Minimize the amount of net water consumption
Chemical Substances	Minimize environmental impact caused by chemical substances
Biodiversity	Identify impact on biodiversity and contribute to conservation
Increase the percentage of No.1 environmentally conscious product sales to 30% (Double fiscal 2010 level)	
Increase environmental contribution through collaboration with stakeholders	

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_1,

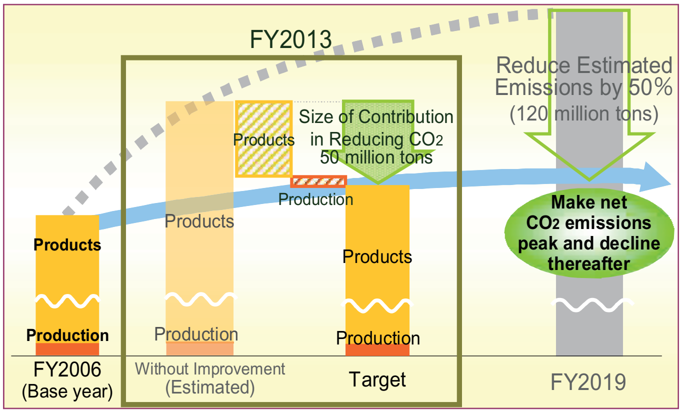

Fig. 1: Breakdown of CO2 Reduction

2.2 Action plan 'GP2018'

To promote the environmental initiatives throughout our business domains, the action plan named 'Green Plan 2018 (GP2018)' was developed as shown in Table 1. We also announced a midterm management plan including several green targets to be achieved by 2012 [1]. Where, aiming at 'integrating contributing to the environment and attaining business growth,' the group-wide initiatives with two major pillars of CO_2 reduction and resources recycling are promoted as a part of environmental management.

3 PRACTICES FOR CO_2 REDUCTION

3.1 Energy saving in production activities

Panasonic decided to make a contribution of reducing CO_2 emissions by 50 million tons in FY2013 in the midterm management plan. The contribution includes the reduction achieved through the use of our products, and the breakdown of it is shown in Figure 1. A rationalized index was also developed to quantify the efforts for reduction of CO_2 emissions according to the midterm management target [1].

Improving productivity makes CO_2 emissions reduce. In other words, every action for energy saving can contribute to both the CO_2 reduction and the productivity improvement as it directly leads to cost reduction and strengthened manufacturing structure. Therefore, we already incorporated CO_2 reduction as one of key management indicators for our manufacturing sites, and this then requires each site to make a positive investment to promote energy saving.

Some concrete activities promoted at our production sites include the implementation of instruments to visualize energy consumption of each production equipment and reduction effect of measures. We already introduced more than 40,000 measurement systems in all of our global manufacturing sites. This initiative enables us to drastically reduce energy wastage. We also conduct energy conservation diagnosis for factories, where internal experts review the manufacturing processes and propose concrete reduction measures at production frontlines. In addition, we share information on excellent reduction activities among our companies via the intranet. As a result of these, in three years from FY2008 to FY2010 we achieved 840,000 tons CO_2 reduction from the base.

3.2 Promoting energy efficient products

To complete the CO_2 reduction target, the improvement of each product's energy efficiency places a very significant position. Compared to our 1990 models, the amounts of annual power consumption of the latest models have been reduced by from 50% to 80% respectively. Also we have a group of representative products incorporating our unique sensor technology for further energy saving. Now, Panasonic is actively working to increase the number of industry-leading energy efficient products.

Penetrating such energy efficient products into the world-wide markets is also important for improving the energy efficiency of whole societies. In this context, global harmonization of rules and conditions to measure the performance of equipment accurately is valuable, and it is really effective for everyone to evaluate the worth of energy efficient products. Panasonic is, therefore, contributing to establish the international standards for products, too.

3.3 Expanding energy solution businesses

As well as energy saving by a wide range of energy efficient home appliances, frontier equipments for energy creation such as solar panels and fuel cells, and novel devices for energy storage such as lithium ion rechargeable batteries are key products to solve energy problems. Panasonic also offers energy management tools which connect them all in order to carry out optimal control. Demonstration of a lifestyle with net zero CO_2 emissions in a whole house including house structure by saving, creating and storing energy and linking its devices and appliances through networking technology is available at our 'eco ideas' House in Tokyo [2].

Furthermore, the system will be extended to community and city levels. Table 2 shows one example, 'Fujisawa Sustainable Smart Town (SST)' project [3]. Fujisawa is a city located at 45km south of Tokyo, and this is the first

Table 2: Project Overview of Fujisawa SST

Development Location	Tsujido-motomachi, Fujisawa City, Kanagawa Prefecture
Land Area	Approximately 19 ha
Planned Land Use	Approximately 1,000 residential homes / commercial facilities / public facilities
Planned Population	3,000 people (1,000 households)
Schedule	Open the town in the fiscal year ending March 2014
Total Project Cost	Approximately 60 billion yen

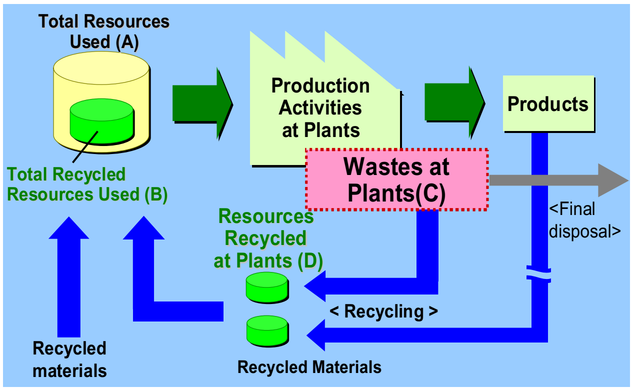

Fig. 3: Recycling-oriented Manufacturing System

smart city project for Panasonic to practically introduce comprehensive energy solutions for homes, buildings and communities. Specifically, we plan to preinstall its solar power generation systems and home-use storage battery systems across the town, including homes, various facilities and public zones. We will be looking at ways to overcome the challenges of adapting such energy solutions with the hope to develop it into a model smart city that can be replicated in other parts of Japan and overseas.

4 PRACTICES FOR RESOURCES RECYCLING

4.1 Promoting recycling-oriented manufacturing

Another major issue in Panasonic's environmental contribution is a concern for resources recycling through 'Recycling-oriented Manufacturing.' To reduce the total amount of resources used, the first task is to downsize our products and minimize the amount of resources needed for each. Then, we must make full use of all the resources that have been fed into our production activities.

In order to make the best use of resources, minimizing the total resources used and maximizing the recycled resources are required while pursuing zero wastes at plants as explained in Figure 3. In the illustration, we aim to increase the ratio of the total recycled resources used to the total resources used (B/A), to more than 16% in 2018. In pursuing zero emissions at plants, we also aim to increase the ratio of resources recycled at plants to wastes produced at plants (D/C), to as much as 99.5% or more at the same time.

4.2 Development of recycled materials using products

Furthermore, by working on 3R (reduce, reuse and recycle) design and by developing new recycling technology, we aim to contribute to improving the efficiency of resources recycling throughout all of society. In the midterm management plan, through company wide collaboration we will make our utmost efforts to improve on all these aspects starting from the design stage on through the entire manufacturing process.

'From product to product' is a key concept of our recycling system. These are some examples of recycled materials using product parts developed in Panasonic. Specifically with regard to air conditioners, copper and aluminum from old heat exchangers are recycled into new heat exchangers. As for TVs, CRT glass is recycled, too. On refrigerators and washing machines, we recycle the plastics from old products to new products, and now are challenging the development of technologies to further increase of their use. We are now considering a new trial about using recycled materials more actively and broadly in our new products. This movement will be bringing a great progress in our environmental vision with the perspective over resources recycling.

5 SUMMARY

This paper summarized Panasonic's environmental vision for the 'No.1 Green Innovation Company in the Electronics Industry' in 2018 and its practices in particular two major initiatives of CO_2 reduction and resources recycling. We believe that energy and material efficiencies are key strategies for the manufacturing industry, and Panasonic will pursue them to achieve our ambitious vision towards 2018.

KONE's Corporate Environmental Activities and Solutions that Contribute to Creating a Positive Impact on the Environment

Hanna Uusitalo
KONE Corporation, Hyvinkää, Finland

Abstract
The direction and shape of the global elevator and escalator industry are driven by four megatrends : urbanization, changing demographics, the increasing importance of safety, and concern for the environment. This paper explains how KONE contributes to sustainable urban development by developing energy efficient solutions that move people smoothly and safely in urban environments.

Keywords:
urbanization, eco-efficiency, sustainability, energy efficiency, elevator, escalator, LCA, EPD

1 SUSTAINABLE URBANIZATION

Buildings consume approximately 40 percent of the world's energy, and elevators and escalators can account between two and 10 percent of the energy consumption of an individual building. The elevator and escalator industry can play a vital role in helping to counter climate change and its negative effects by providing innovative solutions that help to reduce the energy consumption of buildings.

The growth of urban areas is most evident in Asia, where the long-term population growth and migration from rural communities is expected to continue. China, already the world's largest urban nation, is likely see the addition of 350 million people to its urban population by 2025 to reach a total of nearly one billion.

KONE is ready to meet the challenge this presents to the entire building industry. Through global processes combined with a strong local presence in over 1000 locations around the world, KONE is well-positioned to contribute to the different phases of urbanization with a local touch. Building urban areas where people can move around smoothly and safely supports the sustainable development of economies around the world.

2 ENERGY EFFICIENCY, GREEN AND NET ZERO ENERGY BUILDINGS

Since its launch in 1996, the KONE MonoSpace® elevator, powered by the EcoDisc® hoisting technology, has saved an amount of electricity equivalent to that produced by a 400 MW power plant, which is equivalent to:

- The consumption of three million barrels of oil, or
- The CO_2 emissions of 160,000 cars driving once around the world

The biggest environmental impacts created by elevators and escalators relate to the amount of electricity used by the equipment during its lifetime. This underlines the importance of continuing to develop and improve energy efficient innovations for elevators and escalators.

KONE's expertise in eco-efficiency enables us to perform in-depth analyses of traffic patterns, energy consumption, and the potential carbon footprint reduction over the entire operational lifespan of the solutions. The tools used to conduct these analyses are particularly valuable in helping to plan for net zero energy buildings and comply with green building requirements.

KONE actively follows the latest green building and energy efficiency trends related to elevators through its involvement in the working groups that are defining the new ISO 25745 (Energy Performance of Lifts and Escalators) standard, development of parts two and three of the VDI 4707 guidelines (German Elevator Energy Efficiency Performance Guideline), as well as through its involvement with green building associations. KONE also actively participates in the development of international energy measurement standards.

KONE's environmental product declarations (EPDs) provide comprehensive information about the environmental impacts of its products, such as the CO_2 emissions produced and the materials used during both the production and operation of KONE elevators and escalators.

In 2010 KONE became the first company in the elevator and escalator industry to achieve the VDI 4707 guideline A-class rating for its European and Asian volume elevators. Both KONE MonoSpace® and KONE MiniSpace™ have reached the A-class rating.

3 LIFE CYCLE VIEW

KONE is committed to its products throughout their lifecycle, from design and manufacturing to maintenance and modernization.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_2,

KONE's life cycle assessment (LCA), carried out in accordance with the ISO 14040 standard, covers the essential environmental aspects at different stages of the product's lifetime from raw material production, component manufacturing, transportation, installation, use, and maintenance to end-of-life treatment. According to the assessment, our environmental impact excludes acidification (9.79E 05 per functional unit), eutrophication (0.011 per functional unit), ozone depletion (1.04E 08), water withdrawal, noise pollution, and impact on biodiversity.

A life cycle assessment has been conducted on all KONE volume elevators and escalators.

The life cycle assessment shows that our greatest environmental impact stems from the energy consumed by our products during their operational lifetime. Electricity production has a large environmental impact because it is carbon intensive and often relies on fossil fuels, particularly natural gas and crude oil. Energy production also results in atmospheric emissions, which include particulates, carbon dioxide (CO_2), nitrogen oxide (NO_X), and sulfur oxide (SO_X).

3.1 Life cycle assessment of an elevator

The assessment is based on the KONE MonoSpace® elevator, with a load range of 320–1000 kg, an estimated lifetime of 25 years, and a frequency of 150,000 starts per year traveling between five floors. The KONE MonoSpace represents more than two-thirds of all elevators ordered from KONE in 2010.

About 75 percent of carbon dioxide (CO_2) emissions, 51 percent of nitrogen oxide (NO_X) emissions, and 57 percent of sulfur oxide (SO_X) emissions are generated during the use stage. By comparison, material production accounts for 14 percent of the total carbon dioxide emissions, while component manufacturing accounts for six percent. About 90 percent of the total primary energy is consumed during the use stage.

3.2 Life cycle assessment of an escalator

The assessment is based on the KONE TravelMaster™ 110 escalator, with an equivalent step load of 25 kg and estimated lifetime of 15 years, operating 14 hours per day, 6 days per week, 52 weeks per year.

About 91 percent of CO_2 emissions, 91 percent of NO_X emissions, and 86 percent of SO_X emissions are generated during the use stage. By comparison, during material production CO_2 emissions are seven percent, while component manufacturing accounts for one percent. About 90 percent of total primary energy is consumed during the operational stage.

3.3 Monitoring and managing the environmental impact of products

As well as carefully measuring the environmental impact of products during their production and operational life span, it is also important to consider what happens to them when they reach the end of their use. The majority of the materials that make up an elevator or escalator's weight can be directly reused or recycled. KONE acts safely, responsibly, and in accordance with the relevant regulations in relation to the collection and processing of electro-mechanical waste from its products. Wherever possible, KONE aims to reduce or eliminate the need to use hazardous materials in the manufacture of its products.

3.4 Use of highly recyclable materials

At the end of its life cycle, approximately 55 percent of the material weight .of a dismantled elevator can be sorted and reused without pre-processing. The metals that make up approximately 93 percent of an elevator and 91percent of an escalator's material weight are fully recyclable, providing a clear reduction in environmental impact by reducing the demand for primary metals as raw materials. Plastics are used for energy recovery or landfilled. Packaging for our products includes wood (77 percent), cardboard and paper (11 percent), plywood (nine percent), and plastics (three percent).

These materials can be recycled or used for energy recovery. KONE focuses on using wood, cardboard, and paper materials from sustainable sources and provides customers with origin of wood certificates upon request depending on availability.

4 SUSTAINABLE SOLUTIONS

4.1 Eco-efficiency drives the solution creation process

Eco-efficiency is one of the key drivers of our solution creation process and is at the heart of the entire KONE offering, from low-rise and high-rise elevators to escalator and door solutions. When we develop new solutions, the focus is on minimizing environmental impact throughout the lifespan of the equipment, beginning with the extraction of raw materials and ending with recycling, waste treatment, and the reuse of recovered materials.

4.2 Aims of solution creation

In our solution creation, we aim to:

- Reduce energy consumption
- Reduce material use (including packaging and waste)
- Avoid the use of hazardous substances
- Maximize material durability and recycled content
- Maximize recyclability
- Ensure that our products meet voluntary green building certification requirements
- Minimize water consumption

Every solution creation project at KONE must follow detailed eco-efficiency criteria, verified using prototypes and pilots, with a special focus on minimizing energy consumption. In terms of product management, every new change to a product is evaluated against the existing solution to verify that the new solution delivers improved performance in terms of minimized impact on the environment.

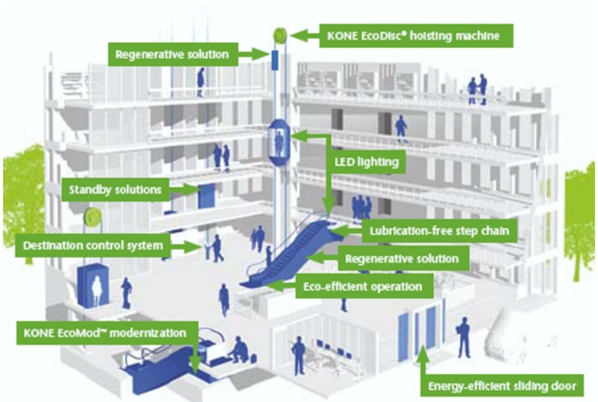

Fig 1: Eco-efficient solutions

4.3 Eco-efficient solutions for elevators

- Elevators equipped with the energy-efficient KONE EcoDisc® hoisting machine are 50–70% more efficient than elevators that use conventional traction 2-speed or hydraulic technology.
- Unlike hydraulic elevators, the KONE EcoDisc® requires no oil or hole drilling.
- KONE's regenerative solutions can provide 20–35% energy savings by recovering the energy created when the elevator is used.
- LED and eco-efficient fluorescent lighting can reduce energy consumption by up to 80% compared to halogen lights.
- Standby solutions power down the equipment when it is not in use, providing substantial energy savings, especially in buildings with periods of low elevator usage.
- The KONE Polaris™ destination control system optimizes elevator traffic, making it possible to reduce the size and number of elevators needed in the building.

4.4 Eco-efficient solutions for escalators

- The lubrication-free step chain saves oil, reduces chain wear, and decreases fire risk.
- Eco-efficient operation can save up to 50% energy by slowing down or stopping the escalator when it is not in use or increasing the efficiency of the motor when traffic is low.
- Regenerative solutions reduce energy consumption by up to 60% by recovering the energy created when the escalator is used.
- LED lighting consumes up to 80% less energy compared to conventional lighting technologies.
- The KONE EcoMod™ solution enables escalator modernization without removing the truss, saving construction time and materials.

4.5 Eco-efficient solutions for building doors

KONE's energy-efficient sliding door solution regulates the door's opening width and opening time based on the outside temperature, providing savings of up to 4000 kWh per year in building heating and cooling costs.

5 ENVIRONMENTAL RESPONSIBILITY IN KONE OPERATIONS

According to KONE's environmental statement, we provide safe, environmentally efficient, and responsible high-performance services, modernizations, and solutions. We strive for continuous improvement in all our business activities by following or exceeding applicable laws, rules, and regulations, and we work with our suppliers and customers to prevent or reduce emissions and waste generated by our business operations.

5.1 Environmental impact of KONE operations in 2010

According to the 2010 assessment, KONE's global greenhouse gas emissions amounted to 3.0 (2009: 2.9) M tCO_2e (million tonnes of carbon dioxide equivalent), of which 21 percent were generated by the production of materials used to manufacture our products, and another 71 percent by the production of electricity used to operate them over their lifetime.

The carbon footprint analysis reveals that less than one tenth of KONE's emissions are a direct result of its operations. In 2010, KONE's operational carbon footprint relative to overall operations (net sales) decreased by two percent compared to 2009. KONE's 2010 absolute operational carbon footprint amounted to 231K tCO_2e (tonnes of carbon dioxide equivalent), representing a three percent increase compared to the 2009 figure of 223K tCO_2e.

With 90K (2009: 92K) tCO_2e in 2010, the major source of carbon emissions continued to be our maintenance vehicle fleet, which is used by our service technicians.

The other major components are our logistics network with 76K (71K) tCO_2e, electricity consumption with 27K (27K) tCO2e, business travel with 22K (16K) tCO_2e, and fuels for heating and processes in buildings with 16K (17K) tCO_2e.

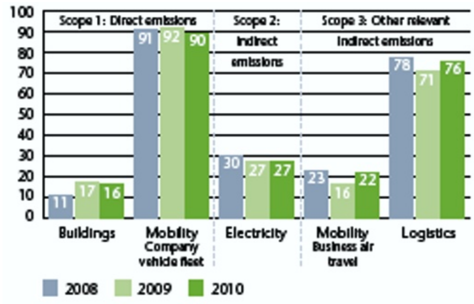

Fig 2: Absolute operational carbon footprint per category, $KtCO_2e$

5.2 Reduction of relative carbon footprint in 2010

In 2010, KONE achieved a two percent carbon footprint reduction relative to net sales compared to the base year of 2009. KONE's absolute operational carbon footprint for 2010 increased by three percent compared to 2009. The increase was partly due to the extension of the reporting scope to cover spare parts logistics and local logistics in countries, as well as increased production volumes. The best results were achieved by our maintenance car fleet, which achieved a 4.6 percent reduction of carbon emissions per unit of equipment under KONE's maintenance, compared to its target of five percent.

In 2010, all KONE's corporate functions and all production units were ISO 14001 and ISO 9001 certified. In 2009, 10 country organizations were certified, and in 2010 one more country organization was certified. The focus for the future is to maintain the achieved certificates and increase the number of certified country organizations. In 2011, two more country organizations are expected to receive certification.

In terms of supplier certification, 98 percent of KONE's strategic suppliers met ISO 14001 requirements by the end of 2010, and work to achieve certification for one remaining strategic supplier is due to be completed during 2011.

5.3 Vehicle fleet actions

Altogether, 39 percent of KONE's operationalgreenhouse gases are emitted by our global vehicle fleet, making it clearly the biggest contributor in terms of CO_2e. In 2010 our fleet consisted of 14,000 (2009: 13,300) vehicles emitting 90K (2009: 92K) tCO_2e. The absolute vehicle fleet carbon footprint decreased by two percent, whereas the relative carbon footprint (per unit in service) reduction was 4.6 percent.

Project O_2xygen was launched in 2008 with the aim of reducing the CO_2e generated by our global vehicle fleet. To help achieve this objective, we have implemented a renewed global fleet policy, improved our vehicle selection lists, and launched the new eco-safe driving program. Although Project O_2xygen concluded in 2009, we are continuing our efforts to further reduce CO_2e and make KONE's vehicle fleet as efficient and eco-friendly as possible through actions such as vehicle rightsizing, a call-out rate reduction program, using route optimization technology, and using alternative fuels that generate lower CO_2 emissions.

5.4 Logistics

Logistics account for 76K (2009: 71K) tCO_2e, or 33 percent of KONE's operational carbon footprint, making it the second biggest contributor after the vehicle fleet in terms of tCO_2e emissions.

The logistics carbon footprint relative to units delivered to customers rose by two percent, and the absolute CO_2 increase was seven percent. The increase was mainly a result of increased production volumes. The increasing focus on the Asian market also had an impact on the carbon footprint development. For 2010, the reporting scope has been extended to cover spare parts logistics, with the exception of shipment by air.

KONE's logistics operations are based on accurate, reliable, and timely information in all phases of the delivery chain, and using distribution models that take eco-efficiency into account. Special attention is paid to reducing the impact of transportation through route and shipment optimization, as well as careful analysis of alternative transportation models. The impact of packaging is managed by using environmentally conscious packaging design, for example, and this applies to both our own packaging and that used by our suppliers.

5.5 Electricity

Electricity consumption accounts for 27K (2009:27K) tCO_2e, or 12 percent of KONE's carbon footprint. The carbon footprint resulting from the use of electricity comprises both electricity consumption and the carbon intensity of electricity production. The electricity is used in KONE's offices, warehouses, and production facilities. Electricity consumption remained at the 2010 level despite the increase in production volumes. In fact, due to the six percent increase in the amount of green electricity used compared to 2009, KONE was able to reduce the greenhouse gas (GHG) emissions generated by the electricity it uses. In total, 11 (2009: 12) percent of the electricity used in our operations comes from renewable sources.

KONE's key country organizations have committed to specific energy consumption and electricity saving programs. For example, KONE's Finnish country organization is aiming to reduce electricity consumption at its facilities by nine percent by 2016, using 2008 as the base year. In turn, KONE's German country organization has signed a 100 percent renewable energy contract with its energy supplier. Our Italian production unit also uses renewable energy; together with other energy saving actions, this resulted in a 35 percent decrease in the factory's carbon footprint in 2010.

5.6 Business air travel

Business air travel accounts for nine percent of KONE's carbon footprint. In 2010 air travel related GHG emissions increased by 36 percent to total 22K (2009: 16K) tCO2e. The relative increase was 37 percent.

KONE actively encourages the use of virtual meeting tools in order to reduce the need for travel. In 2010 virtual meeting time again increased by 40 percent.

KONE also added video conferencing to its set of virtual tools in order to further facilitate global collaboration and decrease the need for travel.

5.7 Fuels for heating and processes in buildings

In 2010 fuels for heating and building processes generated 16K (2009: 17K) tCO2e of GHG emissions. This represents a decrease of seven percent compared to 2009. The reduction was achieved through an increased daily management focus on facility-related environmental issues.

5.8 Highlights of environmental achievements in KONE manufacturing units in 2010

Italy:

- Waste -20%
- Wood waste -37%
- Energy saved with photovoltaic system 4% (Cadrezzate)
- Water -5% (Pero)

Finland:

- Incoming waste -19%
- Scrap steel -24%

China:

- Oil -5% per unit
- Water -33% per unit
- Electricity -18% per unit
- Hazardous waste -44%
- Paper -21% per unit

Czech Republic:

- Water -14 %
- Thermal energy -14 %
- Metal scrap -17%

Mexico:

- Water -5%
- Wood pallet -12%

United States:

- Electricity -20% per unit
- Waste -45%

6 ENVIRONMENTAL TARGETS FOR 2013

KONE's long-term environmental objectives are to further improve the eco-efficiency of solutions, modernize existing elevators and escalators to make them more energy-efficient, and to further reduce the environmental impact of our operations, particularly our operational carbon footprint.

In 2011 KONE set new environmental targets for 2013. We will continue to improve the energy efficiency of our elevator and escalator solutions, and focus on reducing the carbon emissions generated by our operations. The target is to reduce our operational carbon footprint relative to net sales by three percent annually between 2011 and 2013.

By 2013 KONE aims to maintain and extend OneISO (ISO 14001 and ISO 9001) coverage, and continue to contribute to green building requirements. Wherever possible, LEED principles will be implemented at new KONE facilities. In addition, KONE will continue to focus on the sustainability of its delivery chain by ensuring that all strategic suppliers fulfill the requirements of an ISO 14001-certified environmental management system.

New Trends in Ecodesign

Dr. Wolfgang Bloch [1], Dr. Ferdinand Quella [1]
[1] Siemens AG, Corporate Environmental Protection, Munich, Germany

Abstract
Over the last several years the focus on eocdesign moved away from the design of components or simple products only towards the design of systems. Especially the European product-related legislation, e.g. WEEE, RoHS, ErP and REACh, became a major driving force for integrating new design aspects like energy efficiency, materials and resource efficiency and design principles for recycling into the product design process. Standardization of design principles helps companies to meet internationally introduced regulatory requirements. In addition ecodesign principles are extended to the design of manufacturing sites and include the complete supply chain.

Keywords:
Ecodesign principles, European legislation, WEEE, RoHS, ErP, REACh

1 INTRODUCTION

Environmental European legislation has a high priority for the European, mainly in the area regulating product related topics. This is due to the fact that product related topics have to harmonized within the European economic framework and was not specifically regulated by individual countries until now. Having this in mind we can understand how and why topics like e.g. recycling, energy use and critical substances regulations were introduced to the European market.

In general the regulative environment is changing consequently the meet higher expectations of interested parties like NGO's:

- Number of regulations are worldwide increasing, setting minimum requirements
- More political reduction targets are visible
- Automatisms like increasing targets with time are foreseen in latest legislation, but also „toprunner" approach leads to continuous progress
- Numbers of environmentally compatible products are increasing worldwide and companies show the progress
- Basic tools are now available like ecodesign standards and materials record as basis for LCA, ISO 14006 (2011?) will publish missing „Guidelines for incorporating ecodesign into environmental management systems"
- Further standardization / provision of data is required

In parallel the design principles for developing more environmental conscious products changed from a more simple approach of designing components or products only to a more holistic approach of designing complex systems. The extension to plants as a possible next step to create higher reduction potentials is already in front of us.

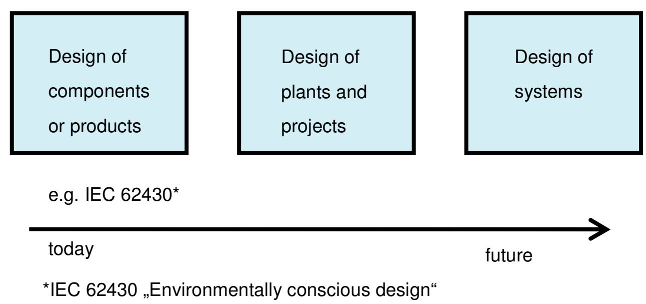

Fig. 1: Extension of Ecodesign scope in the last years

The extension of ecodesign principles for plants may include the following aspects [1]:

- LCA over the complete life cycle, Total cost of Ownership (TOC approach)
- Identify energy consumption drivers: ovens, fans, heating, cooling, energy intensive processes
- Apply already existing environmentally compatible components (purchasing dpt)
- Check software for energy consumption
- Identify local environmental regulations
- Energy reuse, avoid losses, stand-by
- Packaging and transport
- EHS concept for installation, take back and recycling
- Take back, re-use and recycling for manufacturing materials and equipment.

DOI 10.1007/978-94-007-3010-6_3, © Springer Science+Business Media Dordrecht 2012

2 EUROPEAN P RODUCT-RELATED LEGISLA-TION

2.1 Energy related Products Directive

By implementing climate mitigation measures to meet the politically given targets of the Kyoto Protocol the European Commission became aware that by setting emission reduction targets for the "energy intensive industries" only we will not meet the reduction targets. Consequently they introduced a legislation framework to reduce the energy consumption during the use phase of electrical energy using products. A set of "Implementing Measures" was defined together with the industries respectively. The already agreed "Implementing Measures" are listed below:

- Standby and off mode losses of EEE
- Simple set top boxes
- Domestic lighting
- Tertiary sector lighting (office and street)
- External power supplies
- Televisions
- Electric motors
- Circulators
- Domestic refrigeration and dishwashers
- Domestic washing machines
- Fans (motor driven with an electric input power between 125-500 W).

The lasted development regarding this legislation is the extension towards "Energy related Products", like

- Local room heating products
- Central heating products using hot air to distribute heat (other than Central Heating Products)
- Domestic and commercial ovens (electric, gas, microwave), including when incorporated in cookers
- Domestic and commercial hobs and grills
- Professional washing machines, dryers and dishwashers
- Non-tertiary coffee machines
- Networked standby losses of Energy using Products,

but the new view in terms of introducing ecodesign targets, the EU demands by means of **Corporate Social Responsibility** and **Sustainability** higher energy efficiency from manufacturers as well.

One demand in the EU IPP Communication (COM(2003) 302) is a decoupling of energy consumption from economic growth, first target -20 % energy consumption. Decoupling indicators could be: Resource productivity, energy efficiency, resource specific impact.

In general this can only be achieved if…

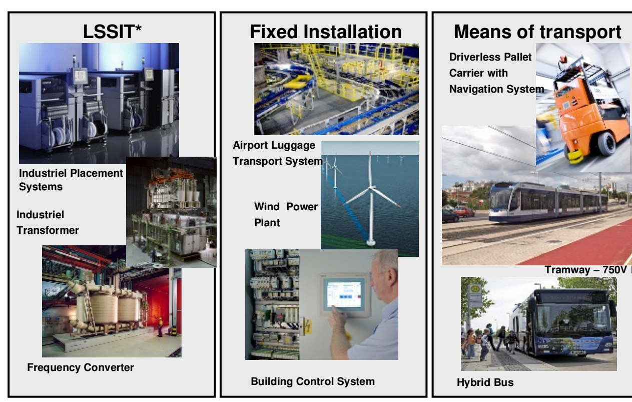
- the quantity of energy consumed by the total volume of products of one kind in the market is estimated and the reduction target is broken down to the next ecodesign process of these products and
- this can go beyond the „toprunner" approach and will be more eager.

2.2 Restriction of Hazardous Substance Directive

The RoHS-Directive (Restriction of Hazardous Substance Directive) was introduced to the market to ensure that all Electical and electronical equipment in scope do not contain certain hazardous substance:

- As of July 1st 2006, the RoHS-Directive restricts the use of Lead, Cadmium, hexavalent chromium compounds, Mercury and polybrominated biphenyls (PBB) and polybrominated diphenylethers (PBDE)
- A maximum concentration value (MCV) of 0.1% by weight in homogeneous material for PB, Cr(VI), Hg, PBB and PBDE resp.
- MCV of 0.01% weight in homogeneous materials for Cd is tolerated.

The actually controversy discussed topics are the changes of the scope of the directive, the review mechanism for all RoHS exemptions and the extension towards new substances. Latest in 2019, the EU Commission will introduce an open scope for all elevtical and electronical equipments. Important is the definition of "**electrical and electronic equipment**" which means equipment which is dependent on electric currents or electromagnetic fields in order to work properly and equipment for the generation, transfer and measurement of such currents and fields and designed for use with a voltage rating not exceeding 1000 volts for alternating current and 1500 volts for direct current.



*Large Scale Stationary Industrial Tools

Fig. 2: Scope exclusions for RoHS are necessary for industry and were supported by Trade Associations

Common efforts by trade associations resulted in a RoHS Recast compromise considering several important topics for Industry. Positively we achieved:

- Important scope exclusions for e.g.
  - Means of transport for persons and goods
  - Large Scale Stationary Industrial Tools
  - Large Scale Fixed Installations

- No additional Bans of further substances
- No Annex III (REACh candidate list for future bans)
- 5yr validity date on exemptions cat. 1-7, 10,11
- 7yr validity date on exemptions cat. 8 & 9
- 24 Application exemptions for cat. 8 & 9
- Better review mechanism for exemptions
- Transition period when exemption removed of 12 to 18 months
- Case-by-case assessment
- CE Marking may result in better transparency,

but there are still some areas for discussion:

- „Open Scope“ (cat 11) implemented in legal text without impact assessment
- Review of Scope until 22.07.2014 not limited to „Open Scope“ impact assessment
- Weak methodology to amend restricted substances in RoHS and independent from REACH
- 1st review of additional substance bans until 22.07.2014
- CE Marking for RoHS results in a market entrance requirement
- Limited Reuse of spare parts (from EEE put on market before July 1st 2006) runs out July 1st 2016

Unfortunately the categories of the RoHS-Directive and the WEEE-Directive are not the same.

2.3 Waste of Electrical and Electronical Equipment Directive

By introducing the Waste of Electrical and Electronic Equipment (WEEE) Directive (2002/96/EC) the WEEE sets collection, recycling and recovery targets for all electrical goods. The main aspects are:

- Producers need to finance collection of all WEEE
- Producers need to register their products falling under the defined categories
- Products need to carry the WEEE label
- Collection rate of 4kg/person annually
- Art. 175 gives certain freedom to each Member State in transposing this Directive.

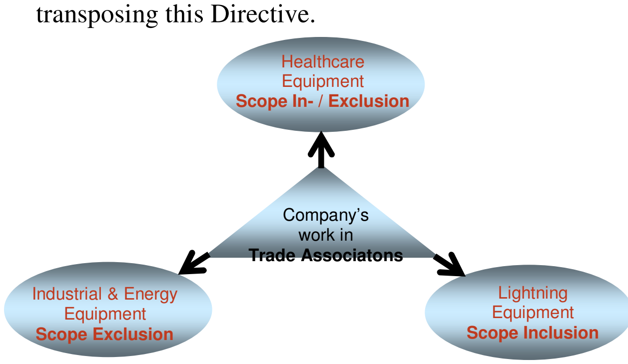


Fig. 3: Needs of an industrial enterprise

Again, industry positioning thru the network of Trade Associations is necessary to introduce feasible legislation. The industry position is:

Scope and Categories of equipment: In general all professional **industrial equipment should be removed** out of the scope. This means all professional industrial equipment.

WEEE collection: **No** producer responsibility should be introduced, to take **full ownership** on WEEE collection.

Rate of Collection, Recovering and Re-use/Recycling: It is **not useful** to introduce a general **collection rate of 65%**. Rather an **individual handling** in respect to the categories is necessary. To strengthen the Waste framework directive the re-use of products is recommended. The new waste hierarchy added re-use to the existing hierarchy:

Prevention before preparing for **Re-use** before **Recycling** before other **Recovery**, e.g. energy recovery and **Disposal**.

Because of higher new WEEE recycling rates re-use might become more important! But, re-use requires an internationally accepted concept of standardization like IEC 62309: Dependability of products containing reused parts - Requirements for functionality and tests.

For producers of high-end technologies the shortage of rare raw materials plays more and more a significant role. Future technologies will change the requirements for raw materials drastically. Many EEE technologies depend on conventional metals like copper and silver but additional growing demand of special metals is to register as lithium, gallium, indium and rare earth. [2]

Therefore long-term strategies to preserve valuable raw materials are essential. This means, that the possible conflicts are no longer inevitable conflicts, but much more useful mutual complements controlled by an intelligent WEEE management strategy.

3 CONCLUSIONS

Potential **Energy Reduction** with already existing electro products are still in the range up to 50 % (example: electro motors, lamps). In the next product generation there is more reduction potential, including Material Resource Efficiency. With the **Extension** of Ecodesign **to plants and systems** there is a new chance for reduction. For the future chances of manufacturing industries a substitution or intensified **Recycling of Specific Materials** is required (example: Indium, Silver, RE).

Designing Supply-Demand Relationships of Food and Renewable Energy towards Ensuring Regional Sustainability: Case Study of Shinjo Village, Okayama, Japan

Kazutoshi Tsuda[1], Keishiro Hara[2] and Michinori Uwasu[2]

[1] Creative Design Studio on Technology, Osaka University, Osaka, Japan

[2] Center for Environmental Innovation Design for Sustainability, Osaka University, Osaka, Japan

Abstract

Regional sustainability with resilience is becoming an important concept. In particular, securing self-sufficiency of food and energy within local communities, together with local independence, is one of the essential conditions for realizing regional sustainability. In order to discuss such self-sufficiency of food and energy, re-valuing local natural resources and enhancing a proper balance between supply and demand of renewable resources within a region is of critical importance. However, studies which address this aspect are very scant. Shinjo village in Okayama prefecture, Japan is a unique municipality trying to enhance self-sufficiency in terms of energy, food and financial conditions, aiming to avoid a possible merger with other bigger cities. Unique visions and proper measures are needed for the village to keep the self-sufficiency viable and to pursue regional sustainability especially at a time when the labor force is shrinking due to the aging population and resultant declining local economy. In this study, we aim to discuss the outlooks of self-sufficiency level for Shinjo village especially from the viewpoint of supply and demand of food and renewable energy (biomasses). We first looked into geographical data and examined ecological conditions and local landscapes, which serve as the basis for evaluating local natural resources. We then developed inventory data of food and renewable energy available within the region by applying material flow analysis (MFA). Based upon the information we evaluated the regional sustainability from the viewpoint of demand and supply balance for food and energy as well as self-reliance of economic conditions. We found that Shinjo village has abundant natural resources more than the amount originally assumed from the existing official statistical data. We proposed institutional and technical options as well as policy measures, which utilize these rich resources, to further enhance regional sustainability of the village.

Keywords:

regional sustainability, natural resources, community environmental management, material flow analysis

1 INTRODUCTION

Sustainability has long been recognized as a crucial concept by the international society. The definition of sustainable development advocated by the World Commission on Environment and Development, "development that meets the needs of the present without compromising the ability of future generations to meet their own needs", articulates the significance of intergenerational responsibility as a sustainability principle [1]. On the other hand, Herman E. Daly, a prominent ecological economist, proposed three conditions for sustainability from resource use and pollution emissions viewpoints [2]. As these principles suggest, our present needs heavily rely on the non-renewable resources such as fossil fuels and minerals, and reducing the demand for those non-renewable resources while promoting the development and utilization of substitutable renewable resources in a sustainable manner is an imperative challenge. However, these sustainability principles alone provides no specific action plans or strategies for achieving sustainability.

Extensive sustainability assessment has been carried out as academic research. While various tools and indicators exist for sustainability assessment, their main focus is on making a balance between environmental conservation, economic development and societal equity. One of the main approaches collects related data and constructs an inventory of the data to demonstrate sustainability assessment by integrating multiple indicators in different domains. In this approach, the target scale can be different, stemming from the global, regional and country level to the small community level. Also the way to aggregate indicators in different domains varies across studies. These approaches are hence effective to

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_4, © Springer Science+Business Media Dordrecht 2012

understand the relative status of the target boundary to others with respect to sustainability components. However, such approach does not necessarily function to grasp the value of local natural resources which is also an important asset for ensuring local sustainability. Re-valuing such local resources and enhancing a proper balance between supply and demand of renewable resources within a region is of critical importance to address regional sustainability. However, studies on this aspect are very scant. In addition, in an attempt to achieving sustainability, it is essential to provide information useful and practical enough for making action plans or policy making. For this purpose, it is required to understand 1) the causal relations among sustainability indicators including socioeconomic ones, and 2) material and energy flow within a certain boundary, in addition to the construction of data base. In this paper, we demonstrate the assessment of regional sustainability through investigation of the relationship between the demand (i.e., the needs of the people) and supply of resources based on the material flow accounting and analysis method. We then briefly discuss institutional and technical options as well as policy measures with an aim to utilize rich resources and further enhance regional sustainability of the village.

2 WHY REGIONAL SUSTAINABILITY？

How to determine a scale or boundary in conducting sustainability assessment depends on the assessment purposes. This study exclusively deals with a small region in Japan that contains a few municipal villages, towns, and cities because of the following reasons. First, the selected region is proper to examine the significance of energy and food security in sustainability. Although everyone admits that energy and food security is important for sustainability, it is not obvious that self-sufficiency for energy and food within a small boundary is necessary. Nonetheless, it is important to understand the supply potentials of energy and food within a certain boundary. The monsoon Asia including Japan is endowed by the rich natural resources and soils, having been able to support large population within the region. Particularly, our target region consists of large farming areas with a few cities, meaning the large potentials of self-sufficiency of energy and food within the region. Once we understand to what extent the region can potentially produce energy and food within the region, it is then possible to reconsider the meaning of the current dependency of energy and food on other countries in terms of sustainability.

Second, we claim that adaptation and resilience, which is in general specific to local socioeconomic and ecological conditions, is another key component for regional sustainability. As for energy supply, large and centralized energy supply systems, which are commonly adopted in many regions in Japan, are vulnerable against natural disaster and other extreme events. While the demand for constructing small scale and decentralized energy supply systems are increasing, understanding regional energy supply potentials will be useful information for specific action plans. In this line, investigating the food supply capacity is also crucial, particularly when considering the fact that the world energy and food prices due to resource depletion show a sharp increasing trend.

The third reason lies in the significance of enhancing economical and political independency of individual regions. Japan is an aging society with decreasing population trends and coming challenges will be specific in individual regions. Hence, decentralization of authority is to be promoted in Japan because regional municipality in general better understands the regional conditions so that they can demonstrate more effective administration in challenging locally specific issues. Additionally, we claim that accumulating sustainability assessment at the regional level is necessary in order to foster the capacity of the region itself for moving it towards a sustainable society.

The fourth reason is related to the third one. We believe that this sort of bottom-up approach can also apply to other regions in Asia in achieving sustainability for a greater region and thus provide meaningful implications for them. Many countries and regions in Asia will become aging society facing region specific sustainability issues and hence capacity building of individual regions in terms of sustainability is important. Moreover, building a network among regions, in which each entity is supposed to be capable of enhancing sustainability by itself, is a critical condition for achieving sustainability at a greater scale. For example, EU has demonstrated that local governments are the main actor when taking initiatives for sustainability while they keep interventions of the central government at minimum.

To be summarized, energy and food security comprises of important components for regional sustainability. As well, regional independency along with capability and resilience possibly contributes to the regional and global sustainability. This is the rationale for why we should consider regional sustainability.

3 CASE STUDY

With this as a background, this paper carries out sustainability assessment for Shinjo village through a construction of natural resource inventory based on the material flow analysis approach. Though past studies attempted to analyze supply and demand balance of resources in a specific region, they lack the viewpoints of regional sustainability based on the analysis [3].

Shinjo village is located in the mountainous area in Okayama prefecture, Japan. According to Köppen climate classification, the climate is of type Cfa (humid subtropical climate). The yearly mean temperature is 11 °C and the mean rainfall exceeds 2,300 mm per annum. The snowfall period lasts 4 months (from December to

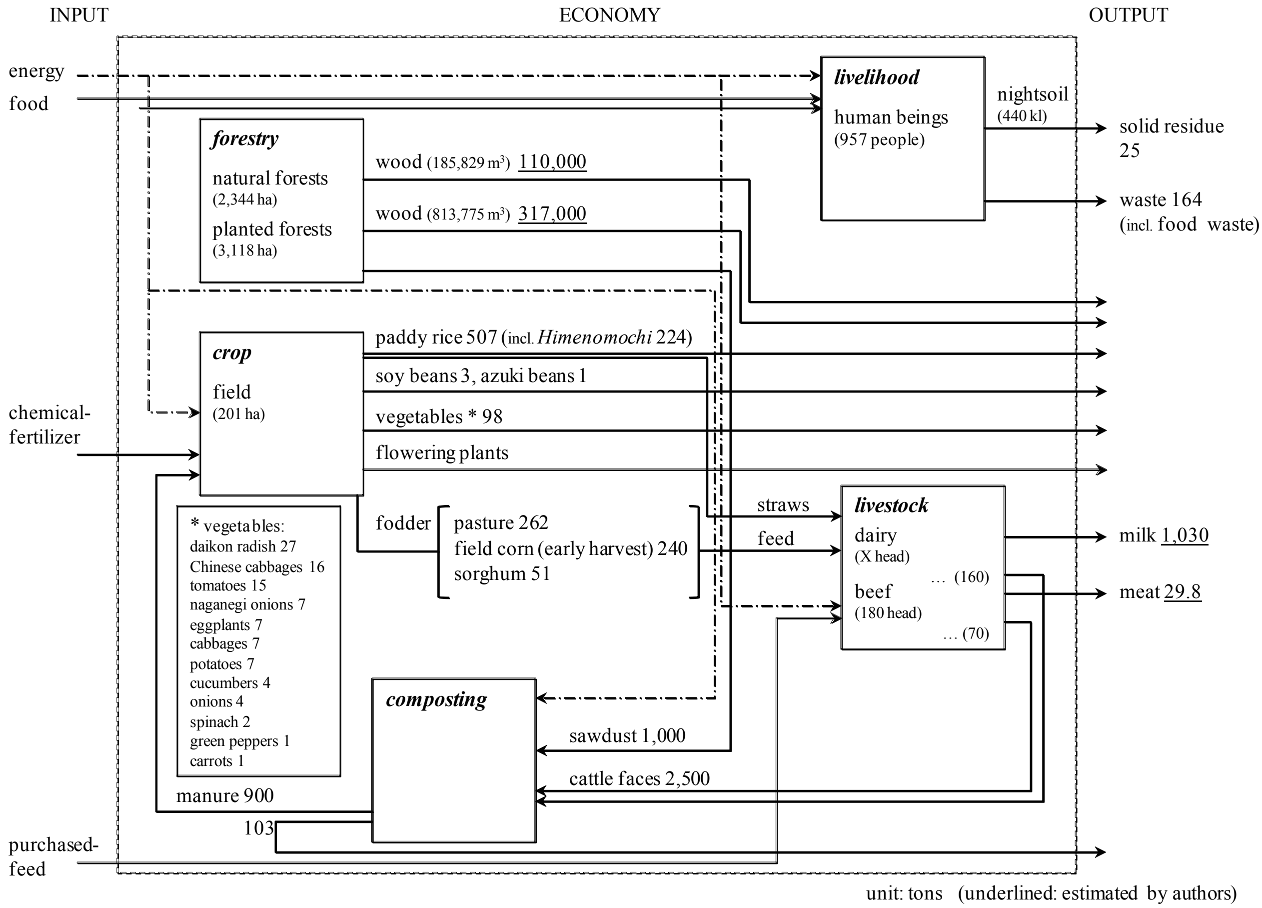

Fig. 1 Matrial Flow of Shinjo Village

March), and the amount of snowfall is also heavy. The total area is 67.1 km^2, of which the area covered by forestry account for about 90 %. The human settlements are scattered along the valleys ranging from 450 to 600 m of altitude [4]. As of 2010, the village has an estimated population of 957 [5]. In Japan, a large number of municipality consolidation cases evolved around 1995, but Shinjo village was one of few villages that refused merger with other municipalities.

3.1 Food

Fig. 1 illustrates the flow of material and natural resources in Shinjo village. The flow chart consists of forestry, agriculture, livelihood, and composting. The unit used in the flow is weight (metric tons) and those weights are directly obtained from official statistics or estimated by the authors [5-8]. Agriculture including rice and livestock is the main industry in Shinjo village. Rice, beef cow, and milk cow respectively account for 35%, 34%, and 22% in the agricultural sales. Small size farmers are dominant in Shinjo village and many of them are facing such issues as low agricultural commodity prices, aging, and absence of successors. As for paddy rice, this village promotes the production of *Himenomochi,* a high quality rice variety suitable to the village's climate. This variety consists of 40% of the total rice production. Shinjo village manufactures and sales *Himenomochi* rice products as local specialties.

They also have had crop rotation practices in the paddy fields, making flowering plants such as autumn bellflower and daily consumed vegetables. Most energy inputs for agricultural production including gasoline and chemical fertilizer come from outside the village. However, they have promoted the production of fertilizer using cattle manure and sawdust.

The estimated sufficiency rate of food supply of the village is 218% on a calorie base. However, the balance between demand and supply is not met. Except for self-consumed rice and vegetables, most of the agricultural production is shipped outside the village while many of the consumed food products including meat, fish and food oil are purchased at supermarket in the neighboring municipalities.

Hence, it requires delving into the contents of food demand and supply. Particularly because of aging and depopulation, household survey will be useful to understand consumption and dietary pattern of the residents.

3.2 Renewable energy

According to Chugoku Bureau of Economy, Trade, and Industry [9], the estimated total energy demand is 27.3 TJ and renewable energy production is 2.1 TJ as of 2009. So, the self sufficiency energy rate of Shinjo village is estimated to 7.76%. All the renewable energy was generated by small scale water-power generations. However, small amount of electric and energy generations by solar power is excluded from the statistics. We found through our field trip that 4 households are equipped with solar panel as of August, 2011. This solar panel introduction can possibly generate 18,300 kWh annually. Consumption data on gasoline, diesel oil and kerosene in the village were to be estimated.

As for biomass energy, charcoal production used to be vigorous decades ago but there are only 10 producers in the village. Chugoku Bureau of Economy, Trade, and Industry [9] estimated energy supply potentials as well. However, their estimates rely only on macro statistics. As large amount of firewood, wood/rice husk charcoal is probably used within the village, field research is necessary to figure out the supply potentials more precisely.

4 DISCUSSION

The previous studies highlighted the significance to regard urban and rural areas as one system and examined the connection forms among the individual areas [10]. Those studies maintained that at the regional level, establishment of resources circulation systems within the regional boundary is one of the effective approaches for the enhancement of sustainability. In general, rural areas are endowed with natural resources while urban areas have large population with dense energy and resource consumption. Identifying the functions of individual rural and urban areas could help promote of resource circulation within the region.

In this study, we showed Shinjo village has sufficient food production while it heavily relies on energy inflow for fossil fuels. On the other hand, the village has large supply potentials for renewable energy and materials. Maniwa city, a neighboring municipality of Shinjo village, is promoting wooden pellet production following the Japan's biomass town initiative. In particular, Maniwa Forest Cooperative attempts to collect wood waste from the mountains including Shinjo village. Although the amount of collected wood by the city is yet only a small scale, cooperative relations should be strengthened to increase bio-fuel production in the region. Furthermore, we emphasized that the residents' aging and depopulation is the biggest challenge for the village social sustainability. Given the biomass potentials for energy production and currently taken initiatives by the neighboring city as its advantages, it can be suggested that the village should find further ways to utilize the rich resources as provision of ecosystem services (including bio-fuels and recreation) to urban residents. Specific measures could include, but are not limited to, maintenance and optimum utilization of biomass resources by means of regional circulations, installation of low head hydro powers, and application of financial mechanisms such as carbon and biodiversity offsets. We conclude this paper by proposing the following as key research questions for this regional sustainability: 1) conducting assessment of ecosystem services in a rigorous and comprehensive way, which includes a completion of a material flow chart for the entire region, and 2) exploring the ways to utilize those ecosystem services along with the establishment of systems to mobilize human resources, money, and materials between the rural and urban areas.

Introduction of Clean Energy System into Shopping Mall Business

-In Bandung Eco-town, Indonesia-

Yoichiro Takada (1)[1], Kiyoshi Dowaki (2)[1], Gatot Yudoko (3)[2]

[1] Tokyo University of Science, Chiba, Japan, [2] Institut Teknologi Bandung, Bandung, Indonesia

Abstract

This research provided new perspective for Bandung Eco-town project with two scenarios about Municipal Solid Waste treatment system in Bandung, Indonesia. We estimated the effect of introduction of methane fermentation system and photovoltaic system into a shopping mall in Bandung, in which stable amount of food scraps would be generated, and photovoltaic system is suitable for Indonesia to reduce CO2 emission since Indonesia is in tropical area. We estimated the potential of methane fermentation system in center of Bandung city too.

Keywords:

Bandung Eco-town, CO2 emission abatement, shopping mall, methane fermentation, PV

1 INTRODUCTION

1.1 Background

Bandung city is one of the quickest developing cities in Indonesia. Bandung has been appointed as one of the cities in the Asia-Pacific region for the development of Eco-town project initiated by the United Nations of Environment Programme (UNEP). The ultimate goal of the Eco-town project is to improve city's environmental quality, that is, aimed to establish a sustainable city. This will be achieved through the implementation of a step-by-step environmentally-friendly city planning and environmental management. The project is also aimed to empower all relevant stakeholders, particularly civil society. Therefore, economic consideration is also an important point besides ecological thought. Although the concept of sustainable development has been sparked off since twenty years ago, yet its implementation both in local and national level is not fully realized. This is due to the practitioners conditions. They are facing a number of obstacles and challenges in creating a balance among the economic, social, and environmental dimension from many sectors of development. It is not surprising that there are still a lot of environmental issues rising, while the government is in the process of adapting the principles of sustainable development. In Bandung, the problems are mainly related to waste. There are not enough waste treatment system, and final disposal site TPA Sarimulti is expected to reach capacity by 2011. Furthermore, the citizen's interest about environment is low. In general, they don't distinguish their wastes with each type of garbage sort.

1.2 Research goal

The research objectives are to provide two scenarios for Bandung Eco-town project. First scenario is about clean energy system in a shopping mall to contribute Eco-town project. Second scenario is additional scenario of first one. In this research, mainly we focus on Municipal Solid Waste (MSW) treatment system and contribution CO_2 emission in a shopping mall in Indonesia, especially in Bandung city.

This paper discusses the renewable energy system such as photovoltaic and/or the methane fermentation which would be contributed to the global warming protection. In the developing country, the economic growth and the environmental contribution might be achieved simultaneously. Based on these requirements, the Eco-town project is raised which means the plan of town construction so as to reduce CO_2 emissions. The local government of Bandung has tried to reduce the waste materials from the residential and/or industrial sectors, because the disposal site would be insufficient. In that case, we have to consider the countermeasure of processing the waste materials generated in this area. In addition, due to photovoltaic system (PV), we analyzed the CO_2 abatement benefit which would be obtained in town area. Finally, this research proposes one Eco-town concept followed model for the sustainable development in Bandung.

2 LITERATURE REVIEW

2.1 Bandung city

Bandung is the capital of West Java province in Indonesia, and the country's third largest city, and 2nd largest metropolitan area in Indonesia, with a population of nearly 2.4 million in only city area in 2010. 31% of Bandung economy is secondary sector such as textile/apparel

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_5,

manufacturing, and 69% is other service such as hotel and restaurant. It is mainly built upon tourism. Therefore, Bandung city is nicknamed "Tourist Shopping City (Kota Wisata Belanja)."

Municipal Solid Waste problem

Municipal Solid Waste (MSW) problem is one of biggest problems in Indonesia, and its amount is getting bigger every year. To make countermeasures for this problem, it is helpful if there is future prediction about MSW production. There is correlation between GDP and amount of MSW production [1]. The history and prediction of annual MSW production per a person from 1980 to 2015 is indicated in Figure 1.

The amount of MSW in Bandung is also increasing because of rapid increasing of population whose rate is 1.55% on an average. Even through final disposal site TPA Sarimulti is expected to reach capacity by 2011, Citizens opposed building new final disposal site. It's because of two most catastrophic waste slides that occurred in the past. One is Payatas landfill in Quezon City of Philippines last July 2000, which involved recorded deaths of 278, and from 80 to 350 missing, presumed to be dead. Another is Leuwigajah landfill in Bandung, Indonesia, which involved 148 deaths last February 2005.

Therefore, open dumping system is no longer available, and the appropriate waste treatment system is needed.

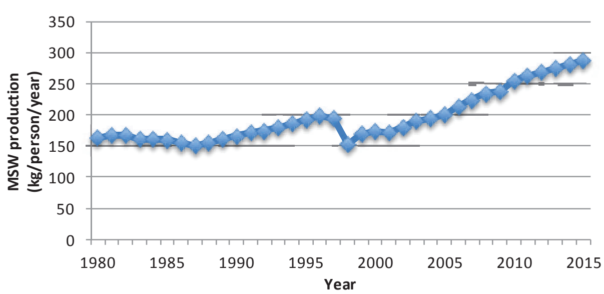

Fig. 1: Annual MSW production per person in Indonesia

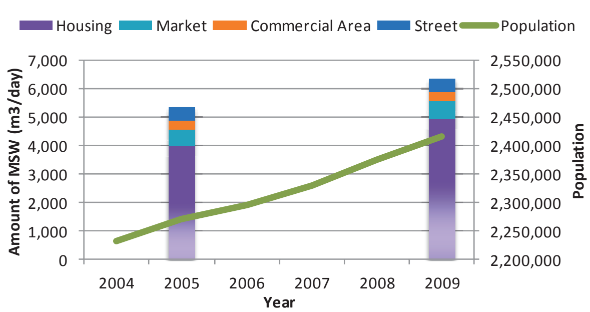

Fig. 2: The amount of MSW and population in Bandung

Shopping malls in Indonesia

Since Bandung city is famous as Tourist Shopping City, there are lots of shopping malls in Bandung city which are crowded almost every day, especially weekend, because so many people come to Bandung city for sightseeing and shopping from other cities.

The average of growth of energy consumption in commercial sector is 5.67% from 2003 to 2007. It's needed to reduce energy consumption or replace it by other clean energy for the abatement of CO_2 emission.

2.2 Methane fermentation system

Since much food waste is produced in Table 1, methane fermentation system is presumed as good and high efficiency treatment system in Indonesia.

In actual condition, one very common waste treatment facility is composting, which is managed by the local government, the private sector and/or the community. The value of methane is higher than compost, and methane has lots of usage, such as direct burning, generating electricity, or supply for fuel cell.

There is no methane fermentation system introduced into shopping malls in Indonesia. However, shopping malls have potential for methane fermentation systems, because they dispose a certain amount of food scraps from restaurants and cafes. In Japan, some demonstration experiments were implemented to gather some actual data for further research.

Table 1: Type of Municipal Waste Composition in Bandung

MSW Composition	%
Organic (bio-degradable)	52%
Inorganic, Non-Recyclable	22%
Other (inert items such as dirt, gravel, concrete, brick, tile)	17%
Inorganic, Recyclable	
Plastics	4.10%
Papers	3.60%
Glass	0.90%
Metals	0.30%
TOTAL =	100%

2.3 Photovoltaic system

As a tropical nation, Indonesia has a very large solar energy potential. Based on solar radiation data collected from 18 locations across Indonesia. Bandung city is in western part of Indonesia with a potential of 4,5kWh/m^2 per day and a monthly deviation of 10%.

Photovoltaic energy has been implemented to harness this large solar potential, and it is used to meet electricity demands for several purposes, including water pumps, televisions, telecommunication equipment, and freezers in health centers with a total capacity of ± 6 MW.

The electricity cost in Indonesia is getting more expensive because electricity supply cost is getting higher. PLN is Indonesian governmental electricity company. The history of the electricity cost and price is shown in Figure 3.

Furthermore, the Indonesian government is planning to increase the electricity tariffs by 10% in average annually starting in April 2012. This move is necessary as the government is trying to reduce the electricity subsidies in 2012 to USD 4.5 billion. This information was released by the Indonesian Minister of Finance Agus Martowardodjo at the Plenary Session of the House of Representatives in Jakarta on 7^{th} of September 2011.

The electricity is expected to be more expensive, and it will make payout time shorter, and make bigger profit from PV systems.

Fig. 3: Electricity price, supply cost, and PLN subsidy in Indonesia

3 SCENARIOS SETTING

3.1 First scenario

First scenario is to introduce waste treatment system clean energy system into a shopping mall.

This research focuses on one actual shopping mall having a hotel in same area in Bandung city. This shopping mall locates along the street having long been renowned as a tourist destination both locally and overseas. The site area of the target shopping mall is approximately 3.5ha, and the store opening hours are 11 hours from 9am to 10pm. The shopping mall doesn’t open their energy consumption data. Therefore, we assumed the energy consumption in this shopping mall by average of energy use intensity of Indonesian shopping malls. That average of energy use intensity is approximately 230kWh/m^2/year. Since there is no data about total floor area of the shopping mall, so we assumed it from similar scale of Japanese shopping mall. The energy consumption of conventional case is approximately 290 million MJ/year.

In Indonesia, a lot of data are not opened to public, especially, in shopping malls. Even the target shopping mall manager declined the offer from Eco-town project officer taking the letter from the head of province. Therefore, this research estimated lots of data from Japanese case and few available data in Indonesia.

According to the concept of Eco-town project, citizens are needed to be educated about importance of environment, and private sectors are required in order to reduce their wastes and energy consumption. Bandung city mainly focuses on industries as private sectors, and the activities in industries are not going well so far, and the concept of Eco-town is not diffused to the citizen. Even through Even through the 3R program is conducted in Segregation, the citizens don't separate their wastes into several kinds of beneficial content. It is necessary to diffuse the concept of Eco-town and increase citizens’ awareness of environment in new approach way.

Visiting facility could reduce opposition rate about new waste treatment system, and providing real image of facility seems to be the best form of public education about environment[2].

Shopping malls are not focused by Bandung city, but they are the places where so many people are gathered. Therefore, a shopping mall can spread around the concept of Eco-town, and improve citizens’ awareness of environment.

3.2 Second scenario

Second scenario is to introduce bigger scale of methane fermentation system in Bandung city, and gather MSW from some shopping malls, hotels, and citizens.

This scenario is only showing the potential of bigger scale of methane fermentation system in consideration of the density of population and MSW production in the center of Bandung city. In this scenario, larger scale of methane fermentation system is built in Bandung city, not inside of shopping mall to gather much amount of MSW from some shopping malls and citizens. Therefore, we don't consider the scale of methane fermentation plant, the place where the plant is built. The location would be affected by the transportation and the actual places where MSW would be able to be collected.

There are few kinds of methane fermentation from some venders. However, almost all methane fermentation systems can produce enough energy for themselves in the bigger treatment scale than 3t/day treatment scale. Furthermore, some methane fermentation system can be expected playability more than in 5t/day treatment scale.

4 ANALYSIS OF EACH SCENARIO

4.1 First scenario

Estimation of methane fermentation system

This study estimates the amount of food scrapes from shopping malls from Japanese data. There is the correlation between the annual amount of food scrap and the number of restaurant and café, to some extent. The coefficient of correlation between them is 0.923, and it’s very strong correlation. So this study estimates the amount of food scrape from the number of restaurant and café.

We estimate amount of food scrape from target shopping mall by regression analysis. The amount of food scrape can be estimated by Eq. 1.

$$y=5.814x+56.249 \quad \ldots(1)$$

From Eq. (1), the estimated amount of food scrap from our target shopping mall was 323.68kg/year.

There are no available data of components of food scraps from shopping malls in Bandung. This makes it impossible to calculate the expected methane yield from the waste. Thus, data from Japanese research conducted in Japan is referred to estimate methane production from methane fermentation system. We assumed that Indonesian components of food scraps are same as Japanese one. Furthermore, there are some methane fermentation systems in Japan, but they don't have big difference between them. Thus, we take data from one demonstration experiment[3]. This demonstration plant operates for gathering data from September in 2009 until December in 2010.

We assumed that almost same result could be produced in this scenario. From the outputs from the methane fermentation system, we replaced energy demands of the shopping mall. In that case, we could get the result shown as Table 3.

In this scale of methane fermentation system, it is needed to add electricity to operate plant. According to International Energy Agency (IEA), the specific CO_2 emission of electricity in Indonesia is 726.138CO_2-g/kWh. Thus, in the case of fermentation system to which 218.4t of food scraps are fed, the total CO_2 emission would be decreased to 18763.4CO_2-kg/year of fossil fuel origin.

Table 2: Operation result and capability of methane fermentation system from Japanese case

Total input of food scrape	218.4 t/year
Biogas production	33440 m^3/year
Electricity production	24720 kWh/year
Expence of electricity in the plant	50560 kWh/year
Input electricity from outside	25840 kWh/year
CO_2 emission	
CO_2 emission per unit of electricity	0.7 CO_2-kg/kWh
CO_2 emission from the plant	18.8 CO_3-kg/year
Efficiency	
Efficiency of electricity generation	14.1 %
Recovery rate of waste heat	31.5 %
Total efficiency	45.6 %

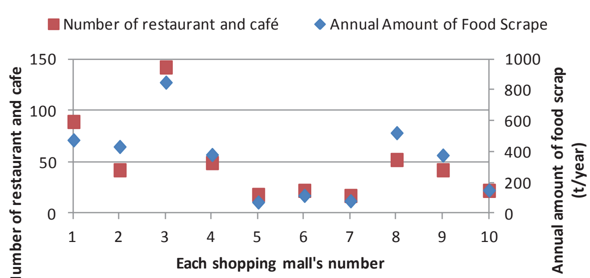

Fig. 4: Correlation between annual amount of food scrape and number of restaurant and café

Photovoltaic system

At first, the average of solar radiation In Jakarta/Bandung is approximately 4.2kWh/m^2 (depending on the location).

One photovoltaic system is provided from one company whose products are popular in Indonesia. The efficiency of the photovoltaic system is 14%-16%. Therefore, the electricity production is 0.588kWh/day, meaning approximately 211.68kWh/year. We need to be careful about the space where the photovoltaic systems are placed. This photovoltaic system uses 80% of space for electricity production, and there is limitation about the space in the shopping mall.

According to PLN statistics 2008, the average price per unit of electricity for commercial department is 842Rp/kWh. It is 1.380Rp/kWh without subsidy for generating electricity.

We assume that the area of roof of the target shopping mall building is 1.0ha, and half of that can be used for the photovoltaic system. In the case, the amount of electricity production is approximately 846.7kWh/year, and the abatement of CO_2 emission is 614,835.6CO_2-kg/year. The installation cost is 28,588,560,000Rp/unit, and the profit to replace to the conventional electricity would be 712,938,240Rp/year. The payout time of the PV system would be 40 years.

4.2 Analysis on basis of second scenario

Based on second scenario, we analyzed the effect of emission abatement.

There are some shopping malls, whose scale is similar to the target shopping mall of first scenario, built in 30km^2 in Bandung as shown in Figure 5. We estimated parameters shown in Table 3, in which the daily organic waste production from housing/settlement within the range of approximately 30km^2 would reach about 220.3t/day. From these conditions, we confirmed that would be enough potential on the big scale methane fermentation system so that the annual profit can be obtained. Also, there are some traditional markets producing lots of organic waste in Bandung city. There's no available data about the amount of organic waste from traditional markets. But it also can be used for methane fermentation system. From those potentials of food scraps, there is potential of methane fermentation system in more than 5t/day treatment scale.

In case of organic waste from housing/settlement, Bandung Eco-town project needs to educate people about 3R. First scenario can be contribution for this scenario.

Table 3: MSW in Bandung in 2009

Category	Source of Garbage	Generated	Collected	
		M^3/day	M^3/day	%
Municipal Solid Waste	Housing/Settlement	4,952	2,853	58%
	Market	619	384	62%
	Commercial Area	303	220	73%
	Street Sweeping	465	291	63&
	subtotal MSW	6,338	3,748	59%

Table 4: Parameters for estimation of amount of organic waste production

Population density	14275.9 persons/km^2
Waste production per person	361 kg/person/year
Ratio of organic in waste	52 %

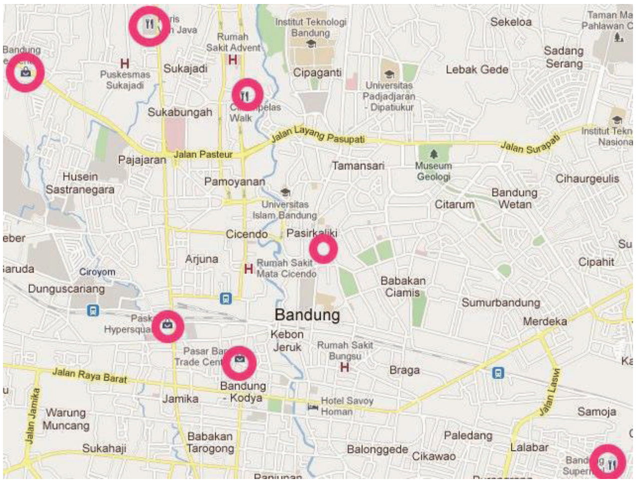

Fig. 5: Location of some shopping malls in Bandung

5 CONCLUSION

This research approached one actual shopping mall in Bandung, which was not mainly focused on by Eco-town project, from the perspective of concept of Eco-town. Results are as follows;

- The 1t/day scale methane fermentation plant in which 218.4t of food scraps is used as feedstock would emit 18763.4CO_2-kg/year.
- The PV system of 4.2kW whose space area is 0.5ha in the shopping mall would reduce approximately 614t-CO_2/year in comparison to the conventional case using electricity from fossil fuels.
- There is good potential on food scraps availability in consideration of the big scale of methane fermentation plant.

Indonesian government should provide subsidies for clean energy systems. In Japanese Eco-town, government provided some subsidies for several kinds of clean energy systems. They encouraged demonstration experiment with private sectors, and improved their concept. So far, Indonesia government still gives a lot of subsidy to fossil fuel. For instance, Indonesian government still focuses on fossil fuel. The subsidies for clean energy systems are still on debate/discussion. But so many experts now try to push the government to consider the renewable energy innovation which we discussed in this paper. The subsidies for several clean energy systems are necessary to make subsidies to make private sectors more corporative and to gather some actual data for further research to improve Eco-town project.

Eco-Friendly Interface Metropolitan Campus Ecology Interface Design

Jen-Hui Tsai [1] Ying-Wen Lu [2] Jun-Ji Haung [3]

[1] Heuristic structures Lab, Department of Architecture Director, NTUT, Taipei, Taiwan

Abstract

Three hundred years ago, Taiwan Taipei City was still a wetland. So in essence it is supposed to be a promising candidate for becoming an eco-city. Yet, as a result of long-term development and expansion of man-made environment, inflexible urban space of frantic routines has made ecology a distant possibility. Constructing an eco-environment of water and greens in order to call back diverse species has become the earnest hope of citizens of Taipei. On the brinks of Zhongxiao East Road, NTUT campus is cornered by the road, buildings and walls. An unfriendly fence exists between the campus and the city, and numerous scooters are parked along the Zhongxiao East Road fence of the campus. The fences knocked off, the abandoned space is utilized to create an eco-river, to construct an eco-environment of water and greens in an attempt to callback diverse species, shape a very friendly campus-city interface, and ceremoniously declare that the open space of a city can be a friendly eco-interface,

from which we can build an eco-campus within and disperse eco-spots in other open spaces without.

Through the linkages in between, we can lay the foundation of an eco-city.

The 80-meter-plus fence along Zhongxiao East Road is taken down to transform the original "sidewalk-fence" image into one of "pedestrian strolling and eco-waterscape." On the strange land outside the original fence, an eco-street is built to demonstrate the image of water ecology and express goodwill to pedestrians via the eco-interface. A swirling waterway is constructed among the existing trees along the side walk to introduce the urban wind corridor into the sidewalk, to caress the surface of the river and bring cool air to the campus.

The interface between the campus and the city changes into a visually penetrable communication place, which not only beautifies urban landscape, but encourages ecological species to perch here, adding rich landscapes and diverse ecological features to the strolling pedestrians.

1 INTRODUTION

Three hundred years ago, Taipei City was still a wetland. So in essence it is supposed to be a promising candidate for becoming an eco-city. Yet, as a result of long-term development and expansion of man-made environment, inflexible urban space of frantic routines has made ecology a distant possibility. Constructing an eco-environment of water and greens in order to call back diverse species has become the earnest hope of citizens of Taipei. On the brinks of Zhongxiao East Road, NTUT situated at the heart of downtown Taipei and the nucleus, of the transportation network, NTUT is surrounded, with major arteries, Near MRT Zhongxiao-Xinsheng Station, it is where MRT Banqiao Line, MRT Muzha Line and MRT Xinzhuang Line meet. Located near the northwest corner of the campus, Guanghua Mall is an important information technology outlet in Taipei City. With Hua-shan Special District for Arts and Jianguo Brewery around, NTUT has become a typical urban campus, a technological, educational and cultural center of the city hat demonstrates features of educational and academic endeavors. On otherwise, NTUT campus is cornered by the road, buildings and walls. An unfriendly fence exists between the campus and the city, and numerous scooters are parked along the Zhongxiao East Road fence of the campus. There for we used the abandoned space is utilized to create an eco-river, to construct an eco environment of water and greens in an attempt to callback diverse species, shape a very friendly, campus-city interface, and ceremoniously declare that , the open space of a city can be a friendly eco-interface, from which we can build an eco-campus within and, disperse eco-spots in other open spaces without. Through the linkages in between, we can lay the, foundation of an eco-city.

2 NTUT AND TAIPEI HISTORICAL CONTEXT HYDROLOGICAL

Back to 1736A.D., in the first year of Guo Xi-Liu moved his family north and settled near Zhonglun, beginning to cultivate around. (nowadays Shung Shen , Da An and Chung Sheng districs, Taipei City). To solve irrigation problems, he organized the farmers to create new waterways. He discovered that the untilled land near Zhongshan Districts today was of development potential. Following survey, he in the fifth year of 1740A.D. began to dig ditches to draw the water of Qingtan Stream. He also cut trenches, pits guided by the bridge north and south trend creek confluence of water, the water conservation engineering make abundant of water-network in Taipei City. 1970A.D.the urbanization environmental change make the water conservation facilities failed, and the historical waterways spaces that used to be visible everywhere have been appropriated and turned into public facilities or trenches, or covered or filled. Behind Liugongjun and development of Taipei City, there was a tangle of historical events. Recovered historical waterways are similar to rivers in ecological function and cultural landscape. In comparison with rivers beyond the embankment, planned recovery of the waterways gives urban residents better waterfront experience, ecological environment and landscape. Therefore, urban development must return to the issue of urban eco-environment order.

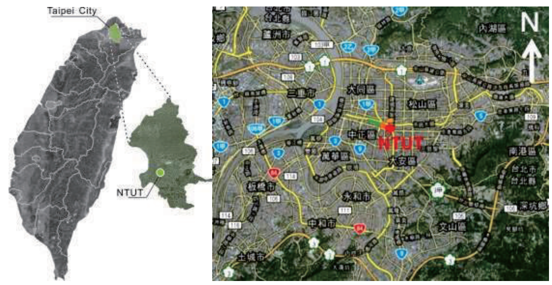

Fig.1:Situated at the heart of downtown Taipei and the Green line of nucleus

Fig.2: NTUT is surrounded, with major arteries, west near to Taipei station and east to MRT Zhongxiao-Xinsheng Station, it is where 5 transportation intersection place, Located near the northwest corner of the campus, Huashand gallery section and Guanghua Mall in Taipei City.

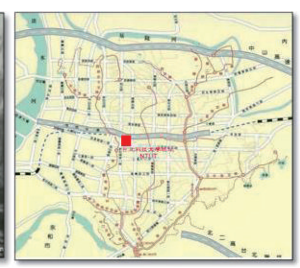

Fig.2: Xinsheng South Road Liugongjun(1963)

Fig.3:Three hundred years to the historical context showing Taipei hydrological context of industrial

Fig.4 Chung Xiao river friendly Eco-interface sketch image

2.1 Every school can build a city campus and the city's water and green

The beginning of NTUT's endeavor to construct the planning concept of eco-campus in response to the green fence of Xinsheng South Road. The following idea was proposed: "An open eco-campus space must be connected to the urban area through ecological interface. Creation of this eco-river is the beginning of a dream and a benchmark in NTUT campus development. Its taking shape marks the start of NTUT quest to become an eco-campus demonstration area and launches restoration of Liugongjun in NTUT Village campus (east campus).

Eco-city is a healthy city with ecological features. Its purpose is to build a living environment that is ecological, comfortable and healthy. Eco-street can mitigate the impact of urban development on environment and merge urban living environment with eco-landscape environment to give the public a place where they can draw near to nature. University campus is an open space in the city and an open educational facility. The interface between this open space and the city becomes an open, friendly waterscape interface that does its part in construction of an eco-city. The campus is part of the urban space. After removing the fences, the campus is merged with the city to form an ecology-friendly campus-city interface, an important link in eco-city construction.(Fig.4)

3 NTUT URBAN CAMPUS CONTENT

The city itself is an organic body that incorporates, various circulations and metabolisms, turning resources, into products and garbage to ensure human survival. It is, also a managerial machine that organizes all urban, activities. With social shifting, urbanization affects the, campus via variables resulting from relations between, he growth of the campus and the city . In the face of urbanization, urban campus gradually, opens up and transforms along the line of diversification, and internationalization. In the city, the campus is no longer merely a place for academic activities and, research undertakings. It has begun to fulfill the essence, of education, which is all-encompassing and expansive.

The cultural features of an urban campus can be used to promote district development, highlight urban characteristics and boost community development, offering a place for citizens to go for recreation and cultural exploration. Campus development is advantageous for urban growth. Yet problems generated by urbanization can limit the scale of the growth. In recent year, campus planning concept has evolved from focusing on the campus itself emphasizing integration and interaction of the campus with its surrounding environment. To the campus, its surrounding environment is beyond control. The peripherals of a campus can only passively, adjust to natural development. In response to the increasing degree of complexity of educational requirements and urban environment problems, how the campus should take the initiative to establish an interactive, mutually-beneficial and mutually-supplementing relationship with the city has become more important than ever.The area of the site totals approximately 1403.07m2. Included in the site are MRT exits, bus stops and Zhongxiao gate, which can bring in large flows of crowds for ecology education. The site is adjacent to this busy corner to enjoy ecological education and exhibit opportunities. Through eco-environment planning and design, an overall concept of "urban eco-street" can be shaped.(Fig.5,6)

4 DESIGN GOAL SITUATION

In this study, the Taipei historical hydrological context, located urban area of NTUT and the campus should have the task of education, the following four design concept and proposed the concept of the design strategy can be achieved. (Fig.7)

Fig.5,6 Chung Xiao river friendly Eco-interface sketch image

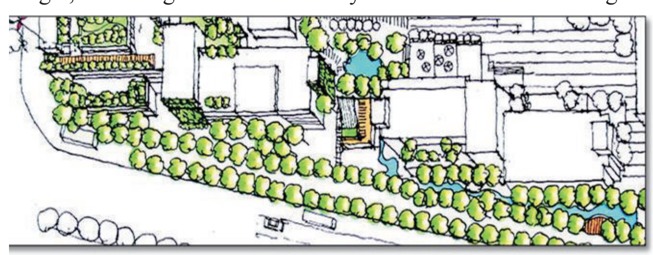

Fig.7 along the Chung Xiao river sketch image

4.1 Friendly Eco-Gateway

The water eco-environment on the border can become the interface between eco-city and eco-campus. Through this water eco-environment the wall, tangible or intangible, can be wiped out to give way to a friendly eco-gateway, which is known for the following characteristics:

a. Water can be shaped into any forms and can awake man's physical and mental desire to experience close encounter with water.

b. Water eco-environment can help cultivate most diverse creatures.

c. School education is a never-ending endeavor. Eco-environment requires persistent dynamic time and spatial process to take effect. Marriage of the two is the niche of the eco-city.

Friendly Eco-Gateway Situation Transforming Strategy(Fig.8)

Fig.8 Friendly Eco-Gateway Situation Transforming Strategy

4-1-1. Reverse back-side image

Turn the back side of the buildings within the fence into the frond side of urban space.

4-1-2. Attract crowd to show care

Multilayer eco-landscape encourages pedestrians to slow down. Overlay red bricks along the sidewalk for pedestrians and bus stop passengers to rest.

4-1-3. Use planting to create the street as a buffing zone

The elevation difference between the river and sidewalk furnishes buffing between pedestrians and ecology.

4.2 Multilayer Eco-Environment that Approximates Nature

The eco-environment in a city needs to take into account interaction of ecology with human activity and with local features. For the purpose of achieving a balance between urban street function and created landscape environment, alleviating interference of current built facilities, and mitigating visual intrusion of artificial facilities.(Fig.9)

a. A habitat that is biologically diversified must have soft, perforated, heterogenic irregular demarcations.

b. Attain maximum ecological benefit with minimum design.

c. Introduce available natural resource to sense its natural power and respect the tolerance of the ecosystem.(Fig10,11)

Fig.9 Artificial facility naturalized sketch image

4-2-1. Artificial facility naturalized

The facility is hidden in the midst of the planting or natural materials. The existing buildings are masked with bamboo fence with vines planted over.

4-2-2. Create diverse water shapes and multi-layer planting

Create a river range of varied depth and width to form different flowing speeds and flow patterns.

4-2-3. Continue existing eco-design

Incorporate the existing sidewalk trees and cause the waterway to swirl in their midst.

4-2-4. Create rich eco-vision

Utilize the smaller vertical visual angle formed via the elevation difference of the sidewalk and the waterway to shape up a greater depth that introduces wider scope of views into a small place.

4.3 Eco-Environment Education Facility

In view of the main artery Zhongxiao East Road, MRT station, bus stops, airport transit stop, Zhongxiao Elementary School nearby, crowd of diverse backgrounds, we can initiate environmental education on ecological issues and release maximized effect of eco-city education.

a. Through evolution of nature, we can display eco-showcase.

b. The best eco-marketing is to demonstrate maximum ecological benefit in the most hostile environment.

Eco-Environment Education Facility Situation Transforming

4-3-1. Eco-Tour-Guide

Organize an eco-tour-guide unit to offer guide services for teachers and students of NTUT and Zhongxiao Elementary School.

4-3-2. Eco-introduction plate

Utilize guide plates to help visitors understand the initiative, concept and influence of the project.

4-3-3. Participation-type eco-education

Organize eco-environment associations and attain the goal of environmental education via showing care and providing services for eco-environment.

Fig.10 Create diverse water shapes and multi-layer planting

Fig.11 Create rich eco-vision

4.4 Demonstration of Cultural Eco-Image

Humanities are the roots of culture. They are cornerstones of a quality city. Care for eco-environment is

demonstration of humanities. Cultural activity is incorporated with eco-environment to extend the image of cultural eco-campus.

a. A selfless concern for eco-environment can become the common language of mankind.

b. Cultural activity can turn this common language into an ambience

Demonstration of Cultural Eco-Imag Demonstration of Cultural Eco-Image Situation Transforming

5-4-1. Introduce water-related cultural activity

In addition to environmental environment shaping, organize water-inspiration activity and design contest in concert with the general education center.

5-4-2. Set up cultural steles

Erect a stone stele on the wooden platform and invite Professor Wu Hua-Yang to write a poem entitled

“Dream” on the stele.

5 CONCLUSION

5.1 Starting point of Urban Ecological Axis

NTUT has spared no effort in its attempt to break existing campus demarcations and integrate with the surrounding environment, making connection with Jianguo Brewery on the north of Civic Boulevard and restoring Liugongjun to the south of Civic Boulevard. Based on this project, it plans to establish linkage with Zhongxiao Elementary School, Huashan Special District for Arts and NTUT eastern campus in the future to create a demonstrative urban water-ecology axis. The purpose is to promote comprehensive development of the urban environment around NTUT and initiate an urban environmental planning that is founded on technology, rooted in humanities and targeted at ecological integrity.(Fig.12)

5.2 Accomplishments of Campus Waterscape

This project tears down the stereotypical stronghold that shuts the campus within walls and creates an eco-street that alleviates the physiological and psychological impacts of urban environment.

The back side of the campus and Zhong-xiao East Road, along which severe traffic impacts have engendered tension and confrontation along, are turned 180 degree around. Now, passengers waiting for the buses, pedestrians, creatures inside and alongside the water, shades of trees and breezes have formed a pleasant scene. This is one of the most natural educations.(Fig.13)

The ecological river in the city is still an ecological manner and growth, ecological environmental balance has been achieved over years and years, there are birds, insects, fish, shelter in the campus ecological corridor. As the ecological variety in recent seven years after the completion of construction of the outside campus Chung Xiao ecological water landscape. Our job is continue to make observations of ecological landscape, biodiversity, logging, planting record of water quality monitoring, and the current growth status of planting: planting the growth in good condition, some have flowers in spring and summer flowering of flowering.(Fig. 14)expect a complete record of the construction process in this eco- water landscape, these technology will be feedback to the construction of ecological communities in the future.(Fig.15) In this decated eco-campus have been operating properly, the legisters deeply experice the enviroment have been changing so well, they strongly promoted the idea to city development and communities, shared with all residients.

Sustainable Consumption of Water by NEGA-Resources Approach

Jialiang Hu (1)[1], Chenqing Wang (2)[1], Günther Seliger (3)[1]
[1] Institute for Machine Tools and Factory Management, Technische Universität Berlin, Berlin, Germany

Abstract
Negative resources (NEGA-Resources) are defined as the resources which could be saved by more efficient technology. NEGA-Resources approach is designed by less resource consumption by more value creation or by both. Water, being one of the most important resources for human living, can be considered in NEGA-Resources perspective, because of huge potentials in sustainable water consumption, energy consumption for water supply and resources for maintenance. In the industrialized societies people tend to enjoy the water consumption with low awareness about resource saving. Based on a generic model of NEGA-Resources approach, modern efficient technology is exploited for resource saving and extra-value creation. A so called water zero-emission house has been designed according to the concept of NEGA-Resources approach. Relevant newly designed components are grey water recycling, black water separation, energy harvesting and information processing for social awareness.

Keywords:
negative resources, sustainable consumption, water efficiency

1 INTRODUCTION

As a concept referring to cleaner production or design for the environment, eco-design describes a design process which takes into consideration the environmental implications of a designed product or process by using various approaches. The goal of such a process is to eliminate undesirable or potentially hazardous effects on the environment [1]. Nowadays, eco-design has extended as design for ecology and economy which takes not only the ecological impacts along whole product lifecycle but also economic even social impacts into count of product development. As the three dimensions of sustainability: ecology, economy and society, there are many similar points between eco-design and sustainability development in the view of product development.

NEGA-Resources approach is used to increase the resource efficiency in product lifecycle. So called negative resources are defined as resources which could be saved by efficient technology. Sustainable development always requires the helps from technology, which is traditionally considered as the motor of social development. This paper presents the NEGA-Resources approach with methods and guide for increasing the resource efficiency along product lifecycle.

A case study shows how to implement the NEGA-Resources approach in the practice, which focuses on water consumption. After describing As-Is situation of water consumption, the model and methodology of NEGA-Resources approach will be implemented to build the prototype of water zero-emission house aiming at low water consumption, high energy efficiency and people's awareness of efficient water comnsumption.

2 NEGA-RESOURCES APPROACH

Negative resources (NEGA-Resources) are defined as the resources which could be saved by more efficient technology. This definition presents the same philosophy as resource efficiency, which also aims at creating more value using less resource. The common resources required in industry are raw material, water, energy, human, knowledge and facility. In the whole lifecycle of product, i.e. design, production, use, recycling and disposal, resource is required to enable the realization of each phase.

2.1 Resources consumption matrix

The relationship between resource consumption and product lifecycle are presented on so called Resource Consumption Matrix which provides a method for qualitative analyzing of resource consumption. Quantitative analyzing is also expectable by experimental data. Fig. 1 shows the resource consumption matrix with example of washing machine along its lifecycle.

The positive value on the matrix means resource consumption to realize product and its function. Negative value means recycling or recovering resource. Typically, in the phase of recycling, raw materials can be recovered from used products by recycling, reuse and remanufacturing engineering. No value means resource consumption in this phase can be ignored. The numbers of plus or minus signs on resource consumption matrix present the quantity of resource consumed in corresponding lifecycle phase.

Knowledge	++	+	+	+	
Facility		++		++	+

Fig. 1: Resource consumption matrix along product lifecycle on the example of washing machine

Therefore, products can be classified as different types due to different quantity of resource consumption during the product lifecycle. In the example of washing machine above, relative larger amount of energy and water is consumed in the phase of use comparing with other lifecycle phases. Based on that, washing machine can be considered as a water-intensive product in use phase. Another example is lathe machine which can be regarded as energy-intensive product in use phase.

There are many products reveal a single property in resource consumption, and also many products have a hybrid property in resource using. Some examples of the product category are shown as following:

- Knowledge-intensive in Design, e.g. electronics, etc.
- Material-intensive in Production, e.g. furniture, disposable products, etc.
- Water-intensive in Production, e.g. paper, chemicals, textile, etc.
- Human-intensive in Production, e.g. watch, etc.
- Water-intensive in Use, e.g. toilet, etc.
- Resources-intensive in Use, e.g. machine tools, etc.
- Resources-intensive in Recycling, e.g. beverage container, etc.
- Resources-intensive in Disposal, e.g. battery, etc.

Actually, the most percentage of resource consumption happens in production and use phases. For example, CO2 emission is usually considered as an indicator of energy consumption, the Product Environmental Reports of Apple Inc. shows that 45% and 46% of CO2 emissions of total product lifecycle are generated in production and use phases [2]. Production phase could be partly considered as the use phase of machines. Therefore, the NEGA-Resources are further confined as the consumptive resources, e.g. materials, water and energy, in product use phase.

2.2 Model of NEGA-Resources approach

A kind of NEGA-Resources approach is to be designed with efficient technology which could turn the positive value into negative. Resource will be not always consumed in product lifecycle, but also can be saved by technology that plays a key role in eco-design and sustainable development.

As mentioned before, consumptive resources are used to realize product lifecycle, in other words, product itself should be designed to create more value with less resource. Value-resource ratio could be taken into account to measure resource efficiency. By analyzing the existing product and its resource consumption the value of resource input could be generated, e.g. water volume or material weight, which used as input reference for the functional realization. Hereby, NEGA-Resources approach begins with the thoughts of resource consumption and value creation, and further provides a new viewpoint for product design with consideration of resource consumption. As Fig. 2 shows, three ways is built inside NEGA-Resources approach such as product design with low input resources, onsite closed-loop resource use and extra-value creation of output resource.

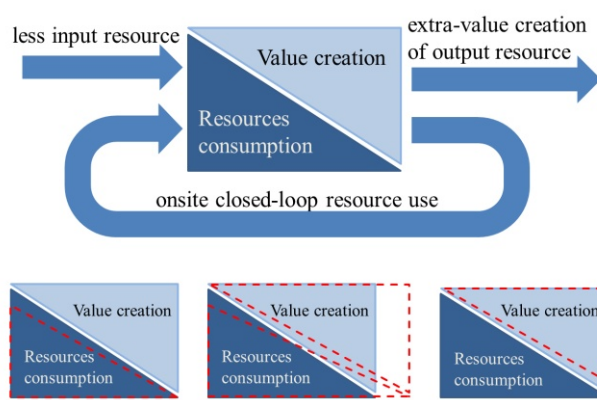

Fig. 2: NEGA-Resources approach for resource use

- Turning resource-intensive product into low resource consumption. The old style products which have been designed without consideration of efficient resource consumption in whole lifecycle could be replaced with new designed efficient one. End users are willing to choose the resource efficient product with innovative design due to increasing resource price and awareness of sustainability. Technology always plays the most important role in reducing resource consumption, not only in innovative product design, but also in improvement of production process.
- Turning mono-use into multi-use of resource. Additional functional module would be added on the product to fulfill the onsite closed-loop resource use. Recycling engineering inclusive reuse and remanufacturing provides huge possibility to recover

raw materials. But recycling works usually as off-site, the used products must be collected by a recycling service center and then recycled or reused again. The effectiveness and efficiency of material recycling depends largely on customers' awareness of sustainability development and benefits of recycling service providers. In the opposite, closed-loop resource use enables an on-site recycling for consumptive resource which could be reused and recycled immediately.

- Turning waste into new resource. Extra-value could be created from the used resource, secondary product and even waste. On the one hand, wastes need more resource to treat it and maybe harmful for environment. On the other hand, waste is resource at a wrong place which could create more value in the further. In global view the resource will create more value in longer lifecycle, and resource efficiency of whole system could be increased.

3 WATER CONSUMPTION

3.1 Water resource

As the origin of life, water is regarded as one of the most important resources of living and industry which has huge potentials in efficient use. The earth's hydrosphere contains the amount of water of about 1386 million km³, of which fresh water takes only 2.5%. However, 68.7% of fresh water is in the shape of ice, snow or polar cap and 29.9% is ground water which is difficult to use. Therefore, only 0.26% of global water quantity is accessible for economic needs and very important for water ecosystems. [3] According to GEO4 report [4], because of growing population, rural to urban migration, rising wealth and resource consumption and climate change, 1.8 billion people are expected to live in water scarce areas and two thirds of the world population could be subject to water stress by 2025.

About 69% of worldwide water is used for agriculture, 22% for industry and 8% for domestic use (household, drinking water, sanitation). In Europe, 50% of water is used for industry while 33% for agriculture and 13% for domestic use [5]. In industry, water is usually used as cooling water, process water, water products (e.g. food industry) and liquid medium material.

3.2 Sustainable consumption of water

The amount of water usage can be reduced with the help of several treatments, so that the resource efficiency can be improved, which results in a higher sustainable development of the countries. With regard to water efficient consumption in industry, a overall water management in plant is needed especially for water-intensive processes.

Water footprint (WF) is an alternative indicator of water use that looks at both direct and indirect water use of a consumer or producer. The water footprint of an individual, community or business is defined as the total volume of freshwater that is used to produce the goods and services consumed by the individual or community or produced by the business [6]. During WF, water use is measured in water volume consumed and polluted per unit of time. As a necessary resource, water is used in all parts of manufacturing process. By reusing or recycling water, water footprint embedded in each product can be reduced and thus leads to less impact on the environment. At the present and in the visible future the most realistic and effective measures of eliminating fresh water in industry would be building an overall water management system with measurements to decrease water consumption in specific processes.

4 CASE STUDY

As mentioned before, water is a resource used everywhere every day in household, industry and agriculture, but water shortage is becoming an emerging problem for human-being. Therefore, water is a kind of NEGA-Resources which could and should be saved by efficient technology. Based on that, a case study named "NEGA-Resources-Approach in Household Water Consumption" has been conducted by our university. The objective of this case study is to design a water zero-emission house which realizes reduction of fresh water consumption, increasing water and energy efficiency and social awareness of efficient water use by using NEGA-Resources approach.

According to the water quality and source, referred water types in household are:

- Fresh water: water supplied by city water authority.
- Storm water: water from rain or melt snow.
- Grey water: wastewater generated from domestic activities such as laundry, dishwashing, and bathing.
- Black water: wastewater containing and urine, flushing water, feces and toilet paper.
- Yellow water: liquid part of black water, i.e. urine and flushing water.

4.1 As-Is situation and goals

In Germany, a single person use about 122 liters fresh water in year of 2007. In comparison, the average water consumption in European countries is around 200 liters/person/day [7]. The distribution of water consumption inside the house is shown in Fig. 3. Various water consumptions can be divided into different levels according to the required water quality, i.e. drinking, body care, washing/shower, toilet flushing. But the required water quality and quantity is contrary to each other, for example, 33% of water is used to flush toilet, in contrast, only 2% for drinking.

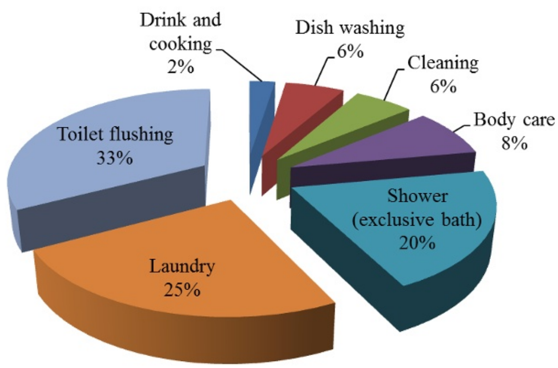

Fig. 3: Distribution of water consumption inside household [8]

Due to rising price of water supply and disposal, inhabitant should pay more money for water consumption. A data from shows form 1990 to 2005, the total price of fresh water per m^3 has increased by 350% [9], meanwhile, disposal of wastewater costs about 14% more than supplied fresh water. Therefore, the general goal of this water zero-emission house is to decrease the consumption of fresh water from 122 liters/person/day to 20 liters/person/day with no wastewater emission and using clean energy for heating water. In this case study, a 3-floor house with 4-people-family (2 adults and 2 children) is chosen to implement the water zero-emission concept.

4.2 Concept of water zero-emission house

Using resource consumption matrix, all the household water appliances are defined as a type of water-intensive products in use. Along the NEGA-Resource approach which offers three ways to improve resource consumption, three kinds of system have been built and integrated within the house. They are: a) grey water recycling system with b) black water separation system, c) energy harvesting system and d) information center.

4.2.1 Grey water recycling system

In order to reduce the fresh water consumption (20 liters/person/day), two measurements are developed: firstly, replace the water-intensive appliances with high efficient products, for example, toilet using 3.5 liters flushing water instead of original 6 liters[10]; secondly, recycling of grey water and storm water, see Fig. 4.

The filter technology offers the possibility of using storm water and reusing grey water. After analysis of each household water appliance, basin for kitchen needs fresh water, assuming that all the drinking water were got here. Grey water can be filtered by two filters that serially connected with each other. Thus, there are two quality levels of filtered grey water. The high level water can be used the water appliances with high hygienic requirement, such as washing machine, dishwasher, shower. The low level water can be used for cleaning, for example, garden, garage cleaning, toilet, etc. The two-level filter system is designed with consideration of costs and investment.

In addition, all the water appliances can use fresh water directly in case of insufficient capability on filtered grey water. Every design or product selection must be evaluated according to water efficiency, energy efficiency and investment.

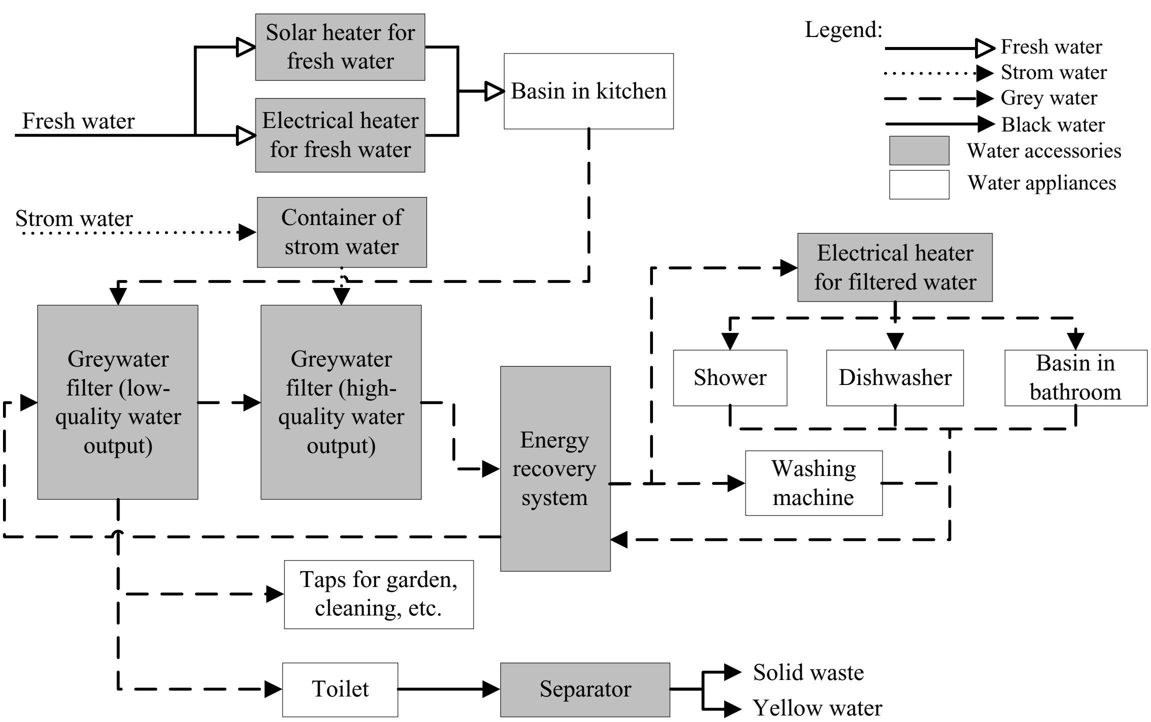

Fig. 4: Grey water recycling system in zero-emission house

Besides of grey water recycling, a black water separation system is also designed to create more value from waste of water consumption [11]. In many countries human waste is used in a traditional way to reclaim fertiliser by separating human waste, i.e. urine and feces. When installing in the house, the separation system should be full automotive without any manual operation. Thus, a kind of toilet waste separation system, which separates the yellow water and solid from black water, is designed based on the capability of 4-person-family. The 3D model of separator realizing 55% dry proportion of solid waste is presented in Fig. 5.

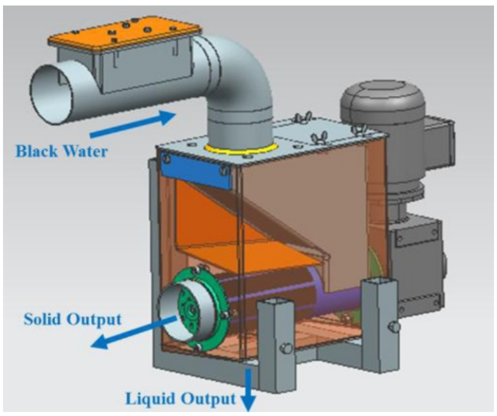

Fig. 5: 3D model of separator for black water separation

4.2.2 Energy harvesting system

Three methods for water heating, solar thermal, electrical heating and energy recovery from wastewater are used in the house to ensure the hot water requirements and meanwhile increase energy efficiency embedded in hot water. Hybrid solar panels with both photovoltaic and solar thermal technology are installed on the roof to use sunlight for heating the fresh water directly. Generated electricity by photovoltaic supplies part of energy consumption in the house. On the case of not enough sunlight or hot water for use, electrical heating system will be used to provide hot water.

Wastewater from shower is usually with temperature of 20-30°C which contains a number of energy normally ignored in water disposal phase. Technology of heat exchanger and heat pump is used to harvest the energy in wastewater. Heat exchanger system is installed before wastewater reaching the filters so that the energy is recovered from the remaining temperature of wastewater. This part of energy can be used to pre-heat the water used later for bath or washing. The energy harvesting system is designed under the concept of onsite closed-loop resource use which can be regarded as a typical implementation of NEGA-Resources approach.

4.2.3 Information center

The information center, which receives various information of water consumption in each water appliance, water temperature in water heating system, condition of whole system especially filters and storm water collector, leads to not only easier condition based maintenance of appliances, but also high awareness of water consumption for user. With the help of information and communication technology, decentralized monitoring system installed on each water appliance. Sensors measure the critical parameters and send the data through wireless communication technology to information center. In addition, grey water recycling system will be also monitored by information center, for example, the level of water in tank, to carry out more effective planning of grey water. People can read the information presented on decentralized monitors, there are information about the amount of water consumption of each appliance. With data of water consumption, the information center can also offer water saving advices by benchmarking or statistical analysis, in order to let user know about his water footprint and what he can do for efficient water consumption.

4.3 Sustainability assessment

Within this water zero-emission house, fresh water consumption per person per day has been reduced to 10 liters. All the black water, which is conducted to separation system, can be totally used to produce fetiliser for agriculture, also provides benefit potentials, see Fig. 6. With the rising price of fresh water and water disposal, such water zero-emission house has both ecological and economic meaning.

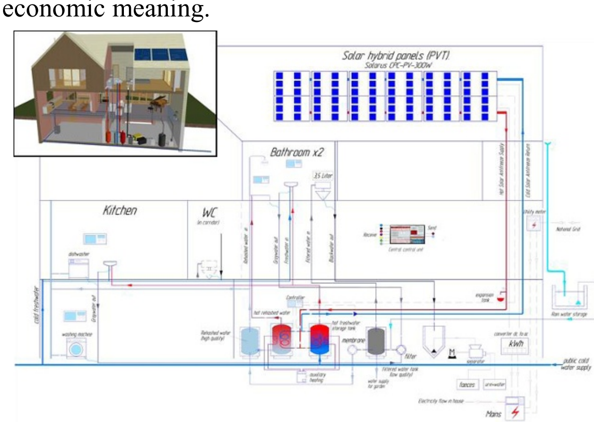

Fig. 6: Water zero-emission house

In order to prove the sustainable contribution, a sustainability assessment tool in terms of environmental, economic, and social aspects is be used based on the criteria system of Sustainability Reporting Guidelines of Global Reporting Initiative [12].

With indicators of decreasing CO_2 emission, energy consumption, fresh water consumption and water disposal for environmental effects; installation investment, operation costs and amortization period for economic value and possible multi-dimensional effect-chains for social impact, sustainability of the water zero-emission house is evaluated. Summarizing by Sustainable development index, all three pillars of sustainability is presented in a single score with a range of 0 to 1000, where 1000 represents the best possible score. Three scenarios are developed to present the comparable assessment: normal four-person-family house, water zero-emission house and future house. Scores for each scenario are calculated as 226, 624 and 815. The assessment result shows that the water zero-emission house has changed the sustainable status as three times as recent situation. Future house scenario presents higher sustainable grade concerning about decreasing costs by expending market, green policy, improvements in the infrastructure and demands of better living standards.

5 SUMMARY

With the concept of NEGA-Resources, an approach to realize high resource efficiency in product use phase is presented in this paper. The case study of water zero-emission house shows, how to implement the approach to achieve sustainable water consumption in household. Efficient technologies have been applied and integrated in the house and contributed to the sustainability of water consumption, e.g. improving the efficiency of water by grey water recycling system, creating more value from waste by black water separation system, recover energy by energy harvesting system, increasing the social awareness of resource saving by information center system. In the future, the NEGA-Resources approach will be expanded into whole product lifecycle, especially applied to increase resource efficiency in manufacturing industry.

Use of Natural Purification of Water Cycle and Water Management as a solution towards Ecodesign

Fatemeh Morteza[1], Mohammad Reza Masnavi[2], Niloofar Khalighi[3]
Research Institute of Environment, University of Tehran, Tehran, Iran

Abstract
One of the major problems now affecting the world is Water Pollution. Natural forms of pollution have been always presented in water systems, Except for exceptional cases, the natural purification processes is able to remove or convert the pollutants to harmless substances. With the development of civilization, human activities accelerate pollutants entering into the water, So that sometimes the amount of these pollutants exceed of the capacity of self purification of water. It means we need to increase the ability of water self purification with natural materials by physical, chemical and biological processes such as aeration, dilution, using of zeolite mineral, phytoremediation, bioremediation and so on. Sustainable use of aquatic resources is suggested as a solution to achieve a sustainable development based on the ability of aquatic ecosystems to maintain a certain level of water quality and preparing water management by eco-design.
Keywords:
Water purification, Phytoremediation, Bioremediation, Sustainable design, Ecodesign

1 INTRODUCTION

Globally we are facing complex Environmental problems which are not limited to one region or country. They are worldwide intricate issues affecting all human beings.The significance of sustainable development aims to attain and balance society needs with both economic development and environmental preservation. In line with this concept, environmental policy has shifted from the end-of-pipe approach to the pollution prevention approach. Water pollution is a major problem in the global context. It has been one of the leading worldwide cause of deaths and diseases [1][2] Water purification generally means freeing water from any kind of impurity it contains, such as contaminants or micro organisms. Water purification is not a very one-sided process; the purification process contains many steps. The steps that need to be progressed depend on the kind of impurities that are found in the water. Different types of water; in addition reviewing the similar cases in the past,it becomes clear that some of the most impressive and moving cultural and urban landscaping are nothing more than solutions to the irrigation system, domestic water supply, transportation, sanitary sewer and flood control problems of the time. But in current times "Living with Water" fundamentally is depend on the dependency of human needs on the centrally organized and mostly invisible infrastructure systems that transport drinking, rain and waste water. We are facing unintelligible urban outspread processes leading to completely new challenges concerning the management and design of urban infrastructure systems and landscapes. The capacity of these water infrastructure systems for shaping urban form, ecological and aesthetic objectives have much been lost. However the simultaneous worldwide processes of extreme and unpredictable urban growth and decline are leading to huge challenges concerning the affordability and functioning of present water infrastructure conceptions and thus demand new solutions such as increasing the ability of water self purification with natural materials either by physical, chemical or biological processes i.e. aeration, dilution, using of zeolite mineral, phytoremediation, and bioremediation. Taking these challenges as a departure point, this paper will introduce the significance of natural processes in the ecological systems and a landscape approach for the design of water management, circulation and purification systems which can be used as a basis or context for eco design of natural landscape.

2 NATURAL PURIFICATION PROCESS

Considering the reduction of permeable surface in the urban landscape, run-off level is increased. Discharge of large amount of sewage and fertilizer in water resources has resulted in pronounced eutrophication. This matter makes some hazards for city dweller's health. The growing population and increase of industrialization and agricultural production in

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_8,

numerous countries require more and more adequate quality of water with low effect on the environment. Therefore, improving self water purification is demanded through the sustainable design to protect water resources. Many physical, chemical, and biotic processes are important determinants for water quality and purification in aquatic ecosystems. [3], [4], [5], [6], [7], [8].

There are some processes and factors which are playing key roles in purification, remediation and enhancement of the quality of the water resources.

Types of Processes and factors of water purification are categorized by Physical, Chemical and Biological functions. Physical processes are including some factors such as Dilution, Adsorption, Sedimentation, Evaporation and Advection and mixing.

Chemical process are including factors such as Hydrolysis, Photochemical reactions, photolysis, Oxidation and reduction and Free radical-dependent destruction, Complication by and binding to other molecules.

Some factors of Biological processes could be mentioned such as Microorganism-dependent oxidations, reductions and other biotransformation, Transformations performed by excretion of chemical substances and enzymes, Accumulation by organisms, Filtering of water by suspension-feeding organisms, Excretion of molecules which are instrumental in increasing the rate of some chemical processes of degradation of pollutants, Producing oxygen that is involved in chemical oxidation of pollutants, Transpiration, Regulation of biological processes of water purification by other organisms [9].

3 THE MAIN PROCESSE OF NATURAL SELF PURIFICATION OF WATER

The dominant processes of the natural self-purification of aquatic ecosystems in the urban landscape can be as following:

(1) Filtration activity or “filters” [8]:

(2) Mechanisms of groundwater recharge, possibly combined with bank filtration, plant purification and/or the use of zeolite mineral, is especially efficient in areas where layers of gravel and sand exist below the earth’s surface

(3) Aeration and increases oxygen in the water

3.1 Filters

Filters comprise the following functional systems:

All invertebrate filter feeders and some vertebrates like fishes. At present, several species of organisms are used in water purification system which improves efficiency and/or ecosystem support. The use of these organisms improving richness of diversity of species which help Ecosystem stability and sustainable design of urban landscape without using dangerous chemical material with harmful effects to the environment that most of them usually have not an environmental life cycle.

Micro organisms, phytoplankton, higher plants, invertebrates, and fish are involved in the self-purification of aquatic ecosystems and the formation of water quality [9]. These groups are necessary for normal self-purification equally. Even the organisms that are not involved directly in the process of improving water quality are often helpful in the key processes of water purification. For instance, many phytophagous organisms cut the large structures of plants into smaller pieces or homogenous mass that is more appropriate substrate for protozoa, bacteria, and fungi that biodegrade that material. The organisms of higher trophic levels are instrumental in regulating the numbers of organisms of lower levels that are the direct participants of water purification [9]. There is a diversity of organisms that are involved in the bio machinery for water purification.

Moreover fishes can limit pests such as mosquitoes. One recent study has found that the wild Salmonella which would reproduce quickly during subsequent dark storage of solar-disinfected water could be controlled by the addition of just 10 parts per million of hydrogen peroxide [10]. Finally, the use of native species is considered as an important element in the process of sustainable resource usage and eco-design approach, because it is the reason of stable design and using of indigenous materials in eco-design is important. Macrophytes, which uptake and sorbs part of the nutrients (including N, and P) and Pollutants entering the ecosystem from adjacent areas; Aquatic plants possess an outstanding ability for assimilating nutrients and favorable condition for microbial decomposition of organic matter.

Aquatic Plants Prefer to absorb Ammonium more than Nitrates, for example in the water depths of surface flow systems which typically vary between 0.1 m and 0.5 m, these systems are densely vegetated. May be the basis of wetland is permeable, so it allows exfiltration of water. In this system which is used in North America, amount of Nitrate in the water is high because of plants and undeveloped open water [11], [12], so it needs to utilize gabion of natural zeolite to increase capture of Ammonium.

3.1.1 Some of Macrophytes can be used in water purification

Phytoremediation has many advantages: it can clean-up a wide range of contaminants while also being cost-effective, natural, passive, and aesthetic. Because views of trees and green spaces can also provide important psychological and social benefits, phytoremediation has the potential to treat more than on-site contamination; it may also help to create stronger neighborhoods and industrial/business districts. For phytoremediation to be effective, the appropriate plant needs to be matched to the site. Not only must the species and varieties used be able to remediate the contamination, but it must also be able to survive well in the growing conditions and also not threaten nearby natural areas.

Phytoremediation Plant Selection

The goal of the plant selection process is to choose a plant species with appropriate characteristics for growth under site conditions that meet the objectives of phytoremediation. There are several starting points for choosing a plant:

(1) Plants that have been shown to be effective or that show promise for phytoremediation. These plants can be found in research publications on phytoremediation, or they can be enumerated by phytoremediation specialists.

(2) Native, crop, forage, and other types of plants thatt can grow under regional conditions. A list of these plants can be obtained from the local agricultural extension agent.

(3) Plants can also be proposed based on those plants growing at the site, extrapolations from phytoremediation research, inferences drawn from unrelated research, or other site-specific knowledge. The efficacy of these plants for phytoremediation would need to be confirmed through laboratory.

Ideally, there would be a plant common to lists (1) and (2), or there would be evidence that a plant common to lists (2) and (3) would be effective. These lists of plants can be narrowed down according to the criteria discussed in the outline of the steps for selecting a suitable plant [13].

3.2 Ground water recharge:

In many regions there is lack of surface water and severe water contamination is to be found. Shallow groundwater resources are often of insufficient quality and over-exploited.

The infiltration surface shall be constructed to preserve and enhance the capability of the soil to pass flows from the basin into the groundwater. Also using the planted surface, rather than crushed stone or sand surface can help to improve the groundwater rechargement quality because it prevent of runoff flowing. Groundwater recharge is the infiltration of surface water into shallow aquifers to increase the quantity of water stored in the subsurface and to improve its quality by processes of natural attenuation [14].

It can be practiced especially in river valleys and sedimentary plains by infiltrating river or lake water into shallow sand and gravel layers. The infiltration technique is chosen according to the hydrogeological conditions, the available ground space, the water need, the composition of the infiltrated water, and the degree of purification to be achieved [15].

The water being infiltrated at first passes filter sand or a layer of zeolite filter. This filter layer retains coarser particles by filtration.

Chemical reactions between infiltrated water, solid inorganic and organic substances in the subsurface, and the groundwater flowing towards the extraction well may cause precipitation of sparingly soluble carbonates, hydroxides and sulphides—governed by pH-value and redox-potential—within the ground layer and the aquifer. Dissolved compounds, among them also contaminants, can be adsorbed especially by clay minerals, iron-hydroxides, amorphous silicic acid, and organic substances [16]. Within the layer of filter sand and the aquifer, a great variety of natural micro organisms exist, which are highly involved in rehabilitation processes [17].

The rate of filtration drops in the course of time, and after a certain period the filter layer must be cleaned or replaced. For example if we use zeolite mineral as a filtration material after a certain period we need clean it with NACL solution.

Besides the purification effects, groundwater recharge also enables a better water management [18].

3.3 Aeration and increases oxygen in the water

Biochemical oxygen demand is a measure of the quantity of oxygen used by microorganisms (e.g., aerobic bacteria) in the oxidation of organic matter. Reduce oxygen in water decreases water quality and finally eutrophycation occurs. There are some methods which help to keep level of oxygen demand of water and maintenance of diversity in the aquatic systems.

3.1 Oxygenating plants

They can be one thing to add to the water to help keep the oxygen level up. There are many different oxygenating plants which are useful, including anacharis, cabomba, hornwort, and more. Adding plants like anacharis, the oxygen will be added to the water and help to keep the fish and other plants healthier.

These plants are known as oxygenators and because they grow completely under water, they add oxygen to the water during their photosynthesis, which is a benefit to the living organisms. They also work to improve the chemistry of the water, including softening the water, maintaining the pH, and more to help keep aquatic organisms as healthy as possible. They work as a natural filter for the water as well and are a natural cover and protection for adult and baby fish. Goldfish use the leaves of the oxygenators to attach their eggs as well.

Oxygenating plants are also very easy to maintain and being take care.

3.2 Enrich the water garden with a fountain or waterfall

Aquatic eco systems need oxygen and by aerating the water with a water fountain or pumps, oxygen can be added. Waterfalls can add oxygen and can add more interest to the water feature in the urban landscape.

4 SUMMARY

In the current times with the rapid growth of population water pollution as one of environmental problems is a global defect. The availability and presence of water in cities is a vital element for sustaining life of inhabitants. In this era of famine, infrastructure failure, climate change, unavailability and lack of resources societies are increasingly becoming aware of hazards of poor management. Although widespread investigations had been done regarding to the water purification, but there is not enough supervision on using Biological water purification methods. The natural purification processes are useful to treat the pollutants to make water with harmless substances for residents.

To achieve ecological and social justice in urban water issues, as well informed understanding of barriers for setting up sustainable urban water management must be proven. Frequently, the main barrier cited is “institutional inertia”, or the negligence of the government, industry, and research sectors to shift gears up.

This paper has demonstrated approaches to explain what drainage and water purification system are, as the way to improve water quality by ecological infrastructures such as Bioremediation and Phytoremediation. Ecological functions and green space percapita can improve dwellers life quality by providing oxygen, Microclima and also by purifying region so these functions can be served as the fundamental components for changing urban and regional landscapes. Accounting for these factors would enhance the thriving of the Environmental potential context in sustainable urban landscape. Making use of dynamic and self-correcting natural processes and the designed urban landscapes are working like “artificial ecologies”. They are containing a higher degree of ecological solidity; require less interposition and monitoring than customary systems and, at the same time, providing attractive landscape experiences. Such manner of pondering can shift the paradigm to the different understanding of environmental designing.

Abstract

In this research, we propose the low emission fuel supply system for electric vehicle and/or fuel cell one. In our system, we consider the traffic situation on the express way in domestic area. There are plenty of waste biomass resources which are generated by trimming trees and/or grass at the both sides of road on the express way. Here, we assume the biomass gasification system of Blue Tower (BT) using trimming trees and/or grass. Through BT system, electricity due to gas engine or fuel cell and/or H_2 due to the purification system can be produced. Moreover, the traffic flow would be depending upon seasonal condition. Based on the uncertainties, we consider the production plan for the fuels.

Keywords:

EV, FCV, biomass gasification system, traffic flow, waste biomass resources, LCA

1 INTRODUCTION

Recently, the support of global warming protection would be extremely significant.

In Japan, especially, the CO_2 emission in the transportation sector was 0.23 billion t-CO_2 as of 2009. This value was approximately 20% against the total CO_2 emissions of Japan. This situation would be promoted to install the low emission vehicles such as electric vehicle (EV) and/or fuel cell one (FCV). For instance, some Japanese carmakers have already sold EV on the commercial basis, and another maker has a plan to do FCV in 2015. However, in order to spread EV and/or FCV, it is necessary to prepare the charge infrastructure of electricity or H_2.

On the other hand, from the viewpoint of fuel supply, we might have to find a good countermeasure so as to reduce CO2 emission. In the case of H_2 fuel supply which is fed into FCV, there is conventional H_2 of fossil fuel origins (ex. Natural gas and/or COG). Since the specific CO_2 emission is higher than that of renewable resources origin, recently, there is the demo-H_2 fuel station based on the electrolysis process through photovoltaic power generation system.

The energy supply due to biomass resources would be promising for the H_2 fuel or electricity supply. Thus, we propose the low emission fuel supply system for EV and/or FCV. Especially, in our system, we consider the traffic situation on the express way in domestic area.

Because there are plenty of waste biomass resources which are generated by trimming trees and/or grass at the both sides of road, these are available as a feedstock for the energy production system. Furthermore, since express way is built for the purpose of driving a long distance, so EV or FCV needs to supply H_2 fuel or electricity on the express way.

Here, we assume the biomass gasification system of Blue Tower (BT). Through BT system, electricity due to gas engine or fuel cell and/or H_2 due to the purification system of PSA (pressure swing adsorption) can be produced. For instance, the performances of BT-SOFC (Solid Oxide Fuel Cell) for power generation and BT-PSA for H_2 production are 18.9%-LHV and 27.2%-LHV, respectively.

Considering the annual traffic flow in the model area, the traffic flow would be depending upon seasonal condition. Based on the uncertainties, we found more profitable production plan for the fuels in cosideration of the maintenance period of BT plant (ca. 2 month). Note that the operating condition of BT plant would be kept at 100% loading efficiency.

At the beginning, we find the optimal solution on BT plant location so as to minimize LC-CO_2 emissions which are mainly emitted by transportation of biomass feedstock such as tree and/or grass or auxiliary power of the plant.

Next, we find the feedstock supply plan corresponding to

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_9, © Springer Science+Business Media Dordrecht 2012

the traffic flow change. That is, our model applies the vehicle routing problem (VRP) which determines the route used as the minimum cost when collecting wastes from one or more disposal sites.

2 PROBLEM DEFINITION

The purpose of our model is to provide a basis for comparing actual performance of electric vehicle and fuel cell vehicle using the biomass gasification system. The comparison should provide information for planning or establishing incentive plans. Therefor, it should be simple, easy to understand.

Our model consists of two phase. One is a BT plant location problem, and another is feedstock supply planning problem.

2.1 Low emission fuel supply system

Figure 1 shows a schematic system flow design in this research. The cut-off trees and/or grass used as biomass feedstock are transported to BT plant due to the 4t-packer truck. The electricity and H_2 which were produced through BT plant are supplied to EV or FCV at a charge station. If the energy produced trough BT plant becomes excess supply, the surplus energy would be able to sell to the conventional market. On the other hand, if energy runs short, it is necessary to purchase energy from an external supplier, that is, a conventional supplier.

2.2 BT plant location problem

In this research, it is assumed that trimming tree and/or grass at both sides of road on the express way are collected to the nearest disposal site. On the express way, it is considered that disposal site is established in IC, JCT, SA, and PA. The tree and/or grass are carried to BT plant, and are used as biomass feedstock.

In this research, the target feedstock is cut-off trees and grass of the West Nippon Expressway Company.

Also, using the basic experimental results, we estimated the following material balance:

$$C_{32.394}H_{49.606}O_{21.431}N_{0.194}+32.394H_2O \rightarrow 26.125H_2+11.605CO+2.769CH_4+8.805CO_2+ 23.638H_2O+0.058N_2+7.01\times10^{-5}NH_3 +C_{3.522}H_{1.449}O_{0.371}N_{0.030} \quad (1)$$

For instance, at 950 ºC in the reformer, and at S/C=1.0, the following reaction formula would be obtained for 1 kg of raw material at 20% moisture content. Based on the material balance, we designed the specification of BT plant and the performance data was estimated for our proposed systems.

Tables 1 and 2 show the specification of BT-SOFC (electricity production case) and BT-PSA (H_2 production case), respectively. Note that the plant scale of BT was assumed to be the same of 5t-dry/d, and that the annual operation days are 300 day/yr in both cases.

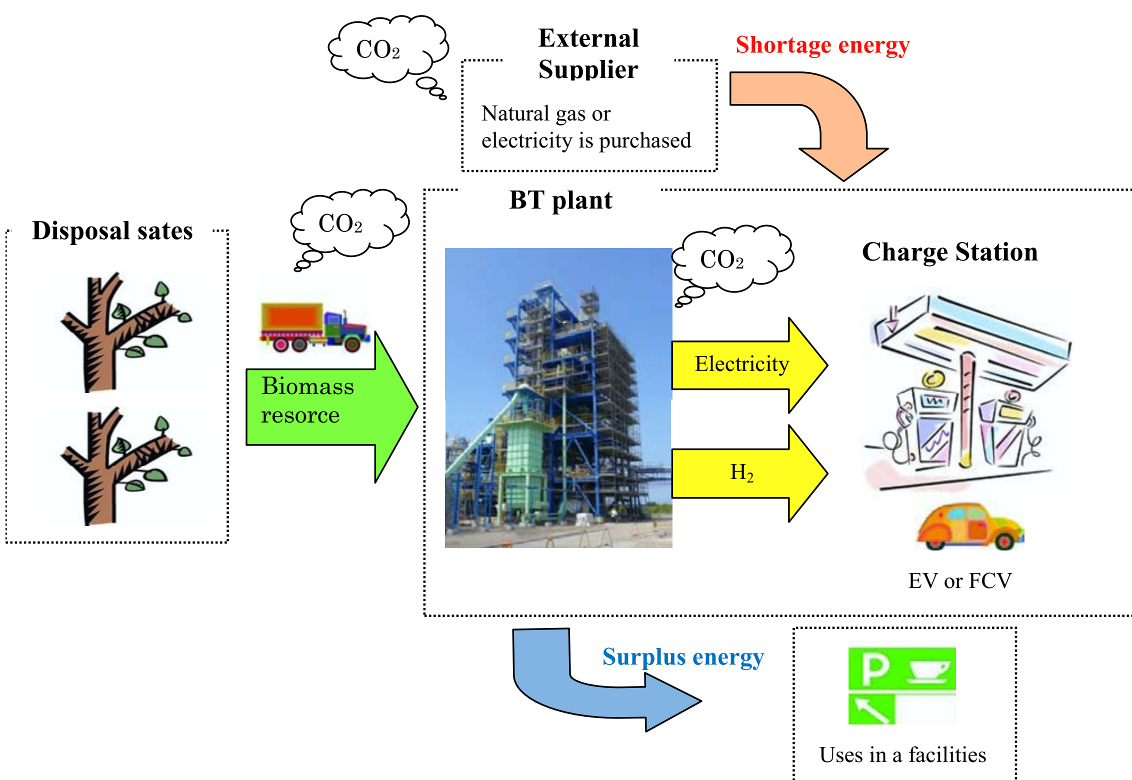

Figure 1: Conceptual diagram of biomass gasification system and energy charge station

In order to compare to the conventional case, it is assumed that the CO_2 emission of H_2 production from Natural gas is 120.8 g-CO_2/MJ [1]. Also, the emission of the conventional electricity in the Chugoku Electric Power Co., INC. is 674 g-CO_2/kWh [2]. Thus, we understand that there is good potential to promote BT systems so as to reduce CO_2 emission.

Table 1: Data of the specification of BT-SOFC

Item	Date	Unit
Total power scale	249.8	kW
Net power scale	197.6	kW
Total power efficiency vs. Feedstock	23.9	LHV-%
Net power efficiency vs. Feedstock	18.9	LHV-%
CO_2 emission for product	0.0	g-CO_2/kWh

Table 2: Data of the specification of BT-PSA

Item	Date	Unit
Volume of H_2	95.2	Nm^3/h
Concentration	99.99	Vol.%
Generation efficiency vs. Feedstock	27.2	LHV-%
CO_2 emission for product	68.0	g-CO_2/MJ-H_2

In this research, the power generation efficiency of BT plant is assumed to operate at 100% loading. That is, it is necessary to transport feedstock required for operation of BT plant from each disposal site. We found location of the BT from which CO_2 emission of a vehicle serves as the minimum. We consider SA and PA as a candidate site of BT. Because EV requires charge time, so it is possible to charge during the break in the SA or PA. And, if electricity remains, using by SA or PA is also possible.

Next, the mixed integer programming for solving the BT location problem is explained. Notation and assumption used by this research is shown in the following.

Notation

N : the number of disposal sites（IC, JCT, SA, PA）

M : the number of candidate sites of BT plant（SA, PA）

Numplant : the number of BT plants

Scalemax : quantity of the feedstock required for operation of BT plant

SP_i : the i-th disposal site（i=1,2,⋯,N）

BT_j : the j-th candidate site of BT plant（j=1,2,⋯,M）

R_i : total quantity of the waste in the disposal site i (t/yr)

F_j : total quantity of the waste in the candidate sites j (t/yr)

X_{ij} : quantity of the waste which transport depot i to disposal site j (t/yr)

D_{ij} : the distance between disposal site i to candidate site of BT plant j (km)

$TotalTransCO_2$: total CO_2 emission of transportation (kg-CO_2/yr)

*Fueluse*_0.8 : quantity of the fuel used when the load factor of a 4t-truck is 80% (L/t・km) (= 0.080)

*Fueluse*_0.1 : quantity of the fuel used when the load factor of a 4t-truck is 80% (L/t・km) (=0.430)

Emicoeff : CO_2 emission coefficient of light oil (=2.62 t-CO_2/kL)

Z_j : Binary variable（If BT plant is build on candidate site j, Z_j =1. Otherwise, Z_j =0.)

Assumption

・Trimming tree and/or grass at both sides of road on the express way are collected to the nearest disposal site (IC, JCT, SA, and PA).

・BT can be built at all the SA and PA.

・Moisture content of raw material transported to the BT plant is 28% [3].

・The plant scale of BT is assumed to 5t-dry/d (dry-base) and the annual operation days are 300 day/yr. The power generation efficiency of BT plant is assumed over 100%. That is, in order to operate a BT plant over 100%, *Scalemax*=2083 (=5t/d÷(1－0.28)wt.%×300day) [t/yr] biomass is necessary. Therefore, the optimal number of BT plants can be solved in the following equation.

$$NumPlant = \left\{ \sum_E R_E \right\} \div Scale\max \qquad (2)$$

・The waste collected to disposal site is transported to one or more BT plants.

・The distance of a packer vehicle is symmetric (D_{ij}=D_{ji}).

・The 4t-packer truck is used for transportation of feedstock. And, the maximum load factor of a vehicle is set to 80%.

・The 4t-packer truck transports the waste from disporsal site to BT plant, and returns to the disporsal site in the empty state.

・Since it is simply, a packer vehicle shall perform transportation to one BT from one disporsal site at once.

・In spite of the load factor of an actual truck, when there is a load, load factor of truck is 80%. And when there is no load, the load factor of a truck is 10%.

Objective function

$$TotalTrans\,CO_2 = \sum_i \sum_j D_{ij} \times \{X_{ij} \times Fueluse\_0.8 + X_{ji} \times Fueluse\_0.1\} \times Emicoeff \quad (3)$$

$$X_{ji} = 0.1 \times X_{ij} / 0.8$$

Subject to:

$$\sum_j Z_j = NumPlant \quad (4)$$

$$\text{Scalemax} \times Z_j = F_j \quad (5)$$

$$\sum_j F_j \times Z_j \le \sum_i R_i \quad (6)$$

$$\sum_j X_{ij} \times Z_j \le R_i \quad (7)$$

$$\sum_i X_{ij} = F_j \quad (8)$$

That is, BT plant location problem is formulized as mixed integer programming. In this research, mixed integer programming is solved using GAMS 23.7.

2.3 Feedstock supply planning problem

Next, we solve feedstock supply planning problem. In the model area, the traffic flow would be depending upon seasonal condition. And, the amount of supply of feedstock also changes with seasons. If electricity or H_2 remains in the BT plant, it can be used on the SA and PA. On the other hand, if electricity or H_2 runs short, we have to supply electricity or H_2 from an external supplier (*ex.* Natural gas and/or electricity of electric power company.).

Furthermore, we have to take the maintenance period of BT plant (ca. 2 month) into consideration and we keep the power generation efficiency over 100%.

In consideration of the above conditions, we try to solve simultaneously vehicle routing problem and feedstock supply planning problem which minimizes CO_2 emission concerning transportation and production.

Notation

$TotalProCO_2$: CO_2 emissions at the time of energy production and fue use (kg-CO_2/yr)

Y_{kt} : Binary variable（If BT plant k maintain in t month, Y_{kt} =1. Otherwise, Y_{kt} =0).

K_{kt_r} : Demand in *t* month of the diffusion rate *r* at BT plant *k* (car/month)

$SumK_{t\_r}$: Demand in *t* month of the diffusion rate *r* at all BT plants (car/month)

K_{max} : The number of vehicles which can be used to per month (car)

A : Augend of CO_2 at the time of supplying from an external supplier (kg-CO_2/car)

Assumption

・Fundamentally, it applies to assumption of above section.

・All the BT plants have to stop during two month continuously for a maintenance.

・When the BT plant stops by maintenance, the demand of the month is assigned to the other plants.

・When demand cannot be satisfied, electricity or H_2 is supplied from an external supplier.

Objective function(1)

$$TotalPrCO_2 = \sum_t Max\left\{SumK_{t\_r} - \sum_k Y_{kt} \times K_{\max}, 0\right\} \times A \quad (9)$$

Subject to:

$$\sum_k K_{kt\_r} = SumK_{t\_r} \quad (10)$$

$$\sum_k Y_{kt} = 2 \quad (11)$$

$$Y_{kt} = \begin{cases} 0, & \sum_{i=1}^{t-1} Y_{ki} = 2 \\ 1, & \sum_{i=1}^{t-1} Y_{ki} = 1 \\ 0,1 & otherwise \end{cases} \quad (12)$$

This research also estimates that of various diffusion rates, assuming that the diffusion rate of EV and FCV will increase in the future. If the diffusion rate of EV or FCV increases, the number of gasoline-powered cars will decrease. Then, we added the CO_2 reduction effect that it shifted to EV or FCV from the gasoline-powered car (GV) [1]. In this research, the reduction effect of CO_2 will be calculated as a difference from 1% of a diffusion rate.

Objective function(2)

$$TotalCO_2 = TotalPrCO_2 - ShiftCO_2 \sum_t (SumK_{t\_r} - SumK_{t\_0.01}) \quad (13)$$

3 CASE STUDY OF BT PLANT LOCATION PROBLEM

The west Nippon epressway company area's trimming trees and grass is used as biomass feedstock, and it considers producing H_2 and electricity in BT plant. The total amount of the biomass feedstock collected from 143 disporsal sites is 5,157 t/yr in 2009. Furthermore, in this research, it takes into consideration not only a express way but building of BT plant which utilized the intact biomass collected from Maniwa city. The total amount of the biomass feedstock collected from Maniwa biomass accumulation base (Maniwa-base) is 9,459 t/yr in 2009.

There are 38 SA and PA which can build BT plant in the model area.

Distance between each sites (SA, PA, IC, JCT and Maniwa-base) is plotted from the map.

As a result of calculating optimal BT location using the above data, the optimum location of BT plant became six places, Syouou-SA, Maniwa-PA, Yuda-PA, Takahashi-SA, Ueno-PA, and Hiruzenkougen-SA (see Figure 2).

Figure 2 : optimal BT location in model area

4 CASE STUDY OF FEEDSTOCK SUPPLY PLANNING PROBLEM

4.1 Energy demand of EV or FCV

When making the energy demand of EV and FCV, we pay attention to the long-distance driver and the tourist. For example, since the cruising range of an EV is about 180 km, when drive more than 180km, it is necessary to charge electricity at an electric station (see Table 3). On the other hand, since the car whose trip length is less than 30 km occupies 93%, shortage of charge station does not occur in now. However, the tourist needs to use a charge station of an outside.

We investigated the traffic flow in the West Nippon Expressway area. In this area, the traffic volume for every month is exhibited by the Japanese government. Therefore, we decided to make energy demand by multiplying traffic volume of a monthly, rate of long-distance driver and the diffusion ratio of EV or FCV [7].

The diffusion ratio of EV has a report that it becomes 20% in 2025 [8], and increasing from now on is expected. Thus, we find the optimal solution on some scenarios. Furthermore, the traffic volume of the tourist of the short-distance drivers was added to the above mentioned demand [9].

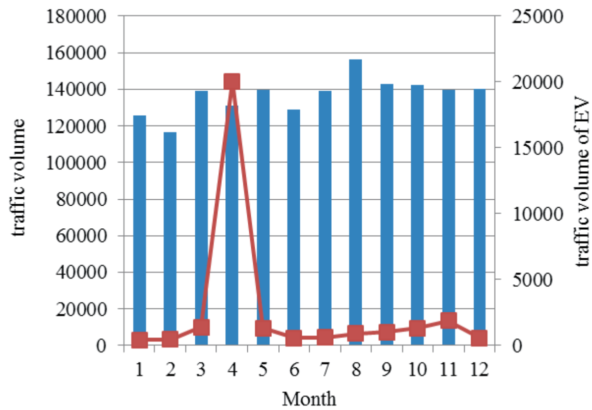

Figure 3: the monthly traffic volume in Syouou-SA

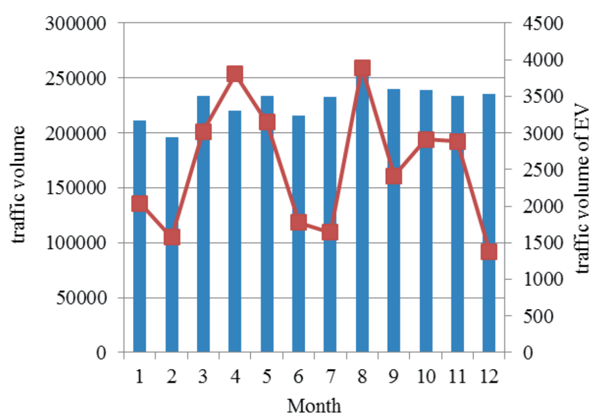

Figure 4: the monthly traffic volume in Maniwa-PA

Table 3: Data of the specification of target vehicles

	Gasolin [4]	EV [5]	FCV [6]
Vehicle type	Toyota NOAH	Nissan LEAF	Honda FC-X
Energy demand (per car)	60 L	24 kWh	59 Nm^3
Cruising range	864 km	180 km	620km

Figure 3 and 4 shows the traffic volume of a car in Syouou-SA and Maniwa-PA. The bar chart shows the monthly traffic volume. In the polygonal line, energy demand of EV of 1% of a diffusion ratio is shown. In the Syouou-SA, the number of tourists is concentrating in April. On the other hand, at Maniwa-PA, the number of tourists fluctuates in a season.

4.2 Comparison of the CO_2 emissions in EV and FCV

Figure 5 shows the variation of the CO_2 emission of EV over a diffusion rate in model area. The horizontal axis of the figure shows the diffusion rate. The vertical axis of the figure shows CO_2 abatement when based on 1% of a diffusion rate.

The solid line of the figure shows the CO_2 abatement when energy is purchased from an external supplier. If energy demand becomes larger than the quantity of energy production of BT, charge station purchases the quantity which ran short from the external supplier. Since there is larger CO_2 emission for energy product of external supplier than BT plant, CO_2 emissions increase it with the increase in purchase quantity.

On the other hand, if a diffusion rate increases, the shift to EV from GV increases. The dotted line of the figure shows CO_2 abatement following the shift to EV from GV.

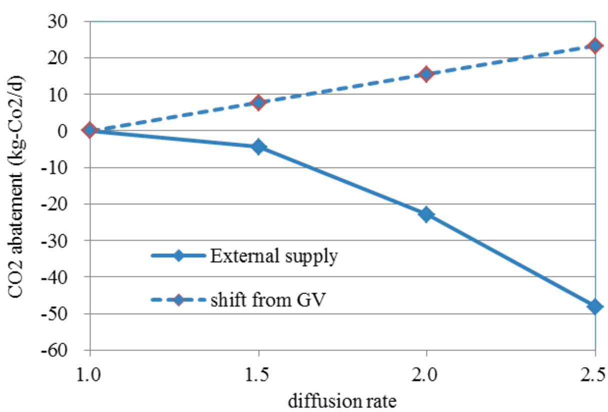

Figure 5: CO_2 abatement in EV

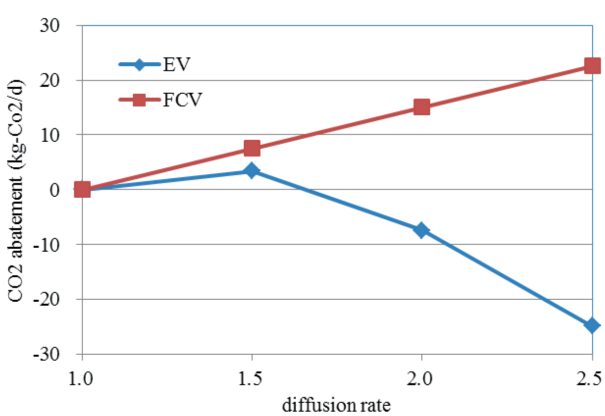

Figure 6: Total CO_2 abatement in EV and FCV

Figure 6 shows the variation of total CO_2 emission in EV and FCV. In the case of EV, CO_2 emissions become the minimum when a diffusion rate is 1.5%. It is because CO_2 emission reduced by shifting to EV from a gasoline-powered car. However, if a diffusion rate becomes larger, variation of CO_2 will increase. This is because the energy which ran short is supplied from an external supplier with large CO_2 emissions.

On the other hand, in FCV, CO_2 variation decreases with the increase in a diffusion rate. It is because the reduction effect by this shifting to FCV from a GV is very large.

5 SUMMARY

In this research, we designed the energy supply model of EV and FCV which used biomass gasification system. In this model, trimming trees and grass at the both side of road are used as biomass resources, and it is possible for reduction of waste treatment expense. The proposed model was applied to the actual biomass resources and traffic flow with a seasonal variation.

Moreover, we determined for the location of BT plant and the production planning of BT plant which achieve the CO_2 emissions minimum. As a result of comparing CO_2 abatement of EV and FCV, it turned out that the way which promoted the diffusion of FCV has an effect in reduction of CO_2. However, the comparison of the cost by the model was not performed. Thus, it might be necessary to reduce the cost due to the installation of eco-friendly system.

Abstract
Most of human activities consist of extensive fossil fuels consumption which has led to undesirable phenomena such as global warming and environmental pollution, which in recent decades have been the most important challenge of the governments and societies. On the other hand one of the most concerning threat and the most vitally important issue which the whole world is facing is how to provide affordable energy supply, which is sustainable and universally available. Renewable energy sources and energy efficiency improvements have the potential to provide the energy needed for human development while delivering substantial poverty alleviation, sustainable development and environmental benefits. Renewable energy parks are some kinds of ecological thematic park which have been proposed in order to educate people, raising the awareness of public in the subject of renewable energies and also producing clean energy.

Keywords:
environmental crisis, clean and renewable energy, renewable energy park, ecological design, Manjil

1 INTRODUCTION AND PROBLEM STATEMANT

The environmental crisis in the all world has already concerned environmentalists and scientists with its major effect on every country. They are affected by various factors such as rising number of the population, exploitation of natural resources, deforestation, overconsumption of the fossil fuels, and waste produced by humans. Extensive fossil fuel consumption in almost all human activities led to some undesirable phenomena such as atmospheric and environmental pollutions, which have not been experienced before in known human history consequently, global warming, greenhouse effect, climate change, ozone layer depletion and acid rain terminologies started to appear in the literature frequently. These phenomena are closely related to fossil fuel uses because they emit green house gases such as carbon dioxide (CO2) and methane (CH4) which hinder the long wave terrestrial radiation to escape into space, and consequently, the earth troposphere becomes warmer [1]. The energy sector is responsible for about three quarter of the carbon dioxide emissions, one fifth of the methane emissions and a large quantity of nitrous oxide. Emissions from fossil fuels are the main contributors to environmental and health problems at the local, regional, and global levels . On the other hand energy is a key element of the interactions between nature and society and is essential to economic and social development and improved quality of life all around the world. Energy production is intricately linked with human life, affecting industry, agriculture and our everyday domestic lives. Hence, the sustainable production of clean energy can mitigate many sustainability issues presently facing mankind, such as greenhouse gas (GHG) emissions, climate change, fossil fuel depletion and energy security [2]. The environmental crisis is perhaps the most long-term crisis, if we do not act now to mitigate it. Climate change threatens to completely change our planet, our societies and our economies. An important environmental challenge during the next decades will be to reduce the impacts of global warming [3]. We need decisive action in the short-term, in order to avoid severe consequences and the real crisis of climate change. In order to avoid further impacts of these phenomena and Under these circumstances the two concentrative alternatives are either to improve the fossil fuel quality with reductions in their harmful emissions into the atmosphere or more significantly to replace fossil fuel usage as much as possible with environmentally friendly, clean and renewable energy sources [1].

Renewable energy is energy which comes from natural resources such as sunlight (solar energy), wind, rain, tides, hydropower and geothermal heat, which are renewable (naturally replenished). Renewable energy is natural energy which does not have a limited supply. Renewable

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_10, © Springer Science+Business Media Dordrecht 2012

energy can be used again and again, and will never run out.

Renewable energy is an indispensable substitute for oil and fossil fuels. The production of renewable clean energy is a prime necessity for the sustainable future existence of our planet [4].

Energy park is one of the cultural, educational, research and practical land use which is recently used in many countries. Renewable energy parks are modern scientific/biological/industrial/thematic parks which would be designed and established upon these mentioned concepts. A/an biological/industrial park is a complex of productive and service industries which are located in a unique site. The different factories and trades are gathered together for economical, managerial and biological reasons and for the use of common resources in a specific place. New/renewable energy parks utilizes clean, renewable energy resources to encourage economic development, provide environmental protection, and offer educational opportunities that together will help lead towards a more sustainable future. We should discuss the strategies of mitigation of greenhouse gases through designing the renewable energy parks and using renewable energies.

Energy parks are some kinds of thematic parks which the main theme of them is energy. Thematic park is an amusement park in which landscaping, buildings, and attractions are based on one or more specific themes.

The current problem of today for supplying energy is not only serious environmental crisis around us but it is the increasing oil and energy price, which is definitely, will be inadequate for our next generation. Rising awareness and changing the point of view to the designing process is one of the ways out of this crisis. Ecological design which is based mainly on sustainability and being in line with the nature and environment is one the most innovative and smart way to deal with our today's environmental crisis. Being creative and constructive, ecological design also stimulates the economic development.

The designing process of Manjil renewable energy park in this paper is in the framework of ecological design. Manjil is located in the north of Iran in the mountains of Alborz and it is known as the windy city of Iran.

Ecological design was defined by Sim Van der Ryn and Stuart Cowan as "any form of design that minimizes environmentally destructive impacts by integrating itself with living processes." [5]. Interest in ecological design reemerged in mid-nineteenth century, when Thoreau, Olmsted, Marsh and others, worried about human intersections with nature. However not until the second half of twentieth century did ecological design and planning gain considerable momentum. Ecological planning and design is more than a tool or technique .it is a way to mediating between human action and natural processes based on the knowledge of reciprocal relationship between people and the land .

2 RENEWABLE ENERGY PARKS:

Renewable energy park is designed to meet the needs of tomorrow's world by addressing today's global challenges. The concept of renewable energy park usually based on "Sustainability", "Technology" and "Education". This concept represents a comprehensive vision of sustainable living that will create a collaboration platform which could have many components that will aim to integrate education, research, development and accelerated implementation of innovative renewable technologies into mainstream society. The function of the park concept intends to work with academic institutions, as well as governmental, industrial and public sectors. These parks can also be productive it means they can be a good source of producing electrical energy and for this reason they are located near energy consuming centers. Nowadays the production of electrical energy from renewable sources is not just a case of study but an irreplaceable ring in the chain of production many countries have already invested on green power and they will still invest more due to the diminishing fossil fuel resources, the Kyoto commitment and the obligations that result from it for every country with regard to the protection of the environment [6].

Some of these energy parks put more focus on research and commercialization of renewable and clean energy technologies along with environmental aspects and these parks usually give services to researches and industries which work on renewable energies and cooperate with the goal of marketing and commercializing the new methods of optimization of energy using.

Indeed, designing energy parks can be highly useful for two reasons first. It can be a good source for preventing environmental pollution resulting from using fossil fuels and emission of greenhouse gases and solve the problem of lack of energy for many countries and the second reason is that using renewable energies can preserve fossil fuels for future generations.

An integrated renewable energy park (IREP) approach can be envisioned for amalgamating different renewable energy industries in resource-specific regions for synergistic electricity and liquid biofuel production with zero net carbon emissions.

3 MANJIL RENEWABLE ENERGY PARK

Manjil is located between N36˚45'18" – N36˚41'42" and E49˚23'6" – E 49˚31'48" in the north of Iran.

It's known as the windy city of Iran; a reputation it owes to its geographical position in the Alborz mountains i.e., at a small cleft in Alborz that funnels the wind through Manjil to the Qazvin plateau.

Fig. 1 : The location of Manjil

.

Furthermore, Manjil is known for its olive gardens and it is a big producer of olive and olive oil in Iran. Manjil is also known for the river Sefīd-Rūd (or "Sepid Rood", "Sefid Rood"). This river that passes by the town is formed in Manjil by two joining rivers and since 1960 has been the site of Manjil dam built on it that significantly contributes to Gilan's agriculture while generating electric power. The lake behind the Sepid Rood dam also ads to the beauty of the area. Manjil is the conjunctuion place of three differnent kinds of weather in Iran.

Because of being a windy area Manjil is capable of harnessing wind energy for electricity purpose. Manjil area has a great potential for capturing wind energy in order to convert it to electricity. It is also very important for development and economy of Manjil. It is one of the best locations in the world for installing wind turbines. Manjil is famous as the energy city of iran, therefore it is one of the most suitable places in Iran to design and establish a renewable energy park.

Fig. 2 : Manjil

The main goals of Manjil renewable enregy park is:

- To provide a suitable site for experts, researchers and students to compile and complete their research and studies in optimizing and using renewable energies.
- Public visits, specially families to instruct and raise the public awareness in regard to energies and renewable energies and their usage which can be very beneficial for people of different age ranges in each society.

Fig. 3 : A wide scenery of Manjil and the wind farm

The design of Manjil renewable energy park is based on some basic principles such as :

- Designing a green and sustainable infrastructure
- Preventing from pollution
- Cleaner production (The cleaner production approach is the continuous use of a general environmental strategy for products and services processes, in order to increase the total efficiency and decrease the harmful impacts for environment and human)
- Utilizing new energy with utmost efficiency
- Cooperating of different industries and companies
- Being an educational, recreational and touristic site.

Manjil renewable energy park tries to produce inexpensive energy in great amount and in this regard provide suitable situations and infrastructure for industries and researchers and by the use of renewable resources , it can be a good pattern for educating the use of these resources and promotion of energy production and conversion clean technologies.

The energy park of Manjil make use of a cycle of production conversion and consumption of energy ,in other words, this park can be used as an exhibition for raising people awareness of renewable energy and can also be used by experts and researchers for educational and research purposes.

In Manjil renewable energy park the attempt is to make use of the available and real elements to create an exciting and spectacular site to reach the goal of educating the public (people , tourists , students and etc.)

There are some points worth mentioning in the design of Manjil park:

- Using real generators to supply necessary energy for the urban spaces, public buildings and houses.
- Planning and applying an energy route in city to show different uses of renewable energies and optimizing of energy usage.
- Spreading the area of park in the manjil city in separate spaces and the same time consistent with park elements.
- Cooperating with schools and universities to expand schools and encouraging research related

to energy into the energy park.

The above mentioned factors made a connection between urban life and park and at the same time are like a permanent instruction of the energy related matters for people. The renewable energy park of Manjil, actually, is an urban community in which productive elements, optimization, education and research related to energy are used together like an alive and sustainable system.

The elements of park consist of three parts which are all located at an ecological matrix of the site: educational and research part, energy production sector and recreational zones. Equipped research sites includes labs and biomass plant buildings which will be used for research and educational aims.

Fig. 4 : A proposed sketch for the Manjil renewable energy park

For achieving the educational goals of the park all planning, design and technology of each building, energy generators and infrastructures are a model and pattern of using clean energies and the park can attract the human and industries and capitals. Producing energy in large amount is visible in the park. Electrical energy is produced by wind turbines and solar panels or photovoltaic cells which are spread all over the site. The placement of Sepidrood dam near the site and the hydropower energy as a renewable one, emphasize on the energy production role of the park. In addition the two mentioned sectors will increase touristic and recreational role and emphasize the strong genious loci of the park.

Thus a whole life and sustainable cycle of energy, industry, research, education, exhibition and recreation exist at park.

Fig. 5 : A proposed sketch for the Manjil renewable energy park

3.1 Designing the renewable energy park of manjil in the framework of ecological design

The designing process of Manjil renewable energy park is based on the framework of ecological design. As stated before Ecological design was defined by Sim Van der Ryn and Stuart Cowan as "any form of design that minimizes environmentally destructive impacts by integrating itself with living processes." [5] .

Ecological design is an integrative, ecologically responsible design discipline . Ecological design, also called green building, is defined as the reduction of pollution and resource use; and the protection or restoration of ecological processes with the intent of minimizing the impact of the built intervention on the local and global environment. [7].

The analogy between the natural environment and human environment has gained much interest. Due to the fact that natural ecosystems are effective at recycling their resources, they are identified as primary examples for the efficient recycling of materials and energy in industry. As a result the natural ecosystem has become a model for the activity of this park.

Ecological Design sees all systems as complex, adaptive systems, whether they contain human actors or not. Ecological Design therefore takes a systems approach. This perspective is essential if one hopes to reintegrate humans with the rest of nature and begin to heal the ecosystems we co-habit. Ecological Design employs transdisciplinary integration, cooperative energy, creative synthesis, and true participatory problem-solving to understand and resolve increasingly complex issues.

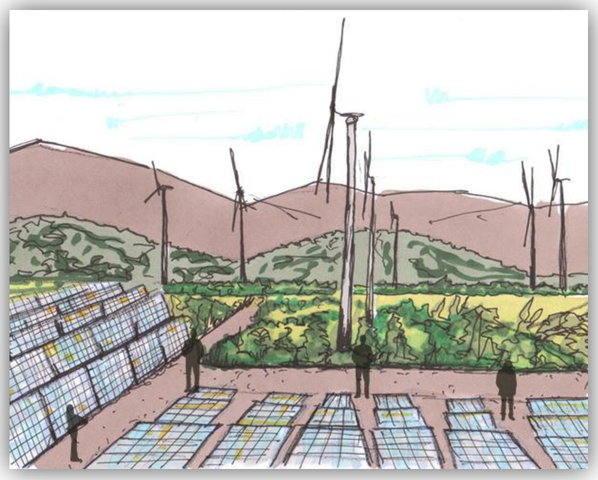

Fig. 6 : A proposed sketch for the Manjil renewable energy park

Ecological design can be applied at a variety of spatial scales. It can be applied in a variety of landscape, including urban, suburban and rural.

In the process of ecological design in the Manjil renewable energy parks the designer will be engaged in the following activities:

- understanding the nature of interaction between human actions and natural processes.

- Understanding and describing the landscape in terms of patterns, process and interactions at many spatial scales to illuminate independent or homogenous area in one or more ways.

- Analyzing the identified homogenous areas

- synthesizing the outcomes of assessment in terms of potential options.

- developing measures for implementing the preferred option.

And so some important points are to be considered.

- Increase the using of natural, clean and renewable energies and optimizing the process of natural cycles as well as water cycle.
- Improvement of seeds, energy, water, nutrients and animals all around the park.
- Improvement of connection of the site boundaries with the outskirts environment.
- Special attention to the ecological niches of animals in the region.

3.2 design strategies

Results of our studies and investigations could be stated as the following strategies:

- It is a tool for research and education in renewable energy and is open to the public.
- The other goal is to provide information to the public by demonstrating different aspects of renewable energy and technology.
- The park is designed for studying integrated energy systems.
- Demonstrate solar energy , wind , biomass , hydrogen and other available renewable energies for the public and offer both students and adults chances to learn about renewable energy, energy conservation, and sustainable environment & building design in a real-world, hands-on environment.
- The park will open up new opportunities for existing businesses.
- It would also be a recreational place for public.
- Designing thematic gardens in the park to show differnet energies in different places , such as solar garden , biomass garden, wind garden and etc.
- Demonstrating various usage of each kind of energy

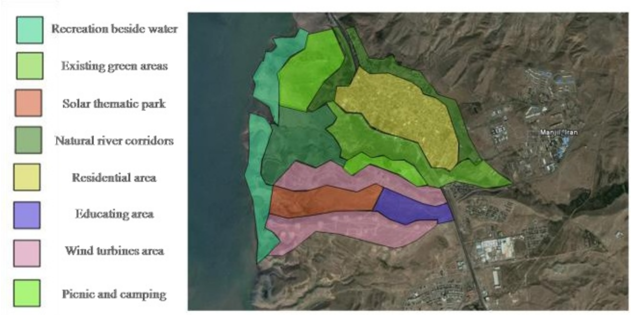

Fig. 7 : the proposed zoning

- The establishment of this park should be based on strong community support and local involvement.
- The park should have an effective and professional management; deliver policy and action for sustainable regional socio-economic, cultural and educational development across the territory.
- This Park must provide and organize support, tools and activities to communicate energy knowledge and environmental and ecological concepts to the public.
- Renewable energy parks should stimulate research and contribute to books and publications.

4 SUMMARY

Today, approximately 80 percent of all energy used in the world comes from burning of fossil fuels. At the same time, an ever-expanding catalogue of energy-saving technologies, as well as reliable and cost-effective sources of renewable energy, is available to policy makers, energy producers and energy consumers. In every part of the world, these technologies make sense from both economic and environmental perspectives . The first step in reducing our environmental and also carbon footprint is becoming more aware of the impact our actions have on the environment. Take some time to brainstorm and create an action plan to change some of our habits that have a negative effect on the environment. Burning fossil fuels such as natural gas, coal, oil and gasoline raises the level of carbon dioxide in the atmosphere, and carbon dioxide is a major contributor to the greenhouse effect and global warming and global warming results in other environmental crisis. Energy resources are essentially used to satisfy human needs and improve quality of life, but may generally lead to environmental impacts (fossil fuels).

So we should change our habits and return to renewable energies . Due to achieving this goal we should introduce and demonstrate green energies to people and describe the advantages and benefits of them . Renewable energy parks would help us to do this duty. Nowadays in order to educate and train people and to accustom public to renewable energies the concept of energy parks and renewable energy parks has been a new, innovative and important solution.

A Methodology for Designing Future Zero-Carbon Electricity Systems with Smart Grid and Its Application to Kansai Area, Japan

Qi Zhang, Benjamin C. Mclellan, Nuki A. Utama, Tetsuo Tezuka and Keiichi Ishihara
Graduate School of Energy Science, Kyoto University
Kyoto 606-8501, Japan
ZhangQi@energy.kyoto-u.ac.jp

Abstract— **Zero-carbon power sources including renewable and nuclear energy are expected to be increasingly rapidly integrated into future electricity systems in Japan. On the other hand, one of the most crucial elements of future electricity systems will be the capability for "smart" controls on both supply and demand sides to perform under real-time dynamics. Therefore, the purpose of the study is to propose a methodology for designing zero-carbon electricity systems with smart grids. The methodology is organized into an input-output framework, and is realized using an hour-by-hour computer simulation to achieve a supply-demand balance in real time subject to various constraints. The methodology is developed as an operable software platform, and it is applied to Kansai area, Japan as a case study to test its practical feasibility. Scenarios with different energy mix in supply side and electric devices in demand side are proposed using the methodology. The analysis result shows that in future electricity systems, controllable loads are helpful for integrating zero-carbon power sources; effective and low cost smart control technologies, batteries, hydrogen storage and fuel cell technologies are crucial for realizing the desired zero-carbon electricity systems. Finally, the practical availability of the proposed methodology is proven through the case study.**

Keywords- scenario analysis; electricity system; demand-supply

I. Introduction

Although the Fukushima Nuclear Accident happened on March 11, 2011 in Japan led to many criticisms on nuclear power again, from a long-term viewpoint, there are very serious energy security problem and global warming pressure. Therefore, zero-carbon power sources including nuclear power and renewable energy are critical for Japan to reduce the high rate of dependence on overseas energy imports and CO_2 emission. However, renewable and nuclear energy pose a significant problem to traditional grid systems, which cannot cope with rapid, intermittent and uncontrollable peaks and falls in electricity demand depending on the time of day and season. Electricity production from renewable energy mainly photovoltaics (PV), wind and wave power depends highly on weather conditions which are unstable and cannot be adequately predicted. Nuclear power as a base load generation source with high capital cost and low operation cost cannot readily alter its power output for technological and economic reasons. Therefore, load levelling and fluctuation absorption remain a problem that power suppliers are unable to overcome by themselves[1][2]. On the other hand, new electric devices such as battery, electric vehicle (EV)[3][4] and heat pump (HP)[5], etc. will soon be added to the current electricity system, and their operation pattern can be controlled in real time. The new electric devices are expected to help electricity systems to integrate more nuclear and renewable energy by absorbing excess electricity and supplying deficient electricity. For this reason, smart control strategies of the electric devices are of vital importance to integrate zero carbon power sources into future electricity systems.

One of the most crucial elements of future electricity systems will be the capability for "smart" controls on both supply and demand sides to perform under real-time dynamics. However, there are many technology options on both sides and the designing of this kind of systems based on various conditions and constraints in a specific area needs an effective and flexible tool. Many models have been developed for analysis of the energy (electricity) mix with renewable energy penetration[6]. In particular, some of them are based on hour by hour simulation[7]. However, there is still not a methodology mainly focusing on zero carbon electricity systems with various new electric devices under various smart control strategies. Therefore, a methodology is proposed in the present study to fill this gap. The core of the methodology is an hour-by-hour computer simulation to realize a supply-demand balance with smart control of the fluctuations on both sides. In the study, continuous baseload and intermittent renewable energy supply, and various demand and supply-side future technology options are incorporated. The input of the methodology is historical electricity load, combined with anticipated new electricity loads and production and lifestyle factors. The objective of the simulation is to develop an electricity system with zero CO_2 emission, less surplus electricity and low cost. The result not only can give the appropriate mix but also the operation patterns of the devices in both supply and demand sides in the electricity system.

The methodology is developed as an operable software platform in the study, and it is applied to Kansai area, Japan as a case study to test its practical feasibility. Scenarios with different zero-carbon power source mix in supply side and different electric devices in demand side are designed subject

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_11,

to various constraints. Finally, the practical availability of the proposed methodology is proven through the case study.

II. METHODOLOGY

A. Framework of the Methdology

An analysis methodology is proposed for integrating more renewable and nuclear energy into future smart electricity systems defined previously with electric devices under their smart control strategies. The basic idea is to conduct analysis into three steps to (1) define a basic model; (2) specify electric device options and their control strategy options based on the basic model; (3) conduct scenario analysis under the specified devices and control strategies to integrate renewable and nuclear energy.

When we consider future electricity systems, we want to know the demand and supply balance; and to know a proposed system is feasible or not. Future electricity demand can be estimated by adding new load to historical load. In order to obtain a feasible electricity system integrated zero-carbon power sources and new electric devices, we need to check the basic demand-supply balance in real time based on input preconditions and predefined operation rules (control strategies). The obtained results are expected to give information on demand-supply balance, mix of system and economic and environmental performances. In general, all the data, rules and results can be organized into technology, economy and environment aspects.

Therefore, we proposed the basic model shown in Fig.1. It is organized in an "Input-Output" framework and realized by hour-by-hour demand-supply balance simulation. The arrows in real line and dotted line in the figure show the data flow and integration respectively. We divide the basic inputs into two classes, one is basic physical data the other is predefined operation rules. Main input data are historical traditional electricity load, solar irradiation, wind speed, fuel supply, installed capacity, CO_2 emissions factor and basic cost information, etc. A number of alternative regulation strategies are classed into technological, economic and environmental perspectives, with emphasis on control strategies of new devices, blackout permission (whether blackouts occur is allowed or not in the electricity system), generation priority of various technologies, upper limitation of excess electricity, range of capacity factor, cost and CO_2 emission constraints respectively.

New electricity devices (battery, EV, HP, etc,) and their combinations are optional, and their control strategies are also defined as optional rules. Outputs are mainly energy balances and the resulting annual electricity production, fuel consumption, total/average cost, total/average CO_2 emission, operation patterns of the new devices under their defined control strategies, etc. Through comparisons of the obtained performance data in different scenarios, appropriated systems can be selected. All the basic data is hourly, however, through statistics, daily, weekly, monthly and annul data can be obtained.

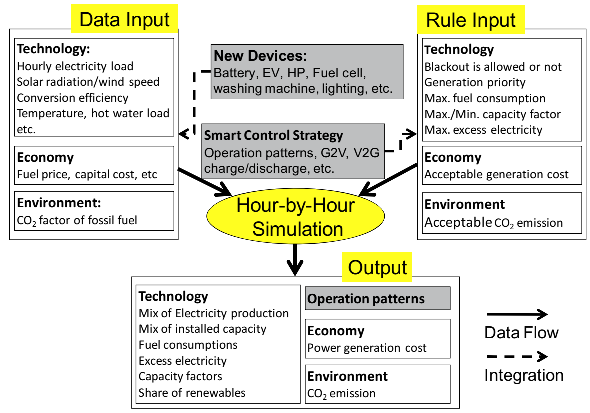

Figure 1. Methdology of sceanrio analysis on future smart electricity systems

B. Flow of the Scenario Analysis

Electricity generations from zero carbon power sources including renewable and nuclear energy are considered as basic supply, when it become more than traditional electricity load, surplus electricity will be consumed by driving HP and/or charging batteries. On the other hand, when basic electricity supply from renewable and nuclear energy is less than traditional load, battery and peak supply try to meet the deficient electricity. Finally, if no blackout happens, the system is considered as technology feasible, otherwise initial data will be changed and new iterative will start.

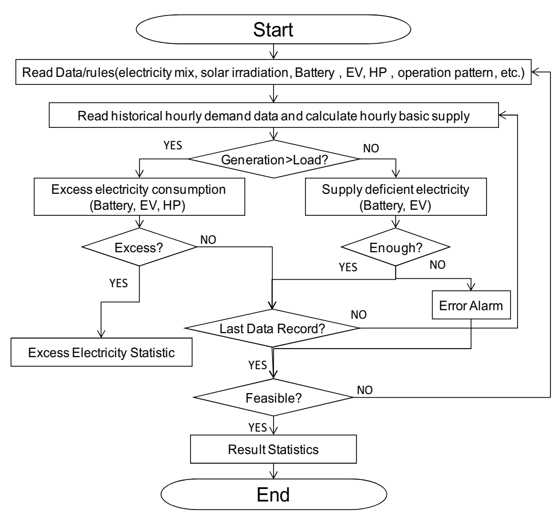

Figure 2. Concept flow chart of the methdology

C. Software Deveopment

The methodology has been developed as an operable computer software using VS.net 2008[8][9] and MS Excel, as shown in Fig.4.

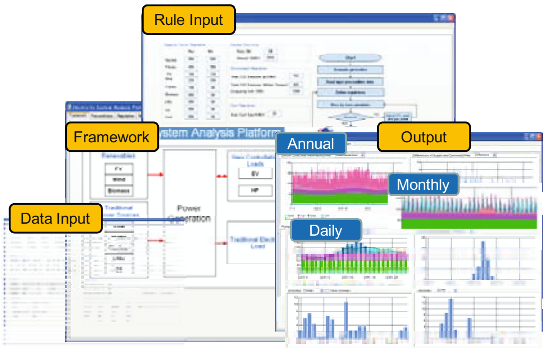

Figure 3. Infterface of the developed software

III. APPLICATION TO KANSAI AREA, JAPAN

A. *Electricity Demand*

The historical hourly data of electricity demand distribution in 2001 of Kansai Area, Japan is shown in Fig.4 [10][11]. In the present study, the final electricity load is the sum of historical load and new load from new electric devices.

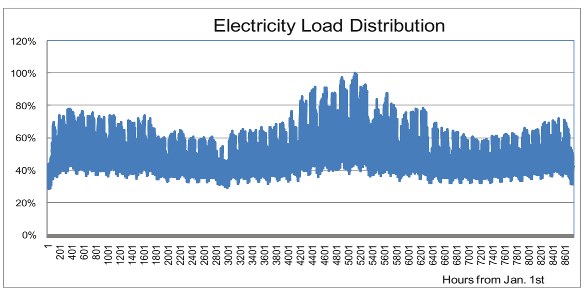

Figure 4. Hourly electricity load

The new loads include Electric Vehicle (EV). Batteries in EVs are not only used to storage surplus electricity and supply deficient electricity but also used to drive EVs, and the latter has priority obviously. The charge of the batteries stops when its SOC reaches 95% and when the SOC of the batteries reaches 30%, which is stipulated as the discharge depth, further discharge of batteries is not permitted in order to save electricity to drive EVs. The hourly data of passenger car on road is shown in Fig.5 through the real-time statistics [12]. The peaks in utilization can be seen to occur during 7:00-8:00 in the morning and 17:00-18:00 in the afternoon. All of the EVs which are not on the road are considered to be connected to grid and available for charge and discharge.

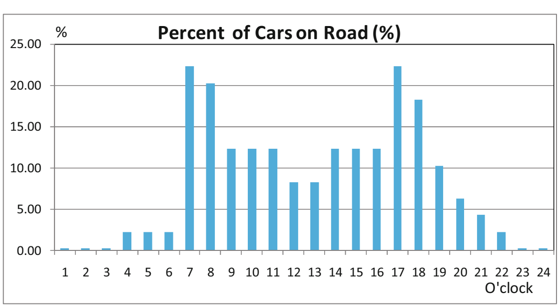

Figure 5. Hourly electricity load

Apart from EV, HP is also a promising future technology for hot water production in the residential sector. It operates on an electrically driven vapour-compression cycle and pumps energy from the air to water in a storage tank, thus raising the temperature of the water, which is especially effective during the periods of maximum solar intensity. In the present study, revised M1 mode is used as the hot water load. It means that 450L hot water at 40ºC is consumed per household on average per day, but the practical temperature of hot water is 65 ºC [13] And the hot water load distribution is shown in following Fig. 6 [14]

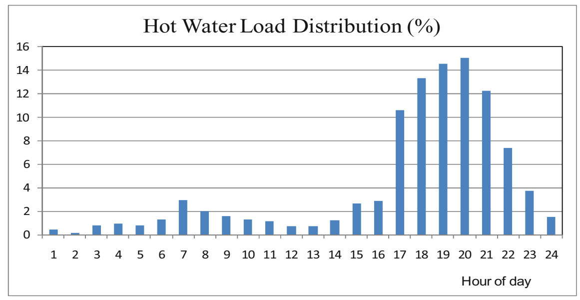

Figure 6. Hourly electricity load

There are 20 million people, 8 million households, and 7.76 million passenger cars in Kansai Area. We assume that a part of cars are assumed to be substituted by EV and a part of households would be using HP for hot water production. Although efficiency of EV in Japan is said to be about 8km/kWh using JC08 model in ideal situation, the practical EPA (Environmental Protection Agency) value-5km/kWh in average is used here [15], and daily travel distance is considered as 30km per EV. HP is used to supply 450 litres of hot water at 40°C according to revised M1 mode. However, the impact that these would have on the electricity load demand would be different according to the patterns of EV charge and HP operation patterns.

B. *Current Electricity Supply*

As shown in Table 1 [10], nuclear power supplies around 46% of Kansai's electricity, 43% is generated from fossil fuel power stations, relying on imported LNG, oil and coal. Hydroelectricity also provides a vital contribution – around 10% of its annual generation

TABLE I. ELECTRICITY SUPPLY IN KANSAI AREA

	Installed capacity		Electricity		CO_2 Emission	
	GWe	%	TWh	%	Million Tonees	%
Nuclear	10.1	28.9%	73.7	47.4%	0	0
Coal	4.4	12.6%	32.1	20.6%	65.6	75.6%
Gas	8.4	24%.1	27.3	17.6%	14.5	16.6%
Oil	8.4	24%.1	9.6	6.2%	6.7	7.8%
Hydro	3.6	10.3%	12.8	8.2%	0	0

C. *Renewable Energy and Excess Eeletricity*

Kansai area, Japan will have to increase substantially the amount of electricity provided by renewable sources, especially ‘‘new’’ sources such as solar and biomass. The wind power is not considered due to very low wind speed in the area. It is very difficult for traditional electricity mix models to integrate renewable energy sources because of the intermittency. Intermittent sources of electricity are expected to have technical and economic limitations in reaching a high level of penetration. Therefore, more intermittent power such as PV penetrated into the system, more excess power will appear when the based load power source level is stipulated as shown in Fig.7. Although, controllable electric devices such as battery and heat pump can absorbe excess electricity, finally the final excess electricity will happen when the absorption capacity is overed. The hour by hour simulation model is therefore vital here to find the feasible electricity mix.

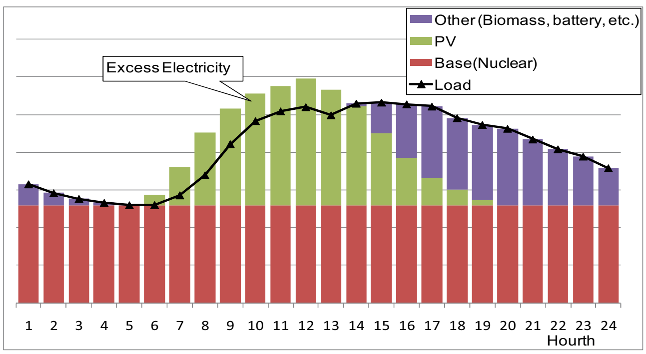

Figure 7. Concept diagram of excess electricity from PV power

IV. SCENARIO ANALYSIS

A. *Scenario Design*

Different penetration scenarios of nuclear, PV, biomass, battery, EV and HP are analyzed in the study as shown in Fig.8. Installed capacity of nuclear power is assumed as 15 and 18 GWe respectively as based supply, and PV power will be integrated as 30 and 15 GWp respectively in two supply scenarios. The deficiency electricity can be supplied from biomass power and hydrogen/methanol fuel cell, which can operate in load-following mode with capacity of altering 100% output in one hour. Pumped hydropower is currently used for load smoothing and energy storage, but will be replaced 100% by batteries including the ones in EVs in the current scenarios. Although the developed model can conduct analysis from technological, environmental and economic perspectives, economic issue is not considered in the present study.

In the demand side, there is no any electric device in D1, however, there are 80 GWh battery (10kWh per household) and 160 GWh battery (another 80GWh battery in factories, power stations, etc) in D2 and D3 respectively. Furthermore, based on the D3, 2 million heap pump for hot water production is assumed in D4. Finally, in D5, 3 million electricity vehicles with 50kWh battery are assumed.

Supply Side

Source	S1 (GWe)	S2 (GWe)
Nuclear	15	20
PV	30	15
Biomass/FC	?	?

×

Demand Side (D1-D5)

	Battery (GWh)	HP (Million)	EV (GWh)
D1	×	×	×
D2	80	×	×
D3	160	×	×
D4	160	2	×
D5	×	2	150

Figure 8. Sceanrio design

B. *Scenario Analysis Results*

The install capacity mix is shown in Fig. 9. Although, PV power has a big install capacity, less electricity can be generated comparing with unit nuclear power plant due to its low install capacity. Furthermore, battery can reduce the requirements of biomass/FC operating in load following mode, for example the comparison of D1 with D2 and D3. The hydrogen can be imported from overseas, also possible be generated from excess electricity from nuclear or PV power.

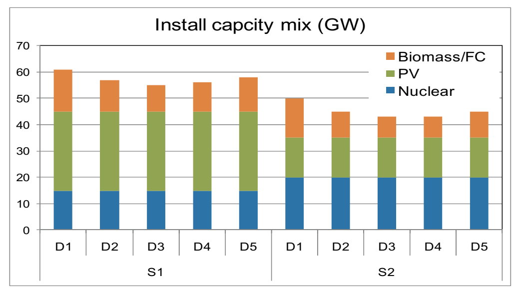

Figure 9. Scenario analysis result: install capacity mix

The results in Fig.10 show that battery, HP and EV can reduce excess electricity from PV power and nuclear power effectively when the D1 is compared with other scenarios. Furthermore, battery can reduce more excess electricity comparing with EV, because the batteries in EVs are used to drive the vehicle with priority and thus supply less available electricity.

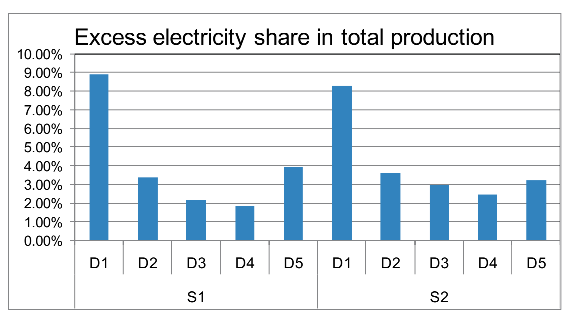

Figure 10. Excess electricity share in total produciton

There are many zero-carbon electricity system scenarios are proposed in the present study. In the future work, the selection of final scenario will be decided by the economy performance. For example, if battery becomes very cheaper than biomass/hydrogen fuel cell, much more battery will be used, on the other hand, more hydrogen/methanol fuel cell or biomass power will be used.

V. CONCLUSIONS

In the present study, a methodology has been proposed to integrate zero-carbon power sources including renewable and nuclear energy into future smart electricity based on input-output hour-by-hour simulation framework and comprehensive smart control strategy on new electric devices- battery, EV and HP. The methodology has been developed as an operable software platform, and it is used to conduct scenario analysis on Kansai Area, Japan. The analysis results show that, apart from nuclear and PV power, biomass, fuel cell based on hydrogen/methanol are crucial for the realization of zero-carbon systems; the excess electricity can be reduced greatly in various scenarios with the help of electric devices and their control strategies. It concludes that battery, EV and HP and their smart control strategies can integrate more zero-carbon power sources into the electricity system. Therefore, the feasibility of the proposed methodology has been demonstrated through its application to Kansai Area, Japan

Future Power of Plastic Solar Cells for Zero–CO_2 Emission Society

Takashi Sagawa[1]

[1] Institute of Advanced Energy, Kyoto University, Gokasho, Uji, Kyoto, Japan

Abstract

Recent progress of plastic solar cells in terms of (1) materials design such as p– and n–type organic semiconductors and nanostructured metal oxide electrodes, (2) thin–film making through dry and/or wet process such as vacuum vaporization and spin–coating, and (3) device structure composed of multilayered thin–films is described. The descriptions refer the photovoltaic performance including I–V characteristics and stability test of the devices in addition to predictive estimation of energy payback time and CO_2 emission rate as life cycle analysis of photovoltaic power generation system.

Keywords:

organic photovoltaics, power conversion efficiency, stability test, energy payback time, CO_2 emission rate

1 INTRODUCTION

Plastic solar cells are lightweight, flexible, and low cost to make as compared to those of the conventional Si and other inorganic semiconductors-based cells. They are one of the promising tools for zero–CO_2 emission society. Efforts now focus on their efficiency and lifetime. Recent progress of the efficiency of polymer-based solar cells has been reached up to 10.1% reported by Mitsubishi Chemical [1]. While Michael McGehee at Stanford University stated that a polymer-based solar cell lasted 7 years [2]. Such progress is based on the multiple developments of various kinds of polymers, organic and inorganic semiconductors, transparent conducting metal oxide coated substrates, metal electrodes, sealing films, and the assembling of these new materials to construct the highly efficient plastic solar cells. In this context, this paper describes recent progress of organic photovoltaics (OPVs) in terms of materials design, thin-film making process, and device structure with regarding the power conversion efficiency (*PCE*), durability (*viz*. stability), energy payback time, and CO_2 emission rate.

2 MATERIALS DESIGN

2.1 Conducting polymers and fullerenes

Plastic solar cell is composed of multilayered thin-films. Typical device assembly is described as follows. Indium–doped tin oxide (ITO) as transparent conducting oxide (TCO), which is deposited on the glass is generally utilized as electrode. Onto the glass–TCO substrate, poly–(3,4–ethylenedioxythiophene)/polystyrenesulfonate (PEDOT:PSS) or other materials such as VO_x, MO_x, NiO is coated as hole-transporting (*viz*. electron-blocking) layer (HTL). Thereafter, mixture of conducting polymer (donor) and fullerene derivative (acceptor) is spin-coated onto the glass–TCO/HTL as active layer. After coating of electron-transporting layer (ETL) such as TiO_x or LiF, vacuum vaporization of Al or other metals as counter electrode forms bulk heterojunction (BHJ) solar cell as glass–TCO/HTL/active layer/ETL/metal.

In order to enhance open circuit voltage (V_{oc}) and short circuit current density (J_{sc}) of the device, one of the most widely used strategies is molecular design of narrow band gap donor polymers through the synthesis of an alternating copolymer from electron–rich (donor) and electron–deficient (acceptor) units in their backbone. In this regard, various kinds of narrow band gap donor polymers have been reported and achieved relatively high *PCE*s up to 7.73% [3–6].

Another strategy for higher V_{oc} is molecular design of novel fullerene derivative, which has optimized lowest unoccupied molecular orbital (LUMO) level as compared with the above polymers. Li *et. al*. had reported successful design of novel fullerene derivatives and attained higher V_{oc} of 0.80–0.87 V and *PCE*s of 5.44–6.48% [7, 8]. Solubility of various fullerenes in organic solvents has been investigated systematically for morphology/surface topology control of active layer of BHJ solar cell [9].

2.2 Metal oxide electrodes

The ideal structure of a BHJ solar cell consists of two phases of donor and acceptor being interspaced with an average length scale of around 10–20 nm equal to or less than the exciton diffusion length. The two phases have to be interdigitated in percolated highways to ensure high mobility charge carrier transport with reduced recombination [10]. Inorganic nanowire–polymer hybrid solar cell is promising to improve the electron conduction to the anode. In this context, polycrystalline TiO_2 nanotube arrays and single crystalline ZnO nanotube

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_12, © Springer Science+Business Media Dordrecht 2012

arrays for polymer hybrid solar cells have previously been developed [11, 12]. Li–doped ZnO and surface modified ZnO with dye showed remarkable efficiency improvement in terms of light harvesting, charge separation, and efficient charge carrier collection of the OPVs [13].

3 THIN–FILM MAKING PROCESS

3.1 Vacuum vaporization

Vacuum vaporization of low-molecular weight organic semiconductor is enable to form homogeneous thin-film with precise thickness by controlling the conditions of vaporization. By using multisublimed materials, highly purified organic semiconductor sometimes shows remarkable enhancement of J_{sc} with high *PCE* [14, 15]. However, significant loss of the starting materials during the vaporization is still problem for practical use.

3.2 Spin–coating

For polymer based OPVs, spin–coating is mostly adopted and remarkable progress has been reported recent years. In particular, additional pre– and/or post–treatments such as thermal annealing, microwave irradiation, addition of co–solvent, slow–drying, resulted effective enhancement of *PCE*, which is ascribed to the improvement of the morphology, crystallinity, and phase-separated state of BHJ [16, 17]. However, application of spin–coating for large area device is not so easy in addition to inevitable loss of the polymer solution during the spin–coating.

3.3 Other methods for printable electronics

Inkjet printing

Printing techniques are the necessary tool for significant cost reduction for OPVs. Although mechanical design of nozzle head and fine-tuning of the “semiconducting ink” are difficult, several groups have succeeded to prepare smooth, homogeneous, and highly efficient organic thin–films by inkjet printing [18, 19].

Spray coating

Spray coating can be done at high production speed and is compatible with various substrates since the sprayed droplets are transferred from the spray nozzle to the substrate without direct contact with the surface. In this process, characteristic performance of OPVs is limited by some drawbacks such as isolated droplets, non–uniform surface and pinholes. In this context, the film formation, surface topography and the morphology of spray coated active layers with additional solvent implemented by using an additional solvent spray deposition have been investigated [20]. Highly efficient OPVs with improved interconnection among droplets and reduced amount of pinholes were obtained by additionally spraying *o*–dichlorobenzene as a solvent after the conventional spray coating of the mixed solution of polymer and fullerene in chlorobenzene to form active layer. Moreover, the additional solvent spray causes changes in the matrix of the active layer resulting in the effective thermal annealing in terms of *PCE*.

4 DEVICE STRUCTURE

4.1 From single cell to tandem cell

Fine–tuning of donor and acceptor materials and careful assembly of the single OPV device will convert 11% of the non-concentrated sunlight. If preparation of an organic tandem device comprised of two sub–cells having different, complementary absorption spectra, is fully succeeded, a maximum *PCE* of almost 15% will be achievable according to Kirchhoff’s law and taking by precise screening of intermediate layer such as Ag or Au clusters as recombination sites [21]. Recent progress attained the *PCE* of 8.3% with 2-cell tandem [22].

4.2 Multicell and sub-module

Roll–to–roll is one of the promising processes to fabricate OPV modules with large area. Guo *et al* demonstrated the attachment of blended solution of polymer and fullerene onto TCO substrate with a gas-permeable silicon film before applying pressure and achieved *PCE* of 3.45% [23]. Krebs *et al* developed novel light–induced thermocleavage polymer and applied it for roll–to–roll process. Large module with the active area of 96 cm^2 was obtained [24]. Combination of screen-printing for making ITO pattern, slot-die-coating for application of ZnO nanoparticle layer coating, with depositions of polymer–fullerene and PEDOT:PSS was performed by using PET substrate for roll-to-roll process. After the device encapsulation with PET protective layer, laminated flexible modules were sent to the many different laboratories and examined their stability and proved their durability for feasible study [25].

4.3 Further extension

Stability test

PCE is the essential parameter for solar cells with respect to maximizing energy production and minimizing cost. A device efficiency of over 10% and a module efficiency of over 5% are regarded as critical market–entry values. On the other hand, lifetime is the second most important parameter for solar cells. For OPVs, a lifetime of 3–5 years (operational lifetime of 3,000–5,000 hours) is regarded as the market–entry point [26]. The organizing committee of the international summit on OPV stability (ISOS) summarized consensus stability testing protocols for OPVs [27]. They defined 3 levels of testing as basic, intermediate, and advanced. Test types are classified into 5 categories as dark, outdoor, laboratory weathering testing, thermal cycling, and solar–thermal–humidity cycling. Details of the conditions had also been settled and further examination will be discussed at the next summit.

Energy payback time and CO_2 emission rate

Net energy gain (*NEG*) becomes positive from negative after some period of time from the first settlement through the continuous accumulation of produced energy. Such duration is called as energy payback time (*EPT*). The balance of initial demand of energy and *PCE* is crucial to determine the *EPT*. On the other hand, CO_2 emission rate is defined as the amount of CO_2 exhaust per unit of produced energy such as 1 kWh, and so on. Komoto reported life cycle analysis of photovoltaic power generation system such as polycrystalline Si (module *PCE*: 13.9%), single crystalline Si (14.3%), amorphous Si/single crystalline Si heterojunction (16.6%), thin film Si (microcrystalline Si) hybrid (8.6%), and CIS (10.1%) for residential use and public/industrial one [28]. *EPT*s for residential use are ranged 1.4–3.0 year, while 1.9–3.4 year for public/industrial use. These values are apparently short as compared with the lifetime of the modules, which is generally over 20 years. CO_2 emission rates are estimated to be 46–78 g–CO_2/kWh for residential use and 62–87 g–CO_2/kWh for public/industrial one. These values are smaller than the average value of conventional utility grids. Regarding the OPV system, long–term examination is required to estimate such analysis. However, because of energy–saving process and recent progress in terms of *PCE* and stability of OPVs, relatively short *EPT* and low CO_2 emission rate are expecting to be realized in future.

5 SUMMARY

New materials of p– and n–type organic semiconductors and nanostructured metal oxide electrodes are expected to enhance open circuit voltage and improve the electron conduction to the anode. Thin–film making through vacuum vaporization, spin–coating, inkjet printing, and/or spray coating should be performed very carefully in order to form highly efficient carrier path. Construction of tandem cell is one of the promising strategies to achieve high power conversion efficiency. For the sake of practical use, roll-to-roll is appropriate technique to make modules with large area. As a consequence, organic photovoltaic system will become one of the future power generation systems showing relatively short energy payback time and low CO_2 emission rate.

Solar induced ventilation for hot and humid regime; efficiency measure case for Tokyo and Jakarta

N.Agya Utama[1], Ben C. Mclellan[1], Keichii N Ishihara[1] and Qi Zhang[1]

[1]Energy Scenario and Planning Group, Graduate School Energy Science, Kyoto University

Abstract

The global energy trend of fossil fuel depletion and potential for worsening natural disasters due to climate change has created worldwide concern not only on how to switch to non-fossil based fuel but also how to reduce energy consumption. One means of reducing global energy consumption is efficiency. The latest information from the IPCC through its AR4 report shows that the easiest and cheapest way to reduce energy utilization is efficiency. Efficiency measures start from power supply through power generation improvement or waste heat recovery; and carry through to end use, such as efficiency in industrial processes or efficiency in the building sectors.

One of the most challenging measures for improving efficiency in the building sector is replacing (partially or entirely) electricity driven appliances while maintaining human comfort. Therefore, this study applies passive methods to partially replace the work of mechanical and electrical devices in buildings by means of improving the air changes per hour (ACH) by utilizing solar induced ventilation or solar chimneys.

The design involves the optimization of solar induced ventilation by using small scale heliostat. The potential improvement is calculated for local climatic conditions in two case study cities - namely Tokyo and Jakarta. The ACH potential was assessed using multi-storey building models (5 storey, 20 unit) apartments.

The results show that solar induced ventilation creating more than 3.3 ACH means that heat, humidity and other pollutants could be removed. Annually for the modeled buildings this has the potential to reduce emissions by approximately 483 kg CO2 in case of Japan and more than 1800 kgCO2 in case of Indonesia. Also it has potential to save up to 250 US$ and 176 US$ for Japan and Indonesia respectively. Moreover with current statistics of apartments in both cities, the potential of CO2 reduction will reach 1.11 x 109 kgCO2 for Tokyo and 7.6 x 108 kgCO2 for Jakarta and monetary savings of approximately 578 million US$ and 73 million US$ for Tokyo and Jakarta respectively.

Keywords: methodology , economy, passive cooling, residential, energy efficient, solar ventilation

1 INTRODUCTION

Nomenclature	
A_{app}	Area of the apparatus (reflectors)
A_{rev}	Area of the receiver (absorber)
$CR_{theoritical}$	Ratio of apparatus to receiver areas
CR_{ideal}	The angle coefficient
η_{app}	Efficiency of the devices
Ts	Sun temperature
$\eta_{optical}$	Optical efficiency
ε_{abs}	Emissivity of the absorber

It has been reported by IPCC AR4 that human activities, mainly since the industrial era, have resulted in increases in the carbon dioxide (CO2) concentrations and therefore has lead to climate change [1]. In order to reduce the potential damage of climate change, global CO2 will need to be reduced by 50-85 per cent of year 2000 levels by 2050 [1]. Energy production is responsible for most GHG emission released into the atmosphere. AR4 demonstrated that improving energy efficiency would play a key role in the mitigation of GHG emission. Buildings have the highest potential for energy consumption reduction with low cost associated with these increases in efficiency.

The greatest share of electricity consumption in most of the tropical countries is cooling [3][4]. This cooling load share comprises the load from both the external heat and internal heat. The share of these two varies though two categories of buildings can be distinguished: In skin load dominated buildings most of the load influenced by external heat and in high-rise type buildings most of the load comes from internal heat. Many studies have been done considering the external dominated load, which consider optimization building envelopes. One of the oldest building codes used in most of the countries in South East Asia is the ASHRAE 1980, though this was based on codes of countries located in the northern

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_13,

hemisphere. External loads are responsible for 70-80 per cent in some houses and 30 per cent of cooling load in certain high-rise residential buildings. Improving the mechanical system in the air conditioning (AC) consumes more energy and is more expensive than improving passive measures in buildings [5].

The future electricity demand prediction should also be assessed in order to improve a country`s energy security, and in this sense the optimization of buildings materials also increases the potential of reducing the electricity demand in the future.

1.1 Passive cooling

The issue on reducing the electricity consumption through cooling is relevant enough, since the number of Households (HH) using AC as cooling system increases year by year. For instance in Indonesia more than 60% urban household uses an AC for its cooling system (mostly split system) and 90% from the middle economic family (minimum family income 400-500 US$ per month) are utilizing the active AC system [6], the number linearly increases due to the country's economic improvement [7] and the increases of the average daily temperature in cities 1.4-1.6 °C [8] in the last 100 years.

Therefore the potential on reducing the electricity consumption in the residential sector is high. However, the improvement of the cooling appliances is promising; however this approach proves to be more expensive [5]. The introduction of passive cooling through buildings materials proves to be less expensive [9], the approaches by means of more adaptable building's facade material and indoor materials or passive cooling to replace the electrical driven appliances.

The application for passive method to increase efficiency in the building sectors has been done in the last couple of decades. In arid region where hot and dry regime is dominant and the temperature different between day and night is relatively high, also relatively clear sky during day and night is beneficial for pond roof type passive cooling either by utilizing nocturnal radiation (without evaporation measures) [10][11] or pond roof passive cooling by utilizing convection, nocturnal radiation and evaporation [12]. Another method of pond roof with evaporative by utilizing gunny wetted clothes also shows promising result [13][14].

The utilization of water based as media to increase the cooling effect and maintain the comfort for indoor room temperature and humidity is working well in hot and dry temperate. However the utilization of water as media for passive cooling in hot and humid temperate are arguably, since high humidity and low nocturnal cooling becomes huge burden to apply those type of application.

The hot and humid climatic condition made the natural ventilation inefficient due to the low air temperature difference between the inside building and ambient; the air temperature difference is normally between 2-5°C. Moreover, in some areas (i.e Thailand and Malaysia) the indoor and outdoor air temperature different indicated in around 0.6- 3.5°C during the day [15][16].

Due to the potential of solar induced ventilation, studies on that strategy had been executed in the hot and humid climate [4-14]. Hirunlabh etal. [4] investigated the potential of a metallic solar wall in removing heat from a house in Thailand. The proposed solar wall was able to induce air flow rate of about 0.01-0.02 kgs1. Mean-while, a house ventilation rate of about 0.08-0.15m3 s1 m2 was able to be induced by roof solar collector in Thailand.[7] Due to this potential, various configurations of roof solar collector had been developed by Hirunlabhetal. [8] in achieving more ventilation rate.

Air movement created by the stack effect is usually not adequate to achieve physiological cooling. It is less than the recommended air speed range for cooling of 0. 15 to 1. 5 m/s in tropical condition (Satwiko, 1994). It can be seen that two means are available for improving air movement: firstly, by increasing the air volume (stack height) and secondly, by increasing the air temperature difference. The indoor air temperature has to be kept low. All the above designs involve stack effect. However, in terms of construction (complexity, technology, etc.) and material (cost, durability, availability, etc.) these designs are not suitable for wide application in low cost housing in tropical countries. [19]

2 METHODOLOGY

$$T_{abs} = T_s\left[(1-\eta)\frac{\eta_{optical}}{\varepsilon_{abs}}\frac{CR_{theoritical}}{CR_{ideal}}\right]^{1/4}$$

Where. T_{abs} is the temperature of the absorber; T_s is the temperature of the sun; ηoptical is the optical efficiency from the reflector (1 equal to the highest absorbent value, we use 0.1); εabs, is the emissivity factor (1 is representing the lowest reflectivity, we use 0.02)

$$CR = \frac{A_a}{A_r}$$

$$CR_{ideal} = \frac{1}{\sin(\theta_a)}$$

Where, Aa is the reflector area; and Ar is the absorber area; θa is the angle degree of the reflector

Buoyancy effect (artificial wind generated)

$$P_s = -\rho g 273 h\left[\frac{1}{T_{ext}}\frac{1}{T_{in}}\right]$$

Where, ρ is the air density (kg/m3); g is the gravity force (9.8 m/s2); h is the tower height (m); Text, is the temperature at stack (absorber), Tin is the inlet temperature (29°C) before entering the tower

$$Q = C_d A\left[\frac{2\Delta p}{\rho}\right]^{0.5}$$

Where Q is the flow rate created by artificial wind (m3/s); Cd is the discharge coefficient (0.65-0.70); A is the area of the opening (m2); ΔP is the pressure difference (Pa); ρ is the air density (kg/m3)

$$ACH = 60\frac{Q}{vol}$$

Where, ACH is the Air Change per Hour; vol is the indoor room volume

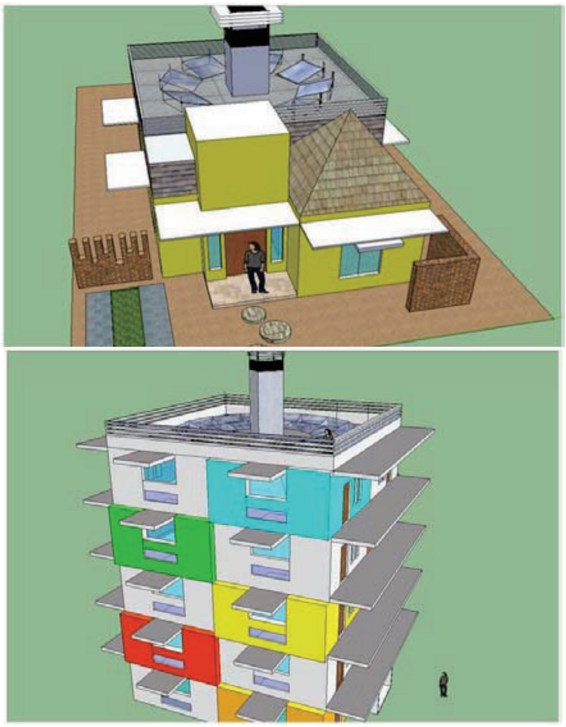

Figure 1 example of the application at dwelling and low rise buildings

Moreover, the flat roof designs for dwelling houses not only beneficial for assembling the solar tower but also reducing the heat gain through roof. The simple simulation by using simulation tools ECOTECT™ shows almost half of the heat gain is reduced for flat roof compare to the traditional pitch roof for Jakarta weather condition. The result by using the simulation tools has been validated by comparing the model and field measurement [20].

3. RESULT

Case in Tokyo, Japan

To calculate how much the proposed system worth in term of electricity reduction, this paper using an assumption with simplified number of buildings (single dwelling and multi-storey) which accounted 5,747,460 household [21] with approximate 91m^2 in average size in the city likes Tokyo [22]. Approximately 60 percent or more than 3.4 million is single dwelling houses and the remaining or more than 2.3 million is multi-storey houses [22].

Case in Jakarta, Indonesia

Based on the housing and household statistics (Susenas) [23] surveyed in 2004, the total number of Indonesian households reached 56.6 million, of which 2.3 million is in Jakarta with 80 per cent of them being single landed types, 2 per cent is apartment/condo type [24], and the remaining 18 per cent is multi-storey or multi-purpose buildings.

Conclusion

The results show that solar induced ventilation creating more than 3.3 ACH means that heat, humidity and other pollutants could be removed. Annually for the modeled buildings this has the potential to reduce emissions by approximately 483 kg CO_2 in case of Japan and more than 1800 kgCO_2 in case of Indonesia. Also it has potential to save up to 250 US$ and 176 US$ for Japan and Indonesia respectively. Moreover with current statistics of apartments in both cities, the potential of CO_2 reduction will reach 1.11 x 10^9 kgCO_2 for Tokyo and 7.6 x 10^8 kgCO_2 for Jakarta and monetary savings of approximately 578 million US$ and 73 million US$ for Tokyo and Jakarta respectively.

Sustainable Manufacturing: Evolution and Future

Fumihiko Kimura[1]

[1] Faculty of Science and Engineering, Hosei University, Tokyo, Japan

Abstract

Environmental consciousness is one of the most important aspects in the development of products and processes. Starting from the end-of-pipe processes, such as recycling, a lot of technological developments have been made for seeking the sustainability of manufacturing activities. For improving the resource efficiency, a comprehensive framework for resource circulation is advocated. Importance of life cycle strategy for integrating system technology and individual component/product technology is discussed. Current research topics and important future issues are shown.

Keywords:

sustainable manufacturing, inverse manufacturing, resource circulation, eco-efficiency

1 INTRODUCTION

Due to the rapid development of industrial activities in all over the world, the environmental influence of those activities becomes critical in recent years for the sustainability of the earth, such as gobal warming, resource depletion and environmental pollution. Consideration of environmental consciousness is one of the most important concern in manufacturing engineering research. This paper reviews the trends of environmental concern in the development of design and manufacturing engineering, and discusses the future perspective of sustainable manufacturing.

In late 80's, the increase of industrial waste and environmental pollution became evident in advanced industrial countries. Various technological developments were made for proper disposal and material recycling of disposed products. Comprehensive legislation have been introduced to enforce the activities of waste reduction and prevention of illegal dumping of waste materials. These activities are considered as the so-called end-of-pipe measure to properly process the generated mass waste. Instead it was srongly discussed the necessity of systematically reducing the mass of generated waste by renovating the products and their manufacturing processes.

In recent years, global environmental problems become more critical, and the more systematic approach is required to fundamentally reduce the environmental burden of human activities. A new paradigm was proposed to shift from mass production and mass recycling to proper production and resource circulation. For this purpose, a concept of resource circulating manufacturing is considered, where a whole product life cycle from product planning to product manufacturing, usage, and final dispoal/recycling is rationally designed, and unnecessary waste generation is systematically avoided. By resource circulation, the total anount of resource usage is expected to reduce, and the environmental efficiency of resource usage becomes higher. In addition to consider physical product production, it is also important to consider appropriate systems for providing product services and change of people's mindset for using industrial products.

By considering the whole product life cycle and clarifying its relations with the global resource circulation, it is expected to be able to evaluate the sustainability of manufcturing activities with respect to global warming, resource depletion and environmental pollution.

In Japan, due to the high rate economic growth in the past, the shortage of waste disposal fields and the increase of environmental pollution became a very critical issue. The government advocated the slogan of changing into the resource circulating society, and the Japanese industry made very strong effort to make their products and manufacturing processes more environmentally friendly and resource efficient. The industry consortium Inverse Manufacturing Forum was established in 1996 for the purpose of promting the concept of resource circulation and environmentally conscious manufacturing[1].

It is very interesting that at the start of the Inverse Manufacturing Forum, its symbol mark was the symbolization of the importance of recycling activity, as shown in Fig.1. Many research and development activities were done in this forum, such as reuse oriented life cycle design methds, a product environmental information management system and service oriented information devices. Throughout these activities, it is gradually evident that, in addition to the individual technology, it is

Proceedings of EcoDesign 2011 International Symposium

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_14, © Springer Science+Business Media Dordrecht 2012

necessary to consider the whole product life cycle and a scheme how to implement the proper product life cycle into the society. After 10 years of research, the Forum proposed the next picture showing the impotance of a top down and back casting approach for guiding the essence of sustainable manufacturing developments, as shown in Fig.2. This progress is considered to describe the evolution of a concept of sustainable manufacturing in past years.

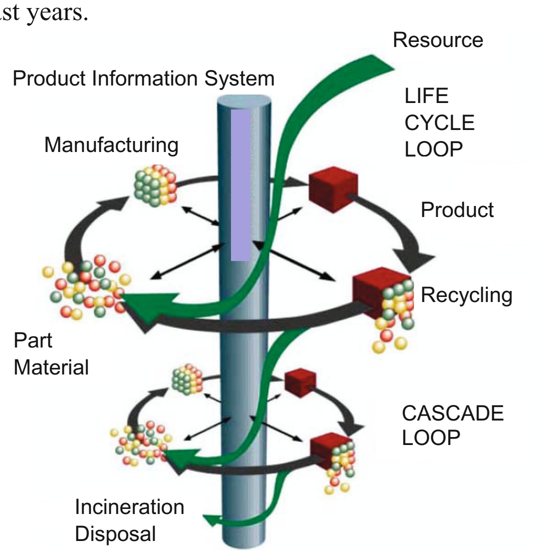

Fig.1 Closed loop product life cycle

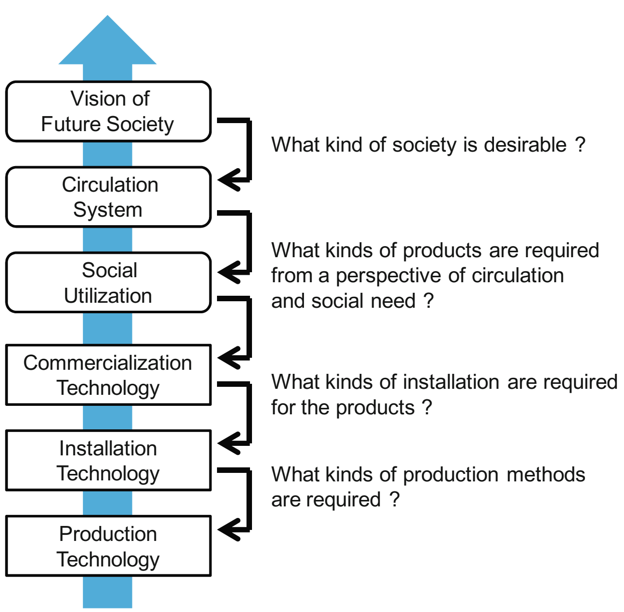

Fig.2 Toward sustainable society

2 MANUFACTURING AND SUSTAINABILITY

2.1 Importance of manufacturing

The discrete manufacturing is considered in this paper. Among the total resource consumption in the world, the amount of resources consumed directly by the discrete manufacturing sector is generally speaking very small. In this respect, sometime it is said that manufacturing is not important for reducing the global CO_2 emission. It may not be true. Manufacturing is tightly related with material production, transportation, social infrastructures and product usage, as shown in Fig.3. If some innovation is introduced in manufacturing, big change and reduction of material usage can be expected. In this sense, if the total life cycle is well designed, manufacturing is considered to be a effective mechanism to manage and to control the global resource flow.

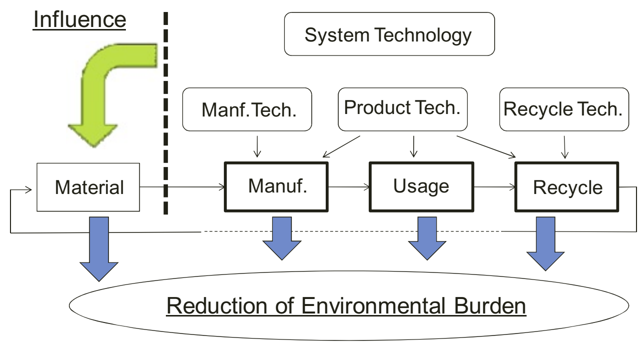

Fig.3 Influence of manufacturing for resource circulation

2.2 Resource and information circulation

In circulation oriented manufacturing, it is important to consider not only physical resource circulation, but also information circulation, as shown in Fig.4 [2]. Manufacturing is considered to transform design information into actual products. With appropriate scheme it is natural to keep the design information with the realized products, then to feedback the information with usage and user information. Such information is effectively utilized for proper reuse/recycling, but also for capturing usage status, adapting the current products to real situations, and creating new product/service concept.

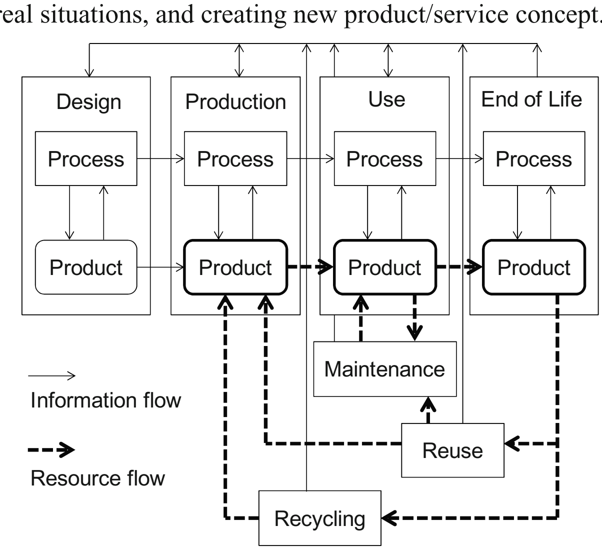

Fig.4 Information circulation in product life cycle

3 SUSTAINABLE MANUFACTURING

Sustainable manufacturing is considered in various aspects as shown in Fig.5. A total framework for sustainable manufacturing is not very much different from the conventional manufacturing, except for focusing on the holistic consideration of product life cycle and resource efficiency evaluation. It is interesting to see the possibility of selecting non-conventional life cycle options from the viewpoint of resource efficiency and environmental evaluation. Some of the examples are parts reuse, product modularization, remanufacturing, manufacturing system reconfiguration, component tracing in product usage, etc.

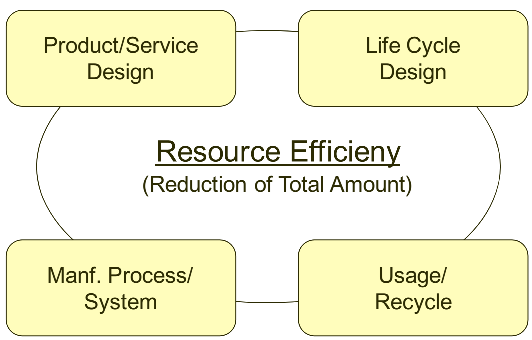

Fig.5 Sustainable manufacturing

For thinking about the total product life cycle, there are two approaches: a system technology approach and an individual technology approach, as shown in Fig.6. For achieving ultimate resource efficiency and reduction of environmental burden, one approach only is not enough, but appropriate combination of the two approaches is essential. The system technology approach includes life cycle design and management, product sharing, leveling of operations, etc. The individual technology approach includes light-weighted design, new materials, low friction design, energy saving, etc.

The followings are some of the important research and development items for sustainable manufacturing.

(1) System planning and product design technology
- Life cycle strategy and scenario planning
- Design guideline and method
- Design for environment

(2) Manufacturing technology
- Material flow analysis
- Clean manufacturing
- Recycling process design

(3) Management technology
- Inverse logistics
- Recycling information system
- Maintenance management

(4) Resource circulation technology
- Resource tracing in product life cycle
- Resource recovery

(5) Evaluation technology
- LCA database
- Life cycle cost and risk assessment
- Embedding LCA in product life cycle design

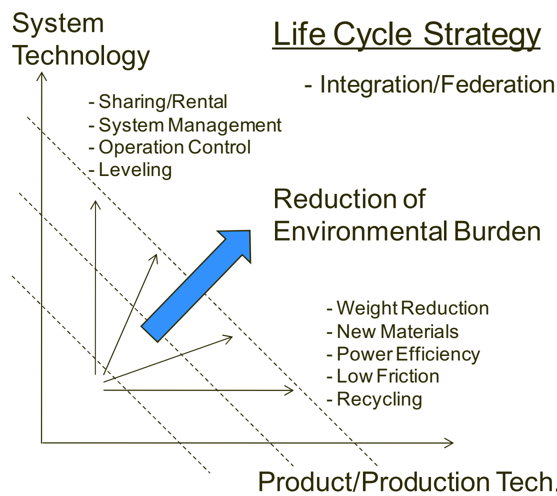

Fig.6 Life cycle strategy

4 FUTURE ISSUES

The basic concept and importance of sustainable manufacturing is well understood. The existing manufacturing technology can be adapted for the new requirements. However many issues still remain with respect to products, processes and systems.

4.1 Product quality management and innovation

Extreme resource efficiency is required, for example, for motor vehicles in developing countries. In such cases, in order to achieve environmentally consciousness with low cost, innovative product technology is demanded, such as low friction mechanism, high stress structures, etc. Not only to seek for long life and high quality, but also to realize appropriate life and quality adapted to market needs, precise life and quality control technology is required. In many cases today's products are in over quality and excess complexity, and then result in resource inefficiency.

4.2 Efficiency in manufacturing process

There are still many sources of inefficiency in manufacturing processes, due to the inherent incompatibility between product life cycle and manufacturing system life cycle. System installation is often too large and complicated for targeted products, and a lot of resources are wasted for indirect operations, such as air conditioning and peripheral device operations.

4.3 Improvement of resource circulation

Resource flow from law materials to production is relatively well managed and efficient, but reverse resource flow from used products to recycling and production is still very unclear and inefficient. Today's manufacturing is global, and resource flow across the country border is very difficult to trace.

4.4 New product/service for social innovation

Innovative new products, such as electric vehicles and electronic paper, can offer new services which consume less physical resources and create new value for users. However in order to implement such new products, new social infrastructure and change of people's mindset are necessary.

5 SUMMARY

Evolution of sustainable manufacturing is considered, ranging from closed loop manufacturing focusing on recycling to resource circulating manufacturing with the whole life cycle design. Important aspects of sustainable manufacturing and future issues are briefly discussed.

Many effective methods and tools for system technology development and individual component/product development are now available. Probably the most difficult issue is how to actually implement sustainable manufacturing scheme with active participation of product/service users and society. Normally users tend to act based on their intuitive consideration about environmental issues, and do not follow rational thinking. According to the economical development of the society, the users buy higher quality products by seeking higher product value. Therefore as shown in Fig.7, even if technology for improving eco-efficiency is introduced, the environmental load may not decrease as expected. It is essential to clarify a vision for sustainable future society, and to realize the change of people's mindset.

Roadmapping of Sustainable Manufacturing Technologies in Japan

Nozomu Mishima[1] and Yasushi Umeda[2]

[1] Advanced Manufacturing Institute, AIST, Tsukuba, Japan

[2]OsakaUniversity, Osaka, Japan

Abstract

To enhance the competitiveness of Japanese industries, continuous R&D efforts of elemental technologies are important. It is also helpful to know the overview of the area to enhance efficiency of the developments. In industrial technologies, since the practical needs in future are the strong driving force, it is necessary to determine appropriate targets of development. Thus, making roadmaps of technological area is useful to know the appropriate and efficient targets of development. Since Inverse Manufacturing Forum is a research association covering R&D area of sustainable manufacturing technologies, the mission to make the roadmap was outsourced to a committee based on Inverse Manufacturing Forum which was organized under Manufacturing Science and Technology Center. This paper briefly introduces about the history and overview of the roadmapping effort of sustainable manufacturing technologies.

Keywords: sustainable manufacturing, inverse manufacturing forum,

1 WHY ROADMAPPING?

Few one disagrees that sustainable manufacturing technologies are the keys to satisfy high quality of life and low carbon society. However, it is very difficult to determine which technologies should be put emphasis on and what kind of approach should be taken, since so many sustainable manufacturing technologies have been proposed and it is impossible to implement all the technologies now. To take a strategic approach towards implementation of sustainable technologies, strategic thinking and categorization of technologies are necessary. The strategy of technological development extracted from these strategic thinking is so-called technological roadmap.

A committee organized under Manufacturing Science and Technology Center has been working on the technological roadmapping from 2007. Some members from Inverse Manufacturing Forum have been working for the committee. Many technologies which were discussed in the Forum were also listed up to the technological roadmap. In 2007, individual technologies were listed. In addition, possible candidates of national R&D project were discussed and three groups of technologies were proposed. Those three were "Highly efficient diverse-types-and-small-quantity production system," "Sustainable society simulator," and "manufacturing and inverse manufacturing integrated production system." In 2008, top-down thinking to show categorization which may help to achieve sustainable society was tried. As the result of the discussion, logic tree of sustainable manufacturing technologies was proposed. In 2009, a new integrated project proposal in integrating above-mentioned three groups was proposed. Again in 2010, modification of technological roadmap was discussed.

In the paper, the approach of roadmapping is explained with the layered categorization strategy of technologies. Then, the three project candidates and its visual images are shown. Through these efforts, the paper tries to draw a big picture of Japanese trends on R&D of sustainable manufacturing technologies.

2 SCENARIO ORIENTED APPROACH

2.1 Typical approach of roadmapping

Effort of making a technological roadmap is recently common in many industries in Japan. If there is a good technological roadmap, it is helpful to know what kind of development should be focused on for efficient R&D effort. For example, if the target of the development is 5 years later, it is necessary to focus on a technology which is predicted to be developed at least later than 5 years. This type of technological roadmaps is typically seen in device technology such as semi-conductor devices, MEMS, and so on. In these roadmaps, level of technologies should be exactly estimated and step-by-step progress of the technologies should be taken into account. Since these roadmaps are based on an extrapolation of practical technologies, these are very useful in predicting technological trends in near or mid-term future.

However, once there is a big change in social situations such as legislations, global economies, reduction target of global warming gas, and so on, this type of approach is not so appropriate. That was the motivation of technological roadmapping of sustainable manufacturing technologies.

2.2 Necessity of back-casting

As it is briefly mentioned in the former section, target of the reduction of green house gas is still under discussion. Therefore, there is a big possibility that a drastic change in the technological trend. It is so-called "paradigm shift" or

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_15,

"quantum jump." In such a situation, the step-by-step approach of roadmapping is no more effective. Instead, the roadmap should list necessary set of technologies to reach the designated goals. And it should clarify which technologies in current world will contribute to enhance sustainability and which technologies should be promoted. This approach is called back-casting. The roadmap of sustainable manufacturing also takes back-casting approach.

2.3 Scenario-based approach

To take the back-casting approach, a scenario which will be the goal of technological development should be decided. The following description is the essence of the scenario which the team decided at the beginning of roadmapping effort. The scenario is targeting 2025.

General situations:

Although there have been many efforts of the reduction of fossil energy consumption, according to the economical growth of newly industrialized country such as China and India, the world consumption of primary energy has reached 1.4 times of that in 2000. Development of renewable energy technologies that are being expected to replace some of the energy supply have been carried out. And the ratio of renewable energy has been increasing steadily. However, a drastic increase has not come yet.

The reduction target of greenhouse gas in 2050 has been agreed by major emitting countries. Corresponding to the agreement, the goal of greenhouse gas reduction in Japan has also been decided. (It is minus 60 to 70% of the amount of 2000.)

Production technologies which can enhance eco-efficiency (value of the products/lifecycle environmental burden) to 4 times of that of 2000 have been developed. However, since technologies have not spread to every industry, the reduction of greenhouse gas emissions in Japan is carried out by the combination of the lean production in industries, reduce designs and energy efficient designs of products, emission trades, the carbon tax and CO2 storage technologies.

However, in 2025, the problem of lack of natural resources is becoming more and more urgent. Thus, not only the linear development of current technologies but also a paradigm shift including the establishment of new lifestyles is being required, to establish the real low-carbon society in 2050.

In addition, more detailed scenarios was decided for all the lifecycle stages of products that are "design," "production," "usage" and "end-of life."

3 HISTORY OF DISCUSSION

3.1 First year; 2007

Through the first year's discussion in the committee, a categorization of element technologies has been carried out. As it is mentioned in the later section, the technologies were categorized to 4 roads and 9 approaches.

3.2 Second year; 2008

Based on the first year's discussion, the committee discussed the intermediate social situations to connect element technologies and the goal (societal scenario). The intermediate social situations have been named "meso-layer." Then, a logical procedure so-called logic tree to start from the meso-layer and reach to elemental technologies was drawn. In addition, 3 groups of elemental technologies that can be possible candidates of national R&D projects have been discussed and decided.

3.3 Third year; 2009

According to the change of the governmental policy, small modifications on the scenario were discussed. Plus, a general direction of R&D to integrate above-mentioned three subjects was considered and drawn on the introductory scenario.

3.4 Rolling of the roadmap; 2010

The roadmap was examined by some new committee members from private companies. Some claims, opinions and suggestions about whether the roadmap is helpful to show the direction of R&D to those private companies were extracted.

4 LISTING AND CATEGORIZATION OF TECHNOLOGIES

4.1 Four roads to sustainability

As it was mentioned in section 3.1, elemental technologies of sustainable manufacturing were categorized based on 4 directions to establish sustainability and 9 approaches to reach the goals.

These are the 4 roads.

1. Life cycle thinking
2. Minimization
3. Heightening of added value
4. Succession of skill

4.2 Nine approaches towards sustainabilitys

Elemental technologies are also categorized to 9 approaches to establish the sustainability. Not same as the usual technological roadmap, aforementioned 4 roads and 9 approaches are not large sections and intermediate sections, because the relations between 4 roads and 9 approaches are many-to-many correspondence. The next are the 9 approaches.

a. Servicizing
b. Visualization
c. Computerization
d. Ubiquitousizing
e. Reutilization
f. Substitution
g. Balancing
h. Standardization
i. Personal training

4.3 Element technologies towards sustainabilies

Each elemental technology for sustainable manufacturing was categorized using aforementioned 4 roads and 11 approaches as labels. Table 1 shown below is a part of the technological roadmap

Table 1 Technological roadmap of sustainable manufacturing technology (partial)

Life cycle thinking	Servicizing	Maintenance technologies	*Estimation technology of residual life * Risk-based preservation technology *Management technology of usage history * Maintenance business
		Design support technologies of environmental conscious business strategies	Software technology of supporting environmental conscious business strategies
	Systemi-zation	Lifecycle design technologies	* Design technology of LC strategies
			* Lifecycle simulation * Comparison technology of alternatives
			* Easy-to-recycle design technology
			* Easy-to reuse design technology
		Reduce design technologies	*Optimum design technology of structures *Utilization technology of high-functional materials *Utilization technology of recovered material and parts
		Lifecycle management technologies	*Management technology of lifecycle information *Management technology of usage history *Fusion technology of products and information
		Management and design technologies of global circulation of products	*Design technology for global product circulation *Technology assure traceability
			*Social system establishment for global product circulation
		Product life management technologies	*Product life prediction technology *Product life diagnosis technology *Product life design technology
		Quality management technologies	*Residual life diagnosis technology * Degradation diagnosis technology *Non-destructive testing technology *Remote testing technology
	Re-utilization	Management technologies of product circulation fro reuse	* Forecast of generation of reusable parts * Management of stock of reusable parts *Production planning utilizing reusable parts

5 SUBJECTS TO PUSH

5.1 13 groups of tecnologies

In the second year of discussion, since the first year's roadmap didn't show which technologies should be focused on strongly, the committee tried to extract group of key technologies that will be inevitable to develop to establish sustainable society. These are the 13 groups of technologies to be put emphasis on.

a. Lifecycle design technologies
b. Sustainability estimation technologies
c. Managment technologies for global product circulation
d. Modeling technologies of products
e. Fusion technologies with products
f. Technologies to ensure traceability
g. Technologies to design good balance of products and services
h. Fusion technologies of products and services
i. Technologies to minimize portotyping
j. High effeiciency various kind and vriant production technologies
k. Manufacturing system technologies to integrate mnufacturing and inverse manufacturing
l. Energy-efficient and resource-efficient technologies in manufacturing processes
m. Manufacturing process technologies with high yield of materials

5.2 Three candidates for national R&D project

In the second year of discussion, the committee also proposed three potential candidates of national R&D projects concerning sustainable manufacturing technologies. Fig.1 to 3 are the schematic images of the 3 subjects.

(1) Sustainability Scenario Simulater

Sustainability Scenario Simulater can express how development and spread of technologies, consciousness of citizens, societal lives and environmental impacts can change along the time, concretely and exactly, including the image of the society..

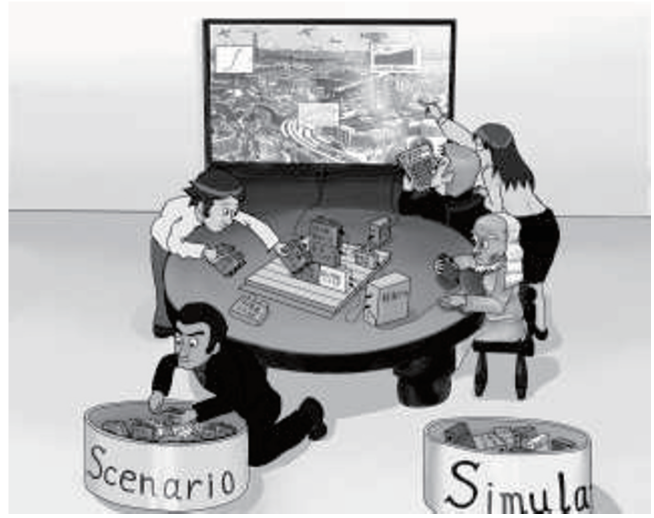

Fig. 1 Sustainability Scenario Simulater

(2) Efficient various-quantity-large-variety production

On-demand manufacturing can be a key to reduce waste, and enhance energy efficiency and resource efficiency of the production. Thus, the new manufacturing system should satisfy "on-demandness" of the production, from upstream to downstream. At the same time, functionalities of the products should be satisfied at a high level. Not only manufacturing process technologies but also diagnosis and prediction technologies of product performances are necessary. This kind of manufacturing system is also helpful to maintain knowhow of manufacturing and personal training.

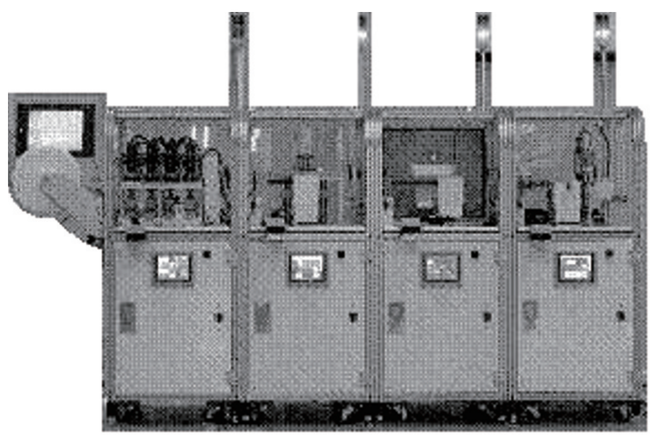

Fig.2 Prototype of the on-demand manufacturing system

(3) Manufacturing system combined with inverse manufacturing system

As it is recently seen in some of electronic products or automobile parts, reuse and remanufacturing of parts are becoming common. These remanufacturing especially combined with manufacturing will be a key technology nowadays to enhance competitiveness of manufacturing. Thus, to carry out R&D of the integrated system will be a good strategy to promote Japanese manufacturing industries.

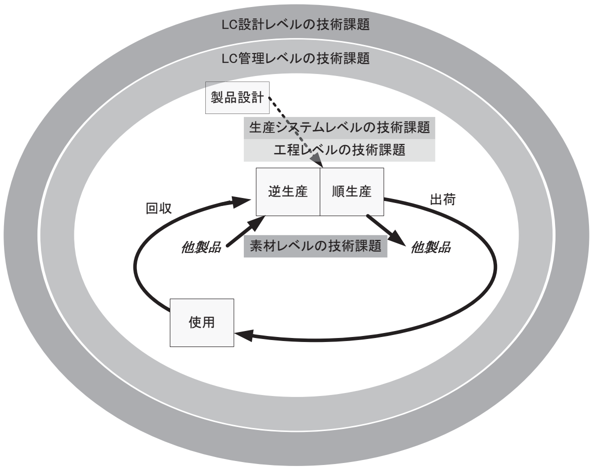

Fig.3 Concept of manufacturing system combined with inverse manufacturing system

6 ROADMAP FOR EFFICIENT R&D

Inverse manufacturing forum is a research consortium to discuss how the sustainable society can be achieved. Members have their own research topics. Concerning the research activities, R&D of actual manufacturing technologies, material technologies, design technologies, etc. have been carried out. Those efforts are the core of technological progress and very important. But, at the same time, for efficient developments and for enhancement of competitiveness of industries, having the overview of the area is helpful. In that aspect, roadmapping of the technologies is also necessary. And of course, for sustainable manufacturing technologies, Inverse Manufacturing Forum is the suitable organization to be in charge of the roadmapping.

Through 4 years effort of the committee, the technological roadmap of sustainable manufacturing technologies has been drawn. In addition, some promising groups of technologies which can be candidates of national R&D project have been extracted. The next step is to utilize the roadmap for efficient and strategic R&D, in private companies and public organizations.

Corporate Environmental Targets Analysis:

Case Study from Japanese Manufacturing Industry

Jan Dusek (1)[1], Yoshiro Fukuda (2)[1]
[1] Department of Engineering and Design, Hosei University, Tokyo, Japan

Abstract
Nowadays it is increasingly important for companies to stay credible in connection with their commitment to address global warming and reduce their environmental impact. One way to do this is to consistently and transparently disclose environmental data. This research aims at investigating the environmental data disclosed by companies, with particular focus on corporate environmental targets. We analyze the historical timeline of corporate environmental targets on a sample of major Japanese manufacturing companies in order to understand patterns of target setting behavior. In a number of cases we identify a significant level of inconsistency. We examine the significance of this phenomenon by conducting a questionnaire among stakeholder group that deals with the issue of corporate environmental disclosure on daily basis – sustainability rating agencies.

Keywords:
environmental targets, environmental performance evaluation, target setting behavior

1 INTRODUCTION

1.1 Research background

The manufacturing industry is responsible for a substantial share of global CO_2 emissions and energy consumption. It is therefore important to closely monitor and manage the environmental impacts associated with the manufacturing industry, both at the industry level and at the company level. It is a globally established practice for major manufacturing companies to report on their environmental impact. CSR reporting and other environmental impact disclosure activities remain voluntary. However, many manufacturers are under increasing pressure from various stakeholders (governments, shareholders, NGOs, etc.) to consistently monitor, disclose and reduce their environmental impacts. In last decade, significantly more manufacturing companies have been issuing CSR reports and disclosing their environmental impact, from both manufacturing and non-manufacturing operations. Many studies have focused on analyzing the content of CSR reports and exploring factors that encourage environmental disclosure [1]. The practices of corporations have also been criticized. Kaenzig [2] concludes that in many sectors corporate disclosures only cover a very small share of the total environmental burden. To our knowledge, there are no studies analyzing the historical time lines and consistency of corporate environmental targets. A key question examined by this study is the development in corporate reporting represented by corresponding environmental targets setting behavior. In most of the more recent CSR reports we can find ambitious environmental visions, goals and targets claiming commitments to achieve zero emissions and zero waste in the distant future. We believe that future targets can only be assessed relative to the context of how companies have performed to their previously stated targets. That is the major motivation for our study.

1.2 CSR reporting in Japan

Japanese CSR reporting is often said to be based upon a Western-led discourse [3] but it also has roots in traditional Japanese business culture [4]. The current practice of Japanese manufacturing companies disclosing environmental data follows internationally recognized formats, such as that of the GRI (Global Reporting Initiative) [2]. The number of CSR reports has been growing rapidly [1]. However, industry standards or common practice guidelines for disclosing emissions associated with the 'supply chain' and 'product use' phases have not yet been established. Recently several studies have focused on the motivation of Japanese companies to adopt CSR reporting and the major driving forces behind this adoption. Socially responsible investment (SRI) in Japan has been one of the factors contributing to the spread adoption of CSR reporting [5]. Studies focusing on environmental reporting are supplemented by research discussing the establishment of environmental management strategies in Japanese companies [6] or research investigating future issues with

environmental management [7]. The major players in the manufacturing industry in Japan have a long tradition of CSR reporting. Some have been formulating their environmental visions, corporate action plans and specific targets in order to demonstrate their commitment to address environmental and social issues for more than decade. The common feature of CSR reports are various targets relating to environmental impacts. We can find the analogy of ambitious goals at the national level as well. At the G8 Summit in June 2008, former Prime Minister Yasuo Fukuda announced a national goal to reduce CO_2 emissions by 60-80% from the existing levels by 2050 [8]. Our analysis of the corporate historical timelines for environmental targets can help us better understand the likelihood of future targets being achieved in corporate Japan, which is then partially indicative regarding targets at the national level.

2 CORPORATE ENVIRONMENTAL TARGETS ANALYSIS

2.1 Introduction

Our research is based on the analysis of sustainability targets. We focus on corporate targets related to environmental impact, particularly CO_2 emissions and energy consumption in the Japanese manufacturing industry. These targets are set voluntarily by the companies, but sometimes also represent the goals of industrial associations, such as Keidanren and its Voluntary Action Plan [9]. First, we screen the available environmental reports to identify the targets and their definitions. Second, we analyze the timelines for individual targets with respect to several factors. In this primary analysis we observe the target, baseline and time frame definition consistency and year-to-year achievement rate. At this stage of the research our aim is to understand the rationale behind target setting, and to identify particular patterns. The development of a sophisticated analytical tool that would allow comparison of the target setting behavior among companies or across industries is beyond the scope of this study.

2.2 Corporate environmental targets

Environmental targets can be classified into several groups of targets that are present in most of CSR reports, such as targets focused on prevention of climate change, conservation of resources, reduction of hazardous substances, recycling, protection of biodiversity, etc.). Rising CO_2 emissions represent a widely recognized symbol of global warming, and this measure is commonly used in Japanese corporate environmental impact studies [10]. Companies tend to use several metrics to monitor the direct impact of their operations – total emissions, emissions intensity, energy used and energy intensity being the basic metrics [11]. In terms of environmental target evaluation, the following aspects are considered to be important: clear definitions of target baselines, time frames, scopes and units; the relevance of the target to the overall environmental impact of the company; the consistency of the target over its duration; the ambitiousness of the target; and the achievement of the target. As a pioneering study in this area, one of our goals is to steer the discussion that would lead to a suitable target progress evaluation tool with capabilities to address all of these aspects.

In the following case study we demonstrate our findings based on an analysis of corporate environmental targets. The phenomenon identified is then addressed by a voice from important stakeholder group – sustainability rating agencies and SRI funds. Our study brings insights from the analysis of environmental target setting behavior and builds the overall knowledge also with practical suggestions based on the experience of rating agencies.

3 CASE STUDY

3.1 Introduction

In 2006, the manufacturing industry in Japan was responsible for 460 mil tons of CO2 emissions [12], where 4% of emissions were contributed by the electrical and electronic industry. CSR reporting has only been common practice among Japanese companies since about 2003 [4], and major companies in the electrical and automotive industries have been among the first to adopt CSR reporting. According to CRRA [13] Japan ranks as number three out of the top twenty reporting countries in the period from 1992 to 2010. CRRA notes that if Japanese language only reports were included, Japan would rank number one. Companies in the electronic and automotive industry have some of the longest records of CSR reporting in Japan. Our motivation for analyzing companies in the electrical and electronics industry is based on the fact that major players in the industry are conducting their operations globally and their reporting practice is therefore subject to intense scrutiny. We assume that the quality of environmental data disclosure is among the highest in corporate Japan. However it is still quite rare for CSR reports to address all of a company's environmental impacts, reflecting all impacts before procurement and after sales.

3.2 Studied companies and data

Our environmental target analysis was applied to a case study – a sample of major Japanese manufacturing companies from the electrical and electronics industry. We first screened data relating to environmental targets for seven companies. The data covered 68 environmental reports issued between 1997 and 2011. Corporate websites and publicly available corporate answers to the Carbon Disclosure Project (CDP) served as another source of data. For the target companies we analyze the available CSR reports and extract the selected information about the environmental targets. For more detailed analysis we selected two companies (A, B), which have the longest records of environmental reporting, with available CSR reports going back to 1997. In these two cases we analyze closely 27 issues of corresponding CSR reports. At this point, it is important to note that in most cases we work under the assumption that the disclosed data is accurate and follows best disclosing practices. We intend to study the data presented by companies themselves. We look at the environmental targets set by companies as one way to communicate with the stakeholder groups and create a public image. As one of the outcomes of this study we identify future opportunities for target setting and improved communication to stakeholders.

3.3 Targets in practice

Numbers or targets and changes implemented are an opportunity to observe dynamic processes in corporate target-setting. Detailed content analysis makes it possible to recognize and understand similar situational patterns leading to shift in a target setting behavior. In our analysis we first draw timelines for studied companies A and B, demonstrating the time of the implementation of an environmental plan, the declaration of an environmental policy or setting up of a new target or its revision. Such timelines make it easy to observe the duration of a target period. In the case of the company A, in 15 environmental reports we identified eight targets (TA1-TA8) under the category of "global warming prevention," relating to emissions from manufacturing sites. Targets were focused on reducing energy consumption per net sales; cutting unit CO_2; reducing GHG emissions other than CO_2; eco-efficiency and absolute CO_2 reduction targets. In the early years, targets focused primarily on covering selected manufacturing sites in Japan, gradually this coverage expanded to include global branches and manufacturing sites. The Table 1 shows a list of targets companies A and B with their basic description. In example, target TA1 was not achieved as planned. As a reason for failing the target company A uses the growth in device business. Similarly target TA2 addressing energy consumption per sales was not achieved (27% increase instead of 25% reduction). Company A in following CSR report states: "*We invested approximately 10 billion yen into the company-wide energy conservation activities in fiscal 2000, but was unable to achieve the target. This has been attributed to the impact of our business restructuring activities and rapid market fluctuations.*" Slower growth in sales due to the downtrend in product prices is another reason when the sales based relative targets fails. TA3 successfully reached its first milestone but then was substituted by another target. Some changes looks minor but have a significant impact on the calculation of the target. For instance TA6 is revised TA4 with "*per unit sales*" substituted by "*per basic unit*". In the case of the company B, a set of nine targets TB1-TB9 in same category was selected and their timelines were analyzed. A similar pattern was identified for both companies. In the early years we can see that often the defined targets are not achieved. The level of target discontinuity or failure of achievement is bigger than in case of the company A. Due to the change of methodology of scope, previously set targets are difficult to track further (TB1). Subtle moves in corporate target setting behavior is also expressed in case of targets TB4 and TB6. The definition of the relative targets was changed from reduction of CO_2 emissions to reduction of energy use converted into CO_2 emissions. According to our calculations neither of these targets was achieved. Targets were set to reduction of 15% in 2005, the actual results were TB4 -4.3% and TB6 -1.1%. Interestingly enough both companies A and B have set their targets in period 2006-2010 (TA7, TA8, TB8, TB9)

Table 1: Environmental targets of companies A and B

A	Target characteristics				
	CO2 Emissions and Energy consumption at manufacturing sites	Base Year (FY)	Target Year (FY)	Coverage	Note
TA1 (1997)	Lower the volume of CO2 emissions at factories to FY 1990 levels	1990	1998	Japan	0% not achieved (+7%)
TA2 (1997)	Reduce the amount of energy consumed per unit of sales by 25%	1990	2000	Japan	-25% not achieved (+27%)
TA3 (1998)	Reduce CO2 emission to 6.5% (0%) increase by 1999 (2005), to -7% by 2010	1990	1999, 2005, 2010	Japan	1999 achieved, discontinued
TA4 (2001)	Reduce CO2 emissions per unit sales by 5% (10%)	2000	2005(2010)	Global	re-definition
TA5 (2005)	Reduct CO2 emissions per unit of actual production 25%	1990	2010	Japan	revised TA3
TA6 (2005)	CO2 emissions 10% reduction per basic unit	2000	2010	Global	revised TA4
TA7 (2008)	Reduction 0.11 (0.3) mil tons of CO2 emissions	2006	2008(2009)	Global	move to absolut targets
TA8 (2008)	Reduction of CO2 emissions to FY 2000	2000	2010	Global	move to absolut targets

B	Target characteristics				
	CO2 Emissions and Energy consumption at manufacturing sites	Base Year (FY)	Target Year (FY)	Coverage	Note
TB1 (1996)	Energy Consumption/Net Sales 25% reduction	1990	2000	Japan	discontinued
TB2 (1998)	Achieve 95% of the energy unit per sales	1990	2002	Japan	revised TB1
TB3 (2001)	Revised to conform to an industry's target of cutting unit CO2 emissions by 25%	2000	2010	Japan	-25% not achieved
TB4 (2001)	Reduce CO2 emissions per unit sales by 15% or more	2000	2005	Global	discontinued
TB5 (2001)	Raise CO2 eco-efficiency by 1.5 times by FY2005 and 2times by FY2010	2000	2005, 2010	Global	1.5 not achieved (1.42)
TB6 (2003)	Reduce energy use converted to CO2 emissions by 15% or more per sales unit	2000	2005	Global	-15% not achieved (-1%)
TB7 (2003)	Reduce 30% emissions of GHG other than CO2 emission related to energy cons.	2000	2005	Global	non-CO2 related target
TB8 (2006)	Absolute reduction in GHG at sites (in terms of CO2) of 7%	2000	2010	Global	move to absolut targets
TB9 (2010)	Reduce GHG emissions by an absolute value of 30%	2000	2015	Global	move to absolut targets

to absolute emissions reduction. We can speculate that this is reaction to global recession and decreasing volume of production. By setting the year with record reaching production volumes as base year, targets then tend to be less ambitious and easier achievable. Both companies react to negative developments by redefining targets, discontinuing targets or setting up of new targets. These changes make it difficult for stakeholders to keep track of corporate progress in reducing environmental impact. The variety of target revisions, redefinitions, methodology and scope changes or annual recalculations (when more accurate coefficients become available) requires detailed content analysis of CSR reports, in depth analysis of individual targets and monitoring of the changes and the reasons behind them. In the number of cases, the explanation for revisions or discontinuations of targets is missing. We understand this is rather challenging task for companies to manage. However, we find the level of inconsistencies disturbing enough to further investigate this phenomenon. The question that kept on rising during our analysis was the following: Were there any negative consequences resulting from these frequent inconsistencies in target-setting behavior? What role would those inconstancies play these days? In the following section we present the results of a questionnaire that gives us a view from the perspective of one stakeholder group.

4 QUESTIONNAIRE

4.1 Outline of questionnaire

The timeline analysis of targets relating to carbon emission led to the identification of several inconsistencies. To address this issue, we conducted a questionnaire directed at globally recognized sustainability rating agencies and SRI funds. We will refer to this stakeholder group as “Raters”. Raters were selected for several reasons. First, they have a rich experience dealing with the corporate environmental reports and they are engaged in dialogue with corporations. Second, the role of rating agencies and SRI funds has been gaining in importance and is expected to become more significant in future. We contacted 34 established raters with an explanation of our research, a summary of our findings and a questionnaire containing following three questions:

1) How do you deal with any inconsistencies of corporate environmental targets in your rating/evaluation process?

2) What is, in your opinion, the best practice in setting environmental targets?

3) Do you believe that corporate environmental target setting behavior is/will be increasingly influenced by the positive pressure of rating agencies and SRI funds?

We have received answers from 8 Raters (namely: Trusco, CSRHub, Oekom research, Climate Counts, Roberts Environmental Center, Union of Concerned Scientists, CO2Benchmark and Corporate Knights) and another 6 Raters have stated reasons why they cannot take a part in the questionnaire. The following is a summary of individual questions and the approaches the Raters are taking when dealing with environmental targets in corporate reports.

4.2 Q1 - Dealing with target inconsistencies

Thee were a variety of answers to first question. Some Raters simply do not deal with target inconsistencies, they give credit if goals are set, but do not evaluate whether or not they are met other than to give credit if the performance has improved since the last report. Others use multiple sources of data for each company to remove systematic inconsistencies (not specifically rating either environmental targets or company performance against these targets). Another Rater considers targets on a project basis. Their experience with the problems and inconsistencies regarding future targets is addressed by focusing on the most accurate picture of a company’s environmental impact: “*and so prioritize ensuring we have accurate annual data that covers 100% of a company’s owned or controlled operations*”. The closest attention to environmental targets paid by one of the Raters is as follows: “*We not only evaluate targets but also performance of reductions, e.g. development of total CO2 emission during the last 5 years. To further deal with inconsistencies, the respective indicators of a company's rating are downgraded if:*”

1) set environmental targets (e.g. reduction of CO2 emissions) are not achieved
2) targets are not very ambitious compared to peer group
3) the time frame and the baseline for emissions reductions are unclear
4) no information is available on whether any company action plans are in place in order to achieve the targets
5) if coverage of data is unclear

The final Rater conducts a company scoring process on an annual basis which enables them to gauge a) whether or not the company is using the same environmental targets from the previous year and b) how the company is performing in comparison to their goals. In instances where the goal has been compromised (e.g. from 20%

reductions by 2015, to 15% reductions by 2015), the company will receive lower scores.

Overall we can see that not all Raters deal directly with corporate environmental targets. However, the practice of addressing target inconsistencies is seen in the responses from two out of five Raters. That itself could be a driving force supporting more consistent target-setting behavior and more relevant goals reflecting overall corporate environmental impact.

4.3 Q2 - Best practice in setting environmental targets

Addressing the question of best practice, we can see similarities across all responses. The Raters call for "*ambitious goals that the company has full intention of meeting and reasonably strong confidence that it can meet*". Furthermore Raters believe that any targets should be communicated publicly and that progress towards them should be reported transparently to the public for their own assessment: *"We believe that then outside observers will be able to correctly gage both the quality of the target and the extent to which the desired result has been achieved."* One of the Raters used specific example of a good target practice: *"In my opinion setting environmental targets that integrate both the intensity of environmental impact (relative to revenue or production) and industry averages are most appropriate."* Additional features of best practice are clear internal responsibilities, baselines and timelines for reduction targets, and action plans and measures for implementing them, as well as clear coverage of measured data and respective targets in terms of, e.g. production units, % of products produced or sales. The strength of target is described by one Rater as being dependent on:

1) the breadth of the target - is it company-wide and does it represent all owned/operated facilities
2) the target baseline year -- the further back the baseline year, the better usually (this isn't always the case, however, as some companies will choose a baseline year where they experienced atypical production levels
3) whether the reduction is "Absolute" or "Intensity" based -- Absolute targets are generally considered "true" reductions, versus intensity-based targets which are considered "relative" to other inputs and outputs.

One of the Raters called for a performance benchmarking as an incentive for companies to at least match the best industry performance and seek continuous improvement: *"The rationale is that target setting in isolation makes little sense for a company. Performance benchmarking should be the way how targets are set."* The same Rater than suggests establishment of a correlation between stock price and environmental performance as a way to encourage companies to meet or exceed their targets. The insights from all Raters help us create an image of what should the ideal target look like and what changes companies should further consider.

4.4 Q3 - Rater's influence

The majority of Raters consider themselves to be influential. They also believe that they will continue to be the influence in future as well. "*Any time corporate performance is scrutinized and the results made public, there is pressure to improve. Some companies, like some politicians, ignore the pressure, but the more likely response is to try to improve.*" One Rater considers the other stakeholder groups to be more important sources of long time pressure: "*Employees, managers (both senior and middle), suppliers, customers, competitors (peer pressure), NGOs, business organizations, the government, and communities - these group collectively (and in some cases individually) have much more power to effect positive change than shareholders and investors do.*" Skepticism was expressed by two of the Raters, firstly: "*The investors are keen to learn company level projections of the environmental impacts, which would take into account targets. However the issues with company's target reporting creates problems for projection estimates and consequently there is not much reliable data on this aspect available in the market.*" And secondly: "*The fundamental role (by law) of the CEO of a publicly held company is to increase shareholder wealth. Period. If a CEO can increase shareholder wealth and create greater gains for the company without investing in GHG emissions reductions, they will generally do so.... especially in the absence of regulation (carbon tax or cap and trade). So although SRI's and consumer awareness through ratings help motivate companies, I think the monumental change required to reduce the impact of industry on climate change needs to come from policy reform.*"

The examples of best practice as well as opinions about the future influence and driving forces of more responsible corporate environmental disclosure as viewed by professionals from rating agencies can be a useful guideline for companies seeking to improve their target-setting behavior.

5 SUMMARY

This research examines companies' environmental performance from the point of view of their environmental targets. In our study we observe common features in corporate target-setting behavior, not simply to point out their misconducts or bad corporate citizenship but rather to find a connection to identify opportunities for added value in this dynamic environment (with an increasing number of SRI funds, CSR raters, and NGOs). Disclosed environmental data and corporate goals are the subject of research scrutiny with the goal of drawing a clear picture of past progress towards reducing CO_2 emissions. We argue that improved environmental target-setting strategies have the potential to result in higher shareholder value by minimizing risk, building up brand value and creating a competitive advantage. Good corporate citizenship is now a common theme for global manufacturing corporations. We believe that eventually major manufacturing corporation will have to embrace the concept of zero or near-zero emissions for all of their global operations, supply chains and environmental impacts relating to product use. The corporate goals as presented to us are ambitious and far reaching. However, we should be wary of focusing on future targets without assessing performance in achieving previously stated targets. This way our study can be a modest guide for companies as they set new targets and reconsider business development and their further role in the society. For researchers, the opinions of rating agencies based on practical experience can serve as a guideline when designing sophisticated tools for evaluating environmental performance. Our future intention is to develop easy-to-understand evaluation metrics that addresses the path from current environmental impact to a more sustainable future, while helping companies communicate their commitment to reducing environmental impact. We believe that the timeline analysis of corporate emission reduction goals is an important indicator. By determining strategic patterns based on a target-achievement, we believe this method has the potential not only to contribute to reduction of corporate environmental impact, but also to increase companies' revenues and reputations. Various analysis and perspectives leave space for further research. We believe the main limitations of this study are the limited number of companies and targets analyzed, as well as lack of detailed target evaluation methodology. The concept of universal corporate CO_2 emissions reduction targets is a topic that we hope will be on the agenda in near future.

A Methodology for Designing Sustainable Manufacturing Scenarios

Yasushi Umeda[1]

[1] Department of Mechanical Engineering, Graduate School of Engineering, Osaka University, Osaka, Japan

Abstract

Although the concept of sustainable manufacturing is very important both for the sustainable society and future directions of the manufacturing industry, its image is quite ambiguous. In order to clarify the image of the sustainable manufacturing and strategies for reaching it, Inverse Manufacturing Forum runs "Sustainable Society Scenario Simulation (3S Simulation)" project from 2006. This paper summarized achievements of this project focusing on scenario representation, scenario design methodology, dynamic scenario, scenario analysis, scenario achieves, and their practical use. The scenario design methodology is effective in guiding scenario design especially in the convergence phase, while it is very difficult to support the divergence phase. 3S Simulation project has contributed to construction of common understanding of the problems to be solved by the sustainable manufacturing. And, it will contribute to design of ideal and realistic sustainable manufacturing scenarios. 3S Simulator discussed in this paper is available through http://www-lce.mech.eng.osaka-u.ac.jp/3s/.

Keywords:

sustainability scenario, sustainable manufacturing, sustainable society scenario simulation, scenario design

1 INTRODUCTION

The traditional manufacturing industry, relying on the mass production, mass consumption, and mass disposal paradigm, has caused various environmental issues including global warming, air and water pollution, and resource depletion [1]. This implies that, if we can change manufacturing paradigm, the manufacturing industry will be a strong driver for realizing sustainable society. In this sense, we define "sustainable manufacturing" as the manufacturing industry that contributes to the realization of sustainable society, including business, manufacturing systems, and product development.

Then, the next questions are what the image of the sustainable manufacturing is and how to reach it. Inverse Manufacturing Forum, Japan [2] has been pursuing this image as one of its main activities. Here, we have taken scenario-based approach, because we needed descriptive representation of future visions of the sustainable manufacturing with thousands of unknown factors and scenario is suitable tool for this purpose. We call this scenario writing project for sustainable manufacturing "Sustainable Society Scenario Simulation (3S Simulation)," which consists of three research topics (see Fig. 1); that is, i) formalizing scenario design methodology, ii) developing computational support environment for scenario design, and iii) writing sustainable manufacturing scenarios. This paper summarizes achievements of the 3S Simulation project focusing on the topics i) and ii) and discusses directions of future works, while Fujimoto *et al.* [3] reports achievements on the topic iii). Based on the discussions until now, we understand that the issue of the sustainable manufacturing is to find out some stable points where both of the global warming problem and the resource depletion problem do not greatly affect human welfare even with assuming rapid economic growth of developing countries.

2 SUSTAINABILITY SOCIETY SCENARIO (3S) SIMULATION

In 3S Simulation project, we focus on "scenario design." Scenario design is not just describing scenarios, but consists of all tasks for composing a scenario and modifying it, including problem definition, data collection,

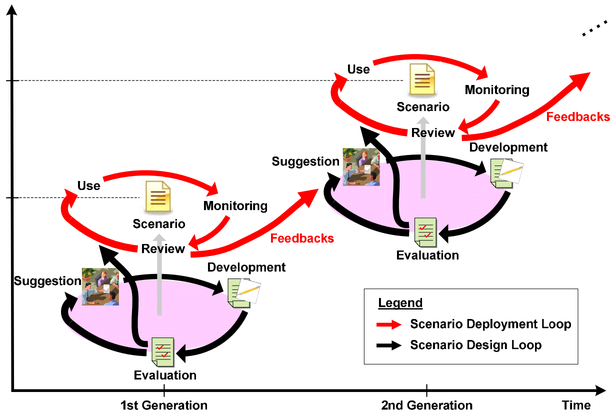

Fig. 2: Sustainable Scenario Design [4]

idea generation, discussions among different stakeholders, scenario development, simulation, analysis of scenarios, and deployment of a composed scenario (see Fig. 2) [4].

One of our main goals is to develop an intelligent CAD supporting the whole process of scenario design in an integrated manner as shown in Fig. 3. We call this computational environment "Sustainable Society Scenario Simulator (3S Simulator)" and set the following research issues with the system architecture shown in Fig. 4 [5]:

1. Representation methodology of a scenario: This topic formalizes scenario representation to clarify its causal structure and relations to associated simulations. This provides us with a formalized and computerized way of representing a sustainability scenario.
2. Scenario design methodology: This topic models the design process of a new scenario, including forecasting and backcasting, and develops a methodology for supporting design of a new scenario by reusing archived scenarios and their associated simulators.
3. Dynamic scenario: A "dynamic scenario" refers to a structured, computerized scenario representation that maintains dynamic links to its associated simulators. These links enable re-execution of simulations with different conditions and permits the modification of the scenario according to the simulation results.
4. Scenario Analysis: This topic supports the analysis of described scenarios, including logical structure analysis, what-if analysis, and sensitivity analysis.
5. Scenario Archives: This topic focuses on archiving scenarios and their simulators by using structured, computerized scenario representation to facilitate understanding and analysis of existing scenarios, as well as design of a new scenario using existing scenarios.

The system architecture of the 3S Simulator shown in Fig. 4 consists of the following five components:

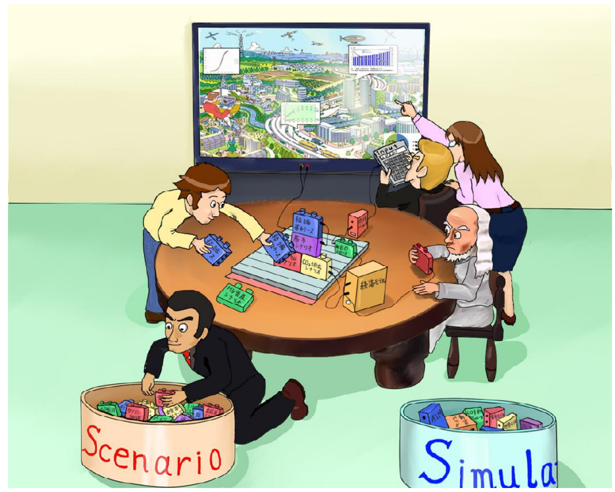

Fig. 3: Image of 3S Simulator [5]

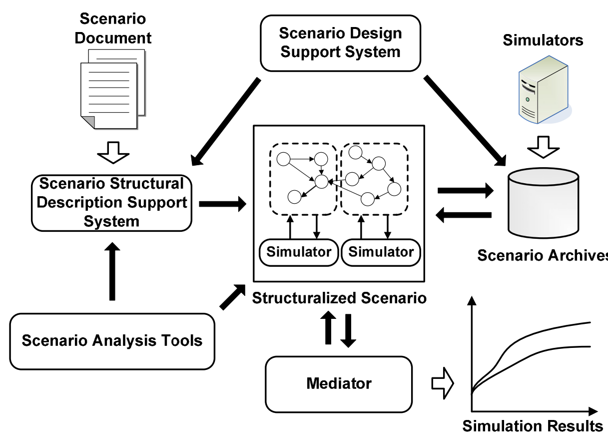

Fig. 4: System Architecture of 3S Simulator [5]

- Structural Scenario Description Support System: structurally supports describing new or existing scenarios.
- Scenario Archives: archives structuralized scenarios and associated simulators used in scenarios.
- Scenario Design Support System: supports designing a new scenario.
- Scenario Analysis Tool: analyzes the logical structure of a described scenario and conducts what-if and sensitivity analyses using its simulators.
- Mediator: exchanges data among simulators used in a scenario in order to run simulations.

3 ACHIEVEMENTS AND ISSUES

We have been developing 3S Simulation methodologies and implementing 3S Simulators, as well as describing various scenarios for about five years. The intermediate summary of achievements and issues is as follows:

3.1 Representation methodology of a scenario

The proposed method based on logical relations [6] was successful in providing formalized and computational representational scheme. We defined a set of types of concepts necessary for representing a scenario. This notation clarified rationale of a scenario such as references, data, and simulation results that the scenario is based on as well as hypotheses and assumptions of a scenario if they are clearly mentioned.

While the representational scheme is successful, we find out some difficulties:

(i) To illuminate storyline of a scenario was more difficult than we expected, because sentences written by scenario designers' are not so logical and the designers do not describe all intentionally or unintentionally. Explicit descriptions are not all but just a tip of an iceberg. Designers assume commonsense and common tacit knowledge with readers. This ratio of hidden iceberg is larger than expected. This makes logical representation of a scenario difficult, but ontological approach (*e.g.*, [7]) may be helpful.

(ii) It is tiresome to structurize scenario description since it is done manually. Here, structurizing means to translate sentences of a scenario into a graph of concepts and logical relations. However, there are undeterminable areas for judging kinds of nodes and links; *e.g.*, hypothesis or fact, and causal relation or logical jump. We consider they are unavoidable; rather, undeterminable sentences are cues for consensus making among stakeholders participating scenario design and we should develop a style of scenario description suitable for 3S Simulator. Ontological approach again might be helpful. And since this problem is similar to the problem of natural language processing, recent processing technologies based on huge amount of data might also be helpful, besides there are not so many scenarios. We are planning to semi automatize the structurization.

3.2 Scenario design methodology

We have succeeded in formalizing the process of scenario design in forecasting manner and backcasting manner. And now we are developing the design process that includes both of forecasting and backcasting in an integrated manner. We believe this is the most theoretically appropriate, since we can find both of forecasting aspect and backcasting aspect in designing a scenario.

However, supporting scenario designers well is another thing. Guidance based on these methodologies might be too rigid for human designers and does not always stimulate them in finding out good ideas in terms of contents of the scenario. We need some tools flexibly supporting designers with allowing trial and error. This is a common feature to the domain of design support methods in general; in other words, intelligent CADs, CADs, and other design support systems can help a designer in efficiency but cannot directly increase novelty or originality of the design results. In general, design process, including scenario design, can be divided into two phases; divergence phase and convergence phase. In the divergence phase, designers generate ideas as many as possible by employing, *e.g.*, brainstorming. In the convergence phase, designers categorize, combine, and detail the generated ideas so as to arrive at several alternatives of design solutions. Basically, design support systems are good at supporting the convergence phase but it is essentially difficult to support the divergence phase. These issues also apply to 3S Simulator. In this sense, the sequence of various intermediate representations of a scenario, which results in scenario description, in our design methodologies (*e.g.*, problem description table, logic tree, storyline, causal network, and so on in the backcasting method [8]) is effective to guide designers in the convergence phase in a stepwise manner.

3.3 Dynamic scenario

Dynamic scenario is a mechanism for enabling re-execution of simulations with different conditions and permits the modification of the scenario according to the simulation results by maintaining dynamic links from a scenario to its associated simulators. This mechanism is quite useful for sensitivity analysis and what-if analysis of a simulation in a scenario. In these analyses, it is very effective that the structured representation of a scenario explicitly expresses relationship among a set of simulation conditions, a simulator, and a set of simulation results. This is one of the main achievements of 3S Simulator. By mapping such relationships, we can do a sort of phase portrait analysis.

Combinational use of different simulators in a session of simulation and treatment of the case where a simulation result affects on conditions of another simulation are future works of this topic.

3.4 Scenario Analysis

Besides what-if analysis and sensitivity analysis, which are deeply dependent on the dynamic scenario, so far we can do just logical structure analysis that distinguishes "logically sound" part of a scenario from the rest. It is useful for, *e.g.*, finding out rationale of a sub-scenario.

We should find out plausible analyses since analysis is the key for supporting the scenario design in practical sense. Examples include:

- Evaluation: Although it might be impossible to evaluate originality, correctness, or completeness of a scenario, it is possible to evaluate a scenario from various aspects such as logical consistency, adequateness of rationale, and degree of logicality (or illogicality).

- It is helpful that the system points out a part of a scenario of which rationale, logicality, description is insufficient.
- Phase portrait analysis mentioned in Section 3.3 may help designers to find out conditions resulting in the future they want to achieve.
- Evaluation of similarity of two different scenarios is helpful for designing scenario by analogy based on the scenario archives.

3.5 Scenario Archives

Constructing archives of scenarios with their associated simulators was tougher work than expected. We structurized various scenarios (*e.g.*, IPCC SRES, IEA WEOs, IEA ETP, and Japan MOE LCS2050), but

- As discussed in Section 3.1, described scenario just a tip of an iceberg. Scenario writers may not have paid enough attention on logicality or reproducibility of scenarios. Basically, nobody describe everything.
- Simulation methods or extrapolation methods are not always mentioned. Even if mentioned, some simulators are not available. Even if they are available, almost no scenario describes simulation conditions completely. In reality, then, it was almost impossible to realize dynamic scenario with existing scenarios, except for scenarios made by our group or colleagues.

We aim at changing this culture and introducing scientific approach (*e.g.*, guarantee of reproducibility) into scenario design, but this is very tough work.

Anyway, we are constructing the scenario archives and more technical issues are:

- Increase of reusability: For increasing reusability of archived scenarios, it is effective to develop methods for decomposing a scenario into reusable building blocks, extracting scenario templates from existing scenarios, and applying case based reasoning techniques for reusing existing scenarios as cases.
- Search: In designing a scenario, it is helpful for designers if the system suggests a part of archived scenario that provides fundamental data, supporting conclusions, or conflicting conclusions.

3.6 Practical applicability

Development of 3S methodologies and its implementation (*i.e.*, 3S Simulator) progresses well with denoting achievements and issues discussed in Sections 3.1 - 3.5. This section discusses practical applicability of the methodologies and tools and its implications.

The scenario design methodology is effective in guiding scenario design with providing various intermediate representations, especially in the convergence phase. In other words, it is very difficult to support the divergence phase and this is the same for design support methods in general. The scenario representational scheme is also useful to represent a scenario with structurizing information.

As a software system, the scenario representation scheme is very powerful to analyze and understand a scenario once it is structurized. Dynamic scenario is also very powerful for sensitivity analysis and what-if analysis once a scenario is connected to a simulator. However, it is difficult to use the system during, for example, a workshop for scenario design; it takes time to structurize texts of a scenario and it needs some experiences to read the structured model of a scenario. It is, therefore, on the way for development of practical scenario design support system. On one hand, improving user interfaces and simplifying and semi-automatizing the structurization of a scenario are needed. On the other hand, expanding the power of systems, including dynamic scenarios, analysis tools, and scenario archives, is promising for increasing the practicality.

Until now on, it is verified that writing scenarios is very useful for scenario designers to think about the sustainable society and the sustainable manufacturing. Scenario writing is a very good tool for thinking about and simulating these topics. On the other hand, how we can use designed scenarios is another question. In other words, we could not deal with the scenario deployment loop in Fig. 2; especially, it is important to develop a mechanism for involving various stakeholders in the deployment loop, including reviewing scenarios, suggesting modifications, and making consensus among participants.

We have found new seeds and needs in this project. A new extension of the methodology we found, for instance, was business strategy planning [9], which provides a simplified scenario design method by supporting designers to design a detailed scenario (*e.g.*, long term business strategy of a company) by employing fundamental scenarios (*e.g.*, IEA ETP scenario). And, it might be a good test bed for verifying the effectiveness of the methodologies and the system to modify our existing scenarios by examining possibility of resource depletion led by developing countries and the effects of the Tohoku Earthquake.

4 CONCLUSIONS

In order to clarify the image of sustainable manufacturing and strategies for reaching it, Inverse Manufacturing Forum runs “Sustainable Society Scenario Simulation (3S Simulation)” project from 2006. This paper summarized achievements of this project focusing on scenario representation, scenario design methodology, dynamic scenario, scenario analysis, scenario achieves, and their practical use. The scenario design methodology is effective in guiding scenario design with providing various intermediate representations, especially in the convergence phase. In other words, it is very difficult to support the divergence phase and this is the same for design support methods in general. The scenario representational scheme is also useful to represent a scenario with structurizing information. As a software system, the scenario representation scheme and dynamic scenario are very powerful to analyze and understand a scenario. However, it is still on the way for development of practical scenario design support system.

Until now on, it is verified that writing scenarios is very useful for scenario designers to think about the sustainable society and the sustainable manufacturing. Scenario writing is a very good tool for thinking about and simulating these topics. Actually, we understand that the issue of sustainable manufacturing is to find out some stable points where both of the global warming problem and the resource depletion problem do not greatly affect human welfare even with assuming rapid economic growth of developing countries. 3S Simulation project has contributed to construction of common understanding of the problems to be solved by the sustainable manufacturing. And it will contribute to design of ideal and realistic sustainable manufacturing scenarios.

3S Simulator discussed in this paper is available through http://www-lce.mech.eng.osaka-u.ac.jp/3s/.

Sustainable Car Society Scenarios: A "Game-changing" Approach

Jun Fujimoto[1] and Dean Poland [2]

[2] Waseda University International, Tokyo, Japan

Abstract

Discussed here are issues concerning standardized measures toward Low Carbon Society in Japan, through depicting a future "Electric-vehicle (EV) Society". In Japan, many activities regarding EV have pervasively spread into society. However, these activities are based on the simple idea that "EVs replace current gasoline vehicles", and have not considered future possible changes. A new design of a car society from a holistic perspective may be strongly required in order to achieve a "Sustainable society" in Japan. Scenario-planning and brainstorming methods were used in order to depict an "extreme" EV society (100% EV). A new kind of society can be created which will eradicate many of the social problems we face in our current style of car-society. These include issues related to an unprecedented aging population, such as decreasing work force, increase in social welfare, and economic stagnation.

Keywords:

electric-vehicle, aging society, game-changing, social-scenarios

1 INTRODUCTION

The number of private cars in Japan continued to increase from approximately 2.3 million in 1966 to 58.1 million (including 17.3 million mini-cars) in 2009. This huge increase in private car ownership has created a car-society, i.e. situations where cars have a dramatic impact on social/economic structures such as dwelling, industry, and health services.

The amount of CO2 emission from the transportation sector is 236 million tons, and accounts for about 20 percent of total CO2 emission in Japan, which was 1.2 billion tons of CO2 in 2008. Because about half of the amount of CO2 emission of the transportation sector comes from private cars, the amount of the CO2 emission from private cars was about 10% of total CO2 emission in Japan.

Against this backdrop, many activities related to EVs (Electric Vehicle) have pervasively spread into Japanese society. These activities include an improvement in battery performance, an increase in the number of battery chargers, grants for purchasing EVs, and so on. However, these activities are based on the conventional idea that EVs should simply replace current gasoline vehicles. This conventional approach seems to be inadequate when searching for effective solutions. Therefore, 'game changing' is essential when thinking about a sustainable car-society in Japan.

This paper presents a "sustainable car-society" in Japan. First, future possible social changes in Japan are addressed. After that, several kinds of future EV societies are depicted using scenario-planning and brainstorming methods. Finally, we consider not only how EV society is compatible with these changes but also how such an EV society can provide radical solutions.

2 WHAT IS "GAME CHANGING"？

Figure 1 shows our concept of "Game changing". The current approach to EV distribution is based on the continuation of current automotive society, i.e. EVs are required with similar performance and convenience of current gasoline cars. However, a different view can be taken. Current cars will not be favored and will fade out because of future social changes. In such a case, a different kind of vehicle will spread into society. It is believed that this new vehicle will be produced due to radical social changes such as aging society, oil depletion, and young people's change in purchasing behaviour. Many people can't accept this concept and the idea that the current car society will come to an end. However, there is evidence to support this concept from the perspective of two areas: radical social changes in Japan, and from the "side effect" of the current car- society.

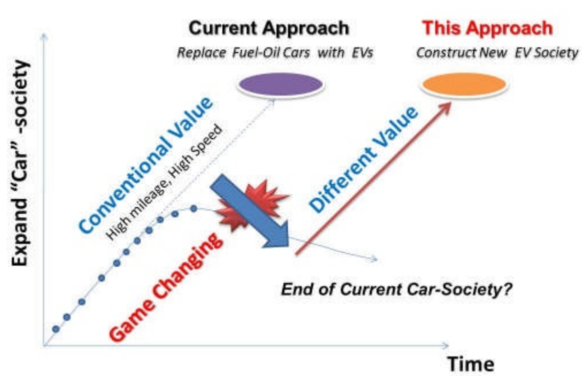

Fig.1 Game changing approach

DOI 10.1007/978-94-007-3010-6_18,

2.1 Social Changes in Japan

Japan has been facing radical social changes. The following are a number of typical changes related to a car-society

-World’s fastest aging society

There is no precedent for an aging society. Figure 2 shows an estimation of the percentage of the aged population toward total population of Japan. The value of people over 65 was estimated to reach 30% in 2025 and 40% in 2055 [1]. Furthermore, the percentage occupied by people over 75 rapidly increases.

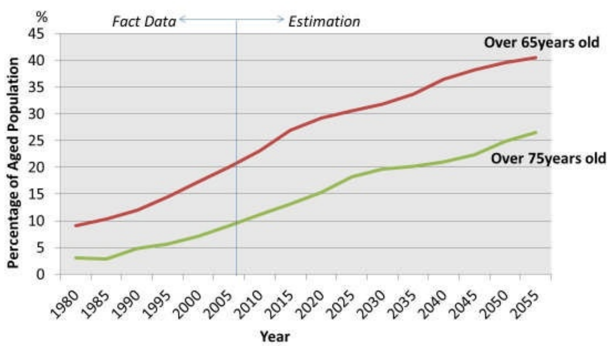

Fig.2 Percentage of aged population in Japan

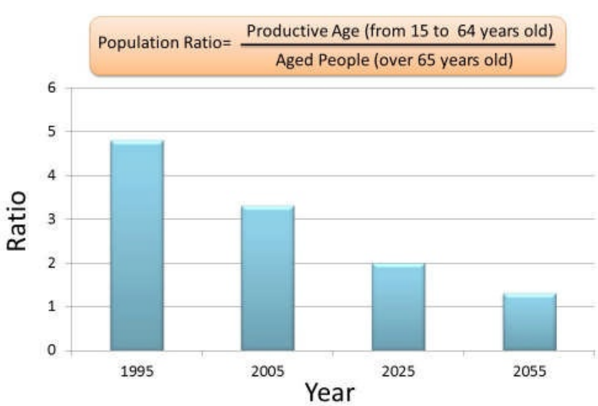
-Over the peak of population

The population of Japan passed over its peak around 2006 due to a low-birth rate. The percentage of children under 15 years old has been decreasing from 1982 [2] Therefore, the population ratio of productive-age people(from 15 to 64 years old) to aged people (over 65) was 4.8 in 1995, 3.3 in 2005, and is estimated to be 2.0 in 2025 and 1.3 in 2055



(Fig. 3).

Fig.3 Who supports aged people in Japan

These statistics point to two essential issues related to people’s form of transportation. First, traffic accidents caused by senior citizens have increased remarkably [3]. Therefore, even if they have a driving license, they lose their desire to drive a car. Second, as the child population decreases, the total number of drivers would decrease rapidly in a future Japanese society. Third, depopulated areas in which senior citizens live alone have been expanding in the countryside. For developing a sustainable format of transportation, a new public system would be required. This would cause an increase of social cost regarding construction and operation of the new public transportation system.

-Decrease in Oil Demand

Furthermore, it is essential to achieve “Low carbon society” in Japan. However, there are some indications that Japan will naturally move towards a lower energy consumption society without the need for radical measures for achieving low carbon society. The demand of gasoline has decreased from 2005. METI estimation regarding gasoline demand was 49 million litres in 2013. As the demand of gasoline was 58 million litres in 2008, it shows that demand will continue to decrease in the future [4]

-Young People’s Consumption

Figure 4 shows the number of shipped cars in the Japanese market. The number of shipped cars peaked in 1996, increased again from 1998 to 2006, then decreased by 2006.

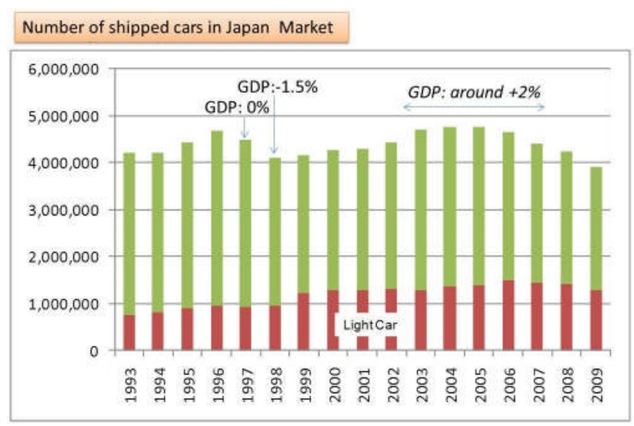


Fig.4 Number of shipped cars in Japanese market

For 17 years, the number of ‘light cars’ such as those under 1,000kg of car weight has gradually become a large part of total shipment. Furthermore, real GDP growth rate (changes from the previous year) in Japan was 0% in 1997 and -1.5% in 1997 [5], suggesting that the decrease in shipped cars during these years were closely related to economic conditions. However, the number of shipped cars from 2003 to 2007 fell from its peak even though GDP growth rate kept to around 2%. Therefore, it appears that the decrease in car purchases is not simply due to a decline in economic conditions. One of the important factors which caused this decline was thought to be young people’s change in purchasing behavior. According to the report “2008 Passenger Cars Market Trend Investigation” the benefit of having a car decreased due to an increase in distribution of games, cellular phones, and personal computers; devices which make it possible to pursue indoor activities and communicate with others at any time. Moreover, the relative "burden" of possessing a car, for example parking fee, maintenance cost, and running cost, increased as economic conditions worsened [6]. Basically, young people are not buying as many cars as previous generations, pointing to a change of attitude towards gasoline cars. This trend suggests young people may be open to the creation of an EV society.

2.2 Side-effects of current car-society

Japan has heavy debts. Because increases of cost related care and medical services for aged people, these debts will increase naturally with an ageing society. Currently we take air-pollution and sound-pollution caused by oil-fuel cars for granted. However, we "reap the benefit of freedom gained by transportation at great cost" [7]. For example, medical conditions such as respiratory disease can be caused by the exhaust gas of gasoline cars. The noise from gasoline car has been linked to mental stress. At great social cost the government spends a large amount of its budget on trying to treat such 'diseases'. How much money do we waste on such negative things? Furthermore, the nation also pays for preventing and measuring environmental problems caused by cars.

Due to the issues expressed above it becomes clear why our current car-society can't continue in the future. Therefore, how do we design a future car-society where EVs can naturally spread widely?

We considered "new society" from fresh perspective.

3 FUTURE ELECTRIC-VEHICLE (EV) SOCIETY

As stated in the introduction, in Japan, many activities regarding EV have pervasively spread into society. However, these activities are based on the simple idea that "EVs replace current gasoline vehicles", and have not considered future possible social changes stated above.

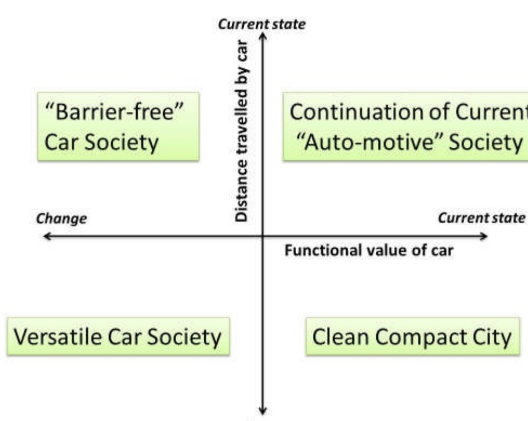

Fig. 5 Future EV society

3.1 Depicting Future EV Society

Scenario-planning and brainstorming methods were used in order to depict an "extreme" EV society (100% EV society). "Extreme" thinking was necessary for avoiding "conventional thinking", that existing technologies simply replace "low-carbon" ones in order to decrease CO2 emissions. The two chosen uncertain factors which have a large impact on future social shaping, were distance travelled by a car (no change or shortened) and functional value of a car (no change or having new value). The former factor is closely related to urban structure in an aging society, the latter is associated with young people's interest regarding a car. These two uncertain factors were expressed by two axes and four quadrants. The future society scenarios below were then placed in each quadrant (Fig.5).

3.2 Continuation of Current "Auto-motive" Society

There were 41.8 million ordinary cars and 15.7 million light-cars in 2007, Japan [8]. This scenario depicts all oil-fuel cars being replaced by EVs, and continuing in the direction of current society. Battery chargers would be set up in all public places due to the low capacity of electricity storage of battery. Furthermore, noncontact-type battery chargers would be used in a highway. People could use EVs in a similar way to gasoline cars. This scenario is the same as the usual scenarios considered in order to achieve "low-carbon" society. This means that there is a lack of consideration for social changes, such as how to transport the aged people (Fig.6)

Fig.6 Continuation of current "Auto-motive" society

3.3 Clean Compact City

In this society, it would not be necessary for an EV to have high mileage and high speed performance. Instead of these, "low speed", which wouldn't harm people in a collision and would make autopilot and auto-parking of a car possible, would be needed. If this society is realized, we could be free from negative cost of traffic accidents and disease caused by exhaust gas and noise-pollution.

The senior citizens could utilize a car and walk around safely in a “silent” town due to EV’s functional performance. Furthermore, an auto-parking system makes “Park &Ride” more convenient. If this society is realized, issues of the transportation for the aged people could be solved. However, a clear vision and leadership of the government would be essential to construct a new “Compact city”. In this society, cars will be mere a tool for people’s short travel. Cars would be utilized in a similar way to bicycles and scooters (Fig.7).

Fig.7 Clean compact city

3.4 Versatile Car Society

The car changes from “transportation device” to “my room with vehicle”. By using the unique characteristics of being “clean” and having a battery, EVs could be usefully integrated into the house.

Fig.8 Versatile car society

Some people who could even bring EVs into a house and use it as a room. Furthermore, there are some people who could live in EV’s docked with an “apartment station” which provides bath, kitchen, rest room, and laundromat. Because EVs have an automatic running mode with low speed, it could be used as a means of transportation for senior citizens who are physically-disabled. Moreover, it would be possible to come home in the automatic running mode after alcoholic consumption. Thus accidents related to drunken driving would become obsolete.

This society could be moderately achieved by using new and innovative ideas from the private sector. The government also has a role to assist its activity. The aged people could move freely, and young people could recover their interest towards new style of “cars” which combine ideas of growth industries, such as IT, Robotic. This could help stimulate Japan’s economy (Fig.8).

3.5 ‘Barrier-free” Car Society

The distance travelled by a car is similar to the scenario of “Continuation of Current Auto-motive Society”. However, there is the difference of how the cars are used. In this scenario, frequency of short trips increases because of the barrier-free concept. “Everyone” can use EV "Anytime" and "Anywhere". Therefore, a "Ubiquitous automotive society" would be achieved. A compact EV could be brought onto a bullet-train (Shinkansen) thus realizing the ‘automatic compact making’ function. An EV could be taken into a shopping center at any time without difficulty. This may reduce the need of stocking large amounts of food in the home. This society is similar to “Versatile Car Society”, but has the added concept of “barrier-free” car. The aged people could even travel long distance in Japan. Therefore, their daily life could be changed radically. This may help them to recover their motivation for extending work life. This would have a positive impact on social issues such as decreasing work force due to a low birth rate, and increase of financial support needed for rapidly aging society. However, there are technological obstacles for achieving “Barrier-free” cars. The government has to help solve such technological problems (Fig.9).

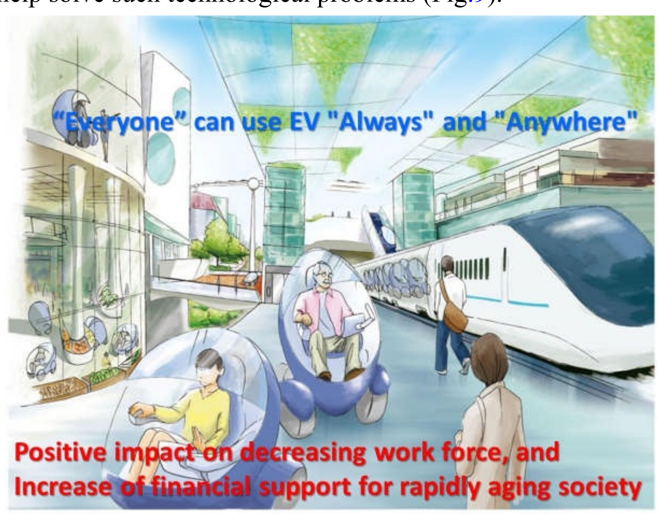

Fig.9 “Barrier-free” car society

4 RADICAL SOLUTION PROVIDED BY EVS

In modern industrialized nations the ‘car’ as a consumer product has symbolized many things: capitalism, status, innovation, environmental damage [9]. Fromm stated “The most striking example of today’s consumer-buying phenomenon is the private automobile. Our age deserves to be dubbed, ‘the age of the automobile’, for our whole economy has been built around automobile production, and our whole life is greatly determined by the rise and fall of the consumer market for cars”[10]. These sentiments are as true for 2011 as they were 30 years ago. Or so it is generally believed? There are already signs that consumer trends in Japan are already changing [11]. In addition to this, Japan has been facing radical social changes described in section 2. Cars and their transportation-systems may have reached a threshold.

Table 1 compares Current Approach, the previous first scenario, with “Game Changing”, the other three scenarios. It is clear that a quite different society is coming and a quite different procedure is needed whether social changes are considered or not.

Table 1 Current approach vs. “Game changing”

	Current Approach	Game Changing
Feature of EV	High mileage/speed	Auto pilot/parking, “Barrier-free”, Low-speed, Private room
Intended user	Productive People	Productive/Aging people
Policy	Advanced Technology development, Increase in number of battery chargers, Grants for purchasing	Social system change in various areas, Relocation of residence, Assist innovative ideas from private sector
Main player in Industries	Car, Electronics	Car, IT, Robot, Material, Electronics, Construction
Social cost reduction	Medical, Environment	Medical, Environment, Traffic accident, Public transportation, Financial support needed for aging society
Resource/ Energy Increase	Electric power consumption:50-100TWh (5-10%), Copper material:4.4million ton, Rare-earth (Nd): 17 thousand ton	
CO2 Reduction	Around 100 million ton (-10%)	

4.1 Car Industries

Regarding the main players in industry, EVs in “Continuation of Current Auto-motive Society” should be manufactured by the car industry in order to continue the basic performances of current cars. On the other hand, EVs in the other social scenarios, such as “Clean Compact City” could be manufactured by a new industry which blends IT, Robot, material, and interior design industries together. These new industries will supply cars which are only suitable for the Japanese market. This style has been called “Galapagos” approach, meaning the product is adapted to fit only one country. This approach has also been adapted by the mobile phone market in Japan. Because social conditions differ between countries, businesses must therefore take the “Galapagos” approach in order for a sustainable car-society in each individual country to be achieved. This is especially true for Japan due to its unique social situation. Meanwhile, the current major car industries have supplied similar types of gasoline cars, such as “high-speed”, “long-distance travelled, and “safe/ comfortable”, into several countries of the world. Therefore, when we consider Japan’s “car-society” in the future, we also cannot ignore the effect of globalization on the car industries. However, the coexistence of global and “Galapagos” businesses may occur in a future Japan market.

4.2 Negative social cost

Currently we take air-pollution and sound-pollution caused by gasoline cars for granted. We reap the benefit of freedom gained by transportation at great cost [7]. For example, medical conditions such as respiratory disease can be caused by the exhaust gas of gasoline cars. The noise from gasoline cars has been linked to mental stress. At great social cost the government spends a large amount of its budget on trying to treat such ‘diseases’. How much money do we waste on such negative things? In a 100% EV society, these social costs would become obsolete.

Three types of society without Continuation of Current “Auto-motive” Society would have less traffic accidents because of low speed car’s operation and automatic running mode, and wouldn’t need social cost in order to construct new public transportation system for aged people. The decrease in traffic accidents would also reduce negative social costs related to the treatment of these accidents. If the negative social cost that we have kept paying could be spent in new social system construction, we may achieve a happier society. It would be necessary to clarify the value of these negative costs in order to make a first step towards achieving a sustainable EV society.

4.3 Resouce and energy increase

Regarding resource/energy consumption and CO2 emission, we assumed there were no large differences between scenarios. The total mileage of private passenger cars in 2008 was 368,235 million km for ordinary cars, and 121,326 million km for light cars (MLTI 2008). If average fuel efficiency of EVs is 10km per 1kWh (best case estimated from current EV), around 50 TWh/ year (tera-watt-hour) of electricity would be required. This was around 6% of total electricity demand of Japan in 2008. If average fuel efficiency of EVs is 5km per 1kWh (practical case including usage of air-conditioners etc.), an increase in electricity demand becomes double. However, it is possible that their increase in energy demand could be supplied by renewable energy [12]. The impact of replacing gasoline cars with EV on resource consumption was also investigated. 4.2 million-tons of copper would be required if gasoline cars are replaced by EVs, which would be difficult to procure in current industry. Economic issues would occur with regard to a lack of copper resource [13]. Therefore, a copper recycling system would be fundamental to constructing an EV society [14].

4.4 Game changing approach

Figure 10 shows differences between current approaches of substituting gasoline cars for EVs and “game changing” approach toward sustainable car society. By considering a range of social factors, we can depict various social scenarios which contribute to a sustainable society.

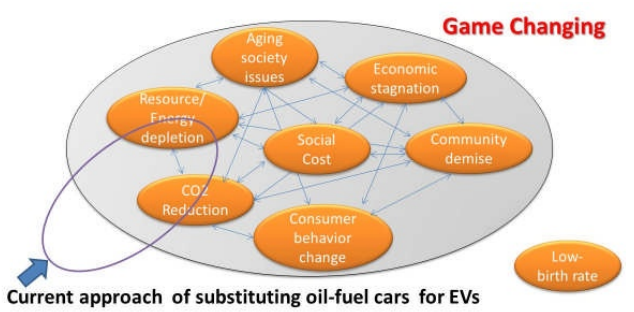

Fig.10 Differences between current approach and ‘game-changing’

5 SUMMARY

As stated in the introduction, in the same way that we had to undergo a radical change with regard to our method of study from pure engineering to a more ‘open’ approach, the scenarios show that our approach to society must also undergo a radical change by utilizing and integrating technology. The current method of substituting gasoline cars for EVs would be misguided if we consider future social changes in Japan. This is a conventional technological approach that is an approach guided only by technological innovation. If we take a more radical approach where technology is integrated with social issues, EVs technology provides us with the opportunity to radically transform social structure. A new kind of society can be created which will eradicate many of the social problems we face in our current style of “car-society”. These include issues related to an unprecedented aging population with low birth-rate, such as increased social cost regarding transportation, and medical care. It may be more effective to start investigating ‘Game changing’ approaches which broaden our horizons. We have to possess a holistic view of social issues (global warming, poverty, explosion of world population, and economic climate), and understand the causality between them. The integration of social science perspectives, such as human behavior and culture, with technology may be inevitable.

6 ACKNOWLEDGMENT

We appreciate the financial support of NEDO (Eco-Innovation program in 2009) and MSTC in helping us to depict scenarios. This research was conducted as part of Grants-Aid for Scientific Research (KAKENHI) Project of Japan from the fiscal year 2008–2012, supported by MEXT, Japan

Abstract

Designing scenarios is a hopeful approach for realizing sustainable society. Sustainable Society Scenario (3S) Simulator is an integrated scenario design support environment. The purpose of this article is to discuss the effectiveness of the scenario design support method in 3S Simulator. Here, we employ a backcasting scenario design support method. The key approach of this method is employing logic trees. A logic tree supports backward thinking and structuring ideas into scenarios. We designed "Manufacturing corruption scenario" as a case study. The purpose of developing this scenario is to discuss unsustainable future of manufacturing industry for designing "Sustainable manufacturing scenario." In the case study, we succeeded in designing the scenario based on the proposed process and two different corruption patterns are derived by constructing a logic tree. Through the case study, we identified the advantages of the design support method of 3S Simulator in structuring the designers' idea into a scenario.

Keywords:

Sustainable manufacturing, scenario, scenario design, backcasting

1 INTRODUCTION

Realization of sustainability is the most important issue of our society and drastic changes are needed for our society. For construction of sustainable society, manufacturing industry plays an important role, because manufacturing industry produces artifacts that are essential to the society from natural resources. In order to realize sustainable society and sustainable manufacturing part of it, drawing images and pathways toward them is a hopeful approach. For this purpose, developing scenarios is a useful means. Here, a scenario includes one or more stories, each of which connect descriptions of a specific future and the present situation in a series of causal links [1]. Especially, we call scenarios about sustainable society and its constituents as sustainable society scenarios. IPCC's Greenhouse Gas emission scenario [2] and IEA's Energy Technology Perspectives [3] are famous examples of sustainable society scenarios.

When developing a scenario, the scenario designers need to collect large amount of information, conduct times of discussions for drawing future visions and describe stories based on the collected information and the result of the discussion. Although scenario development requires long time and large amount of work in this way, there is no computational support for it. In order to tackle this problem, our research group has proposed Sustainable Society Scenario (3S) Simulator, which is an integrated design support environment for sustainable society scenarios [4]. The purpose of this article is to discuss the effectiveness of 3S Simulator and its scenario design methodology through a case study of scenario design.

This article is organized as follows. Section 2 introduces the concept of 3S Simulator. Section 3 describes the methodology used in this article, including scenario representation method and scenario design method. In section 4, a scenario is designed as a case study. Section 5 discusses the effectiveness of 3S Simulator based on the case study. Section 6 concludes this article.

2 SUSTAINABLE SOCIETY SCENARIO (3S) SIMULATOR

As mentioned in Section 1, 3S Simulator is an integrated scenario design support environment. 3S Simulator supports designing sustainable society scenarios by representing, composing, analyzing, and relating scenarios [3]. In order to develop 3S Simulator, the following five research topics have been set [3]; scenario representation method, scenario design method, dynamic scenario, scenario analysis, and scenario archives.

3S Simulator models the design process both in forecasting and backcasting [5] and develops a methodology for supporting these processes [5]. Here, forecasting and backcasting are two manners for developing scenarios; while forecasting explores the futures from the present situation, backcasting at first sets future visions and then going backwards to the present. This article discusses the effectiveness of backcasting scenario design method. It is because backcasting is effective to draw the future visions far different from the present, such as the visions of sustainable manufacturing.

3 METHODOLOGY

3.1 Appoach

There are three difficulties in designing a scenario. The first one is difficulties in backward thinking of backcasting scenario design process, finding out some causes from an effect. Second difficulties are that in generating future visions in a scenario. The last one is difficulties in composing a scenario from the result of discussion, thought, data collection, analysis, and simulation.

In order to tackle these difficulties, the key approach for the backcasting scenario design method is to employ logic trees [7]. Generally, a logic tree is used for analytical problem-solving. A logic tree breakdowns a key problem into specific sub problems. In the proposed method, a logic tree represents a set of causal pathways to meet the target, which is the condition that must be achieved in the future.

A logic tree supports backward thinking, finding some causes from an effect, by visualizing causal pathways. Determine the target at first, and ordering requirements generated by discussion and thought into a logic tree, the scenario designers can structure ideas in backward direction. In this way, the designers can gradually develop future visions that meet the target through structuring ideas in the logic tree. The designers can deploy main events and actions included in the sub scenarios from causal pathways represented in a logic tree. These main events and actions can be used as guidelines to composing the detail of sub scenarios from the result of discussion, thought, data collection, analysis, and simulation.

3.2 Scenario representation method

In this method, we employ Scenario Structural Description Method [8] for describing sub scenarios. It provides us with a computerized way of representing scenarios. The aim of Scenario Structural Description Method is to support understanding and analyzing scenarios rationally, by clarifying their logical structure and relations with associated simulations. Scenario Structural Description Method supports the designers in composing the detail of sub scenarios from the result of discussion, thought, data collection, analysis, and simulation by clarifying the relationships among them.

3.3 Logic tree

In the proposed method, a logic tree is represented as Fig. 1. A logic tree is composed of a target, requirements, which are events and actions necessary to meet the target, and causal relations among them. In addition, we set two types of causal relations in a logic tree, that is, exclusive and non-exclusive relations. When the causes of an effect are connected with exclusive relations, these causes do not occur at the same time. For example, node (a) and (b) in Fig. 1 are connected with exclusive relations to the target, so the conditions represented by node (a) and (b) are not realized at the same time.

In a logic tree, a sub tree represents a pattern to meet the target. We name it a causal sequence. Two causal sequences are picked up from the logic tree shown in Fig. 1. The designers can deploy the main feature of a sub scenario, the main events and actions connected with causalities, from a causal sequence. The way the designers deploy the main feature is described in section 3.5. Exclusive relations support the designers in picking up causal sequences. The causal sequences include exclusive events or actions do not occur at the same time, so those causal sequences are independent patterns to meet the target.

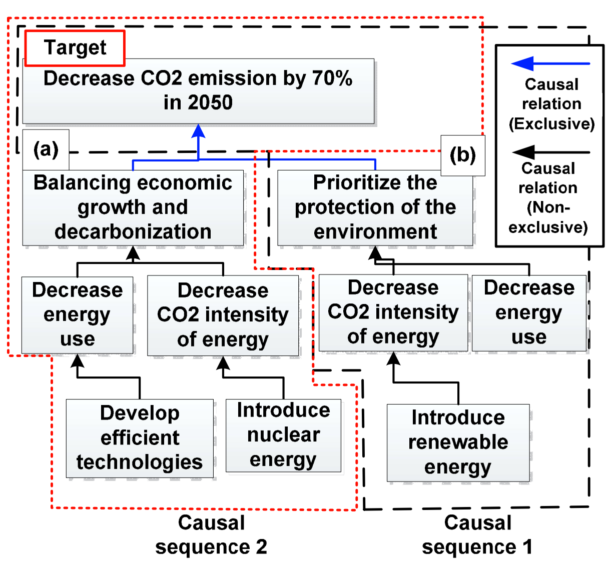

Fig. 1 An example of logic tree

3.4 The elements of a backcasting scenario

Fig. 2 summarizes the elements of a backcasting scenario. A backcasting scenario is composed of the five elements; (a) a problem, (b) a target, (c) a logic tree, (d) storylines, and (e) sub scenarios.

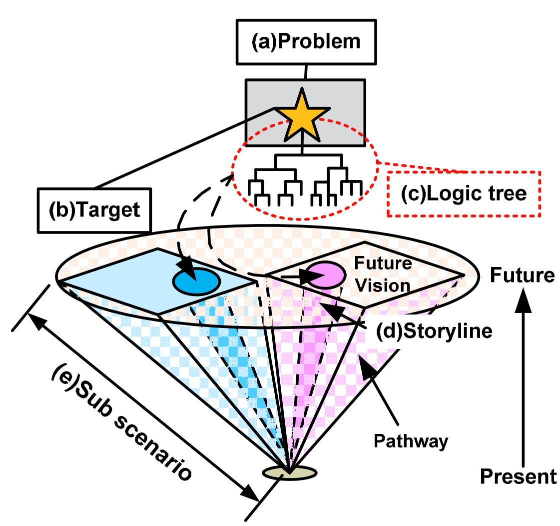

Fig. 2 The elements of a backcasting scenario

(a) Problem: the problem describes the objectives and backgrounds of the scenario to be designed.

(b) Target: target is a part of problem and represents the condition must be achieved in the future visions described in the scenario.

(c) Logic tree: a logic tree represents a set of causal pathways to meet the target.

(d) Storyline: a storyline is the main feature of a sub scenario, which are main events and actions connected with causalities in the sub scenario.

(e) Sub scenario: a sub scenario describes a future vision and pathways between the present and the future vision.

Here, a future vision represents a situation in the end year of the scenario, and a pathway is transitional events and actions between the future vision and the present that are connected with causalities. When describing sub scenarios, a storyline of each sub scenario is at first derived from the logic tree.

3.5 The design process

The design process proposed in this method is composed of four steps as shown in Fig. 3. The designers can design a scenario in backcasting manner through developing the five elements proposed in section 3.4 in the four steps. In step (1), the designers discuss and determine what to write in the scenario including target. In step (2), the designers spread a logic tree from the target. In step (3), the designers determine scenario structure, which means which sub scenario is included in the scenario and what is the main feature of each sub scenario. Lastly, in step (4), the designers describe the detail of each sub scenario.

Step (1) Setting a problem

In this step, the designers clarify the problem of the scenario to be designed. The designers discuss the objective, theme, time horizon, targeted region, and stakeholders included in the scenario. Then, they should discuss the ideal future that they want to achieve and set the condition must be achieved in the ideal future, namely, set the target of the scenario.

Step (2) Constructing a logic tree

In step (2), the designers brainstorm requirements to meet the target and ordering the result of the brainstorming into a logic tree like Fig. 1. The designers set the target as the root node, and order the result of brainstorming in the backward direction, from effects to their causes. When constructing a logic tree, the designers distinguish exclusive causal relation and non-exclusive causal relation.

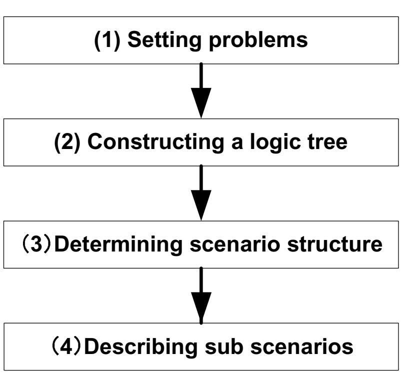

Fig. 3 The design process

Step (3) Determine scenario structure

In this step, the designers determine the scenario structure, (*i.e.*, the number and topics of sub scenarios) and their storylines.

At first, the designers pick up causal sequences by discussion, data collection, or analysis. In this step, exclusive relation helps selecting causal sequences. In Fig. 1, two causal sequences are picked up from the logic tree based on the exclusive relation among the target and nodes (a) and (b)

At last in this step, the designers describe storylines of sub scenarios by tracing causal relations forward from the terminal nodes in the causal sequence to the target. For example, a storyline is derived from the causal sequence 2 in Fig. 1:

"Introduction of nuclear energy decreases CO_2 intensity of energy. And development of energy efficient technologies decreases energy use. These factors enable both high economic growth and 70% of CO_2 emission reduction in 2050."

Step (4) Describing sub scenarios

In this step, the designers describe the detail of each sub scenario. In this method, sub scenarios are described using Scenario Structural Description method [8]. When describing sub scenarios, the causal sequences are used as a guideline for description of sub scenarios. The designers collect and analyze data and conduct simulation in order to add details of sub scenarios.

4 CASE STUDY

This article conducts a case study of scenario design methodology of 3S Simulator. This case study is a part of the project "Development of Sustainable Society Scenario Simulator for designing the vision of sustainable manufacturing." One of the objectives of this project is to design "Sustainable manufacturing scenario." In this project, the scenario is designed in two steps; drawing the unsustainable future of the current style of manufacturing and then describing the images of future manufacturing industry that overcome the catastrophic situation. As the first step, a scenario named "Manufacturing corruption scenario" was designed in this case study. We carried out workshops for designing this scenario based on the proposed method and we arranged the result of the workshops into the scenario.

4.1 Step (1) setting problems

Table 1 summarizes the problems in this case study. Referring to the objective of the project "Development of

Table 1 Problems of "Manufacturing Corruption Scenario"

Item		*Description*
Title		Manufacturing corruption scenario
Theme		Patterns and requirements of Japanese manufacturing industry's corruption.
Objective		Draw the catastrophic future of Japanese manufacturing industry and pathways to it.
Time horizon	Start year	2010
	End year	2050
Region		The world
Main Actor		Japanese manufacturing industry
Actors		consumers, material suppliers, energy suppliers, components suppliers, other countries, and so on…
Target		Japanese manufacturing industry breaks down

Sustainable Society Scenario Simulator for designing the vision of sustainable manufacturing," our research group at first set Japanese manufacturing industry as the main actor of this scenario. And we set the world as a targeted region because international trade is essential to Japanese manufacturing industry. We set "corruption of Japanese manufacturing industry" as the target of this scenario. And we detailed the definition of the target as follows;

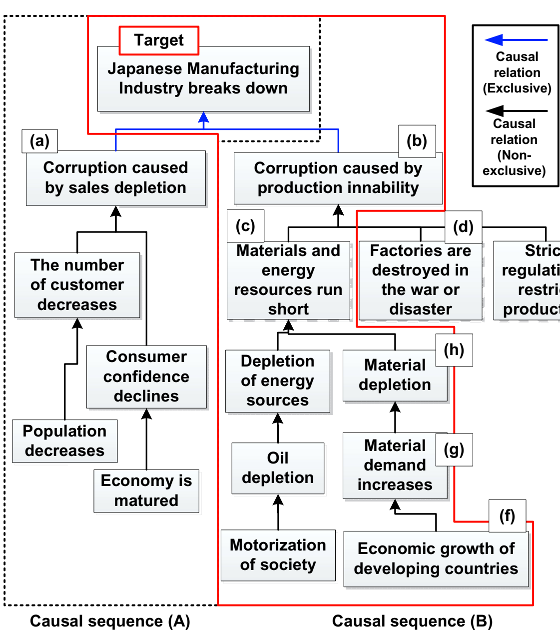

Fig. 4 The logic tree constructed in the case study

- The manufacturing industry cannot keep the employment in Japan
- The standard of living in Japan, such as standard of medical service or public health declines

This is because the important role of the manufacturing industry is to create employment and keep or improve living standards.

Other items in Table 1 are determined through the discussion among the participants of the workshop.

4.2 Step (2) constructing a logic tree

After setting the problems, we brainstormed the requirements to meet the target and simultaneously constructed the logic tree as shown in Fig. 4. Through constructing this logic tree, we developed two exclusive corruption patterns; (a) corruption caused by sales depletion and (b) corruption caused by production inability.

4.3 Step (3) determining scenario structure

In this step, by the discussion and data analysis, we picked up two causal sequences (A) and (B) from the logic tree. In Step (2), we set (c) "materials and energy resources run short" as a cause of (b) "corruption caused by production inability." Based on this causal relation, we conducted an analysis about resource depletion. We picked up copper as an example of depleting resource, and we collected data and analyzed future copper demand and supply [9]. When picking up causal sequence (B), we focused on the production inability caused by resource depletion by excluding node (d) and (e), referring the result of the analysis [9].

Based on causal sequences (A) and (B), we developed two sub scenarios, "Demand decline sub scenario" and "Resource depletion sub scenario." The storylines of these sub scenarios are respectively deployed from the causal

Table 2 Storylines of the scenario

Sub scenario	*Storyline*
Demand decline sub scenario	Population decreases and it causes the decline of customers. In matured economy, consumer confidence declines. Japanese manufacturing industries will breakdowns because sales depletion caused by these factors
Resource depletion sub scenario	Economic growth of developing countries and motorization of society increase the material and oil demand. Increased resource consumption causes the resource depletion. As a result, Japanese manufacturing industries will corrupt, because they cannot acquire enough material and energy for production

sequences as Table 2.

4.4 Step (4) Describing sub scenarios

In this step, we described the detail of each sub scenario. We added the detail of the sub scenario to the main feature of a sub scenario represented in the corresponding causal sequence. Fig. 5 represents a part of resource depletion sub scenario. Nodes (a), (b), and (c) in Fig. 5 correspond to causal sequence (B), these nodes respectively corresponds to (f), (g), and (h) in Fig. 4. We supplemented nodes about copper usage in developing countries, (d) and (e), between (a) and (b). Node (f) is the result of data analysis [9], which is referred by (c) to describe the detail of the situation of copper depletion.

4.5 Conclusions of the scenario

Through steps (1) to (4), we designed "Manufacturing corruption scenario." We concluded this scenario as follows:

"In 2050, developing countries are still in economic growth, so Japanese manufacturing industry can find new market somewhere in the world. On the other hand, copper will run out in the middle of 2030s. Therefore, from 2010 to 2050, resource depletion causes catastrophic situation of Japanese manufacturing industry."

5 DISCUSSIONS

In the case study, we designed Manufacturing corruption scenario using the proposed backcasting scenario design support method. Through the case study, 3S Simulator and its scenario design support method was effective in structuring the designers' ideas into a scenario. Specifically, we identified the following advantages in designing a scenario:

1. Logic tree employed in this method supports backward thinking in backcasting scenario design process by visualizing the relationships between the target and its causes. By ordering brainstormed ideas into the logic tree, we succeeded in extracting the two different future corruption patterns in the case study.
2. Through brainstorming and construction of the logic tree, the designers can identify the topic that they should consider in detail. In the case study, we identified resource depletion as the topic to collect data and conduct a data analysis. The result of this analysis supported us in picking up the causal sequence corresponds to resource depletion sub scenario.
3. By picking up causal sequences from a logic tree, the designers can easily clarify the main feature of a sub scenario. In the case study, when making resource depletion sub scenario, we picked up resource depletion as the main topic of this sub scenario and trimmed away other features, such as production inability caused by regulations and warfare. Distinction of exclusive link and non-exclusive link supports picking up causal sequences from the logic tree and By tracing the causal relations in a causal sequence, the designers can easily describe the storyline of sub scenario corresponding to the causal sequence.
4. Describing the sub scenarios in Scenario Structural Description Method, the designers can clarify the relationships among the materials of scenarios, *i.e.* the main feature of the sub scenario deployed from the logic tree, collected data, and result of discussions, data analysis, and simulation. It supports scenario designers in composing the scenario of these materials.

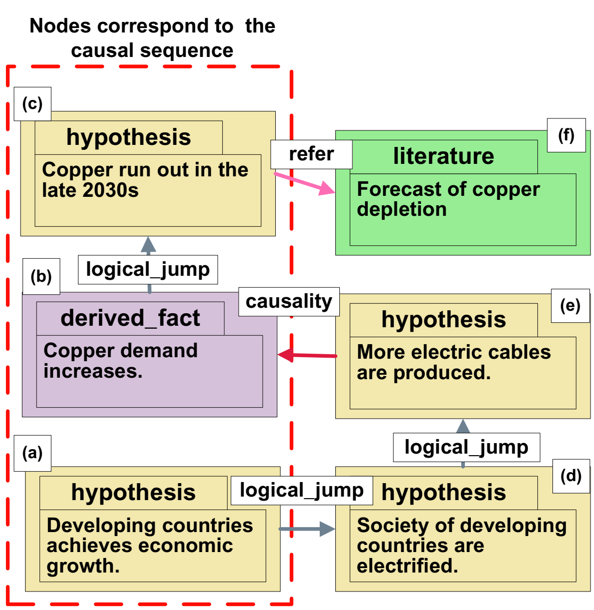

Fig. 5 The detail of resource depletion sub scenario described in step (4)

In contrast, backcasting scenario design support method of 3S Simulator does not support generating ideas from discussions, thoughts, data collection, analysis, or simulation. These procedures of scenario design are out of focus of proposed scenario design support method.

6 CONCLUSIONS

In this article, we discussed the effectiveness of scenario design support method of 3S Simulator. We designed "Manufacturing corruption scenario" by using backcasting scenario design support method as a case study. Through the case study, we identified the advantages of 3S Simulator and its scenario design support method in structuring ideas into a scenario.

Future works include updating this methodology, methodology for relating different scenarios on 3S Simulator, and designing "Sustainable manufacturing scenario."

Dynamic Simulation of Renewable Electricity Supply in Japan

Haruki Tsuchiya
Research Institute for Systems Technology, Tokyo, Japan

Abstract
This paper reports on a dynamic simulation of electricity supply from renewable resources in Japan. After the surveys on potential energy of domestic renewable resources in Japan, a dynamic simulator is developed to evaluate the electricity generation from hydro power, solar photovoltaic, wind power, geothermal and biomass together with backup power and battery storage. The simulation is performed to calculate electricity supply for a target year around 2050. The hourly meteorological data of solar radiation and wind speed in 150 sites are used for dynamic calculation. From the simulation result we estimated the construction cost of renewable electricity generation plants, backup power plant and battery storage.

Keywords: renewable energy, solar photovoltaic, wind power, energy storage, backup power

1 INTRODUCTION

The domestic renewable energy sources are important from the view point of safety, security, energy independence and no carbon dioxide emission. It is not difficult to show the scale of national electricity supply mainly from renewable resources, such as solar photovoltaic(PV), wind, hydro, biomass and geothermal power.

In such studies, the annual electricity demand is compared with the available renewable energy sources, and the accounting balance table is used to show the necessary scale of renewable energy. Such accounting is basically static, but in case of electricity supply, there are dynamic problems of demand-supply matching and the necessary scale of electricity storage to absorb the fluctuations caused by PV and wind power generation.

To analyze these subjects, we developed a computer program to simulate renewable electricity supply with battery storage to supply the hourly electricity for demand patterns throughout a year.

2. DYNAMIC SIMULATOR OF ELECTRIC SUPPLY FROM RENEWABLE SOURCES.

The dynamic simulator is designed to estimate hourly renewable electricity supply using meteorological data to satisfy electric demand as follows.

2.1 Meteorological Data

The hourly data of solar radiation at 63 sites and the hourly wind speed data at 150 sites in Japan are used to calculate PV and wind power. The sites are distributed nation wide as dots shown in Fig.1. The data for 2001, 2002, 2003 and 2005 are prepared. [1]

2.2 Electricity Demand

There are ten electric power companies in Japan. They supply nearly 84% of national electricity demand. The rest of electricity is almost self-produced by energy-incentive industries. Ten supply grid areas from north to south are (1)Hokkaido, (2)Tohoku, (3)Kanto, (4)Chubu, (5)Hokuriku, (6)Kansai, (7)Chugoku, (8)Shikoku, (9)Kyushu and (10)Okinawa as numbers shown in Fig.1.

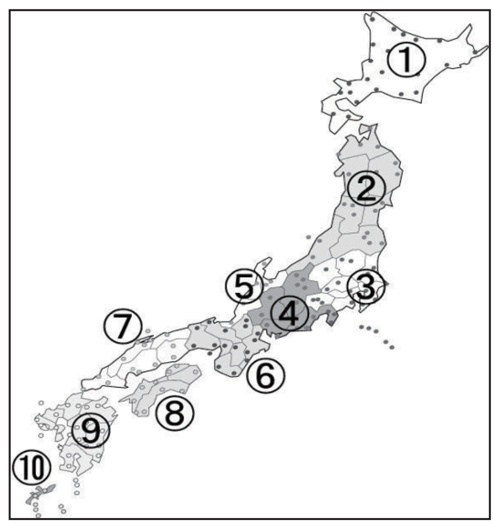

Fig.1 Map of ten areas of electricity supply in Japan

The electricity grid of Okinawa area is remote and not connected with the grid of other power companies, so we do not treat the electricity supply of Okinawa area in this study.

The mutual connection lines among the nine power grids are not so large. They are somewhat independent. Even more there is difference of grid frequency between 50 Hz in the east and 60 Hz in the west areas, which was caused

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_20, © Springer Science+Business Media Dordrecht 2012

by technology import from Europe and USA hundred years ago. But we did not treat the constraint of mutual electricity flow between grids in this study and we treat the nine areas as a single grid.

Tab.1 shows the monthly electricity supply data by generation category for nine grid areas in 2008, excluding Okinawa. The columns of pumped hydro present negative numbers that is the loss of lifting water amounts to 30% of stored electricity. The column of new energy is geothermal, solar and wind. The column of purchase means electricity purchase from other power supply companies. [2]

Tab.1 Monthly electricity supply of nine areas (GWh, 2008)

Month	Hydro	Thermal	Nuclear	New Energy	Purchase	Pumped Hydro	Total
1	3,190	42,860	23,760	10	14,828	−558	84,090
2	4,110	36,656	20,442	18	13,124	−390	73,959
3	5,383	39,236	19,633	17	13,094	−344	77,020
4	5,740	41,449	17,223	3	11,008	−586	74,837
5	6,112	40,260	18,693	3	10,800	−679	75,189
6	6,478	38,893	18,778	7	13,702	−737	77,121
7	6,003	49,864	22,443	11	16,036	−1,142	93,215
8	4,992	45,191	24,474	10	16,584	−1,201	90,050
9	4,732	43,316	20,037	17	14,921	−822	82,201
10	3,635	40,185	19,771	8	13,798	−538	76,859

12	3,273	42,269	22,078	10	15,111	−379	82,362
Total	56,451	501,554	247,097	129	165,986	−7,725	963,492

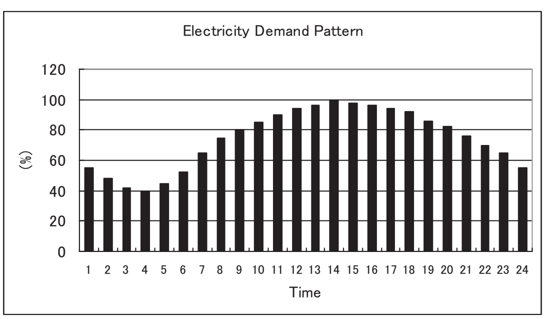

Fig.2. Hourly electricity demand pattern for a day

The hourly electricity demand pattern for a day is known as Fig.2, which depends on seasons. The demand is low in early morning and rises toward noon and reaches peak in the afternoon, and slowly decreases to midnight. The electricity peak is at 16:00 in winter and at 14:00 in other seasons in this study

3. Renewable resources

The situations of renewable resources in Japan and their simulation procedures are as follows.

3.1 Solar PV

"PV Road map: PV2030+" shows future possible scale of PV by NEDO in 2010. It reports PV will be used more than 550GW in 2050. [3] They will be built on roofs and walls of buildings and variety of land areas.

In this study, the hourly electricity generation from PV panel is calculated using horizontal solar radiation data at about 60 sites in Japan. The calculation method is to split horizontal radiation into direct beam and scattered irradiance and to combine both solar lights on the panel located at south oriented with tilt angle. [4] The optimum tilt angle is set at "latitude -5" degree at each construction site as is known experimentally. The inverter of 94% efficiency is included with partial load factor curve.

3.2 Wind Power

In this study, 2MW wind machine with three blades and horizontal axis is used to calculate the wind power in respective sites. The blades start to rotate at cut-in wind speed 3m/s, and stop at cut-out wind speed 25m/s. The conversion efficiency is assumed 40%. The diameter of rotor is 80m and hub height is 56m. Wind speed of meteorological data is extended by 1/6 th power factor law to calculate the wind speed at hub height. [5]

The wind data sites include remote islands. They are used for this study as wind machines are already built on semi-off shore in shallow coast lines of Pacific Ocean and they will be built off shore far from the coast lines in the future.

Japan wind power association estimated the future scale of wind power on land and off shore as 50GW or more for 2050. [6]

3.3 Hydro Power

The capacity of hydro power is 20.73GW now and will be 27.6GW in 2050 by official prediction. [7]

There are 25.64GW pumped hydro now. However it is not treated in this study in order to simplify the dynamic storage behavior.

3.4 Geothermal Power

The rated output of geothermal plant is 520MW today. The 2050 geothermal vision by Japan geothermal association shows the annual electricity generation amount by three scenarios, base scenario, best scenario and dream scenario.[6] In this study, we applied best scenario 4,819MW conservatively. The plant works constantly throughout a year.

3.5 Biomass

Japan is basically rich in biomass resources as the 69% of national land area is forest. Report by National Institute for Environmental studies shows that 1,779PJ thermal amount is available from biomass. [6] If half of the amount is converted to electricity at 20% efficiency, it is 49.42TWh, 5,642MW. This number is applied in this study.

3.6 Backup power

Natural gas power will be a candidate for backup power. The necessary fuel consumption for backup power shows the shortage of electricity supply and is one of the concerned subjects of this study.

3.7 Battery

The efficiency of battery is assumed as 95% of charge and 95% of discharge including inverter. The depth of charge is assumed as 100% for simplification. The inverter capacity is assumed 5 hours to fill the storage. Battery capacity (MWh) was presented by the time length (hours) during which it is possible to supply the average electricity demand (MW). It is also a concerned subject of this study as shown in latter part.

4. SIMULATION METHOD

The inputs to simulation program are as follows.

(1) Selection of the data year among 2001, 2002, 2003 and 2005.

(2) The ratio of future electricity demand against 2008 level.

(3) The supply share (%) of PV and wind against electricity demand

(4) The time length (hours) of battery capacity.

4.1 Electricity demand in the future

The energy demand of Japan in the future is discussed to decrease because of population decrease and efficiency improvement. The population of Japan began decreasing in 2008. The population forecast for 2050 is 74% (A scenario) and 78% (B Scenario) of year 2000 level in the study of "low carbon society scenario 2050" by National Institute for Environmental Studies.[8][9]

GDP growth rate is forecasted officially as low as 1% for period 2020-2030. The society will shift to more service oriented, with less material production and more recycling of industrial materials. Electricity demand around 2050 will be decreased by improving technologies such as light emitting diodes, high COP air conditioners, efficient home appliances, energy saving office machines and inverter controlled motors. So we assume the energy demand in this study will be relatively decoupled with GDP growth and the electricity demand around 2050 will be 60% of the year 2008 level.

4.2 Scale of PV and wind power

The 150 sites having meteorological data of solar and wind power are distributed nationwide. To calculate the electricity generation by PV and wind power in each area, the hourly generation amount by single unit of 100kW PV and 2MW wind machine for respective areas are calculated and stored in hard disk at first.

As annual shares of PV and wind power are input parameters, the amounts of electricity generation are supposed to be proportional to the annual electricity demand of nine areas respectively. As the wind power sites having capacity factor less than 18% are excluded, finally 42 sites are selected among 150 sites for data year 2005. Solar data are available for 63 sites for data year 2005.

Tab.2. Power plant (MW) and generation (GWh) by PV 50% and Wind 20% in respective areas (CF=capacity factor)

Area	PV	PV generation	CF of PV	Wind	Wind generation	CF of Wind	Electric Demand
	MW	GWh	%	MW	GWh	%	GWH

Shikoku	8,179	9,633,423	13.45	669	3,853,369	65.73	19,266,846
Kyushu	21,544	28,175,280	14.93	4,979	11,270,110	25.84	56,350,568
9 Area Total	239,561	289,047,600	13.77	38,391	115,619,100	34.38	578,095,313

The necessary unit numbers of PV 100kW and wind machine 2MW are calculated as proportional to annual electricity demand of respective areas. These unit numbers of PV and wind machines are multiplied with hourly generation which is stored in hard disk to calculate electricity supply throughout dynamic simulation for the target year.

Tab.2 shows the PV and wind power calculated by the assumption of PV 50% and wind 20% of the annual electricity demand. The nationwide site selection of wind power resulted in the capacity factor 34.38% which is within experimentally known ranges.

4.3 Dynamic computational process

After settling the demand and scale of renewable resources, computer calculations are performed in the following order. The hourly electricity demand (D) is subtracted by renewable supply consequently as follows.

1) Electricity Demand (D) is supplied by geothermal which is constant throughout a year. Hydro power is supplied according to supply pattern that is predetermined depending on time.

D = D – geothermal– hydro power

The updated D is the demand for next stage as follows.

2) The next step depends on the amount of updated demand.

2-1) If PV and wind are less than demand, that is D > PV+wind power,

D=D - (PV+wind power)

Updated demand is supplied from biomass power.

D = D – biomass power

If it is not sufficient for demand, battery discharge can supply to demand.

D=D – battery discharge

If demand remains still, then demand is supplied by backup power. Backup power=D

2-2) If PV and wind are larger than demand,

that is PV + Wind> D then battery is charged.

Battery charge = (PV+wind) – D

If battery is fully charged, then the rest of electricity is accounted as excess.

Excess= (PV+wind) –Battery charge – D

Throughout dynamic simulation, the energy balance is confirmed at every hour by the following equation.

Excess = Power generation – Electricity demand

+ Battery discharge – Battery charge –Battery loss

Where,

Power generation = PV + Wind power

+ Hydro + Geothermal + Backup power

4.4 Details of simulation

The simulation starts on 1st April with battery half charged and ends in 31st March of next year for which the meteorological data of the same year is used.

Fig.3 shows the supply patterns of PV, wind, geothermal, hydro and battery discharge on 11th to13th in January.

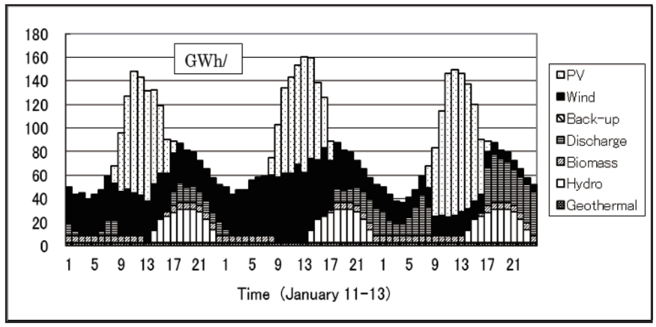

Fig.3. Supply of PV, wind, backup, discharge, biomass, hydro, and geothermal, (GWh/h)

The electricity demand grows in the morning and peaks around 14:00. Geothermal power is constant supply as base load. Wind power shows supply fluctuations. PV has bell-shape supply patterns in daytime. Hydro power supply is under the schedule peaking around 18:00.

4.5 Simulation summary

One of the simulation summaries of renewable electricity supply is shown in Tab.3. The supply shares are PV 50% and wind 20% of annual demand. The battery capacity is 8 hours (528GWh) in this case. It shows that renewable sources can supply electricity to the expected electricity demand within the scales of published materials by respective communities of energy experts.

Tab.3 shows the share of hydro 13.64%, geothermal 4.38%, biomass 7.25% and backup power 10.73% against the annual electricity demand. The sum of excess (4.5%) and battery loss (1.48%) is 5.98 %, which must be equal to the generation supply 106% minus 100%, that is 6 %. Small difference is caused by the initial charge to battery when simulation starts.

It is important that the peak of backup power is fairy large, 49,535MW in this case. The sum of PV, wind and other renewable energies are 95.27%, which is less than 100%. So the renewable power is lack of supply. The system has characteristics that even if renewable power is less than 100%, there is excess power. It is because of fluctuations of PV and wind power.

The battery capacity is 8 hours multiplied with average power 66GW, that is 528GWh. As the sum of PV and wind is 277.9GW, the battery capacity is 1.9kWh per 1kW of PV and wind. This ratio is not large compared with experimentally known small PV and wind system having battery.

Tab.3 The summary of simulation for data year 2005.

Electricity Supply	Unit	Total
Photovoltaics Capacity	MW	239,561
Wind Power Capacity	MW	38,391
Battery Capacity	GWh	528
Electricity Demand	GWh/year	578,095
Average Electricity Demand	MW	65,993
Peak Electricity Demand	MW	101,300
Total Electricity Generation	GWh/year	612,782
_Photovoltaics	GWh/year	289,048
_Wind Power	GWh/year	115,619
_Hydro Power	GWh/year	78,869
_Geothermal Power	GWh/year	25,333
_Biomass Power	GWh/year	41,902
_Back-up Power	GWh/year	62,013
Total Share of Generation	%	106
_Share of Photovoltaics	%	50
_Share of Wind Power	%	20
_Share of Hydro Power	%	13.64
_Share of Geothermal	%	4.38
_Share of Biomass Power	%	7.25
_Share of Back-up Power	%	10.73
_Peak Back-up Power	MW	49,535
Battery Charge	GWh/year	85,724
_Battery Discharge	GWh/year	81,543
_Battery Loss	GWh/year	8,569
_Battery Loss/Demand	%	1.48
_Max Charge Level	%	100
_Average Charge Level	%	34.94
Excess Electricity	GWh/year	25,996
_Excess Electricity/Demand	%	4.5

4.6 Battery storage level

Fig.4 shows daily average battery storage level and backup power in the above case. The daily battery storage level shows decrease in summer and autumn because of characteristics of wind power. When battery charge level is low, backup power is high.

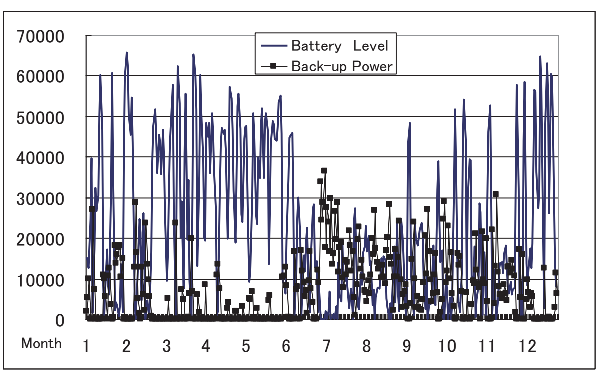

Fig.4 Daily average of battery storage level and backup power (MWh/h)

5. CONSTRUCTION COST OF RENEWABLE ENERGY SYSTEMS

How much is the construction cost of renewable energy systems? Photovoltaic cost has declined along with learning curve in the past 30 years.

The PV cost is analyzed by learning curve, and the past price records show that the cost decreased to 82 % at every time when the cumulative production doubled in 1979-1999 in Japan. [10]

Tab.4 Cost of PV by learning curve

Year	Annual Production	Cumulative production	Annual Domestic Market	Cumulative Domestic Install	Cost
unit	MW	MW	MW	MW	$/kW
2010	2,002	9,509	801	3,362	7,003
2020	12,397	71,880	4,959	28,310	3,894
2030	19,253	231,076	7,701	91,989	2,775
2040	29,899	478,303	11,960	190,880	2,247
2050	46,432	862,239	18,573	344,454	1,894

Production rate=+20% (−2020), =+4.5%(2021−2050) $1=80 yen
Domestic Use=40% of production, Progress Ratio=81.78%

We estimated the future PV cost by learning curve as shown in Tab.4. We assumed the PV production with 20% annual increase to 2020 and 4.5% increase from 2021 to 2050. PV Export will be 60% of annual production and the rest (40%) will be for domestic use annually. The progress ratio of leaning curve is estimated by regression analysis as 81.78% during 1979-2009. The progress ratio is cost reduction ratio when the cumulative production is doubled. The exchange rate is 1$ for 80 yen.

The column ‘Cumulative Domestic Install’ in Tab.4 shows the installed cumulative PV capacity. As the life time of PV is supposed 20 years, PV capacity 344-92=252GW will be installed between 2031 and 2050 and will be working in 2050. The average cost of PV is 2,193$/kW during this period.

Wind power is nearly commercialized. Battery cost also declined during competitive development for electric vehicles. There are several candidate technologies of battery. NaS, Nickel-hydrogen, and Lithium Ion are in competition. The battery will be used in the future at the cost of $200/kWh or less.

Tab. 5. The unit cost of energy plants around 2050

Technology	Cost	unit
Photovoltaic	2,193	$/Kw
Wind	1,500	$/kW
Battery	200	$/KWh
Backup Power		
Plant	900	$/kW
Fuel	8	$/KWh

The unit cost of PV, wind, backup power plant and battery around the year 2050 is supposed as shown in Tb.5. The plant scale of renewable energy systems of simulation result and the unit cost Tab.5 are used to estimate construction cost as shown in Tab.6. The fuel cost for backup power is shown for comparison.

Tab.6 The plant cost of renewable energy systems

Technology	Capacity	unit	Cost	unit
Photovoltaic	239,561	MW	525.36	Billion$
Wind	38,391	MW	57.59	Billion$
Battery	528	GWh	105.60	Billion$
Backup Power				
Plant	49,535	MW	44.58	Billion$
Fuel	62,013	GWh/y	0.496	Billion$
Total			733.13	Billion$
(Total dose not include Fuel cost)				

Tab.6 shows the construction cost of largely renewable energy systems is 733 billion$. If the investment is planned to be allocated into 20 years, the annual investment will be 36.66 billion$.

6. CONCLUSION

Using meteorological data in nine areas nationwide in Japan, dynamic simulation of annual renewable electricity supply and cost analysis of the future energy systems are presented. Main conclusions are as follows,

1) Renewable sources can supply electricity to the expected electricity demand around 2050 within the scales published by respective communities of energy systems.
2) Construction cost of renewable energy systems around 2050 is estimated. Annual investment for construction of renewable plant, backup plant and battery storage is 36.7 billion$.

Abstract
Various sustainability scenarios have been developed to visualize images of a sustainable society, such as the IPCC's scenario. However, it is unclear whether or not such existing long-term scenarios are feasible in terms of resource depletion. The purpose of this paper is to propose a method for analyzing the balance of long-term copper demand and supply, aiming to assess feasibility of existing sustainability scenarios. This paper proposes two approaches, *i.e.*, macro and micro approaches, in order to estimate copper demand in a comprehensive manner. In the macro approach, metal demand is estimated using GDP/capita and population. The micro approach estimates metal demand based on dissemination of products. As a case study, this paper estimates copper demand in a long-term energy scenario. The results show that cumulative demand of copper will be beyond their reserve base after 2038. The results also indicate that, though copper consumptions will increase because of shifts from gasoline vehicles to electric vehicles, their impact to the whole consumptions is not dominant.

Keywords:
sustainability scenario, estimation, resource depletion, copper

1 INTRODUCTION

We are faced with various kinds of problems, such as global warming, pollution, and population pressure. Describing scenarios is considered one of the most hopeful solutions to deal with environmental-related problems by envisioning pathways to a sustainability society. An example is IPCC's scenario [1], which tackles with the climate change caused by the effect from greenhouse gas emissions.

Although there are many scenarios to deal with these problems, it is unclear whether such scenarios are feasible in terms of resource laminations. For instance, while existing sustainability scenarios that describe images of a low-carbon society often assume dissemination of electric vehicles (EVs), they do not pay attention to increases of metal demand by EVs. In fact, the amount of copper required for manufacturing an EV is 5 times as much as that for a gasoline vehicle [2]. Additionally, resource consumptions including copper will increase with economy and population growth in emerging countries, especially in China and India.

The purpose of this paper is to assess the feasibility of long-term scenarios by analyzing the risk of copper depletion. In this paper, copper depletion risks are identified by evaluating the balance of copper demand and supply.

We propose two approaches (*i.e.*, macro and micro approaches) to estimate copper demand in two ways to assess the feasibility of the scenario from the different viewpoints based on sustainability scenarios. Macro approach estimates whole copper demand using GDP and population. This approach takes economic and population growth into account. On the other hand, micro approach estimates copper demand based on the number of the products introduced in the long-term scenarios in order to evaluate the influence of introducing certain products to copper demand. To analyze the risk of copper depletion, we employ reserve base of copper as an indicator that shows the maximum of supply. Reserve base means the technical limitation of copper supply, not including economical limitation [3]. As case study, we analyzed ETP 2010 [4], which is an energy-related scenario, and identified depletion risk of copper until 2050 based on that scenario.

2 LITERATURE-REVIEW

There are various related works on estimating metal demand. Halada*et al*. developed correlation formula about 22 metals, including copper, between consumptions of each metal and GDP/capita based on the Japanese statistics over past 50 years [3]. Sawada analyzed cumulative demand of copper, showing the correlation between copper consumptions and electricity consumptions [6]. These works are useful in estimating the future whole demand of metals, however, they do not estimate copper demand properly based on sustainability scenarios. These approaches can't identify the copper demand carried by increasing low-carbon products, which are expected to increase in order to reduce greenhouse gas

emission. That is the importance is to estimate copper demand based on the sustainability scenarios, and to identify the affection of introducing specific products to copper depletion.

3 METHODOLOGY

3.1 Approach

This paper evaluates the feasibility of long-term scenarios by assessing depletion risk of copper. For this purpose, we propose a method to evaluate the relationship between cumulative copper demand and supply based on sustainability scenarios. In estimating cumulative copper demand, we propose two approaches (*i.e.*, macro and micro approaches) in order to analyze the risk of copper depletion from two different viewpoints; the macro approach estimates copper demand carried by economic and population growth, while the micro approach estimates copper demand due to wide diffusion of specific products. It is because long-term scenarios usually describe numeric data of GDP, population and number of products expected to be introduced or sold. We then define the ratio of demand to reserve base [3] (RDRB) as an evaluation indicator of judging whether copper will be exhausted or not.

3.2 Macro approach

The macro approach uses a two-line model to estimate copper demand in order to reflect the economic and population growth. The two-line model means the correlation between GDP and copper consumptions, as Halada proposed [5]. According to his research, per capita consumptions of copper become stable after GDP/capita surpasses a certain level.

Fig. 1 shows the relationship between GDP/capita and annual copper consumption per capita from 1960 to 2010[7][8][9][10]. Based on the two-line model, we obtained formulas of copper consumption as follows:

$$y = 0.000482x \; (0 \le x \le 22{,}590) \qquad (1)$$

$$y = 11.0 \; (x > 22{,}590) \qquad (2)$$

Fig. 1: Historical data on annual copper consumption

where x is GDP/capita (2000 US$/capita) and y is annual copper consumption/capita (kg/capita). We derive these formulas by approximating plots on Fig. 1 to suite well the two-line model. We identified the transition point (certain level) at 22,590 (2000 US$/capita) judging from the shifts of slopes of the lines.

This paper calculates world annual copper consumption with these formulas, using GDP and population that are assumed in sustainability scenarios. Cumulative copper demand is defined as time integration of annual consumption in each year.

3.3 Micro approach

The purpose of the micro approach is to evaluate the influence of introducing certain products to copper demand. In this approach, we divide products into two categories in order to calculate copper demand; (i) one is specific products, influence of introducing that to copper demand we assess, (ii) the other is non-specific products that are other than specific products.

The micro approach defines annual copper demand as sum of copper demand relating (i) and (ii), and cumulative copper demand as time integration of annual copper demand. Annual copper demand relating (i) is calculated by multiplying the weight of the copper per product by its annual sales. On the other hand, annual copper demand relating (ii) is supposed as much as current consumption of them in order to know whether introducing specific products affects to the copper depletion or not.

3.4 Ratio of cumulative demand to reserve base

We evaluate the balance of copper demand versus supply by defining the ratio of cumulative demand to reserve base [3] (RDRB). Cumulative copper demand is estimated from each of the two approaches. Reserve base is, as this paper mentioned above, one of the best known indicators suggesting the technical limitation of copper supply, not including economical limitation [3]. In this paper, when RDRB surpasses 100%, we consider copper as an exhausting metal and the scenario as unfeasible.

4 CASE STUDY

This paper applies the proposed method to a long-term energy scenario called Energy Technology Perspectives (ETP2010) [4] to analyze the feasibility of the scenario. ETP2010 consists of two sub scenarios, *i.e.*, Baseline Scenario and BLUE Map Scenario. The former sub scenario assumes that the governments introduce no new energy and climate policies, while the latter assumes to deploy existing and new low-carbon technologies in order to halve energy–related CO_2 emissions by 2050 (compared to the 2005 level). In this case study, we estimate copper demand and then calculate RDRB of both sub scenarios.

Table 1: Assumptions on world GDP, population, wind & solar power according to ETP 2010 [4]

Category	2007	2050	
		Baseline	BLUE Map
GDP (billion 2000 USD)	39,493	133,299	
Population (million)	6,609	9,150	
Wind power generator (GW/year)	83	593	1,081
Solar panel (GW/year)	7	246	718
Truck & Bus (million sales/year)	26	60	47

4.1 Assumption of ETP 2010

In this case study, we calculate cumulative copper demand from 2009 to 2050 based on the ETP 2010 [4]. Given this timescale, we adopt the reserve base of 2009 (10 billion metric tons) [3] as the denominator of RDRB. We estimate copper demand based on assumptions for each of the macro and micro approaches as follows.

Assumption used for macro approach

ETP 2010 assumes growth of economic and population with same scales in both scenarios from 2007 to 2050 (see Table 1).

Assumption used for micro approach

This paper assesses the effect of introducing specific products to copper demand in the micro approach. In this case study we focus on automobiles and two kinds of power generator systems (*i.e.*, solar and wind power generator). These technologies are enthusiastically introduced in BLUE Map scenario in order to reduce more CO2 emissions than Baseline scenario. The dissemination of these products is obtained from ETP 2010. On the other hand, the amount of copper used for other products is fixed as much as that as of the 2009 level, as depicted in Table 2. BLUE Map scenario will introduce more clean generation technologies than Baseline scenario but less truck and bus (see Table 1). This is because the freight in BULE Map scenario is assumed to shift to train. Contrary to the truck and bus, BLUE Map scenario expects to deploy cars as much as Baseline scenario and the annual sales of cars at 2050 in both scenarios are estimated to be twice in 2010 (see Fig. 2). As depicted in Fig. 2, the types of cars are different in each scenario. Though ETP 2010 explicitly mentions the dissemination of these products, there is no description about how much these products contain copper. We assume the weight of copper used for each product from external resources, as shown in Table 3.

(GV: gasoline vehicle, DV: diesel vehicle, HEV: hybrid electric vehicle, PHEV: plug-in hybrid electric vehicle, EV: electric vehicle, HFV: hydrogen fuel-cell vehicle

Fig. 2: Annual sales of passenger automobile [4] (Left: Baseline, Right: BLUE Map)

Table 2: Copper usage by end-use sector in 2009[7][8]

Category	Sector	Copper consumption	
		Amount (thousand tons)	Percentage (%)
Electric & Electronic equipment	Power utility	2,098	11.5%
	Cooling	1,098	6.0%
	Electronic	634	3.5%
	Tele-communication	599	3.3%
	Diverse	1,948	10.7%
Building construction	Electric power	4,353	23.9%
	Plumbing	1,103	6.0%
	Architecture	270	1.5%
	Commu-nications	159	0.9%
	Building plant	110	0.6%
Transportation equipment	Automobile	1,313	7.2%
	Other transportation	798	4.4%
Consumer & General products	Consumer & General products	1,498	8.2%
Industrial machinery & equipment	Industrial machinery & equipment	2,264	12.4%
Total		18,244	100%

4.2 Results

Fig. 3 shows the results by both approaches (*i.e.*, macro and micro approaches). The result by the macro approach (green line) shows that the RDRB is 168% at 2050 and surpasses 100% around 2038. On the other hand, in the micro approach, RDRB at 2050 of Baseline scenario and BLUE Map scenario is 91% (red line) and 98% (blue line), respectively.

Table 3: Amount of copper included in products

Product		*Copper used*	*Remarks*
Automobile (kg/car)	Gasoline vehicle	15.0	Data is obtained from Reference [2]. Assume that a truck & bus uses 4 times copper that is contained in a gasoline vehicle.
	Diesel vehicle	15.0	
	Hybrid electric vehicle	28.9	
	Plug-in hybrid vehicle	41.6	
	Electric vehicle	91.6	
	Fuel cell vehicle	15.0	
	Truck & Bus	60.0	
Wind power generator (t/GW)		578	Data is obtained from Reference [11].
Solar panel (CIGS) (t/GW)		15.0	

Details of cumulative copper consumption divided into 5 sectors are shown in Fig. 4. In transportation equipment (including automotive sector), the cumulative copper consumption in BLUE Map scenario is 288 million tons and in Baseline scenario is 221 million tons. The difference of copper consumption in this sector results from the difference of the diffusion of EVs and PHEVs between Baseline and BLUE Map scenarios. The annual copper consumption in automotive sector is presented in Fig. 5. Fig. 5 illustrates that in BLUE Map scenario EVs and PHEVs require 390 thousand tons and 280 thousand tons, respectively. Consequently, in 2050, BLUE Map scenario consumes 1.6 times more copper than Baseline scenario. By comparing the annual consumptions in 2009, Baseline scenario will consume more than 2.6 times in 2050 due to dissemination of trucks, buses and gasoline vehicles.

The difference in electric & electric equipment comes from introducing more amount of clean power generator in BLUE Map scenario than Baseline scenario (see Table 2). The cumulative copper demand in this sector is 283 million tons in BLUE Map scenario and 276 million tons in Baseline scenario. This indicates that the amount of copper consumed by clean power generators (*i.e.*, solar and wind power generator) is minor relative to automobiles.

Fig. 5: Annual copper consumption in automotive sector

5 DISCUSSION

5.1 Risk of depletion

This paper proposed two approaches to estimate copper demand based on the long-term energy scenario. As shown in Fig. 3, the value of RDRB calculated by the macro approach will reach 168% at 2050 in both scenario because of economic and population growth, mainly in developing countries. This indicates that copper will be depleted by 2050 based on the assumption of ETP 2010.

According to the result from the micro approach, deployment of automobiles and clean energy generators made RDRB (2050) from 91 to 98%. That means diffusion of these products does not make the scenarios unfeasible, meaning the impact of introducing these products is minor. On the other hand, electric & electronic equipment, building construction and transportation equipment, which are called basic infrastructure, are expected to be dominant sectors to copper demand. These sectors in developing countries may require much more amount of copper to make facilities in accordance with economic and population growth. Estimating increasing consumption of copper from these infrastructure-related sectors is one of our future issues.

5.2 Uncertainties in estimation

There are some uncertainties in our estimation of copper demand as described below.

Substitution for copper

With the technical improvement in manufacturing, copper can be replaced with alternative materials. For instance, aluminum is expected to be substituted for copper in power cables, electrical equipment, and automobile radiators [3]. Additionally, many materials (*e.g.*, plastics in water pipe, drain pipe) also have possibility of substituting for copper [3]. Gathering information of possibility of substitutions for copper is necessary for further estimation of copper demand.

Recycling

Recycling is a key measure to conserve mineral resources. Copper is recycled around 16% in the world [7][8] and will be improved with, *e.g.*, technological improvement. In order to examine effect of recycling, it is necessary to construct a copper demand-supply model that enables to analyze life expectancy of copper-used products and amount of copper available from these products.

Technical innovation

Reserve base may change its amount by the invention of new mining technologies. In fact, the value of reserve base has been increasing. Reserve base is 10 billion tons in 2009 but was 650 million tons in 2000 [3]. Thus, we should continuously pay attention to technical matters and resource information for more accurate estimation of copper demand.

6 CONCLUDION

This paper analyzed the copper demand and supply to assess the risk of copper depletion based on existing sustainability scenarios. For the sake of estimation of copper demand, we proposed two approaches (*i.e.*, macro and micro approaches). The macro approach uses GDP/capita and population for estimation, while the micro approach employs the number of products that disseminate in the scenarios.

As a case study, we examined a long-term energy scenario called ETP 2010. The result by the macro approach revealed that ETP 2010 is unfeasible because of the depletion risk of copper due to the demand increase in developing countries. On the other hand, the result by the micro approach indicated that the diffusion of low carbon technologies, such as EV and PV, is not a crucial factor to copper depletion.

Future works include assessing the effect of copper recycling for improvement of estimation. In addition, we will continue to obtain mineral resource and technical information and build a copper demand-supply model for improving the accuracy of the copper demand estimation.

Design for Resource Efficiency

Matthias Finkbeiner[1], Laura Schneider[1], Markus Berger[1]
[1] Chair of Sustainable Engineering, Technische Universitaet Berlin, Germany

Abstract

There are already several approaches for Design for Environment or Design for Recycling and recently also the topic of resource efficiency received increasing interest. While procedurally existing ecodesign concepts might be also applicable for Design for Resource Efficiency, the main issue is to define relevant yet practicable indicators to measure resource efficiency. Depending on the definition, it can comprise raw material consumption only or the consumption and pollution of natural resources. Consequently, there is a variety of indicators available. However, resources are not only an environmental concern. Raw material availability is a critical issue for many industrial sectors which finally leads to a new area of protection, the economic material availability. Therefore, amongst others, new characterization factors are proposed by taking into account anthropogenic material stocks in addition to the lithospheric stocks.

1 INTRODUCTION

The integration of environmental aspects in product design and development has been recognized as an important strategy towards sustainable production and consumption. There are already several approaches for Design for Environment (DfE) or Design for Recycling (DfR), but recently the topic of resource efficiency received increasing attention. While procedurally existing ecodesign concepts might be also applicable for Design for Resource Efficiency (DfRE), the main issue is to define relevant yet practicable indicators to measure resource efficiency.

Even though the necessity of a sustainable use of natural resources is widely accepted, there is neither consensus on how "resource use" is clearly defined nor how it should be measured. Depending on the definition, it can comprise raw material consumption only or the consumption and pollution of natural resources. Consequently, there is a variety of indicators available.

This paper summarizes some relevant findings with regard to current resource efficiency indicators (see section 2), a new indicator to measure natural resource availability from an environmental point of view (section 3), additional criteria for an economic area of protection with regard to resources (section 4) and the potential to implement these into a DfRE-approach (section 5).

2 INDICATORS MEASURING RESOURCE USE

This section summarizes previous work of Berger & Finkbeiner with regard to indicators measuring resource use [1]. For deriving indicators the first challenge is to select an appropriate definition of resources. In a conventional sense, a resource is defined as "A concentration of naturally occurring solid, liquid, or gaseous material in or on the earth's crust in such form and amount that economic extraction of a commodity from the concentration is currently or potentially feasible" [2]. Based on this definition, physical indexes like mass and material input per service unit [3] or impact assessment indicators such as abiotic depletion potential [4] could be used to quantify resource use. Another resource definition has been introduced in the "Thematic Strategy on the sustainable use of natural resources" [5], which defines resources as "raw materials such as minerals, biomass and biological resources; environmental media such as air, water and soil; flow resources such as wind, geothermal, tidal and solar energy; and space (land area)." Accordingly, indicators measuring the pollution of natural resources like acidification, global warming, or ecotoxicity potentials [4] should be consulted in order to quantify resource efficiency.

For a number of different indicators results of 100 materials from the GaBi and ecoinvent databases were compiled using the GaBi 4.3 software [6]. The results obtained by different resource- and emission-oriented as well as single-score indicators were compared by means of linear regressions analysis to check for potential dependencies between indicators. The analyses revealed large differences regarding the correlations between indicators. While no significant correlations were found between emission oriented indexes (R^2=0.40–0.62), strong linear regressions were identified between indicators assessing raw material consumption (R^2=0.65–0.98). Therefore, the number of indexes can be reduced when defining resource use in a conventional sense. This phenomenon can be explained by the facts that all indicator results are dominated by the consumption of fossil fuels and that characterization models of these correlating indexes rely on net calorific values when computing characterization factors for fossil energy carriers.

When addressing resource consumption in life cycle assessment (LCA), current characterisation models for

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_22, © Springer Science+Business Media Dordrecht 2012

depletion of abiotic resources provide characterisation factors based on (surplus) energy, exergy, or extraction–reserve ratios. However, all indicators presently available share a shortcoming as they neglect the fact that large amounts of raw materials can be stored in material cycles within the technosphere. These "anthropogenic stocks" represent a significant source and can change the material availability significantly. Therefore, the anthropogenic stock extended abiotic depletion potential (AADP) [7] as a new parameterisation to model the depletion of abiotic resources was developed and is introduced in the next section.

3 THE ANTHROPOGENIC STOCK EXTENDED ABIOTIC DEPLETION POTENTIAL (AADP)

This section summarizes previous work of Schneider et al. which introduced the anthropogenic stock extended abiotic depletion potential (AADP) [7]. Gerst and Graedel [8] pointed out that the continued increase in the use of metals over the twentieth century has led to the phenomenon of a substantial shift in metal stocks from the lithosphere to the anthroposphere. As this stock will become available in the future for recycling and reuse, the accumulated stocks in society have to be acknowledged when assessing the future resource availability or the depletion potential of a material. As resources are depleted only when they leave the economy in a form that functionality can no longer be restored [9], these "anthropogenic stocks" represent a significant source and can change raw material availability significantly [10]. Thus the aim of the work of Schneider et al. was to introduce new characterisation factors, the anthropogenic stock extended abiotic depletion potentials (AADP), for the impact category depletion of abiotic resources. With these new characterisation factors, resource consumption is assessed by taking into account anthropogenic material stocks in addition to the lithospheric stocks to reflect the scarcity of resources more realistically. To include the anthropogenic stock into the assessment of resource depletion, data from material flow analyses (MFA) can be used [10].

The characterisation model is based on the ADP of Guinée et al. [4] but uses resources instead of ultimate reserves and adds the anthropogenic stock :

$$\text{AADP}_{\text{i,resources}} = \frac{\text{extraction rate i}}{(\text{resources i} + \text{anthropogenic stock i})^2} \times \frac{(\text{resources antimony} + \text{anthropogenic stock antimony})^2}{\text{extraction rate antimony}}$$

It was shown for a set of ten different metals that this new characterisation model leads to different characterisation factors. Even though this new characterisation model still mainly addresses an environmental area of protection, the choice of resources instead of ultimate reserves already addresses the interface to the economic dimension of resources. However, to reflect the economic scarcity of resources adequately requires the inclusion of even further aspects. An example for such an approach is introduced in the following section.

4 THE ECONOMIC MATERIAL AVAILABILITY AS A NEW AREA OF PROTECTION

This section summarizes previous work of Schneider et al. which introduced a method to address material availability as new area of protection [11]. Several geological and economic criteria are identified and selected according to their potential and relevance for quantifying economic material availability. These indicators are intended to put material requirements in perspective of availability, capacity constraints and demand. Different options for assessing these indicators are modelled and tested with regard to their usefulness and applicability.

The analysis is also based on recently published reports by the committee on critical mineral impacts on the US economy [12] and the Ad-hoc working group of the European Commission [13] that have identified several risks to supply. Similar indicators have also been assessed and used by Rosenau-Tornow et al. [14].

Several criteria were identified and selected according to their potential and relevance for quantifying economic resource availability:

- ❖ Recycling rate
  → recycled content of a material
- ❖ Reserve-to-production ratio
  → geological availability
  (based on current production technologies)
- ❖ Country concentration
  → reserve concentration to certain countries
- ❖ Company concentration
  → concentration of production/
  extraction activity to certain companies
- ❖ Political stability
  → stability and safety associated with a country
- ❖ Demand growth
  → assumed increase of demand in future

In order to illustrate the relevance of the new area of protection and the corresponding indicators, a comprehensive case study was accomplished. The life cycle inventory of a product of the automotive industry was assessed by means of the newly developed economic material availability indicators. The results were evaluated and compared to results obtained by means of the conventional abiotic depletion potential. However, no direct comparison is possible, as these results are based on different methodologies. For that reason, a significance analysis was used to show how individual materials contribute to the overall results and, beyond that, to illustrate the effect when taking into account other aspects beyond geological availability. In this comparison special focus is put on the contribution of fossil energy consumption which dominates the results of conventional impact categories by usually more than 95 % [1].

By introducing a new area of protection and in providing a set of new characterization factors denoting economic material availability, the proposed method expands life cycle assessment practice towards life cycle sustainability assessment and will promote a more comprehensive assessment of resource use and availability.

5 IMPLEMENTATION OF A DFRE-APPROACH

In this section, it will be highlighted how the resource efficiency indicators discussed above could be implemented into product design and development.

5.1 DfE-Approaches

A general outline of integrating environmental aspects into product design and development can be found in ISO TR 14062 [15]. According to Finkbeiner et al. [16] the environmental burden caused by a product is largely determined in the early development phase. Later corrections to product design can only be effected at high expense. The sooner design for environment is integrated into the development process; the greater the benefit will be in terms of minimizing environmental load and costs. This means 'building' environmental protection into the products from the very beginning. Ensuring this is the task of DfE. The goal is objective and measurable improvement of environmental compatibility and, simultaneously, compliance with the demands of more and more customers who consider environmental aspects like the reduction of fuel consumption and emissions or the use of environmentally acceptable materials.

As an example, the DfE concept at Mercedes-Benz implements a procedure based on simultaneous engineering comprising three main elements [16]:

1. A methodological procedure which allows integration of environmental targets and measures into the Mercedes-Benz Product Development System. This procedure defines interfaces with development phases and is used as a formalized PDCA cycle (Plan, Do, Check, Act).
2. Tools and databases to assist the DfE procedure in simulating and evaluating the environmental performance of future vehicles or parts.
3. An organizational structure that formalizes the integration of DfE into the development process

5.2 DfR-Approaches

Design for recycling (DfR) has a long tradition and was also driven by legal demands. It is – however – only one part of a more comprehensive DfE approach and often the DfR part does not address the most significant environmental interventions of a product. It can be defined according to the Danish environmental protection agency (EPA) Eco Design Guide [17] as a method that implies the following requirements of a product:

- easy to dismantle,
- easy to obtain 'clean' material-fractions, that can be recycled,
- easy to remove parts/ components, that must be treated separately,
- use as few different materials as possible,
- mark the materials/polymers in order to sort them correct and
- avoid surface treatment in order to keep the materials 'clean'."

From the perspective of life cycle based sustainability assessment [18] all these DfR-approaches are not necessarily sustainable, because they only look at the “output” side of a product and try to make it easy to deal with the waste at end of life. From a sustainability perspective, it is necessary to look at the “input” side, i.e. how much of these materials actually replace virgin materials. Sometimes recycling increases overall environmental burdens and resource demands. This is a reason, why DfRE is more efficient and effective than DfR.

5.3 DfRE-Approach

Rather than a traditional DfR-approach, it is proposed here to use the concept of Design-for-Resource Efficiency (DfRE). DfRE is built on the general features of ISO TR 14062 and the three DfE-elements described in section 5.1. Comprehensive resource efficiency indicators as outlined in the sections 3 and 4 should be used as performance characteristics of the alternatives in the product development process. While DfR can help to implement some recycling concepts that have been recognized as sustainable, DfR is not useful as an assessment approach. For the resource oriented assessment of products, DfRE-indicators are a more meaningful choice.

Open Manufacturing for Value Creation Cycles

Steffen Heyer (1)[1], Guenther Seliger (2)[1]

[1] Institute for Machine Tools and Factory Management, Technische Universität Berlin, Berlin, Germany

Abstract

Regaining components and materials from used products can cope with the challenge of shrinking resource availability with growing global demands for useful physical artifacts. Value creation cycles constituting consecutive multiple phases of usage and remanufacturing enable for increased use productivity of resources. They can be stimulated in entrepreneurial initiatives with global reference by creative approaches of sustainable engineering. Setting up knowledge communities about successful experiences on sustainable open manufacturing creates innovative commons to exploit globally available knowledge in local application. A model of value creation commons instantiated in competitive product and material cycles is presented and illustrated by examples of implementation.

Keywords:

Recycling, material flow, commons, additive processes

1 INTRODUCTION

About 40 years ago, the Club of Rom introduced the issue of limited resources in growing markets. Still then, the situation did not improve and no generally accepted solution found.[1] However, to achieve a reasonably demanded sustainability on our globe, non-renewable resources must not be disposed anymore but regained in product and material cycles. Legislations for recycling of products are helpful but breakthroughs can be expected if dynamics of competition and cooperation in globalized markets are utilized by innovative technologies to cope with the challenge.[2]

Combining recycling and manufacturing in a consolidated planning approach enables demand driven material cycles rather than fulfillment of laws and regulations. The necessary knowledge base for such planning task about recycling, manufacturing, available waste and demanded materials is difficult to establish in dynamic markets. Different stakeholders like end-user, product designer, manufacturers and material broker may contribute with their individual insight.

In this paper, the concept of value creation cycles as integrated planning-model for manufacturing and recycling processes with focus on materials is presented. This model is translated into an open manufacturing architecture as collaboration platform for entrepreneurial initiatives. With knowledge about additive processes and upstream recycling, potentials of the model for local value creation cycle are shown and a possible use cases be presented.

2 AVAILABILITY OF NATURAL RESOURCES

As the earth can be understood as clothed system, non-renewable materials and renewable materials are limited. The geological limit reflects the total amount of so-called primary raw materials on earth like for iron with 29% of the earth mass. Not all 29% iron can be economically excavated with today's technology. Accessible natural reserves are predicted to last in case of chrome 15 years, copper 34 years and iron ore 69 years, taking current annual excavation rate and technologically accessible material into account [3]. The time of depletion is pushed into the future by technological innovation and investments in new mines. Most mines last decades and in order to gain venture capital, geological assessments are used to prove the existence of natural reserves. These reserves normally last about the payout time of a mine. Newly revealed natural reserves are added to the global amount of accessible material. For materials like iron ore or cupper, mining capacity can be increased by starting new excavation sites. Capacity for so-called couple materials are more difficult to increase. For example tellurium and indium are by-products of copper or lead excavation. Capacity increase mainly happens do to capacity increase of the primary materials. Beside technical or financial limits, geopolitical ambitions limit the global accessibility of materials. Most recent example is China, producing 97% of all rare earth elements world-wide. Metals such as neodymium or scandium, particularly important in high-tech industry, belong to this group. To support local economy, China continuously reduces its export – in 2010 by 40%. Besides countries, few companies like Vale and BHP Billiton from Brazil as well as Rio Tinto from Australia became monopolies and influence the structure of the global material market.

To increase availability, materials can be gained out of used goods as so-called secondary raw materials. This approach is limited too due to limited availability of used goods and the adequate return rate. In the European Union the recycling rates are e.g. for aluminum 32% and for copper 76% [4]. In case of aluminum, production of secondary raw material uses 20 times less energy than for primary raw material.

3 VALUE CREATION IN CYCLES

Products and their manufacturing systems are traditionally reflected in their respective life cycles. In literature, the following basic concept of life cycles can be found [5]:

- **Flow oriented** life cycle phases reflect the flow of products and materials, oriented to their supply chain and chronological progress, like resource extraction, product development and manufacturing. The concepts vary between cradle-to-grave and cradle-to-cradle.
- **Condition oriented** life cycles demonstrating the dynamics of different systems by showing the development of certain characteristics like growth, maturity, saturation and decline of products.
- **Integrated** life cycles combine different life cycle phases with relevant characteristics, for example sales numbers, turnover, costs or ecological impact in different phases.

The different concepts are intended to describe different phenomena of product-market relations. As flow oriented life cycle concepts give an overview of theoretical end-of-life options like material recycling, remanufacturing or reuse and their related material flows. However, the number of particular products is rather low where material or components are used to create the same product once more or even a similar kind. In practice, secondary material follows a similar direction as primary material and goes into production, at location where needed and in required amount and quality. To reflect this behavior, the concept of value creation cycles was developed. Starting with recycling as the material source and ending with useful artifacts. Applying value creation cycles means to enable demand driven recycling. Not only are products produced on demand but used products should be recycled in order to substitute primary by secondary raw material for new products.

As depicted in Fig. 1, the concept of value creation cycles consists for a life cycle *n* of usage phase, production phase and recycling phase as well as value creation and product engineering. The use phase represents the final artifact, whether it is a product or belongs to a service/PSS. In the production phase, artifacts are created by manufacturing processes. In the recycling phase, products are transformed into materials or parts of new products. As the production phase proceeds, undefined material substantiates into specified artifacts. The phase of product engineering contains all the activities of product designing, satisfying customer demands or to create new markets with innovative products and services. Engineering of value creation contains all activities of strategic planning and operative scheduling of manufacturing and recycling processes. [6]

Number of parts in modern products with their countless parts, used materials, available recycling and manufacturing processes, and equipment capacities make the engineering process of value creation heavily depended on the knowledge base. Such knowledge base is difficult and inefficient to be established by a single person or company. Utilizing the combined power of many, contributing with their individual knowledge, offer a promising chance to establish such required knowledge base.

4 OPENNESS IN MANUFACTURING

Conditions and means of value creation changed in time regarding required qualification, used technology, locality and involved stakeholders. Around the 1970s-1980s, one-

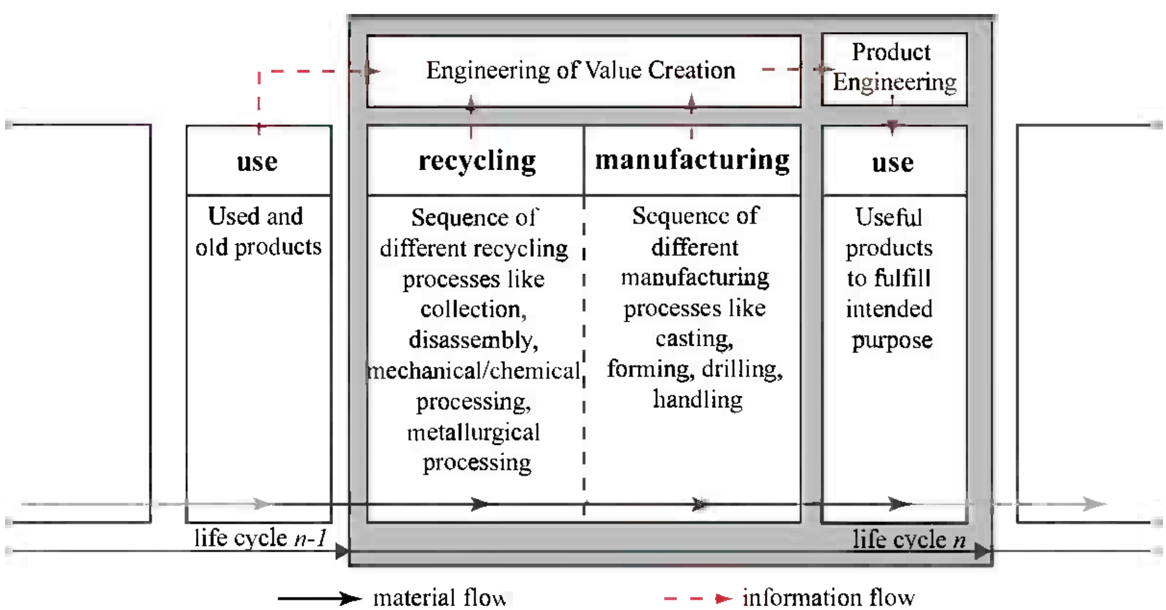

Fig. 1: Value creation cycles – model

way communication of producer aimed to gain access to target predetermined groups of buyers. It evolved to two-way communication, to increase market insight and establish a relationship of producers and customers. However, customers were seen as passive buyers with a predetermined role of consumption until the 1990s. Beyond 2000, customers were increasingly seen as co-creators in a joint value co-creation process [7], [8]. Customers as passive recipient of products change to prosumers, who actively consume and produce [9].

For intangible products like software, users were integrated in the design processes before since decades. In the 1980‘s, the Free Software Foundations was founded at the MIT [10]. Idea is to offer software that can be used, studied, and modified without restriction, copied and redistributed in modified or unmodified form. Software is handled as commons. Someone picks up and modified the software and later on shall return the improved version back to a common pool [11]. To indicate that free available software doesn’t mean free of cost, the open source initiative started in the 1990’s [12], adding licenses as legal frame for intellectual property rights to the existing commons approach.

4.1 Open design and open innovation

Initiatives including some degree of openness aim to increase of development capacity by outsourcing design tasks to an undefined generally large group of people in the form of an open call [13]. Variations like open design, open innovation and crowed-sourcing in general deal with intangible products, e.g. software, product designs or movie plots. These products do not require special equipment or a centralized creation as they can be shared via internet. For intangible products like the open source software Linux and its derivatives represented in 2008 a business volume of about $36 billion/a [11].

When design, manufacturing and use of tangible and intangible products, merge together, manufacturer are not able to control every detail anymore. Customer creativity, self-organization, individual and flexible adaptation as well as extensive knowledge transfer create a new concept of value creation, called open manufacturing [14]. At the Massachusetts Institute of Technology, so called Fab Lab (fabrication laboratory) were first introduced. In these Fab Labs, customers are enabled to produce self-designed products by operating small scale and simple machine tools [15]. In July 2010 were 45 labs in 16 countries operated by independent initiatives [16].

However, equipment is generally fixed to one place and shared by different customers, whereas the open source appropriate technology (OSAT) aims provide local communities with easily and economically equipment, made from readily available resources [17].

5 MODEL FOR VALUE CREATION COMMONS

Possibilities to use recycling output as feedstock for manufacturing depends heavily on available (recycling) and required (manufacturing) material. Information about the waste-to-product transformation process has to be adjusted for the individual instance and requires a broad knowledge base. By setting up knowledge communities with innovative commons, globally available knowledge may be used in local application. By utilizing the innovative force of such knowledge communities – globally distributed persons – requires the problem to be structured and until a certain point standardized. The already existing examples of open manufacturing were analyzed in order to develop an information model for value creation commons.

Idea, concepts, descriptions, etc. about a single process step or process chains do not compete for marked share but as similar processes occur, competition can and should be expected. This is comparable to horizontal and vertical integration in networks, where producing enterprises are confronted with an increasing complexity and a growing number of products and variants. In industry, companies focus more and more on their core competencies in order to survive in global competition, increasingly divide the value creation among numerous partners and organize themselves for global value creation in networks [2]. From top-down perspective, value creation can be considered as a network consisting of horizontal and vertical integrated modules and from a bottom-up perspective modules can contribute to respective networks. The dynamic shift between module and network perspective may allow revealing potentials for increasing material and energy efficiency and effectiveness. Value creation modules are characterized by a set of the value creation factors: Product (what? how many? which quality?), process (how?), equipment (whereby?), organization (when? where? What order?), and human (who?).

5.1 Character of communities contributions

Community driven initiatives do not follow traditional ways of industry collaboration where required input, expected output and intended benefit for each stakeholder have to be defined in the beginning. Why somebody is contributing in what kind of form have to consider when designing calue creation commons.

Why contributing?

Why people get involved in activities where their contribution does not directly pay off in a monetary way unlike most traditional business concepts? In open design, marketing and similar areas, the following forms of motivation can be observed:

- **Pragmatically**: To learn skills by doing that may be become relevant in their professional work or career and get-in-touch with persons that could be helpful to boost their careers.

- **Social**: To get recognition in peer groups and in improve personal feeling of self-worth, by helping others as an altruistic attitude; to establish community identification and being part or forming an lifestyle movement.
- **Hedonistic**: To establish an joint consumer empowerment or fight a mutual enemy (company); being some kind of brand zeal and may get access to certain privileges like product test; to live out creativity and uses self-expression

Networks like Facebook or twitter address primarily social forms of motivation, whereas open manufacturing and its element of tangibility offer the chance to address the other two forms as well.

Who contributes?

In community initiatives like open source software development, the 1-9-90 rule can be observed [11]. 1% of the community can be considered as very committed core individuals, driving large amounts of the activity, creating new content and provide infrastructure to a certain degree. 9% of the community sometimes modify content, but rarely create content from scratch. 90% of the community represent the “audience”, just reading or observing without active contribution.

What kind of contribution?

Knowledge contributions like experiences, ideas, concepts, etc. about physical artifacts and liked processes can be related to [19]:

- **Functionality**: adding, improving, narrowing or broaden the field of application
- **Use**: providing manuals or tutorials to increased ease of use and refined operation techniques; improved interoperability with other artifacts
- **Cost**: Lowering material and operation cost by increased efficiency and effectiveness
- **Components**: Substitution of components, which e.g. may be easier to acquire
- **Design**: Personalizing general appearance by varying design features
- **Build**: Improved description of assembly procedure and decrease production equipment requirements
- **IT**: Integration by creating new IT connections and interfaces and improved design architecture.

Beside the actual content, suggestions and ideas regarding improvements of the knowledge sharing infrastructure can be expected.

5.2 Contributions for value creation commons

The combination of value creation modules as steps in a value creation chain cannot be seen as permanent state rather than constantly adjust to meet more profitable configurations. Generic ways of reconfiguration when dealing with process chains from a perspective of companies are [20]:

- **Focusing:** Focusing on specific processes, improving these, traditionally couple with reducing the overall value added. (F)
- **Integrating:** Creation of horizontally substituting or vertically completing connections (P,S)
- **Coordinating:** Dissolving process steps into several other, e.g. to enable outsourcing of processes steps (M,P)
- **Condensing:** Integrating several process steps into one single process (M,P)
- **Expanding:** Adding processes into existing process chains (M,P)
- **Reconstructing:** Redesigning existing process chains (M,P)

As indicated in brackets above, value creation modules including their factors and the horizontal and vertical connections are modified or added in the different ways. In the sense of the above presented model, graph and its elements can be modified regarding:

- **Factors** (F): Specifying or correcting of different factors (Focusing)
- **Modules** (M): Copying/mirroring in order to instantiate modules including its factors for different application (Focusing)
- **Connections**(P,S): Adding, rearranging or removing connections of process chain and synergies between different modules (Integrating)
- **Modules and connections** (M,P): Adding connection and modules for example to create parallel processes chains of introduce new application fields (Coordinating, Condensing, Expanding, Reconstructing)

5.3 Usefulness of value creation commons

Including new ideas in value creation commons can expected to be done by ca. 10% of the community. The benefit for the other 90%, more or less consuming the knowledge should work in two directions.

From a bottom-up perspective, for single value creation modules, different process chains should be able to be identified where a promising and competitive integration could be possible. For a given stage n (input) all possible stages $n+1$ (output) or for a stage n (output) all required stages n-1 (input) should be obtainable.

From a top-down perspective, to manufacture a specific artifact, all possible process chains should be obtainable, including the respective input material and necessary equipment. Characteristics of alternative process chains allow narrowing down possibilities to identify solutions, appropriate for individual use cases.

5.4 Design of value creation commons

To model the relations between different value creation modules in networks, a multigraph with two layers of connections is used. Frist layer consists of directed connections, representing the consecutive process steps to transform input material into output material like a vertical integration in value chains. Second layer consists of undirected connections, representing similarities regarding process, product or material like a horizontal integration in value chains. The mathematic description of the network as value creation commons, consisting of modules is:

- $VCC = (M, P, S, f_1, f_2)$ .. Value creation commons as graph

With (knots)

- M .. Value creation Modules with
  $M = \{m_1, . . . , m_o\}$
  and connections (edges)
- P .. with f_{n-1}:$P \rightarrow M$ and f_n:$P \rightarrow M$
  Process flow (directed) where
  $P = \{p_1, \ldots , p_i\}$
  $f_{n-1}, f_n \in M$ .. start and end between two points
- S .. with f_{n-1}, f_n:$S \rightarrow M$
  Synergies between two points (undirected) where
  $S = \{s_1, \ldots , s_j\}$

with

- $M \cap P = \varnothing$ and $M \cap S = \varnothing$ and
  $o, o, j, n \in \mathbb{N}$

For two points, the connection is depicted in Fig. 2.

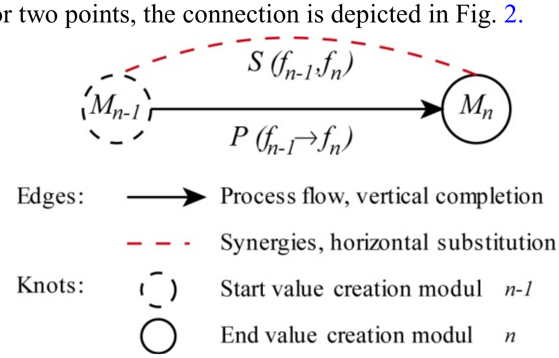

Fig. 2: Graph representation of value creation commons

6 CASE STUDY FOR LOCAL VALUE CREATION CYCLES

Process chains of daily- life and consumer goods are due to the number of parts and required manufacturing processes difficult to entirely grasp. Short process chains can be achieved by reducing the material diversity, applying additive processes to achieve near net shapes products and organize the processes local to avoid logistics. To demonstrate the idea and mechanics of the presented model, a use case for local manufacturing and recycling with few process steps are described in the following.

6.1 Case study outline

Destroyed roads or missing water and energy supply are not uncommon in emerging countries like Sierra Leone, postwar areas like Somalia or regions of natural catastrophes like Haiti. Water and food may be provided by non-governmental organizations (NGOs), utilizing available local logistics capacities. Supply of tools and equipment to improve conditions of living and working, is rather limited. Plastics waste like PET bottles, plastic bags or glass as leftover from food and water supply could be used as material source to locally realize simple tools, equipment and items of everyday living. Dependencies on external material supply could be reduced. It has to be expected that the qualification level regarding manufacturing is very low. Via Global System for Mobile (GSM) communications, product, process or equipment ideas may be shared, allowing locals to create a high variety of artifacts in the sense of self-sustaining help.

6.2 Process chain

Thermoplastics scrap is used as raw material to produce easy goods. In order to skip sorting, availability of pure material without contamination has been assumed. After shredding scrap, the plastic pellets are extruded to a thread as feedstock for 3D printers. Beside plastics, glass can expect to be available as well. For glass, the process chain consists of shredding glass to powder and laser sintering the powder to useful goods. Fig. 3 depicts the value creation modules for both process chains.

6.3 Physical realization and local integration

Following the process chain for plastics, shredding, extrusion and 3D printing was realized as small size facility. Due to local conditions regarding infrastructure – transport, energy supply –, qualification of local operators and social environment, equipment has to be inexpensive, modular, easy to use and easy to maintain. Solar panels or diesel engine serve as decentralized energy supply. GSM communication connects the decentralized facility to share schematics of manufactured products, operation descriptions of equipment and used materials from other users as well as gained experience. All information can be seen as commons pool. Producing items of everyday living for their own use and products for others, a positive impact in the sense of self-sustaining help can be expected.

7 SUMMARY AND OUTLOOK

Limited materials availability of non-/renewable materials affects modern manufacturing. Product and material recycling represent an alternative material source. However, recycling activities are rarely designed to meet required material demands. In the presented value creation simultaneously planned to realize situation specific recycling. Knowledge of numerous process-combinations

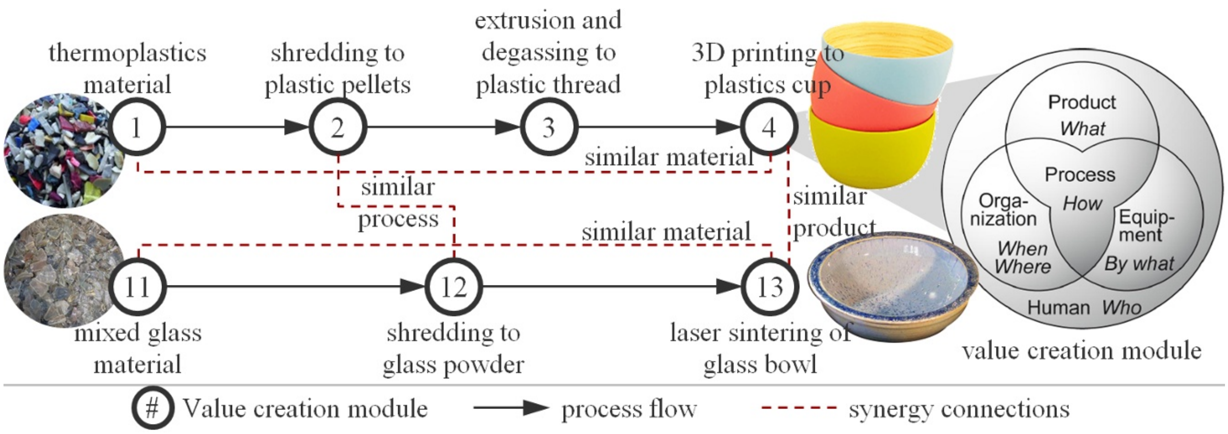

Fig. 3: Recycling and manufacturing with plastics and glass as simplified value creation commons

cycles, recycling and manufacturing processes are is hardly gained by individual planner. Transforming the concept of value creation cycles into a value creation commons allows a wide community to collaborate and utilize their joint knowledge. The shown model of value creation commons is described and instantiated using additive processes with upstream recycling. In future work, an easy to use design tool for value creation commons have to be developed, to ease contribution as much as possible.

Electromagnetic Field Analysis on the Behavior of Selective Breakage at Phase Boundary in Electrical Disintegration

Rintaro Hayashi[1], Takehiro Urabe[1] and Shuji Owada[2]

[1] Department of Earth, Resources and Environmental Engineering, Graduate School of Creative Science and Engineering, Waseda University, Tokyo, Japan

[2] Faculty of Science and Engineering, Waseda University, Tokyo, Japan

Abstract

It is important in the comminution stage of waste treatment to liberate objective components from others for achieving the following compositional separation. However traditional (mechanical) comminution methods usually have problems of low selectivity of the breakage of phase boundary and low energy efficiency.

Electrical disintegration (ED) is one of the best communition technologies to break selectively at phase boundary and achieve good compositional liberation of the products. When high voltage pulse is applied in a flash to a composite particle, dielectric breakdown occurred preferentially at phase boundary, followed by sublimation of the boundary materials by Joule heat after electron avalanche, then, tensile stress becomes directly applied to phase boundary. In the process, good liberation could be obtained in relatively a large size range and energy required for the liberation becomes much lower than in the conventional comminution methods.

This paper aims to make clear the ED mechanism by combining electromagnetic simulation using finite element method and the experiments with synthetic particles which are composed of various mineral particles distributed in cement paste. In the simulation, charge density and Maxwell stress generated at phase boundary are calculated and compared with the liberation degree of ED products. It was found that high breakdown voltage is necessary for the samples of insulator minerals because only a small charge is accumulated at phase boundary but that high electrical charge is accumulated at phase boundary for insulator minerals at electrical breakdown. It was demonstrated that high electrical charge and Maxwell stress generated at phase boundary could be driving forces of preferential breakage at phase boundary, in other words, good compositional liberation in the ED

Electrical Disintegration, Comminution, Liberation, Electromagnetic Field Analysis

1 INTRODUCTION

Recovering useful components from waste is necessary with increasing various resources demands and the amount of waste generated. Therefore, the liberation of objective components from others in the waste is necessary as a pretreatment for achieving effective compositional separation, such as by energy saving physical separation, of the waste materials. Presently, most of solid wastes are communited with mechanical grinding and milling, but these methods have problems of over grinding to generate too fine particles and of much energy requirement, because few selective breakage at phase boundary is realized.

Electrical Disintegration (ED), in broader term, is a high voltage pulse communition which is classified in to two types. One is Electro-Hydraulic Disintegration (EHD) which is a shock wave comminution by applying high voltage in water. The other type is the Electrical disintegration (ED), in narrow term, which breaks materials in water from the inside by applying high voltage directy to them. ED is considered to be an energy saving method than EHD and can make better liberation, because tensile stress can be directly applied to the materials, especially at phase boundary. Hereafter, the ED described in the paper indicates the one in narrow term.

The mechansm of the ED was demonstrated by U.Andres [1] in which the ED process was classified into the following four stages.

1. Formative stage of current path: Electrically excited states are locally produced in the polarized dielectric when high voltage pulse is applied to a material.
2. Tree initiation of current path: Local field

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_24,

enhancement breaks intramolecular bonds, sublimates the solid by Joule heat and generates a pattern of thin (~1 μm) capillaries of current path.

3. Tree growth: The tree grows when capillaries develop in the direction from anode to cathode with supersonic velocity (10^6 m/s). In these capillary channels the energy of the pulse does not dissipate by heat condition, sound waves or fracturing solid during the propagation of channels. The small loss of energy takes place because of luminosity of channels.
4. Plasma expansion and electrical breakdown: In the return streamer the plasma channel expands rapidly. The temperature of plasma rises up to 45000 K, then, results in the complete electrical breakdown of solids.

Past researches in the ED made studies, for example, on the recovery of coal substance from impurity minerals [2] [3], and on the recovery of aggregates from wasted concrete [4], and so on [5] [6]. From the above results, ED is considered to achieve good liberation among compositional materials and contribute much as a pre-treatment of compositional separation in the field of waste treatment and mineral processing. However, the detailed mechanism of liberation has not been clarified yet [7] [8]. Therefore, this paper aimed to make clear the mechanism of selective breakage at phase boundary by using electromagnetic field analysis, in which relationship among the charge density accumulated at phase boudary, the Maxwell stress, and the liberation degree of ED products were analysed. Calculation was carried out by the finite element method (FEM) using free-software named "EMP3" developed by the Field Precision LLC.

2 EXPERIMENT

2.1 Samples

ED experiments were conducted using cement paste based synthetic samples in which mineral particles are dispersed. Mineral species were quartz, calcite, pyrite (from Yanahara and Spain), galena, cassiterite and rutile, as shown in Table 1.

Table 1: Electrical properties of the minerals and cement

Name of minerals	Composition	Relative permittivity	Conductivity
		-	S/m
Quartz	SiO_2	3.93	4.45×10^{-5}
Calcite	$CaCO_3$	7.66	4.28×10^{-5}
Pyrite (Yanahara)	Fe_2S	10.9	61.3
Pyrite(Spain)	Fe_2S	10.9	14.1
Galena	PbS	18	18.8
Cassiterite	SnO_2	23.7 [9]	1×10^{-4}～1000 [9]
Rutile	TiO_2	110 [9]	1×10^{-3}～1×10^{-2} [9]
Cement	-	26.8	1.54×10^{-2}

Minerals were communited and classified into the size range of 1.68 to 2.38 mm. The volume ratio of the mineral particles were set at 10 % in a sample lump, molded in 50 mm diameter and 100 mm height using a plastic tube. In the molding, the sample was rotated for one day for the mineral particles to be distributed uniformly in the lump, then, cured for 6 days. Finally, molded samples were cut in rectangular pieces of the size, 10×10×8 mm.

2.2 Equipment used

High-voltage generator, IVG-80G model, manufactured by the Pulse Electronic Engineering, Co., Ltd., was used in the ED experiments. Fig. 1 shows the conceptual diagram of the ED equipment.

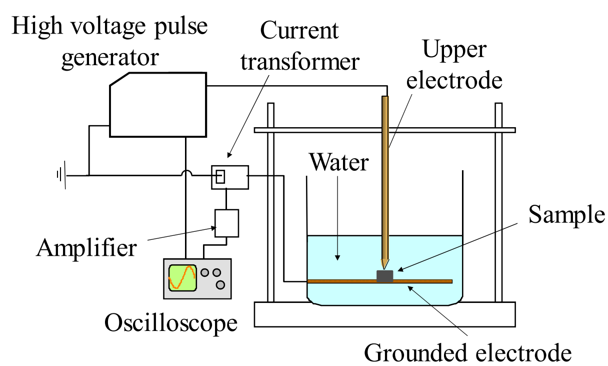

Fig. 1: Conceptual diagram of ED equipment

Table 2: High voltage pulse generator

Duration of wave front	μs	1.2
Duration of wave tale	μs	50
Nominal voltage	kV	80
Combined electrostatic capacity	μF	0.25
Maximum charge energy	J	800
Utilization ration	%	More than 80

2.3 Experimental Procedure

In the ED experiments, one piece of the sample was placed between the electrodes and high voltage was applied from 20, 24, 28 kV, ..., by the step of 4 kV, to the sample until the sample was broken from the top to bottom. The value of the maximum voltage divided by sample thickness, 10 mm, is difined as Dielectric Breakdown Strength ("DBS" in kV/m) of the sample.

After ED, particle size distribution of the broken sample was measured using the JIS standard sieves. Fig. 2 shows the size distribution of the ED products. Most of the samples tend to have similar size distribution.

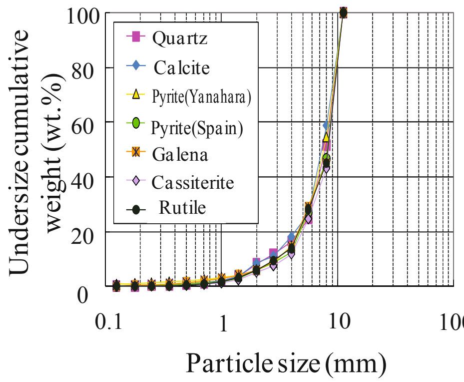

Fig. 2: Size distribution of the ED products with various mineral particles distributed in cement paste

2.4 Liberation

After the sieving, the liberation degree of mineral phase in each particle size range was measured. Liberation degree, L_B, is defined as the ratio of the amount of an objective component, B, which formed in free particles, X, to the total amount of the component, Y.

$$L_B = \frac{X}{Y} \qquad \ldots(1)$$

3 ELECTROMAGNETIC CALCULATION

3.1 Single Particle Model in Calculation

A simplified "Single Particle Model'' was created in three-dimensional meshes tool. Fig. 3 shows the diagram of this model in which one dielectric sphere mineral particle, 5 mm of diameter, is located in the center of cement paste. The size of cement paste was set at 10×10×10 mm, and of absorber was set at 10×10×1 mm.

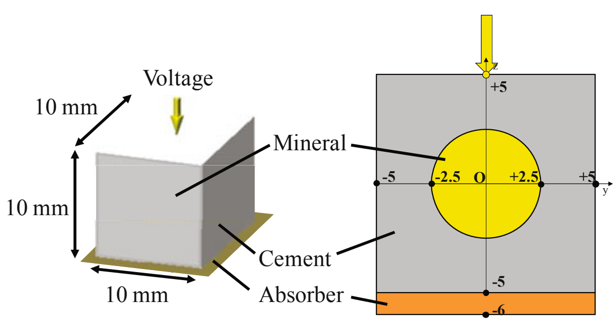

Fig. 3: Single particle model

3.2 Calculation

Unit fraction in the FEM was set at in a cubic of the size 0.1×0.1×0.1 mm. Electromagnetic field analysis begins with solving the following Maxwell equations.

$$\nabla \times E = -\frac{\partial(\mu H)}{\partial t} \qquad \ldots(2)$$

$$\nabla \times H = J + \frac{\partial(\varepsilon E)}{\partial t} \qquad \ldots(3)$$

$$\nabla \cdot (\varepsilon E) = \rho \qquad \ldots(4)$$

$$\nabla \cdot (\mu H) = 0 \qquad \ldots(5)$$

Here, E is electric field (V/m), H is magnetic field (A/m), J is current density (A/m), ε is dielectric constant (F/m), μ is magnetic permeability (H/m), ρ is space-charge density (C/m^3).

Driving terms in the Equ. (2) to (5) are ρ and J, and they are correlated through the equation of continuity in the following.

$$\frac{\partial \rho}{\partial t} + \nabla J = 0 \qquad \ldots(6)$$

In order to calculate the change in the E of each unit fraction as a function of time, the calculation involves the charge added to the system, in addition to the charge change in the system according to the Equ. (7).

$$J = J_0 + \sigma E \qquad \ldots(7)$$

Here, J_0 is the applied current density at t=0 and σ is electrical conductivity. The following two equations are introduced from the Equ. (2) to (7).

$$\oint E \cdot \mathrm{dl} = -\iint dA \frac{\partial}{\partial t}(\mu H \cdot \mathrm{n}) \qquad \ldots(8)$$

$$\oint H \cdot \mathrm{dl} = \iint dA\left[\frac{\partial}{\partial t}(\varepsilon E \cdot \mathrm{n}) + \mathrm{J_0} \cdot \mathrm{n} + \sigma \mathrm{E} \cdot \mathrm{n}\right] \qquad \ldots(9)$$

Step time was set at 10^{-14} s and the electrical properties of the materials adoppted the values shown in Table 1. Once J_0 is set at each unit fraction, H is obtained from Equ. (9), then, E is also obtained by substituting the H for Equ. (8). After these calculations are done in all the unit fractions at one step of time, the E value obtaiend is substituted for Equ. (9) at a next step in order to obtain the change in E as a funciton of time.

4 RESULTS AND DISCUSSION

4.1 "Dielectric Breakdown Strength" and electric charge at phase boundary

Fig. 4 shows the relationship between the maximum current density accumulated at phase boundary by applying high voltage and the "DBS". Applying voltage corresponds to the "DBS". The samples of highly insulating minerals, quartz and calcite, have a tendency to have high "DBSs", which indicates that a large amount of electric charge is accumulated at phase boundaries of these minerals until the breakdown.

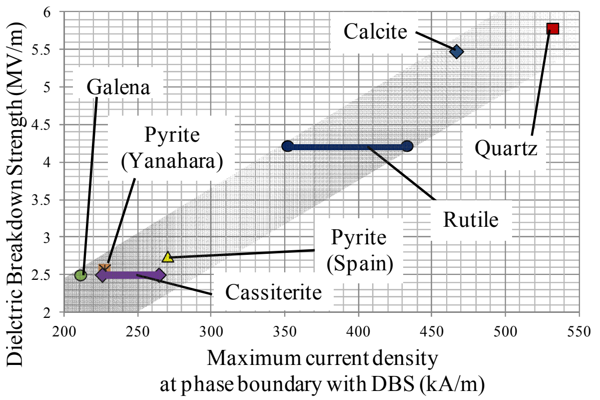

Fig. 4: Relationship between "DBS" and the maximum electric current density at phase boundary when applying the same voltage to the "DBS" of each sample

4.2 Liberation and electric charge at phase boundary

In the ED, liberation property of each sample must be changeable by the amount of electric charge accumulated at phase boundary. Fig. 5 shows the relationship between the maximum current density at phase boundary by the above calculation and the liberation degree measured for various ED products with different size ranges. This figure indicates that the higher electric charge accumulated at phase boundary, the higher liberation degree could be obtained in all size ranges and that the tendency is more obvious for the samples of higher "DBS". These facts would indicate that the sample materials in which insulating minerals, such as quartz and calcite, are dispersed need high voltage for the breakdown but that the ED products show a high liberation property.

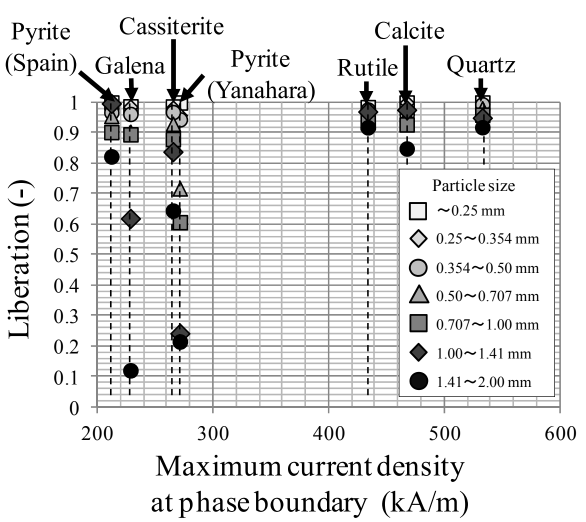

Fig. 5: Relationship between liberation degree and the maximum current density at phase boundary

4.3 Liberation and the Maxwell stress

The Maxwell stress, F_{Max}, is generated because of the difference of electric potential between the phases and is indicated as the following equation.

$$F_{\mathrm{Max}} = \frac{1}{2}\varepsilon_{\mathrm{in}} E_{\mathrm{in}\text{-}t}{}^{2} - \frac{1}{2}\varepsilon_{\mathrm{out}} E_{\mathrm{out}\text{-}t}{}^{2} + \frac{1}{2}\varepsilon_{\mathrm{out}} E_{\mathrm{out}\text{-}n}{}^{2} - \frac{1}{2}\varepsilon_{\mathrm{in}} E_{\mathrm{in}\text{-}n}{}^{2} \quad \ldots(10)$$

Here, E_{in} and E_{out} are electric fields in the inside and out materials, respectively in "Single Particle Model", and $\varepsilon_{\mathrm{in}}$ and $\varepsilon_{\mathrm{out}}$ are dielectric constants of inside and outside materials, suffix n indicates normal direction and t indicates tangential direction. Fig. 6 shows the relationship between the liberation degree of ED products and the maximum Maxwell stress at phase boundary.

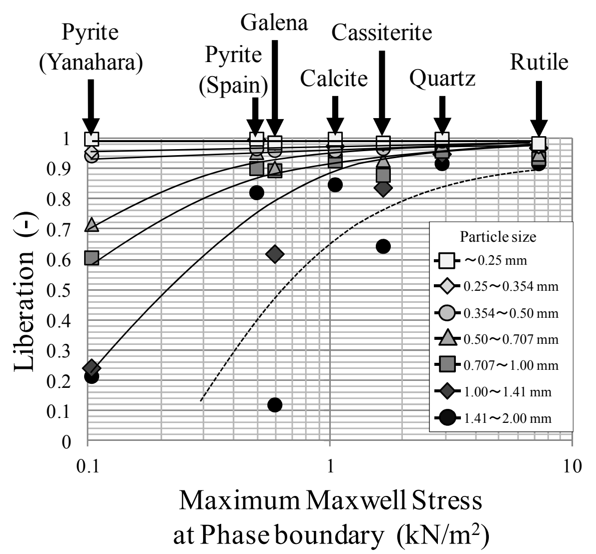

Fig. 6: Liberation degree and Maximum Maxwell stress at phase boundary

Higher liberation can be achieved by higher maximum Maxwell stress at phase boundary in each particle size. From the results, we can demonstrate that the Maxwell stress generated at phase boundary must become a driving force of the selective breakage at phase boundary and gives higher liberation products in the ED.

5 SUMMARY

This study aimed to clarify the mechanisms of selective breakage at phase boundary in the ED, by comparing the data of ED experiments with the current density and Maxwell stress accumulated at phase boundary that were calculated by FEM. Major contents are summarized in the followings.

1. The materials including highly insulating minerals have a tendency to have high "Dielectric Breakdown Strength", which indicates that a large amount of

electric charge can be accumulated at phase boundaries until breakdown, then, the ED products show a high liberation property.

2. In the ED, the electric charge and Maxwell stress induced at phase boundary could be driving forces of selective breakage at phase boundary and could produce the comminuted pieces of good liberation.

Exergy Analysis of CO_2 Heat Pump Water Heating Systems

Ryohei Yokoyama [1]

[1] Department of Mechanical Engineering, Osaka Prefecture University, Sakai, Osaka, Japan

Abstract

CO_2 heat pump water heating systems have been commercialized and widespread. It has become more and more important to enhance the system performance. In this paper, the performance of the systems is investigated from the exergy viewpoint. Exergy destructions results from the overall temperature drop due to heat loss from the tank surface and the temperature mixture due to heat conduction. A conventional system as well as a system revised by extracting water with middle temperatures from the middle of the storage tank are investigated. First, a numerical simulation is conducted to determine the hourly changes in the flow rates and states of the systems. Then, the exergy analysis is conducted based on the results obtained by the numerical simulation. The exergy destructions and efficiencies of the components are clarified quantitatively for both the systems.

Keywords:

heat pump, water heater, thermal storage, carbon dioxide, system performance, numerical simulation, exergy analysis

1 INTRODUCTION

Air-to-water heat pumps using CO_2 as a refrigerant have been developed. In addition, water heating systems each of which combines a CO_2 heat pump with a hot water storage tank have been commercialized and widespread. They are expected to contribute to energy saving in residential hot water supply [1, 2].

The performance of a CO_2 heat pump is affected only by instantaneous air, and inlet and outlet water temperatures. The technological development especially for compressors and heat exchangers has enhanced the coefficient of performance (COP) of CO_2 heat pumps. On the other hand, the performance of a water heating system is affected not only by instantaneous air and feed water temperatures but also by hourly changes in the heat pump operation, hot water demand, and their resultant temperature distribution in the storage tank. It has become more and more important to enhance the system performance.

It takes much time to conduct the performance analysis on water heating systems in consideration of the aforementioned items under various conditions by experiment, and it is expected that numerical simulation enables one to do it very efficiently. Some studies have been done for the performance analysis on water heating systems by numerical simulation [3, 4]. The author has conducted the performance analysis in consideration of hourly changes in the heat pump operation, hot water demand, and their resultant temperature distribution in the storage tank [5, 6].

In this paper, the performance of CO_2 heat pump water heating systems are investigated from the exergy viewpoint. The exergy analysis has been conducted on CO_2 heat pumps [7]. In this paper, the exergy analysis is focused especially on storage tanks by treating two systems. One is a conventional system with a standard storage tank, and the other is a revised one with a special storage tank. The hot water storage during a long time causes two types of exergy destructions, which result from the overall temperature drop due to heat loss from the tank surface and the temperature mixture due to heat conduction. In the conventional system, the latter type of exergy destruction reduces the COP and exergy efficiency of the CO_2 heat pump. On the other hand, in the revised system, the performance can be enhanced by extracting water with middle temperatures from the middle of the storage tank. This can reduce the temperature mixture due to heat conduction and its relevant exergy destruction. This can also increases the COP and exergy efficiency of the CO_2 heat pump.

First, a numerical simulation is conducted for both the conventional and revised systems to investigate the hourly changes in the flow rates and states of the systems. Then, the exergy analysis is conducted based on the results obtained by the numerical simulation. The exergy destructions and efficiencies of components are clarified quantitatively for both the systems.

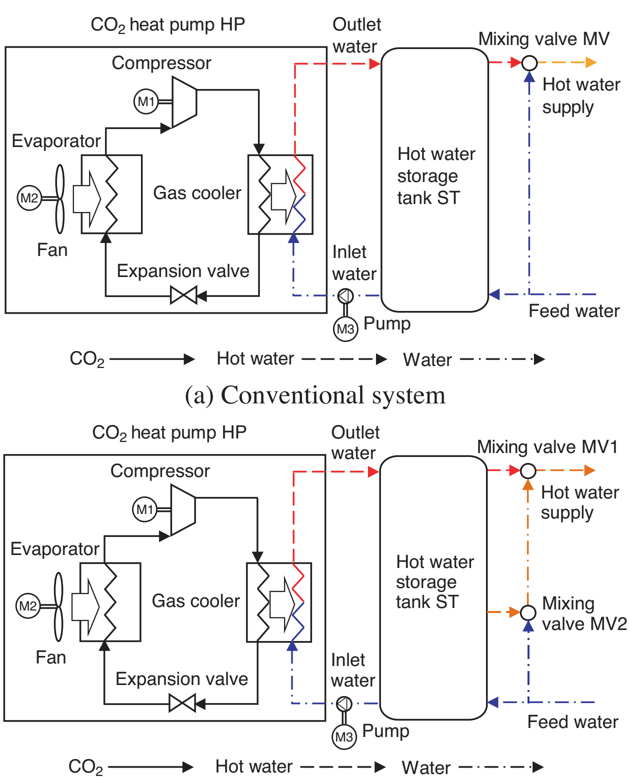
2 CO_2 HEAT PUMP WATER HEATING SYSTEMS

Figure 1 shows the configurations of the CO_2 heat pump water heating systems investigated in this paper. Each system is composed of a CO_2 heat pump and a hot water storage tank. The CO_2 heat pump is composed of a compressor, a gas cooler, an expansion valve, and an evaporator. The system is equipped with a fan, a pump, and motors M1 to M3 as auxiliary machinery. Here, inlet and outlet water is defined as water at the inlet and outlet of the gas cooler, respectively. The system heats water using the refrigeration cycle of the CO_2 heat pump, stores hot water in the storage tank, and supplies it to a tapping site.

Figure (a) corresponds to the conventional system with a standard storage tank. Hot water is extracted only from the top of the storage tank. Figure (b) corresponds to the revised system with a special storage tank. Hot water is extracted from both the top and middle of the storage tank depending on the temperature distribution in the storage tank. This system is used to enhance the performance by extracting hot water from the middle of the storage tank and reducing the part with middle temperatures which tends to expand due to heat conduction.

3 NUMERICAL SIMULATION

To conduct the exergy analysis, it is necessary to determine the hourly changes in the flow rates and states of the systems. Here, the flow rates and states at the periodically steady state with the period of a day are used for the exergy analysis. For this purpose, it is assumed that although the hot water demand changes hourly, its pattern does not change daily, and the periodically steady state is attained after several days, even if any initial state is given.



(a) Conventional system

(b) Revised system

Fig. 1: Configurations of CO_2 heat pump water heating systems

3.1 Simulation model

A simplified static model is adopted for the CO_2 heat pump [6, 8]: Although the CO_2 heat pump includes several components, they are not taken into account explicitly, and it is expressed by one model. The mass flow rates and temperatures of water at the inlet and outlet, COP, heat output, power consumption, and air temperature are adopted as basic variables whose values are to be determined. The mass and energy balance relationships as well as the energy input and output relationship are adopted as basic equations to be satisfied. The remaining equations to be considered are approximate functions of the power consumption and COP, and they are expressed in relation to the air, and inlet and outlet water temperatures.

A one-dimensional dynamic model is adopted for the storage tank [5, 6, 8]. To consider the one-dimensional vertical temperature distribution in the storage tank, it is vertically divided into many control volumes with the same volume, in each of which the water temperature is assumed to be constant. It is also assumed that the heat transfer occurs by water flow and heat conduction as well as heat loss from the tank surface. The mass flow rates and temperatures of water for the control volumes are adopted as basic variables whose values are to be determined. The mass and energy balance relationships for the control volumes are adopted as basic equations to be satisfied.

A static model is adopted for the mixing valves. The mass flow rates and temperatures of water at the inlets and outlet are considered as basic variables, and the mass and energy balance relationships are considered as basic equations to be satisfied.

At the connection points among the CO_2 heat pump, storage tank, and mixing valves, connection conditions are taken into account to equalize the values of the corresponding variables. The outlet water temperature is given as a control condition. The feed water temperature as well as the mass flow rate and temperature of hot water to the tapping site are given as boundary conditions. The air temperature is given as an ambient condition.

As for the concrete formulation of the simulation model, refer to reference [6]. The validity of the simulation model has been verified through an experiment and a three-dimensional thermo-fluid numerical simulation. As for this verification, also refer to reference [6].

3.2 Solution method

The aforementioned modeling for the numerical simulation is conducted by a building block approach.

The equations for the CO_2 heat pump and mixing valves are static, while those for the storage tank are dynamic. Therefore, the modeling results in the following set of nonlinear differential algebraic equations:

$$\left.\begin{array}{l} \boldsymbol{f}(\boldsymbol{x}(t), \dot{\boldsymbol{x}}(t), \boldsymbol{y}(t), t) = \boldsymbol{0} \\ \boldsymbol{x}(t_1) = \boldsymbol{x}_{\mathrm{I}} \end{array}\right\} \quad (1)$$

where $\boldsymbol{f}$ is the vector for all the equations, $\boldsymbol{x}$ is the vector for the variables with their derivatives, or the temperatures of water for all the control volumes of the storage tank, $\boldsymbol{y}$ is the vector for all the other variables without their derivatives, $\dot{\boldsymbol{x}}$ is the derivative of $\boldsymbol{x}$ with respect to time t, and $\boldsymbol{x}_{\mathrm{I}}$ is the initial value of $\boldsymbol{x}$ at the initial time t_1.

The set of equations is solved by a hierarchical combination of the Runge-Kutta and Newton-Raphson methods.

4 EXERGY ANALYSIS

4.1 General equations

Even if the periodically steady state with the period of a day is used for the exergy analysis, the flow rates and states change with time throughout the day. Therefore, the instantaneous exergy balance relationship at the unsteady state is used [9]. Figure 2 shows the definition of symbols necessary for the exergy analysis. With this definition, the instantaneous exergy balance relationship is expressed as follows:

$$\frac{dE^{\mathrm{cv}}(t)}{dt} = \dot{E}^{\mathrm{in}}(t) - \dot{E}^{\mathrm{out}}(t) + \left(1 - \frac{T_0}{T(t)}\right)\dot{Q}^{\mathrm{in}}(t) - \dot{W}^{\mathrm{out}}(t) + p_0\frac{dV^{\mathrm{cv}}(t)}{dt} - \dot{E}^{\mathrm{des}}(t) \quad (2)$$

where $\dot{E}^{\mathrm{in}}$ and $\dot{E}^{\mathrm{out}}$ are the exergy flow rates at the inlet and outlet of the control volume, respectively, $\dot{Q}^{\mathrm{in}}$ and $\dot{W}^{\mathrm{out}}$ are the heat flow and work rates, respectively, E^{cv}, V^{cv}, and T are the stored exergy, volume, and temperature of the control volume, respectively, $\dot{E}^{\mathrm{des}}$ is the exergy destruction rate in the control volume, p_0 and T_0 are the pressure and temperature at the reference state, respectively.

By integrating this instantaneous exergy balance relationship during a certain period from t_1 to t_2, the following total exergy balance relationship is derived:

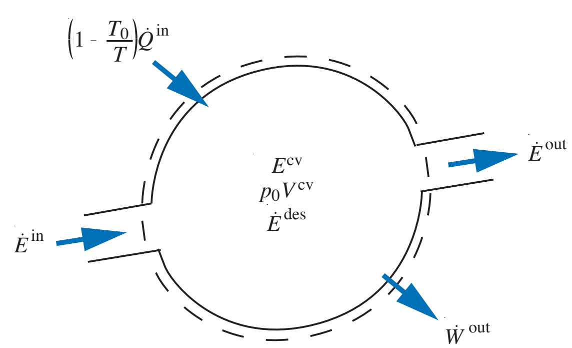


Fig. 2: Definition of symbols for exergy analysis

$$E^{\mathrm{cv}}(t_2) - E^{\mathrm{cv}}(t_1) = \int_{t_1}^{t_2}\dot{E}^{\mathrm{in}}(t)\,dt - \int_{t_1}^{t_2}\dot{E}^{\mathrm{out}}(t)\,dt + \int_{t_1}^{t_2}\left(1 - \frac{T_0}{T(t)}\right)\dot{Q}^{\mathrm{in}}(t)\,dt - \int_{t_1}^{t_2}\dot{W}^{\mathrm{out}}(t)\,dt + p_0\left(V^{\mathrm{cv}}(t_2) - V^{\mathrm{cv}}(t_1)\right) - \int_{t_1}^{t_2}\dot{E}^{\mathrm{des}}(t)\,dt \quad (3)$$

If the period is set at a day, the states in the control volume return to the initial ones after the day. In this case, therefore, the total exergy balance relationship is reduced to

$$\int_{t_1}^{t_2}\dot{E}^{\mathrm{in}}(t)\,dt - \int_{t_1}^{t_2}\dot{E}^{\mathrm{out}}(t)\,dt + \int_{t_1}^{t_2}\left(1 - \frac{T_0}{T(t)}\right)\dot{Q}^{\mathrm{in}}(t)\,dt - \int_{t_1}^{t_2}\dot{W}^{\mathrm{out}}(t)\,dt - \int_{t_1}^{t_2}\dot{E}^{\mathrm{des}}(t)\,dt = 0 \quad (4)$$

4.2 Application to CO_2 heat pump water heating systems

To conduct the exergy analysis on the CO_2 heat pump water heating systems, it is necessary to evaluate the exergy stored in the storage tank, the exergy flow rates of water from and into the storage tank, and the heat flow rate from the tank surface. Here, since the effect of the potential, kinetic, and chemical exergy is negligibly small, they are neglected, and the physical exergy is only taken into account.

First, the stored exergy is defined as

$$E^{\mathrm{cv}}(t) = m^{\mathrm{cv}}(t)\left\{(u(t) - u_0) + p_0(v(t) - v_0) - T_0(s(t) - s_0)\right\} \quad (5)$$

where m^{cv} is the mass, and u, v, and s are the specific internal energy, volume, and entropy, respectively. On the assumption that the specific volume and heat are constant, Eq. (5) is reduced to

$$E^{\mathrm{cv}}(t) = m^{\mathrm{cv}}(t)\left\{c(T(t) - T_0) - cT_0 \ln\frac{T(t)}{T_0}\right\} \quad (6)$$

where c is the specific heat.

Next, the exergy flow rate is defined as

$$\dot{E}(t) = \dot{m}(t)\left\{(h(t) - h_0) - T_0(s(t) - s_0)\right\} \quad (7)$$

where $\dot{m}$ is the mass flow rate, and h is the specific enthalpy. Since the effect of the pressure energy is negligibly small, Eq. (7) is reduced to

$$\dot{E}(t) = \dot{m}(t)\left\{c(T(t) - T_0) - cT_0 \ln\frac{T(t)}{T_0}\right\} \quad (8)$$

Finally, the heat flow rate per area is assessed based on the model for the heat loss from the tank surface as follows:

$$\dot{q}^{\mathrm{in}}(t) = -U\left(T(t) - T_0\right) \quad (9)$$

where U is the overall heat transfer coefficient.

The exergy destruction $\dot{E}^{\mathrm{des}}$ is assessed by substituting Eqs. (6), (8), and (9) into Eqs. (2) to (4).

5 NUMERICAL STUDY

The numerical simulation is conducted for eight days in mid-season on each of which an hourly change in a hot water demand is assumed. In addition, the exergy analysis is conducted based on the results obtained on the 8th day.

5.1 Conditions

The following are the conditions used for the numerical simulation and exergy analysis:

System specifications

Table 1 shows the specifications of the CO_2 heat pump water heating systems. The values of model parameters included in the equations are estimated based on measured data for existing devices. The rated heat output of the CO_2 heat pump is set at 4.5 kW. As an example, Fig. 3 shows measured values and approximate functions for the power consumption, COP, and their resultant heat output of the CO_2 heat pump in relation to the inlet water temperature for the air and outlet water temperatures of 16 and 85 ℃, respectively. Here, each value is relative to its rated one for the air, and inlet and outlet water temperatures of 16, 17, and 65 ℃, respectively. The volume of the hot water storage tank is set at 370 L.

The number of control volumes for the storage tank is set at 200, and the sampling time interval for the Runge-Kutta method is set at 10 and 180 s for the cases with and without water flow, respectively.

Ambient conditions

The feed water temperature in mid-season is set at 17 ℃, which is prescribed by the Japan Refrigeration and Air Conditioning Industry Association (JRA) [10]. The air temperature is also set at 17 ℃, so that the air and feed water temperatures are consistent with each other as the temperature at the reference state. These values are assumed to be constant throughout the the days.

Table 1: Specifications of the systems

Equipment	Specification	Value
CO_2 heat pump	Rated heat output	4.50 kW
Hot water storage tank	Volume	370 L
	Height	1.45 m
	Diameter	0.57 m
	Overall heat transfer coefficient	0.80 W/(m^2·°C)

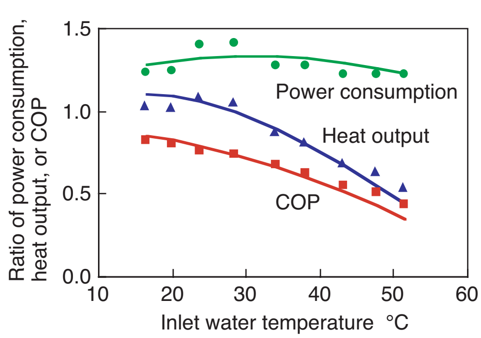

Fig. 3: Performance of CO_2 heat pump

Hot water demand

The hourly changes in the flow rate and temperature of the standardized hot water demand are given as shown in Fig. 4, which is also prescribed by JRA [10]. Here, the height of each vertical line means the flow rate, as indicated. The temperature is shown above each vertical line. In addition, the thickness of each vertical line means the duration.

Operation conditions

The system is assumed to be operated in the charging and tapping modes independently during the times 0:00 to 7:00 and 7:00 to 24:00, respectively. In the charging mode, the outlet water temperature of the CO_2 heat pump is set at 85 ℃. In addition, the CO_2 heat pump is started up at 2:00 and is shut down with a shutdown condition satisfied at an appropriate time before 7:00. The shutdown condition is that the inlet water temperature of the CO_2 heat pump attains 40 ℃.

As for the revised system, the combination of the top and middle of the storage tank from which hot water is extracted is determined depending on the temperature of water at the middle. When the temperature is higher than the supply temperature plus 5 ℃, hot water is extracted only from the middle. On the other hand, the temperature is lower than the supply temperature minus 5 ℃, hot water is extracted from both the top and middle. Otherwise, hot water is extracted only from the top, which is used for the conventional system. In the study, the extraction position at the middle is set at the 130th control volume from the top.

As the initial condition, the temperature of water in all the control volumes of the storage tank is set at the feed water temperature at 0:00 on the 1st day.

5.2 Results by numerical simulation

As an example of the results obtained by the numerical simulation, Fig. 5 shows the temperature distributions in the storage tank at 7:00 after charging and 24:00 after tapping at the periodically steady state on the 8th day for the conventional and revised systems. The temperature gradient at the part with middle temperatures for the revised system is larger than that for the conventional one. As a result, the volumes of hot water stored at 7:00 and unused at 24:00 for the former are larger than those for the latter.

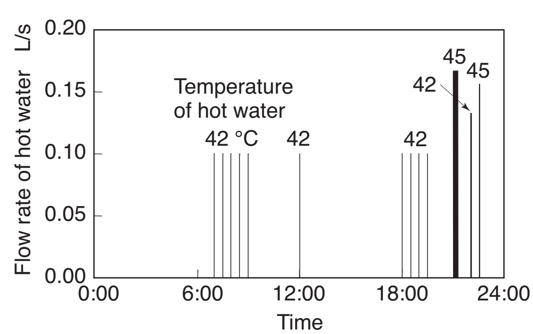

Fig. 4: Hourly change in hot water demand

In addition, the temperatures at the lower part with middle temperatures for the revised system are kept lower than those for the conventional one, which makes the COPs during charging for the former higher than those for the latter.

5.3 Results by exergy analysis

Heat pump

First, the exergy analysis is conducted on the CO_2 heat pump. Figure 6 shows the hourly change in the exergy efficiency for the conventional and revised systems. Here, the exergy efficiency is defined as the ratio of the difference between the exergy flow rates at the outlet and inlet to the power consumption. The exergy efficiency is constant after heat pump startup, because the temperature of water at the bottom of the storage tank is constant, and the COP is also constant. The exergy efficiency decreases drastically before heat pump shutdown, because the temperature of water at the bottom of the storage tank increases and the COP decreases. These changes in the exergy efficiency are similar to those in the COP. However, the exergy efficiency increases slightly on the way of heat pump operation, and this change is different from that in the COP. This is because the flow rate of water increases with the temperature of water at the bottom to keep the outlet water temperature, and the exergy flow rate at the outlet increases correspondingly, but that at the inlet does not so increase because of low temperatures of water.

Hot water storage tank

Next, the exergy analysis is conducted on the hot water storage tank. Figures 7 and 8 show the exergy balances for the conventional and revised systems, respectively. Figures (a) and (b) correspond to the charging mode during the period from 0:00 to 7:00 and the tapping one during the period from 7:00 to 24:00. The exergy at the inlet and outlet, the exergy destructions due to heat loss and conduction, and the change in the stored exergy are included in each figure. The exergy input for the revised system is slightly smaller than that for the conventional one. This is because the exergy efficiency of the CO_2 heat pump for the revised system is higher in some times and lower in the other times than that for the conventional one, as shown in Fig. 6. The exergy destruction due to heat loss is larger than that due to heat conduction for both the systems. Both the exergy destructions for the revised system are larger than those for the conventional one. The reason for this is as follows: As shown in Fig. 5, the part with high temperatures of water or the heat loss for the former is larger than that for the latter; In addition, the temperature gradient or the heat conduction for the former is larger than that for the latter. As a result, the exergy output for the revised system is smaller than that for the conventional one. This is because water with lower temperatures is utilized by its extraction from the middle of the storage tank. The lower exergy output for the former is balanced by the higher exergy efficiency of the mixing valves due to lower exergy destruction in mixing.

Summary

Table 2 summarizes the aforementioned results obtained by the energy analysis. Tables (a), (b), and (c) show the daily exergy input and output, exergy destructions, and

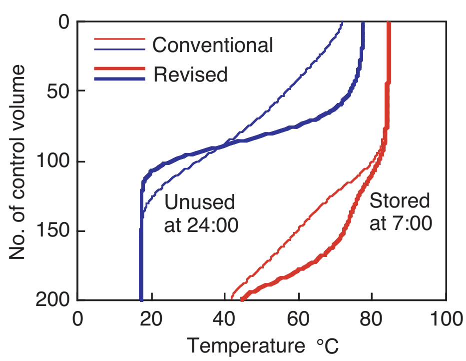

Fig. 5: Temperature distributions in storage tank

Fig. 8: Exergy balance for revised system

Table 2: Summary of results by exergy analysis

(a) Exergy input and output

(Unit: kJ/d)

System	Conventional	Revised
Power consumption	16 699	16 502
Heat pump output	5 930	5 868
Storage output	4 323	3 826
Hot water supply	1 997	1 997

(b) Exergy destructions

(Unit: kJ/d)

System	Conventional	Revised
CO_2 heat pump	10 769	10 634
Hot water storage tank	1 607	2 042
Heat loss	1 354	1 594
Heat conduction	253	448
Mixing valve(s)	2 326	1 829
Total	14 702	14 505

(c) Exergy efficiencies

System	Conventional	Revised
CO_2 heat pump	0.3551	0.3556
Hot water storage tank	0.7290	0.6520
Mixing valve(s)	0.4619	0.5220
Total	0.1196	0.1210

exergy efficiencies for all the components. The exergy efficiencies of the CO_2 heat pump and storage tank are the smallest and largest among all the components for both the systems, respectively. Under the conditions in this study, the total exergy efficiency for the revised system is slightly higher than that for the conventional one. However, it is beneficial that the stored exergy for the former is much larger than that for the latter.

6 CONCLUSIONS

The exergy analysis has been conducted on CO_2 heat pump water heating systems based on the results obtained by a numerical simulation for performance analysis. A conventional system as well as a system revised by extracting water with middle temperatures from the middle of the storage tank have been investigated. These systems have been compared in terms of exergy destructions and efficiencies of components.

The following are the main results obtained though a numerical study:

- The exergy efficiencies of the CO_2 heat pump and storage tank are the smallest and largest among all the components for both the systems, respectively. The exergy destruction due to heat loss is larger than that due to heat conduction for both the systems.
- The exergy efficiencies of the CO_2 heat pump, storage tank, and mixing valves for the revised system is slightly higher, lower, and higher than those for the conventional one, respectively.
- The total exergy efficiency for the revised system is slightly higher than that for the conventional one. However, it is beneficial that the stored exergy for the former is much larger than that for the latter.

Abstract

In "Ultra Long-term Energy Technology Visions 2005 " by the Japanese government , only "High Efficiency Heat Pump Water Heater " is shown as the vision for the future water heater . Actually, the electrically-driven type heat pump water heater using CO2 as refrigerant (Eco-Cute) have been developed and explosively spreading on the back of the economical late-night electricity rate system and all electrification strategy. In the meantime, with respect to the heat pump technology in the gas industry, although there are many track records of the technology used for air conditioning, there are rare cases of such technology used for water heating. Under such situation, in 2006, Hiroshima Gas started a study of "The Gas Engine Heat Pump Water Heater", which is a combination of "The Small-type Gas Engine" and "The Heat Pump". This time we will report on the element study we conducted, and analysis result of the exergy .

Keywords:

Gas Engine , Heat Pump , Exergy

1 INTRODUCTION

With the rising demand for energy saving as the gas water heater for household due to soaring energy prices and global environmental problems, the "Condensing Type Water Heater" and "Household Cogeneration" are promoted by the gas industry. In the meantime, "Ultra long-term energy technology vision" announced by the Japanese government in 2005, the Eco-Cute of "High Efficiency Heat Pump Water Heater" was shown as the development vision for the future water heater.

With respect to the heat pump technology in the gas industry, although there are many track records of the technology used for air-conditioning "GHP air-conditioning" , there are rare cases of such technology used for water heating. Under such situation, in 2006, Technical Research Institute of Hiroshima Gas started a study of "Gas Engine Heat Pump Water Heater" which is a combination of "Small-Type Gas Engine" and "Heat Pump." This time we will report on the contents of the element study.

2 GAS ENGINE HEAT PUMP WATER HEATER OUTLINE

This system is equipment in which heat pump used for air-conditioning is driven by gas engine, the equipment produces hot water through heat with collection heat from the atmosphere and heat with utilization exhaust heat of the gas engine. As the characteristics of the system, the equipment such as engine and compressor can be stored in the heat insulation box, the exhaust heat of the gas engine and the heat from such equipment can be recovered as heat source of the heat pump. It has become to improve the decrease in thermal efficiency in the winter-time low temperature season, which was a weak point of the heat pump water heater.

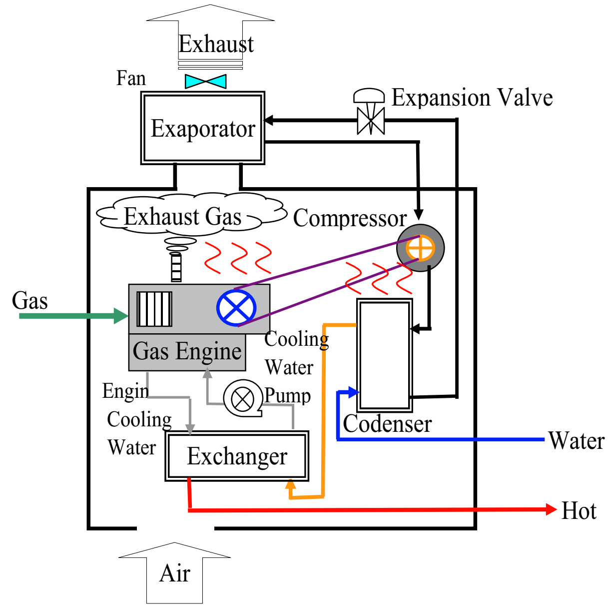

Fig. 1: System Outline

DOI 10.1007/978-94-007-3010-6_26, © Springer Science+Business Media Dordrecht 2012

Assuming that the heating value of consumed gas is 100%, and supposing that the shaft power of gas engine is 25%, Coefficients of Performance (COP) of the heat pump is 6.5 and the heat loss of the engine is around 10%, the expected best thermal efficiency of system will exceed 200% in primary energy equivalent. (Shaft Power 25%×6.5+Exhaust Heat Recovery 65%=228%)

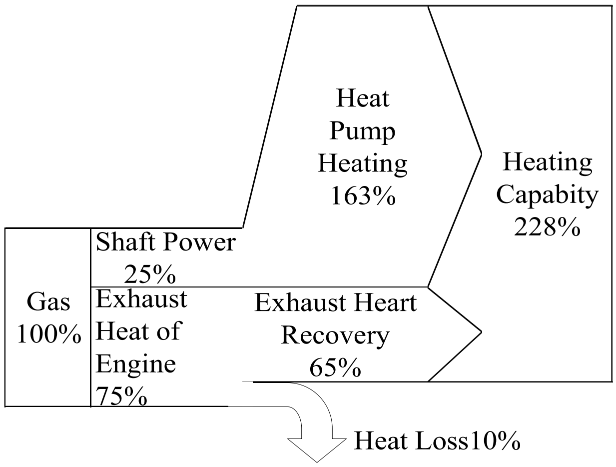

Fig. 2: Expected the Best Thermal Efficiency of System

3 PRODUCTION OF EXPERIMENTAL EQUIPMENT AND TARGETS PERFORMANCE

In producing the experimental equipment, we considered cost reduction and utilized the existing all-purpose products for the main equipment (the gas engine, compressor and heat exchanger) which are mass-produced, inexpensive and easily available.

We carried out preliminary tests before conducting full-scale performance confirmation tests , we changed some parts of the equipment to complete the experimental equipment.

Fig. 3: The Experimental Equipment

Since we utilized the existing all-purpose products for main components of the experimental equipment, this time we predicted that its target heat efficiency would be slightly lower in comparison with the exclusive use design. For this reason, in order to grasp theoretical performance of the experimental equipment and decide on target thermal efficiency, we reproduced its constitution in a process simulator (VMGSim) to predict the performance.

As a result of the analysis by the process simulator, because thermal efficiency in primary energy equivalent was assumed to be 151% at hot water outflow temperature of 60oC under winter environmental condition, we carried out the performance confirmation tests with this as a target.

Table 1: Experimental Equipment Specifications

Name of Components	Specifications
Gas Engine	163cc Single Cylinder, 4 Cycle
Compressor	Belt Drive Compressor , Oblique Plate Capacity-type
Condenser	1.4m^2, Plate-type Heat Exchanger
Evaporator	23m^2, Coil-type Heat Exchanger
Expansion Valve	Temperature Control System-type Electronic Expansion Valve
Refrigerant	HFC -134a
Ventilation Equipment	400～2100m^3/h , Ventilation Fan
Storage Box	1.2m×0.6m×1.1m
Engine Exhaust Recovery Equipment	0.7 m^2, Plate-type Heat Exchanger
Hot Water Tank	150 liters Capacities
Circulation Pump Hot Water	0.5～25 liter/min (Flow Control)
Circulation Pump Cooling Water	25 liter/min (For Engine Coolant)

4 PERFORMANCE CONFIRMATION TESTS

We confirmed the best thermal efficiency of the experimental equipment under seasonal environmental conditions (summer-time, intermediate-time and winter-time).

As for the specific test method, the room temperature and feed water temperature in the environmental test room were kept constant, then we controlled "Gas Engine Heat Pump Water Heater" at predetermined engine revolutions, we conducted performance confirmation tests after making the operation of the experimental equipment stable by adjusting feed water so that it can reach the targeted hot water outflow temperature. The test results of 60°C hot water are as shown in Table 2.

Table 2: Tests Result under the Seasonal Conditions (Hot Water Outflow Temperature 60°C)

Seasons (Temperature)	Thermal Efficiency (%) (*details)	Hot Water Outflow Volume (ℓ/min)	Hot water Capability (kW)
Summer (24 °C)	187 (122 , 64)	2.0	5.8
Inter-mediate (16 °C)	164 (99 , 65)	1.7	5.6
Winter (5 °C)	141 (89 , 52)	1.4	5.0

*details : Left , Heat Pump Efficiency
Right , Engine Exhaust Heat Recovery Efficiency

The thermal efficiency under winter-time condition was 141% which was 91% in performance of the target value (155%). The heat pump efficiency is the same, but the engine exhaust heat recovery efficiency declined remarkable than the result of analysis simulator. As mentioned above, we predict that it was caused by ventilation quantity from outside and heat loss of the storing box due to lower temperature inside the box.

In addition, the relation between test air temperature at each hot water outflow temperature and thermal efficiency (Performance Curves) is as shown in Fig. 3.

Because the relation between thermal efficiency and test air temperature at each hot water outflow temperature is linear, because the inclination and interval became constant, we can predict thermal efficiency of the experimental equipment at the ambient temperature.

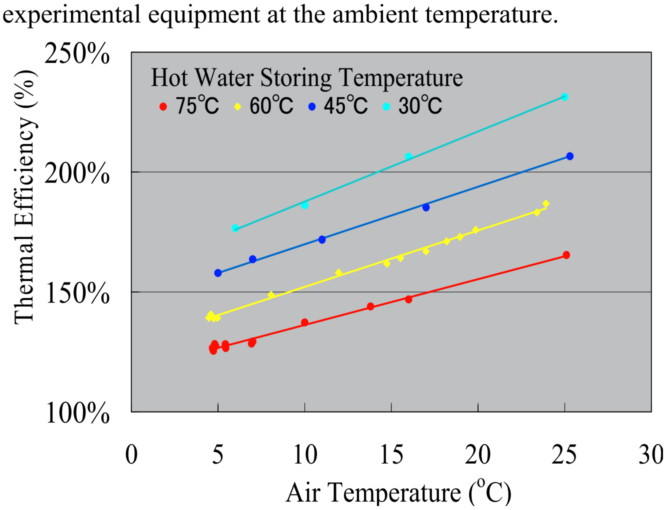

Fig. 3: Relation between Thermal Efficiency and Air Temperature (Performance Curves of Experimental Equipment)

5 EXERGY DESIGN OF THE EXPERIMENTAL EQUIPMENT

We conducted a study on improvement of thermal efficiency of the experimental equipment by exergy design. We grasped exergy flow and exergy efficiency of the energy system, and studied improvement of parts where hot water supplying energy and exergy loss at each process are substantial. The study results of the exergy evaluation are as shown in fig.4. Under winter-time operating condition, the heat pump efficiency is 89%, the engine exhaust heat recovery efficiency is 52%, however, based on the exergy analysis, the heat pump efficiency is 5%, the engine exhaust heat recovery efficiency is 10%, respectively.

6 CLOSING

We produced this experimental equipment using generally available all-purpose main components which we can get easily such as the gas engine. However, we succeeded in achieving thermal efficiency (primary energy equivalent) of 141% (91% in performance of the target value) under the severe winter-time environmental conditions (air temperature 5°C). This is about two times higher than the efficiency of the conventional type gas water heater which has been widespread in Japan. This will enable us to substantially reduce gas consumption and carbon dioxide emissions when operating the water heater. Furthermore, by the exergy analysis we have come to visualize or quantity the loss which could not be expressed by the conventional enthalpy analysis and find a clue to the performance improvement. We will continue to make efforts in the performance improvement of the equipment utilizing the exergy design which will minimize the exergy loss.

In closing, we hope that the results of this study will enable us to contribute even a little to promotion of lower carbon society in the future.

Abstract
The model of zero emission house [ZEH] made full use of leading-edge energy saving and new energy technology of Japan was exhibited at G8 Hokkaido Touyako Summit held on July 2008. Introduction in Japan is set as the goal of starting popularization of ZEH from 2015, change all newly-built houses to ZEH by 2030 and change all houses including existing house to ZEH by 2050. We have developed new style desiccant air conditioner which can supply dry cool air in summer and warm humidified air in winter by using heated water of solar heat or CGS. In this paper, we publish the energy saving efficiency of the incorporation of this desiccant air conditioner into ZEH and case example of exergy analysis compared with heat pump systems in summer extremely hot day.

ZEH, CGS, Heat Pump, Desiccant Central Air Conditioner, Exergy

1 INTRODUCTION

Due to the impact of the Great East Japan Earthquake on March 11 and the accompanying accident in the Fukushima Daiichi Nuclear Plant, there is an increasing demand for energy saving. At the same time, zero emission houses (ZEHs) for consumer use are attracting attention as a measure against global warming, and their demonstration is being promoted in various parts of Japan [1]. ZEH is a housing design aimed at avoiding CO_2 emissions by using photovoltaic power generation and other methods. Osaka Gas is conducting demonstration tests of a smart energy house (SEH) that utilizes photovoltaic power generation, fuel cells and storage batteries. The air conditioning in this SEH combines a commercial air conditioner with a desiccant unit. With focus on solar water heaters and gas engine cogeneration units of improving efficiency for domestic use, we are developing ventilation and central air conditioning for detached houses using the hot water generated by the units [2]. This air conditioning system ably combines dehumidification and regeneration capacity of desiccant and cooling capacity of water spray with air passage switching function to attain dehumidification cooling and humidification heating functions similar to those of air conditioners. The effect of this system, which is currently under development, on reduction of power consumption in households in summer was assessed with the process simulator VMGSim using assumed outdoor temperature and humidity values, preset indoor temperature and ventilation air flow as the parameters. In addition, the performance of the devices constituting this system was evaluated to identify the devices to be improved to reduce exergy loss, and its anticipated primary energy saving effect was compared with that of a conventional heat pump air conditioner and hot water energy supply system using grid power.

2 IMPROVEMENT OF HEAT & POWER SYSYTEM FOR DOMESTIC USE

As a commercial product to compete with the natural refrigerant heat pump hot water heater called “Eco Cute” released in 2001, “Eco Will,” a gas engine power generation system for domestic use, was put on sale in 2003. Table 1 shows the changes in its specifications. While the temperature of the stored hot water is 75 ^{o}C, the maximum temperature of the supply water is 80 ^{o}C due to an upper limit to the temperature of the hot water for cooling the main unit of the gas engine; also, the power generation efficiency on a lower heating value basis has been increased to 26.3% from 20% at the time of the release. In consideration of the trend for improvement in the power generation efficiency of the tens of kW class of gas engines, it is expected that power generation efficiency of gas engines for domestic use will exceed 30% in the future.

Table 1: Changes in the specifications of gas engine for domestic use.

Release date	Efficiency [%]			Gas input kW [LHV]	Gas consumption [Nm3/h]
	Power	Exhaust heat recovery	Total heat		
Mar. 2003	20	65	85	5	0.443
Oct. 2008	22.5	65	85.5	4.45	0.394
Jun. 2011	26.3	67.5	92	3.81	0.337
future	(30)	(60)	(90)	(3.34)	(0.295)

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_27,

The fuel cells for domestic use such as SOFC, which currently attract attention as high-efficiency power generation units, are being developed with a target of commercializing units with power output of 700W and hot water output of 620W (with power generation efficiency of 45% and waste heat utilization efficiency of 40%).

While we have proposed a system that can also use the high-temperature waste gas from solid-oxide fuel cells as air for regenerating desiccant, this paper assesses the energy saving effect of the system that can use waste heat from the gas engine already available in the market as part of the heat source for regeneration of the desiccant.

3 CENTRAL AIR CONDITIONING SYSTEM USING HOT WATER

Figure 1 illustrates the central air conditioning system using the hot water generated by a gas engine cogeneration unit for domestic use and a solar heater. The air conditioner is installed near a gas engine cogeneration unit with power output of 1kW, and the dehumidified cool air processed by the unit is supplied through air ducts in summer to various rooms including living room, dining room, bed room, study room and children's room. The cooling heat load for the central air conditioning with outdoor temperature of 35 ^{o}C and indoor temperature of 27 ^{o}C is assumed to be up to 4kW in a detached house with a floor area of 120 m^2 in the Kansai area, based on the coefficient of heat loss specified in the energy-saving standard for houses [3].

Figure 2 shows the equipment configuration of the whole system, and Figure 3 presents a psychrometric chart on the dehumidifying and cooling operation. The air conditioning system is outlined below. Hot water of approximately 80 ^{o}C heated with solar heat and waste heat from the gas engine is used as heat source for regeneration of the desiccant rotor. During mid-day hours, when the cooling heat load is large, with the aim of increasing the cooling heat load, indoor air in the amount equivalent to the air taken in from the outside is introduced to the desiccant rotor and dehumidified to lower the absolute humidity to around 8g/kgDA. The process air, heated to about 48 ^{o}C with the heat generated as a result of the dehumidification, is cooled with indoor air and supersaturated outdoor air. The cooling heat load is set to be 4kW. Then, in consideration of the moisture of 330g/h generated from human bodies, etc., water is sprayed to the process air to reduce the absolute humidity to below that of the indoor air. After spraying, the dehumidified cool air of around 22 ^{o}C is supplied through air ducts to the rooms. The psychrometric chart indicates that the temperature of the regeneration heat source can be lowered with the application of same amounts of outdoor and indoor air to the desiccant rotor. The ventilation air flow to generate cooling heat load of 4kW is 390 m^3/h, and the cooling air supply is about twice this amount.

The devices of the proposed system are configured such as to allow consideration of the cases where solar heat or waste heat from the gas engine cannot be used and where the regeneration air can be heated with city gas burner to increase the cooling heat load. Solar heat received during the daytime is stored in the hot water storage tank and can be used at night as a heat source for regeneration of the desiccant.

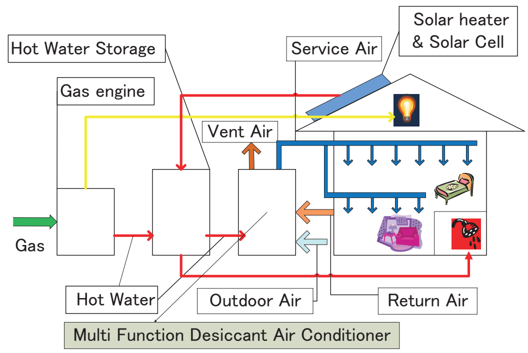

Figure 1: Image of the central air conditioning system.

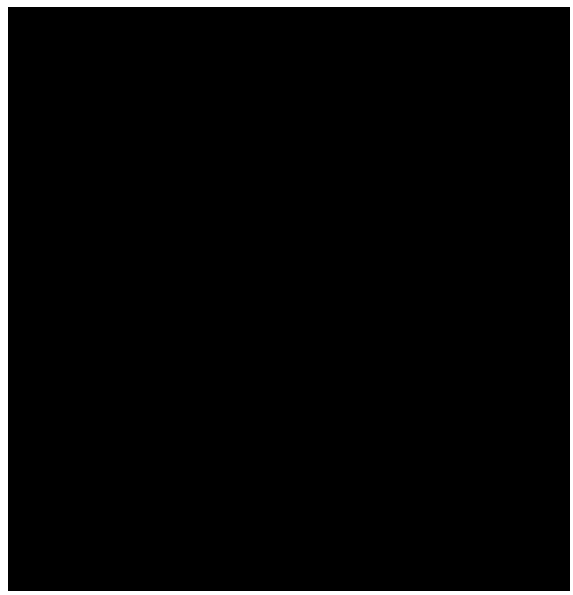

Figure 2: Equipment configuration of the whole system.

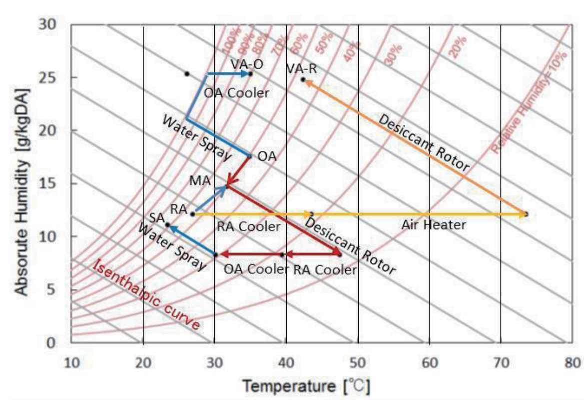

Figure 3: Psychrometric chart during dehumidifying and cooling operation.

Figures 4 and 5 respectively show temperature-heat load characteristics of the process air cooler (to cool the process air with indoor air and water-sprayed supersaturated air) and the regeneration air heater (to heat indoor air with hot water) that can address a cooling heat load of 4kW. The exchange heat quantity in Figure 4 less the heat input of the blower is the cooling heat load for the desiccant air conditioning system. Since the heat load of the hot water to heat the regeneration air in Figure 5 exceeds the waste heat collected from the gas engine with rated power output of 1kW, the shortfall will be met with the solar heat stored in the hot water storage tank. Relatively high thermal performance is assumed based on the premise that the minimum approach temperature of the heat exchangers is around 5 ^{o}C.

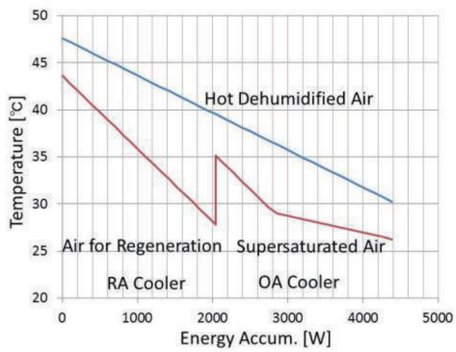

Figure 4: Temperature-heat load characteristics of process air cooler.

Figure 5: Temperature-heat load characteristics of regeneration air heater.

Figures 6 and 7 show the Sankey diagrams of an energy supply system with dehumidification cooling and hot water supply functions using waste heat from gas engine and city gas burner on enthalpy and exergy bases, respectively. Based on the exergy assessment of this system, the largest losses in the gas engine are generated in connection with combustion in the cylinder and cooling in the cylinder jacket, while the largest losses in the dehumidification cooling system stem from use of the city gas burner, efficiency of the blower, and heat exchange of desiccant rotor, hot water heater, etc. In the desiccant unit in Figure 6, the latent heat generated by spraying water to the dehumidified supply air is added to the cooling heat load mentioned above. Quantitative assessment is described in the examination of the factor analysis.

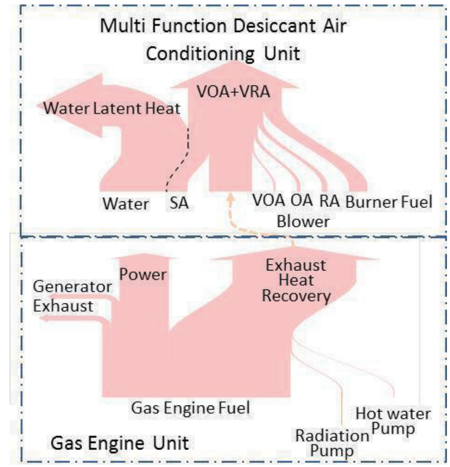

Figure 6: Sankey diagram based on an enthalpy basis.

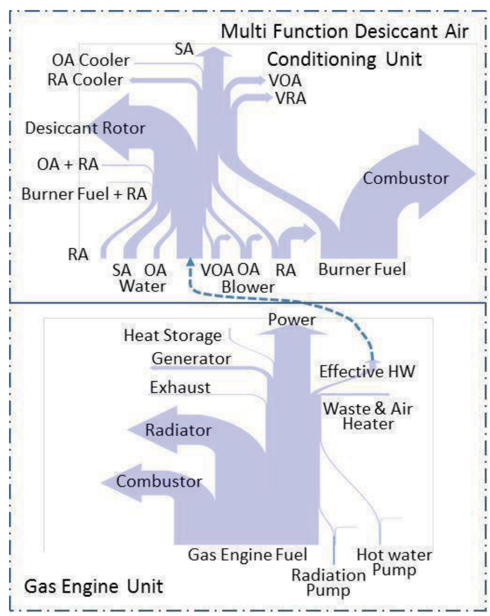

Figure 7: Sankey diagram based on an exergy basis.

4 AIR CONDITIONING AND HOT WATER SUPPLY SYSTEM USING HEAT PUMP

The "top runner system" enforced by the Energy Saving Act in 1999 mandates the display of energy consumption efficiency, etc. on products, and currently designates 23 kinds of equipment including air conditioners and hot water supply systems. The efficiency has direct impact on the sales of air conditioners in particular, and competition for improving their efficiency has intensified. Natural refrigerant heat pump water heater, which significantly saves energy in comparison with traditional electric water heaters, is included in the 10 items of the JSME Technology Roadmap. According to the literature, the energy consumption coefficient (coefficient of performance, COP), which is determined by dividing the quantity of heat production by energy input, is anticipated to increase from 3.5 at the time of the release in 2001 to 6.0 in 2030. These air conditioners and heat pump water heaters are currently obligated to display their efficiency in terms of APF (annual performance factor).

Based on the values shown in the catalogs of these products, we have developed a process simulation model to evaluate power consumption for dehumidification cooling and water heating, using outdoor temperature and humidity, preset indoor temperature, and ventilation air flow as well as the temperature of input water and heating temperature of water heaters as the parameters. Figure 8 illustrates the model. The air conditioner is a model with regenerative dehumidification capacity. R410A and CO_2 are assumed to be the refrigerants for the air conditioner and heat pump water heater, respectively. The power consumption can be calculated based on the outdoor moisture and heat taken in by ventilation and heat leakage from outside of the building in addition to the operation specifications of the desiccant mentioned above. The operation time and power consumption of the heat pump water heater to supply the same amount of hot water supplied by the gas engine cogeneration system mentioned earlier can be calculated in consideration of heat radiation during the storage of the hot water.

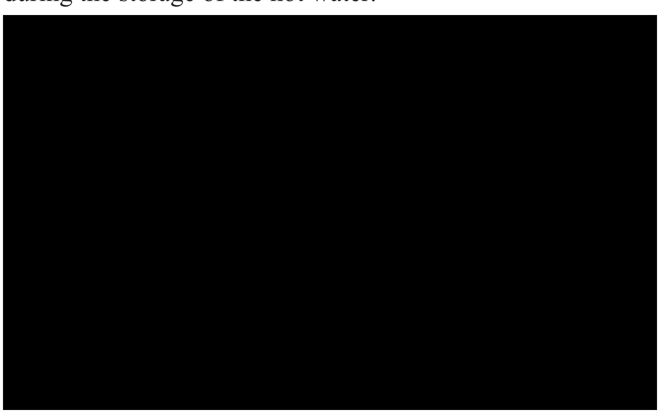

Figure 8: Equipment configuration.

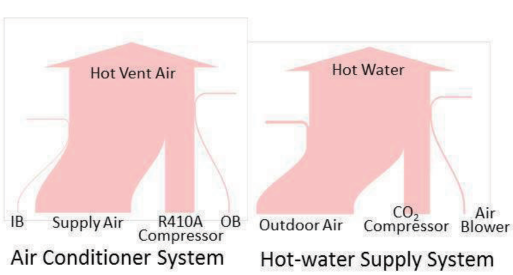

Figure 9: Sankey diagram based on an enthalpy basis.

Figures 9 and 10 show the Sankey Diagrams of this system based on enthalpy and exergy respectively. Exergy in the heat pump is mainly lost from the compressor, valve, evaporator, and condenser. As the temperature of the stored hot water in the hot water supply system is usually as high as 65 °C or more, the mixing process of hot water and tap water during use causes large losses.

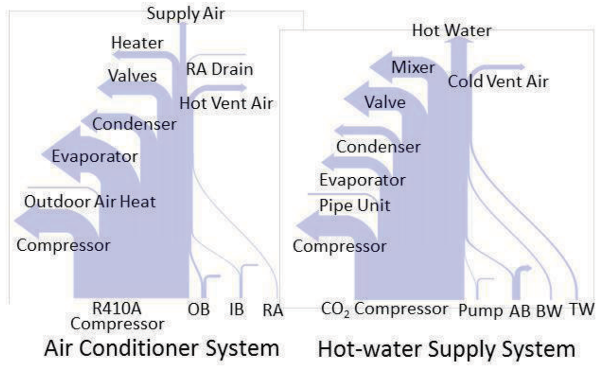

Figure 10: Sankey diagram based on an exergy basis.

5 QUANTIFICATION AND COMPARISON OF LOSS IN THE ENERGY SUPPLY SYSTEM FOR DOMESTIC USE

Based on data from Japan Meteorological Agency, typical changes in the temperature and humidity for an extremely hot day in Osaka and Kyoto this year are simulated and presented in Figure 11. As the sun goes up and the outdoor temperature rises, relative humidity declines. On the other hand, absolute humidity is constant at approximately 17g/kgDA throughout the day unless the weather changes, and discomfort index is over 77 even at night, at which half the people feel uncomfortable.

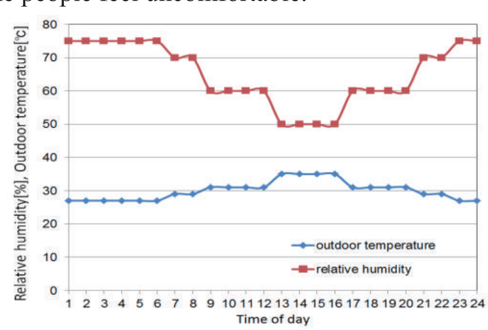

Figure 11: Outdoor conditions of an extremely hot day.

The power consumption and hot water requirement under the outdoor conditions simulated above were determined with indoor temperature of 27 °C, absolute humidity of 12g/kgDA and ventilation air flow of 390 m^3/h.

With the outdoor temperature of 30 °C or more, the process air flow was assumed to be twice as much as ventilation air flow to increase the cooling capacity. For the purpose of calculating the operation time of the cogeneration system and heat pump hot water heater, the daily hot water requirement was set to be 6kWh. To simplify the comparison of different systems, the energy saving effect of photovoltaic power generation was excluded. Although it was necessary to consider the axle efficiency of the rotary machine, inverter efficiency, and motor efficiency to calculate the power of the rotary machine, only the information on power consumption in the catalog was available, and adiabatic efficiency was therefore used to calculate the power consumption of the rotary machine in the process simulator.

5.1 GAS ENGINE SYSTEM FOR DOMESTIC USE

For the examination of this system, two cases on power generation efficiency of the stoichiometric gas engine for domestic use were selected, namely 26.3% (the current value) and 30% (a value expected in the future), and the temperature of the hot water supply was set to be constant at 80 ^{o}C. The waste heat utilization efficiency in the two cases was respectively set to be 63.7% and 58% in anticipation of some heat loss due to radiation, and the gas engine was assessed on an exergy basis temperature with the outdoor temperature of 35 ^{o}C. The assessment results with the input fuel to be 100 are shown in Table 2. The overall thermal efficiency is respectively 92% and 90% on an enthalpy basis and 30.1% and 32.9% on an exergy basis. It is obvious that improvement in power generation efficiency results in reduction in loss from the radiator. The energy requirement on a lower heating value basis in case of operating the gas engine from 7 a.m. to 11 p.m. is tabulated. Table 3 shows the exergy analysis of the desiccant air conditioner under different outdoor conditions as well as its power consumption according to the specifications and operation time. The types 35-A, 31-B, 29-C, 27-D, and 35-E involve different outdoor temperatures and supply air flows. The Arabic numerals represent the outdoor temperature, and the supply air flow is approximately 750 m^3/h in Types A, B and E, and 380 m^3/h, or about half of the former, in Types C and D. Types A and B are operation with high cooling capacity additionally using solar heat; Type C is operation with intermediate cooling capacity using waste heat from gas engine; and Type D is dehumidification operation using the heat of the stored hot water. In Type E, city gas is combusted to increase the cooling capacity. The results of the exergy analysis of the desiccant air conditioner shown in Figure 7 and the assessment of loss in this table demonstrate that the use of city gas for heating the regeneration air generates very large amount of combustion loss. In the calculation on the process, the dehumidification efficiency of the desiccant rotor was set to be 85% or less, and the head and efficiency of the blowers to be 350 Pa and 35%, respectively. For the heat transfer property of the heat exchangers, the minimum approach temperature with the maximum load was set to be 5 ^{o}C. In the exergy evaluation, the outdoor temperature was different between the cases. When the evaluation temperature dropped, the exergy loss in the blower efficiency increased correspondingly. The power consumption of the blower in case of operation for 24 hours a day is shown in the lower right of the table.

Operating Time [hrs]	4	8	4	8	
Required Power [wh]	1,537	3,092	963	1,915	7,507

The amount of dehumidification by the desiccant air conditioner, which depends on the difference between indoor and outdoor absolute humidity, is 2.0 to 2.6 kg/h with ventilation air flow of 390 m^3/h. The room cooling capacity is influenced by regeneration temperature and outdoor absolute humidity, and increases as the temperature of the supply air falls. Even when the regeneration air temperature is 72 ^{o}C, the supply air can be cooled to 20 ^{o}C or less with water spray if the outdoor absolute humidity drops.

The cooling capacity, including the latent heat of the water, exceeds 5kW in Types A and B.

5.2 HEAT PUMP SYSTEM

Using the process simulator based on the values in catalogs prepared by manufacturers, the latest air conditioner was considered to have the minimum approach temperature of 3 ^{o}C, compressor with 75% efficiency and blower with 40% efficiency under its rated capacity. Table 4 shows the exergy evaluation results and power consumption of the air conditioner and heat pump hot water heater. As the outdoor temperature and dehumidification amount decrease, the power consumption of the compressor and blower falls. At the outdoor temperature of 35 ^{o}C, the COP of the air conditioner and heat pump hot water heater were 5.15 and 4.72 respectively, while their exergy values were 7.1% and 31.9% respectively. In the heat pump hot water heater, the effective exergy efficiency dropped to less than half due to mixing with supply water and heat radiation from the hot water storage tank.

Table 4: Evaluation of the heat pump system.

5.3 ASSESSMENT OF ENERGY SAVING EFFECT AND SURPLUS POWER

The replacement of the existing air conditioner with the proposed desiccant air conditioner is expected to produce energy saving effect of 1,574W (net output of gas engine: 925W, power consumption of desiccant: 384W, and power consumption of air conditioner: 1,033W).

Then, efficiency in the generation of surplus power was evaluated in the two cases of the grid power conversion efficiency of 40% (the current value) and 55% (the efficiency of the latest gas turbine combined cycle) on a lower heating value basis. The daily power consumption of the air conditioner and hot water supply was divided by the grid power conversion efficiency mentioned above to determine the primary energy requirement.

The primary energy corresponding to the surplus power of the gas engine is the daily energy consumption of the gas engine less the above energy requirement. Accordingly, the efficiency in the generation of surplus power can be calculated by subtracting power requirement of the desiccant air conditioner from net power consumption of the gas engine and dividing the difference by the primary energy corresponding to the surplus power. With blower efficiency of 35% and 55%, power surplus is respectively 6,693Wh and 9,470Wh. The values determined with the calculation mentioned above are shown in Table 5.

Table 5: Efficiency in the generation of surplus power.

System Power	blower efficiency 35%		blower efficiency 55%	
	Gas Engine Power efficiency			
	26.3%	30.0%	26.3%	30.0%
40%	61%	193%	86%	272%
55%	27%	39%	38%	55%

6. CONCLUSION

The exergy analysis has identified the components of the energy supply systems that need to be improved in the future. Especially, the energy supply system using the existing gas engine cogeneration unit for domestic use is more beneficial than the combination of existing power system efficiency and Eco Cute, but has no advantage when compared with the latest combined cycle because of the exergy loss due to combustion and heat transfer in the heat source device, and it is therefore necessary to improve the cogeneration efficiency. Meanwhile, in the central air conditioning system using desiccant, which is currently under development, it is essential to improve the blower efficiency. Nevertheless, in light of the current situation that peak power consumption has to be reduced, the air conditioner that makes use of waste heat at the peak power time in summer is attractive even if it is based on gas engine for domestic use. In the future, the power saving effect of the energy supply system in winter and throughout the year, as well as the effect of replacement of the heat source equipment with SOFC will be examined from the aspect of the exergy design of the devices.

Abstract

Toward realizing a low-carbon society as well as ensuring energy security, there is an urgent need to describe scenarios for future energy systems. A cogeneration system (CGS) is one of key technologies and it is, in particular, promising for apartment buildings because of its high efficiency. This paper describes a scenario of introducing a CGS to apartment buildings in order to analyze the effect of this system using exergy as an evaluation indicator. Results show that dominant exergy losses of a CGS arise in combustor and radiator. Compared with the current energy system, a CGS has a potential of reducing energy consumption by introducing a desiccant air conditioner instead of a conventional air conditioner.

Keywords:

cogeneration system, scenario, apartment building, exergy, sustainable society

1 INTRODUCTION

The concept of smart grids draws more attention than ever as a promising enabler for achieving a low-carbon society as well as ensuring energy security. A smart grid refers to an electricity network that uses digital and other advanced technologies to manage the transport of electricity to meet the varying electricity demands of end-uses [1]. In a smart grid, introducing combined heat and power (CHP) systems, or cogeneration systems (CGS), is one of hopeful options. Advantages of CGS include providing consumers with not only electricity but also heat, which may lead to improving energy efficiency. In particular, CGS for apartment buildings is more energy efficient than that for detached houses [2].

However, it is still ambiguous about which conditions are suitable for introducing CGS, which future uncertainties might be driving forces or obstacles for CGS, and to what extent CGS is energy efficient compared with other energy systems. To answer these questions, this paper describes a scenario of introducing CGS to apartment buildings. In this paper, "scenario" means not a prediction, but a set of plural futures that might unfold [3]. Toward this end, this paper firstly presents a framework of designing scenarios for energy systems. We then describe two scenarios, *i.e.*, business as usual (BaU) scenario and CGS scenario, based on this framework. When analyzing these two scenarios, we conduct exergy analyses for examining energy efficiency. Exergy analyses are useful for designing more efficient energy systems by identifying inefficient parts in existing systems [4].

2 POSSIBILITIES OF COGENERATION SYSTEMS FOR APARTMENT BUILDINGS

2.1 Advantages and disadvantages of cogeneration systems for apartment buildings

While there are various types of cogeneration systems (CGS), their components may involve gas engine, fuel cell, boiler, and heat pump. Since CGS is capable of generating both power and heat using gas, it is robust over instability of centralized power grid. In this regard, CGS is a means of ensuring energy security for each individual consumer as the Japan's national long-term energy policy is now unpredictable and nuclear power plants might be closed in the future. CGS is more advantageous for apartment buildings than detached houses because efficiency of power generator becomes higher when the rated capacity is larger. In fact, centralized hot water distribution systems based on cogeneration systems have been adopted in parts of apartment buildings in Japan.

On the other hand, dissemination of CGS has been hindered due to some problems, such as considerable heat loss in hot water pipes, low utilization of the system in summer during which hot water demand is low, and low economic viability. Another possible obstacle is surge in energy prices, such as natural gas prices. In a long run, energy prices are projected to gradually increase in accordance with increase in global energy demand [5]. Given this situation, we have been developing a new CGS for multi-family apartment buildings. This CGS uses small diameter pipes with the use of heat storage units in each house for hot water supply and room heating for realizing

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_28,

high energy efficiency in terms of heat distribution. Also, we have started developing a new type of desiccant air conditioner that uses hot water for keeping the room dry and cool during summer and humidified and warm during winter. This development intends to reduce heat loss of CGS and improve entire efficiency of the energy system.

2.2 Related work

A number of studies have been carried out on analyses of energy systems [6][7]. Balta, *et al.* [8] analyzed energy and exergy efficiencies for several energy options, such as electric boiler and cogeneration. Yamaguchi, *et al.* [2] simulated effects of CGS for apartment buildings, showing that CGS which used a gas engine as a main generator reduces the annual use of primary energy. They also showed that, however, CGS brought heat loss or more heat than the consumers' demand in summer. Aiming to avoid abandoning the heat generated by CGS, Hirano, *et al.* [9] conducted energy and exergy analyses of CGS with desiccant air conditioner for detached houses. They revealed that energy efficiency of CGS would be improved when a desiccant air conditioner was used instead of conventional heat pump air-conditioning systems.

However, long-term perspectives of energy systems, including CGS, have not adequately explored. While existing studies rather focuses on energy efficiency of specific energy systems, economic and environmental assessments for CGS will easily change in the future because some external factors surrounding the energy systems are of high uncertainty. These factors include political situations, energy prices, consumers' behavior, and technological advancement. As related works, several future scenarios on energy systems (*e.g.*, [1][10]) have been published; nonetheless, they usually focuses solely on electricity systems, not mentioning heat systems.

3 FRAMEWORK OF DESIGNING SCENARIOS FOR FUTURE ENERGY SYSTEMS

3.1 Basic concept

To design scenarios for future energy systems, which are not limited to CGS, we propose a framework for scenario design as illustrated in Fig. 1. The basic idea is to describe scenarios not from a technological viewpoint only, but from a holistic viewpoint, which include technological, social, economic, and political aspects. As an approach to structuring these complex components in designing such scenarios, this paper defines three levels as illustrated in Fig. 1 as follows:

- Social level: defines future situations regarding social, political, and economic factors which are associated with the energy system.
- Regional level: defines targeted regions/areas and human behavior or lifestyles. This level involves information associated with regions/areas, such as geographical and climate data.
- Technological level: defines configurations of energy systems, such as CGS and renewable energy systems.

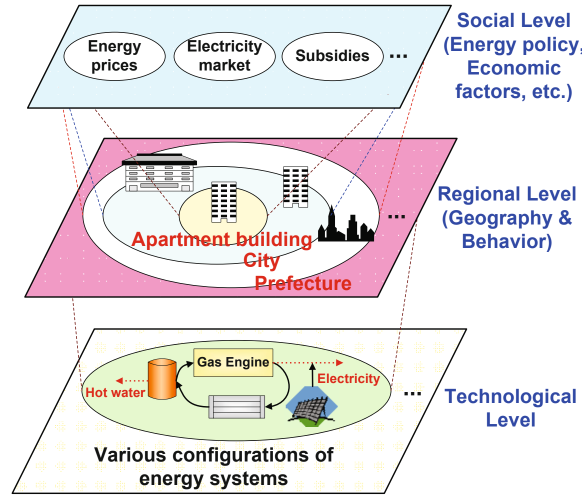

Fig. 1: Concept of describing energy systems scenarios

We describe a scenario by listing factors related to energy systems, classifying them based on the three levels above, and then connecting those factors with each other in order to make a story. In technological level, we construct a model of each individual configuration of energy systems. Taking CGS as an example, elements of CGS may include gas engines, high-efficiency fuel cells, highly-efficient heat pumps, and other advanced devices as its components. Based on the existing method of scenario design [11], the scenario design processes are composed of five steps as shown below:

1. Setting a problem of a scenario to be designed.
2. Listing factors which are related to energy systems, classifying them into the three levels in Fig. 1, and relating them with each other in each level in order to clarify the causal relationship among the factors.
3. Setting conditions of the factors listed in Step 2, followed by writing a story as text by detailing the relationships between the factors.
4. Executing simulations based on the conditions set in Step 3.
5. Describing several sub scenarios, usually 2-4 scenarios by repeating Steps 2-4, and comparing the sub scenarios.

3.2 Concept of scenario design system

Our research project plans to describe various scenarios for a variety of energy systems, including a scenario of introducing CGS to next-generation apartment buildings.

Table 1: Descriptions of each scenario

<table>
<tr><th rowspan="2">Level</th><th colspan="2">Scenario descriptions</th></tr>
<tr><th>(A) BaU Scenario</th><th>(B) CGS Scenario</th></tr>
<tr><td>Social</td><td>The current political, economic, and societal systems are maintained.</td><td>Power selling is applicable even to the power generated by CGS. CGS becomes more attractive to consumers by giving them subsidies from the government.</td></tr>
<tr><td>Regional</td><td colspan="2">The targeted area is a 400-unit apartment building, located in Osaka, Japan. This building has 180m-length pipe with a diameter of 4 inches and the area of the rooftop is 1,000m^2. The lifestyle of the residents is assumed to be unchanged from the present. The duty of cooling and heating in the apartment building is set as follows:
• Cooling duty of air conditioner: 432kW (cooling duty per household: 3.6kW/household, 120 households are keeping their air conditioners on)
• Hot water: 279kW (water flow per household: 10L/min (0.6m^3/h), hot water temperature: 40°C, outdoor temperature: 35°C, 40 households are using hot water)
In Scenario (B), the heat supply from the solar heating system is set at 163kW, by assuming that the heat flux from the sun is 0.32kW/m^2 (in Osaka [15]), solar heating systems are placed on 70% of the whole rooftop (700m^2), and the efficiency of solar heating is 72.4% (see Table 2).</td></tr>
<tr><td>Technological</td><td>The configuration of the energy system is described in Fig. 2. Electricity is distributed from the grid power, while heat is generated by a conventional gas boiler. The adiabatic efficient for air conditioner and the efficient of blower are assumed to be 75% and 40%, respectively.</td><td>The configuration of the energy system is described in Fig. 3. Electricity is supplied primarily from a gas engine and even from grid power unless the power meets the demand. Desiccant air conditioners are installed in each apartment. Solar heating systems are installed on the roof of the building. The hot water supply system (heat pump) is used for heating tap water up to 65°C as the heat pump is efficient when water temperature is low.</td></tr>
</table>

We are developing a system for helping to design these scenarios using Sustainable Society Scenario (3S) Simulator [12], which supports a scenario design team in describing and analyzing the scenarios. In describing the scenario, we execute simulations of various configurations of energy systems as well as conduct exergy analyses of these systems. In the simulations, we employ VMGSim [13] in order to model and analyze various energy systems.

The ultimate goal of developing this system is to connect 3S Simulator [12] with VMGSim [13]. 3S Simulator serves as a platform for describing a scenario where we articulate, in a text form, conditions of external factors of energy systems as well as the specifications of the energy systems. VMGSim plays a role of simulating various energy systems based on the conditions set in the scenario for assessing those energy systems quantitatively.

4 CASE STUDY

4.1 Two scenarios described in the case study

Based on the proposed framework, this section presents a case study of describing two scenarios, *i.e.*, (A) BaU Scenario and (B) CGS Scenario. Scenario (A) assumes a conventional energy system of Japan, while Scenario (B) assumes introducing CGS in an apartment building.

In this case study, we set the following assumptions for

Table 2: Specifications of energy devices in Scenario (B)

</table>

both scenarios:

- We analyze energy efficiency in daytime of an extremely hot day in summer in Osaka, in which heat demand is least of the year. Outdoor and indoor temperatures are set at 35°C [14] and 27°C, respectively. Water and gas temperatures are 30°C.
- We operate each device of energy systems in such a way that heat demand for the residents is satisfied. Note that the gas engine in Scenario (B) runs with its rated output for achieving high efficiency, whereas extra electricity from the gas engine is delivered over to the power grid, if any.
- We focus on heating and cooling systems as energy systems since only heating and cooling differ between Scenarios (A) and (B), while other energy devices, such as refrigerators and TVs, are installed in the same way in both scenarios.

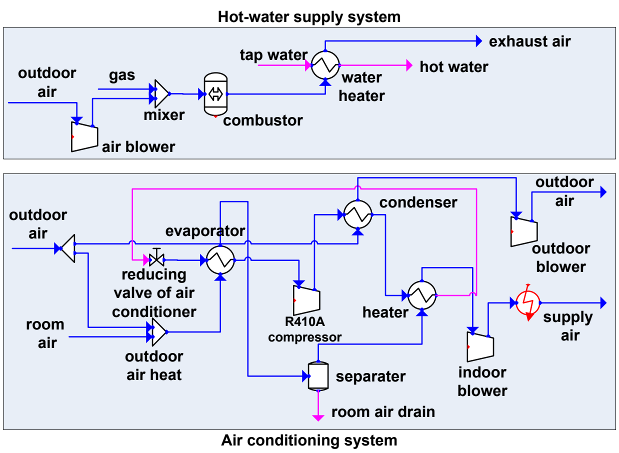

Fig. 2: Configuration of energy systems in Scenario (A)

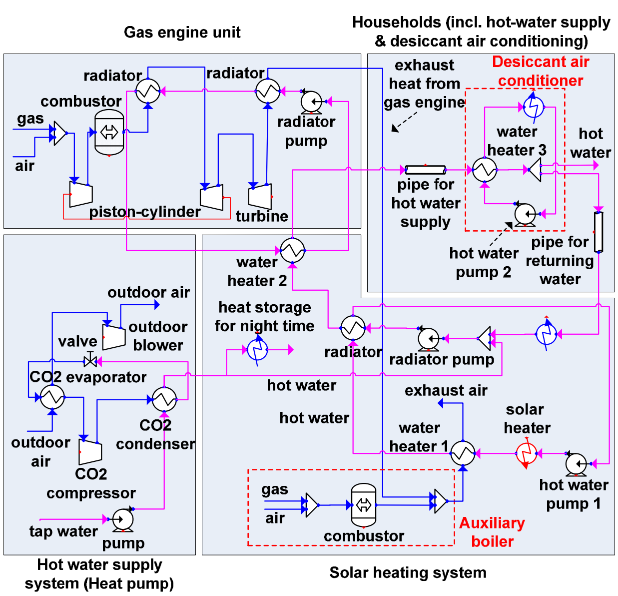

Fig. 3: Configuration of energy systems in Scenario (B)

Table 1 depicts an overview of each scenario in the three levels. Scenario (B) introduces gas engine, desiccant air conditioner, hot water supply system (heat pump), and solar heating system (see Fig. 3). The auxiliary boiler, a part of the solar heating system, is used when solar heat is not enough in, *e.g.*, cloudy days. Table 2 summarizes specifications of system components used in Scenario (B).

4.2 Simulation results of each scenario

Fig. 4 and Fig. 5 describe Sankey diagrams of Scenarios (A) and (B). As shown in Fig. 4, the exergy efficiency of the hot-water supply system (boiler) and air conditioning system (heat pump) in Scenario (A) is 0.9% and 12.5%. The sum of the exergy loss of evaporator, compressor, and condenser amounts to 72.9% in the air conditioning system.

In Scenario (B), electric power generated by gas engine is 393.9kW (rated output), while the power consumption by the cooling and heating systems shown in Fig. 3 is 74.6kW (see Table 3). In other words, the net power generation of CGS is 319.3kW (= 393.9 - 74.6), which is available for energy devices other than cooling and heating systems. The results of Fig. 5 indicate that the overall efficiency of the gas engine unit is 47.2% (power: 42.2%, hot water: 5.0%), while its exergy loss mainly arise in combustor and radiator (47.2%). The efficiency of hot-water supply system is 21.2%. In the solar heating system and households, the solar heater contributes to 4.3% as input exergy.

The comparison of primary energy input between Scenarios (A) and (B) is summarized in Table 4. Note that this comparison assumes that the power consumption by energy devices except for cooling and heating systems is 319.3kW so that the two scenarios become comparable. That is, since CGS provides extra power of 319.3kW in Scenario (B), we impose the same load on the primary power consumption of Scenario (A). In this case, the primary energy consumption of Scenario (B) (1,019.7kW) achieves 25.4% reduction from that of Scenario (A) (1,367.7kW).

4.3 Discussions on the results

The comparison between Scenarios (A) and (B) reveals that, as depicted in Table 4, Scenario (B) is more energy

Table 3: Power consumption and generation by cooling and heating systems of the apartment building

Item	Scenario		Remarks
	A	B	
Power consumption (kW)	77.4	74.6	Needed power for operating cooling and heating systems.
Power generation (kW)	0	393.9	Supplied power from the energy systems in the apartment building.

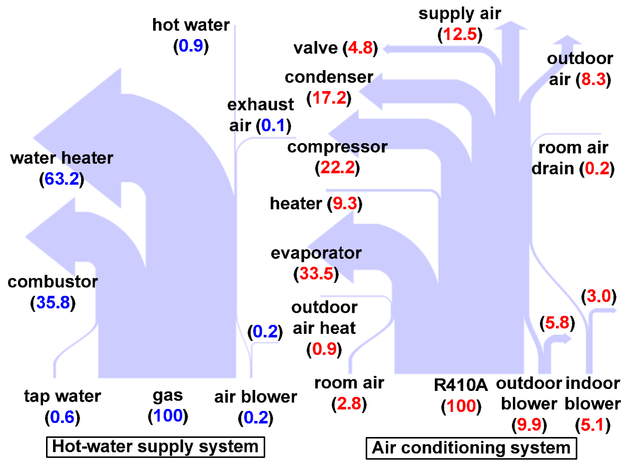

Fig. 4: Sankey diagram for Scenario (A)

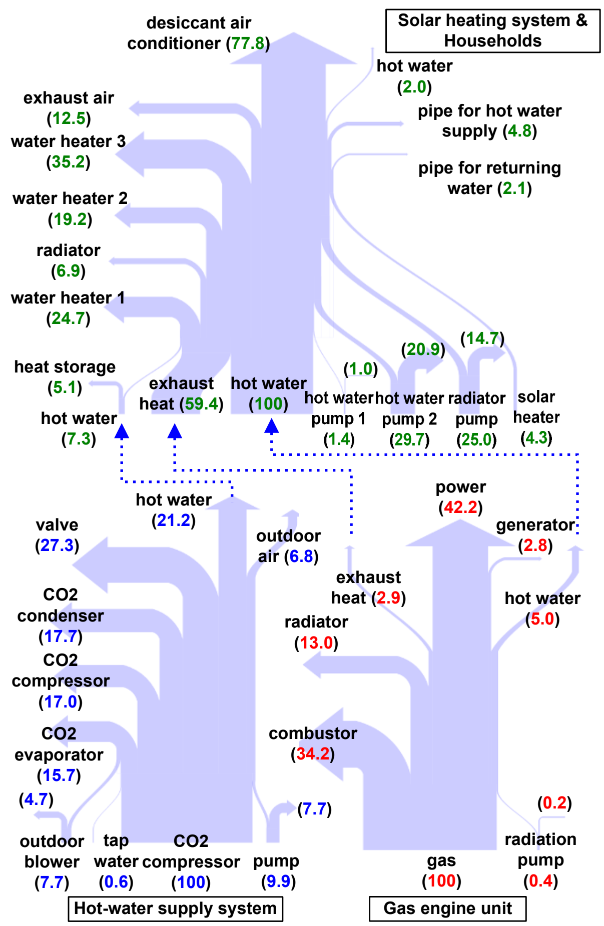

Fig. 5: Sankey diagram for Scenario (B)

efficient in terms of primary energy input. CSG of Scenario (B) does not generate much heat loss by the gas engine even in summer regardless of what existing studies on CGS pointed out (*e.g.*, [2]). Reasons for this improvement include (1) introducing a highly-efficient gas engine for apartment buildings (efficiency: 41.5%), (2) employing desiccant air conditioners, which requires much heat (77.8%, see Fig. 5) for operation, instead of conventional ones, and (3) installing solar heating systems on the rooftop. To make the energy system of Scenario (B) more efficient, the result depicted in Fig. 5 indicates that exergy loss of CO2 condenser, compressor, and evaporator should be reduced. In Scenario (B), while the hot water demand in this case study is 24.0m^3/h, extra hot water of 0.03m^3/h (see Table 4) is stored in the heat storage for night time, *e.g.*, for taking a shower after work.

Table 4: Comparison of primary energy consumption

Item	Scenario A	Scenario B	Remarks
Primary gas, power, and water input to the apartment building			
Primary gas consumption (kg/h)	19.2	66.9	
Primary power consumption (kW)	77.4	0	Used for cooling and heating
	319.3	0	Used for energy devices except for cooling and heating systems
Water (m^3/h)	24.00	24.03	
Primary energy consumption in the apartment building (in higher heat value; HHV)			
Gas (kW HHV)	292.7	1,019.7	HHV of gas:45MJ/Nm^3
Power (kW HHV)	1,075.1	0.0	Conversion efficiency of electric power: 36.9%
Total (kW HHV)	1,367.7	1,019.7	

However, Scenario (B) consumes 3.5 times larger amount of gas than Scenario (A). This implies that Scenario (B) might not be cost-effective in a long run. For further analyses of the scenarios described in the cases study, we should assess, at least, costs (including fixed and running costs) and CO2 emissions of each scenario. This is one of our future works. Another problem is that this case study presents only two scenarios. To expand a range of possible images of future energy systems, we should design a wide variety of alternative scenarios based on the proposed framework. In this context, we also should create several scenario variants from Scenarios (A) and (B) by changing assumptions. For example, by modifying assumptions in regional level, we can examine different lifestyles or different regions to install energy systems as scenarios. We are planning to design various scenarios in accordance with various configurations of energy systems as well as various social, political, and economic systems, using Scenarios (A) and (B) as a prototype.

5 CONCLUSIONS

This paper presented a framework for describing scenarios of various energy systems, classifying scenario elements into three levels – social, regional, and technological levels. Base on this framework, we described two scenarios called (A) BaU Scenario and (B) CGS Scenario in order to analyze the effect of introducing cogeneration systems (CGS). The results revealed that CGS is a promising means for improving energy efficiency as it provides both power and heat. In particular, it was indicated that there is a possibility of saving primary energy consumption by installing desiccant air conditioner together with CGS. Future works include:

- Conducting further analyses on CGS, such as assessing the described scenarios from the viewpoints of cost and CO2 emissions.
- Designing a variety of scenarios by assuming various configurations of energy systems as well as social, political, and economic systems.
- Developing system for supporting scenario design by connecting 3S Simulator and VMGSim.

Abstract

Exergy evaluation system with cloud computing technology has been developed for anyone to perform exergy analysis on a homepage for various energy conversion systems, such as gas engine, desiccant air conditioner, and fuel cell, etc. In this system, parameter studies on each system can be conducted on the homepage, changing initial conditions. The calculation results are obtained in the form of some tables, graphs, and sankey diagrams so that users can experience a process of minimized exergy loss without any paid software. To provide an example of exergy design, SOFC (Solid Oxide Fuel Cell) cogeneration system for domestic use is described. The results show that exergy loss of the cell stack and some heat exchangers are mainly reduced, increasing power generation efficiency by the fuel utilization ratio.

Keywords: Exergy, Energy conversion system, SOFC, Process simulation, Cloud computing

1 INTRODUCTION

The accident of the nuclear power plant triggered the increasing of energy concern, so that the development of cogeneration system and renewable energy technology of solar heating and wind power are accelerating. The improvement of total system efficiency and cost reduction are important to popularize the cogeneration and natural energy system in addition to the improvement of each component efficiency. Thus, the exergy have been attracting attention to evaluate energy quality and to specify the energy waste in system.

Exergy is defined by using second law of thermodynamics, and can evaluate the thermal energy as equivalent energy of power. The system evaluation can be achieved by use of exergy, considering the energy quality difference of natural and fossil energy. Furthermore, exergy can evaluate loss based on a increase of entropy, which enthalpy cannot evaluate. The system design method to minimize these exergy loss is called “exergy design”. It is superior in terms of identification of devices that should be improved in an energy conversion system. The exergy was attracting attention several times [1][2], but exergy has not been widely popular, because great procedure is required to perform exergy analysis and exergy efficiency is smaller than enthalpy efficiency in most energy conversion system. However, it is easy to conduct an exergy analysis with developing computational devices and process simulator

In this study, the exergy analysis for the various energy conversion system to popularize the exergy design [3]. In this paper, the exergy design concept was described, and the exergy design was conducted for SOFC (Solid Oxide Fuel Cell) cogeneration system of domestic use. Finally, exergy evaluation system, which can perform exergy design for various energy conversion system on the homepage, was introduced.

2 EXERGY ANALYSIS AND DESIGN CONCEPT

Enthalpy is generally used to evaluate performance of energy conversion system, considering first law of thermodynamics. The energy defined by first law of thermodynamics is always preserved. On the other hand, exergy is defined as the maximum work that can be done by the system and a specified reference environment. The exergy of a system or a stream is composed of physical and chemical exergy.

$$E = E_c + E_p = E_c + (H - H_0) - T_0 (S - S_0), \qquad (1)$$

where E is exergy, E_c is chemical exergy, E_p is physical exergy, H is enthalpy, S is entropy, T is absolute temperature, subscript 0 is reference state, respectively.

The difference of enthalpy and exergy analysis are shown to consider heat transfer process in a heat exchanger. The input and output of enthalpy and exergy are a following relationship without heat loss from the heat exchanger,

$$\sum H_{in} - \sum H_{out} = 0, \qquad (2)$$

$$\sum E_{in} - \sum E_{out} = EL \geq 0, \qquad (3)$$

where EL is exergy loss, subscript in and out are input and output, respectively. The total of enthalpy is always preserved, but that of exergy is not preserved due to irreversible process of heat transfer.

Figure 1 shows schematic diagram of a heat exchanger for enthalpy and exergy analysis. The working fluid is water, the input water pressure is atmosphere, flow rate is

Stream	F[kg/h]	T[°C]	H[W]	E[W]
IN_1	1.0	90.0	104.7	7.22
IN_2	1.0	40.0	46.6	0.42
OUT_1	1.0	70.0	81.4	3.59
OUT_2	1.0	60.1	69.9	2.22
(Input - Output)	---	---	0.0	1.83

Table 2 Comparison of enthalpy and exergy evaluation.

Contents	Energy conversion criteria	
	Enthalpy	Exergy
Energy amount	○	○
Energy quality	×	○
Reference state	×	○
Pressure evaluation	×	○
Composition evaluation	×	○
Exhaust gas and heat loss	○	○
Mixing loss	×	○
Combustion loss	×	○
Rotation loss	×	○
Heat transfer loss	×	○
Decompression loss	×	○

1.0 kg/h. The pressure drop of the heat exchanger is not considered. The reference state is temperature of 25 °C and atmosphere pressure.

Table 1 shows calculation results. The total of enthalpy is preserved, but that of exergy is not preserved. The exergy loss of 1.83 W occurred in the heat exchanger.

Table 2 shows the comparison of enthalpy and exergy analysis. Enthalpy can consider amount of energy and exhaust loss, but cannot consider the quality of energy, composition, etc. Exergy can evaluate all terms including amount of energy, energy quality, composition, irreversible process loss of combustion, mixing, decompression, etc.

Figure 2 shows PDCA (Plan-Do-Check-Act) cycle of exergy design. First, a target system is modeled (Plan: Process modeling). Secondly, exergy analysis is done to evaluate the exergy loss of each device and exergy efficiency(Do: Exergy analysis). Then, a scheme minimizing the exergy loss is devised from the result of exergy analysis (Check: Loss evaluation). Finally, the scheme is done if there is a potential to get a return of investment. Consequently, that PDCA cycle is repeated, so that the system efficiency is improved. Designers without exergy design improve a system, considering similar process unconsciously. The exergy design is effective to quantify and visualize the system loss that can not be visualized using enthalpy analysis.

Fig.2 PDCA cycle of exergy design.

3 CLASSIFICATION OF ENERGY SYSTEM

The exergy evaluation system [5] for 5 classification energy conversion system has been developed in our homepage to popularize exergy design, using process simulator [4] and cloud computing system. Cloud computing is the delivery of computing over network or internet, whereby users can use a software or service without installing any software in a local computer. The detail of exergy evaluation system is described later. The released exergy evaluation systems are listed bellow;

- Classification A : Cogeneration system with town gas
  - Gas turbine
  - Gas engine
  - Fuel cell (SOFC: Solid Oxide Fuel Cell)
- Classification B: Power generation system from thermal heat
  - LNG power generation system
  - Rankine cycle system
- Classification C: Heat supply system of hot water and air heating
  - Gas hot-water heater
  - Heat pump heater with natural refrigerant
  - Vapor re-compression (Future plan)
- Classification D: Air conditioning
  - Air conditioner
  - Desiccant air conditioner
- Classification E: Natural energy utilization
  - Water spray cooling

In addition these system, the physical property estimation software with thermodynamics and physical property software [6] has been released on our homepage. This software allow the user without any paid software installation get physical property of natural gas, hydrogen, oxygen and nitrogen, carbon oxide, and carbon dioxide, etc.

4 EXERGY ANALYSIS OF SOFC SYSYTEM

To provide an example of exergy design with our homepage, the exergy analysis of fuel cell cogeneration is introduced. The target fuel cell is SOFC. The operation temperature of SOFC is as high as 600-900 °C, so that SOFC can operate without noble metal catalyst.

Furthermore, fuel can be reformed with thermal exhaust heat, and carbon oxide can be used as fuel. SOFC has been expected to use as electric power generation of a combined cycle and coal gasification system in the past, but the development of SOFC for the cogeneration system of home appliance is recently accelerating.

The exergy analysis is carried out for SOFC of which generation capacity is 700 W. The exergy analysis of a large scale device SOFC [6]-[8] has been performed, but there are few studies in terms of a minimized exergy loss. Figure 3 shows the schematic diagram of SOFC cogeneration.

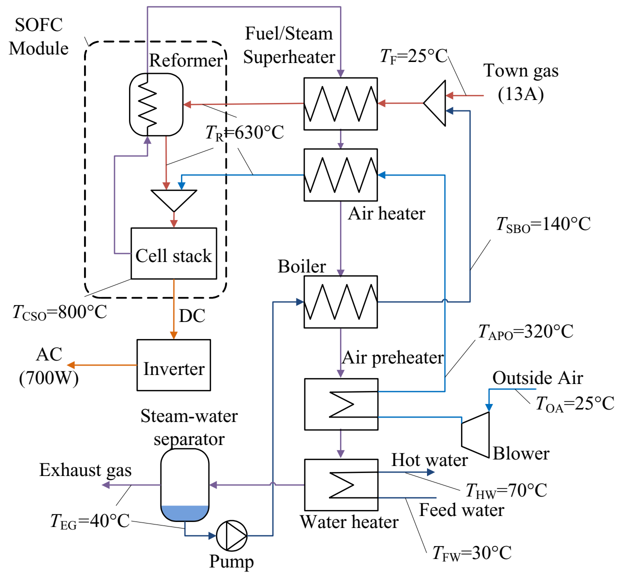

Fig.3 Schematic diagram of SOFC cogeneration system.

In this system, town gas (13A) is reformed to generate hydrogen and carbon oxide in the reformer. Then, hydrogen and carbon oxide are reacted on the electrode in the cell stack to generate power. The unreformed town gas in the reformer can be reformed in the cell stack to generate hydrogen, so that the reform efficiency of town gas in the SOFC module is approximately 100 %. DC electricity from the cell stack is converted into AC with the inverter. The hot exhaust gas from the cell stack is used for absorption heat of reformer and for heating source of fuel, air, and water. The water used for steam-reforming reaction is obtained from water in the exhaust gas. Thus, the SOFC can operate without supply of outside water.

The SOFC model is calculated using the process simulator [4]. The water flow used for fuel reforming is determined using steam to carbon ratio *S/C*,

$$F_{H_2O} = S/C \times \left(F_{CH4} + 2F_{C2H6} + 3F_{C3H8} + 4F_{C4H10}\right), \qquad (4)$$

where *F* is mole flow [kgmole/h].

The fuel reforming is calculated, using steam reforming reaction (R1) and water gas shift reaction (R2) at a given reforming temperature,

$$C_nH_{2(n+1)} + nH_2O = nCO + (2n+1)H_2, \qquad (R1)$$

$$CO + H_2O = CO_2 + H_2. \qquad (R2)$$

For the simplicity, the equilibrium calculation is conducted with (R1) and (R2) for initial fuel composition, where all composition except methane are completely reacted using reaction (R1), in order to estimate fuel composition after fuel reforming.

The electric generation reaction of hydrogen and carbon oxide at electrode in the cell stack is given,

$$H_2 + \frac{1}{2}O_2 \rightarrow H_2O, \qquad (R4)$$

$$CO + \frac{1}{2}O_2 \rightarrow CO_2. \qquad (R5)$$

The methane that is not reformed in the reformer is reacted before the calculation of the electric generation (R4) and (R5). The consumption amount of hydrogen and carbon oxide in the reaction (R4) and (R5) is determined, using fuel utilization ratio U_f,

$$U_f = \frac{(F_{H2})_{ele}}{F_{H2}} = \frac{(F_{CO})_{ele}}{F_{CO}}, \qquad (5)$$

where $(F_{H2})_{ele}$ and $(F_{CO})_{ele}$ are the consumption flow rate [kgmole/h] of hydrogen and carbon oxide, respectively.

The power generation efficiency of SOFC η_{AC} is defined, assuming that fuel is methane,

$$\eta_{AC} = \eta_{DC} \times \eta_{inv} = \frac{\Delta G_{H2} \times 4}{\Delta H_{CH4}} \times \eta_{ref} \times U_f \times \frac{V}{V_0} \times \eta_{inv}, \qquad (6)$$

where η_{AC} is power generation efficiency, ΔG_{H2} is Gibbs free energy of hydrogen at a given operation temperature of the cell stack, ΔH_{CH4} is heat of formation [kcal/kgmole HHV] of methane at the fuel supply temperature 25 °C, η_{ref} is the fuel reforming efficiency, V_0 is theoretical voltage [V], V is operation voltage [V], η_{inv} is the inverter efficiency. The fuel reforming efficiency is a hundred percent, because it is assumed that methane unreformed in the reformer is reformed in the cell stack. The theoretical voltage is defined as the following equation,

$$V_0 = \frac{-\Delta G_{H2}}{\left(4.60984 \times 10^4\right)}. \qquad (7)$$

The theoretical voltage is 0.98 V at the operation temperature of 800°C.

The hydrogen and carbon oxide that are not reacted in (R4) and (R5) are converted into water and carbon dioxide though the combustion reaction.

Table 3 shows the calculation conditions. The air to fuel ratio is 23, operation voltage is 0.75 V, operation temperature is 800 °C, heat loss to higher heating value of fuel is 0.05 [W/W HHV], the inverter efficiency is 0.90, reforming temperature is 630 °C. The input fuel and fuel utilization ratio are set as 1700 W and 0.70 to reproduce

η_{AC} of 41 % HHV at the power generation of 700 W that is corresponding to the rated operation condition of the typical SOFC cogeneration for home appliance. Table 4 shows fuel composition of town gas (13A). The town gas is composed of methane, ethane, propane, and isobutane.

Exergy of streams shown in Fig.3 are defined by equation (1). The temperature and pressure at the reference state are 25 °C and ambient pressure, respectively. The chemical exergy is estimated using the following equation,

$$E_c = \sum_i \left(E_i^{\circ} \times F_i \right), \qquad (8)$$

where E° is standard chemical exergy [kcal/mole], subscript i indicates chemical component shown in table 5.

Figure 4 (a), 4 (b) shows the enthalpy and exergy sankey diagrams illustrated from calculation results. The enthalpy sankey diagram of Fig. 4 (a) shows that electricity efficiency is 40.9 % HHV, the thermal recovery efficiency (Hot water) is 37.8 % HHV, so that total efficiency is 78.7% HHV. Enthalpy analysis can evaluate the exhaust gas loss, heat loss, and inverter loss. The highest loss is the exhaust gas of 11.9 %. The exergy sankey diagram of Fig. 4(b) indicates exergy loss of cell stack, reformer, fuel and steam mixing, every heat exchanger in addition to loss evaluated by enthalpy analysis. The highest exergy loss occurs at the cell stack of 19.8%. The exergy loss of the reformer is 2.5%, which is much smaller than that of the cell stack. This is because the chemical exergy is regenerated in the process of the fuel reforming by use of the physical exergy of the exhaust gas from the cell stack.

To improve the cell stack performance for reduction of the exergy loss, high fuel utilization rate and heat loss reduction are desirable [9]. In this study, the exergy analysis is performed with varying the fuel utilization ratio from 0.70 to 0.90 for the fixed heat loss ratio. There is increase in the amount of electricity as the fuel utilization

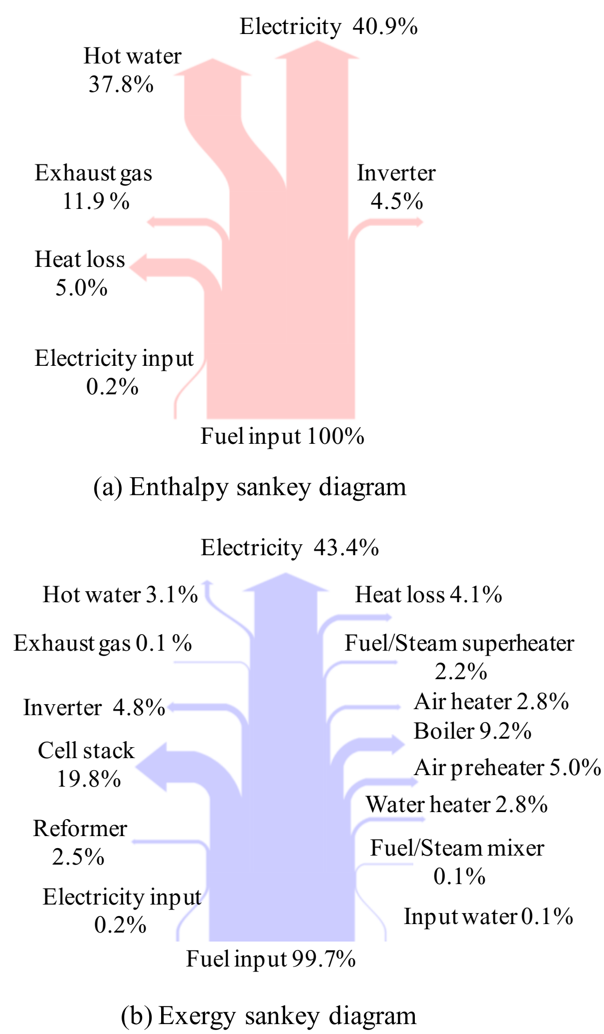

Fig.4 Sankey diagram.

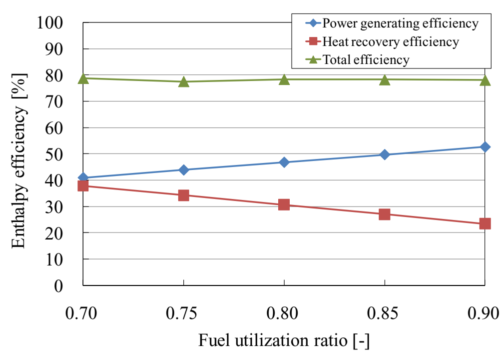
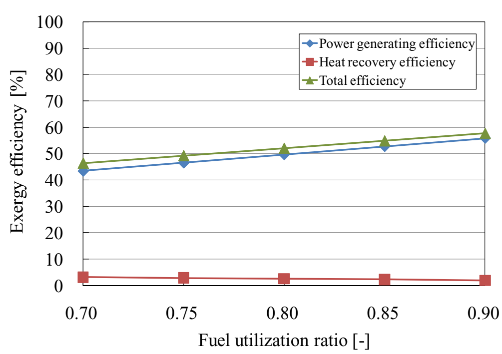
rate increases. Thus, the amount of the input fuel is varied to maintain the amount of electricity of 700 W.

Figure 5 shows the effect of the fuel utilization ratio on power generation, heat recovery, and total efficiency. Figure 5 (a) is the result of enthalpy analysis, while Fig. 5 (b) is that of exergy analysis. The total efficiency of the enthalpy analysis is almost the same value 79% with increasing the fuel utilization ratio, but the total efficiency



(a) Enthalpy analysis



(b) Exergy analysis

Fig. 5 Effect of the fuel utilization ratio on generation, heat recovery, and total efficiency.

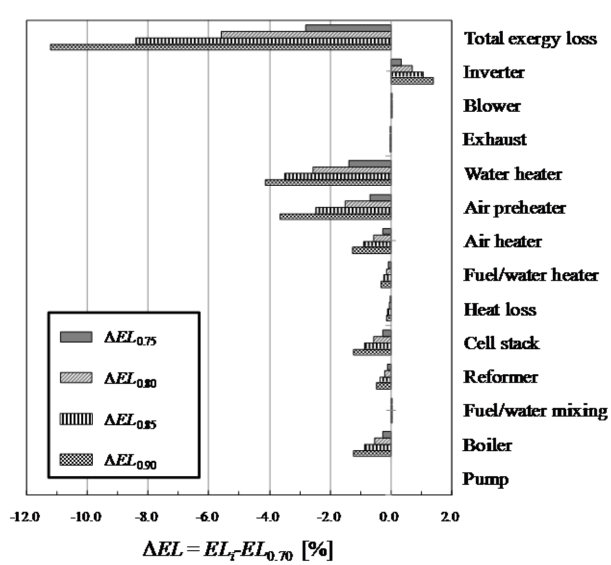


Fig. 6 Effect of fuel utilization on exergy loss.

of the exergy analysis is increased with increasing the fuel utilization ratio. When the power generation efficiency is increased, the heat recovery efficiency is decreased without relying on the analysis method. But the thermal heat of hot water has low quality of energy, so that there is increase in total efficiency of exergy as power generation efficiency increases.

The amount of exergy loss change is shown in Fig. 6 in order to specify which exergy loss are decreased with increasing the fuel utilization. The amount of exergy loss change is defined,

$$\Delta EL_j = EL_j - EL_{0.70} \quad (9)$$

where ΔEL is the amount of exergy loss change, $EL_{0.70}$ is exergy loss at the fuel utilization ratio of 0.70, subscript j indicates fuel utilization ratio of 0.75, 0.80, 0.85, and 0.90.

Figure 6 shows ΔEL of total exergy loss at fuel utilization ratio of 0.90 is dropped to 11.1%. This is achieved mainly by the exergy loss change of the heat exchangers of the water heater, air preheater, air heater, and boiler in addition to that of the cell stack. Therefore, this figure indicates that heat transfer performance of heat exchangers should be improved to increase fuel utilization ratio.

5 CLOUD COMPUTING SYSTEM FOR EXERGY EVALUATION

Figure 7 shows that the screenshot of our homepage for the SOFC cogeneration system that is developed in Japanese. Users input initial conditions and push calculation start button to get calculation results of a result table, enthalpy and exergy sankey diagrams, and some graphs, while graphs are not installed in the calculation page of SOFC.

Figure 8 shows the schematic diagram of cloud computing system for enthalpy and exergy analysis. Users push calculation start button, WEB server performs enthalpy and exergy analysis with the initial condition that users input, calling the process simulator via excel. The calculation load occurs at WEB server, not local computers of users. To realize this system, ASP.NET with IIS (Internet Information Service) is installed in WEB server. The sankey diagram is illustrated at user's local computer with Microsoft®Silverlight™. The connection between local computer and WEB server is conducted by asynchronous communication with AJAX (Asynchronous JavaScript and XML) in order to update only an essential portion in the page for improve of user availability. The calculation time from calculation start to displaying result is a few second. By the use of this system, the exergy analysis for various energy conversion system can be achieved, without any paid software, from local computer and Smartphone in which web browser of internet explorer and Firefox, etc. is installed.

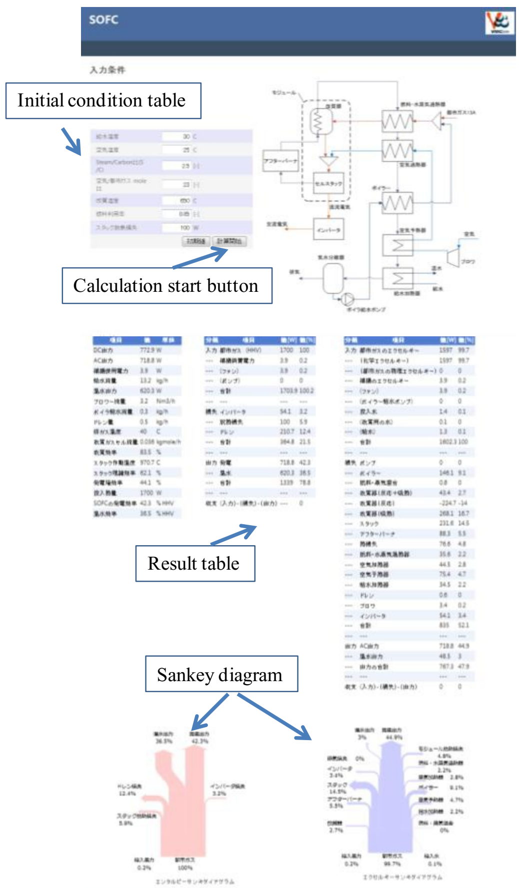

Fig. 7 Screenshot of exergy evaluation system for SOFC.

6 SUMMARY

In this study, the exergy analysis for various energy conversion system has been conducted to popularize a system development with exergy design. Thus, the exergy evaluation system on our homepage has been developed and released using a cloud computing technology for anyone to use exergy analysis program that we developed. In this paper, the exergy analysis of SOFC cogeneration system for home appliance is descried to provide the example of exergy analysis by use of exergy conversion system on our homepage. The result shows that the maximum exergy loss occurs at the cell stack. To minimize the exergy loss of the cell stack, the calculation is performed with varying the fuel utilization ratio. The results show that the exergy loss of the cell stack and some heat exchangers are reduced with increasing fuel utilization ratio. This indicates that heat transfer performance of some heat exchangers should be improved to increase fuel utilization ratio. In the future, we are going to increase the number of the energy conversion system that can perform exergy analysis on the homepage, and to develop English version of our homepage. Furthermore we will develop the energy conversion system, using exergy design.

[1] Osaka Gas Co., Ltd., Osaka, Japan

Abstract

In this paper, we report the outline of the Senboku LNG terminals, with a focus on Terminal 1, and the facilities using the LNG cold. In addition, by evaluating the efficiency of the facilities in terms of exergy, we consider the vision to improve utilization of LNG cold.

Keywords:

LNG Terminal, LNG Cold, Exergy, CO_2

1 INTRODUCTION

1.1 Increase in global demand for LNG

These days, it has been required to reduce the amount of CO_2-emission in every business. Natural gas (NG) has been more and more important because it emits, when burned, less CO_2 than other kinds of fossil fuel such as oil and coal.

There are two ways to transport NG. One way is to transport NG through pipelines from a production site to a city. Another way is to liquefy NG in a production site and then transport the Liquefied Natural Gas (LNG) by tankers offshore. About 28% of NG consumed is transported in the latter way. In recent years, more and more LNG has been transported to many countries around the world[1]. Fig. 1 shows what percentage of global trade volume of NG each of the two transportation ways account for in 2009. Fig. 2 shows what percentage of global import volume of LNG each country account for in 2009. Fig. 3 shows the trend in global trade volume of LNG from 1999 to 2009.

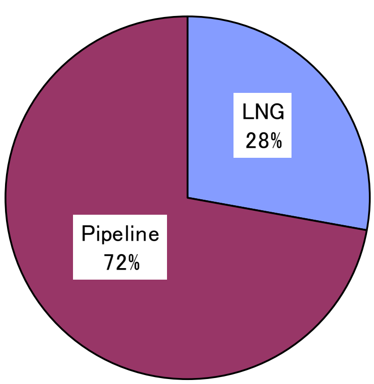

Fig. 1: The percentage of global trade volume of NG which each of the two transportation ways accounts for in 2009 [1].

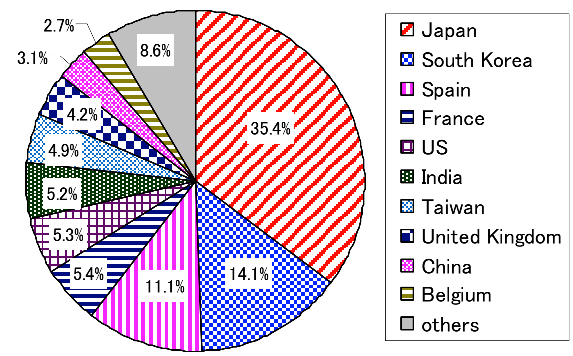

Fig. 2: The percentage of global import volume of LNG which each country accounts for in 2009 [1].

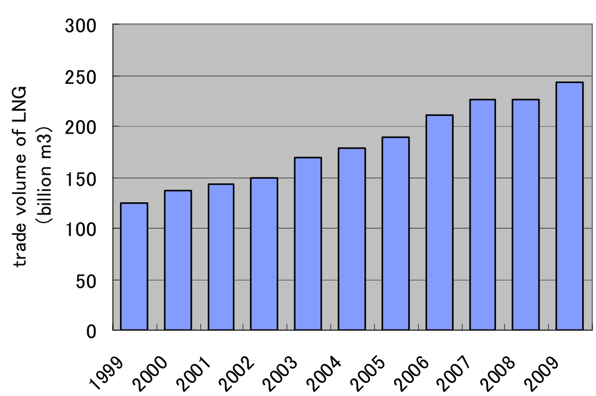

Fig. 3: The trend in global trade volume of LNG from 1999 through 2009 [1].

1.2 Cold energy of LNG

The temperature of LNG is approximately -160 degrees Celsius with higher energy density than that of wind

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_30, © Springer Science+Business Media Dordrecht 2012

power or solar energy. We can reduce electric power for cooling a substance when we cool it by heat exchange with LNG. We call this way "LNG cold energy utilization". When LNG is composed of Methane 89vol%, Ethane 6vol%, Propane 4vol% and Butane 1vol%, for example, available chemical energy of LNG is 14,400kWh/LNG-t and available cold energy of LNG is 240kWh/LNG-t(that is equal to approximately 2% of the chemical energy) [2]. If we aim at energy saving, it is essential to make effective use of the cold energy in addition to the chemical energy.

Today, Japan, which imports over 60 million tons of LNG a year (that is approximately 35% of total imports in the world [Fig. 2]), is the world's biggest importer of LNG. If we could convert about 15% of the cold energy of LNG annually imported into electricity, the amount of the electricity would be equal to the power consumed by about 400 thousand houses for a year [3].

2 THE FEATURES OF OSAKA GAS' LNG TERMINALS

2.1 Introduction of Osaka Gas

Osaka Gas is one of the city gas companies in Japan and started to import LNG in 1972. Today Osaka Gas has long-term contracts with 6 countries, namely Brunei, Indonesia, Malaysia, Australia, Qatar and Oman, and imports about 7 million tons of LNG from those countries and others in 2010. Osaka Gas will newly start to import LNG from Russia in 2011, and from Papua New Guinea in 2013 by long-term contracts.

Osaka Gas has three LNG terminals, namely Senboku LNG Terminals (Terminal 1 and Terminal 2) and Himeji LNG Terminal. Osaka Gas supplies city gas, which is produced in these three terminals, to about 7 million customers in the 6 prefectures of Kansai Region [Fig. 4].

2.2 Utilization of LNG cold energy in Osaka Gas

In Senboku LNG Terminals (Terminal 1 and Terminal 2) and Himeji LNG Terminal of Osaka gas, we make good use of LNG cold energy with many types of facilities, including plants such as air liquefaction and separation [Fig. 5], carbon dioxide liquefaction [Fig. 6], cryogenic power generation, and BOG re-liquefaction with cold energy storage system [Table. 1]. For example, the air liquefaction and separation plant with LNG cold energy has saved 50% of the amount of electric power consumed in other plants without LNG cold energy.

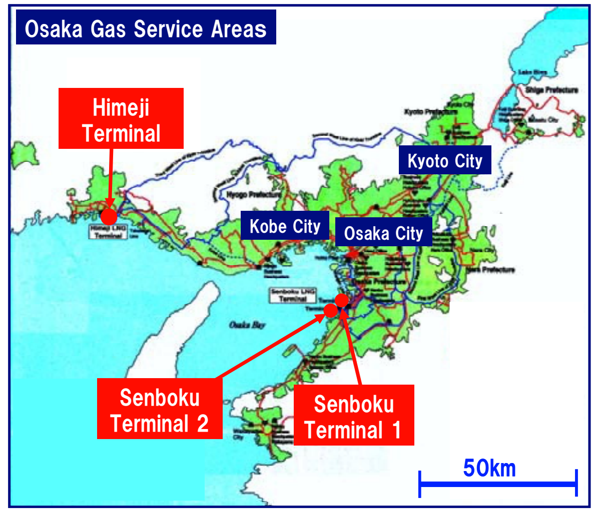

Fig. 4: Osaka Gas service areas.

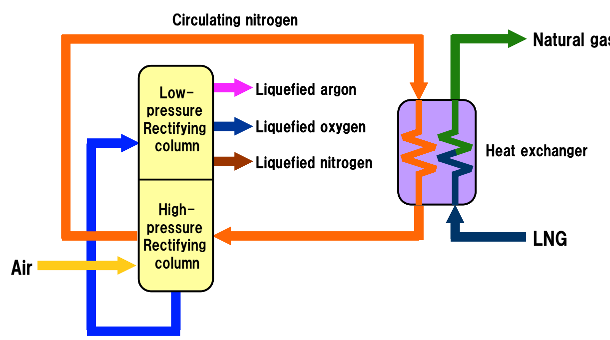

Fig. 5: Flowchart of the air liquefaction and separation facility using LNG cold energy.

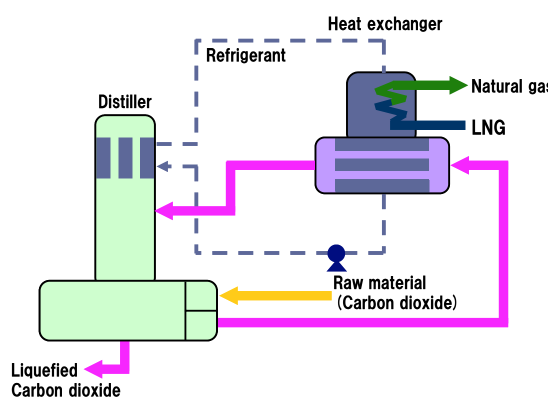

Fig. 6: Flowchart of the carbon dioxide liquefaction facility using LNG cold energy.

Table. 1: The facilities using LNG cold energy in each LNG terminal of Osaka Gas.

Senboku Terminal 1			
The facility using LNG cold	Start of operation	Installation site	The LNG cold utilization rate*
Air-condition with LNG cold	1978	in the terminal	approximately 100 %
Carbon dioxide liquefaction	1980, 2004	in the terminal	
Warm water chilling	1987	in the terminal	
Brain chilling	1987	in the terminal	
Expansion turbine	1989	in the terminal	
Air liquefaction and separation	1993	in the terminal	
Ethylene plant	2011	in a neighboring factory	

Senboku Terminal 2			
The facility using LNG cold	Start of operation	Installation site	the LNG cold utilization rate*
Cryogenic power generation	1979, 1982	in the terminal	approximately 50 %
Air liquefaction and separation	1983	in the terminal	
BOG re-liquefaction with cold energy storage system	1997	in the terminal	

Himeji Terminal			
The facility using LNG cold	Start of operation	Installation site	the LNG cold utilization rate*
Cryogenic power generation	1987	in the terminal	approximately 50 %
Expansion turbine	2000	in the terminal	
Intake air cooler	2004	in the terminal	

*This is the ratio of the volume of LNG vaporized at facilities using LNG cold to total volume of vaporized LNG in each terminal.

In Terminal 1 (Senboku LNG Terminal 1), in particular, we have achieved effective use of LNG cold energy, connecting the plants with those of neighboring factories, taking advantage of the location in industrial complex.

2.3 Efforts towards advanced utilization of LNG cold energy in Senboku LNG Terminal 1

Fig. 7 shows the outline of the utilization of LNG cold energy in Terminal 1. In every vaporization processes shown in Fig. 7 except for Open Rack Vaporizer (ORV), we can use LNG cold energy effectively. However, in ORV, we can't use it because LNG cold is wasted to sea by heat exchange with sea water.

In Terminal 1, in January 2011, we started to supply LNG cold to the neighboring factory's ethylene plant [Fig. 8] and this has enabled us to save energy and reduce CO_2-emission considerably with some improvements on operation in Terminal 1. As a result, we could accomplish the 100% (volume-based) utilization of LNG cold in Terminal 1. This means that now we don't have to use sea water to produce city gas in Terminal 1.

Thanks to the electric power reduction through this use of LNG cold energy, the amount of CO_2 reduction for a year in Terminal 1 has reached about 113 thousand ton. This amount of CO_2 is equivalent to that of CO_2 absorbed by coniferous forest in the area of one-quarter of Kyoto city.

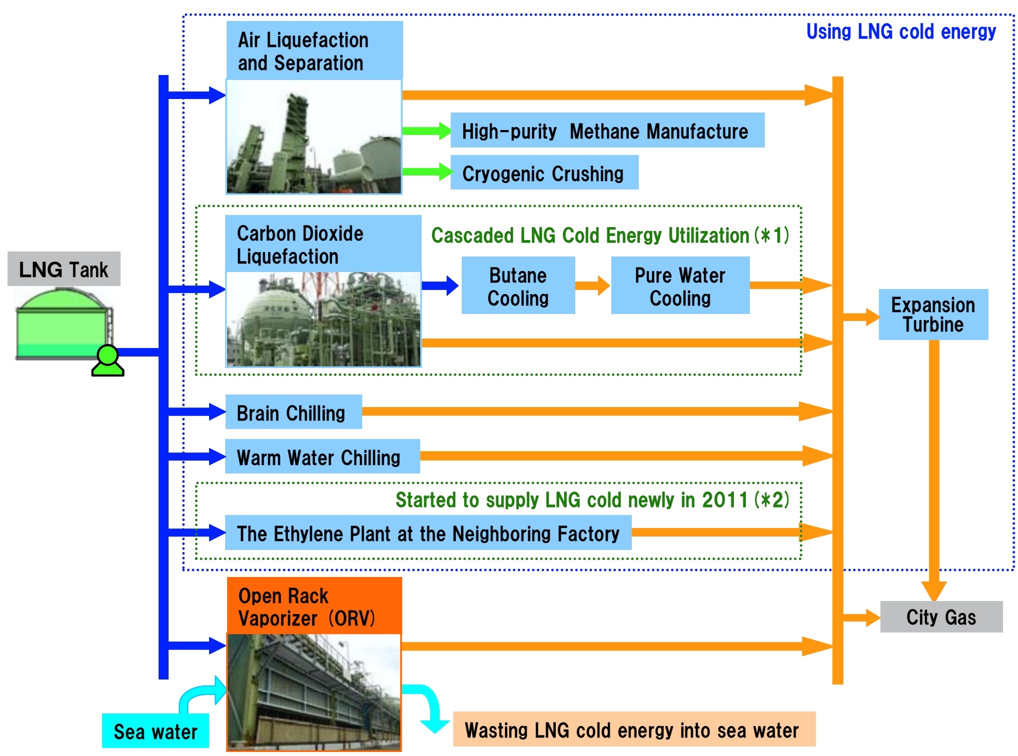

Fig. 7: The outline of the utilization of LNG cold energy in Terminal 1.

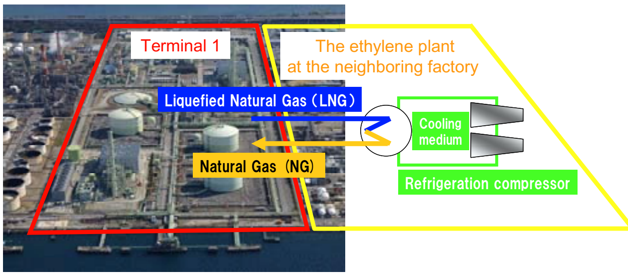

Fig. 8: LNG cold supply from Terminal 1 to the ethylene plant at the neighboring factory.

3 EVALUATION OF LNG COLD ENERGY FROM A NEW STANDPOINT

3.1 Application of exergy-based evaluation

In the past, we've evaluated the utilization of LNG cold energy in terms of volume (the ratio of the volume of LNG vaporized at facilities using LNG cold to total volume of vaporized LNG), because this way of thinking is simple to understand. However, in order to make more efficient use of LNG cold energy, we need to improve the quality of the utilization of LNG cold energy. So, in this paper, we try to evaluate the quality of the energy by applying exergy-based evaluation.

The exergy of a system is the maximum useful work possible during a process in which the system reaches the condition for equilibrium with environment. This is expressed in the following formula [formula. 1].

$$E = (H - Ho) - To(S - So) \qquad \text{[formula. 1]}$$

E : the value of the exergy

H : the value of the enthalpy

S : the value of the entropy

T : the Temperature

The variable with subscript 'o' means the value 'on the condition for equilibrium with environment'

By applying exergy-based evaluation, we can evaluate not only heat energy but also energy as pressure of LNG cold [4].

In 3.2 and 3.3, we report the case of evaluating the efficiency of LNG cold utilization in Teminal 1 in terms of exergy.

3.2 Evaluating the efficiency of the facilities using LNG cold in terms of exergy

"Exergy efficiency" is considered to be one of the indicators representing how efficient LNG cold is transferred to the targeted material [4]. In this paper, we define "20 degrees Celsius (Temperature), 101.3kPa (Pressure)" as the condition for equilibrium with environment. Under the condition, we calculate the exergy efficiency of existing facilities using LNG cold in Terminal 1 or supplying LNG cold to the ethylene plant [Fig. 9]. Exergy efficiency is defined as below [formula. 2].

$$\eta^i = \frac{\Delta E^i{}_{user}}{\Delta E^i{}_{LNG}} \times 100 \qquad \text{[formula. 2]}$$

η^i : the exergy efficiency of the facility i (%)

$\Delta E^i{}_{user}$: amount of the exergy the targeted material obtains at the facility i $(kWh/LNG-t)$

$\Delta E^i{}_{LNG}$: amount of the exergy of LNG cold energy consumued at the facility i $(kWh/LNG-t)$

The bottom of the fraction [formula. 2] represents the value when the exergy of LNG at outlet of the facility is subtracted from that at inlet of it. The top of the fraction [formula. 2] represents the value of the exergy which the targeted material obtains in the facility. Table. 2 shows the values of $\Delta E^i{}_{user}$, $\Delta E^i{}_{LNG}$, and η^i in each facility using LNG cold.

Table. 2: Information on the exergy efficiency of each facility using LNG cold.

	$\Delta E^i{}_{user}$ (kWh/LNG-t)	$\Delta E^i{}_{LNG}$ (kWh/LNG-t)	η^i (%)
Ethylene Plant	82.41	111.64	74
Air Liquefaction and Separation	77.14	112.85	68
Carbon Dioxide Liquefaction	37.45	102.76	36
Brain Chilling	9.29	89.85	10
Warm Water Chilling	0.00	102.28	0
Expansion Turbine	33.22	45.59	73

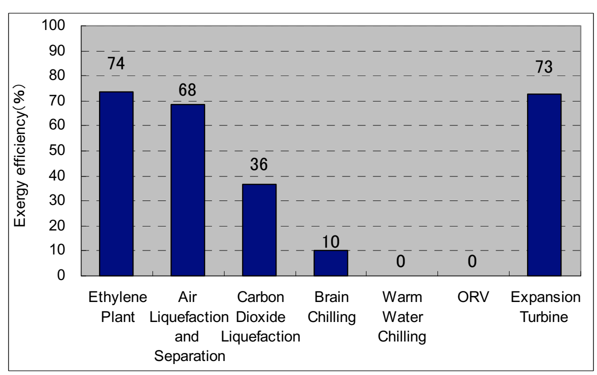

Fig. 9: Exergy efficiency of each facility vaporizing LNG.

In general, the smaller the difference between temperature of a targeted material and that of LNG, the higher exergy efficiency is.

At water chilling facility using LNG cold, LNG cold contributes to reducing electricity used for cooling tower.

But, the exergy efficiency is evaluated negatively by Formula.1, because the temperature of cooling water is higher than 20 degrees Celsius as the condition for equilibrium with environment. However, the value of the exergy in the water chilling facility case is so small that we approximately regard the exergy efficiency as zero in this paper.

Fig. 9 shows that the exergy efficiency in supplying LNG cold to the ethylene plant is the highest in Terminal 1. This means that LNG cold is the most efficiently used there. This high efficiency is achieved by installing heat exchangers in series for exchanging heat between LNG and targeted materials at six stages between low temperature (-100 degrees Celsius) and atmosphere temperature (20 degrees Celsius).

3.3 Evaluating the comprehensive quality of LNG cold utilization in the LNG terminal in terms of exergy

We try to understand how the quality of LNG cold used in Terminal 1 comprehensively has changed by starting to supply LNG cold to the ethylene plant. In this paper, we defined "the exergy efficiency of LNG cold utilization in Terminal 1". Fig. 10 shows the concept of the exergy efficiency.

Table. 3: The value of exergy of LNG (NG) in each condition.

Condition (Temperature, Pressure)		The value of the exergy (kWh/LNG-t)
LNG	-160 degrees Celsius, 106.4 KPa	239.8
NG	20 degrees Celsius, 0.75 MPa	70.6
NG	20 degrees Celsius, 2.35 MPa	109.5

We need to make use of some of LNG exergy as pressure energy to supply city gas to pipelines. After LNG is gasified to natural gas through a LNG cold utilization facility, a part of the vaporized gas is introduced to the expansion turbine and then supplied to a trunk line at 0.75 MPa and the rest of the gas is directly supplied to another trunk line at 2.35 MPa. Table. 3 shows the value of exergy of LNG (NG) in each condition.

So, we calculate "the exergy efficiency of LNG cold utilization in Terminal 1" by formulas below [formula. 3 ~ formula. 5]. The top of formula. 3 (i.e.formula. 4) means sum of the exergy obtained by the targeted materials at each facility inTerminal 1. The bottom of formula. 3 (i.e.formula. 5) means the available exergy of total LNG cold in Terminal 1, except the exergy used for supplying city gas.

In this paper, we take no account of the effect of LNG pump on exergy of LNG cold because the effect is very small.

$$\eta^{all} = \frac{E_{used}}{E_{utilizable}} \times 100$$ [formula. 3]

$$E_{used} = \sum_{all\ i} \Delta E^{i}{}_{user} \times LNG^{i}$$ [formula. 4]

$$E_{utilizable} = 239.8 \times LNG^{total} - \{70.6 \times LNG^{\exp ander} + 109.5 \times (LNG^{total} - LNG^{\exp ander})\}$$ [formula. 5]

η^{all} : *the exergy efficiency in Terminal 1 (%)*

$E_{utilizable}$: *total amount of available exergy of LNG cold energy in Terminal 1 (kWh)*

LNG^{i} : *volume of LNG vaporized at the facilitiy i (ton)*

LNG^{total} : *total volume of LNG (ton)*

$LNG^{\exp ander}$: *volume of LNG supplied through Expansion Turbine (ton)*

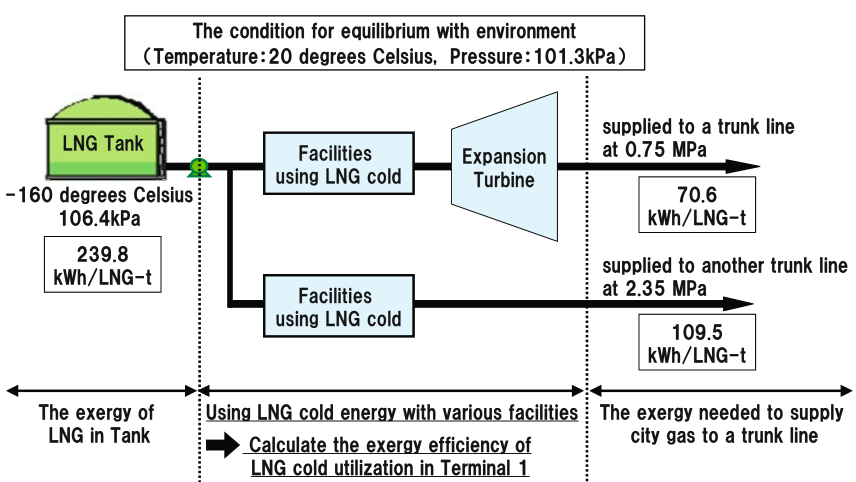

Fig. 10: The concept of "the exergy efficiency of LNG cold utilization in Terminal 1".

Table. 4: Comparison of "the exergy efficiency of LNG cold utilization in Terminal 1" between before and after starting to supply LNG cold to the ethylene plant.

LNG cold energy utilization facilities and LNG vaporizer	The value of the exergy the targeted material obtains in each facility (kWh/LNG-t)	Total LNG mass of each facility for two months (t) LNG cold energy utilization in Ethylene Plant	
		before	after
Ethylene Plant	82.41	0	75805
Air Liquefaction and Separation	77.14	75129	72268
Carbon Dioxide Liquefaction	37.45	9222	8105
Brain Chilling	9.29	4951	7531
Warm Water Chilling	0.00	34645	28035
Open Rack Vaporizer (ORV)	0.00	466	0
Expansion Turbine	33.22	74069	96951
The exergy efficiency in Terminal 1 (%)		45	54

Table. 4 shows the comparison of "the exergy efficiency of LNG cold utilization in Terminal 1" between before and after starting supply LNG cold to the ethylene plant. ("before": February to March in 2010, "after": February to March in 2011)

As shown in Table.4, the value of the exergy efficiency of LNG cold utilization in Terminal 1 has been increased from 45% to 54% after we started to supply LNG cold to the ethylene plant. Thanks to the supply of LNG cold to the ethylene plant, the rate of using LNG cold at the facilities with the high exergy efficiency was increased. As a result, we could accomplish more advanced utilization of LNG cold in Terminal 1 from the view point of not only "volume" but also "quality" than before.

In Terminal 1, the rate of LNG cold utilization is already 100% (volume-based), but the exergy efficiency has not reached 100% yet. So, from now on, it is important to make more advanced utilization of LNG cold by improving the quality of the utilization.

4 SUMMURY

Today, we need to make more efficient use of LNG cold in LNG terminals because it is very important to save energy.

In this paper, first, we remarked the purpose of evaluating the efficiency of the LNG cold utilization in terms of exergy, and then we introduced the case of such evaluation in Terminal 1.

We understand that we can make more efficient use of LNG cold in Terminal 1, mainly by following two ways. One way is improving the quality of the LNG cold utilization at the facilities with low exergy efficiency, such as the water chilling facility. The other way is increasing the ratio of the amount of LNG vaporized at the facilities using LNG cold with high exergy efficiency, such as the ethylene plant.

From now on, we will make positive efforts to save energy by comprehensively evaluating the effects of the LNG cold utilization in terms of exergy and cost.

Abstract
The life cycle framework and flow charts for select of energy budget and battery parameters are proposed. The required battery capacity and charging circuit are arranged by local weather conditions. Then, the placement configuration is arranged based on physical structures. From the system reliability point of view, MTBF becomes shorter as the temperature increase. Avoiding high temperature situation can extend sensor node's life. Green design considerations at early stage of system design are helpful to build a proper system framework and technology implemented.

Keywords:
wireless sensor network, solar cell, energy budget

1 INTRODUCTION

The wireless sensor network is researched recently for mobile and distributed network application. A Wireless Sensor Network (WSN) consists of spatially distributed autonomous sensors to cooperatively monitor physical or environmental conditions, such as temperature, pressure, motion or pollutants. It is now used in many industrial and civilian application areas. Limitation of energy supply has constantly impeded the progress of WSN towards large scales and true autonomous operations [1].

The advantage of wireless sensor network is the flexibility; each node in a sensor network is typically equipped with a radio transceiver or other wireless communications device, a micro-controller, and a battery. Owing to the distributed nature of WSN, the battery replacement and maintenance is a very time-consuming process.

Compact and integrated WSN is currently developed to minimize power consumption and energy providing problem. Smaller size implies less raw material and lower environmental impact during manufacturing process. The transceiver with minimum bandwidth and suitable electromagnetic wave coverage range also implies fewer requirements for battery replacement.

The wireless sensor network also brings environmental impact during manufacturing, product use or at the end of product life. For example, batteries may contain cadmium, mercury, copper, nickel, and lithium, which may create a hazard when disposed incorrectly. Although each wireless sensor node is a small component, it operates as a clustering network system. For proper estimation of the environmental impact during life cycle, the boundary of the scenario needs to extend to the whole system operation. Therefore, it is important to consider the possible design parameters and related environmental impacts in early design phase.

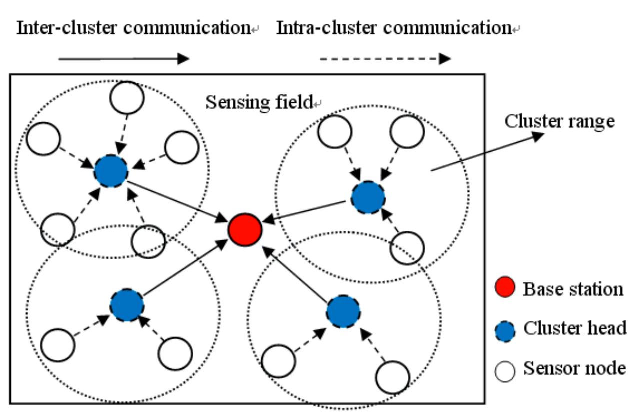

Fig. 2 Wireless Sensor Network (WSN) consists of spatially distributed autonomous sensors

DOI 10.1007/978-94-007-3010-6_31,

2 TECHNOLOGY

Sensor networks are designed especially for deployment in adverse and non-accessible areas without a fixed infrastructure. Therefore, energy conservation plays a crucial role in the proper operation of these networks. Solar powered wireless sensor network had been proposed and demonstrated [2] with various combination of technical attributes. Depending on the parts and technology chosen, there are many factors that will affect the system performance and environmental impact of WSN.

2.1 Solar powered Wireless Sensor Network

Several network protocols that perform solar-aware routing were proposed [3]. Proper network protocols while utilizing solar power can improve system flexibility and provide significant energy savings. Incorporating the solar status of nodes in feasible routing decision making results in reduced overall battery consumption.

Corke [4] discussed hardware design principles for long-term operation solar-powered wireless sensor networks. The assumptions and principles appropriate for long-term operation from primary cells are quite different from the case of solar power with its abundant energy supply and regular charging cycles. The system used NiMH battery technology which does not require complex charging circuitry. In the presented outdoor environments, it allowed significant relaxation of the severe energy constraints. The presented data from field measurement illustrated the use of solar energy and rechargeable batteries to achieve 24×7 operations for over two years, in March 2005.

Small size compact and integrated WSN was developed to minimize energy supply problem [5], the size of sensor node circuit is only 20×20×6 mm, and the pilot study shows reasonable application potential in outdoor environments. Some system also utilized indoor light to generate electricity [6], but it must leave the lights on to get the energy needed to partially charge device over night. The energy wasted from the indoor lights is much greater then the energy obtained.

2.2 Solar panel and LCA data

While power from the sun itself is renewable and green, the equipment necessary to capture and convert solar energy into usable electricity still have a carbon footprint during its life time.

A life cycle analysis study proved that solar cells are cleaner than conventional fossil fuel power generation [7]. Amorphous silicon had shown successful operation in normal conditions, the process step is simpler than mono-crystalline cell, therefore the panel requires less energy consumptions in production phase.

Mono-crystalline silicate cells have the highest energy conversion efficiency of 14 percent, but it requires the most energy to produce. It emits 55 grams of global warming pollutant per kilowatt-hour, which is only a fraction of the near one kilogram of greenhouse gases emitted by a coal-fired power plant per kilowatt-hour. From the carbon emission's point of view, solar powered systems are 90 to 300 times lower than those from coal powered plants [8].

Four most common types of PV cells: multi-crystalline silicon, mono-crystalline silicon, ribbon silicon and thin-film were reviewed by [8]. Even taking into account the low efficiency of thin-film solar cells or the energy needed to purify silicon for the other types of PV, the results proved significantly fewer emissions in their entire life cycle than the fossil fuels needed to produce an equivalent amount of electricity.

Energy-related acid emissions of m-Si modules are 16× less with PV electricity generation than with the average Dutch electricity supply system [9]. The non-energy-related releases of SO_2 are about 5% of the energy-related emissions for the base case. The energy requirement and emissions per amount of electricity generated are in the same order of magnitude as those found for amorphous silicon modules. This is caused by a two times higher solar cell conversion efficiency for m-Si modules which compensates the two 2 times higher energy requirement during manufacture.

Materials that dominate the material requirements of m-Si modules are the bulk materials like glass and aluminum. The study suggested that module design has to be reconsidered in order to facilitate recycling of module components. The process step contributes dominantly to the emissions that occur during the life-cycle of the PV module. Due to the 100-fold thicker Silicon layer in m-Si cells (150-300 μm for m-Si vs. 350-500nm for a-Si cells), the emissions of (non-energy-related) CO_2 and SO_2 are about 200 times larger than the values for amorphous silicon solar cell modules [9].

2.3 Charging circuit

Design considerations for battery charger includes designing the circuit, loading, impedance and panel structure. Some solar charging circuits were selected and implemented for field trial of different WSN applications. It includes the charging circuit, switching, protection circuit, and the leveling circuit. In [10], the iron phosphate type lithium-ion batteries were safely charged to their maximum capacity and the thermal hazards associated with overcharging were avoided by the self-regulating design of the solar charging circuit. The solar energy to battery charge conversion efficiency reached 14.5%, including a PV system efficiency of nearly 15%, and a battery charging efficiency of approximately 100%. This high system efficiency was achieved by directly charging the battery from the PV system with no intervening electronics, and matching the PV maximum power point voltage to the battery charging voltage at the desired maximum state of battery charge.

2.4 Battery and environment

Major Parameters of battery selection includes cost of battery, energy density stored within battery which dominated the physical size of battery, the permitted cycle of recharge and the side effects of end of life. The rate of degradation of Lithium-ion batteries is strongly temperature- dependent. Operating at high temperatures can result in the destruction of the cell. The Arrhenius effect helps to get higher power out of the cell by increasing the reaction rate, but higher currents give rise to higher I^2R heat dissipation and thus even higher temperatures. Unless heat is removed faster than it is generated, it possible causes thermal runaway [11].

The first stage is the breakdown of the thin SEI layer on the anode, due to overheating or physical penetration. The initial overheating may be caused by excessive currents, overcharging or high external ambient temperature. The breakdown of the SEI layer starts at the relatively low temperature of 80ºC.

The data [11] shown that starting at about 15 ºC cycle life will be progressively reduced by working at lower temperatures. Operating slightly above 50 ºC also reduces cycle life but by 70 ºC. The battery thermal management system must be designed keep the cell operating within its sweet spot at all times to avoid premature wear out of the cells. The cycle life quoted in specification sheets provided by manufactures normally assumes operating at room temperature. This would be unrealistic for harsh environment applications.

3 GREEN DESIGN CONSIDERATIONS

While powering from the sun itself is renewable and green, the equipment necessary to capture and convert solar energy into usable electricity have a carbon footprint. The wireless sensor network also brings environmental impact during manufacturing, product use, or end-of-life. It is important to consider the technology available and related environmental impacts in early design phases.

The life cycle framework had been applied to photovoltaic module design. These metrics are based on energies used during material production, manufacturing, and transportation. Although the energy data of each phase of product life vary over a wide range, low and high values can be used to do a basic estimation

As a WSN application designer, the major parts that can contribute within the life cycle are the use phase. The manufacturing phase impact can also be minimized by proper selection of technology and parts.

3.1 Procedure & Overview

Small changes at the design stage can have a far greater positive effect than trying to mitigate impact during and after production. The general wireless sensor network consists of four different devices; the PV generator, the control electronics, the battery and the mechanical frame. Environmental impact is related to factors such as PV module size, battery size, frame and electronic packaging material required and control electronics. Minimized environmental impact can be achieved through properly choosing the parameters of those variables. Flow chart for selecting solar panel parameters is shown in Fig. 3. Based on scenario and weather conditions of WSN application, we can select panel type and size. With the LCA data and supporting analysis tools, the judgments can be made based on environmental impact, weight, installation and cost. Firstly, the required battery capacity is determined. Secondly, the charging circuit and usage condition is arranged. Thirdly, the placement configuration is arranged based on actual physical structures.

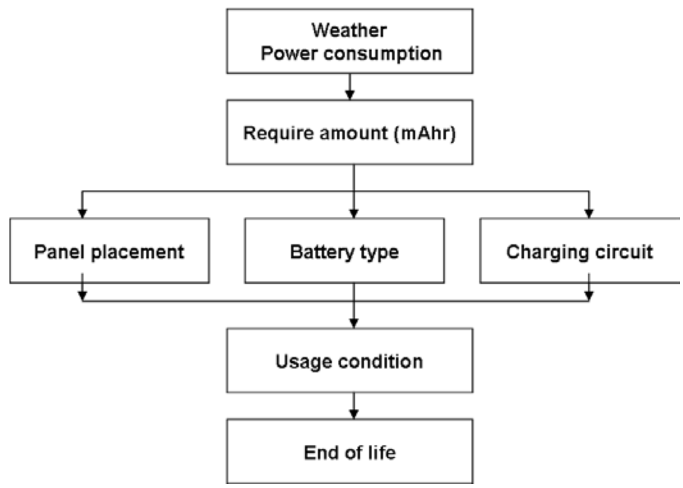

Fig. 3 Flow chart for select of energy budget and battery parameters

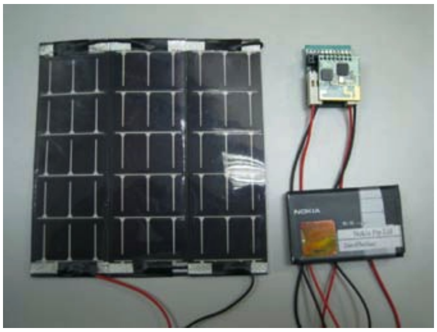
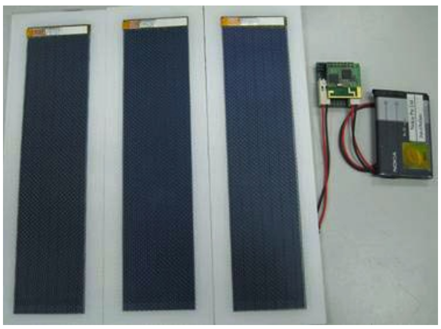
3.2 WSN and panel chosen

The WSN under study is a small size compact and integrated wireless sensor node, which was developed to minimize energy supply problem [5]. While operating in normal mode, it consumes only 29mA/27mA. The voltage tolerance is 2.7 to 3.6V DC, it means it also can survival in worse energy conditions. The battery used the Li-ion battery from NOKIA (3.7-volts), the charging capacity is 1020 mAh.

Due to its reasonable dimension, it can easily apply in environmental parameters monitoring and many outdoor networking situations. The compact size also benefits power usages and battery life.



(a)



(b)

Fig. 4 IP-Link 1223 outdoor solar charging system

For solar panel we choose Solar Focus 1SC1, as shown in Figure 4. The three-layer composite amorphous-silicon solar technology can effectively absorb different spectrum of solar light. Using three layer hierarchical stack, red, green and blue in the solar spectrum can be efficiently absorbed through different layers.

3.3 Charging circuit

During designing the circuit, loading, impedance, some of solar charging circuits were selected and implemented for field trial. Design parameters are adjusted and compared from both cost and efficiency. For example, reduction of switch counts and driving circuits can achieve the advantages of compact size, low cost and high efficiency. For simplicity, the basic diode and capacitor charging circuit (Fig. 5, 6) was implemented. There are no active parts in the charging circuit; consequently, it consumes less power while in operation.

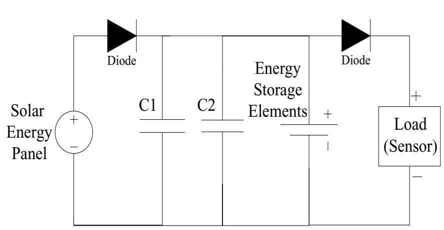


Fig. 5 Charging circuit diagram of solar charge control

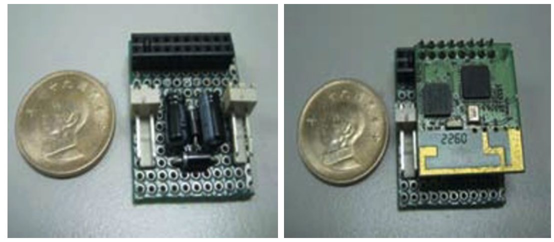

(a) (b)

Fig. 6 Physical implementation of the solar powered WSN (a) the charge control circuit board (b) wireless sensing node and charging protection circuit board

To minimize the space required and packaging dimension, the WSN and charging circuit board was attached by socket. During the chassis design, three dimensional placements were checked with battery and components. The design concerns of system frame are the fixing of solar panel with different kinds of basement, electronic packaging dimension and the adjustment of panel skew angle based on available space.

4 MEASUREMENT AND ESTIMATION

The small size compact and integrated wireless sensor node were built and measured its performance to verify possible energy supply problems.

4.1 Measurement facility

For long term evaluation of system performance, Onset HOBO U12 standalone data loggers were utilized. It provides 12-bit resolution for detecting data, direct USB interface, and a 43K measurement capacity. It could monitor voltage, temperature, humidity, light intensity for several weeks.

Figure 7 indicates the battery voltage is strongly dependent on the ambient light intensity. The temperature sensor locate within U12 does not directly contact with the solar panel, therefore it indicate the local ambient temperature around the panel. The measured temperature increases at noon, and can reach as high as 45° C. With three solar panels in series, it produces electricity for 5.8V-6.4V and charging current 80mA-235mA. The battery voltage increase rapidly as the ambient light intensity increased. Normally the charging process reaches 95% of capacity within two hour period of time.

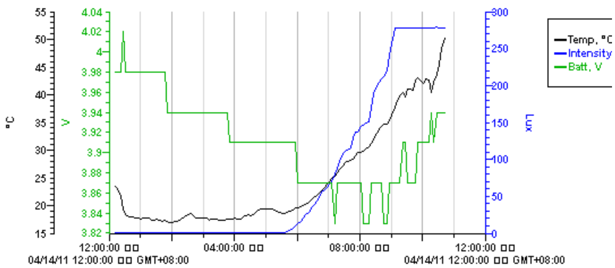

Fig. 7 Charging voltage measurement during 12 hours (light intensity, battery voltage, temperature)

According the weather conditions, energy absorbed by the solar panels will be very different. For example, on sunny days direct sunlight at noon time will give a maximum current of about 235mA, and during late afternoon, current drops to around 35mA. In this situation, WSN need operate by proper routing protocol which allows signal transmitted through the node with enough energy storage. The simple calculation of battery life and charging efficiency can be found in [13].

4.2 Reliability issues

Panel's temperature also affects power output of the solar panel. The mechanism is related to the complex cell chemistry. To estimate temperature related effect, we measure the solar panel output voltage and current under load while the temperature rises.

Table 1 Effect of temperature variation

			
Temperature Panel	**voltage**	**Temperature Panel**	**voltage**
26℃	7.50 V	26℃	5.45 V
28℃	7.28 V	28℃	5.35 V
30℃	7.17 V	30℃	5.30 V
32℃	7.20 V	32℃	5.22 V
34℃	7.23 V	34℃	5.16 V
36℃	7.25 V	36℃	5.09 V
38℃	7.22 V	38℃	5.03 V
40℃	7.19 V	40℃	4.97 V

A power resistor was used across the positive and negative outputs of the solar panel. The projecting light was utilized to heat up the surface of solar panel. Previous experiments had shown us that the peak power output of these panels is obtained with a load resistance of around 56 Ohms. A Pasco data acquisition device was used to take voltage, current, and temperature readings. The relationship between temperature and the solar panel power output voltage, between 26 and 40 degrees there was a drop in power output from a peak of 7.5V down to 7.19V (Table 1). The total power loss due to the increase in temperature reaches almost 5%. It means by maintaining a lower temperature, the system failure rate will decrease and output power can also be increased.

4.3 Solar Panel Configurations

Solar panel configurations also influence the WSN temperature that attached on the panel. From the system reliability's point of view, MTBF becomes shorter as the temperature increase. Higher temperature during component assembly or usage leads to component life reduction, thermal fatigue, plastic IC popcorn effect, delaminating of multi-layer PCB, etc. Reducing the temperature can reduce the need of maintenance requirement of both WSN nodes and system.

The progress of WSN towards large scales and true autonomous operations need the flexibility of installation. Once installed people can not easily change the reception angle by adjusting skew angle of the panel surface. Based on the situations of surrounding environment and the sunshine conditions, the actual installation maybe varied. To estimate the effect of installation and surrounding environment, two kinds of configurations are shown in Fig. 8, with RC concrete wall (-c) or thermal insulated material (-i). The thermal insulated material can reduce heat conduction through the structure.

(a) (b)

Fig. 8 Installation configurations

The measured temperature variation of four kinds of configurations is listed in Table 2. The result of configuration (b)-i shows the lowest temperature, the reasons is low heat conduction from structure and panel's convection heat transfer efficiency is high (Fig. 9). Highest temperature is configuration (a)-c, therefore it needs more open space to improve convection heat transfer efficiency and reduce the heat transfer from structure.

Table 2 Measurement of penel temperature

Configuration	Temperature
(a)-c	42.3
(b)-c	37.8
(a)-i	39.4
(b)-i	37.3

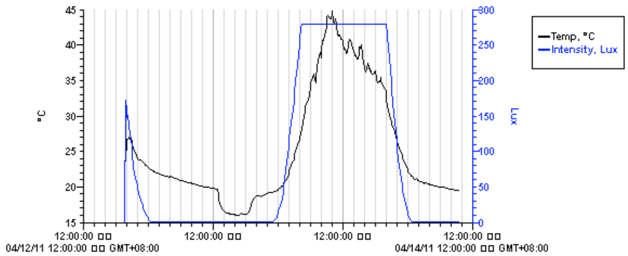

Fig. 9 Measured panel temperature while outdoor light intensity changed (ambient temperature is 30 $^{\circ}$ C)

4.4 Maintenance issue

To calibrate maintenance costs, we need information about expected failure rates of components. Each component of the sensor node has a different failure rate. The PV panel has an expected life cycle of 20 years, but without routine maintenance the panel may fail after 10 years. The battery has an expected life cycle of 4 years, but this can be reduced to a range of 1 years. The charge controller can last 5 years, depending on the level of misuse.

The highest rate of equipment failure occurs with the battery is most often the result of battery misuse. Overall projected system failure rates determine the required number of visits to an installed WSN. Routine maintenance by a trained technician is required to increase usage life time of sensor nodes. Frequency of required visits for normal WSN will be much higher than that of WSN with solar panel. Therefore, the cost of the solar panel can easily recover by the cost of maintenance.

By constantly monitoring the voltage level and smart routing protocol, the WSN with solar gives lower maintenance cost. The network can monitor the status of each node periodically to detect that if a WSN node fails or is defective. This reduces the cost of using WSN technologies and a more reliable distribution networks to ensure a successful implementation

5 CONCLUSIONS

Through the integration of wireless sensor network technologies and solar charging system, the development of low power, high performance, and long lasting nature of wireless sensor networks can be achieved. This will extend the life of nodes in wireless sensor network and the feasibility and effectiveness of the system. Firstly, we build a solar power system for green wireless sensor network platform, then, the solar charging efficiency of sensor networks node were measured.

In the future, a wide range of WSN application will make sensor networks an integral part of our lives. Solar energy reduced the problems of unstable power and loading effect. Although the life cycle impact from each phase of product life can vary over a wide range, design parameters can still be compared from both cost and system maintenance in early development phase.

An Empirical Inquiry on the Effect of Cleaner Local Energy Production on Consumer Carbon Footprint

Jukka Heinonen (1)[1], Riikka Kyro (2)[1], Seppo Junnila (3)[1]

[1] Aalto University, School of Engineering, Espoo, Finland

Abstract

This study analyzes the effect of cleaner local energy production on the consumer carbon footprint. The results in consumption based carbon footprint assessments have traditionally indicated that a significant change in consumption patterns or lifestyles would be needed to achieve the often aspired, ambitious 50-80% cutoffs in the carbon emissions on a community level. However, it is also known that a majority of the emissions related to all goods and services derives from energy. Thus cleaner local energy would not affect only the emissions from housing in the consumer carbon footprint but also the carbon load from the consumption of goods and services produced with the same energy.

Keywords:

energy, lifecycle assessment, LCA, carbon, CO_2, greenhouse gas, GHG, consumption

1 INTRODUCTION

Numerous studies have demonstrated that emissions associated with energy production dominate the greenhouse gas (GHG) emissions caused by human activities [1-2]. A recent study of 18 European metropolitan cities found as much as 79 to 97% of the GHG emissions of the studied cities to derive from energy production.

Consumption based consumer carbon footprint calculations have traditionally estimated the shares as significantly lower [3, 4]. This is likely due to that only emissions derived from housing energy use have been allocated as emissions from energy production. In other words, it is ignored that energy production is accountable for a majority of emissions related to all consumables and services as well.

As the single most important source of GHG emissions from consumption, housing energy offers the largest mitigation potential [3, 5]. However, the share of housing energy of the GHG emissions of a consumer has been reported being substantially less than 50 % in many studies [3, 5, 6]. Since building energy consumption and energy production mode are the key decisions on a city level to affect the carbon footprints, often aspired ambitious 50-80% cuts in carbon emissions would only be possible through significant changes in the individual consumers' consumption patterns, as a significant share of the emissions derives from goods and services [3, 4]. This study suggests, however, that cleaner local energy production modes would affect, not just emissions from direct housing energy use, but also the emissions attributable to the consumption of goods and services, making this a substantially more effective way to mitigate the GHG emissions on a community scale. This applies especially to emissions from services consumption, the majority of which derive from local energy production.

This study presents a consideration of the effect of cleaner local energy production on consumer carbon footprint employing a scenario analysis. The primary aim is to demonstrate the significance of the choice of energy production mode. The effects of cleaner energy production on the GHG emissions are assessed with a consumption based hybrid LCA model. Besides direct housing energy consumption, the effect of the cleaner local energy production on the carbon footprints of locally produced services is assessed. This will create better understanding on the significance of cleaner local energy production on the consumer carbon footprint.

The Finnish capital city Helsinki is analyzed in the study. In the first stage of this paper the carbon footprint of an average resident of Helsinki is assessed and the distribution of the emissions is analyzed employing the hybrid LCA model developed earlier by the authors [3, 5, 7]. In the second stage, the carbon mitigation effect of cleaner local energy production is analyzed with the assessment model.

2 METHOD

This study examines the GHG emissions attributable to private consumption, e. g. carbon consumption, with an aim to incorporate all life cycle emissions into the inventory. This is achieved by employing a hybrid lifecycle assessment (hybrid LCA) model developed by the authors in previous studies [3, 5, 7].

The method is based on is a combination of the two prevailing assessment techniques, process life cycle assessment (process LCA) and input-output life cycle assessment (IO LCA). Of these two techniques, process-LCA is the traditional and the most utilized method [8]. In Process LCA the emissions attributable to a certain good are assessed process by process based on energy and mass

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,

DOI 10.1007/978-94-007-3010-6_32,

flows. The accurateness of the method is potentially very high. However, the technique suffers from a couple of problems inherent to all process based LCAs. First, the amount of processes adding to the emissions inventory of a certain good is often very large in cradle to grave assessments. The assessments thus tend to be very laborious and time consuming to conduct. Second, related to the workload, the assessments suffer from truncation error from the boundary selection as all the processes cannot be assessed. These may potentially be very high even with inclusion of multiple production chain processes [8, 9]. Third, the energy and mass flow data needed for the assessments may not be easily available.

An alternative for process-LCA is input-output-LCA. The method assesses the emissions attributable to a certain good (the outputs) based on monetary flows (the inputs) [10]. The method is based on output tables that describe the industry interdepencies within an economy. Based on these, the tables add together all the emissions within an economy related to a monetary transaction on one sector. The method is similar to the input-output statistics of national accounts, but in this case the output tables include the emissions data in addition to the economic activity relations. In output tables an economy is divided into industry based sectors so that the economy is fully acknowledged. This is one of the primary sources of uncertainty in input-output-analysis. The output tables are averages that may include figures from very different industries, and the result thus may not describe well the object of the inquiry. In addition, possible temporal (inflation and currency rate differences) and regional (industry structure differences) asymmetries of data and the model, and the assumption of domestic production of imports [9] create possible sources of bias. However, the method is fast and rather easy to use. The inventory is also always complete, as no boundary cutoffs are needed. In addition, the monetary input data is often easier to obtain than data for process analyses.

The third category, hybrid LCAs, have emerged to combine the strengths of the two presented approaches and to reduce the inherent weaknesses related to them [9]. As was described above, the IO and process method have different uncertainties related to them creating space for a combining approach. The first hybrid approaches are from as far as from the 1970's, but the method has become more popular in environmental impact assessments since the late 1990's. In hybrid LCAs, full coverage of production and delivery chains can be maintained with the use of input-output tables, but the accuracy is raised with utilization of process data for the assessment of the most important processes.

The hybrid LCAs can be divided into three categories [9]. In tiered hybrid LCA the most important first order and lower stream processes are assessed with process data whereas the rest of the production and supply chain emissions are assessed with IO approach. The second option, input-output-based hybrid analysis can be utilized when detailed monetary data within the IO sectors are available. In input-output-based hybrid analysis the important IO sectors are further disaggregated to incorporate specific process data. The third alternative is integrated hybrid-LCA that incorporates detailed unit process level information in physical quantities into the input-output model representing the surrounding economy that embeds the process-based system.

The assessment model employed in the study is based on the tiered hybrid LCA method. The model follows the WRI scope three definition [11] in including the full lifecycle emissions of all private consumption. Furthermore, the perspective is consumer responsibility meaning that the GHG emissions are allocated to a consumer based on his/her consumption.

3 STUDY DESIGN

The study analyzes the annual consumption based carbon footprint, carbon consumption, of an average resident of Helsinki. Helsinki is the largest city in Finland with over 500,000 inhabitants, over 10% of Finnish population. The area is affluent in Finland [12] and represents divergent availability of services. The average resident of Helsinki purchases goods and services with 17,400 € annually. The table 1 presents the distribution of the consumption within five broad consumption areas. The local power generation is fossil fuels based [13], which increases the significance of improving the carbon intensity of the power production.

Table 2: Distribution of the annual consumption of an average resident of Helsinki

Consumption area	Amount
Tangible goods	5,200 €
Housing	5,900 €
Transport	1,900 €
Services	3,800 €
Air, Maritime and Package Travel	500 €
Total	**17,400 €**

The input data consist of the consumption survey of Statistics Finland which presents the consumption of an average inhabitant in very high detail, including roughly 1,000 categories of goods and services. For the GHG modeling the data are aggregated down to 59 consumption sectors, and further to the above mentioned five consumption areas to present the GHG assessment results.

The monetary inputs are converted into GHG emissions employing the Carnegie Mellon University economic input-output LCA (EIO-LCA) model [10]. In addition, in the first stage, the WRI scopes one and two [11] emissions of energy production for housing, the fuel combustion of private vehicles and public transport are assessed utilizing

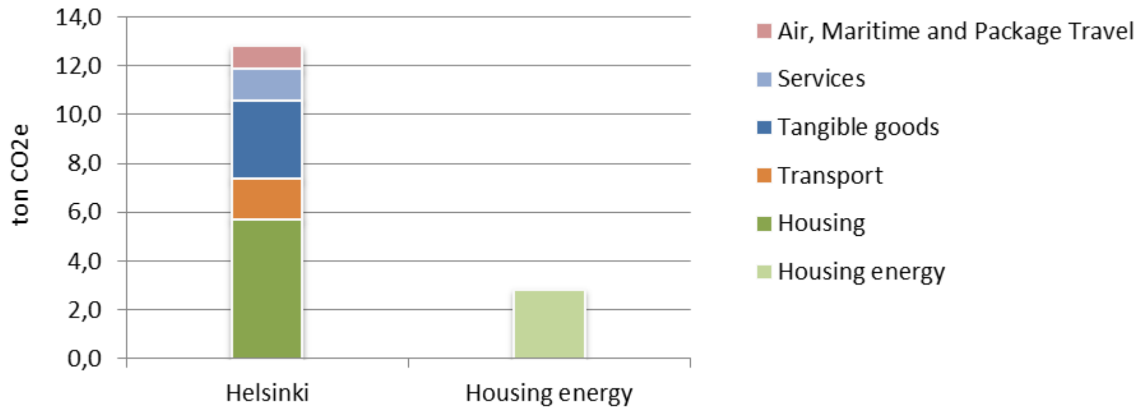

Fig. 1: The annual carbon consumption of an average resident and the share of the emissions of housing energy.

local emissions data, whereas for the rest of the emissions the EIO-LCA output tables are employed.

In the second stage the services produced predominantly locally are identified. After this, the effect of cleaner local power generation is analyzed with a 100% renewables scenario, in which zero production phase emissions are assumed, but the production chain emissions remain. While unrealistic in short term in the context of CHP production dependent Helsinki, the scenario demonstrates the potential related to cleaner local energy production. Furthermore, the decrease in the GHG emissions is linear respective to the share of renewables, the selected scenario thus being easily convertible to lower renewables' shares also.

4 RESULTS

The average resident of Helsinki purchases goods and services with 17,400 € annually. Based on the assessment model ,this results in GHG emissions, or carbon consumption, of 12.8 tons of CO2e.to. As Figure 1 depicts, housing is the dominating source of GHG emissions. The share of the sector is 5.7 tons, of which housing energy (heat and electricity) comprises a share of 2.8 tons. The housing sector is followed by the emissions from consumption of tangible goods (other than housing related) with 3.2 tons of CO2e, transport with 1.7 tons, services with 1.3 tons and air, maritime and package travel with 0.9 tons.

In addition to the housing energy, the carbon intensity (g CO2e/kWh) of local energy production affects directly the carbon load of local services. The services category in the assessment model includes 10 sectors altogether. The share of heat and electricity of these is 65% on the average ranging from 50% in health services up to 80% in culture, sports and recreation services.

In the 100% renewables scenario we assume zero production phase emissions. The downstream production and delivery chain emissions are assumed to remain constant and thus generate some energy related emissions.

Figure 2 depicts the change in the GHG emissions of an average consumer in the 100% renewables scenario including the 10 services sectors and housing energy.

Altogether the 100% renewables scenario would result in 3.2 tons of CO2e lower annual emissions on the level of carbon consumption of an average resident of Helsinki, and the annual carbon footprint would amount to 9.6 tons of CO2e. Of this, a majority, close to 2.5 tons, derives from housing energy related emissions and the remaining 0.75 tons from services. The overall mitigation effect of cleaner local energy production in the 100% renewables scenario is thus 25%.

5 DISCUSSION

This study was set to analyze the effect of cleaner local energy production on the carbon consumption (annual per capita GHG emissions) of a consumer. The study employed a consumer responsibility perspective [Norski väitös] allocating to a consumer the emissions related to all emissions attributable to the consumption of goods and services. The effect of cleaner energy was assumed to affect the housing energy and also the carbon load from services which predominantly utilize local energy.

In the study the carbon consumption of an average resident of Helsinki, the capital of Finland, was assessed. For this a hybrid LCA model developed previously by the authors [3, 5, 7] was employed. The effect of cleaner energy was examined through a 100% renewables scenario, in which the local fossils based fuel-mix was assumed to be replaced entirely with renewables.

The assessment of the annual carbon consumption of an average resident of Helsinki resulted in 12.8 tons of CO2e carbon load. The largest contributor was found to be housing with a share of 5.7 tons. Of this, 2.8 tons comes from housing energy. Consumption of tangible goods, other than housing related, adds 3.2 tons of CO2e, transport 1.7 tons, the object of the study, services, 1.3 tons and travelling abroad 0.9 tons.

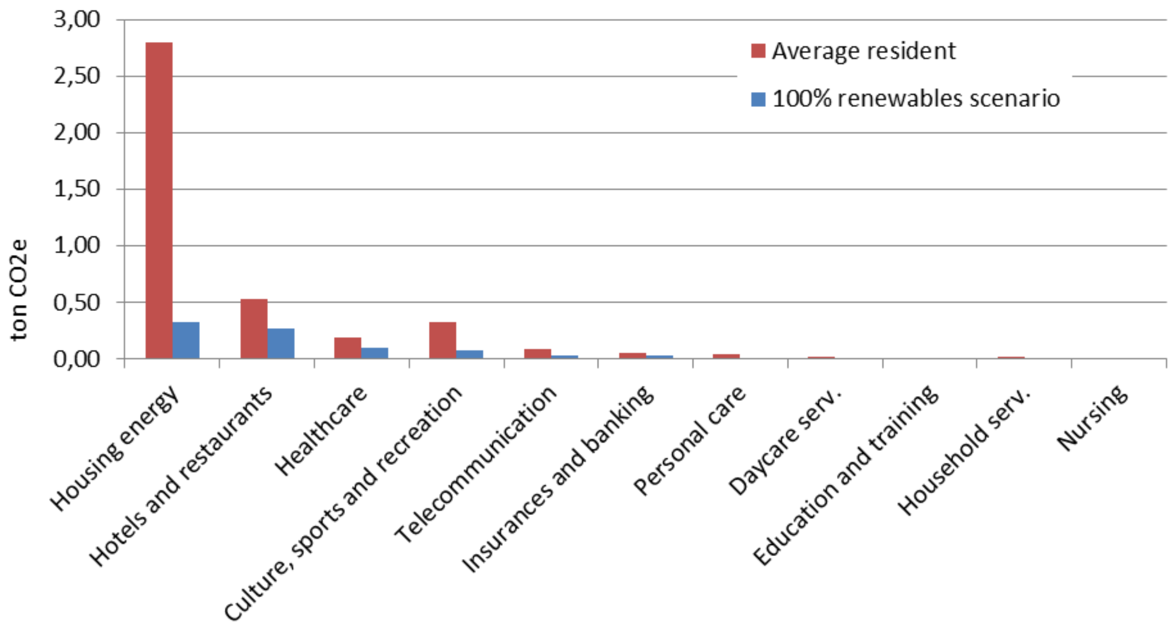

Fig. 2: The mitigation effect in 100% renewables scenario in housing energy and services sectors.

When the 100% renewables scenario was employed, the carbon consumption of an average resident was found to decrease by 3.2 tons of CO2e (25%). Of this, nearly 2.5 tons comes from housing energy and the remaining 0.75 tons from services. Within the 10 services sectors forming the Services consumption area in the LCA model, on average 65% of the GHG emissions were identified to derive directly from energy. However, the overall carbon load from many of the services is so low that the mitigation effect stays moderate. Thus it would still seem that not any single development is enough to achieve even the 50% GHG emissions reduction target mentioned in the Introduction of the paper. Such significant reductions would also require changes in the consumption patterns or significant reductions in the carbon loads of all goods and services.

The study has a few easily identifiable deficiencies. The utilization of the IO LCA method raises uncertainties inherent to all analyses with the method. In addition, new problems arise from the employment of US industry based EIO-LCA model in Finnish context. Employing hybrid techniques can decrease these in general, but also raise new possible sources of bias. However, in this study the model was taken as such based of earlier work of the authors. A detailed description of the qualities of the model as well as a profound discussion about the true deficiencies and their significance can also be found from earlier academic publications of the authors [3, 5, 7, 14].

One specific deficiency in the analysis of this paper is the narrow recognition of local services. In addition to the analyzed services, a majority of all tangible goods include local services in the form of sales facilities, customer service etc. Inclusion of these into the analysis would somewhat increase the effect of decreasing the carbon intensity of local energy production, but probably not be enough to significantly change the overall result.

Domestication of small-scale renewable energy systems – A case study of air heat pumps, residential micro wind stations and solar thermal collectors in Finland

Jouni K. Juntunen[1]

[1] Aalto University, School of Economics, Helsinki, Finland

Abstract

A thorough understanding of the user is crucial in technological design and development. The domestication framework has been used in sociology of consumption to open up technology adaptation processes where technology becomes part of the everyday life of people. This study applies domestication framework for air heat pumps, solar thermal collectors and micro-wind generator technologies. An experimental case study is based on semi-structured interviews and observation of residential household and summer cottages in Finland. Trialing of technology and incremental increase of usage and further investing demonstrate users to aim for smooth evolutionary approach in energy technology adaptation. Modularity, extendibility, interoperability with other energy systems are key design requirements to enhance adaptation.

Keywords:

renewable energy, sociology of consumption, domestication, air heat pump, solar energy, wind energy

1 INTRODUCTION

Historically energy provision became based on networked infrastructure and centralized systems, which has led to a passive role for the most energy end-users [1,2]. From residential housing viewpoint energy systems work in the background and provide air and water heating and cooling with minimal requirement of daily monitoring, configuring or maintenance by inhabitants. However, the need for low carbon solutions and rising energy prices are changing local residential energy consumption and renewable energy is increasingly produced locally on site, which makes production distributed, requires technology adaptation, learning of use and changes or considerations in inhabitants' daily life.

Domestication is a concept within studies of the sociology of technology that has been developed to describe and analyze processes of technology's acceptance, rejection and use. The concept [3–5] emerged from a series of studies, which sought to understand the appropriation of artifacts in the specific social setting of the home [6]. However, the sociology of consumption is not especially well equipped to deal with domestic infrastructures supporting the evolution of normal standards of daily material life [7]. Thus the framework has been rarely used for infrastructure type of technologies, such as residential energy systems. Now that residential renewable energy systems are breaking away from the infrastructure role and becoming more visible and meaningful for consumers, a new avenue opens up for researchers.

In this paper the domestication framework is applied for three different residential renewable energy technology, air heat pumps (AHP), micro wind stations (WS) and solar thermal collectors (STC). These technologies have significant differences regarding daily use and needed user involvement. Air heat pump technology is visible and designed for frequent user interaction. Wind station performance is subject to changes in wind conditions. In the optimal case solar thermal collectors work in the background without need of attention. The research question I ask is: *what kind of domestication processes are involved with residential sustainable energy production and use?*

The advancement of innovation research has lead to the blurring of the distinction between design, implementation and use [8]. Research on the social shaping of renewable energy technology in the context of residential housing provides valuable insights for designers and policy makers for understanding inhabitants' role when designing and regulating residential energy systems.

In the following, I will first elaborate on domestication framework used for empirical analysis. This is followed by a section explaining data sets and methods of this study. Three different technologies are analyzed within the domestication framework. Finally, a discussion of these findings, study implications and limitations of current study.

2 BACKGROUND OF THE STUDY

2.1 Domestication framework

Domestication as a concept originated in large part from anthropology and consumption studies [9]. The concept represented a shift away from models, which assumed the adoption of new innovations to be rational, linear,

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_33, © Springer Science+Business Media Dordrecht 2012

monocausal and technologically determined. It presented a framework and research approach, which is taking into account diversity and complexity of everyday life and technology's place within its dynamics, ritual, rules and routines [5]. Through domestication artifacts become invisible taken for granted elements of everyday life [6]. Silverstone and his colleagues have presented theoretical scheme to study use of technology by proposing four dimension or states in a household's dynamic uptake of a technology. After purchase an object goes through a process of appropriation (1), whereby it is taken possession of by its users. In this stage objects acquire a meaning and become authentic. During the objectification (2) an object is installed and finds its place in household. An object becomes incorporated (3) when it starts being integrated into routines and habits. In conversion (4) users display their ownership of a new product to the outside world both by displaying the object via discourse [10].

Domestication can be seen as period in the biography of artifact about its introduction into the domestic setting. The process of consumption and of embedding the object into the household is one of sense making, of transformation the alien object to ascribe it meaning in the symbolic reality of the household [5]. Biographies of things describe change and transformation of technology but at the same time they reveal the changing qualities of the shaping environments through which they pass [10,12]. In consumption consumed item is incorporated into the personal and social identity of the consumer [13,14]. At the same time people generate interpretations and application of technological systems that often diverge from the ones originally inscribed in them [15]. In this domestication represents a step away from the belief in the one-sided transformative power of technology: an area that the domestication approach clearly develops further was the study of innovation and diffusion [5].

The domestication of consumer goods has been relatively widely studied starting from 90's [9,16]. Previous studies have examined especially electronics and media technology in considering the contexts in which ICT were experienced [17,18,5,19,16]. But it has proved to be useful tool for analyzing for example e-learning technologies [20] and health technology [14]. Aune's study of energy use and metering are rare example of a domestication study concerning energy technology [21,22].

Before presenting domestication processes of residential renewable energy technology, I first briefly outline the Finnish market for the technology, provide basic descriptions of three case technologies and introduce data and methods.

2.2 Small-scale renewable energy production in Finland

The usage of renewable energy sources in Finland has steadily increased. Raising energy prices, progress in renewable energy technologies, energy regulation changes and changes in attitudes towards sustainable lifestyle are increasing demand of renewable energy systems such as air heat pumps, micro wind stations and solar thermal collectors. There are 1,1 million detached houses in Finland, which have over 100 000 Air Heat Pumps (AHP) and over 14 000 Exhaust Air Heat Pumps (EAHP) installed [23]. Solar thermal market is very small in Finland. In 2009 installation area was in total 26973 m2 which produces 18 881 KW(th) worth of energy [24]. Micro wind is very rarely used and statistics include only commercial projects and capacity.

An air heat pump is used for both cooling and heating. External unit of the device diverts heat from outside air in to heat up air, which is blown via internal unit into a building. In the process a pump can provide up to 2-4 COP (co-efficiency of performance) compared to direct electric heating. Air heat pump can usually be used for cooling purposes, which is electricity-consuming activity.

A solar thermal collector converts solar radiation into a more usable or storable form such as water. Water is stored to hot water cylinder. To prevent freezing of collector in Nordic climate, mixture of water and propylene glycol is used as heat exchange fluid that heats water in heat exchanger. Living area is heated by radiant heating where heated water is circulated in radiators or in underfloor heating.

Micro wind micro-wind generators can provide electricity for private use in both rural and urban environments. In Finland micro wind is often used to power up off-grid summerhouses, but it can be used to replace residential energy consumption by self produced renewable energy. Batteries are used to store generated electricity.

3 DATA AND METHODS

The study was organized around semi structured in-depth interviews. This article focuses on inhabitants who live in private homes and in summer cottages throughout Finland. Interviewed users were selected via Internet discussion forums and via personal networking. The data includes 3 air heat pump cases, 3 solar thermal collector cases and 2 micro wind cases. These seven 30-60 minutes interviews included 7 men and 2 women (one interview for couple).

The requirements for wanted users were: (1) Nonprofessional user who's work is not involved in commercial development of residential energy technology and systems (2) Is using case products in detached family house or summer cottage and has freedom to make decision regarding own energy system purchases and use

(3) Has been using the system over a year.

A screening of Internet forums was used for finding and selecting suitable persons for long interviews. The forums used were ilmalampopumput.info (discussion on usage experiences section) and ilmaisenergia.info (discussion on solar thermal general and own projects section). Analysis is based on triangulation of data sets from forums, interviews and observations. One user visit, observation, was carried out in northern Finland.

4 DOMESTICATION PROCESSES OF RENEWABLE ENERGY SYSTEMS

4.1 Appropriation

Why are the consumers bothering with their own energy production when there is a countrywide grid available and energy can simply be taken from a plug on a wall? There is motivation to save in energy cost, but surprisingly often a reason for renewable energy investments was convenience or easier use energy system. Combining renewable energy technologies with existing systems can make system use more convenient overall or help only in some parts of the year. User of wood pellet heating was satisfied to old system configuration on wintertime, but summer time solar thermal collector takes over and provides free energy without any maintenance and make energy provision very convenient.

According previous studies people who manifest strong environmental concerns have strong motivations to set up small-scale production plants [25]. In this study sustainability was not among main reasons to install renewable energy technology. For rather special and niche type of technology that is not widely adopted, such as solar thermal collectors or Solar PV in Palm and Tengvard study, people stress more environmental concern as motivation.

Different motivations and reasons associated with selecting renewable energy technology for domestic use can be recognized especially between permanent residence and temporary summer cottage. For adults primitive summer cottage conditions can be well thought choice. In Finland summer cottage conditions can be rather primitive, but this makes possible sensuously rich experience [26]. For teenagers living without electricity can be annoyance and balance is sought:

« When twins were teenagers, they wanted to have television in the summer cottage and solar panel was then installed. Later on I installed also wind generator to extend power availability for darker period on autumn (summer cottage 1) ».

Electricity availability is significant upgrade and brings possibility to add new appliances to summer cottage. However meaning of technology changes over time. For example a summer cottage wind generator user described how television for kids lost significance when they were not visiting the place, and new activities and needs took over. Charging a mobile phone became the most important utility electricity can do. Cost saving motivation was present in this case only via alternative cost of providing electricity. Grid can be extended to new locations, but connection fee is high and with own renewable energy production the cost can be avoided.

Table 1: Energy systems at case houses

Interviewee	Energy systems installed
Householder 1	AHP, electrical heating
Householder 2	AHP, electrical heating
Householder 3	AHP, oil
Householder 4	Wood pellets, STC, oil
Householder 5	STC, oil
Householder 6	STC, wood stove, AHP
Summer cottage 1	WS, PV solar
Summer cottage 2	WS, AHP, electrical heating

4.2 Objectification and incorporation

All air heat pumps and two solar thermal collectors and one wind generator case was installed by services companies. One solar thermal collector and Micro-wind station was an self-installation.

Installation of the system

In air heat pump cases placing of both internal and external unit required careful consideration. Noise and wintertime ice forming put requirements for external unit location. In countryside even insignificant metallic industrial noise can be considered annoying. Although units are relatively large, when asked, users said not to be bothered of aesthetics but at the same time they describe how they covered external unit with a hut.

In a similar way, solar thermal system has both internal and external parts. Solar collectors are installed on the roof on south or west side and unit is not visible internally in the house. With larger roof renovation embedding of collector is easy and flat collector becomes almost invisible. But even in most typical installation, where collectors are clearly visible on the roof, solar collectors on roof were not considered disturbing.

Good wind conditions are basic requirement in selection of wind station location. Area should be open, preferable from all directions. In principle higher the installation tower, better the wind condition is, but in real environment there are many factors that should be taken into considerations.

« Initially it was one block higher, but I removed 1 meter. I noticed that trees have fewer branches down here. I have also removed some branches (Summer cottage 1) ».

Local adaptations

The interviews reveal how people do small modifications to the systems. Following three cases are examples of micro innovations, adaptations and configuration done by users to increase usability the system, ease of use and comfort.

(1) In solar thermal collectors performance is not optimal early spring or late autumn. Additional valves are installed to improve performance (Householder 4).

(2) In a room with high ceiling reconfigurations for air heat pump is done by installing extension cord for for sensor to improve temperature metering accuracy (Householder 2).

(3) In Nordic climate winter is causing maintenance for air heat pump users. A pump creates frost and ice that cumulates and can cause damage for the unit. Plastic sledge is used to collect ice below the unit and make the removal of ice easier (Householder 3).

Technology metamorphosis of domestic energy technology is rather inflexible and has clear distinction to consumer goods. It is never considered as a toy and actual usage purpose can't change with most of renewable energy technologies. Unexpected usage purposes do not rise up. In this study air heat pumps is the only multipurpose product and it is used for both heating and cooling. It can be seen as device for consumption and production. Users may be starting from one end and move towards the other. In two cases air heat pump was purchased for summer purposes and cooling but later one usage was extended to heating. In one case usage extended usage to the other direction from heating to cooling.

Establishing maintenance routines

All case technologies require some maintenance, air heat pump most frequently when wind generator is almost self sufficient. Internal unit of heat pump has filters that require regular cleaning, however, frequency varies a lot. In minimal use cleaning period is up to two months. This seems to be difficult period to remember and take part of normal housing routines. House cleaning is done more often and cleaning of air heat pump can't be integrated to weekly cleaning and in less frequent cycles cleaning is often forgotten.

Solar collector and wind generator are minimally present in daily life routines. When enough collectors are installed or supporting sources are used for water heating, such as electricity, there is no need to take account reduction in solar generation. In some cases system is build on various local energy sources and other sources take over and keep water temperature on desired level when solar power is limited.

Solar collectors are monitored more on times when temperature is not high enough for full production i.e. during spring and autumn. Also changing settings may be done then concerning water circulation. In summer use only consumption water is needed and room heating is disabled.

Taking hot water sufficiency into account is rare when hot water availability can be guaranteed with electrical heating. Order of household activities is not changed because of cheaper operation, although inhabitants are aware of saving possibilities.

4.3 Conversion

All the users in this study considered new system with renewable energy sources improvement when compared to previous system. Data reveal how differently consumers create requirements for consumer goods and goods with production capabilities. In consumption (pleasure) consumer good ties always capital, it doesn't provide dividends, its monetary value rarely increases and thus people are not necessarily interested of the payback time. In case of production goods, the payback time and profitability arguments are required to rationalize purchases. One of the interviewees discusses this on her blog [27]:

« When do you get your money back? When are these solar collectors paying themselves back? Is this profitable system? I doubt that in normal renovations people need to answer similar questions: "when is your satellite antenna paying back, or swimming pool, or roof window ? »

The question is certain technology profitable in comparison to other commercial energy alternatives is not considered significant, especially if investment is considered reasonable.

An investment to energy production can be seen as capability building. It increases independence from the grid but also opportunities of the grid are started to be seen. As one interviewee write on the blog (Tuulahdus, 2011):

« Before I was dreaming about organizing a celebration where big tongs are used to cut lines to the national power grid. Now I dream about solar panels that are connected via inverters to the grid (Householder 6) ».

The sign of the successful integration of technology in the household sector is that the product has a symbolical aspect in addition to the utility-aspect. Aune claims this symbolic aspect lacks in energy technologies [22]. Findings of this paper mostly support Aune's findings. However, some signs of expression of identity can be noticed in case of solar thermal collector that are still relatively special in Finland and easily visible for neighborhood externally outside of house. This is inline with studies of PVs and wind power [25]. Air heat pump owners did not have special environmental beliefs or concern for the environment and thus having air heat pump visual outside of house can't be considered as communicating of meaning or lifestyle to externals via energy efficient product purchases (see motivations in [28] and Palm & Tengvard 2011).

5 DISCUSSION

5.1 From trials to trust

It's noteworthy that there is strong trial or experiment attitude towards renewable energy production. Expectation level is not necessary high before the purchase and beginning of the use. Users are not seeking for radical one solution that fixes whole system and all previous problems. They rather want to see what new technology is capable of and make further changes and energy system investments later on. T-K. Lehtonen writes about technology trials [29] in adaption, which indeed describe well process of decision making in renewable energy projects. Users describe technology purchase as test. It is not fully replacing old systems, it's acquired to support existing system, work with it and make it more cost efficient or convenient in use or both. Initial learning and adoption is a trial where technology's real performance is tested and new purposes can be found.

5.2 Intertwined energy production and consumption in domestic space

An household is more than a site for a consumption. Rather, especially in case of residential energy systems, it is a place that is turning back towards highly intertwined, inseparable site of both production and consumption. Understanding of residential energy systems and social change towards renewable energy use requires partial departure from consumption studies approach.

Changing role of energy consumer calls for introduction of micro entrepreneurship type of components into the research. There is a thin line from energy production for own use to over production and energy provision to the other users and market. Understanding energy production in local site creates important knowledge for future purposes when two directional energy grids, smart grids, become available. Users now have the possibility to produce their own power, but they still face difficulties when trying to resell extra power generated back to the grid. There is antipathy against large energy utility companies and dependency on centralized power grid and energy supply (See also Palm and Tengvard 2011 study and way to protest against energy companies motivation). Value of national distribution network seen from new direction. It's network for selling, as much as for buying.

GENERAL CONCLUSIONS AND RECOMMENDATIONS

In this study I have focused on appropriation, configuring, daily using and conversing technology from consumer viewpoint. I have left out design process of goods and as a consequence, not included notion of script [30], which is widely used analytical tool inside science and technology studies and useful for comparing designers' conceptions of technology and actual user behavior. In renewable technologies, with relatively straightforward way of using the product, notion of script may provide meaningful analytical tool to provide interesting insights. Also, in wider scope, regarding understanding technology policy, I also recognize importance of social learning [6,] processes involving people, communities, companies outside of domestic site to the domestication processes described earlier. This are important future research opportunities but a wider framing and set of analysis together with format of conference paper would have negatively impacted to detail of description in this stage.

Environmental impacts arise through the interplay of technology, consumption and everyday life [31]. A better understanding of the role of end-users in processes of technology diffusion could help the development of environmentally friendly final products and enhance the adoption rate of these technologies and lifestyles. Renewable energy production in residential house context is mostly motivated by financial reasons, convenience and utility. There is strong variation between these requirements case by case and complacency is achieved already when key factor is well fulfilled. Although energy production investments are larger and less frequent than purchases of typical household consumer goods, switching from old system to new is not revolutionary. Trialing of technology and additional increase of use and investing to renewable technology demonstrate users to have smooth evolutionary approach in energy technology adaptation. Modularity of design to expand capacity of certain technology or combine different technologies conveniently should be high on manufacturers agenda.

The most advanced users see opportunities in co-generation of energy and are willing to additional investments when smart grid enables more open energy market for small producers. Detached houses and dispersed community structure provide favorable conditions for smart grid that should be tested in small scale trials before mass market operations.

Co-creational Environmental Excellence in Socially Exchangeable Modular Energy System and its Leading Design Methodology based on System of Systems Viewpoint

Yutaka Nomaguchi (1)[1], Yutaka Kuriyama (2)[1], Kikuo Fujita (3)[1]
[1] Osaka University, Japan

Abstract
This research discusses the co-creational environmental excellence focusing on a socially exchangeable modular home fuel cell co-generation system, and proposes its leading design methodology introducing a viewpoint of "system of systems" which broadens the scope of a design problem from the optimization of an individual system to the optimization of system of systems by integrating local optimization, multi-agent simulation, and scenario based planning. The design problem is decomposed into three sub problems i.e., (i) design optimization of variety of system modules such as a fuel cell unit and a heat exchanger which meets variety of energy demand of a residence, (ii) design optimization of a service system for introducing and exchanging fuel cell modules, and (iii) design optimization of a bounty system for popularization of a home fuel cell. A scenario is composed by combining alternative solutions of the sub problems, and is evaluated with a multi-agent simulation which predicts household behaviors for a introducing and exchanging a home fuel cell and then calculates social cost and consumed energy. The results show the possibility of co-creational environmental excellence in a socially exchangeable modular energy system, and the possibility of a system-of-systems approach for optimizing such an open-ended, complicated design problem toward the high-level environmental excellence.

Keywords:
Energy system, environmental excellence, system of systems, leading design

1 INTRODUCTION

Today's societal demand for environmental sustainability has been prompting all stake holders, such as governments, local communities, manufacturing companies, households, to simultaneously involve with its problem solving. They should cooperatively contribute to environmental excellence and gain any benefits through its total optimality. However, this is an extremely open-ended problem, since factors cannot be defined explicitly and all factors contain uncertainty. The high-level environmental excellence should be achieved through a co-creational mechanism in which each stake holder not only optimizes its problem locally but also coordinate with each other toward a total optimal solution.

This research looks at leading desing of socially exchangable modular houme fuel cell systems as an example, and proposes its design methodology to achieve high-level environmental excellence through co-creation of systems. This research introduces a viewpoint of "system of systems" which broadens the scope of a design problem from the optimization of an individual system to the optimization of systems by integrating local optimization, multi-agent simulation, and scenario based planning.

2 DEPLOYMENT OF SYSTEM THEORY AND EXPECTATION FOR CO-CREATIONAL ENVIRONMENTAL EXCELLENCE

2.1 Co-creational environmental excellence

System can be generally defined as "an aggregation of elements which depend on and interact with each other.[1]" In engineering domain, a word *system* is used to represent an artifact, e.g., a product system, a service system, a social system and so on. This research also uses the word in that meaning.

There are some approaches to enhance environmental excellence of an individual system, e.g., a manufacturer designs products with less environmental load materials or modularization for easy reuse and recycling, a customer buys environment-friendly products, a policy maker builds a bounty system to promote environment-friendly activities, and so on. A more high-level environmental excellence can be considered by incorporating those individual approaches. Generating such an effective value through interactions of autonomic stake holders is called *co-creation* [2]. A system built by co-creation can astronomically reconfigure its structure responding to changes of environment, such as changes of customers' demand, and then show high-level optimal performance.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_34,

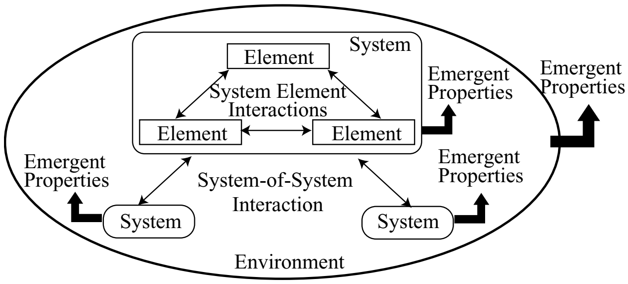

Fig. 1 : System of Systems

2.2 Viewpoint of "system of systems"

Co-creational environmental excellence is an answer to expanding system design theory. A range of today's system design has been expanding. That is not only because an individual system becomes large-scaled and complicated, but also because a society now demands that a system should be designed considering both of system performances and the affects to its environment. An expanded object of system design is called *system of systems* (abbreviated to SoS in the rest of this paper). Its necessity is noted especially in aerospace industry and defense-related industry in the United States. SoS is a large-scaled system consisting of multiple autonomic systems as shown in Fig. 1. A range of design is not limited to an individual system but expanded to various systems which have complicated interrelationships. Therefore, design problem of SoS requests any new approach other than conventional methods of system design, e.g., top-down system analysis, top-down system modeling, top-down formulization, and optimization based on them.

2.3 Emergent approach

Emergent is one of effective approaches to design of SoS, to which it is difficult to adopt conventional system design methods [2]. In philosophy, systems theory, science, and art, emergence is the way complex systems and patterns arise out of a multiplicity of relatively simple interactions of autonomic system as shown in Fig. 1. The behavior of each system is bound by the emergent properties. In emergent theory, an autonomic system is called agent. The emergent causes co-creation.

This research adopts an emergent approach and proposes a design method for SoS as shown in Fig. 2. Firstly, systems elements concerning with a design object and interrelations among them are enumerated. A system model of the whole of design problem is built based on the clarified elements and interrelations. It is decomposed into sub design problems. Each sub problem is solved locally to obtain a set of solution candidates. In this local problem solving, an optimization is performed for some sub design problems, which can be mathematically formalized and any optimization method can be adopted. A set of solution candidates for the whole design problem, each of which is called scenario, is composed by enumerating combination of alternative solution candidates of sub problems. A multi-agent simulation is performed under each scenario to evaluate the solution candidate.

Because SoS design is open-ended, any new approach is required for evaluation of its solution candidate. This research proposes that ideal situation should be assumed before the evaluation, and it is used as a target. A designer compares scenarios with the ideal situation, critiques them based on the comparison, and decides whether or not the scenario is good enough as the solution. If necessary, he/she should go back to the previous phases to refine sub problems, system modeling, and system element definition.

Based on the emergent approach introduced in this subsection, the rest of this paper focuses on the leading design of exchangeable modular home fuel cell systems and discusses its methodology toward co-creational environmental excellence.

3 SOCIALLY EXCHANGABLE HOME FUEL CELL SYSTEM

3.1 Home fuel cell cogeneration system

Distributed generation, also called on-site generation, is one of probable solutions for sustainable society. In industrial countries, most of their electricity is usually

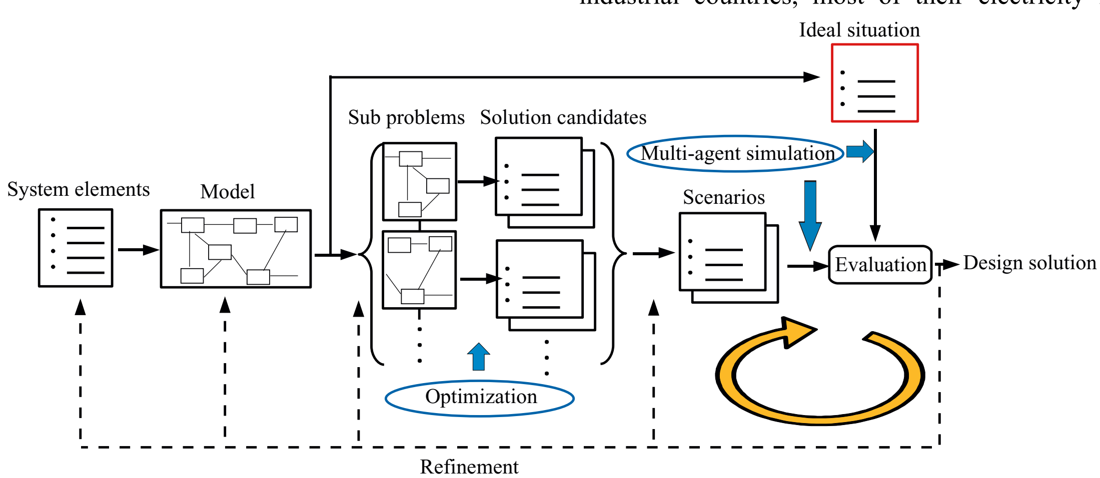

Fig. 2 : Emergent approach for SoS design

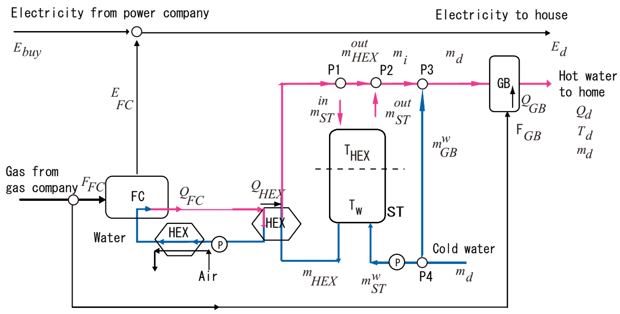

Fig. 3 : System architectmre of home fuel cell

generated in large centralized facilities. These plants have excellent economies of scale, but usually transmit electricity long distances and negatively affect the environment. Distributed generation is another approach. It reduces the amount of energy lost in transmitting electricity because the electricity is generated very near where it is used, perhaps even in the same building. This also reduces the size and number of power lines that must be constructed.

A home fuel cell co-generation system (CGS) is a representative example of popularizing distributed generation systems. CGS is a system that simultaneously generates two useful secondary energies [4], usually electricity and useful heat. It generates electricity by a power station, such as gas turbine or fuel cell, captures by-product heat emitted during electricity generation, and uses it for boiling water or air-conditioning. Fig. 3 shows system architecture of home fuel cell. It generally consists of three modules, e.g., fuel cell power station (FC), gas boiler which works as a backup heat engine, and hot water tank (T_{HEX}). A fuel cell co-generation system is being noticed as a probable energy system because of its high energy efficiency. However, it has not yet been popularized, because its introduction cost and running cost is high although a government supports its popularization by a bounty system.

3.2 Fluctuation of energy demand

Rated output of a home-use energy system should be designed corresponding to energy demand of a household which introduces the system. If rated output of an introduced CGS is larger than energy demand, it causes redundant running cost. If it is smaller than energy demand, energy efficiency becomes lower.

The number of household members, on which the energy demand depends, changes through life stages, such as marriage, birthing and independence. That change takes place everywhere in a society, and causes fluctuation of energy demand. Because an energy system's life span is long enough, it should be designed considering the fluctuation. This research assumes that energy demand of different household will fluctuate differently, but distribution of energy demand in the whole society will remain largely stable.

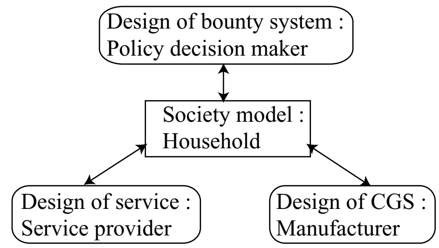

Fig. 4 : Sub problems

3.3 Possibility of co-creational environmental excellence with socially exchangeable modular home fuel cell

Total performance of CGS depends on its modules' performance. It is expected to respond to fluctuation of energy demand by exchanging some modules properly. It is also expected to respond to physical deterioration with a low cost by exchanging a deteriorated module instead of replacing the whole system.

If various energy demands distribute among society, and distribution of energy demand in the whole society will remain largely stable, it can be considered that each household shares the modules and exchanges them when the energy demands changes. A household can choose an optimal one corresponding to its energy demand. An exchangeable module will reduce introduction and operation cost of home fuel cell will reduce, and then promote its popularization.

4 LEADING DESIGN METHODOLOGY OF SOCIALLY EXCHANGABLE MODULAR HOME FUEL CELL CGS

4.1 Leading design

This research supposes that a socially exchangeable home fuel cell CGS is popularized, and that co-creational environmental excellence is achieved by it. That is a near future scenario. Toward designing such an advanced system, a concept of leading design is important. Leading design is a concept to support designing a highly advanced artifact for which necessary technical seeds are not sufficiently developed [5]. This research is based on the concept, and proposes leading design methodology of to-be energy systems.

4.2 Definition of sub problems

It is not feasible to solve the whole leading design problem as a single problem considering factors stated in the previous section. This research decomposes it into the following three sub design problems.

1. Design of CGS, that is, design of CGS module, its variants and operation schedule corresponding to energy demand.
2. Design of services of introducing CGS and exchanging modules.
3. Design of a bounty system.

Those three sub problems are integrated by a social model that is implemented by a multi-agent simulation considering interrelationships among the systems as shown in Fig. 4.

4.3 Steps of leading design

The leading design is performed in the following steps based on the approach stated in Subsection 2.3 considering the sub problems and their interrelationships.

(i) Modeling fluctuation of household energy demands and household behaviors of introducing/exchanging CGS

A multi-agent simulation that simulates energy demand fluctuation is built considering four life events which change the number. Household behavior of introducing or exchanging CGS is also modeled.

(ii) Design optimization of CGS

An optimal product family of CGS is designed under energy demand fluctuation given by a multi-agent simulation built in step (i).

(iii) Design of service system, design of bounty system

Multiple alternative solution candidates of a service system and a bounty system are obtained.

(iv) Computing cost and energy efficiency

Scenarios are composed by combining the solution candidates given in step (ii) and (iii). Each scenario is evaluated by total cost in a society and social energy efficiency calculated by a multi-agent simulation.

The following subsections of this section explain the details of those steps. The detail of step (iii) is explained by a design example in Section 5.

4.4 Modeling fluctuation of household energy demand and household behaviors of introducing/ exchanging CGS

Modeling fluctuation of household energy demand

Energy demand consists of electricity demand and gas demand. Household energy demand depends on the number of household members as shown in Fig. 5 [6]. It can be roughly classified into three patterns, i.e., single person household (S1), two to four person household (S2) and over five person household (S3).

This research considers four life events which change the number of household members, i.e., birth, marriage, independence and death. A nominal probability distribution is given to each factor. A model that simulates human life based on the four factors is built with a multi-agent simulation. A life model can predicts change of the number of household member, and fluctuation of energy demands based on the data shown in Fig. 5. Random numbers r_E and r_Q are multiplied to electricity demand and gas demand, respectively, in order to consider that different household has different energy demand because of difference of its lifestyle even if the number of household members is same. r_E and r_Q are given by two-

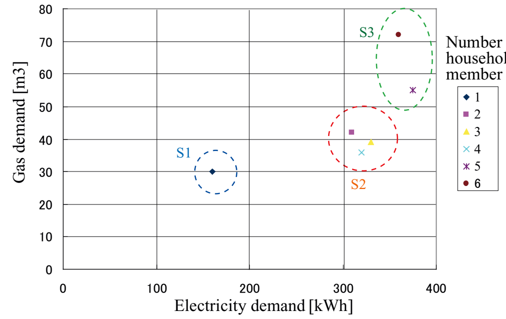

Fig. 5 : Patternized energy demand

dimension normal distribution with covariance, because electricity demand would correlate with gas demand.

Modeling household behaviors of introducing/exchanging CGS

It is assumed that household introduces CGS if the sum of its introducing cost and its running cost is less than the sum of electricity cost and gas cost in the case of no CGS. Introducing cost of CGS is modeled by a monotonically decreasing function of the number of manufactured fuel cell, because its manufacturing cost will decrease because of economy of scale.

A fuel cell of CGS should be exchanged in the future, because of its physical deterioration and energy demand change. This research assumes that a household decides to exchange a current fuel cell module for new one which meets energy demand when any of the following conditions is true.

(i) A fuel cell comes to the end of its physical life.

(ii) The other module comes to the end of physical life. That is, a fuel cell can be exchanged in the opportunity of exchanging the other module.

(iii) The following inequality is satisfied; $C_1 - C_2 > C_t$, where C_1 is annual running cost of current fuel cell, C_2 is annual running cost of new optimal fuel cell, and C_t, is exchange cost.

4.5 Design optimization of CGS

Design of modules and product family

A variety of rated output of CGS is needed in order to meet a variety of energy demand. This research defines two factors as design variables of CGS family design problem, i.e., maximum amount of gas inputted to fuel cell [kW], which controls rated output of fuel cell power station, and capacity of boiled water tank [L]. It is assumed that the common gas boiler is used regardless of energy demand, and its rated output of gas boiler is 17.5[kW], because a gas boiler is just a backup heat generator. An objective function is the sum of annual write-off of introduction cost, annual running cost and annual energy cost, which sums electricity cost and gas cost,. A mathematical model of electricity amount and heat amount generated by a fuel cell power station, and a mathematical model of heat amount generated by a gas boiler are needed to calculate necessary amount of electricity and gas corresponding to energy demand. This research uses liner approximated models of them [4][7].

Optimization of operation schedule

A daily schedule of operating fuel cell power station should be optimized when CGS is designed. This research assumes a daily fluctuation of electricity demand and gas demand [6], and obtains an optimal operation schedule in advance, which minimizes daily energy cost under the daily fluctuation of energy demand. That optimal schedule is given to the design optimization of CGS modules stated above.

4.6 Computing cost and energy efficiency

An objective function of total cost C is an annual cost of each household, which sums introduction cost and running cost. It is given by the following equation;

$$C = \frac{\sum_{t=1}^{T}\sum_{i=1}^{N}(IC_i^t + EC_i^t + TC_i^t)}{\sum_{i=1}^{N} n_i} \quad (1)$$

A subscript t and i denotes a value of t th year of i th household. T is years of simulation span. IC^t_i is annual writing-off of CGS introduction cost. EC^t_i is annual energy cost. TC^t_i is module exchanging cost. n_i is the length (years) that i th household exists. N is the total number of household that exists in T years.

An objective function of energy efficiency E is given by the following equation;

$$E = \frac{E_{out}}{E_{in}} \times 100 \quad (2)$$

$$E_{out} = \sum_{t=1}^{T}\sum_{i=1}^{N}(ED_i^t + QD_i^t) \quad (3)$$

$$E_{in} = \sum_{t=1}^{T}\sum_{i=1}^{N}(FP_i^t + FFC_i^t + FGB_i^t) \quad (4)$$

E_{out} is total energy output, that is, total energy consumption in a society. E_{in} is total energy input in a society. ED^t_i is electricity demand. QD^t_i is gas demand. FP^t_i is primary energy amount inputted to a power plant in order to cover household electricity demand. FFC^t_i is gas amount inputted to a fuel cell power station. FGB^t_i is gas amount inputted to a gas boiler.

5 DESIGN EXAMPLE

5.1 Overview

This section demonstrates an example of leading design based on the methodology stated in Section 4. A span of a multi-agent simulation is 30 years. As proposed in Subsection 2.3, values of objective functions at the ideal situation are used as a design target. Scenarios are evaluated by comparing with that target. Fig. 6 shows values of objective functions and outlines of Pareto optimal solutions under the scenarios introduced in the design example, and transition of Pareto optimal solutions corresponding to refinement of scenarios. A horizontal axis of Fig. 6 is a value of Eq. (1), and a vertical axis is a value of Eq. (2). A data label in Fig. 6 denotes a scenario number.

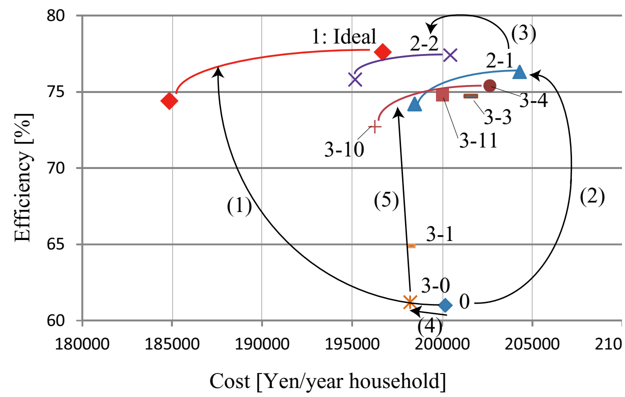

Fig. 6 : Evaluation of scenarios

5.2 Scenario of ideal situation

Firstly, a situation that CGS has not been popularized is considered. All energy demand of household is covered by buying electricity from a power company. All heat demand of household is covered by a gas boiler of household. This situation is named scenario 0. The results of a multi-agent simulation show that C will be 200,176 yen and E will be 61.0% as shown in Fig. 6.

Next, realization of socially exchangeable modular home fuel cell CGS is assumed as an ideal situation. It is assumed that the number of CGS lineup is 100, module exchange cost is zero, and manufacturing cost of CGS lowers to asymptotically stable value. This situation is named scenario 1. In order to obtain an outline of Pareto optimal solutions with a small computation cost, this research obtains two extreme Pareto optimal solutions with a single objective function, i.e., a cost optimal solution and an energy efficiency optimal solution. Comparison between the results of scenario 1 and the results of scenario 0 shown in Fig. 6 reveals that cost reduction of about 15,000 yen and efficiency improvement of about 15% can be expected by realization of socially exchangeable modular home fuel cell CGS (Fig. 6 (1)).

5.3 Scenarios of CGS family design and operation system design

Scenarios of CGS family design and its operation system design are composed under the assumption that all household will introduce CGS.

Case of designing three CGS variants

This subsection firstly considers a situation that a manufacturer designs three CGS variants each of which covers each of patterned energy demand S1, S2 and S3 explained in Subsection 4.4. This is named scenario 2-1. The optimization is performed with genetic algorithm (differential evolution) powered by OPTIMUS. Table 1 shows specs of fuel cell power station and boiled water tank as the results of the optimization. A multi-agent

Table 1 : Optimization results of three fuel cells

	Fuel cell output [kW]	Tank capacity[L]
S1	0.28	53.0
S2	0.43	53.0
S3	0.57	53.0

simulation is performed under that scenario. The results reveal that energy efficiency comes up to the target level, but cost is 10,000 yen higher than the target (Fig. 6 (2)). One explanation for the results is that CGS which many households introduce has higher rated output than household energy demand. That is because the number of CGS variants is too few to cover distributed household energy demand. It is also revealed that only 85% of households have never exchanged modules because of high exchange cost. Those results show that socially exchangeable modular home fuel cell CGS cannot be realized by this scenario.

Case of designing three CGS variants

Next, the other situation is considered. A manufacturer modularizes a cell unit of a fuel cell power station such that its rated output can be easily configured by combining proper number of cell units. This design example assumes a cell unit which rated output is 0.2 kW, and its exchange cost is 50% of exchange cost of the whole fuel cell module. This situation is named scenario 2-2. Comparison between its results and the results of scenario 2-1 reveals that efficiency comes up to the target level, and cost comes close to the target (Fig. 6 (3)). 96.4% of households have exchanged modules. Those results lead to the conclusion that scenario 2-2 is probable.

5.4 Scenarios of bounty system

In a design of bounty system, a household is assumed to decide introduction of CGS based on the rule defined in Subsection 4.4. The situation of scenario 2-2 is assumed as for CGS family design and its operation system design. Scenarios are composed assuming some situations of bounty, e.g., no bounty is paid (scenario 3-0), a certain amount of bounty is paid every year to a household which introduced CGS (scenario 3-1 to 3-4), bounty is paid every year but its amount is reduced every five years (scenario 3-5 to 3-13). Table 2 shows the details of representative scenarios, values of objective functions and percentages of household which introduces CGS. Cost includes government's expense for bounty. When there is no bounty, only 1.8% of households introduce CGS. Improvement of cost and efficiency is fractional (Fig. 6 (4)). Any bounty system can promote energy efficiency, and cost increase is not so large (Fig. 6 (5)). It is revealed that about 13% improvement of energy efficiency can be expected by the same amount cost as scenario 3-0. That is because bounty promotes popularization of CGS, and it causes manufacturing cost reduction. According with the results shown in Table 2, scenario 3-10 is cost optimal, where initial amount of bounty is large but it is reduced

Table 2: Evaluation of bounty system design

Scenario	Bounty system: Yearly	Bounty system: Reduction	Cost	Efficiency	Intro. ratio
3-0	0	0	198,221	61.2	1.8
3-1	1,000	0	198,126	64.9	18.0
3-3	5,000	0	201,590	74.7	89.1
3-4	7,000	0	202,649	75.4	93.5
3-10	5,000	3,000	202,649	72.7	81.1
3-11	7,000	1,000	200,025	74.8	86.6

after five years. Scenario 3-4 is efficiency optimal, where larger amount bounty promotes more popularization.

6 CONCLUSION

This research proposed a design methodology to achieve high-level environmental excellence through co-creation of systems focusing on leading desing of socially exchangable modular houme fuel cell CGS. This research introduces a viewpoint of "system of systems" which broadens the scope of a design problem from the optimization of an individual system to the optimization of systems. The design example shows that some probable design solutions can be found by the proposed method incorporating local optimization, multi-agent simulation, and scenario based planning.

This research used "artisoc," which is a multiple agent simulator provided charge-free by Kozo Keikaku Engineering Inc. We are deeply grateful to it.

Abstract

The idea of utilizing natural ventilation for passive cooling and hence reducing the energy for air conditioning systems of buildings has increasingly attracted the attention of researchers. In urban areas however, a kind of comprehensive approach considering simultaneously the outdoor wind environment and the natural ventilation has been mostly neglected. This study firstly investigates, the effective criteria on the resulting wind environment at pedestrian level, in the outdoor spaces, and secondly defines criteria and indicators in different residential neighborhood patterns which led to an assessment of the resulting ventilation potential of the neighborhood blocks. The results of parametric three-dimensional modeling studies, using Computational Fluid Dynamics (CFD) have been used to identify criteria more precisely. In the context of Iran, by focusing on Tehran, this article aims to indicate the application of the effective criteria in several configurations of neighborhoods, each represent a kind of typology, in order to assess wind environment around the neighborhood blocks. Finally, the article developed a framework which may be used as a guide for urban designers/planners to create a more ecologically and environmentally sustainable urban form.

Ventilation, Pedestrian-level wind environment, Neighborhood patterns, CFD

1 INTRODUCTION

Considering wind environment effects on urban spaces such as Dispersion of pollutants, diffusion of heat, comfort and safety of pedestrians, and also the energy related effects such as natural ventilation of buildings, indicates the necessity of understanding the wind behavior and its environment to be taken into account in the sustainable urban design approach.

Apart from which of the above effects are prior regarding the geographic situation and climatic conditions of site, it is essential for an urban designer, to have knowledge of the effective criteria forming a wind environment. The necessity will be also multiplied regarding the increase in world's urban population[1] and hence the need of high rise buildings and skyscrapers on the one hand, and the cost of a conventional wind environmental advice (wind tunnel), which led it to being postponed to the quasi-final design steps, on the other; although the use of computational models has been noticeably increased in recent years which makes the wind environment analysis easier, faster, and also more affordable.

Computational fluid dynamics, usually abbreviated as CFD, is a branch of fluid mechanics that uses numerical methods and algorithms to solve and analyze problems that involve fluid flows. Computers are used to perform the calculations required to simulate the interaction of liquids and gases with surfaces defined by boundary conditions [2].

The main purpose of this study is to suggest a framework which can be assumed as one of the environmental consideration an urban designer should have in his mind, in order to improve the urban spaces' environmental quality as well as buildings' energy efficiency. This article does not aim to investigate the parameters related to the CFD method and interpret the dynamical equivalent. Rather it seeks the main results of previous studies which have been carried out using CFD analysis and tries to clarify their relationship with the basic factors which are used in urban design in order to organize the effective criteria by definition of a framework which can be used by the urban designers not only in new urban development but also in reconstruction of the existing urban texture.

1 The world's urban population was 2.9 billion (47.2%) in 2000 and is expected to rise to 5 billion (60.2%) by 2030. During 2000–2030, the world's urban population is projected to grow at an average annual rate of 1.9% [1].

2 BACKGROUND

Computational Fluid Dynamics, or CFD, uses advanced computer software to model the flow of fluids through a processing facility. The fluid may be in liquid, gas or loose particle form, or a combination of them. Using computer simulation a wide range of variations in physical design and operational parameters can be tested and refined until a set is identified which gives optimum performance[2]. One of the software uses the CFD method, is the software "Fluent". Since it is mechanical software and deals with the small size obstacles and objects, it requires a huge amount of computations in order to analyze wind behavior at the scale of an urban.

Recently, Meteodyn has developed "UrbaWind", which is automatic CFD software for computing the wind in urban environment for small wind turbines. The model used in UrbaWind allows taking the wind effects into account by solving the equations of Fluid Mechanics with a specific model that can represent the turbulence and the wakes around buildings as well as the porosity of the trees and the effects of the ground roughness (asphalt, water or grass). In comparison with the software Fluent, Urbawind's advantage is that it has been dedicated for the analysis at urban scales, which led to a less time-consuming computational process. In order to validate UrbaWind's results, different study cases proposed by the Architectural Institute of Japan have been set up[3]. Urbawind's output and input data can be illustrated as fig.1. There are several input types needed to get the 3D plan output. This paper aims to develop a framework used in the 3D site plan as the input.

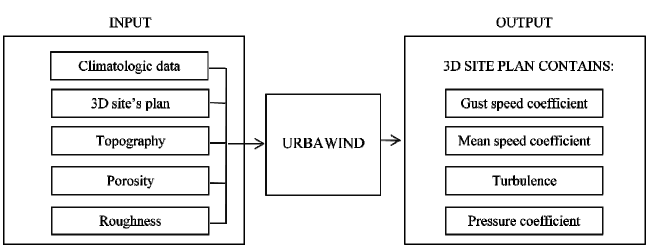

Fig. 1: Scope of Urbawind software(by author based on [3])

UrbaWind solves the equations of Fluid Mechanics, i.e. the averaged equations of mass and momentum conservations (Navier-Stokes equations) When the flow is steady and the fluid incompressible.

3 DEVELOPING A FRAMEWORK

There are several studies based on wind tunnel tests or numerical models which examine wind environment around buildings [4],[5],[6],[7],[8]. They suggest that apart from site's situation (i.e. porosity and vegetation) and local wind characteristics, there are several criteria regarding buildings which form the characteristics of the wind over an actual ground surface. Building configuration, e.g. its height, width, building arrangements and density are some of the significant factors affecting wind velocity near the ground level [4, 9].

Many studies has been focused on street canyons and indicate how the ratio of building height to the width of street (called aspect ratio) affects the wind environment [10], [11],[12],[13],[14]. Bottema [15] after introducing the wind amplification factor which links local mean wind speed to mean wind speed at an ideal meteorological site, defines topography and surrounding terrain, building or building groups and details of site as the effective criteria on wind amplification factor at various scales(i.e. region, city, district)[15]. Kubota et al [4]suggests the gross building coverage ratio and gross floor area ratio as the criteria to reveals the relationship between the building density and the average wind velocity at pedestrian level. It indicates that an increase of the gross building coverage ratio decreases the mean wind velocity ratio. It also concludes that the average pedestrian-level wind velocity of cases can be explained well by the gross building coverage ratio rather than by the gross floor area ratio. Fig.2 shows some effective criteria on wind environment which have been mentioned by previous studies.

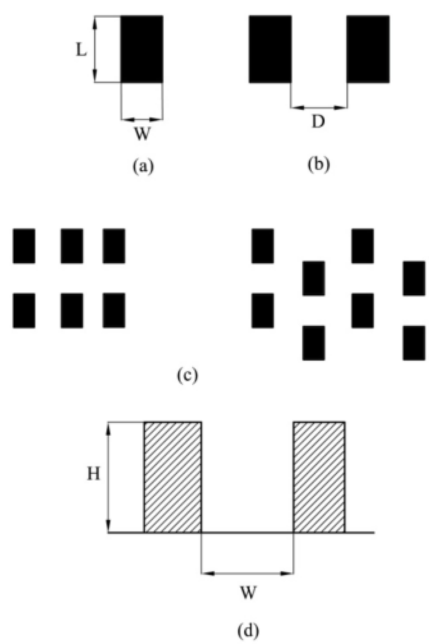

Fig. 2: Scope of effective criteria on wind environment mentioned by previous studies (a) building's dimensions (b) block's distances (c) blocks' arrangement (d) aspect ratio

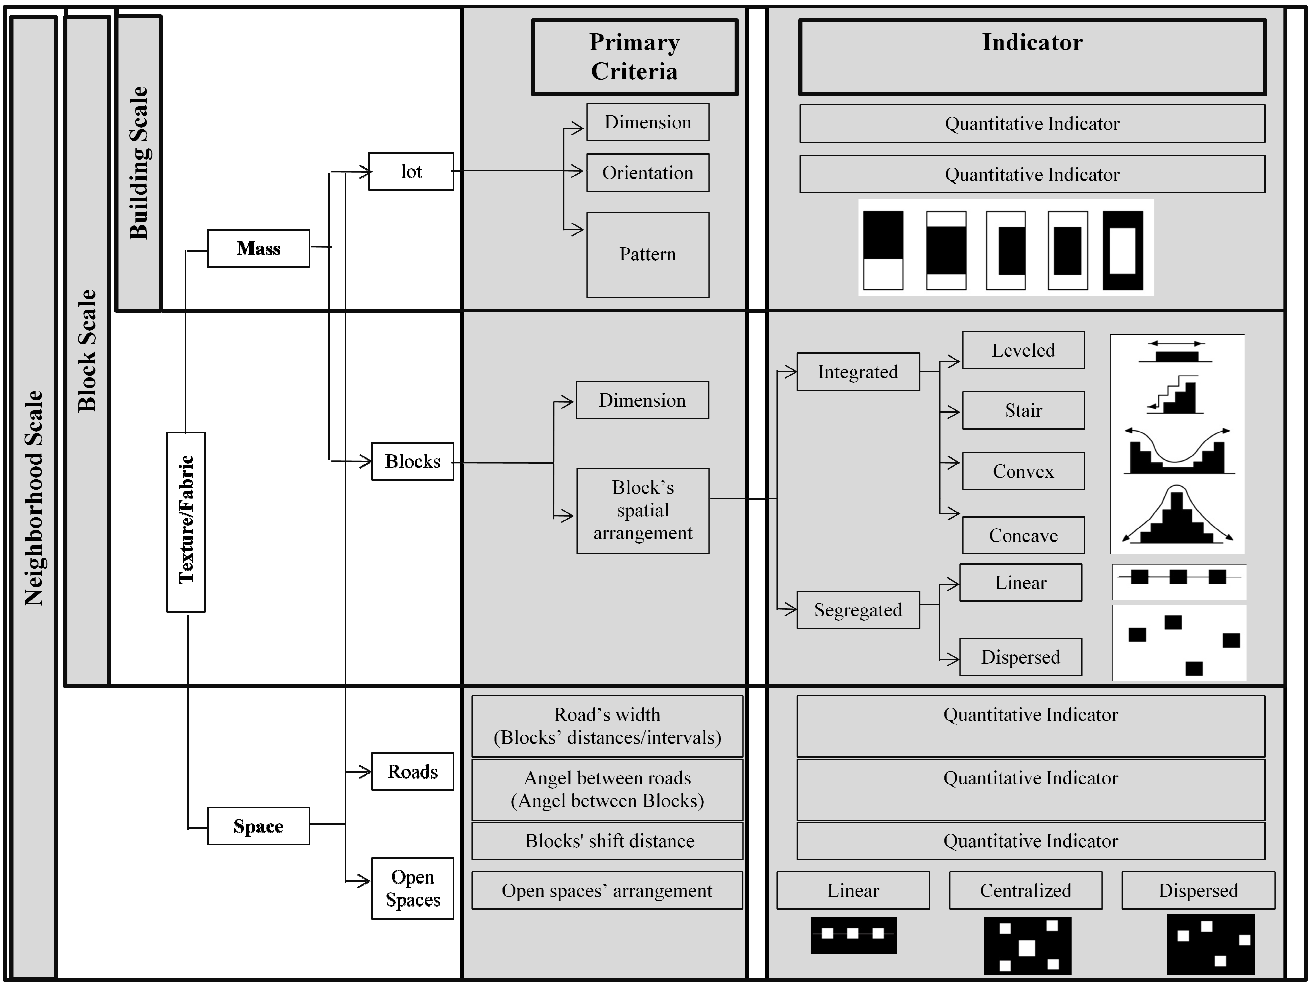
Considering these studies the main effective criteria on the airflow behavior according to the CFD method can be illustrated as Diagram1. In the diagram, three scales ranging from building to neighborhood are shown. A kind of fabric can be identified for each scale by means of mass and spaces (voids). Therefore each scale has its own criteria and indicator categorized regarding whether they concern the mass or the space. The building scale's main criteria as far as it considered as a lot are, dimension (i.e. orientation, and pattern which indicates how the building is being arranged in a lot. The first two criteria can be identified by the quantitative indicator and the last one, by qualitative indicator. As the upper scale and formed by standing a row of lots in a vicinal way, a block can be defined by its dimension and spatial arrangement.



Diag. 1: Conceptual Framework: Effective Criteria and quantitative and qualitative indicators on wind environment in various scales from building to neighborhood (by authors)

Because of the obstacle's height effect on wind behavior and also inevitable existence of buildings with various heights in a block, it should be considered blocks' profile and the height changes rhythm (that is whether it's increasing, decreasing, and constant or …). Containing all the previous criteria, the neighborhood has its own spaces containing roads and open spaces. Roads criteria are road's width, angel between roads and its continuity which can be construed as the blocks' overlapped distance or blocks' shift distance which all can be identified by the quantitative indicator.

Some notes are worthy to be mentioned regarding the above diagram. Some criteria (i.e. the ratio of building height to the width of street, area's foot print, gross floor area ratio …) which have been mentioned by the previous studies can be assumed as secondary criteria which can be derived from the primary one above. The quantitative indicators in the diagram 1 should be identified by local regulation, building's codes, and per capita standards or by the urban designers' suggested guidelines through the results and observation of computational simulation of CFD. Nonetheless a quantitative range for them can be defined as indicated in table1.

4 NEIGHBORHOOD TYPES

There are two divergent views about the size of city quarter or neighborhood. There is that view represented by Jacobs which stressed the political function of the quarter. Another view held mainly by physical planners relates the size of the quarter to a comfortable walking distance from its center to periphery[16].

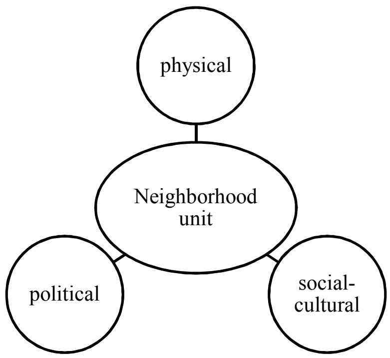


Fig. 3: Scope of Neighborhood's aspects (by authors based on [16])

Focusing on the physical aspects of the neighborhood unit, this paper regards neighborhood as an urban unit which one can reach within 10 to 15 minutes' walk from center to periphery.Surveying different existing neighborhood patterns in Tehran according to their urban fabric, open spaces pattern and the roads network and hierarchy led to identification of three main neighborhood types as following:

Table 1: Quantitative indicators of effective criteria on wind environment

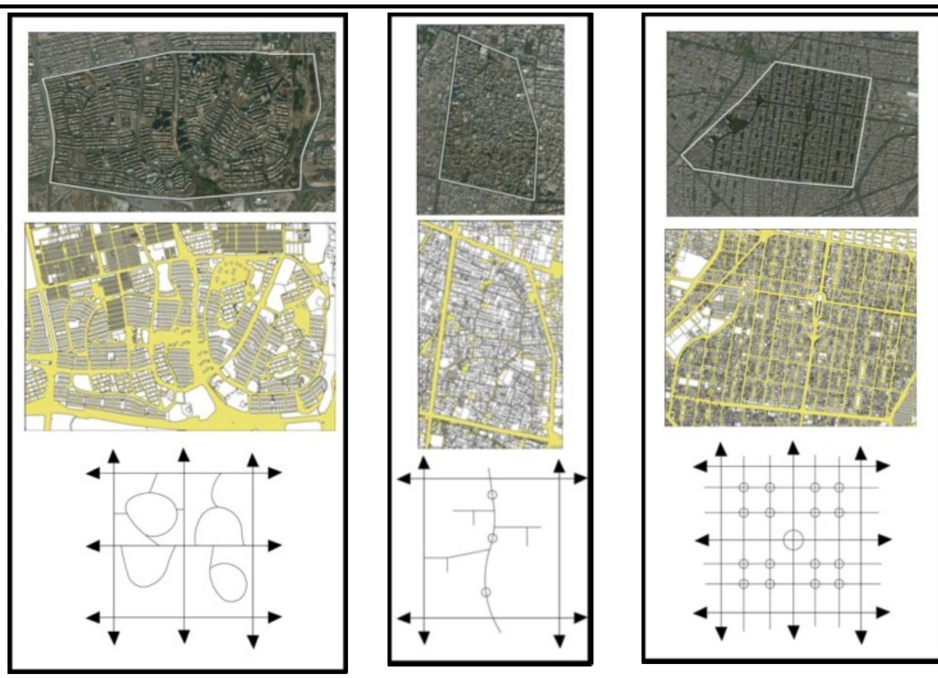
Primary Criteria	Quantitative Range	
Lot 's orientation	0-180 degree	
Roads' width (meter)	Major arterial	45
	Minor arterial	30
	Collector-feeder	18
	Local street/ cull de sacs	10
Angel between roads	0-90 degree	
Block shift distance 	o≤a	

Type A: The main square at center, main roads deriving from that, continuing through the surrounding fabric, high building density at center decreasing toward surroundings.

Type B: clustered model, roads with the well defined hierarchy, open spaces mostly arranged in the main road, fine fabric.

Type C: Grid model, hierarchy of roads and open spaces (fig.4).

Fig.4: Different neighborhood types, Tehran (by author, 2011)



Type A: *Shahrak e Gharb* Type B: *Oodlajan* Type C: *Haft hoz*

Table 1: Neighborhoods' indicators of effective criteria on wind environment

			Type A	Type B	Type C
					Scale	Criteria		Indicators		
Lot	Dimension (meter)	Length	45	20-30	30
		Width	20	10	15
		Height	6-12	9	15
	Orientation(degree)		0-180	0,30,90,150,180	90
	Pattern				Block	Dimension (block's length(meter))		120-250	70-100	80-200
	Spatial arrangement				Neighborhood	Roads' width(meter)		15-45	1.5-8	10-30
	Angel between roads		0-180	0,30,90,150,180	0,90
	Open spaces arrangement		Dispersed 	Linear 	Centralized 
One important note regarding neighborhood types defined above is, their land use intensity scale which defined by the quantitative indicator between 0 and 1. It also can be regarded as the area's footprint criterion (mentioned as secondary criterion before), that as it approaches the value 1, it means that the neighborhood fabric get much more compact and dense. Among the neighborhoods above, Type B with the intensity scale value of about 0.8 can be respected as a dense neighborhood. Although this is needed to be proved by the results from computational model, it can be expected that such a dense neighborhood would be impenetrable facing the local wind and it would play a huge obstacle role against that.

5 CONCLUSION

Considering different types of necessary input data for computational fluid dynamic (CFD) analysis, and focusing on the geometric data which is "3D site plan", this paper reviewed the previous studies on wind behavior which have been held by the CFD method. Therefore the primary effective criteria on wind behavior regarding the geometric characteristic of building and blocks have been recognized and a framework of effective criteria on wind environment, quantitative and qualitative indicators, categorized by building, block and neighborhood scales has been suggested. As shown in the diag.1, in the building scale, lot's dimension, orientation, pattern, in the block scale, in addition of building scale's criteria, block's dimension and its spatial arrangement and finally in neighborhood scale, in addition of lower scales' criteria, roads' width, angel between roads, blocks' shift distances and open spaces arrangement, are the primary criteria. Then some ranges, can be assumed for the quantitative indicators have been suggested in the table1. Finally the developed conceptual framework has been applied for the three most common neighborhood types in selected systematically Tehran city; then each neighborhood type's character has been introduced by the qualitative and quantitative indicators of the suggested criteria in the framework. So the urban designer can use it as a primary assessment in the early stages of design and before the 3D plan analysis stage by CFD. This framework can be used by the urban designers not only in new urban development but also in reconstruction of the existing urban texture and it introduces and generates a knowledge of effective criteria as tools which can be applied by an urban designer to control the environmental quality of urban areas toward urban sustainability in a favorable way. This article took the first step in the process of an approach which tries to assume wind as an environmental factor in the early steps of design and before the application of computational model; further studies can be dedicated to next steps by a definition of the quantitative ranges for the suggested indicators which led to a safe and favorable wind environment.

Energy Harvesting for Distributed Microsystems – The Link between Environmental Performance and Availability of Power Supply

Benecke, S.[1], Rueckschloss, J. [1], Middendorf, A.[1], Nissen, N. F.[2], Lang, K.-D.[1,2]

[1] Technical University of Berlin, Berlin, Germany

[2] Fraunhofer Institute for Reliability and Microintegration (IZM), Berlin, Germany

Abstract

Efforts in reducing power consumption of microelectronic components and developments in the area of energy harvesting devices have led to technically feasible solutions for autonomous power supply of distributed microsystems. Reliability by means of availability of the required energy is a fundamental constraint for replacement of batteries. At the same time environmental impacts of the technical solution need to be kept low. In this paper we will present a framework for modeling energy budgets depending on non-ideal environmental loads. A new indicator describing availability and risk of materials implemented is introduced, which is then applied to compare environmental performance of different design decisions.

Keywords:

Energy harvesting, system-oriented design, resource availability and risk indicator (RARI)

1 INTRODUCTION

The interest in microsystems integrating own power conversion units using energy from the surrounding environment is steadily growing. Main application fields can be found in industry because of the chance to save significant maintenance costs due to extended system lifetime without the need to change batteries on a regular basis. Moreover, reduction of battery use in wireless application is desired from an environmental point of view. Trade-off considerations comparing environmentally critical materials of both, energy harvesting devices and batteries vs. operation time were previously conducted [1][2]. The first step towards an environmentally conscious solution is the comparison of technologically feasible options. Ambient conditions as well as the ability to buffer deviations from ideal operating conditions will finally determine the choice of components, overall dimensions and therefore amount and composition of materials implemented. The developed framework for modeling and optimization of the energy conversion chain provides a foundation for further considerations regarding energy budgets and environmental impacts.

2 SYSTEM-ORIENTED MODELING APPROACH

The idea behind the modelling concept for energy harvesting devices is shown in Fig. 1 for the example of thermoelectric energy harvesting systems converting temperature gradients into electricity. In order to model the complete conversion chain of the harvesting system, components are first categorized corresponding to their functionality and split into parameterized sub-models. In case of the thermoelectric energy harvesting chain this comprises the thermoelectric converter itself as well as peripheral electronic devices for voltage conversion and energy storage.

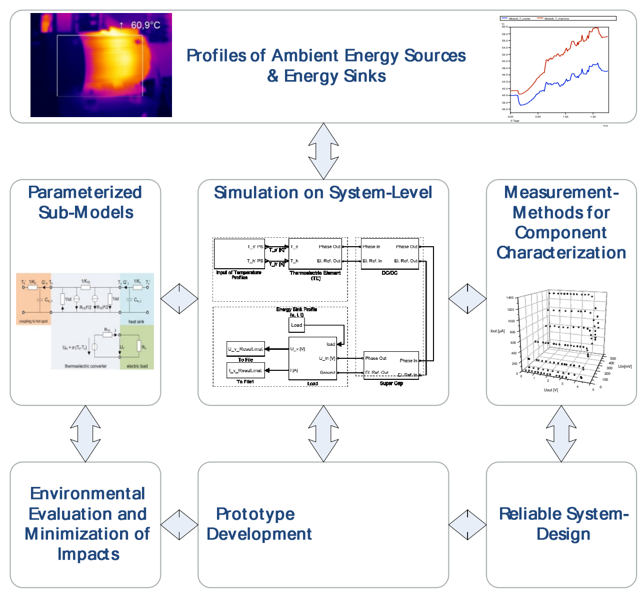

Fig. 1 – Concept of system-oriented modeling approach

The sub-models are then transformed into a common modelling platform with defined interfaces for coupling of the single modules describing the relevant physical domain. Parameters to sufficiently describe these components with regard to their effect on the power conversion path are identified. Parameter sets for specific, interchangeable devices are generated from measurements in case information provided by datasheets is not sufficient. Typical examples are thermoelectric devices,

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_36, © Springer Science+Business Media Dordrecht 2012

Where specifications usually only partially contain the required data for simulation of energy flows in the proposed framework. This is especially true for simulation of system behavior at other than room temperature levels, requiring temperature-dependent parameter curves of the module. For analysis of dynamic processes, time-dependent parameter sets might also be required, e.g. leakage current of capacitors. Moreover input profiles of ambient energy available as well as output profiles of the energy consuming devices (energy sinks) need to be coupled to the simulation environment. On the basis of the provided framework, feasibility of energy harvesting setups in varying environments can be evaluated in an early development phase. System optimization by identification of critical parameters becomes possible as effects of changes in design on module-level can directly be linked to overall system performance. From the model, acceptable parameter deviations or drifts can be derived for the system to be working within targeted specifications. For environmental analysis firstly technological alternatives can be compared on a common basis. Secondly effects of elimination, minimization or replacement of environmentally critical components can be investigated. A suitable, optimized solution of components chosen is finally turned into a hardware test setup.

3 APPLICATION SCENARIO

Maintenance and repair are significant expense factors for operating a facility, plant or machine. Efficiency and profitability can be increased by applying intelligent concepts of condition monitoring, cutting down expenses caused by unscheduled downtimes or complete engine breakdowns. Moreover, by applying condition based maintenance, operating time between service intervals can be increased significantly. Recent studies at Technical University of Berlin and Fraunhofer IZM focus on the design of condition monitoring systems for industrial applications. Within the frame of the project 'ECoMoS' (Energy-autarkic condition monitoring system) a sensor network of self-sufficient micro systems is currently developed for condition monitoring purposes of machine parts in paper plants. The wireless sensor system proposed within the framework of the project 'ECoMoS' represents such an innovative approach for applied condition monitoring (Fig. 2). The developed system includes an acceleration sensor which is attached to the vibrating machine being monitored. A digital signal processor performs hardware-based algorithms to complete a Fourier transformation of the acceleration signal and does further analysis of the characteristic spectrum. A first diagnose of the systems condition is carried out onboard. In case of a warning a protocol with the attached FFT is sent to a base station via proprietary communication standard. Further steps can then be decided by operating staff of the paper mill. Minimum threshold value for operating voltage was defined 3.3V corresponding to the specifications of the IC solutions implemented. In order to keep energy demand low, duty cycle operation of the system was chosen with current pulses below 50mA over periods of 10s for each measurement. While the first prototype already proofed to be fully functional [2], a second generation integrating all electronics of the sensor system as well the thermal path for thermoelectric energy conversion will be introduced (Fig. 2).

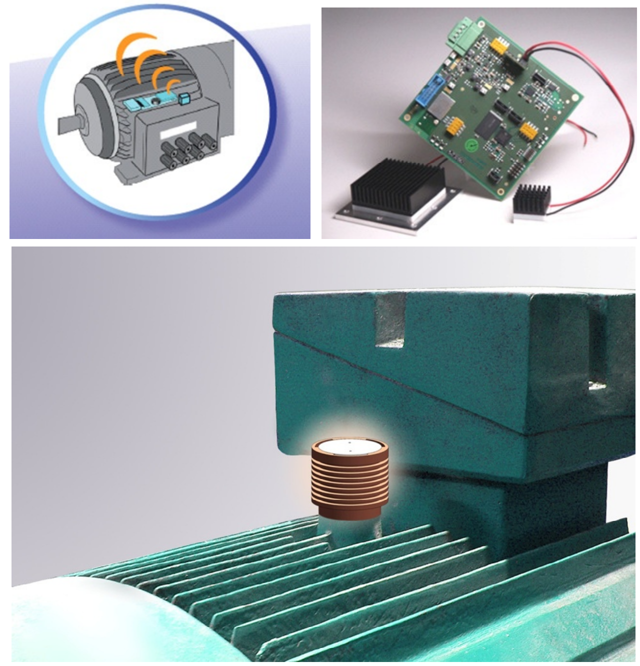

Fig. 2 –Self-sufficient sensor node: System study (top, left), first prototype from discrete components (top, right), final integrated concept (bottom)

4 SYSTEM SIMULATION

The setup of the electronic subsystem for voltage conversion and buffering including parameters of the chosen components was fully described in [2]. Sub-models described were implemented in Matlab/Simulink, using predefined SimScape components from electric and thermal physical domain.

Properties	TEG A	TEG B
Dimensions [mm·mm·mm]	20,0·20,0·3,4	30,0·30,0·3,6

α [mV/K]	12,7	54
Rth [K/W]	5,92	3,19
Ri [Ω]	0,37	3,41

Table 1 – Properties of thermoelectric devices investigated

The complete energy harvesting model consists of the thermo-electric modules (TEG) opposed to a temperature gradient, a Linear Technologies DC/DC converter, LTC3108, and the energy storage, a CAP-XX ultracap, HS230, as central module blocks. As for the thermoelectric devices, two options were compared in the latter thermal simulations, Type A and Type B (Table 1), without changing the electronic voltage conversion and energy buffer. Both modules significantly differ regarding Seebeck-coefficient α, thermal resistance R_{th}, electric resistance R_i, weight and size therefore determining system behavior in conjunction with the chosen thermal path.

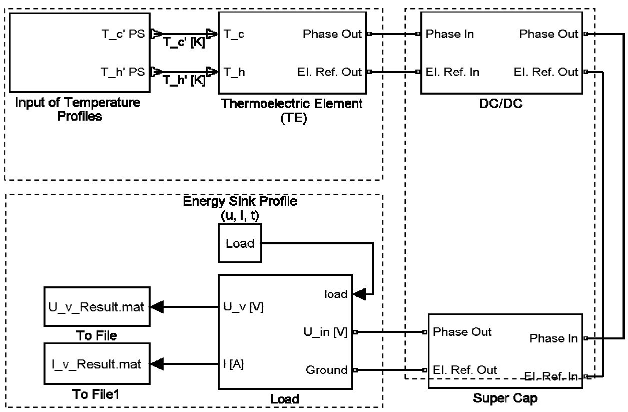

Fig. 3 – Simulink block diagram of the harvesting system

As central multi-physics modeling platform a Simulink model (Fig. 3) was developed. Input connections are provided by two interface blocks for coupling of ambient temperature profile data into the model. These inputs require the temperatures at the thermoelectric elements hot and cold side. From these profiles the temperature gradient is calculated and fed into a controlled heat source in a heat flow network consisting of thermal resistances and capacities describing the thermoelectric device as well as heat conducting layers for mounting between hot and cold side. Parameters are adapted in dependence of the average operating temperature applied to the system using look-up tables providing temperature dependent parameters of the modules. Thermal voltage is linked to the temperature difference via the Seebeck-coefficient and is used to control a voltage source in the electrical path of the thermoelectric element. The output of the DC/DC converter is modeled as a voltage source being controlled from input and output voltages defining the operating point as discussed. For the energy buffer, the ultracap is represented by an ideal capacity and an electric series resistance. Moreover, the leakage current was taken into account being modeled as an additional current source in parallel to capacitor and resistance. The load profiles of the consuming electronics of the sensor system can be applied by an additional block within the platform. Fig. 12 shows the block diagram with interconnections between the modules. The use of parameterized building blocks that can easily be adapted and extended to the targeted application leads to a modeling framework as a starting point for an efficient design of self-sufficient energy supplies for sensor networks. The model was then fed with input data of hot and cold side of data for both TEG options A and B simulated in combination with the newly developed housing concepts using ANSYS Icepak computational fluid dynamics (CFD) software. Hot spot temperature of 61°C on the motor blocks' surfaces as well as ambient temperature of the surrounding air of 35°C in the machine hall were determined from field measurements at the paper mill. Average power provided to the consuming electronics at a constant voltage of 3,3V at the output terminals of the harvesting chain was calculated for the different housing setups discussed below.

5 CONSIDERED HOUSING OPTIONS WITH INTEGRATED THERMAL PATH

While the first prototype consisted of discrete, separate components, the idea of a fully integrated self-sufficient electronic system is introduced in Table 2.

Part	Function	
1	Lid	1
2	Location electronics	8 2
3	Thermoelectric module	
4	Therm. isolating ring	
5	Therm. isolated screws	3 4
6	Location sensor	5 6
7	Coupling hot spot	
8	Surrounding medium (air)	7

Table 2 – Housing of integrated self-sufficient sensor system

The Bi_2Te_3-based thermoelectric device (TEG A or TEG B) is mounted in between a bottom mounting base, attached to the hot surface, and a top cooler with integrated cavity for inclusion of the electronic system. Both metal parts are fabricated from either aluminum or copper. They are screwed together using thermally isolating sleeves around the screws and an isolating spacer defining a fixed height for thermoelectric module inclusion. Silicone-based heat-conductive pads are included on hot and cold sides of the thermoelectric modules accounting for height tolerances by the manufacturer and damping when opposing the module to mechanical loads. There are significant advantages regarding the construction. Firstly including the electronics into the cooler of the thermal path will increase lifetime of the components and reduce parasite effects, e.g. leakage currents at the ultra cap by lowering operation temperature. Secondly, housing the thermoelectric device will prevent it from direct exposure to humidity and chemicals applied in industrial environments. Driven by design restrictions concerning overall dimensions and mechanical robustness preventing usage of conventional cooler designs, modules M1 to M4 described in Table 3 were analyzed regarding its suitability for power conversion as well as its environmental impacts in the following chapters. Modules M1 – M3 include thermoelectric element TEG A, featuring a smaller footprint, thus higher thermal resistance compared to TEG B, whilst Seebeck-coefficient is significantly lower. This is the maximum footprint of a standard peltier device chosen for the metal housing with diameter 45mm applied in modules M1 and M2. Thermal conductivity of the thermal path was increased in M2 by using Cu instead of Al (M1). With M3 and M4 the outer dimensions of the housing were increased to allow for larger surfaces opposed to the surrounding, cooling air, thus increasing heat transfer at higher velocities of air flow around the device. Effects of adding functional thermoelectric material was increased in construction M4 by implementing TEG B.

Table 3 – Design alternatives considered for power conversion

6 CFD-SIMULATION OF TEMPERATURE DISTRIBUTION

For simulation of temperature distribution within the design alternatives, geometry models of M1 – M4 were set up in ANSYS Icepak using simplify operations for transfer of complex geometries from CAD-files. The thermoelectric devices TEG A and TEG B were modeled as homogenous building blocks allocating the specific heat conductivity of the module in the direction of the major heat flow to the system properties. Material properties of metals and isolators were taken from Icepak library for the specific components chosen. Boundary conditions were set after applying standard hexahedral mesh to the model. All modules were aligned orthogonal to the z plane with the main direction of heat transfer in z-direction. A constant temperature of 61°C resembling available hot surfaces at the application scenario was applied to the lower x-y-plane of the cabinet. The opening option was chosen for all remaining walls of the cabinet allowing for open heat exchange with the environment. Ambient temperature of surrounding medium at initial state was set to 35°C, according to measurements at the paper mill. For simulation of natural convection effects, activation of gravity in –z direction was activated. In x direction flow of fluid (air) particles was increased in four steps. 0m/s (solely natural convection) accounts for worst case, rather unlikely situations, when no circulation of air flow is guaranteed around the sensor node. A typical velocity of 0,2m/s was then followed by values of 0,5m/s and 1m/s resembling forced convection through devices, e.g. fans in the motor block found within immediate distance from the mounting base. Fig. 4 demonstrates the exemplary result of a simulation applied to M4, using forced convection of 1m/s.

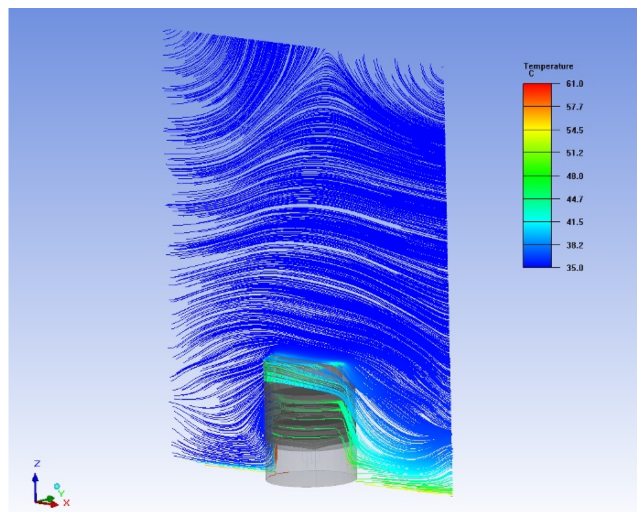

Fig. 4 – Exemplary simulation result of forced convection [1m/s] applied to M4

At distributed locations at hot and cold side of the simulated TEGs within the models, temperature values were determined as input parameters for the previously described simulation workflow in Simulink.

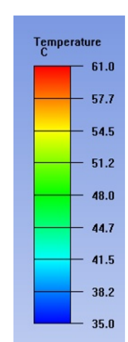

Fig. 5 – Temperature distribution in y-Plane at M4 at natural convection (left) and forced convection at 1m/s (right)

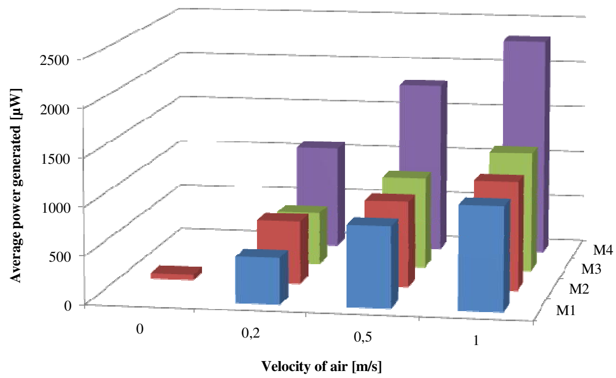

Fig. 6 – Average power available vs. module and air flow

Results for the available energy budgets are shown in Fig. 6. From this overview it can be shown, that natural convection effects will only be sufficient to start the sensor node when using the copper-based housing frame (M2), allowing for optimum heat transfer within the thermal path. Available temperature gradients at designs M1, M3 and M4 will not be sufficient to start the DC/DC converter without forced convection. With increase of air velocities all options will provide sufficient electricity to start-up the system. The copper-based frame will improve heat conductance through the device in comparison to the Al housing. Still, with rising values for air flow around the device, there will be hardly any gain in temperature difference. In this case, increasing the cooler size in comparison to M1 will have a much stronger effect on energy conversion. Finally, for all cases of forced convection, applying the larger thermoelectric element in conjunction with the larger cooler option will lead to a significant rise in average output power that cannot be achieved by merely changing the properties of the thermal path.

7 ENVIRONMENTAL ASPECTS OF ENERGY HARVESTING SYSTEMS – INTRODUCING THE RARI 2011 INDICATOR

As previously conducted studies in [1][2] have shown, each harvesting technology bears materials that have the potential to be environmentally critical, requiring study of environmental impacts already in early design stages.

Table 4 – RARI 2011 in the Periodic Table of Elements

However, use of energy harvesting technologies can lead to a significant reduction of toxic environmental impacts in comparison to conventional battery-based solutions in case reasonable system dimensions and operating times can be achieved. As a consequence a stable power-output needs to be guaranteed even under non-ideal ambient conditions whilst dimensions and use of environmentally harmful materials need to be minimized in early phases of the design process. With the application of self-sufficient sensor nodes in so-called 'mount-and-forget' applications, a deeper look at possible dissipation of materials used for energy harvesting components gains in importance. Therefore in this publication, scarcity of materials used for the previously introduced energy harvesting system will be discussed. For this purpose the newly developed method of the 'Resource availability and risk indicator (RARI 2011)' is applied in order to analyze the effects of design decisions on environmental performance. The indicator was developed and introduced in [5] motivated by rising demand for resources by a continuously growing world population. On the contrary limited availability and finite nature of resources, esp. in the electronics sector, ask for a more careful usage of these materials. In practice evaluation of resource criticality is complex as electronic products contain several materials, most coming from highly branched suppliers all over the world. Thus, there was strong need for an easy-to-handle indicator, enabling the designer to do a first screening of the product in early design stages. The RARI 2011 covers typical electronic metals esp. when drawn from ores, as close to 100% of these are imported in Germany [6] leading to a strong dependency on foreign distributors. Moreover, mining of metals is in general a severe intrusion in environmental processes. Plastics will remain out of consideration within this first version of the indicator.

The following aspects were included in the RARI 2011:

- Requirement for innovation, evaluating the statistical range of coverage, based on the U.S. Geological Survey [7]
- Origin, evaluating concentration (and therefore possible monopolies) on countries based on the Herfindahl-index
- Origin, evaluating the political stability of producing countries based on a study published by BMWi [8]

Each substance can be attributed a substance-specific RARI value on a scale of 0 (not critical) to 100 mg-1 (extremely risky) as an aggregated value calculated from inputs of the studies mentioned above. In the RARI 2011 indicator model updated input data from the latest USGS is included. For calculating the total RARI-value for the evaluated product, masses of the substances included are multiplied by the substance specific RARI and then aggregated to the $RARI_{Total}$ value. Table 4 includes an overview of RARI2011 values in the periodic table of elements. Modules M1 – M4 were then evaluated using the RARI2011 method. As can be seen from the exemplary study of module M1 in Fig. 7, the metal Al used for building the housing significantly counts for the overall $RARI_{Total}$ due to it's high contribution to the total mass of over 95%.

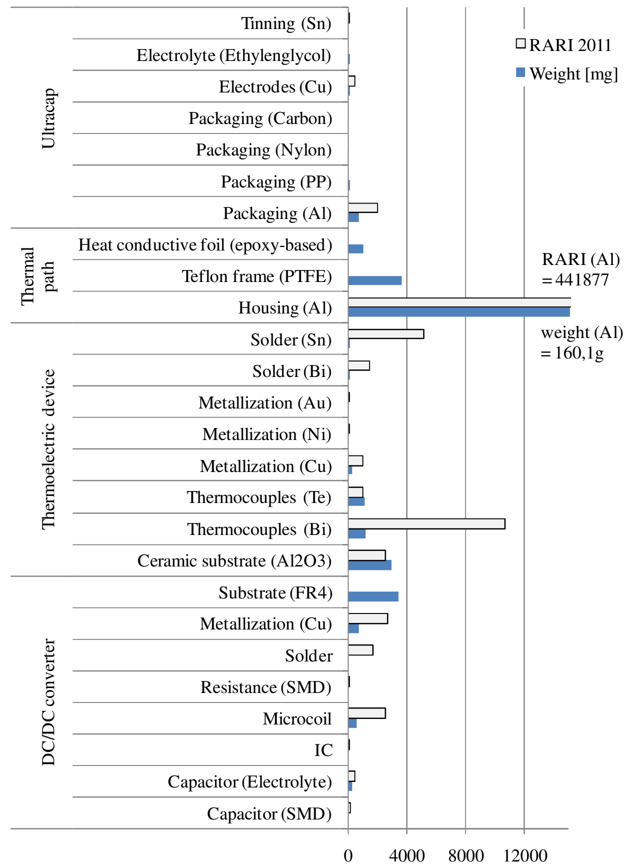

Fig. 7 – Weights and equivalent RARI values for module M1

In case of the copper housing option, there will be a vast rise of $RARI_{Total}$. Not only leads the high density of copper base material to an increase of the total risk indicator. Also ist the specific RARI larger then for aluminum, as production is concentrated in Chile. Thus, for further comparison, choice of either copper or aluminum as well as the size of the cooling concept will almost exclusively determine the total RARI indicator. For 'mount-and-forget' applications this will directly reflect dissipation of resource critical materials – In cases where recycling, esp. of the pure metal blocks building the housing, is an option, a closer look at materials contained in minor amounts of weight is necessary. Although only contained in small amounts, bismuth as part of the active thermoelectric material will exhibit the second largest contribution to the $RARI_{Total}$. This is due to the fact, that production mainly takes place in China (about 62%) and Peru, limiting access to these materials. Moreover, range of coverage is comparatively low. Tin used in soldering material of the thermoelectric legs as well as the electronics is regarded the most critical material within the device regarding the substance specific RARI. China, Indonesia and Congo account for most parts of the production, also exhibiting the risk of possible political instabilities. In comparison to the remaining electronic subsystem, the thermoelectric device thus provides the most critical substances within the designs when neglecting the housing metal. Also these will be the materials to be dissipated most likely at end of life, as recycling options will be scarce for these compounds of non-homogenous materials.

8 DISCUSSIONS: AVAILABILITY OF POWER VS. RESOURCE CRITICALITY

In Fig. 8 gain of average power by changing the design is compared to changes in RARI resource indicator.

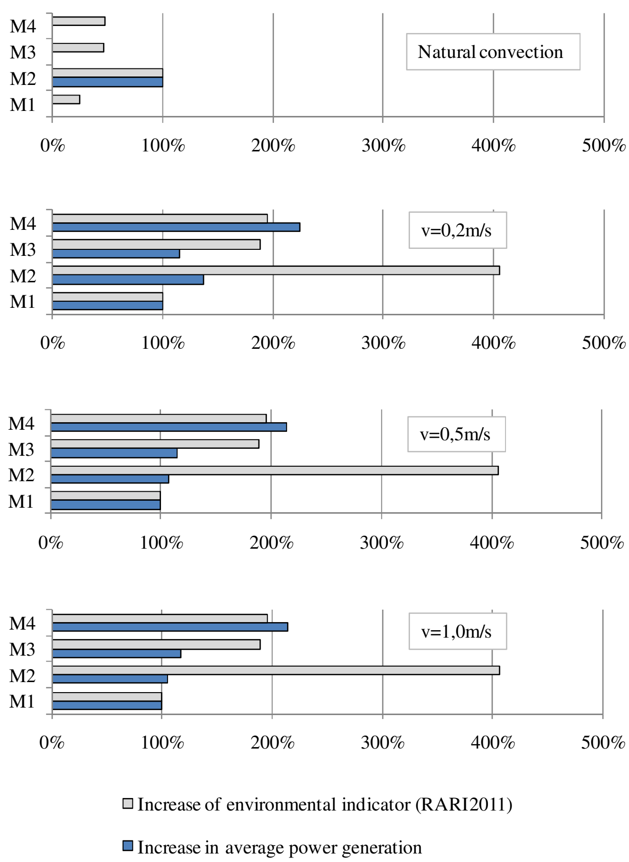

Fig. 8 – Gain of average output power vs. increase in resource indicator

At natural convection, the environmentally critical Cu-based solution is the only technical feasible option – thus applicable at locations were no or only low air flow is available. Even if flows of 0,2m/s can be detected, the Cu-based option will provide more energy than the extended Al-based cooler dimension in conjunction with the smaller thermoelectric device TEG A. This will be necessary if small system dimensions need to be achieved or in case copper will be returned to recycling processes even after long-time usage. For air flows of 0,5m/s or more, switching to the larger Al-based cooler geometry will lead to even slightly higher temperature gradients at significantly lower environmental expenses compared to the Cu-based solution. Increasing the active materials by exchanging the thermoelectric device will lead to a significant rise of average power output whilst merely influencing the $RARI_{Total}$.

9 CONCLUSION

Design decisions and their effect on system performance from both, an environmental as well as technical point of view were studied for a thermoelectric energy harvesting systems. The relations between an increase in system capacity to account for deviations from standard working conditions, the necessary over sizing and the shift in environmental impacts were discussed. The proposed approach can support eco design of energy harvesting based solutions by determining a reasonable degree of robustness for the targeted application and evaluate different design options of how to get there. For the conducted example of thermoelectric energy harvesting systems the choice of the best solution strongly depends on the boundary conditions: A design approach with optimum performance at natural convection might not necessarily be best suited at forced convection szenarios from technical as well as environmental perspective. Moreover, recycling options need to be evaluated upfront – In case solid metal parts that can easily be recycled will be returned to recyling processes at end of life, extending the range of a given thermoelectric device by increasing cooler dimensions or thermal conductivity will be an environmentally conscious solution. Instead, if dissipation of all included materials can be foreseen, increase of active materials for power generation can lead to lean design by minimizing large amounts of passive materials for cooling. Systems studies as carried-out in this paper need to be conducted over the broad application range in order to determine reasonable trade-offs. The presented method for evaluating resource criticality proofed to be suited for a first evaluation of energy harvesting systems and will be further applied also for complex szenarios, e.g. when comparing to battery-based solutions.

How Policies Stimulate Innovations– Evidence from Dioxin Emissions and Home Appliances Recycling

Helmut Yabar[1], Michinori Uwasu[2] and Keishiro Hara[2]

[1] University of Tsukuba, Graduate School of Life and Environmental Sciences, Japan

[2] Osaka University Center of Environmental Innovation Design for Sustainability, Japan

Abstract

How environmental policies affect technological developments and economic competitiveness has been an enduring question among engineers as well as economists. This paper attempts to clarify the impact of Japanese waste management policy on technological innovation using dioxin emissions from incineration and the recycling of home electric appliances in Japan as two case studies. We discuss the policy relevance of streamlining push-pull relationships between knowledge creators and technology users. We found that technological innovations usually start with social concerns regarding environmental issues (demand pull). The government then introduces policies to meet those concerns and the industry develops new technologies to comply with such policy requirements (technology push). For our case studies, relevant Japanese patent data were gathered for the period 1990–2008. To demonstrate that environmental regulations induce technology innovation, we conducted statistical analysis to compare the number of patents related to each regulation between the period under regulation and period outside the regulation. In order to control for the potential exogenous effects of factors such as business cycles and demand changes on technological development, we compared the ratios of the case studies related patents to the total number of environment-related patents. The results show that the number of related patents for most technological types is larger after the regulations were introduced. The results also show a decreasing pattern in patent citations once the targets have been met suggesting a possible weakness in these types of regulations due to lack of incentives for further innovations.

Keywords:

environmental policy, induced innovation, patent data, lock in.

1 INTRODUCTION

Technology innovation has played a central role in providing safer and comfortable lives for people. However leaving technology innovation to the market alone has been one of the causes of technological lock-in, which has prevented the emergence of sustainable technologies [1]. There have been many studies that challenged the belief that environmental regulations would affect the industrial competitiveness of countries. Porter for instance argued that stricter environmental regulations would trigger innovations and increase the competitiveness of firms [2]. On the other hand there have also been studies that didn't find any significant impact of environmental regulations on innovation [3].

This paper analyzes the impact of policies and regulations on technology innovation using the Japanese experience in dealing with dioxin emissions from incineration and the recycling of specific wastes as case studies. We found out a pattern regarding the environmental technology innovations in Japan. Usually these innovations start with social concerns regarding environmental issues or resource scarcity (demand pull). The government then introduces stricter regulations to meet those concerns (policy push) such as emission standards for dioxin, SO2, etc, or recycling targets for end-of-life products. Finally the technology community and industrial sector develop the innovations necessary to comply with those regulations.

2 INDUCED INNOVATION: DEALING WITH TECHNOLOGICAL LOCK IN

2.1 Overcoming lock-in

Induced innovation states that changes in the relative price of the factors of production will spur innovation to economize the use of that factor [4]. Technological lock-in refers to the difficulty in escaping the specific paths followed by technologies and technological systems [5]. To explain the lock-in mechanism Dosi [6] introduced the term technological paradigm i.e. technological progress shaped by the following of specific rules and principles in the way of thinking. Arthur [7] argued that the increasing return to adoption mechanism enhances the attractiveness of adopting a specific technology once it has secured an initial lead and will eventually lock in the market. Moreover such technologies create barriers that will try to prevent the emergence of new alternatives. By supporting specific technologies, institutions also show increasing

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_37, © Springer Science+Business Media Dordrecht 2012

return to adoption and the interaction between both systems will reinforce their lock-in [8]. Other mechanisms such as policies and regulations could also trigger environmental innovations by breaking lock in, promoting niche markets, encouraging feedback from market formation, etc. In the case of environmental technology innovation process, for instance, in order to address the social concerns regarding environmental problems (demand pull), the government introduces environmental policy or regulations (policy push). The technology development sector then develops the innovations to comply with the policy requirements.

2.2 The use of patents to measure innovations

There have been several studies that focus on the impact of environmental policy and regulations on technological innovations with mixed results. Jung et al [9] analyzed the incentive effects of environmental policy instruments to promote advanced pollution abatement technology and found out that auctioned permits and emission taxes and subsidies have the greatest impact on innovation. Fischer et al [10] analyzed the impact of auctioned permits, emission taxes and free permits on innovation and found out that either one can induce innovation but neither one has a stronger effect on innovation. Jaffe et al [11] found empirical evidence consistency with theoretical findings in the sense that market-based instruments are likely to have greater impacts than command and control approaches on environmental technology innovations. With the more ready availability of proxies for measuring innovation trends like patent data, there have been increasing research initiatives on analyzing the effect of policy on innovation. When analyzing technological innovation patent data provides many advantages [12, 13]:

- Patent classification provides useful information on the different types of R&D and hence track the advances in specific technological fields more accurately;
- The date of application of patents can give us information on the level of R&D activity;
- International patent data provides information on the level of diffusion of technologies across countries;
- Patent citation can be used as an indicator of further knowledge development or knowledge flow; and
- The rate of assigned patents will provide information on their commercial or market potential.

3 INDUCED INNOVATIONS IN JAPANESE WASTE MANAGEMENT POLICIES

3.1 The case of dioxin emissions from waste incineration

The Waste Management and Public Cleansing Law of 1970 promoted waste technologies with high and rapid volume treatment capacity such as incineration. Incineration technology has been important in Japan because of its capacity to reduce waste volume significantly Since the amount of daily wastes was relatively small in the 70's, local governments operated mostly small scale and batch-type incinerators. The change in lifestyle of the 80's due to higher living standards was the main driver for not only the increase in the amount but also the nature of wastes. This change increased the demand for products in small packages which in turn increased the amount of plastic waste generation [14]. Public health concerns related to dioxin emission associated with plastic incineration started to increase from the early 90's. Various studies found that dioxin emissions were higher in low-combustion and batch-type incinerators (see [15] and [16]). To address this public health concern the government introduced the Law Concerning Special Measures against Dioxin in 1999 [17]. As shown in Fig. 1, the law, which set the target to reduce dioxin emissions by 90% by 2003 taking as a base the year 1997, proved to be effective since the target was surpassed by phasing out small scale and batch incinerators with continuous type ones and introducing dioxin trapping technologies [18].

3.2 The case of electric home appliances recycling

Japanese policies have basically focused on promoting effective use of resources and minimize the environmental and health impacts of production and consumption systems (Japan is a resource-dependent country). Since the early 90's the government enacted various laws based on the 3R approach: the Containers and Packaging Recycling Law (1995); the Home Appliance Recycling Law (1998); the Construction Materials Recycling Law (2000), the Food Recycling Law (2000); and the End-of-Life Vehicles Recycling Law (2002) [19]. These laws targeted specific wastes including containers and packaging (plastic, glass and paper), electric and electronic home appliances, cars, construction materials and food-related wastes. In the case of electric and electronic home appliances, for instance, the law targeted four key products: air conditioners, refrigerators, televisions and washing machines. In this case all the recycling targets were met and surpassed.

4 THE IMPACT OF POLICIES ON INNOVATIONS

4.1 Analysis of patent trends

In order to determine whether the environmental policies where the actual drivers of specific innovations or not we analyzed the Japanese patent database. For the identification of the relevance of patents we first analyzed the related Japanese technological processes for both the dioxin emission reduction and home appliances recycling. Table 1 and Table 2 show the summary of the identified patent groups. (We used the International Patent Classification Codes and assigned shorter specific codes for the sake of simplicity). Figure 2 shows the patent number trends for both dioxin and home appliances respectively for the period 1990-2008. To demonstrate that environmental regulations (the presence of law) affect environmental R&D, we conducted a t-test analysis to compare the number of patents related to the regulations between the periods under and without the law presence. In the case of dioxin we divided the period terms into: 1990-1996, 1997-2003 and 2004-2008. The rationale for this classification is that the Dioxin Law was enacted in 1997, the plan was enforced in 1999 and the emission standards were met in 2003. In the case of the home appliances we divided the trends into two periods: 1990-1998 and 1999-2008. In this case we selected this division because the Home Appliances Recycling Law was enacted in 1998 and enforced in 2001. Table 3 presents the t-test results. During the period under the regulation, the number of related patents for most technological types is larger than in the period in which there is no regulation or the regulation targets have been met. These results indicate that proper regulations possibly induce the development of environmental technologies.

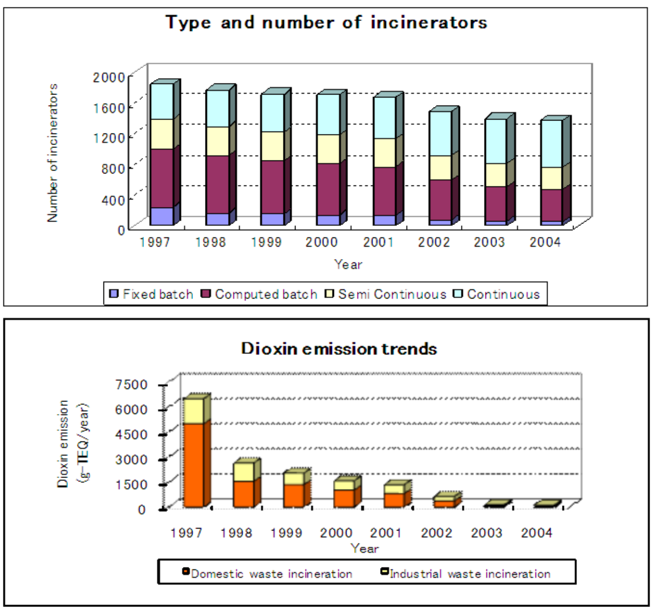

Fig. 1 Trends in incineration types and dioxin emissions

Table 1: Patents related to dioxin emissions

Patent Code group (IPC)	Assigned code	Outline of the patent group
F23G5/027	P1	Incineration of waste: pyrolising or gasifying stage
F23G7/06	P2	Incinerators or other apparatus for consuming industrial waste: of waste gases or noxious gases, e.g. exhaust gases
F23J1/00	P3	Removing ash, clinker, or slag from combustion chambers
F23J3/00	P4	Removing solid residues from passages or chambers beyond the fire
F23J15/00	P5	Arrangements of devices for treating smoke or fumes
F23J15/00*	P6	Arrangements of devices for treating smoke or fumes (* Without considering SOx and NOx)
F23N5/00	P7	Systems for controlling combustion
B01D46/00	P8	Filters or filtering processes specially modified for separating dispersed particles from gases or vapors
B01D53/00	P9	Separation of gases or vapors; Recovering vapors of volatile solvents from gases; Chemical purification of smoke, fumes, or exhaust gases
B09B3/00	P10	Destroying solid waste or transforming solid waste into something useful or harmless
B09B3/00*	P11	Destroying solid waste or transforming solid waste into something useful or harmless (*Related specifically to plastics and rubber)

Table 2: Patents related to home appliances recycling

Patent Code group (IPC)	Assigned code	Outline of the patent group
B01D21/00	R1	Separation of suspended solid particles from liquids by sedimentation
B03C1/00	R2	Magnetic separation
B03C1/00*	R3	Magnetic separation (* solid-solid separation)
B03C1/02	R4	Magnetic separators
B03C7/00	R5	Separating solids from solids by electrostatic effect
B03C7/02	R6	Separators (solid-solid)
B03B5/00	R7	Washing granular, powdered or lumpy materials; Wet separating
B03B5/28	R8	Sink-float separation
B07B1/00	R9	Sieving, screening, sifting, or sorting solid materials using networks, gratings, grids, or the like
B07B4/00	R10	Separating solids from solids by subjecting their mixture to gas currents
B07B7/00	R11	Selective separation of solid materials carried by, or dispersed in, gas currents

Table 3: Statistical analysis comparing patent trends inside and outside regulation period

Patent type	t-test hypothesis	Patent type	t-test hypothesis
Dioxin emission reduction	$H: \mu^{law}-\mu^{non\text{-}law}>0$	Recycling	$H: \mu^{law}-\mu^{non\text{-}law}>0$
Type P1	***	Type R1	**
Type P2	***	Type R2	**
Type P3	***	Type R3	*
Type P4	**	Type R4	***
Type P5	***	Type R5	**
Type P6	***	Type R6	**
Type P7	*	Type R7	**
Type P8	*	Type R8	**
Type P9	**	Type R9	**
Type P10	***	Type R10	Reject
Type P11	***	Type R11	Reject

Note: ***, ** and * denote statistical significance at the 1%, 5%, and 10% levels, respectively. The regulation period for the dioxin law is 1997-2003. The regulation period for the recycling law is 1999-2008.

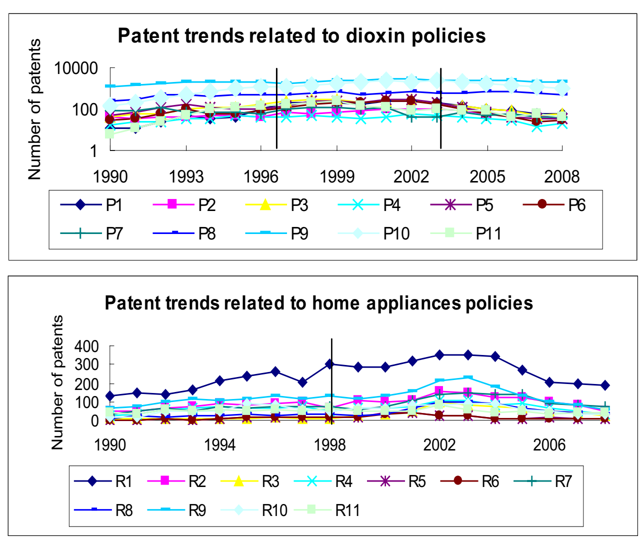

Fig. 2: Patent trends of case studies

Furthermore, in order to control for the potential exogenous effects of factors such as business cycles and demand changes, we compared the ratios of the case studies related patents to the total number of environment-related patents. From the results the ratio of dioxin-related patent to the total was 0.33 under the regulation period and 0.29 under the unregulated period. Likewise, the ratio of recycling-related patent to the total patent was 0.06 under the regulation period and 0.04 in the unregulated period. Again, we conducted the t-test, obtaining the results that the ratios of the environment-related patents were statistically higher under the period in which regulations were effective.

5 SUMMARY

This paper attempted to clarify the impact of Japanese waste management policy on technological innovation using dioxin emissions from incineration and the recycling of home electric appliances in Japan as two case studies. For our case studies, relevant Japanese patent data were gathered for the period 1990–2008. To demonstrate that environmental regulations induce technology innovation, we conducted statistical analysis to compare the number of patents related to each regulation between the period under regulation and period outside the regulation. In order to control for the potential exogenous effects of factors such as business cycles and demand changes on technological development, we compared the ratios of the case studies related patents to the total number of environment-related patents. The results show that the number of related patents for most technological types is larger after the regulations were introduced. The results also show a decreasing pattern in patent citations once the targets have been met suggesting a possible weakness in these types of regulations due to lack of incentives for further innovations. Furthermore the study also demonstrates the policies not only helped achieve specific end-of-pipe targets but also promoted further innovations such as the innovations at the design and production phase. In the case of home appliances we found that the environmental policies have pushed for the design of easier to recycle components and the design of parts and products with minimal use of hazardous substances such as chlorine-based components in plastic production which is associated with dioxin generation.

Abstract

This report describes investors' decision-making related to environmental Socially Responsible Investment (SRI) by administering a questionnaire with virtual stock-selection conditions and information related to both financial and environmental performance. Our findings are as follows: First, prospect theory is not valid with decision-making over environmental achievement. Second, a person's level of environmental consciousness has little effect on decision-making related to environmental performance. Third, four clusters with each different decision-making property were found using cluster analysis. Finally, significant differences were found in behaviors related to negative and positive financial performance. These findings are expected to be an aid in managing SRI funds, which requires consideration of both financial and social objectives.

Keywords:

socially responsible investment, behavioral finance, prospect theory

1 INTRODUCTION

In recent years, companies have been required to consider corporate social responsibility (CSR). Corresponding to this trend, numerous socially responsible investment (SRI) funds have emerged over the past decades.

Renneboog et al. provide an overview of the state of academic literature on SRI. They refer to the multi-task nature of SRI: SRI portfolio managers pursue both financial goals and social objectives [6]. Then how should they manage SRI funds? To solve this problem, it is necessary to discuss two SRI stakeholders: firms and investors.

Regarding firms, the question is whether CSR profits firms or not. For this question, numerous studies have been conducted. For example, Pava and Krausz review over 21 empirical studies [5]. Hamilton et al. investigate the performance of 32 SRI funds and 320 non-SRI funds. These empirical studies do not demonstrate that SRI funds perform worse than conventional funds [2]. Mackey et al. propose a theoretical model and argue that socially responsible activities undertaken by firms do not maximize the present value of their firm's future cash flows yet still maximize the market value of the firm [4].

With respect to investors, the question is how investors make choices related to economic efficiency and social objectives. Bollen claims that a conditional multi-attribute utility function can represent SRI investors. Such a function is derived from conventional fund performance and socially responsible attributes, especially when SRI funds deliver positive returns [1]. This is the first step to the theory of decision-making over social achievements.

In analyzing decision-making under risk such as investment, the academic field of behavioral finance cannot be ignored. Kahneman and Tversky propose prospect theory to explain human decision-making under risk using questionnaires, in which respondents, given two choices, choose a lottery to join [3].

To analyze decision-making in SRI, we extend Kahneman and Tversky's questionnaires to decision-making under information of both financial returns and environmental efforts by companies, which served as a CSR-representative activity.

This study particularly examines investors' behavior related to environmental performance, which has not been clarified theoretically.

2 QUESTIONNAIRE

This section explains the questionnaire we administered. The questionnaire was administered in December 2009 to 4843 Japanese people who were in their 20s to 60s: 2961 men and 1882 women. Of the respondents, 3335 had some investment experience.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_38,

Q1 You are going to invest 100 thousand yen in either of company A or B. Both companies have emitted 10 million tons of carbon dioxide gas in last accounting period. The following is a prospect of monetary return of investment and effort for the environment in this period for each company. Which company do you want to invest in? Choose one company, and you must choose either of the two.

Company A

Financial return: You will certainly gain 100 thousand yen.

Effort for the environment: This company will reduce its carbon dioxide emission by 2 million tons and emit 8 million tons with probability of 60%, and increase the emission by 2 million tons and emit 12 million tons with probability of 40%.

Company B

Financial return: You will certainly gain 100 thousand yen.

Effort for the environment: This company will certainly emit 10 million tons, the same amount as the last period.

Fig. 1 Sample of Stock-selection Question.

Choose a suitable answer for the following questions from strongly agree, agree, disagree and strongly disagree.

Q01 I always try not to harm the environment.

Q02 I am not interested in environmental issues.

Q03 Although I think it is better to be green, I don't want to spend money for it.

Q04 Companies should reduce carbon dioxide emissions.

Q05 I sometimes feel effects of global warming in daily life.

Fig. 2 Environmental Consciousness Questions.

2.1 Questions with virtual stock-selection situations

The questionnaire mainly comprised 24 questions, each of which was set in a virtual decision-making situation of stock selection. From two names, a respondent chooses a stock in which to invest, considering their stated prospects of both financial and environmental performance.

The prospects of financial performance are represented as combinations of probability and the amount of monetary gain/loss. Those of environmental performance are combinations of probability and the amounts of carbon

Table 1 Conditions of Stock-Selection Questions and Results

	Name	Financial Performance		Environmental Performance				Results[1]	Expected value of environmental achievement (million tons)
		Probability	Amount of gain (thousand yen)	Probability	Amount of reduction (million tons)	Probability	Amount of reduction (million tons)		
Q1	A	1	100	0.6	2	0.4	-2	58.8%*	0.4
	B	1	100	1	0			41.2%*	0
Q2	A	1	100	0.6	2	0.4	4	47.7%*	2.8
	B	1	100	1	2.5			52.3%*	2.5
Q5	A	1	100	0.4	2	0.6	0	49.2%	0.8
	B	1	100	0.3	3	0.7	0	50.8%	0.9
Q6	A	1	100	1	2			62.7%*	2
	B	1	100	0.75	3	0.25	0	37.3%*	2.25
Q10	A	1	100	0.6	-2	0.4	-4	34.8%*	-2.8
	B	1	100	1	-2.5			65.2%*	-2.5
Q15	A	1	-100	0.6	2	0.4	-2	59.1%*	0.4
	B	1	-100	1	0			40.9%*	0
Q16	A	1	-100	0.6	2	0.4	4	48.9%	2.8
	B	1	-100	1	2.5			51.1%	2.5
Q22	A	1	-100	0.6	-2	0.4	-4	34.4%*	-2.8
	B	1	-100	1	-2.5			65.6%*	-2.5

* 5% Level of significance

[1] Ratio of respondents who chose the name in the same column.

dioxide emissions. One question is presented in Fig. 1.

Each of the 24 questions has different probabilities and amounts for financial returns and environmental efforts.

2.2 Questions on environmental consciousness

In the questionnaire, we also asked respondents their level of environmental consciousness: how much they care about the environment. The questions are shown in Fig. 2.

3 SCOPE OF ANALYSIS

As stated in section 1, this study specifically assesses investors' behavior toward the environmental performance of a firm. A respondent's behavior toward financial performance is assumed to be consistent with prospect theory. Therefore, we analyzed 8 of the 24 stock-selection questions showing no uncertainty in the prospects of financial returns. Table 1 presents conditions of the eight questions and their results.

4 RESULTS

4.1 Comparison with prospect theory

First, we verified whether prospect theory is valid with decision-making over environmental performance.

Based on the results shown in Table 1, we compared the choices that are expected to be the majority if prospect theory were valid with environmental achievement to those which actually are the majority in the questionnaire. Table 2 presents the comparison.

Table 2 Comparison with Prospect Theory

	Expected	Actual
Q1	B	A
Q2	B	B
Q5	A	-
Q6	A	A
Q10	A	B
Q15	B	A
Q16	B	-
Q22	A	B

-: No significant difference is found.

According to Table 2, actual results are not consistent with expectations implied by prospect theory, meaning that prospect theory is not valid for people's behavior related to the environmental performance of a firm.

4.2 Environmental consciousness and investment behavior

A main concern of the SRI study is whether decision-making of SRI investors differs from that of conventional investors. From this viewpoint, a hypothesis is raised that a respondent's level of environmental consciousness affects investment behavior related to environmental performance. To verify this, we analyzed results of environmental consciousness related questions, as introduced in section 2.2.

For each question, we put respondents into two groups with respectively differing levels of environmental consciousness: respondents who answered 'strongly agree' or 'agree', and those who answered 'strongly disagree' or 'disagree'.

Then we made up 40 pairs consisting of each stock-selection question and environmental consciousness question and compared the results between the two groups using a McNemar test.

Table 3 Number of stock-selection questions that show significant and non-significant differences

	Significant difference	No significant difference
Q01	1	7
Q02	3	5
Q03	1	7
Q04	4	4
Q05	1	7
total	10	30

As Table 3 shows, significant differences were found between the two groups in only 10 pairs; no significant difference was found in the remaining 30 pairs. We therefore infer that a person's environmental consciousness has little effect on that person's decision-making related to environmental performance.

4.3 Cluster analysis

We conducted a cluster analysis of the results for questions in Table 1 using the group average method. Respondents are divided into four clusters. Table 4 shows results of stock-selection questions from each cluster.

For convenience, we now classify the eight questions into the following three groups to discern each different property of decision-making.

Group 1 (Q1, 5, 6, 15): PREFERENCE FOR CHANGE

Questions in this group determine whether a respondent has a preference for change in environmental performance: a tendency to avoid investing in a company whose carbon dioxide emissions in the current period is expected to be equal to that in the last period.

In these questions, one firm in the alternative is expected to emit the same amount of carbon dioxide gas as in the last period with some possibility, whereas the other is expected to either reduce or increase its carbon dioxide emissions.

Table 4 Results from each Cluster

	Cluster 1		Cluster 2		Cluster 3		Cluster 4	
	A	B	A	B	A	B	A	B
Q1	92.6%*	7.4%*	1.9%*	98.1%*	84.8%*	15.2%*	11.0%*	89.0%*
Q2	25.5%*	74.5%*	29.5%*	70.5%*	86.3%*	13.7%*	64.9%*	35.1%*
Q5	56.2%*	43.8%*	45.8%*	54.2%*	48.3%*	51.7%*	31.4%*	68.6%*
Q6	66.3%*	33.7%*	77.1%*	22.9%*	52.8%*	47.2%*	24.7%*	75.3%*
Q10	34.2%*	65.8%*	15.5%*	84.5%*	48.5%	51.5%	59.9%*	40.1%*
Q15	76.1%*	23.9%*	20.4%*	79.6%*	84.1%*	15.9%*	23.4%*	76.6%*
Q16	22.8%*	77.2%*	22.6%*	77.4%*	94.9%*	5.1%*	88.0%*	12.0%*
Q22	40.9%*	59.1%*	19.0%*	81.0%*	41.5%*	58.5%*	35.8%*	64.2%*

*5% Level of significance

Table 5 Characteristics of Clusters

	Change	Certainty	Rationality
Cluster 1	++	+	
Cluster 2		++	
Cluster 3	++		+
Cluster 4			++

++: has the property

+: has the property, but dominated by another property

Group 2 (Q1, 2, 6, 10, 15, 16, 22): PREFERENCE FOR CERTAINTY

Questions in this group determine whether a respondent prefers certainty of environmental performance.

In these questions, one company is expected to reduce or increase carbon dioxide emissions by a certain amount with probability of 100%, whereas others have uncertainty related to the amount.

Group 3 (Q1, 2, 5, 6, 10, 15, 16, 22): PREFERENCE FOR RATIONALITY

Questions in this group ascertain whether a respondent makes choices based on the expected environmental achievement.

For all eight of these questions, the expected values of carbon dioxide emissions differ between the two firms.

The results exhibited in Table 4 reveal each cluster as having the following properties. Cluster characteristics are presented in Table 5.

Cluster 1 (1651 respondents): PREFERENCE FOR CHANGE AND CERTAINTY

In all four questions of group 1, larger numbers of respondents in cluster 1 show a preference for change. Additionally, in 5 of 7 questions belonging to group 2, larger numbers of respondents make decisions that show a preference for certainty. In the remaining questions, preference for change is dominant over that for certainty.

However, rational decisions are made in only half of the eight questions of group 3.

Therefore, the behavior of a typical respondent in cluster 1 is inferred as follows: if the question is a group-1 question, the subject makes decisions based on a preference for change. If not, the subject makes decisions based on a preference for certainty.

Cluster 2 (1409 respondents): PREFERENCE FOR CERTAINTY

In all seven questions of group 2, larger numbers of respondents in cluster 2 show a preference for certainty.

However, the results are consistent with a preference for certainty in 1 of 4 questions that belong to group 1. In addition, rational decisions are made in only 3 of 8 questions of group 3.

Therefore, it is inferred that a typical respondent in cluster 2 makes decisions based on a preference for certainty.

Cluster 3 (1486 respondents): PREFERENCE FOR CHANGE AND RATIONALITY

In 3 of the 4 questions that belong to group 1, more respondents in cluster 3 show a preference for change. Regarding group 3, in 5 of the 8 questions, larger numbers of respondents show rationality. Furthermore, in one of the remaining three questions, preference for change was dominant over rationality. In contrast, in only 2 of 7 questions of group 2 do respondents show a preference for uncertainty.

Therefore, behavior of a typical respondent in cluster 3 is inferred as follows: for a group-1 question, the subject makes decisions based on preference for change. If not group-1, the subject makes decisions based on rationality.

Cluster 4 (299 respondents): PREFERENCE FOR RATIONALITY

In 5 of 8 questions belonging to group 3, greater numbers of respondents in cluster 4 show rationality. However, results of none of the 4 group-1 questions are consistent with preference for certainty and only 3 of 7 group-2 questions are consistent with rationality.

Therefore, it is inferred that a typical respondent in cluster 4 makes decisions based on rationality.

Table 6 Ratio of respondents who choose name A and results of McNemar test

	Cluster 1		Cluster 2		Cluster 3		Cluster 4	
Financial performance	(1, 100)	(1, -100)	(1, 100)	(1, -100)	(1, 100)	(1, -100)	(1, 100)	(1, -100)
Q2 – Q16	25.5%	22.8%	29.5%**	22.6%**	86.3%**	94.9%**	64.9%**	88.0%**
Q1 – Q15	92.6%**	76.1%**	1.9%**	20.4%**	84.8%	84.1%	11.0%**	23.4%**
Q10 – Q22	34.2%**	40.9%**	15.5%*	19.0%*	48.5%**	41.5%**	59.9%**	35.8%**

* 5% Level of significance

**1% Level of significance

According to this cluster analysis, three properties are identified as characteristics of human behavior toward environmental achievement: preferences for change, certainty, and rationality. Among them, preference for change—the inclination that people prefer either an increase or decrease of green house gas emissions to constant emissions—stands out because this is rarely observed in decision-making over monetary gains. It might suggest that, in SRI, a certain number of people appreciate companies' trial of activities, whether the company succeeds or not: they do not like doing nothing.

4.4 Behavior in negative financial conditions

It is often assumed that the financial performance of SRI funds is worse than that of non-SRI funds. How do investors consider this problem of social cost? To answer this question, we compared the results of two questions with the same environmental performance and opposite financial performance.

From the eight questions in Table 1, we paired results of Q2 and Q16, Q1 and Q15, and Q10 and Q22. Here we will write, "return of X thousand yen is expected with the probability of x" as (x, X) and "Y million tons of emission will be reduced with the probability of y" as (y, Y).

Between questions in these pairs, the conditions of environmental performance are common. However, the financial performance of both firms in the alternative is (1, 100) in one question of the pair, and (1, -100) in the other. Therefore, simply expecting the results between the questions in each pair should not differ because environmental performance is set in the same condition between the questions in the pair, and two firms do not differ in financial performance in both pairs. However, results of the McNemar test show that the null hypothesis––that no difference exists in respondents' decision-making between conditions of positive and negative financial returns—is rejected in most cases.

Table 6 presents the ratio of respondents who choose A in questions in the pairs and results of McNemar test.

Q2 (positive) and Q16 (negative)

Environmental performance in these questions is (0.6, 2) and (0.4, 4) for A, and (1, 2.5) for B; the environmental performance is positive.

According to Table 6 , in cluster 2, larger numbers of respondents choose B in Q16 than in Q2, which means that the preference for certainty is enhanced in negative financial conditions. In contrast, in clusters 3 and 4, the numbers of respondents who choose A are larger, meaning that a preference for certainty is weakened in a negative financial condition.

Q1 (positive) and Q15 (negative)

Environmental performance in these questions is (0.6, 2) and (0.4, -2) for A, and (1, 0) for B. The environmental performance is neutral.

According to Table 6, in cluster 1, larger numbers of respondents choose B in Q15 than in Q1, meaning that preference for certainty is enhanced in a negative financial condition. In contrast, in clusters 2 and 4, the numbers of respondent who choose A are greater, which means that the preference for certainty is weakened in a negative financial condition.

Q10 (positive) and Q22 (negative)

Environmental performance in these questions is (0.6, -2) and (0.4, -4) for A, and (1, -2.5) for B; the environmental performance is negative.

According to Table 6, in clusters 1 and 2, larger numbers of respondents choose A in Q15 than in Q1, meaning that the preference for certainty is weakened in a negative financial condition. In contrast, in clusters 3 and 4, the numbers of respondents who choose B is larger. Consequently, the preference for certainty is enhanced in a negative financial condition.

Table 7 presents a summary of the results presented above, which suggest that a person's preference for certainty is affected by negative financial conditions. Results also clarify that the effects of negative financial performance differ among positive, neutral, and negative environmental conditions for each cluster.

Table 7 Behaviors in Negative Financial Conditions

Environmental Performance	Positive	Neutral	Negative
Cluster 1		+	-
Cluster 2	+	-	-
Cluster 3	-		+
Cluster 4	-	-	+

+: Preference for certainty is enhanced

-: Preference for certainty is weakened

Blank: No significant difference is found

5 CONCLUSIONS

For this study, we conducted a questionnaire with virtual stock-selection conditions of SRI.

First, we verified whether prospect theory is valid with environmental achievement as well as monetary gains. Respondents' behavior related to environmental performance is not consistent with prospect theory.

Second, we investigated whether respondents' level of environmental consciousness affects their behavior related to environmental performance. Results clarified that the level of environmental consciousness has little effect on their decision-making about environmental performance.

Third, we conducted cluster analysis of respondents based on their answers. We obtained four clusters and identified three properties of decision-making related to environmental achievement: preferences for change, certainty, and rationality.

Finally, in negative financial conditions, respondents are affected according to the clusters to which they belong. Furthermore, the effects of negative financial performance differ among positive, neutral, and negative environmental conditions for each cluster.

The results reported herein can be an aid in establishing environmental SRI funds. Results described in section 4.2 implied that a person's level of environmental consciousness has little effect on a person's decision-making related to environmental performance. Therefore, in managing SRI funds, it might not be necessary to consider different environmental consciousness among customers. In addition, cluster analysis clarified that only 6.2% of respondents belong to cluster 4: respondents who make rational decisions. Rather, more respondents tend to prefer either change or certainty of environmental performance. Therefore, environmental SRI fund with names of firms with higher certainty or companies that take initiatives for the environment or other objectives in some way—irrespective of risk—are preferred to funds that are managed based on the expected value of environmental performance.

Finally, further studies are expected to address the question of why preference for change is observed in some of respondents and why different behaviors exist among clusters in negative financial conditions.

Innovative Financing Mechanisms for Energy Efficiency Retrofits in Buildings – A Shift in the Traditional Paradigm

Christopher Charles Seeley
The William J. Clinton Foundation & Asian Institute of Technology (AIT)
cseeley@clintonfoundation.org

Abstract

The retrofitting of existing buildings is no doubt an attractive means of saving energy, reducing greenhouse gas emissions and creating jobs in the process. Energy efficiency has been unanimously regarded as the fastest, lest expensive and lowest risk method of addressing carbon emissions all over the world. Most existing commercial buildings are significantly less efficient than new buildings, and modifications can be made to improve efficiency typically by 20% to 40% using commonly accepted practices and widely available technologies. For building owners this often translates into an increase in the property value, increased cash flows, the ability to attract and keep desired tenants and an added recognition of being a good corporate citizen. The investment required to make these changes typically can offer paybacks of 5-10 years, providing competitive investment returns, and ongoing operational and maintenance cost savings at the same time. Despite this potential, there remains a significant barrier – access to competitive financing which reflects the unique characteristics and complexities of both energy efficiency projects and building owners alike.

Key words: building retrofits, energy efficiency, energy performance contracting, financing, off balance sheet financing

1. Introduction

Property owners, in general, do not have the up-front funds or do not want to use existing funds to invest into energy efficiency projects no matter how attractive they may appear. For the average building owner, energy efficiency projects represent an investment that they are just not certain about. They don't necessarily know how to place a numerical value on the savings as they aren't as tangible or clear as other more traditional investments. They are also skeptical about whether the savings will really pay them back in the time frames promised or the proposed technologies and systems will really deliver as promised by vendors, and hence the returns on this specific investment become cloudy.

Commercial office building owners are even less incentivized to invest into energy efficiency projects as their tenants reap the benefits of any reduction of utility bills without having to share in the initial investment of the project and re-negotiating leases with multiple tenants in the building can be time consuming, complicated and unwelcome. Many building owners have covenants with lending institutions that do not allow their buildings to be further leveraged while others, especially institutional investors want the flexibility to sell their properties if they receive a bid above their threshold pricing and do not want to increase existing debt levels, especially when paybacks extend well over the projected hold period.

Recently, there has been an increasing willingness of commercial lenders to consider loans for energy efficiency retrofits. However, there are complications relating to the existing credit history. Most commercial assets are held by limited liability companies (LLCs) formed to hold single buildings or at most a portfolio of buildings. These LLCs may not have been set up for very long and hence would not have established a credit rating. This presents lenders with an unattractive client to begin with and is highly unlikely to lend without requiring the provision of fixed asset collateral or significantly high interest rates as an unsecured loan.

2. Current limitations in the financing sector

Despite the numerous barriers mentioned earlier, according to the Efficiency Valuations Organization (2009), "one of the most significant of these barriers is a lack of commercially viable financing, which is not caused by a lack of available funds per se, but rather an inability to access existing funding capacity at local banks and financing institutions on commercially attractive terms." There exists a very clear disconnect between the traditional banking sector and that which is needed to make an energy efficiency project take place.

Commercial banks are still approaching energy efficiency financing from either a corporate lending or a project financing perspective looking for the standard fixed asset collateral and limiting lending to 70% to 80% of the asset base. They have failed to accept the equipment installed as part of the project as sufficient collateral and are not willing to recognize the energy efficiency cost savings as acceptable cash flow as a

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_39, © Springer Science+Business Media Dordrecht 2012

reliable repayment source and hence assign no value to the cash flow generated.

But this is not all; unfortunately they still see energy efficiency projects as being relatively small investments and are not willing to invest into the development of internal capacity to enable them to understand the complexities of energy efficiency projects, the technologies involved, the different delivery models, and how to evaluate the risks associated with each one effectively and efficiently.

3. Self-Financing

Public and private entities with sufficient internal funds may consider self-financing their energy efficiency project. A building owner can fund such a project by drawing on its capital budget, or operating budget or by tapping funds for deferred maintenance. Depending on the building owner's financial position, self-financing often represents the least expensive means of financing a project because it avoids the need to pay interest and transaction costs on incremental borrowing. Internal financing also minimizes the "cost of waiting," or energy cost savings opportunities foregone as a project waits for funding to be approved and processed.

Attractive returns are possible if a building owner invests its own resources to pay for the up-front project costs in what is essentially a project equity investment to be paid back through energy savings.

4. "Off Balance Sheet" Financing

As a result of the slow pace at which the commercial banking sector (and institutional financing organizations) has addressed financing energy efficiency, there has been an increasing emergence of customized energy efficiency financing structures all over the world, mostly to overcome the initial capital outlay constraints faced by building owners. "For the first time in decades, dating back to the initial use of shared savings contracts in the 80's, new EE financing structures are emerging that allow end users to avoid the initial capital outlay associated with the installation of EE measures, thereby enabling the completion of efficiency projects that, absent outside funding, would go undone" (Hinkle and Kenny, 2010).

Hence, the ideal mechanism would be one which addresses most of the major barriers – no (or as little as possible) upfront capital required, no lien waiver needed from mortgagee, savings guaranteed by ESCO, in case the building is sold, the contract obligations can be assigned to the new owner, and there's no fixed asset collateral required to enable the project to take place.

One such financing structure is often referred to as Operating Lease Agreement (OLA). An operating lease commands that both legal and economic ownership of the equipment rests with the lessor indefinitely. From an accounting perspective, an operating lease obligation can be considered "off-balance sheet." In reality, the lessee is actually paying rent for the service that the equipment provides, rather than paying for the purchase of the equipment itself. Because the equipment legally belongs to the lessor, the lessor can take advantage of the tax benefits of ownership such as accelerated depreciation. Because the lessee is not considered to own the equipment, no asset or long-term liability rests on the organization's balance sheet, and lease payments can be allocated from the lessee's operating budget.

This type of an arrangement can benefit organizations that are at or near their borrowing capacity, or simply do not wish to use their existing credit facilities for energy efficiency as their focus is still on their core business activities. It also enables a simpler decision making process in a multiple ownership structure that needs to approve any new debt.

The investor is at peace of mind as the organization's responsibility for making timely payments under the operating lease are absolute, and not contingent upon whether sufficient guaranteed savings materialize. Under this agreement the building owner's regular payment obligation is to the lessor.

The actual energy efficiency project details and contract, including the guaranteed savings and shortfall payments (the EPC) are a separate agreement and rest between the building owner and the ESCO.

5. Methodology - Energy Performance Contracting

There are numerous models utilized to retrofit buildings from the traditional 'bid-spec' model to the more complex procurement methodologies traditionally used by public authorities. However, one such model which is seen to provide the most attractive structure for financing, (and the least risk to both building owner and investor) is the Energy Performance Contract (EPC) where the ESCO develops, designs, implements, commissions and guarantees the outcome of a turn-key energy efficiency project. In this model the ESCO assumes the performance risk component of the project and agrees to either repay the building owner for any shortfall in savings or invest into additional equipment/modifications to the energy efficiency project in order to deliver the guaranteed savings. This model provides assurance to the building owner (and financier) that the project will deliver a certain amount of savings which can then be allocated to repaying any financing that was taken out for the project.

Energy Performance Contracting has been widely used as a method for contracting building retrofits for several decades, particularly in the U.S. public and institutional building sectors. By guaranteeing a minimum amount of energy savings, EPC allows all building owners to assess the payback and thus the financial returns on their energy efficiency project. Some owners may be able to finance the entire cost of new equipment and technologies by using the energy savings alone, negating the need for initial capital expenditure.

While in other cases it may be possible to structure the debt repayments so that the minimum required payments are less than the actual cost savings, hence providing a positive cash flow that can be reinvested into other initiatives such as cosmetic renovations or expansion activities. In this approach building owners immediately realize the positive impact energy efficiency can have on operating budgets without having to wait for the actual return on investment to occur. Other main characteristics include:

1. *Turn-Key Project* - EPCs focus on a turn-key process of delivering a project whereby one ESCO is responsible for design, documentation, installation, project management, commissioning, and ongoing monitoring and verification (M&V) of energy conservation measures. This methodology takes a comprehensive and holistic approach to a building (HVAC, lighting, building envelope, control and management systems, on-site generation) and calculations, recommendations and measures are based upon a life-cycle analysis (operational costs over the equipment life) rather than the initial upfront 'purchase price' as being the deciding factor behind decision making.

2. *Performance Guarantee* - EPCs are based upon a 'performance guarantee' whereby the ESCO provides a guarantee on the performance of the Energy Conservation Measures (ECMs) that the ESCO is recommending to implement. This performance guarantee is usually presented as a guaranteed amount of energy (kWh) to be saved. The basis for these calculations in a project are usually a combination of efficiency gains as well as operational and maintenance savings.

3. *Leveraging/Bundling* – The EPC methodology enables a project to be based upon one final project profile which means that a number of Energy Conservation Measures (ECMs) can be combined together within the project to make up this final profile. Hence, ECMs which have high energy savings potentials and shorter payback periods can be used to leverage larger, more complex ECMs which may not have such attractive financial characteristics. This results in larger total project savings (and hence greenhouse gas emission reduction) and a lower combined or 'bundled' project payback period, with the only downside often being a larger required initial investment.

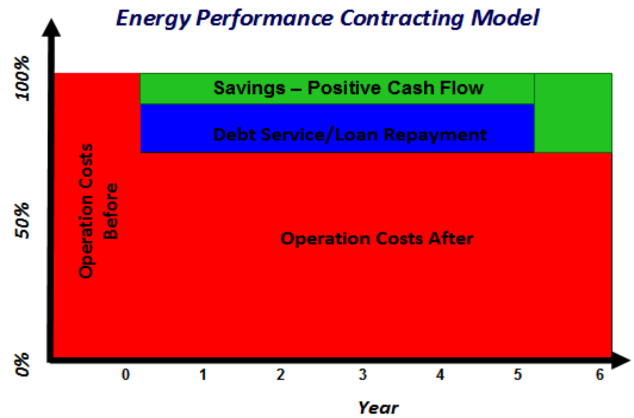

Figure 1: Energy Performance Contracting

6. The Structure

The actual energy efficiency component of the whole project is still undertaken by the ESCO and project activities such as the preliminary assessment and the Investment Grade Audit are kept separate from the 'investor'/financier. The ESCO will bear responsibility for any delays in implementation and completion.

When the project is ready to be implemented, the building owner and the financier will enter into an agreement which outlines the terms and conditions of the provision of capital, and the repayment obligations. The financier will own all assets related to the project that are installed into the building, with an emphasis on the specific location of the (main) equipment. This equipment will be defined as being owned by the investor with a specific agreement to allow this equipment to be used (and operated) by the building owner (lessee). The investor will hold a first priority security interest on these assets. For equipment that may be installed in various locations throughout the building, the investor will hold a subordinated security interest.

Payment obligations will fall under the OLA between the building owner and financier and are usually set out in either monthly or quarterly repayment schedules. The repayment structure is usually set up to reflect the minimum energy cost savings guaranteed by the ESCO, however there is often the option of making either higher or more frequent repayments or on the other hand, prolonging the repayment agreement to enable the building owner to take advantage of a positive cash flow scenario.

Upon making the final repayment, the ownership of all energy efficiency assets will be transferred to the building owner at a pre-agreed price.

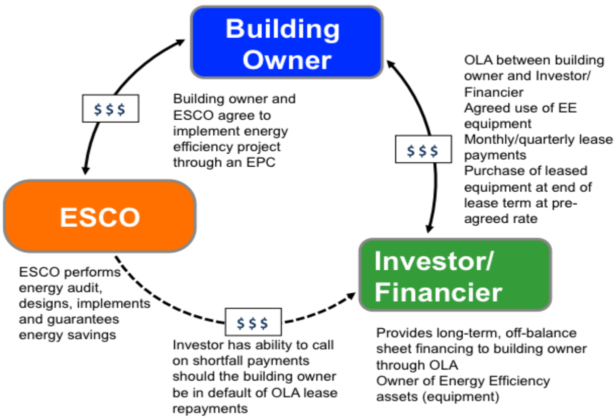

Figure 2: The Operating Lease Agreement

7. Establishing a proven track record

It is well accepted that energy efficiency has tremendous potential to contribute to the mitigation of greenhouse gas emissions all over the world, especially in cities with a large number of existing buildings. At the same time however, the commercial banking sector has remained conservative in their approach, attempting to fit energy efficiency into their standard corporate lending practices and lack the knowledge and innovation to meet the unique characteristics and complexities of energy efficiency projects. They have not invested sufficient resources to develop the internal capacity required for this market.

On the other hand, there has been a significant increase in the development of customized financing mechanisms from non-traditional lenders to cater to the financial conditions and preferences of building owners to address the barriers that they face when contemplating undertaking such projects. As these sector specific financing models become more established, well proven and more widely utilized, it is likely that the commercial banking sector follows suit in a much larger scale than what is being seen at the moment.

"For sustainable and sizeable channels of financing the local banking sector is ultimately the key in most every country. Where the local banking sector is too weak, immature or simply uninterested, any of a variety of arrangements may be worthwhile to provide initial energy efficiency project financing or begin to introduce the energy efficiency lending business into the market" (Taylor et al, 2008)

Successful Eco–Sustainability
Toward a Company–related Environmental Labeling

Author Name (Mr Yoichi Sakuma), Author Name (Mr Hans-Jochen Lueckefett)
UL Japan, Inc., K&L GmbH

Abstract
Today, eco-design is an important goal for many companies in the world. And this for various reasons: environmental legislation, a company's green image, protection of the environment. These motives require companies to consider different aspects of eco-design: the environmental impact of a product, the legal requirements to be compliant, a confusing number of existing labels worldwide and customers' resistance to pay more money for a sustainable product. To succeed on the market with sustainable products requires a defined sustainability strategy that goes beyond existing regulation. An important aspect to achieve exceptional green products might be to certify the company as a whole for its environmental performance, instead of certifying a single product. The presentation will offer an assessment of product versus company related eco-strategies.

Keywords:
Eco-design, ErP Directive, Green image, Eco-label, Eco-certification

1 BACKGROUND

In 2005 the European Union put into effect the first framework directive for creating eco-design criteria targeting energy-using products (EuP Directive 2005/32/EC). The directive was reviewed and newly published in 2009 with the new name of ErP Directive on energy-related products (Directive 2009/125/EC).

What are these directives aiming at? They want to establish a framework for the setting of eco-design requirements for energy–related products. These requirements are going to be defined by so-called "implementing measures" which the EU Commission issues after consultation with stakeholders. The work of the EU Commission currently focuses on energy efficiency. The list of implementing measures already published and those under preparation may give an overview about the scope of this new legal provision.

Table 1: Overview of existing implementing measures (Status: 2011/09/22)

Regulation	Product Group	Date of Application
Regulation (EC) No 1275/2008	Standby and off-mode losses	7/1/2010, **7/1/2013**
Regulation (EC) No 107/2009	Simple set-top boxes	25/2/2010, **25/2/2012**
Regulation (EC) No 244/2009	Non-directional household lamps	1/9/2010, 1/9/2010, 1/9/2011, **1/9/2012**, **1/9/2013, 1/9/2016**
Regulation (EC) No 245/2009	Tertiary sector lighting products	13/4/2010, 13/10/2010, **13/4/2012, 13/4/2015, 13/4/2017**
Regulation (EC) No 278/2009	External power supplies	27/4/2010, **27/4/2011**
Regulation (EC) No 640/2009	Electric motors	16/6/2011, **1/1/2015, 1/1/2017**
Regulation (EC) No 641/2009	Circulators	**1/1/2013, 1/8/2015**
Regulation (EC) No 642/2009	Televisions	1/7/2010, 20/8/2010, 20/8/2011, **1/4/2012**
Regulation (EC) No 643/2009	Domestic refrigerators and freezers	1/7/2010, **1/7/2012, 1/7/2013, 1/7/2014, 1/7/2015**
Regulation (EU) No 1015/2010	Household washing machines	1/12/2010, **1/6/2012, 1/12/2012, 1/12/2013**
Regulation (EU) No 1016/2010	Household dishwashers	**1/12/2011, 1/6/2012, 1/12/2012, 1/12/2013, 1/12/2016**
Regulation (EU) No 327/2011	Fans	**1/1/2013, 1/1/2015**

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_40, © Springer Science+Business Media Dordrecht 2012

Table 2: Overview of coming implementing measures (Ongoing preparatory studies not included, Status: 2011/09/22)

Lot	Product Group	Working Document/ Consultation Forum	Reg. Committee	EU Parlia-ment/ EU Council
10	Air conditioners and comfort fans			X
1	Boilers	X		
2	Water heaters	X		
3	Computers and monitors	X		
4	Imaging equipment	X (voluntary agreement)		
8/9	Tertiary lighting	X (amendment)		
10	Domestic ventilation and kitchen hoods	X		
11	Pumps	X		
12	Commercial refrigerators and freezers	X		
16	Household tumble driers	X		
17	Vacuum cleaners	X		
18	Complex set-top boxes	X		
19	Domestic lighting part II "directional lamps"	X		
26	Networked standby losses	X		
ENTR Lot 5	Machine tools	X (voluntary agreement)		
	Medical imaging equipment	X (voluntary agreement)		

How does the EU identify the products for which implementing measures are going to be prepared? The directive itself stipulates the selection criteria:

- more than 200,000 units sold per year in the EU,
- significant environmental impact,
- significant potential for improved ecological performance because the current performance of the product is widely spread among competitive products on the market.

Implementing measures apply uniformly everywhere throughout the 27 EU member states, as they are issued as EU regulations. The ErP Directive makes manufacturers or their authorized representatives or importers responsible for ensuring conformity. Conformity must be proved by the CE mark.

2 THE GREEN IMAGE

What are the effects of the ERP directive?

2.1 The customer's view

Political institutions and industry are getting mixed messages from markets. On the one hand side, customers are answering questions about the importance of environmental product attributes positively. On the other side the customer's willingness to pay more for a product which combines price-performance with improved environmental attributes is still low.

The situation may have changed with the steep rise in energy prices. European private households appreciate the energy–label – so far e.g. for washing machines and dishwashers, and since 2011/11/30 also for television sets. But there is no evidence yet that other eco–design criteria are also getting on the radar screen of the consumer.

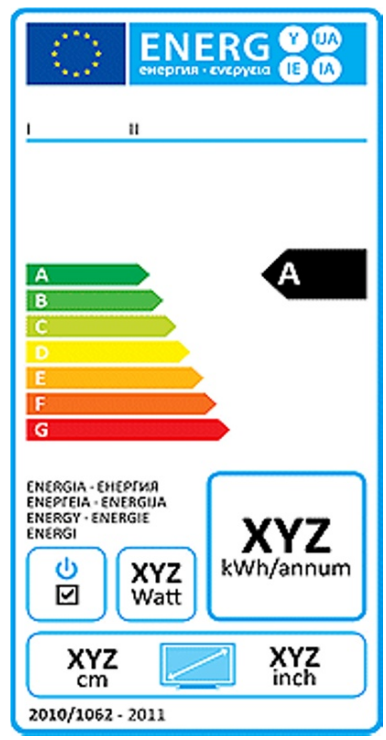

Fig. 1: New energy-label for televisions

2.2 Enforcement

Every piece of environmental legislation requires government enforcement. Otherwise there will be a distortion of competition between the good and the bad boys. The good boys will suffer from higher manufacturing and other costs compared with the bad boys saving money simply by non-compliance.

Therefore, industry was requesting the EU and the member states to improve systematic enforcement activities covering the environmental legislation of the last 10 years which includes the ERP Directive, too. As the more systematic approach to government enforcement started only recently and not in all 27 EU member states simultaneously, there is no reliable evidence available about industry's compliance behavior.

2.3 Industry's challenge

Independently from consumer's behavior and government enforcement activities, the launch of the eco–design legislation influenced companies asking questions about how to build or how to improve a green image. There are a couple of answers to this question:

2.3.1 Compliance with mandatory legislation does not help building or improving a green image. Legal provisions are making all products falling under the scope of the legislation "me too". Therefore compliance is positioning companies among the pack, but not ahead of the pack.

2.3.2 The only other way that governments and NGOs are offering for creating and improving a company's green image are eco-labels. Most eco-labels, in fact, are including a big number of challenging eco-design criteria which companies must fulfill in order to get it. In conclusion and in theory, eco–labels like the Blue Angel for instance do have the potential to improve the green image of a company. However, it is questionable if eco-labels are a good way to present a green image in particular from a global perspective. Firstly there is a confusing number of different eco-labels in the industrialized regions of the world. Please see examples from Europe and Asia.

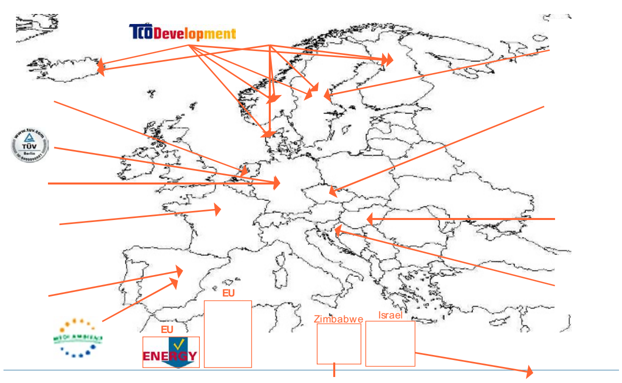

Fig. 2: EMEA – all known eco–labels

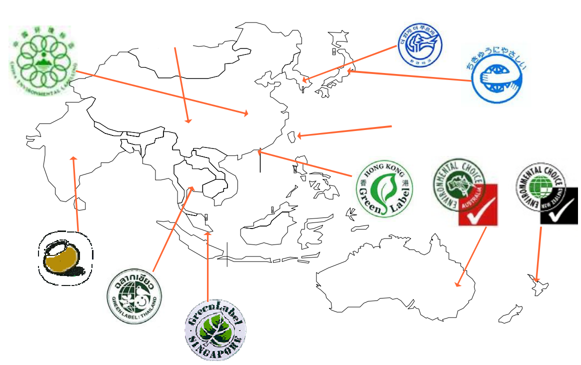

Fig. 3: Asia Pacific Japan – all known eco–labels

In addition, eco-labels are more or less of local importance only. They may satisfy national or regional markets. But there is no way to use an Asian eco-label for proving environmental product performance on the European or American market and the other way round to use the Blue Angel for the Asian markets. Companies and even NGOs like Greenpeace acknowledge this weakness of eco–labels.

3 A NEW PROPOSITION FOR A PROVEN GREEN IMAGE

With the background of the existing legislation and the variety of eco–labels industry requires an answer to the question whether there is a way to prove environmental performance on the global markets in a less confusing way compared to the situation today. It would be extremely desirable for globally acting companies to demonstrate environmental performance uniformly with the same tools on all markets.

There seems to be a new answer to this question of industry: a label certifying the company's environmental sustainability and not the company's products, one after the other. Why could such label be an instrument for demonstrating environmental performance without confusing markets and customers? There are a couple of answers to that question:

- A label which applies to a company reduces the number of necessary labels dramatically. A label for a single product does not allow the conclusion that all the other products of that company are equally environmentally friendly. However, a company cannot be environmentally sustainable without having environmentally friendly products as well as an overall environmental performance. If this wasn't the case, the company would not earn the label.
- A company certificate makes it easier for customers to compare competitors: as far as environmental performance is concerned, the comparison takes place on the company level and not on the level of the single product.
- The process for certifying the company does not hinder the launch of new products. In other words: the company must not worry about time to market. As the certification process covers a variety of environmental aspects, the company can run it independently from its key processes (R&D, manufacturing, marketing and sales).

An example of such company-related eco–certification is the ULE 800 standard. It covers the following areas (domains):

Table 3: Company related eco-certification with ULE 800 – the domains

Governance for Sustainability	sustainability strategic planning, board oversight, internal stakeholder engagement, ethics policies, and creating the infrastructure and fostering the behaviors that create a culture of sustainability
Environment	product stewardship, sustainable resource use, environmental management systems, energy efficiency and carbon management, materials optimization, facilities and land use, habitat restoration, and waste prevention
Work Force	professional development, workplace integrity, employee satisfaction and retention, workplace safety, and employee health and well-being
Customers and Suppliers	fair marketing practices, product safety, customer support and complaint resolution, and sustainable supply chain management, monitoring and improvement
Community Engagement and Human Rights	community impact assessment, community investment, and human rights issues

Designing-in Sustainability in Industrial Projects and Processes

Ben C. McLellan [1], Glen D. Corder [2]

[1] Graduate School of Energy Science, Kyoto University, Kyoto, Japan

[2] Sustainable Minerals Institute, University of Queensland, Brisbane, Australia

Abstract

Industrial projects represent significant potential for economic development in their host countries. Likewise, they also present the potential to cause significant social and environmental impacts. While much consideration has been put into the design for sustainability of products, there is still a significant gap in the integration of sustainability considerations into industrial projects and processes. Moreover, there is an additional need to bridge the theory of sustainable design and the "on-the-ground" needs of the designers of such projects. This paper discusses one framework which has been developed to help bridge this gap, as well as the results and learnings from its application to high impact "real world" projects. The paper discusses the problem from a range of perspectives including: what the gap between current and ideal practice is, what needs to be incorporated in a sustainable industrial project, what methods have been applied, and the relative theoretical and practical success of the current framework.

Some of the key outcomes from the case studies to date have included the development of plans for the roll-out of integrated social and environmental initiatives to reduce cost and environmental impact while improving societal acceptance and resilience. Research learnings have indicated the need for a structured framework for identifying potential opportunities and risks, as well as the importance of timing and integration with existing project management systems.

Keywords:

sustainable development, design, industrial, process, project

1 INTRODUCTION

Sustainable development is a challenging concept for the designer of industrial processes to incorporate – especially when these projects tend to involve extreme processing conditions, high throughputs and large footprints on multiple scales. However, sustainable development (SD) principles are often touted by the corporate leadership of companies without full consideration as to how these can be incorporated in the design of new processes or projects (e.g. [1]). Furthermore, the literature on design of industrial projects and processes to meet principles of sustainability is highly porous [2] (in contrast to the literature on sustainable design of products).

The object of this paper is to provide a brief overview of the state-of-play of industrial process design for sustainability, and describe recent work that has taken steps towards filling some of the gaps in both academic understanding and practical application.

2 SUSTAINABILITY IN DESIGN

2.1 Approaches from industry

As an example of industrial design, the minerals industry may be seen to be quite highly performing in the area of sustainability at the corporate level, having undertaken significant global stakeholder dialogue and committed to sustainable development at the highest level [1, 3]. However, when it comes to actualizing these commitments, the industry has not found it easy. In regards to the approach of project developers and designers in this industry, decisions on resource projects are traditionally based on the answer to three fundamental questions: (a) is it technically feasible?, (b) does it make financial sense? and (c) will government/community allow it?

This approach may be broadly comparable across heavy industrial projects. The practical application of these aspects means, respectively, that (a) tried-and-tested technology or processes are applied and reapplied with little innovation from project to project; (b) financial investment in sustainability is seen as non-core, and therefore typically avoided or omitted; (c) the lower limit of acceptability is the benchmark for projects – as typified by environmental regulatory processes. These approaches neither support the integration of sustainability principles nor, it may be argued, enhance the ultimate feasibility, financial performance or acceptability of the project.

Additional to these limitations, project design and management processes typically work to reduce the possibility of integrating innovation to improve contribution to sustainable development through the drive for: (a) KPI's that do not include or reward sustainability;

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_41,

(b) projects being divided-up into design silos that communicate too infrequently, thus limiting cross-pollination of sustainability initiatives; (c) highly compressed timeframes and budgets; (d) standards and regulations that create “low bar” goals and do not incentivize higher performance; (e) task-orientation and separation that leads to design conflict, sub-optimal solutions and a lack of broader perspective on the project from the majority of the design team; (f) limitations on spending at the early stages of design, which is where the best opportunity for improving the project can be obtained.

It must be noted that some companies are trying to bring greater integration of sustainability, but that these efforts tend to be marginal in relation to the overall project.

A special note for environmental impact assessment (EIA) and social impact assessment (SIA) must be made. These potentially highly useful and effective tools have been integrated into the regulatory system of many countries, in order for project approval to be granted. However, these studies are often outsourced or tendered to companies that are not undertaking the major design. This can give a useful legal separation that may impress regulators with the perception of non-bias, however it also means that the effort undertaken in EIA / SIA is not immediately or directly fed-back into the design process. In addition, these tasks are often undertaken too late in the design process to make much more than end-of-pipe or superficial changes.

2.2 Tools from academia

There have been a number of tools developed through academic effort over the past decades which are receiving some industrial uptake, although often mistimed. Key tools include environmental footprinting, life cycle assessment (LCA) and a variety of principles and methodologies for cleaner production, waste minimization [4], green engineering [5]. There have also been a large number of associated assessment tools and metrics developed (e.g. [6]).

As these tools have been integrated into software packages, they have received some level of uptake by industrial process designers. However, most of these tools are based on post-design assessment, rather than guiding or assisting the design in a proactive manner. Thus, although important, they lack an element of creative input to enhance design for sustainability (DfS).

2.3 Design methodologies from academia

A number of DfS methodologies have been proposed for process design [7-11], but no industrial take-up has been reported. While this could in part be the result of a lack of reporting of such applications by industry, it is considered more likely to be an indication that take-up has not occurred. There are known to be other in-house methods or tools that have been indicated in the literature, but not thoroughly explained due to confidentiality and commercial advantage [12]. Other tools and approaches are mentioned on many engineering consultants’ websites (e.g. http://www.ghd.com/global/about-us/sustainability/) and some have been made publically available [13]. Despite the mention by industrial players, there is little indication of their application, which is a vital element in the success of such methodologies.

One frequently cited approach [8] adds: an initial scoping of sustainability criteria, identification of alternatives, and assessment on these criteria, before the traditional design process. This occurs at an early stage of the project, prior to preliminary design. Further additional steps involve assessment of sustainability after each iteration of design (or at the end of each project stage). This iterative approach, and the integration with the project management cycle is vital, as described in the next section.

The remaining cited methodologies focus specifically on the design phases of the project and involve mathematical or computer-based optimisation of a number of indices or metrics representative of sustainability of the alternative process flow sheets [9-11]. Stewart, et al. [9] include a preliminary step of comparing possible raw materials or products however, the remainder of these methodologies is quite similar. Alternatives are generated by application of standard design methods and assessed or evaluated using tools mentioned in section 2.2. These assessment processes are limited to environmental impacts, and largely ignore the location-specific aspects that make each project unique, and ultimately affect sustainability of an industrial installation [14]. The integration of social and location-specific aspects is a complex issue which is not well treated by existing design methodologies or tools such as LCA.

2.4 Importance of the project cycle

In “real world” industrial design projects, as opposed to academic design exercises, the project management system typically dictates the time, data and scope for innovation that is available at each process stage (Fig 1). It is vital to match any DfS strategy with the project management system, in order to enable timely and appropriate integration of sustainability.

If there is no correlation between a DfS methodology and the project cycle, then the methodology will not be successful. Two examples follow: (a) the use of highly detailed flowsheet anaylsis or optimization at the conceptual stage of a project. This will not succeed because the required data is not available and uncertainties are too high. (b) the attempt to introduce new flowsheets or processes in the detailed design stages. This will be rejected on the basis of the timing and required cost to rework the project.

The importance of correlation with the project management system goes further, in that existing tools such as LCA need to be applied appropriately in order to gain support of internal stakeholders and to provide appropriate information to the design team.

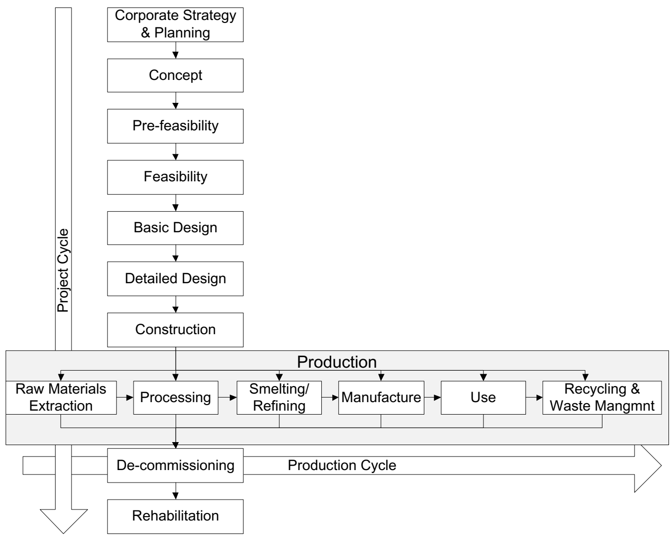

Fig. 1: Project-production cycle

The following sections describe a methodology that has been developed to overcome these gaps.

3 THE SUSOP® MECHANISM

3.1 Development

Recognising that most of the proposed DfS methodologies have been academically-derived, the SUSOP® (SUStainable OPerations) mechanism took a different approach, being a collaboration between industrial and academic partners. This has led to a DfS methodology that acknowledges and incorporates industrial realities, while still aiming to provide an academically rigorous solution for integrating sustainability considerations in design. Moreover, due to this collaborative arrangement, the methodology was able to be tested on actual, ongoing minerals industry projects.

3.2 SUSOP® components

The mechanism comprises three major components that form the backbone of the framework:

1. Sustainability opportunities and risks identification (SUSID™). A significant characteristic of this element is that it includes 'new ideas' generation.
2. Sustainable Development (SD) Assessment – to conduct a detailed evaluation of the shortlisted or high-priority opportunities and risks.
3. Decision Support - to provide assistance with decision-making at project toll gates.

A schematic of the main elements of SUSOP® are presented in Fig 2. With recognition of the different stages of the project cycle, the particular elements applied at each stage are tailored to the available level of data and the key tasks required for normal project delivery.

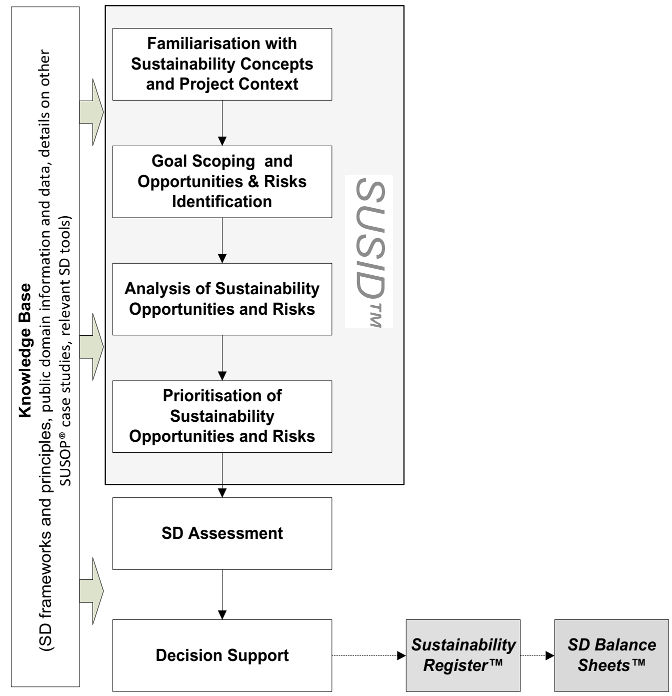

Fig. 2: SUSOP® Framework

Sustainability Opportunities and Risks Identification (SUSID™)

There are four steps in SUSID™:

1. Familiarisation with Sustainability Concepts and Project Context;
2. Goal Scoping and Opportunities & Risks Identification;
3. Analysis of Sustainability Opportunities & Risks;
4. Prioritisation of Sustainability Opportunities & Risks.

The first two steps and the last step are run in a workshop environment while the third step is analysis conducted by SUSOP® Practitioners.

The aim of the Familiarisation step is to create a common understanding of the project context (key technical and financial characteristics, local environment and the social context at the local and regional levels) and core sustainability principles and frameworks for the workshop attendees. The attendees draw out the linkages between the project context and the sustainability framework and relevant sustainability principles, such as the ICMM's ten principles [1], or corporate sustainability policies. By discussing and formalizing the designers' knowledge of the project and sustainability principles from the beginning, design and innovation can start to be driven based on a new paradigm.

The Goal Scoping and Opportunities and Risks Identification step comprises two key activities. The first activity is the generation of project-specific sustainability goals based on the company's corporate sustainability principles or policy. It is an extension of the Familiarisation process and provides the seeds for the second activity, Opportunities and Risk Identification.

Opportunities and Risk Identification is one of the key elements of SUSOP®, distinguishing it from alternative methodologies. Specifically designed prompting questions and key words based on widely accepted sustainability concepts are employed to identify sustainability opportunities that could potentially improve the SD contribution of the project. Risks caused by the project to SD are also identified and, if possible, solutions are suggested to mitigate these risks. Innovative solutions typically emerge when participants understand and appreciate the connections between the proposed project and the broader societal and environmental context. Both sustainability risks and opportunities are listed in the Sustainability Register™ which is then carried forward by the project team across the project development cycle for further attention in subsequent phases.

Analysis of Sustainability Opportunities and Risks is undertaken by specialized SUSOP® Practitioners to further analyse and verify the outcomes from previous steps, and investigate the potential for other opportunities or identify additional risks. An important part of this step is establishing clusters, connections or linkages between opportunities and risks, to develop a preliminary understanding of the overall sustainability impacts. Based on the analysis in this step, an initial shortlist of opportunities and risks is produced.

The outcomes from the Analysis step are then presented to the project team in the Prioritisation of Sustainability Opportunities and Risks step to validate (based on sustainability considerations) and confirm a shortlist of opportunities and risks for future evaluation and assessment. By the end of this step, the project team agrees on a prioritised list of opportunities and risks, including those that require immediate action.

SD Assessment

The SD Assessment involves the detailed evaluation of the prioritised sustainability opportunities and risks. Where possible, quantitative tools are used to investigate and evaluate the top ranking opportunities and risks on the basis of their sustainability impacts (positive and negative). It must be noted that the level of quantification, and the tools used must reflect the available data and project stage.

Decision support

The final component is decision support. This is an important area of consideration in DfS, with so many (often conflicting) areas of priority and impact. This step draws on existing techniques, such as multi-criteria analysis techniques, to provide substantive guidance on the selection of initiatives that will deliver enduring sustainability benefits as well as satisfy key business performance criteria.. An SD Balance Sheet™ is used to graphically demonstrate the different SD impacts and benefits of alternative design options, and is also useful in the decision support situation. The "Five Capitals" model [15] is used as the default framework – as shown in Fig 4. In addition, the Sustainability Register™ presents the outcomes from applying SUSOP® in a format that feeds into the standard project management systems.

4 CASE STUDIES

4.1 Concept phase – site selection

Two case studies are discussed in this section. The first was a concept phase study that was to assist the client in making a decision on plant location based on criteria beyond their usual risk and cost metrics. The project was in a developing country with minimal domestic infrastructure, poor access to cheap energy, low technical or skilled labour force.

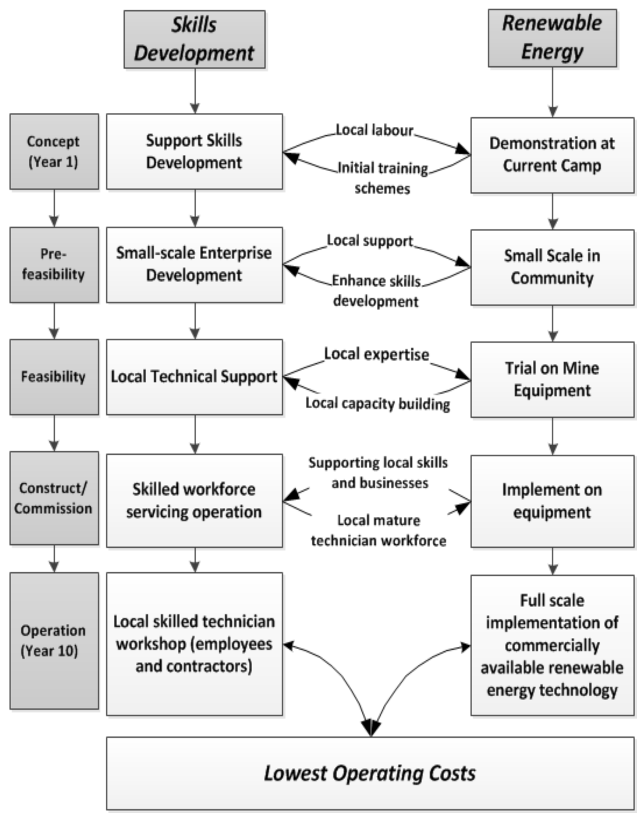

Fig. 3: Integrated development plan.

Applying the SUSOP® methodology identified more than 70 opportunities for improving SD contribution through waste reuse, community initiatives and low impact processing options. These were further analysed and grouped into a number of clustered opportunities that could be integrated on a whole-of-project scale.

One of the key outcomes from this case study was the development of a plan for progressively bridging the skills and energy gaps over the subsequent project phases, so as to ultimately reduce project costs. The savings in project operational costs, which could be derived by training local workmen rather than importing expensive expatriates and by reducing dependence on imported energy sources, were a key "selling" point for the plan.

4.2 Pre-feasibility study – waste treatment

The client was at the pre-feasibility stages of a minerals processing expansion, in a developing country. The project was to compare a variety of existing options for effluent treatment on a sustainability basis, and to suggest further improvements.

From this study, sustainability opportunities to support effluent management were identified, such as creating local enterprises to provide consumables, producing 'green' by-products and implementing a small-scale wetland to replace a conventional effluent treatment facility. These outcomes will deliver significant improvements to social and natural capitals compared with the base case option, and substantially satisfy key elements of the corporate sustainability policy.

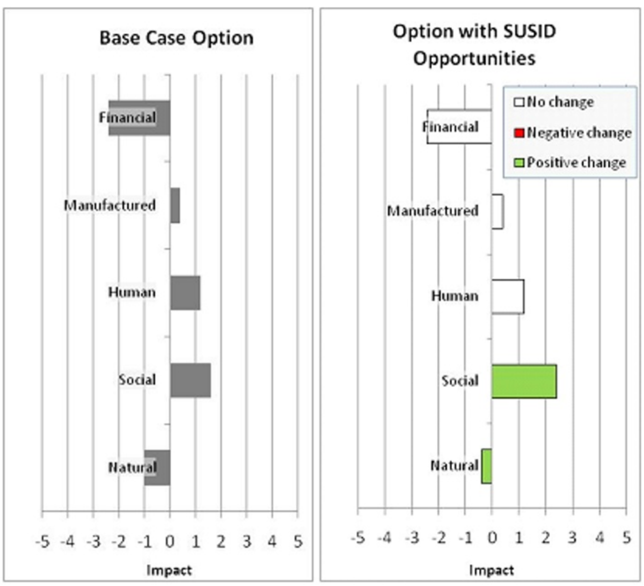

Fig. 4: SD Balance Sheet™ – applying the "Five Capitals" SD framework

Being at the pre-feasibility stage, sufficient data was available to complete a quantitative estimate of the potential of the different options, as well as to produce SD Balance Sheets™ for each option before and after the integration of sustainability initiatives (Fig 4). Significant positive change was found to be possible for social and natural capital, while manufactured and human capital were not significantly improved. Furthermore, financial capital remained negative, but this was consistent with the required expenditure for effluent treatment – a non-profit generating activity.

4.3 Learnings

A number of key learnings have emerged from the application of SUSOP®. Firstly, a number of key elements must be included in order to drive more sustainable design – including multi-stakeholder innovation sessions, assessment and decision-making tools with a consistent SD framework throughout. Secondly, the DfS process must integrate into the existing project management system, acknowledging the limitations of data and scope that give boundaries to the potential for innovation. Thirdly, the identification of opportunities and risks requires a structured approach – in some cases essential to prompt ideas, and in other cases essential to limit or restrict ideas to within project scope. Without these elements, a DfS methodology is unlikely to receive uptake or perform its purpose satisfactorily.

5 CONCLUSIONS

This paper describes some of the challenges for designers attempting to integrate sustainable development principles into industrial process design. It describes key elements of one structured mechanism, and the relative success that the process has achieved in application.

Unlike most existing approaches, the SUSOP® framework attempts to integrate closely with existing project management systems, and to fit with the limitations of scope that each project stage delivers.

ACKNOWLEDGEMENTS

This project was carried out under the auspice and with the financial support of the Centre for Sustainable Resource Processing (www.csrp.com.au), which was established and supported under the Australian Government's Cooperative Research Centres Program. The SUSOP® research and development team comprises industry participants, Hatch and GHD, and research providers, the University of Queensland, University of Technology Sydney and CSIRO.

Industrial design accolades: Do they support socially sustainable product innovation?

Mariano Ramirez
University of New South Wales, Sydney, Australia

Abstract
This paper looks for evidences of socially sustainable product innovations amongst the entries recognized in international industrial design awards. The winning designs for the last four years in three of the most popular mainstream accolades were investigated and profiled. The analysis shows that attention to socially sustainability in design is gradually picking up. Several special awards that pay special attention to social sustainability issues were found, suggesting that support for this type of innovation in the design profession is growing.

Keywords
Industrial design awards, socially sustainable product innovation, socially responsible design

1 INTRODUCTION

Industry accolades recognize the efforts of design practitioners and manufacturers in offering highly innovative products and outstanding solutions in the marketplace. They stimulate the understanding of the business and public realms about the impact that excellent design could bring to the quality of human life everywhere and to the national and global economies.

1.1 Product design accolades

Accolades for industrial design creations can be generally categorized generally into two types. One is an endorsement scheme for well designed products, whereby submitted entries are given commendations depending on how they conform to the assessment criteria and benchmarked with similar products in their particular category. In this mode the design award functions like a seal of design quality. The entrants do not compete with other products but instead demonstrate that they are exemplars of good design. Many products receive equal recognition, and there can be multiple winners at various levels. Commonly the designs entered in these endorsement schemes are required to be already in production and available for usage or purchase in the market. Most of the long-running mainstream industrial design awards are of this type.

The other type is based on an open contest where products vie for the honor of being named the best among the submitted products in meeting the competition brief. In this category only one product is adjudged the best and awarded the highest accolade, such as a gold prize. The second best gets the silver prize, the third best the bronze, and there can be a few honorable mentions or highly commended works too. In this award system, only one or a few products emerge as winners. The great majority of designs entered into this award type are conceptual.

Unfortunately many of the ground-breaking ideas entered in the competition-type design awards do not get realized into actual production, perhaps due to lack of financial viability, practicality or manufacturing resolution. Often as a concept progresses during the iterative process of new product development, several technical constraints are imposed along the way, causing the idea to reshape, sometimes significantly, to address the production and other requirements; the project could also ultimately be shelved if a feasible business model cannot be assured.

The criteria for evaluating products for design accolades vary, but in general they assess the following product qualities and keywords:

- Innovation, novelty, originality.
- Aesthetics, styling, semantics, emotional content.
- Functionality, usability, ergonomics.
- Quality, durability, finish, material, construction.
- Safety, user protection, standards compliance.
- Sustainability, real need, environmental impact reduction, long lifetime; resource efficiency, end-of-life consideration, disassembly, maintainability.

The above adjudication criteria successfully distinguish good design and design excellence in the marketplace from bad design and dull, unexciting products. Ecological sustainability is now being addressed by all major awards as a prerequisite to entry, in recognition of the need to minimize the overall lifecycle impacts of manufactured products.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_42,

1.2 Socially Sustainable Product Innovation

In 1971 the activist professor Victor Papanek wrote that "much recent design has satisfied only evanescent wants and desires, while the genuine needs of man have often been neglected by the designer" [1]. He advocated that market-oriented designers go beyond "appearance design, styling, or design cosmetics", and use their talents to solve the pressing needs of the disadvantaged minorities in society: the disabled, the elderly, the developing countries, people surviving under marginal conditions, and others often ignored by the design profession [1].

Papanek's pleas for designers and creative professionals to contribute to real change in the world through good design provided the impetus for the emergence of "socially responsible design", defined as "the use of design to address social, environmental, economic and political issues" [2]. This ideology campaigns for all humans to acknowledge their moral obligation to act for the betterment of society and life in general. A proposed model for socially responsible design, based on the management approach of corporate social responsibility, identifies crime, education, government, health, fair trade, ecology, social inclusion and economic policy as the eight socially significant domains to which designers can direct their creative problem solving skills [2].

Many recent design movements and philosophies can be linked to socially responsible design. There is "socially responsive design", which "takes as its primary driver social issues, its main consideration social impact and its main objective social change" [3]. Analogous to this is "humanitarian design", which upholds the universal and egalitarian rights and dignity of every human being through appropriate solutions. These include such approaches as "design for the bottom of the pyramid" [4], "design for the millennium development goals" [5], "design for the other 90%" [6], "design for the majority" [7], and "design for development" [8]. "Ethical design" is grounded in principles that are popularly accepted in society as morally right values. Another relevant but ambiguous principle is "democratic design", which suggests that good design should not be reserved for the affluent few but rather made accessible to everybody; it could also refer to participatory design in which stakeholders are actively involved in identifying problems and in co-creating the right answers to their needs. Universal or inclusive design represents another ethos, promoting non-discriminatory products that are inherently usable by as many people as possible, whether able-bodied or physically challenged. All these movements allude to an emerging stream of "design activism" among people who passionately want to "use the power of design for the greater good of humankind and nature" [9].

Socially sustainable product innovations, as used in this paper, includes all product-based solutions that empower individuals and groups to advocate, facilitate, catalyze, and realize positive change in the present and future of their community and that enrich their quality of life and wellbeing without sacrificing environmental or economic sustainability. They are long-term practical solutions that foster societal cohesion, promote the public good, repair the "social fabric", and build the trustful "social capital" needed by neighborly networks in shaping their communal destinies. They endorse social justice and tackle social ills in global society. They save and promote human lives, and equip people with the capabilities to develop themselves and to look after their own livelihood. They accelerate the adoption of sustainable everyday behaviors or lifestyles and facilitate the efficient delivery of socially beneficial services to the community. They allow design to penetrate to disadvantaged groups in human society.

Socially sustainable product innovation differs from "social innovation". With regards to their approach of using creative and design-led thinking to meet varied social needs and to enhance civil society, they are similar; however, the results of most "social innovations" [10] are intangible collaborative service blueprints, capacity-building strategies and social value creation activities rather than tangible product designs for supporting sustainable social systems. Many social innovations tend to be outcomes of rethinking of services to be more responsive, pleasurable, experience-enriching, and behavior-changing. Bottom-up initiatives of "creative communities" [11] demonstrate that social innovation can indeed occur without any material product development. Socially sustainable product innovation, on the other hand, highlights the contribution that traditional product-oriented designers can make in boosting the impacts of design to the benefit of global society.

This study focuses on product designs that can potentially trigger, support and orient sustainable social innovations. While it is accepted that less product centricity is highly likely to reduce environmental loads significantly [12], this paper argues that industrial designers are well placed through their training in object-oriented product development to contribute to the enhancement of less resource exhaustive solutions that work well in the communities they are intended to benefit. They have successfully demonstrated their capability in designing product components that facilitate the efficient and effective delivery of user benefits through product-service systems [13], as well as enrich the experiences of participants in these systems.

2 METHODOLOGY

This paper investigates the accommodation of social sustainability within international industrial design awards. Design awards and competitions are viewed here as public venues where practitioners display their abilities in offering meritorious solutions to a range of design issues, and where organizers demand the most notable outcomes in the industry through the evaluation criteria that they establish.

The research was firstly narrowed down to the popular awards (Table 1) which most designers aim to be recognized in. The archives of these awards were consulted, and a content analysis was conducted against the definitions and conditions for socially sustainable product innovation set out in the preceding section; this method follows another research done by the author on Australian design awards [14]. After tabulating the number of awards given out yearly, it became evident that the study will entail analysis of an exceedingly huge number of winning designs, even when student entries and conceptual proposals have been excluded (Table 2).

Table 1. Mainstream industrial design awards in the study.

Award	Accolades	First award	Web site	Operator
Good Design | Product Design, USA	Good Design	1950	www.chi-athenaeum.org	Chicago Athenaeum Museum of Architecture and Design
iF | Product Design Award, Germany	iF Award	1953	www.ifdesign.de	International Forum Design GmbH
Red Dot Award | Product Design, Germany	Red Dot, Honorable Mention	1955	www.en.red-dot.org	Design Zentrum Nordrhein Westfalen
G-Mark: Good Design Mark, Japan	Good Design Award	1957	www.g-mark.org	Japan Industrial Design Promotion Organization
AIDA: Australian International Design Awards	Design Award, Good Design	1958	www.designawards.com.au	Good Design Australia
IDEA: International Design Excellence Awards , USA	Gold, Silver, Bronze	1980	www.idsa.org	Industrial Designers Society of America

Table 2. Accolades awarded, excluding students and concepts.

Award	2007	2008	2009	2010
AIDA	42	61	73	111
G-Mark	1043	1067	1034	1110
Good D	400+	433	587	494
IDEA	49	157	118	152
iF-pd	742	811	785	756
RedDot-pd	666	863	926	1073

Due to time constraints, the study was further limited to the last four years of three mainstream awards: the Australian International Design Awards (AIDA), the International Design Excellence Awards (IDEA) based in the USA, and the International Forum Product Design Award (iF-pd) based in Germany. The G-Mark of Japan and the Red Dot Award of Germany had the most number of awardees; the analyses of these will be incorporated in a future publication. The Chicago Athenaeum Good Design Awards, while being the world's first accolade for industrial design, was excluded because the archives do not provide any explanatory text to describe the winning products. The other five awards provide rather detailed descriptive information about the winners, allowing deeper understanding of the design; IDEA, G-Mark and Red Dot even supply the jurors' rationales for awarding the most outstanding products.

3 RESULTS

Graphing the results of the analysis of the three award schemes in the study (Figure 1), it can be seen that the socially sustainable product innovations can be categorized into the following product groupings:

3.1 Designs for saving lives and fostering good health

Consistently outnumbering all other winning designs in the three schemes are products which are categorized as "medical", "scientific" and "health care". Clearly these products are directly involved in saving lives and promoting good health, safety and wellbeing that would enable people to participate and contribute to society. Most of these were items for in-hospital patient care, and many were also for home use. These include

- In-hospital bedside care: universal trolley stretchers, vital signs monitors, intravenous containers, electric beds, neonatal incubators, infusion workstations, respiratory ventilators, bedpans, catheter handsets.
- Emergency rooms: knee bandages and braces, ultrasonic nebulizers, asthmatic inhalators, pressure garments, hypothermia cooling kits, obstetric forceps, orthopedic braces, spinal immobilization backboards, cold compression therapy.
- Clinical diagnostics: portable ultrasound tools, breast volume scanners, ECG, MRI, lung function screeners, melanoma detectors, sleep study, prostate exam chairs; analyzers for blood chemistry, cancer and infections in tissue samples, cell metabolism.
- Surgery: operating tables, instruments for surgery and laparoscopy, workstations for organ recovery and transplantation, touch-free faucets, surgical lights.
- Domestic use: forehead thermometers, blood pressure monitors, blood glucose testers, breast pumps, asthma puffers, infrared heaters, sleep apnea masks, hearing aids, eating aids, wheelchairs, prefilled syringes, body fat scales, walking frames, HGH injectors.

The majority of these award winning medical products are not necessarily groundbreaking; indeed they are mostly incremental innovations in a mature market. Interestingly, some of the rather radical innovations come from Philips:

- Philips Lifeline PERS (personal emergency response service), a cordless phone system with a wearable medical alert button and back-to-base station for immediate assistance and emergency coordination, to enable frail elderlies to maintain their independence and continue living at home.

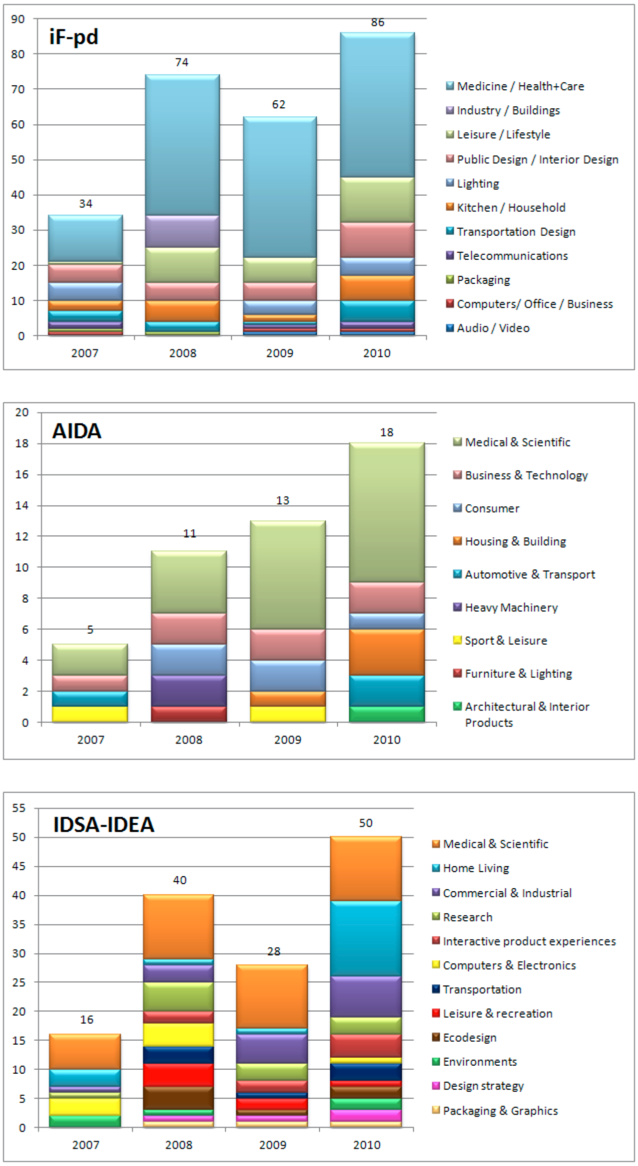

Figure 1. Breakdown of socially sustainable product innovation by categories in design awards.

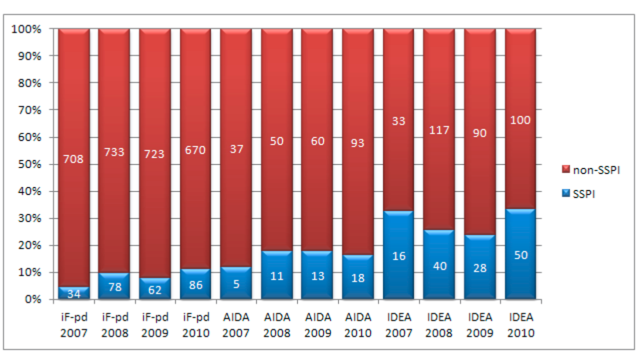

Figure 2. Proportion of socially sustainable product innovations.

- Philips' interactive toy CAT (computerized axial tomography) scanner, also known as "kitten scanner", designed to help lessen children's anxiety about the scanning procedure by using role play and storytelling to learn what to expect.
- Philips Breath Counter, a solar-powered respiration-monitoring device to enable health-care workers in developing countries to detect pneumonia and accurately and reliably identify and classify cases of the disease in just 60 seconds.

Relevant to this category also are products used to save lives and improve human living conditions during disasters and emergencies. These include rapidly deployable shelters (RDS), rapid deployment flood walls (RDFW), firefighting devices, fire sprinklers, vehicle crash extrication tools, and winches.

3.2 Designs for low-impact recreation and lifestyles

Products that enable participation in behavior-changing recreational activities constitute the second largest number of socially sustainable product innovations, although only 1/3 the number of medical and scientific products.

- Products which enable and enhance participation in sustainable mobility and commuting. These include folding bicycles, city bikes, road bikes, electric bikes, as well as cycling accessories such as safety lights, handlebar grips, tire levers, helmets, pannier bags, water flasks, security locks, and parking stands.
- Products which afford safe and pleasurable participation in healthy outdoor activities. These include life jackets, rechargeable flashlights, backpacks, amphibious lanterns, head lamps, snow shovels, educational tennis gloves, portable solar panels, hedge shears, watering cans.
- Products which promote sustainable procurement. These include personal shopping trolleys, handy grip for plastic bags, reusable shopping bags.

Again most of these were incremental innovations. Some of the far-reaching innovations here include:

- Kiddie's Paradise Wavy Tactile Path, an educational sensory and tactile toy inspired by trails in a rice field, helping children to improve their coordination, balance and ability to adapt to different environments.
- Yakkay bicycle helmet with hat covers, where safety and style are united and equally valued, encouraging the design conscious to consider commuting by bike.
- Stelton Shopper, a reusable nylon shopping bag with designer graphic prints; while not in use, it folds and hides away into its own plastic handle.

3.3 Designs for pleasurable public and work spaces

The third largest group is comprised by products categorized in the various awards as "public design", "environments", "architectural and "interior products", "commercial and industrial products".

- Products which promote enjoyment of public outdoor spaces. These include modular street and park furniture systems, information kiosks, litter bins, self-cleaning city toilets, smokers lobby, recycling kiosks.
- Products which enhance sustainable transportation. These include modular public transport shelters, smartcard load rechargers, ticket validators, e-ticketing terminals, and electric car fast charging points.
- Products which enhance safe working environments and conditions. These include construction safety harnesses, vibration control gloves, Optalert™ eyewear for managing driver fatigue and drowsiness.

More revolutionary innovations in this category include:

- Wall AG Dog Service Station encourages dog owners to clean up after their dogs; system includes waste bag dispenser and pedal-operated odorless disposal unit.
- NYC Condom Dispenser, an initiative of the New York City Department of Health which offers free condoms in public places as an effective measure against HIV infections and unwanted pregnancies.
- Better Place Charge Spot provides fast-charging power outlets for electric vehicles in public places.
- Mobility Vision Integration Process, deck of creativity cards and online brainstorming tool to investigate how expert designers can support and accelerate dialogue about the future of sustainable mobility.

3.4 Designs for healthy everyday living

This group incorporates those in the "consumer products", "household", "residential", "home living", "kitchen" and "personal" categories in the three awards.

- Products which provide a healthy and safe living environment. These include: allergy-free vacuum cleaners, air ionizers, water purifiers, child safety gates, modular planters and hydroponics for apartment kitchen gardening.
- Products which prevent wasteful consumption. These include battery chargers, water saving shower heads, trash compactors, non-electric ice pop maker, reusable shipping containers, air multiplier fans, and kitchen sink water reuse bucket.
- Products which follow universal design principles. These include the One Touch™ can opener, easy-to-use corkscrews, kitchen aids, padlocks, scissors.

The more disruptive innovations in this category are

- Makedo, a reusable connector system that enables construction and creation with found materials.
- Stacket, a space-efficient square bucket for places where storing rationed water is the norm.
- Easy Latrine, an affordable household sanitation solution for developing countries. This simple design was awarded the IDEA Best in Show in 2010.
- Philips Chulha, a low-smoke biomass stove designed for households in rural India. Reducing indoor air pollution that causes fatal respiratory diseases, this project is a demonstration of Philips' "Philanthropy by Design" approach.
- IDEO Human-Centered Design Toolkit, a free innovation guide that empowers NGOs and social enterprises in the developing world to address needs of those living on less than $2 a day.

3.5 Other socially sustainable innovations

The other product categories showed only a few good examples of social sustainability. Computer and office equipment could be represented by the Motion C5 mobile clinical assistant, the Perkins mechanical Braille typewriter and the One Laptop per Child (OLPC), a revolutionary $100 laptop to bring learning, information and communication to children in developing countries.

In the Packaging and Graphics category the best examples were "Design for Democracy: Ballot + Election Design", a book which set the national guidelines for designing clearer ballots and polling place signage; and "Out of the Box", a design study to investigate and find solutions to the increasing divide between older Europeans and digital mobile communications.

4 DISCUSSION & CONCLUSIONS

It should be noted that sometimes the winning designs are not placed in the most suitable product category, and there are probably too many product groupings; it would be desirable in future studies to reconsider combining some categories and re-categorizing some products.

While it may appear that the iF product design award has more socially sustainable product innovations than the other schemes, Figure 2 shows that, relative to the number of awards given out, the socially sustainable fraction of iF-pd is in fact the smallest among the three. The four-year average on the proportion of socially sustainable designs for iF-pd is only 8.4%; in comparison AIDA has 16% while IDEA has a 29% mean.

It was also found that most of these awards recognize sustainable design through a special award or by running a parallel awards scheme. However, they all focus on ecological aspects and do not really promote social sustainability (Table 3).

Table 3. Sustainable design accolades within mainstream awards.

Award	Design for Sustainability accolade
AIDA	Design Award | Sustainability for the single most environmentally conscious design of the year. Started in 2007.
G-Mark	Long Life Design Award for products which have a history of at least 10 years of production and distribution. Sustainable Design Award for products which contribute to lasting values in the future. Multiple winners every year. Started in 2008.
Good Design	Green Good Design Awards, separate scheme. Started in 2009. €300 entry fee. 34 recipients in 2009, 64 in 2011.
IDEA	Designs of the Decade, separate scheme. Subcategories: solutions to a developed world social problem, developing world social problem, most responsible design solution, best

	sustainable design solution, and others. Ran in 2000, 2010.
	IDEA Ecodesign Category. Ran from 2006 to 2010.
iF-pd	iF Ecology Design Award. Ran from 1997 to 2001.

This study also found that the financial cost to participate in these design awards can be very high. The lowest charge was US$ 390, for entry into the Good Design Award (see Table 4). The Best of the Best winners in the Red Dot shell out at least US$ 6808, which includes use of the label, a double page on the yearbook and design diary, and a one-year exhibition in the Red Dot museum for small objects such as mobile phones; large appliances, vehicles and furniture systems pay up to US$ 10,140.

Table 4. Participation costs in design awards.

Award	Charge	Cost US$
AIDA	Entry (yearbook & exhibition free)	$1089
G-Mark	1st screening	$130
	2nd screening	$649
	Yearbook	$390
	Exhibition	$260
Good D	Entry	$350
IDEA	Entry (yearbook & exhibition free)	$100 ~ $350
iF-pd	Registration	$488 ~ $646
	Winner	$3734
Red Dot	Registration	$287 ~ $345
	Excess size	$72 ~ $216
	Winner & honorable mention	$3232~$6104
	Best of the best	$6808~$10140

Some of the mainstream design awards have categories which invite concepts, explorations or projects still at proposal stage. Some of these conceptual winners show promise in addressing social sustainability issues, but because this paper is only interested in realized solutions, these unrealized entries were excluded from the analysis.

Relevant to this study, competitions specifically celebrating socially responsible design were also found. The INDEX: Award "Design to Improve Life" in Denmark is the most prestigious, rewarding its five winners with €100,000 each. The Saatchi & Saatchi Award for World Changing Ideas gives $50,000 cash plus $50,000 marketing consultancy to one winner. Other schemes include the ICSID World Design Impact Prize, the Victor J Papanek Social Design Award "Design for the Real World Redux", the Spark Design & Architecture Awards, and the Core 77 Design Awards which has a "Design for Social Impact" category. Some of these require that the entries must have been realized in production while some are open to conceptual proposals.

Product design accolades do their job well in highlighting the excellent work of industrial designers and the manufacturers they work with. However, given the urgency of climate change and environmental disasters that are attributed to the impacts of not-so-responsible designs, it is sensible to rethink whether designers and manufacturers should continue pursuing the market-oriented approach of offering consumers endless streams of award-winning material "stuff" to own.

As the analyses show, designers and manufacturers are indeed capable of designing excellent solutions that are socially sustainable. While the proportion of such innovations is still low in comparison to the rest of the awards, it is promising to see growth in this area. BusinessWeek noted that in 2008 a "strong sense of social responsibility ran through most of the winning entries" [15], and that this trend was repeated in 2009 [16].

That mainstream design accolade schemes are so costly to enter might be one reason why we see relatively few socially sustainable product innovations entering and winning. Indeed the financial investment in participating could be better spent on supporting the product to reach more intended beneficiaries in society. Social designs do not necessarily gain the commercial advantage that traditional industrial design objects get from winning these mainstream awards. It is more practical for them to gain recognition through the special design competitions on social impact, which are either free or low-cost to enter and also could offer huge monetary prizes for winners. The other reason, of course, for lack of social design presence in the awards is that the humanitarian innovations are not seen to have enough visual appeal to be worthy of such design awards.

The successful examples of socially sustainable product innovations in this paper prove the stimulating and empowering agency that industrial design has in helping usher a world that is more equitable and beneficial for more people. As evidenced by the charts, more designers and manufacturers are increasingly embarking on endeavors that advance the betterment of humanity; this is commendable, and we hope to see this trend continue in the future. Sustainability is a relatively new ballgame for designers [14], and the attempts of the design industry worldwide to engage in this challenge should be supported and encouraged, particularly in strengthening its capacity to contribute towards a truly sustainable future.

The Teaching-Research Nexus in the Rise of Sustainability Science: Scope and Approach

Harald E. Otto
Department of Mechanical Engineering, Università Politecnica della Marche, Ancona, Italy

Abstract
Fundamental changes in the way research is approached and conducted, together with continuous changes in economics as it moves towards a weightless economy where knowledge and technological innovation replace mass production, together with developments and efforts worldwide aiming towards sustainability, are challenging institutions of higher education to rethink their missions and to re-structure their research and education programs. Post-modern societies now seem about to introduce mass education, due to the new orientation of the economy towards knowledge and innovation. This is a situation unprecedented in the entire history of higher education, and it offers both tremendous opportunities and considerable drawbacks if mishandled. In this first part of a two part paper, several important issues are examined in relation to the approach to and scope of research and teaching from the viewpoint of synergy between them on an interdisciplinary and multidisciplinary basis.

Keywords:
sustainability science, green engineering, teaching-research synergy, higher education

1 INTRODUCTION

The rise of post-modernism and the provision of higher education to the masses have gradually changed the ways and places in which knowledge is produced in contemporary society. This is also reflected in a wide range of scientific and scholarly activity, as well as in the next generation and application of technology. In [1], this change is described as a transition from *Mode 1 science* to *Mode 2 science*. Mode 1 science describes scientific and scholarly activity which is disciplinarily homogeneous, and organized in a hierarchical form featuring a strong tendency to preserve this structure. Problems targeted and solved are usually within the realm of interest of a specific scientific community. In contrast, Mode 2 science features a problem-solving methodology that is much broader and is placed in a transdisciplinary social and economic context. Here knowledge is acquired in a more exploratory way in the context of application, providing a strong problem-driven and practice-oriented approach. Various actors and stakeholders from different disciplines and fields of expertise provide a participative mode of knowledge production within a heterogeneous network that is extended to various locations beyond the limits of familiar traditional institutions of higher education and research (see also [2]). This Mode 2 science is similar in nature to what has been identified as *science for the post-normal age* in [3]. Along with intensifying concerns for sustainability among the general public, in science, and in various societal, political and economic sectors, and the rise of what is known either as Mode 2 science or as post-normal science, a new research program has begun to emerge, currently referred to as *sustainability science.* Sustainability science focuses on the dynamic interactions between nature and society, employing a new methodology for knowledge production, which is demand driven, with consideration given to uncertainties, and is subjective and exploratory in nature, thus featuring a more heuristic approach to acquiring insight into and providing solutions for complex problems of sustainability.

A lot of pedagogic research in higher education concerned with the nature and evidence of synergetic relationships between research and teaching still tends to take place at a generic level, considering traditional approaches, methods, and (infra)structures, as related to domain specific research and education, without adequately taking into account current developments in how, where and by whom knowledge advancement is carried out employing which methods and tools according to which paradigms. The purpose of this paper is not to provide yet further evidence of a teaching-research nexus in current education models but to point out and bring to the attention of a wider academic community potential and opportunities that could foster synergy between research and teaching if concepts and models of curriculum design are adapted to current modes of knowledge advancement, and the demands of educating future generations of graduate students are drawn from the requirements of current efforts in problem-solving and professional practice within the context of sustainability science.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_43,

The paper is structured as follows. In section 2 some background is given along with a discussion on related work. In section 3 the context of sustainability science is briefly outlined from the viewpoint of development regarding its principles, recognition in academia and practice, and body of community, research, and education. In section 4 basic ideas and concepts of the approach are presented and discussed, and this is followed by a summary given in the last section. Additional issues related to higher education in the context of sustainability science, regarding infrastructure and method of conduct, will be examined in the second part of this paper (in [4]).

2 BACKGROUND AND RELATED WORK

2.1 Education as an activity

From an activity-based viewpoint, education is regarded as the process by which society transmits a part of its accumulated values, knowledge and skills from one generation to another. The term *education* is derived etymologically from the Latin word *educare*, which means *to bring up*. The modern system of education is subdivided into primary, secondary and tertiary education. Within the given context of this paper the focus will be on the last, which is also referred to as higher education. The process of education consists of three sub-processes, usually identified as teaching (the activity and efforts of teachers to impart learning to the students), learning (the process by which knowledge and skills are obtained by those who study or are taught), and instruction (the facilitating of learning by a teacher). Currently, the most commonly identified learning styles or learning modalities are auditory learning based on listening to instruction, visual learning based on observation, and kinesthetic learning based on engaging in activities and hands-on work (cf. [5]). Within pedagogic research regarding the research-teaching nexus in higher education, the instructional relevance of learning styles is not so much a concern, due to new teaching strategies related to new paradigms of research and teaching. These put the teacher more into the role of an inquiry and discussion facilitator and guiding coach for individual knowledge discovery. The students become more engaged in active learning, and thus play an active part in the development of their own knowledge and patterns of understanding.

2.2 Concepts of the teaching-research nexus

Within work on defining concepts that allow for the investigation and linking of the research-teaching nexus to knowledge production and curriculum design, a three-dimensional model space for curriculum design has been constructed by Healey [6] partly based on the work by Griffith [7]. The basic three model directions (dimensions) are linked to emphasis (on research content vs. research processes and problems), focus (on teacher vs. student), and treatment of students (as audience vs. participants). This model can be used for the classification of the different curriculum designs currently either considered or employed in most colleges and universities, as briefly outlined in the following.

A *research-led* curriculum design follows a teacher-focused model that is based on traditional knowledge transmission with students as a more passive audience featuring an emphasis on research content rather than methods and research processes. The *research-oriented* curriculum represents another teacher-focused model with students as audience, though with an emphasis on research methods and processes, thus facilitating learning and understanding of both knowledge and the methods and techniques that produce and advance knowledge. In this context, teaching also considers skills relating to scientific inquiry and research experience per se. *Research-tutored* curricula feature a strong emphasis on both research content and active student participation in the learning process through tutorials, i.e. small group classes where subject matter related to student essays and papers is discussed collaboratively. Note that this particular curriculum design is peculiar to the Oxbridge tutorial system (cf. [8]). A *research-based* curriculum design is largely oriented on inquiry-based learning with a focus on students, who, in the ideal case, literally act as participating junior researchers, thus minimizing or even eliminating the classical division of roles between teacher and student. In this model, the research skills and experience of teachers can best be integrated into the processes of teaching and learning with a high potential for benefit for both teacher and students. And finally, from the viewpoint of the scholarship of teaching (cf. [9]), if teachers are actively involved in researching not only their own domain, but also pedagogical issues relating to inquiry into teaching methods and the learning process itself, their curricula are identified in [7] as *research-informed*. Within this curriculum model, ideally the design and contents of each curriculum will be regularly updated as new results of either a pedagogical or a domain specific nature become available.

Two different models are proposed in [10]. One describes the current practice in many institutions of higher education, while the other is considered a much better alternative, and is aimed at fostering synergy between teaching and research. The latter, though only gradually beginning to take shape in tertiary education, is based on the concept of research and the teaching process from the viewpoint of academics. Within the former model, teaching is regarded a mere transmission of mostly propositional knowledge, which in turn is generated and advanced using resources that actually in part compete with their counterparts in teaching, and thus rather decrease the chances of any synergy. Within the latter model, teaching is a student-focused process aimed at the development of sophisticated levels of intellect and skills within students who are destined to become members of academic communities of practice where knowledge is advanced in a socio-political context.

Yet another alternative model used to build a framework for analyzing the teaching-research nexus is described in [11]. This model employs a three-level nexus consisting of the *tangible*, the *intangible*, and the *global nexus* relating to knowledge acquisition through research. It examines the attitudes of students towards knowledge while also considering the academic milieu, and departmental influences on undergraduate education through research agenda and policies. Additional views and experiences relating to issues within teaching and research in the context of higher education for the 21st century can be found, for example, in [12,13].

3 SUSTAINABILITY SCIENCE ON THE RISE

3.1 Early developments

Over the past two decades, the concept of sustainability has become increasingly important both locally and globally, and has influenced the decision making and activities of all communities and of humanity as a whole as it works towards a future which offers increased harmony between human activities and the systems of the biosphere. It was during the early 1980s that the term *sustainable development* first came into use. It gradually began to replace earlier concepts within what had been known in the 1970s as the philosophy of *ecodevelopment*. The latter had featured a heavy focus on scientific principles rather than practical and political applicability, and thus had limited its potential to gain a more widespread acceptance. An important milestone for the role of sustainable development came in 1987, when the term was adopted in the UN-initiated Brundtland Report entitled *Our Common Future*. This crucial step prompted the elevation of sustainable development into a guiding principle during the United Nations Conference on Environment and Development (UNCED) held in Rio de Janeiro, when 180 nations signed a protocol named *Agenda 21* that encompasses it. A little more than a decade ago, the emergence of a new type of science and engineering then begun to be discussed explicitly, both in national academies and at international conferences (cf. [14,15]).

3.2 Efforts at establishment

About a decade ago, recommendations and policies such as those of the National Research Council of the United States of America and the International Council for Scientific Unions [16,17] began to address central issues related to sustainability science, such as the complex and dynamic interactions between nature and society that are reflected in the problems addressed by research and development priorities. International efforts to establish and advance sustainability science and engineering in different forms and places display in many cases a rather ad hoc approach resulting in different directions and approaches. For example, in Asia, most prominently in Japan, a technology-based approach is prevalent, with more human aspects being integrated into the approach only recently. In the United States of America, by contrast, interdisciplinary research on complex human-environment systems is favored. On the other hand, approaches in Europe are more transdisciplinary and implementation oriented, with a strong tendency to move towards participatory and iterative processes. Along with those efforts, small communities have developed which are actively pursuing sustainability science and engineering, though these are often oriented towards specific topics relating to the environment, economy or technology. To overcome the barriers of isolation often faced by those communities, sustainability science networks began to develop, in the form of alliances, science partnerships and forums such as the *Network for Transdisciplinary Research*, the *Resilience Alliance*, and the *Science and Innovation for Sustainability Development Forum*. Along with the formation of these networks and organizations, in academia there came the foundation of international journals such as *Sustainable Development*, *Sustainability Science*, and *Current Opinion in Environmental Sustainability*, while efforts in integrative scholarship produced the first books in this new field (for more details and references see the latest discussions, for example in [18,19]).

In higher education, issues of sustainability were initially introduced through aspects of green engineering, a discipline that actually spans all of the traditional engineering specialties, combining natural science, engineering practice, and technology, with environmentally conscious values and principles. However, green engineering does not usually include societal issues and the opinions of all stakeholders involved within its basic concepts and approaches. Later, these efforts were extended according to the nine principles of sustainability engineering, which unfortunately were overdue and were developed only belatedly at the Sandestin conference in 2003 (cf. [20]). Recently, new undergraduate and graduate curricula in many industrial nations all over the world have been dedicated directly to the concepts and principles of sustainability science and engineering. Some universities have even established whole departments or even institutes dedicated to sustainability. These developments have been motivated and reinforced by many national professional engineering accreditation bodies, which demand from engineering programs at institutions of higher education the production of new student generations with an understanding of the basic skills and know-how related to concepts of sustainability as well as sustainable technology and development. For a more detailed overview with concrete examples and further literature references, the interested reader is referred to [21,22,23].

4 DEVELOPMENTS AND NEW DEMANDS

Early efforts to include green engineering, and later sustainability science and engineering, in the traditional education of science and engineering at institutions of higher education were mostly carried out without the benefit of any systematic guidance such as concrete principles that could be used to design appropriate curriculum models, letting alone having models to analyze and assess their efficiency or even to identify any synergy between research and teaching in higher education. Definitions of green engineering and sustainability science do not actually provide any substantial support in this matter. Another problem is that curriculum design is still not taking full advantage of many results in pedagogic research on higher education. The integration of all types of scholarship, as presented in [9], is still far from becoming reality in academia. And to make matters worse, recently introduced research assessment systems, such as the research assessment exercise (RAE) in the United Kingdom, actually increase the difficulties in adapting and improving curriculum design to meet current demands and the essential requirement of higher education for a broader mass in a society where knowledge is growing rapidly and changing constantly. This is due to the inappropriate way of measuring research with a focus on a particular type of knowledge generation. In addition, one should not neglect the fact that, along with all these trends, the student profile has also changed. Today's new generations of students are more industrious and expect their higher education, which tends to become ever more expensive, to facilitate the acquisition of skills and know-how that will enable them after graduation to get the job done in practice at work.

4.1 Efforts in curriculum design

With the introduction and development of sustainability science and engineering, and new modes and approaches regarding research and knowledge advancement, major shifts related to focus, context, content and processes are undeniable. The focus has shifted from pursuing curiosity in phenomena of the physical world to solving problems in the real-life world. Along with this shift in focus, the context of research has shifted from disciplinary to multidisciplinary. These shifts in turn induce shifts in the content of research and its related processes. Within such a scenario, a re-conceptualization of education is indispensable for the future analysis and advancement of synergy between research and teaching in higher education. In particular, an adjustment of current curriculum models is necessary for analyzing the research-teaching nexus that has been developed within the focus and context of disciplinary research and education.

Now, as a first step towards determining the direction and nature of such an adjustment, it seems to be an elegant, promising and straightforward approach to take a closer look at the individual concepts and components used to define and classify the curriculum designs discussed earlier. In this way, we may be able to locate and analyze a possible synergy between research and teaching and relate it to an extension of the horizontal curriculum model defining main domains, namely research content and research processes, as discussed in the scenario above. In particular, within the former, disciplinary depth needs to be regarded as intertwined with the principles of sustainability science and engineering, and we must also take into consideration the knowledge, principles and methods of different disciplines that come along with multidisciplinary breadth. The structure of the latter is extended according to the overall nature of processes and problems within sustainability science and engineering, namely interdisciplinarity and transdisciplinarity. This requires us to include the acquisition of skills and know-how related to interdisciplinary integration and the development of transdisciplinary competencies.

Within such extended model dimensions and context, curriculum designs that emphasize research content, such as the research-led curriculum design, need to consider, besides their disciplinary subjects, additional subjects related to the principles of sustainability science and engineering such as life cycle assessment and systems approaches. Of course, modifications in disciplinary depth, multidisciplinary breath, and the resulting total content volume need to be carefully tuned regarding time constraints relating to the overall length of current undergraduate and graduate education. Curriculum designs that emphasize research processes and problem solving require even more complex rethinking and restructuring. For example, research-oriented curriculum design needs to take into account the same considerations as research-led curriculum design. However, additional skills related to interdisciplinary approaches and integration also need to be considered. These include being able to locate and work with pertinent information, identify and compare different approaches and methods, and develop a holistic understanding of a complex problem within an integrative framework. For research-oriented curriculum designs where processes of inquiry and problem solving are highly integrated into the student learning activity, additional skills, know-how, and competencies are required, relating to both interdisciplinary and transdisciplinary research and education. Since the nature of problems usually designates the methods and tools employed to solve them, this approach stands quite in contrast to curiosity-driven and traditional discipline-based inquiry [24]. In particular, as identified and pointed out in [25,26,27], various skills need to be taken into account. These include the ability to analyze complex problems from real life, hermeneutical abilities to interpret correctly not only readings on scientific instruments but also the meanings of identical terms used differently in individual disciplines, knowing how to participate in projects with interdisciplinary and/or transdisciplinary structures, knowing how to connect to various internal and external stakeholders, and knowing how to communicate across academic disciplines. These skills can be seen as an extension of student skills relating to working together in teams, communications, and presentations, commonly regarded as generic graduate skills [28] within a traditional disciplinary context.

4.2 Open issues related to curriculum design

In the following, some additional issues related to the discussion in the previous sub-section, and considered important, are examined briefly. To foster a critical attitude towards knowledge as part of the scientific disposition in students (cf. intangible nexus in [11]), courses on philosophical aspects of the discipline should be included along with domain-specific lectures. However, in the case of sustainability science, this approach is of limited use since a philosophy of sustainability has not been established yet. The only choice is to consider suitable topics within the philosophy of science and the philosophy of technology as interim substitutes. Another quite important issue, though still widely neglected, is the loss of valuable insight, experience and know-how gained during sustainability research. During the problem-solving process in a research project, a multidisciplinary team usually works together on an interdisciplinary / transdisciplinary basis. However, after project completion, each project member leaves and moves on to a new task in a different project. Within this context, for example by employing a research-based or at least a research-oriented curriculum, valuable synergy between research and teaching could be created by trying to pass on to students this valuable gained insight, experience and know-how, that is otherwise lost. At this point, to minimize the loss, it is recommended that we should at least implement measures and support for documenting the essentials of such insight and experience in the form of textbooks that can be used in courses to support the building of capacities and competencies in future generations of students. Related to this issue, in sustainability science and engineering in general, the scholarship of integration (cf. [9]), which includes the writing of textbooks, still lags far behind other disciplines. There are few good textbooks currently available. Moreover, advances in knowledge and innovations made during the course of problem solving within a research project need to be well integrated into both the disciplinary context to which they belong and the larger pattern of science, technology and society.

5 SUMMARY

After briefly outlining the nature and goals of sustainability science while taking a whirlwind tour through its short history of development, the author hopes to have made it clear that, among several dominant themes, two central issues gave rise to related research concepts and approaches, such as interdisciplinarity and transdisciplinarity. These two central issues are the linking and dialogue between knowledge and content on the one hand and process and activity on the other, along with mutual learning by all stakeholders, while considering new demands regarding the tertiary education, skill acquisition, and competency building of science and engineering students. The resulting interdisciplinarity and transdisciplinarity have been applied in sustainability research to the concepts and models of traditional domain-based curriculum design, and developed in order to identify and analyze relationships and synergies between research and teaching in higher education. The given approach will hopefully stimulate those involved in education and proliferate in further research in this direction on a multidisciplinary level. We need to employ the most suitable conceptual and theoretical components, skills and know-how from within sustainability science and pedagogic research in higher education to provide a constructive impetus to nurture the next generation of scholars, experts and practitioners to advance, as well translate into practice, sustainability research and teaching.

The Teaching-Research Nexus in the Rise of Sustainability Science: Infrastructure and Way of Conduct

Harald E. Otto
Department of Mechanical Engineering, Università Politecnica della Marche, Ancona, Italy

Abstract
Economic trends and the nature of current economic and educational policies in most advanced industrial nations, and in the transnational organizations which they support, are signaling a transition from a mass production economy to a knowledge economy and towards sustainability. As a result, society worldwide is facing challenges and pressure to move towards increased knowledge generation and technological innovation as a means of economic activity, which will also support sustainable development. Within this scenario demands on higher education to provide appropriate education and lifelong learning pose a tremendous challenge that is further complicated by the obvious contradiction between the intellectual viewpoint and the economic viewpoint regarding the nature of a true knowledge society. In this second part of a two part paper, several issues are taken up from within this context by focusing on the synergy between post-modern research as a form of problem-solving oriented knowledge generation and the development of new forms of teaching aimed at fostering active learning with a student focus.

Keywords:
sustainability science, knowledge society, teaching-research synergy, higher education

1 INTRODUCTION

The latest stage of development in global economic restructuring is a move from post-industrial mass production to the emerging knowledge economy. This has brought a globally competitive need for innovation in new products and processes developed by the research community, whether it be a research and development department at a commercial enterprise or an institute in a university. The need to get human activities in balance with the biosphere is becoming as pressing as the need for producing a specialized labor force which is computer literate, sustainability literate and well trained in handling data uncertainty and complex information and relationships, as well as in developing digital models, respecting different opinions, and innovating on processes and systems in respect to sustainability.

Taking these developments one step further, it seems that at some stage in the post-modern society of an advanced industrial nation everybody will become some kind of sustainability-oriented knowledge worker. This means that in turn many organizations will need to become sustainability-oriented knowledge institutions, with knowledge itself then being not merely diffused by traditional knowledge-producing institutions such as universities, but rather suffused throughout the entire society. Since knowledge in itself is reduced in value if kept contained, only its wide distribution can provide for an increase in value. Within such a scenario many challenges arise regarding the role of traditional institutions accepted as authorities in the fields of both knowledge production and knowledge dissemination, as all institutions of higher education are assumed to be, and the role of the professional knowledge producer and knowledge forwarder and distributor. The nature of the latter is becoming fuzzier with the advent of new curriculum models and information technology-based educational support and management tools (see also discussions in [1,2,3,4]). At the same time, with a demand for new teaching strategies fostering a student-focused active learning mode with an emphasis on scientific inquiry, research processes and problem-solving (cf. [5,6]), the traditional well-defined boundaries between teaching and research are gradually diminishing.

Let us combine the central implications of this development with the developments in research, which are continually widening both the concept and the practice of research from the modern highly empiricism-influenced process of scientific inquiry to an interdisciplinary problem-solving process of generating knowledge in the form of solutions accountable to field specific, socio-economic and ecological domains, and taking into account uncertainty while also considering the interests of a variety of stakeholders. Then, more than ever before, we find that research and teaching now feature overlapping elements. This situation makes efforts to facilitate and foster the research-teaching nexus not only promising in many directions, but literally an appealing must. Unfortunately, as current practice shows, this potential is recognized by only a few, and in general not well understood. This is particularly evident if one takes a

DOI 10.1007/978-94-007-3010-6_44,

deeper look at the current policies of advanced industrial nations, and the transnational organizations which they support, regarding their approach to and conduct of higher education and their evaluation and rewarding of research and teaching within it.

This is the second part of a two part paper structured as follows. In section 2 some background is given along with related work on issues concerning the emergence of the knowledge economy and factors concomitant to the development of knowledge and sustainability in the societies of advanced industrial nations. In section 3 issues related to higher education are dealt with in the context of sustainability science, with particular emphasis on information and communication technology (ICT) as infrastructure and on how the research-teaching nexus is regarded from the viewpoint of emerging knowledge economies. Lastly, some conclusions are drawn in the last section.

2 POST-MODERN ECONOMY AND SOCIETY

The second and, more so, the third industrial revolution facilitated the rise of powerful economic societies based on an unprecedented, ever increasing consumption of all forms of energy. This was made possible by technological innovation, which eventually provided an energy form that is clean and can be made available efficiently and cheaply to consumers at any time and almost anywhere (cf. [7]). Now electricity, as one driving power of modern information technology, together with information per se, brought about newly emerging forms of society and of economies, all struggling worldwide to cope with the problems of their generation: storage, distribution and protection of energy and information.

The developments of the past three decades causing global economic and technological changes in advanced industrial economies have been conceptualized and described as the emergence of knowledge/information societies and their respective knowledge/knowledge-based economies [8,9,10]. Due to the difficulty of defining the term knowledge itself, the above terms are unfortunately still used interchangeably in the current literature. However, some basic distinctions can be made. For example, within a knowledge economy, knowledge itself becomes a property in the form of an economic good, whereas in a knowledge-based economy knowledge is merely treated as a tool. Moreover, since information is not identical to knowledge, perhaps the term information society should not be equated with the term knowledge society. The term *knowledge economy* was popularized in the late 1960s by Peter Drucker in reference to the application of knowledge to spur economic development (cf. [11], p. 263). This conforms with most contemporary views that knowledge is about to become the most important production factor in advanced industrial economies, replacing the traditional factors of land, labor and capital. According to some studies (for example, see [12]), it is assumed that in the foreseeable future knowledge-based industries and organizations might be in a position to provide over half of total employment while generating more than 50% of total gross domestic product (GDP). From a conceptual viewpoint this implies that, besides knowledge, also the higher education of knowledge workforces is becoming a kind of human capital that is seen as a new type of productive asset, which can be employed as or turned into an economic good seeking a high value return for the provision of services.

Within this scenario, as rightly argued in [9], information technology provides the technological basis for a knowledge economy. However, as the infrastructure technology that it has now become, it is also increasingly becoming the technological basis for research in almost any scientific and engineering discipline, thus being intertwined with the processes of knowledge generation and dissemination. It even transcends the role of a mere technological base when it is combined with vast amounts of information and know-how in order to facilitate new ways of knowledge generation that had never even been imagined not so long ago (cf. [13]).

3 UNFALTERING TRENDS AT CROSSROADS

Knowledge economies are on the rise and with them come the concomitant trends outlined earlier. Current public opinion holds that all individuals and societies have to adjust to this new global reality, and the concept and need for lifelong learning as one means to secure it are strongly promoted by most governments, professional associations, and transnational organizations. This in turn is leading to an ever increasing student population expanding in both heterogeneity and size, facing a still small and quite traditional and somewhat homogeneous faculty population. Such a situation has been unprecedented in higher education for centuries and is putting further demands and concerns on how higher education is approached and planned, which methods and tools should be used, and how research, teaching and learning should be conducted and related to each other. Besides age, social and educational background, and work experience, the most significant difference in the current student population is the way they approach technology, in particular ICT, a phenomenon referred to in the literature as the *digital divide*. The younger student generation born within the last two decades, sometimes referred to as the *Millennials*, has had the opportunity of growing up with the technology which is now found almost everywhere in our lives, a situation very different from that of older generations. These *Millennials* are said to be the student generation, which is composed of *digital natives* (see [14]). Being a digital native, however, does not automatically imply that a person has any knowledge of computational thinking or true computer literacy, or possesses any know-how regarding methods of data intensive knowledge generation. As several studies suggest, being a digital native, at least for the current generation of younger students, means that certain communication and interaction habits and patterns have developed, while related attitudes, methods, and means of operation have changed (see also discussions in [15,16,17]).

3.1 ICT as infrastructure

Besides physical structures, infrastructure includes organizational structures and the facilities required for the operation of a society or organization within a given context. Due to its ubiquity and dominance, in the following the main focus will be on information and communication technology. In this situation, the traditional approach of one size fits all regarding curriculum designs does not apply any more. If one is to facilitate and foster synergy between research and teaching, one of the challenges is now to analyze and relate the actual research, experience and competency of the faculty to the expectations, background and experience of the growing heterogeneous student population. At the same time, one must put the latter into perspective in relation to the requirements of higher education, as a means of forming responsible, well-educated citizens who in turn will reinvigorate, correct and improve this cycle for the good of future generations.

New generations of curriculum designs, aimed at enabling and benefiting from the research-teaching nexus, also need to be refined in regard to the potential of the paradigms, methods and technology used in current research, in particular ICT and data intensive knowledge generation, which increasingly influence research in most science and engineering disciplines. For example, one may consider a real small piece of contemporary research for a particular curriculum within a research-based curriculum model (cf. [18,19]) relating to sustainability science and engineering and aimed at including as many aspects and dimensions as possible, as discussed in part one of this paper [20]. Insofar as the domain knowledge, expertise and competencies of the faculty and research teams involved go, inquiry and problem-solving attempts from the real world must form a part of what faculty and research teams know and do. Otherwise this endeavor becomes reduced to a formal exercise with predetermined results which have already been produced many times by previous student generations. Due to the problem complexity, the high dynamics of changing parameters and states, the variety of stakeholders, fluctuating data, varying uncertainty in information, developments in technology, etc., the nature and demands of problem-solving within sustainability science and engineering can hardly be captured by a student-focused research-based teaching approach except when it is placed on an authentic base. Another very important issue that needs to be made explicit here is the fact that, when the nature and structure of a selected problem are determined, not only is part of the context of discourse selected, but also a tentative scope regarding the tools, data, domain knowledge, skills, etc. is defined. Again this can be done efficiently and competently only in regard to real research, experience, and the competency of the faculty. Perhaps in other forms of curriculum design such as the research-led model [18,19], where the emphasis is more on research content, with the student audience more or less passive, the research considered can be either the faculty's own research or research with which the faculty is very familiar but which was carried out by others and which is used in reference material, such as a well-documented case study.

Even if no concrete solution can be produced to a particular course assignment, because the problem was too complex and difficult, or because there was not enough time, or because the students' knowledge, skills and competencies were wrongly estimated, or for any other reason, still the journey to that point, i.e. the learning and evolving as both an individual and a group within the environment of a community of mutual learners and guiding scholars, will have been as important as, perhaps even more important than, reaching the destination, i.e. actually producing a genuine contribution to the advancement of knowledge. Of course, in this context, concepts such as progress, success and failure and their proper interpretation/evaluation need to be carefully reconsidered. For example, does failure refer to a situation where an individual or a group gave up somewhere in the middle of the journey, and thus did not reach the destination, or, in the worst case, does it mean that they did not even take the first step with which any journey, no matter how long, begins?

Within such a scenario, ICT infrastructure provides tremendous potential for support. For example, many aspects of real faculty research can be made available to students for active learning during a course at a level of presentation, completeness, integration and access mode unprecedented before. Results documented in reports or scholarly publications could be viewed simultaneously with their data, while either basic charts or sophisticated interactive data visualization displays could be chosen as the data representation mode. Such visualization displays even offer the means to facilitate hands-on experience, suitably monitored by the faculty, in partial interactive manipulation of data in order to trace and reproduce how certain theories have been verified and how new results and insights have been discovered based on those data. Access to data repositories or software tools that were used to obtain such data in the first place could also made available online in a limited form for educational purposes through, for example, a dedicated portal. Contact with the faculty and with classmates using ICT and its infrastructure also offers great potential for fostering additional curricular communication and greatly assisting in reducing the time required for feedback by removing many of the difficulties of traditional interpersonal interaction by defying the limits of time and space, thus making physical location and presence less relevant to communication. However, as it is with many technology-mediated activities, we must not have unrealistic expectations of the newly opened possibilities, nor should we abuse them. Today's ICT infrastructure can offer information access on an almost ubiquitous 24-7 base, supporting on-demand service and information for user-driven access, referred to in [21,22] as *demand pull*. These features have already become a matter of course in our emerging network societies, and particularly so for the digital native student generation. In the given context, this means that an ever-increasing amount of information is available in digital form at any time and in any place. Access to and retrieval of information is now less of a problem or concern, but evaluation of its value, quality and authenticity certainly is a problem. As a matter of fact, most of the knowledge most individuals possess is not personally verified. The most common way to accept newly acquired information as truth or particular type of knowledge is to have verified the source, or simply to trust the source due to its competency in this matter or its authority. This is exactly where institutions of higher education, faculties, and higher education per se come in. In our technology-mediated world of information deluge, information and knowledge generated from within and provided by them comes from a source where scholarship, experience in inquiry, research and teaching, and competency have been developed and refined uninterrupted for a long period of time. For centuries, institutions of higher education have been respected authorities in the advancement and dissemination of knowledge and they still are so.

An increasing number of online courses offered by many institutions of higher education worldwide already seem to exploit some of the abovementioned features, while relating to certain patterns in service expectancy and interaction habits of the current student population. However, more research is required regarding the design of those online courses in order to find ways to include the value of research and faculty experience on one hand and of student experience and learning progress on the other, so that we can facilitate and foster the generation of synergy, while improving the effectiveness and quality of distance learning per se. All this can be used and translated into practice within higher education for the benefit of all, both for current society and for future generations yet to come. However, certain rules regarding approach and method of conduct need to be taken into account. These relate to respect, responsibility, accountability, scholarship and the cultivation of active mutual learning within dedicated communities and will help to avoid issues such as those discussed in the following sub-section. If such rules are not taken seriously, they may actually destroy the possibilities and potential offered to us by the modern advances in technology.

3.2 Knowledge and the concept of property

Current practice in higher education tends increasingly to adopt the business view that education and knowledge are some sort of commodity with students as customers. This is especially so in newly established institutions of higher education, and the trend, which challenges the traditional concept of learning per se, actually has an inhibiting effect on the research-teaching nexus. If the notion of knowledge and ideas as property is taken seriously, one also has to face the matter of copyright law, the primary purpose of which is to protect an author's intellectual property and ideas. What is mostly overlooked is the fact that copyright law was originally enacted to balance the limited property rights of authors with the long-term rights of the public to promote learning through the spread of ideas. However, due to a continued movement of copyright law towards increased protection for an author's intellectual property without any additional benefit for the public, the original intention of promoting access and learning is gradually becoming lost. And along with this trend, unfortunately, the nature and understanding of what ideas and knowledge are, is also shifting, which negatively impacts the advancement of both learning and knowledge. Coming back to the context of the research-teaching nexus, for particular student-focused curricular designs such as the research-based curriculum, there is ideally and theoretically a high potential for benefit for both teacher and students. In these designs, the students literally act as participating junior researchers, thus minimizing or even eliminating the classical division of roles between teacher and student, while actively participating in a sort of guided and limited generation of new knowledge. The domain knowledge, research skills and experience of teachers can best be integrated into the processes of teaching and learning, facilitating not only the transfer of propositional knowledge but also ways of developing competencies, know-how and problem-solving skills that later partially translate into what is sometimes referred to as *tacit knowledge* [23].

However, various problems arise with the current view of knowledge and education as commodities. First, the student is becoming a co-producer, contributing to the generation of economic goods, thus reinventing the role of learner in higher education (cf. [24]). In this new context, the current copyright law, which actually protects every manuscript, note, presentation and e-mail, obviously limits any creative work and collaboration, thus greatly reducing or even preventing any synergy between research and teaching. Actual cases reported in [22] cite student inquiries about copyright ownership for work developed in collaboration with their supervisors and teachers. That, in turn, prompts faculty members to fear that they might lose control or even ownership of their intellectual property. Students are asking their professors to sign non-disclosure forms before submitting their class projects, due to concerns that some of the content of their work, ideas and knowledge now seen as their own property, might be stolen by their teachers for their own research, or patented afterwards without their consent. In other words, the generation of new knowledge is now seen as a form of economic production, and this is further evidence of a worrisome trend. However, there are some positive developments, such as the *Creative Commons* (see http://creativecommons.org), which aims at providing mechanisms to adjust the current copyright law towards a notion of "some rights reserved". This provides a means for sharing, i.e. allowing non-profit use of work by others, while reserving for-profit use to the author, thus creating a balance that ought to work for both views, the traditional academic view of free thought and knowledge advancement through inquiry, sharing and discussion of ideas and theories, and the emerging knowledge economy which sees knowledge as an economic good.

Another concept arriving with this view of knowledge commoditization is that of a *shelf life* for knowledge. For conventional economic commodities, the shelf life defines the length of time for which an item remains usable or fit for consumption or sale. Now in principle these measures can also be applied to a certain extent to knowledge, the newly emerging economic good. Taking a closer look at the current trend and at literature dedicated to this development, we find that the rise of network societies, along with ever faster developing ICT, clearly signals that higher education and its institutions are no longer in the traditionally exclusive position of providers and portals of declarative or propositional knowledge. That is to say that they are no longer simply able to disseminate information generated within their own walls or accumulated and advanced or forwarded by others. This they have been accustomed to do through scholarly publications or by employing the models of teacher-focused curricula with students mostly acting as a passive audience. This change is due to several factors, with rapidly developing technology certainly being one of the most influential, further increasing the speed of knowledge generation on one hand, while rendering what we know outdated almost as quickly. On the other hand, an increase in online learning, in order to reduce costs (cf. [25]), and the shortsighted and biased funding for higher education which is now common practice in all industrialized nations worldwide seem to work against efforts to facilitate active learning in richer and more sophisticated environments and against curriculum designs that actually value and promote skill acquisition, the development of competency, and the understanding of the methodology of learning as well as the content of what is learned.

4 CONCLUSION

It is becoming evident that changes stemming from demands on higher education are influenced most by policies paying tribute to the emerging knowledge economy in advanced industrial nations. It seems that disintegration rather than integration of scholarship is now the norm at institutions of higher education. This is evidenced by the way in which, for example, research, teaching and dissemination of knowledge in the form of scholarly publications are separately evaluated and rewarded. Such a development is actually counterproductive to the epistemic and intellectual nature of a true sustainable knowledge society.

On the other hand, because of the fundamentally changing way in which research is carried out with the support of information technology as both an infrastructure technology and a means for the provision and analysis of data and information in quantities and quality never seen before in science and engineering in the history of mankind, actually many of the tools are becoming more like those used in research. This is also true of infrastructure technology, and the nature of some elements and activities within the scholarship of teaching. At the same time, some of their counterparts in research are becoming more like those in teaching. In other words, teaching and active learning in higher education are about to become more like post-modern research. Thus the potential and possibilities for synergies between research and teaching are also becoming greater in quantity and stronger. One approach to this might be to find ways of improving integrated scholarship in concrete cases, based on the idea of fostering the research-teaching nexus, trying to identify the apparently increasing number of common elements, and analyzing their nature and contribution in respect to the four dimensions as outlined. This approach, of course, will show its strength only if translated into practice and put to the test.

Taking up again the metaphor of traveling used earlier in this paper, if we consider the current state of the art in pedagogical research, post-modern knowledge generation, and information and communication technology, the potential for higher education to provide means to let our minds reach for places they have never been before is tremendous and fascinating. However, this potential and the current developments in our society should not be misunderstood, or even perhaps misused, so that we confuse or gradually replace higher education with a kind of higher apprenticeship as in vocational training. Vocational training actually has different goals and concepts operating under different aspirations, where the acquisition of basic domain knowledge and skills is usually traded in exchange for early, mostly underpaid or even unpaid, participation in the production of economic services and goods. As pointed out, great potential and fascinating possibilities exist despite the many current challenges we face and the worrisome trends we see rising and gaining momentum at different levels and in different directions. But there are also many options still available to us. The choice is within the responsibilities of each individual, though in the end the journey on the long and difficult road to a truly sustainable knowledge society with green infrastructures and technologies is a collective one.

Environmental Policy and Environmental Change in a Three-Sector Growth Model

Zhang Wei-Bin
Ritsumeikan Asia Pacific University, Beppu-shi, Japan

Abstract
This paper proposes a three-sector economic growth model with physical capital accumulation and environmental change on the basis of the neoclassical growth theory with an alternative approach to household behavior. The model synthesizes Uzawa's two-sector economic growth model and the environmental change in some traditional dynamic models of environmental economics. Both labor and capital distributions among the three sectors are determined by market mechanisms under the government intervention. We simulate the model to demonstrate existence of equilibrium points and motion of the dynamic system. In particular, we demonstrate effects of changes in the government policy and preference upon both short-run and long-run economic behavior of the system. The simulation demonstrates that the dynamics shows the same pattern of economic growth as predicted by the Solow model and exhibits the same relation between the income and environmental change as depicted by the environmental Kuznets curve.

Keywords:
the environmental Kuznets curve, tax, capital accumulation, environmental change, labor distribution

1 INTRODUCTION

The purpose of this study is to examine interactions between environmental change and economic growth. In recent years environmental issues have received more attention than ever. Global warming threatens living conditions of mankind and local environmental catastrophes are daily reported in TVs. It is challenging for economists to explain economic mechanisms and consequences of environmental changes. Environmental issues have increasingly caused attention in the literature of economic growth and development [1, 2, 3]. As mentioned in [4], one can find three effects that are important in explaining the level of environmental pollution and resource use. The three effects are: (i) increases in output tends to require more inputs and produce more emissions; (ii) changes in income or preferences may lead to policy changes which will affect production and thus emission; and (iii) as income increases, the economic structure may be changed which will causes changes in the environment [5]. It is argued that the net effect of these effects tends to result in the environmental Kuznets curve. It is well known that Kuznets [6] postulated that economic growth and income inequalities follow an inverted U-curve. The environmental Kuznets curve refers to the same relation between environmental quality and per capita income. Nevertheless, a large number of empirical studies on the environmental Kuznets curve for various pollutants find different relations - for instance, inverted U-shaped relationship, a U-shaped relationship, a monotonically increasing or monotonically decreasing relationship - between pollution and rising per capita income levels [4].

Economic growth often worsens environmental conditions. On the other hand, as a society accumulates more capital, more resources may be used to protect environment. Issues related to interdependence between economic growth and environment have been examined from different perspectives. This paper is concentrated on tradeoffs between economic growth, consumption, and pollution. This study attempts to make a contribution to the literature by examining interdependence between savings and dynamics of environment with an alternative approach to consumers' behavior. It is an extension of the growth model with environment proposed by Zhang [7]. The paper is organized as follows. Section 2 introduces the basic model with wealth accumulation and environmental dynamics. Section 3 examines dynamic properties of the model and simulates the model, identifying the existence of a unique equilibrium and checking the stability conditions. Section 4 studies effects of changes in some parameters on the system. Section 5 concludes the study. The appendix proves the analytical results in Section 3.

2 THE BASIC MODEL

This paper reexamines dynamics of the two-sector economic model proposed by Uzawa [8], by adding the environment and environmental sector to the model. The economy has two production sectors and one environmental sector. The Uzawa model extends the Solow model by a breakdown of the productive system into two sectors using capital and labor, one of which produces capital goods, the other consumption goods. Households own capital of the economy and distribute their incomes to consume the commodity and to save.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_45,

Exchanges take place in perfectly competitive markets. We assume a homogenous and fixed population. The labor force is distributed among the three sectors under perfect completion in labor market. We select commodity to serve as numeraire (whose price is normalized to 1), with all the other prices being measured relative to its price.

In the literature of environmental economics, pollution may affect productivity through the channel that pollution directly affects production technology or the productivity of any input. Let subscript index, i and s, stand for capital goods and services respectively. We assume that production is to combine labor force, $N_j(t)$, and physical capital, $K_j(t)$. We add environmental impact to the conventional production function. The production functions are specified as follows

$$F_j(t) = A_j \Gamma_j(E) K_j^{\alpha_j}(t) N_j^{\beta_j}(t), \quad A_j, \alpha_j, \beta_j > 0,$$
$$\alpha_j + \beta_j = 1, \quad j = i, s, \tag{1}$$

where $F_j(t)$ is the output level of sector j at time t, $\Gamma_j(E)$ is a function of the environmental quality measured by the level of pollution, $E(t)$, and A_j, α_j and β_j are parameters. It is reasonable to assume that productivity is negatively related to the pollution level, i.e., $\Gamma_j(E) \le 0$.

Markets are competitive; thus labor and capital earn their marginal products. The rate of interest, $r(t)$, and wage rate, $w(t)$, are determined by markets. The marginal conditions are given by

$$r(t) + \delta_k = \frac{\alpha_j (1 - \tau_i) F_i(t)}{K_i(t)}, \quad w(t) = \frac{\beta_i (1 - \tau_i) F_i(t)}{N_i(t)},$$
$$w(t) = \frac{\beta_s (1 - \tau_s) p(t) F_s(t)}{N_s(t)},$$
$$r(t) + \delta_k = \frac{\alpha_s (1 - \tau_s) p(t) F_s(t)}{K_s(t)}, \tag{2}$$

where δ_k is the given depreciation rate of physical capital and τ_j is the fixed tax rate on sector j, $0 < \tau_j < 1$, $j = i, s$.

Consumers make decisions on choice of consumption levels as well as on how much to save. We apply an alternative approach to preference structure of consumers over consumption and saving. We denote per capita wealth by $k(t)$, where $k(t) \equiv K(t)/N$. Per capita current income from the interest payment $r(t)k(t)$ and the wage payment $w(t)$ are given by

$$y(t) = r(t)k(t) + w(t).$$

We call $y(t)$ the current income. The per capita disposable income is given by

$$\hat{y}(t) = y(t) + k(t). \tag{3}$$

The disposable income is used for saving and consumption. At each point of time, a consumer would distribute the total available budget between saving, $s(t)$, and consumption of services, $c(t)$. The budget constraint is given by

$$c(t) + s(t) = \hat{y}(t). \tag{4}$$

It should be noted that this study does not explicitly take account of consumers' awareness of environment. For instance, consumers may prefer to environment-friendly goods when their living conditions are changed. With regard to how much money the economic agent should spend on environmental improvement, As argued in [9], at a lower level of pollution, the representative agent does not care much about environment and spends his resource on consumption; however, as the environment becomes worse and income becomes higher, more capital will be used for environmental improvement. We may take account of changes in consumers' behavior, for instance, by assuming that the representative consumer spends a proportion of the disposable income on environment or the tax rate on the consumer's consumption is explicitly related to income and consumption level.

At each point of time, consumers have two variables, $s(t)$ and $c(t)$, to decide. We assume that consumers' utility function is a function of $s(t)$, $c(t)$, and $E(t)$, as follows: $U(t) = U(c(t), s(t), E(t))$. For simplicity of analysis, we specify the utility function as follows

$$U(t) = c^{\xi_0}(t) s^{\lambda_0}(t) E^{-\chi_0}(t), \quad \xi_0, \lambda_0, \chi_0 > 0,$$

where ξ_0 is called the propensity to consume and λ_0 the propensity to own wealth. A detailed explanation of the approach and its applications to different problems of economic dynamics are provided in [7]. It should be noted that in [10] and [11], it is assumed that utility depends negatively on pollution, which is a side product of the production process. As reviewed [12], "environmental economics has been slow to incorporate the full nature of the household into its analytical structures. … [A]n accurate understanding household behavior is vital for environmental economics." Our approach to household behavior is still over-simplified as, for instance, we analyze an economy with a single good and a single pollutant. We will deal with household behavior more realistically by, for instance, introducing multiple goods into the utility functions and each good has distinct features with regard o pollution (and may be subject to different environmental policies). We may also take account of family structure in the modeling. How to take account of different aspects of reality is illustrated in [7], even though it may be difficult to construct practically meaningful and analytically tractable models. Maximizing $U(t)$ subject to budget constraint (4) yields

$$c(t) = \xi \hat{y}(t), \quad s(t) = \lambda \hat{y}(t), \tag{5}$$

where

$$\xi \equiv \rho \xi_0, \ \lambda \equiv \rho \lambda_0, \ \rho \equiv \frac{1}{\xi_0 + \lambda_0}.$$

We now find dynamics of capital accumulation. According to the definition of $s(t)$, the change in the household's wealth is given by

$$\dot{k}(t) = s(t) - k(t). \quad (6)$$

The equation simply states that the change in wealth is equal to saving minus dissaving.

Demand and supply balances

The demand for services equals supply of services

$$c N = F_s(t). \quad (7)$$

Let N and $K(t)$ stand respectively for the (fixed) the population and total capital stock. The labor force is allocated between the three sectors. As full employment of labor and capital is assumed, we have

$$K_i(t) + K_s(t) + K_e(t) = K(t),$$
$$N_i(t) + N_s(t) + N_e(t) = N. \quad (8)$$

We now describe dynamics of the stock of pollutants, $E(t)$. We assume that pollutants are created both by production and consumption. We specify the dynamics of the stock of pollutants as follows

$$\dot{E}(t) = \theta_f F_i(t) + \theta_c C(t) - Q_e(t) - \theta_0 E(t), \quad (9)$$

in which q_f, q_c, and q_0 are positive parameters and

$$Q_e(t) = A_e \Gamma_e(E) K_e^{\alpha_e}(t) N_e^{\beta_e}(t), \ A_e, \alpha_e, \beta_e > 0, \quad (10)$$

where $N_e(t)$ and $K_e(t)$ are respectively the labor force and capital stocks employed by the environmental sector, A_e, α_e, and β_e are positive parameters, and $\Gamma_e(E)$ (≥ 0) is a function of E. The term $\theta_f F$ means that pollutants that are emitted during production processes are linearly positively proportional to the output level [13]. The parameter, θ_c, means that in consuming one unit of the good the quantity θ_c is left as waste [14]. The parameter θ_c depends on the technology and environmental sense of consumers. The parameter θ_0 is called the rate of natural purification. The term $\theta_0 E$ measures the rate that the nature purifies environment. The term, $K_e^{\alpha_e} N_e^{\beta_e}$, in Q_e means that the purification rate of environment is positively related to capital and labor inputs. The function, $\Gamma_e(E)$, implies that the purification efficiency is dependent on the stock of pollutants. It is not easy to generally specify how the purification efficiency is related to the scale of pollutants. For simplicity, we specify Γ_e as follows $\Gamma_e(E) = \theta_e E^{\upsilon}$, where $\theta_e > 0$ and $\upsilon > 0$ are parameters.

We now determine how the government determines the number of labor force and the level of capital employed for purifying pollution. We assume that all the tax incomes are spent on environment. The government's tax incomes consist of the tax incomes on the production sector, consumption, wage income and wealth income. Hence, the government's income is given by

$$Y_e(t) = \tau_i F_i(t) + \tau_s p(t) F_s(t). \quad (11)$$

Ono [15] introduces tax on the producer and uses the tax income for environmental improvement in the traditional neoclassical growth theory. For simplicity, we assume that the government's income is used up only for the environmental purpose. As there are only two input factors in the environmental sector, the government budget is given by

$$(r(t) + \delta_k) K_e(t) + w(t) N_e(t) = Y_e(t). \quad (12)$$

We need an economic mechanism to analyze how the government distributes the tax income. We assume that the government will employ the labor force and capital stocks for purifying environment in such a way that the purification rate achieves its maximum under the given budget constraint. The government's optimal problem is given by

$$\text{Max}\, Q_e(t) \quad \text{s.t.: } (r(t) + \delta_k) K_e(t) + w(t) N_e(t) = Y_e(t).$$

The optimal solution is given by

$$(r(t) + \delta_k) K_e(t) = \alpha Y_e(t), \ w(t) N_e(t) = \beta Y_e(t), \quad (13)$$

where

$$\alpha \equiv \frac{\alpha_e}{\alpha_e + \beta_e}, \ \beta \equiv \frac{\beta_e}{\alpha_e + \beta_e}.$$

We have thus built the dynamic model. We now examine dynamics of the model.

3 THE DYNAMICS AND ITS PROPERTIES

We now show that the dynamics of the economic system can be expressed by the two-dimensional differential equations system with $k_i(t)$ and $E(t)$ as the variables.

Lemma 1

The economy is governed by the following 2-dimensional differential equations

$$\dot{k}_i = \Lambda_{k_i}(k_i, E),$$
$$\dot{E} = \Lambda_e(k_i, E), \quad (14)$$

where the functions in (14) are only dependent on $k_i(t)$ and $E(t)$ which are given in the appendix. Moreover, all the other variables can be determined as functions of $k_i(t)$ and $E(t)$ at any point of time by the following procedure: k by (A11) $\rightarrow K = k N \rightarrow k_s$ and k_e by (A1) $\rightarrow N_i$, N_s and N_e by (A8) $\rightarrow$ $K_i = k_i N_i$, $K_s = k_s N_s$ and $K_e = k_e N_e$ by (A8) $\rightarrow r$, w and p by (A3) $\rightarrow F_i$ and F_s by (1) $\rightarrow$ Q_e by (10) $\rightarrow \hat{y}$ by (3) $\rightarrow c$ and s by (11).

As the expressions of the analytical results are tedious, it is difficult to explicitly interpret the results. For illustration we specify the parameter values and simulate the model. We specify the parameters as follows

$$\Gamma_i = E^{-b_i},\ \Gamma_s = E^{-b_s},\ \Gamma_e = E^{b_e},\ b_i = 0.1,\ b_s = 0.05,$$
$$b_e = 0.3,\ N_0 = 5,\ \alpha_i = 0.3,\ \alpha_s = 0.35,\ A_i = 1,\ A_s = 1.1,$$
$$\alpha_e = 0.5,\ \beta_e = 0.3,\ A_e = 0.5,\ \lambda_0 = 0.4,\ \xi_0 = 0.2,$$
$$\delta_k = 0.05,\ \tau_i = \tau_s = 0.05,\ \theta_f = 0.2,\ \theta_c = 0.25,\ \theta_0 = 0.05. \quad (15)$$

The population is fixed at 5. The propensity to save is much higher than the propensity to consume the commodity. Under (15), the dynamic system has a unique equilibrium point. The equilibrium values are given as in (16)

$$K = 7.58,\ E = 13.63,\ F_i = 1.19,\ F_s = 3.79,\ Q_e = 0.50,$$
$$N_i = 1.46, N_s = 3.39,\ N_e = 0.15,\ K_i = 1.76,\ K_s = 5.14,$$
$$K_e = 0.68,\ k_i = 1.21,\ k_s = 1.51,\ k_e = 4.69,\ f_i = 0.81,$$
$$f_s = 1.12,\ r = 0.14,\ w = 0.54,\ p = 0.79,\ k = 1.52,$$
$$c = 0.76. \quad (16)$$

The two eigenvalues are -0.25 and -0.07. This guarantees the stability of the steady state. Hence, the dynamic system has a unique stable steady state. We identified that the dynamic system has a unique stable equilibrium under (15). With the initial conditions, $k_i(0) = 1.4$ and $E(0) = 13.8$, we plot the motion of the system as in Figure 1. The length of the simulation period is 40, which is long enough for the system approach its unique equilibrium point. The national capital stock and capital stocks employed by the two sectors fall over time. The current income, the output level of the industrial sector, the wage rate and consumption level are all reduced. The labor force shifts from the service sector to the environmental and industrial sectors over time. The rate of interest rises as the capital intensity is falling. The level of pollution rises initially and then falls.

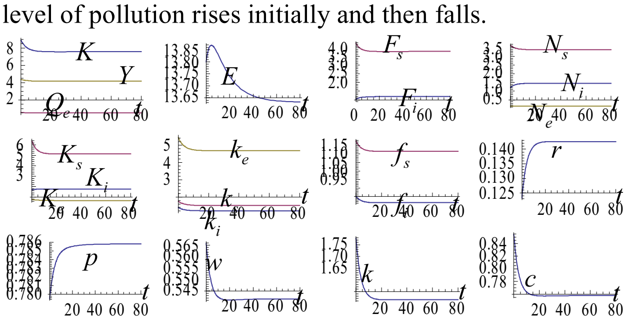

Figure 1: Motion of the economic system

4 COMPARATIVE DYNAMIC ANALYSIS

This section examines effects of changes in some parameters on the motion of the economic system. First, we study the case that all the parameters, except the speed that consumption pollutes the environment, are the same as in (15). We increase the parameter in the following way: θ_c: $0.25 \Rightarrow 0.30$. The simulation results are demonstrated in Figure 2. In the plots, a variable $\overline{\Delta} x_j(t)$ stands for the change rate of the variable $x_j(t)$ in percentage due to changes in the parameter value. We will use the symbol $\overline{\Delta}$ with the same meaning when we analyze other parameters. The rise in the speed that consumption pollutes the environment, reduces the national and two sector's capital stocks, wage rate and level of the consumption good, the interest rate. The labor force employed by the environmental sector is affected slightly. The level of pollution is increased over time. Hence, if the consumers have less awareness of environment, all aspects of the living conditions are deteriorated. When the consumers more intensively pollute environment, there are more pollutants. As the environmental condition is deteriorated, the productivity becomes lower, which leads to less capital and lower wage rate. As the dynamic system has a unique stable equilibrium, it approaches its steady state.

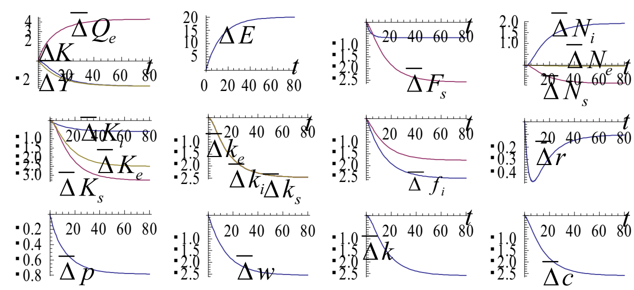

Figure 2: The pollution by consumption becomes stronger

If we raise the environmental tax rate on consumption as follows: τ_i: $0.05 \Rightarrow 0.07$, then the dynamic path of the economic system is shifted as illustrated in Figure 3. Initially, the economic system suffers and the environment deteriorates. But soon the economic conditions are improved and the environment becomes better.

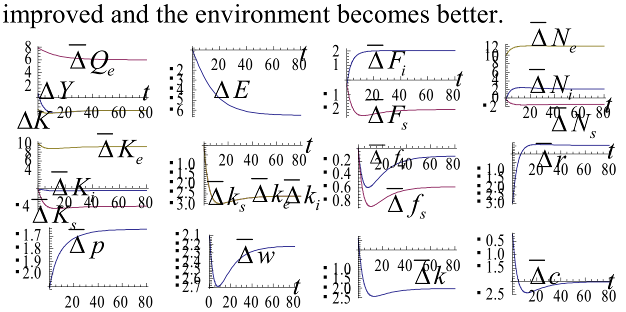

Figure 3: The environmental tax rate on the industrial output is increased

5 SUMMARY

This paper proposed a dynamic economic model with physical capital accumulation and environmental change on the basis of the neoclassical .growth theory. The model is a synthesis of the neoclassical growth theory and the traditional dynamic models of environmental change with an alternative approach to household behavior. This paper re-examined the Uzawa two-sector growth model with an alternative utility function. Different from the two-sector growth models with the Ramsey approach in the literature, we used a utility function, which determines saving and consumption with utility optimization without leading to a higher dimensional dynamic system like by the traditional approach. The model describes dynamic interactions among physical accumulation, environmental change, economic structure and division of labor with different environmental policies. We simulated the model to demonstrate existence of equilibrium points and motion of the dynamic system.

6 PROVING LEMMA 1

We now show that the dynamics can be expressed by the two-dimensional differential equations. From (2) and (13), we obtain

$$k_i = \bar{\alpha}_i k_e = \bar{\alpha}_s k_s, \tag{A1}$$

where we omit time index and

$$k_i \equiv \frac{K_i}{N_i}, \; k_e \equiv \frac{K_e}{N_e}, \; k_s \equiv \frac{K_s}{N_s}, \; \bar{\alpha}_i \equiv \frac{\beta_e \alpha_i}{\alpha_e \beta_i},$$

$$\bar{\alpha}_s \equiv \frac{\beta_s \alpha_i}{\alpha_s \beta_i}. \tag{A2}$$

By (A1) and (2), we solve

$$r = \alpha_i (1 - \tau_i) A_i \Gamma_i k_i^{-\beta_i} - \delta_k, \quad w = \beta_i (1 - \tau_i) A_i \Gamma_i k_i^{\alpha_i},$$

$$p = \frac{\bar{\alpha}_s^{\alpha_s} w}{\beta_s (1 - \tau_s) A_s \Gamma_s k_i^{\alpha_s}}. \tag{A3}$$

We see that k_e, k_s, r, w and p are functions of k_i and E. From $w N_e = \beta Y_e$ in (13) and (11), we have

$$N_e = \beta \tau_i \frac{F_i}{w} + \beta \tau_s \frac{p F_s}{w}. \tag{A4}$$

By this equation and (2), we have

$$N_e = \frac{\beta \tau_i N_i}{\beta_i (1 - \tau_i)} + \frac{\beta \tau_s N_s}{\beta_s (1 - \tau_s)}. \tag{A5}$$

From (A5) and (7), we have

$$\bar{\tau}_i N_i + \bar{\tau}_s N_s = 1, \tag{A6}$$

where

$$\bar{\tau}_i \equiv \frac{1}{N} + \frac{\beta \tau_i}{N \beta_i (1 - \tau_i)}, \quad \bar{\tau}_s \equiv \frac{1}{N} + \frac{\beta \tau_s}{N \beta_s (1 - \tau_s)}.$$

From (A2), (A5) and $K_i + K_s + K_e = K$, we have

$$\tilde{\tau}_i N_i + \tilde{\tau}_s N_s = \frac{K}{k_i}, \tag{A7}$$

where we also use (A1) and

$$\tilde{\tau}_i \equiv 1 + \frac{\beta \tau_i}{\bar{\alpha}_i \beta_i (1 - \tau_i)}, \quad \tilde{\tau}_s \equiv \frac{1}{\bar{\alpha}_s} + \frac{\beta \tau_s}{\bar{\alpha}_i \beta_s (1 - \tau_s)}.$$

From (A5)-(A7), we solve the labor distribution as functions of K / k_i as follows

$$N_i = \left(\tilde{\tau}_s - \frac{\bar{\tau}_s N k}{k_i} \right) \tau_0, \quad N_s = \left(\frac{\bar{\tau}_i N k}{k_i} - \tilde{\tau}_i \right) \tau_0, \tag{A8}$$

where

$$\tau_0 \equiv \frac{1}{\bar{\tau}_i \tilde{\tau}_s - \tilde{\tau}_i \bar{\tau}_s}.$$

From $c = \xi \hat{y}$ and the definition of $\hat{y}$, we have

$$F_s = (1 + r) \xi K + \xi N w, \tag{A9}$$

where we use $c N = F_s$. Insert (1) in (A9)

$$\frac{A_s k_i^{\alpha_s} \Gamma_s(E)}{\bar{\alpha}_s^{\alpha_s}} N_s = (1 + r) \xi K + \xi N w, \tag{A10}$$

where we use $k_s = K_s / N_s$ and $k_i = \bar{\alpha}_s k_s$. Substituting N_s in (A8) into (A10), we solve

$$k = \Omega(k_i, E) \equiv$$

$$\left[\frac{\tau_0 \tilde{\tau}_i A_s k_i^{\alpha_s} \Gamma_s(E)}{N \bar{\alpha}_s^{\alpha_s}} + \xi w \right] \left[\frac{\bar{\tau}_i \tau_0 A_s k_i^{\alpha_s} \Gamma_s(E)}{\bar{\alpha}_s^{\alpha_s} k_i} - (1 + r) \xi \right]^{-1}, \tag{A11}$$

where r and w are functions of k_i. We express k as a function of $k_i(t)$ and $E(t)$. From (A2), k_s and k_e are functions of k_i. From (A8), N_i, N_s and N_e are functions of k_i. By the following procedure, we can express other variables as functions of $k_i(t)$ and $E(t)$ at any point of time: r, w and p by (A3) → Q_e by (10) → $\hat{y}$ by (3) → c and s by (5). By these results and from (9) we get the following differential equation

$$\dot{E}(t) = \Lambda_e(k_i(t), E(t)) \equiv \theta_f F_i(t) + \theta_c C(t) - Q_e(t) - \theta_0 E(t). \tag{A12}$$

We do not provide explicit expressions of the functions as it is straightforward to do so and the expressions are too tedious. Taking derivatives of (A11) with respect to t yields

$$\dot{k} = \frac{\partial \Omega}{\partial k_i} \dot{k}_i + \Lambda_e \frac{\partial \Omega}{\partial E}, \tag{A13}$$

where we also use (A12). From (3), (5) and (6), we have

$$\dot{k} = \lambda w - (1 - \lambda r - \lambda) k. \tag{A14}$$

Insert (A13) and (A11) in (A14)

$$\dot{k}_i = \Lambda_{k_i}\left(k_i(t),\, E(t)\right) \equiv$$
$$\left[\lambda\, w - (1 - \lambda\, r - \lambda)\Omega - \Lambda_e \frac{\partial \Omega}{\partial E}\right]\left(\frac{\partial \Omega}{\partial k_i}\right)^{-1}. \tag{A15}$$

We have thus proved Lemma 1.

The Impact Analysis of Waste Plastic Trade between China and Japan－From Policy View

Xiangfeng MENG[1] and Tokuhisa YOSHIDA[1]

[1]Graduate School of Environment and Energy Engineering, Waseda University, Japan

E-mail:mengxiangfeng@toki.waseda.jp

Abstract

The 3R policy in Japan promoted the recycling of waste resources; however, at the same time, it also triggered a rapid increase in the export of waste plastics to China. As a result, domestic material recycling (MR) of waste plastics generated in Japan has been declining, which may lead to a hollowing out of Japan's waste plastic recycling business. In this study, we conducted a macro analysis of the effects of the 3R policy in Japan and the economic situation of Japan and China on the flow of waste plastics by following changes in trade volume of waste plastics between the two countries from the 1990s through 2010. From the results of this analysis, it can be seen that waste plastics exports from Japan have continued to increase, driven by the legal structure related to the 3R policy in Japan and the rapid increase in the demand for plastics in China. However, the export from Japan seems to be already reaching a limit. On the other hand, when viewed from China's perspective, China has been importing waste plastics not only from Japan but also from about 120 countries around the world. Total imports in 2009 amounted to approximately 7.3 million tons, while imports from Japan (1.35 million tons) accounted for only about 20% of total waste plastics imports. The immediate cause is the rapid economic growth of China; however, various policies in China have also further increased the demand for plastics. Therefore, the demand for waste plastics in China is expected to continue increasing in the future. In addition, among waste plastics imported to China, inappropriate items included among the waste plastics have been on the rise in light of the Basel Convention, and there are concerns about the effects of environmental pollution resulting from the recycling business in China.

Keywords:

waste plastics, waste trade, material recycling, 3R policy, the Basel Convention

INTRODUCTION

Currently, many countries in the world are pursuing their own policy of promoting the cyclical use of waste resources, with the aim of forming a sustainable society. As an initiative to promote the formation of a cyclical society in Japan, the Containers and Packaging Recycling Law was enacted in 1995, while at the same time, the demand for plastics has continued to increase in China due to its rapid economic growth. In particular, waste plastics including waste PET (polyethylene terephthalate) have been exported in vast quantities from Japan to China, starting at the beginning of this century.

Simultaneously, domestic material recycling in Japan, which is the highest priority in the three kinds of recycling methods (material recycling (MR), chemical recycling (CR) and thermal recycling (TR)) for the formation of a cyclical society in Japan (3R policy), has been gradually faded out, and material recycling has been maintained by exports to China.

On the other hand, China has imported vast quantities of waste plastics from around the world backed by its resource policies. As a result, however, improvement of the safety inspection of imported waste plastics and measures for prevention of environmental pollution at recycling plants are becoming important issues.

In this study, we analyze in detail the process of expanding trade in waste plastics between Japan and China after 1997 based on statistical trade data from Japan and China, and also, work to understand the state of nonconformity of waste plastics China imported from around the world to standards based on customs statistics. Through this analysis, we clarify the actual state of cyclical use of waste plastics between Japan and China, straighten out issues concerning international cyclical use of resources from an environmental, economic and political viewpoint, and consider how to deal with the issues that exist in the future.

1. STUDY METHOD

Based on export and import statistical data of waste plastics in both Japan and China during the period of 14 years from 1997 when the Containers and Packaging Recycling Law was enforced to 2010, we clarify a macro trend in the secular changes in waste plastics trade between Japan and China. In addition, we identify and

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,

DOI 10.1007/978-94-007-3010-6_46, © Springer Science+Business Media Dordrecht 2012

count the cases of nonconformity among waste plastics imported from Japan to China during the period from 2003 to 2009 in light of the "Environmental protection control standard for imported solid wastes as raw materials - Waste and scrap of plastics" based on the materials released by the General Administration of Quality Supervision, Inspection and Quarantine of the People's Republic of China to consider legally inappropriate waste plastics trade cases. Furthermore, based on the development of policies related to the promotion of cyclical use of waste resources in both Japan and China and economic trends in both countries, we give an analytical consideration of factors to promote waste plastics exports from Japan to China and clarify environmental protection-related issues.

2. BACKGROUND ON THE INCREASING DEMAND FOR WASTE PLASTICS IN CHINA

Currently, China has set environmental protection management standards for waste plastics recycling plants; however, the standards have not been fully complied with on site. China has promoted recycling waste plastics by offering preferential treatment such as tax breaks; its prior policy is to save the oil consumption and manage the price of plastic products. According to the observation analysis report of China Customs Statistics "Increase in Waste Plastic Imports via Tianjin Port in January 2011," recycling one ton of waste plastics saves about five tons of oil [1]. This is because the production of one ton of plastic requires nearly four tons of oil, if waste plastics are recycled once and ultimately used as fuel, it will save five tons of oil. The total amount of waste plastics recycled in China in 2009 was approximately 17 million tons, including imports. This translates into savings of about 80 million tons of oil. Therefore, recycling waste plastics has a significant meaning to China's national strategy.

2.1 Changes in the amount of plastic used in China

In China, demand for virgin plastic materials has been increasing since 1994. From 1995 to 2000, in particular, the annual growth rate of demand reached about 20%. Although the growth rate somewhat slowed thereafter, demand has continued to grow by about 10% annually after 2000. Imports of virgin plastics increased to meet demand until 2002; however, reflecting an increase in the domestic production capacity, virgin plastics imports have decreased since 2003. Meanwhile, waste plastic imports have rapidly increased since 2000, and their imports have maintained an upward trend throughout the period to date in spite of the global recession in 2008. Since around 2002, a surge in oil prices has further increased the demand for waste plastics.

Fig. 1 shows changes in the amounts of China's domestic procurement and imports of virgin plastic materials and

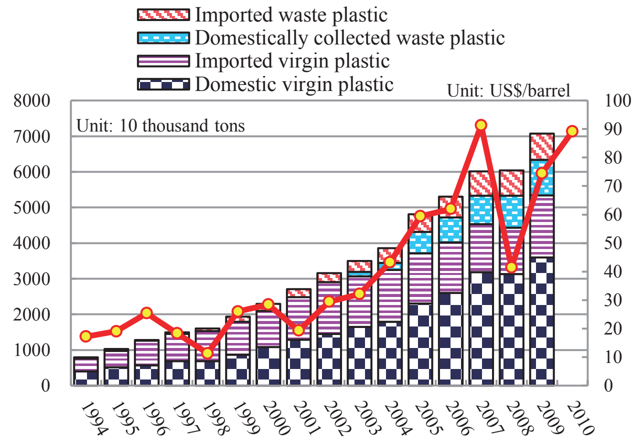

Fig. 1: Changes in the Amount of Plastic Used in China
* Data on the amount of domestically collected waste plastics is from 2003
Source: China Statistical Yearbook, China Customs Statistics, Changes in WTI Crude Oil Prices[2]

waste plastics and changes in oil prices (WTI crude oil prices) during the 15 years from 1994 to 2009. China's demand for plastics reached an all-time high of about 70 million tons in 2009, when the amount of domestic production was 36 million tons and imports of virgin plastic materials were 17 million tons. Meanwhile, imports of waste plastics totaled 7.3 million tons and the amount domestically collected totaled 10 million tons. Thus, waste plastics satisfy 25% of China's total current demand for plastics

2.2 Status of China's waste plastics imports

Imports of waste plastics totaled 3.02 million tons in 2003 and doubled to 7.3 million tons in 2009. China is now the largest importer of waste plastics in the world, and about 70% of total waste plastics shipped worldwide are imported by China. Of the 117 countries, the major countries and regions (Hong Kong, European countries, US, Japan, Taiwan, and South Korea) account for about 80% of total waste plastic imports [3]. However, as shown in Fig. 2, annual increase rate of waste plastic import in China dropped from the average of about 20% during 2003-2007 to 2% in 20008. In 2009, the rate slightly recovered to 4%.

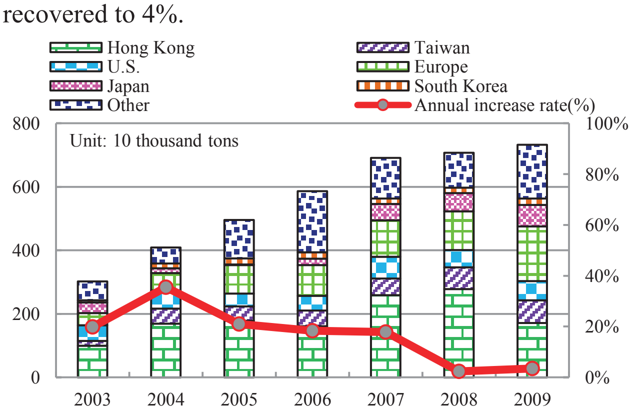

Fig. 2: Changes in Waste Plastic Imports by Country during 2003–2009
Source: Calculated from World Trade ATLAS

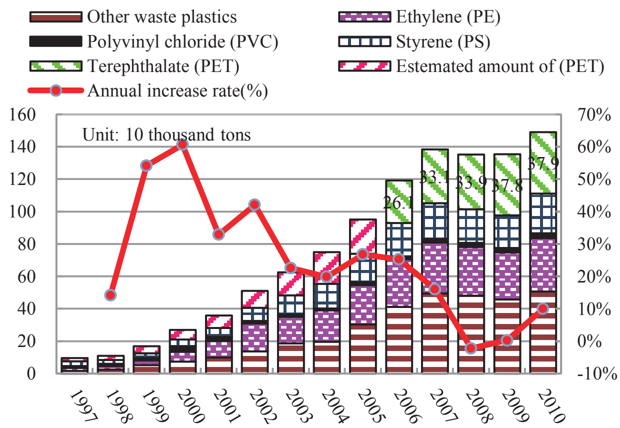

Fig. 3: Changes in Waste Plastic Exports from Japan to China
Source: Trade Statistics of Japan, Ministry of Finance, Government of Japan[4]
Note: Figures above differ from those in Figure 2 as they include exports through Hong Kong.

Furthermore, in 2009, the percentage of waste plastics imports through Hong Kong decreased, while there was an increasing trend in direct imports from overseas to the inland China. This is because direct shipments save time and reduces transportation costs more than import via Hong Kong as there are many waste plastics recycling plants in the inland China.

2.3 Import of waste plastics from Japan

As shown in Fig. 3, exports of waste plastics from Japan to China have rapidly increased since 2000, but due to the impact of the financial recession at the end of 2008, the demand for waste plastics in China temporarily decreased because of a decline in the export of Chinese plastic products to overseas markets, such as the U.S. and Europe in particular, and as a result, exports of waste plastics from Japan to China showed a slight decline. Along with the economy recovering in China in 2009, exports to China once again created an upward trend to reach a record high of 1.49 million tons in 2010, exceeding the record of 1.38 million tons in 2007 [4]. Among waste plastics, exports of only waste PET to China have maintained an upward trend in spite of the recession. However, it seems that plastic consumption has already peaked in Japan, and no substantial increase in the generation of waste plastics can be expected in the future. Therefore, the market of material recycling in Japan is expected to diminish further.

3. POLICIES OF BOTH COUNTRIES ON THE INCREASE IN THE FLOW OF WASTE PLASTICS

3.1 Factors attributable to the system of Japan's Containers and Packaging Recycling Law

The Containers and Packaging Recycling system imposes obligations on citizens to separate their waste, and municipal governments to carry out sorted collection and separate storage of waste and deliver the separated waste to the Japan Containers and Packaging Recycling Association free of charge. The Law also provides a system to impose obligations on producers and users to conduct recycling and pay recycling fees (commission). Furthermore, the Law imposes obligations on municipal governments to pay costs of sorted collection and separate storage as well as to pay commissions on behalf of small businesses. For this reason, the number of cases has been increasing where municipal governments that have to bear high costs sell the waste PET bottles they collected to China (Chinese buyers) for a fee in response to strong requests from China, without delivering them to the Japan Containers and Packaging Recycling Association.

Meanwhile, for recycling business operators, business conditions have worsened because of a rise in procurement costs due to a recent increase in exports to China and the sluggish growth in demand due to a rise in prices of products recycled from waste PET (flakes or pellets). According to interviews from the Containers and Packaging Recycling Association and some PET bottle recycling plant in Kawasaki Prefecture, Japan, although the company has world-class recycling technology, it is difficult for them to secure the product market because pellets recycled from waste PET bottles are more expensive than virgin materials.

To maintain the waste PET recycling market, a commission system for recycling business operators and a contribution scheme for municipal governments has been introduced as a result of a revision to the Law in 2006 [5]. However, because costs including those related to the collection of waste PET still remain high, the market for recycled products cannot expand in Japan. The immediate cause is that the cost of recycled products is relatively high compared to that of products made with competing virgin materials. Thus, it can be considered that high recycling costs are a major factor that hinders the growth of Japan's recycling system. The 3R policy has placed an emphasis on maintaining a stable recycling market without leaving it entirely to the highly fluctuating market. However, the growing waste plastics market in China is putting pressure on the management of Japan's waste plastic recycling businesses.

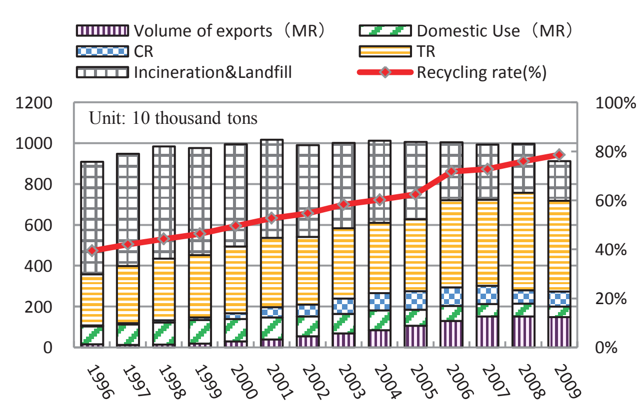

Fig. 4: Breakdown of Waste Plastic Treatment in Japan
Source:Plastic Waste Management Institute

Table 1 China's Policies to Promote the Use of Waste Plastics

Year	Policy	Contents
2006	The 11th Five-Year Plan	The plan to promote the use of plastic as an alternative material to steel and wood materials
2008	Corporate Income Tax Concessions for Enterprises Engaged in Comprehensive Resource Utilization [6]	This treatment imposes an obligation of 100% use of waste plastics, and provides the enterprises that have achieved the target with concessions for corporate income tax on 10% of their sales
2009	Circular Economy Promotion Law of the People's Republic of China	This law was enforced with the aim of minimizing the impact on the environment and improving resource efficiency by reducing and recycling waste
2010	Easing of Import Restrictions	Restrictions on the import of PET bales (plastic waste in the form of PET bottles) were lifted
2011	The 12th Five-Year Plan	The economic development policy was transformed from a traditional export-led policy to a domestic-demand expansion policy

Recent trend of waste plastic treatment, including recycling in Japan is shown in Fig. 4. Total recycling ratio is apparently very high, but, thermal recycling (TR) and chemical recycling (CR) are dominant and material recycling (MR) stays only about 20%. Material recycling within Japan is declining steadily since 2000, and in 2008, 75% of material recycling is conducted overseas, mostly in China. In other words, Japan actually depends on China for its material recycling, and as a result, the domestic material recycling industry for waste plastics is hollowing.

3. 2 China's resource recycling promotion policies

Besides the aforementioned economic reasons, China's recent policies shown in Table 1 serve as factors that accelerate China's demand for plastics and imports of waste plastics. The reason for this is that it will be more difficult for China to procure resources in the future. In concrete terms, policies to promote the use of plastics and import of waste plastics are as follows : (i) in the Circular Economy Promotion Law enacted in January 2009, China set a basic policy which prioritizes "reducing," "reusing," and "recycling" in the same way as in Japan [7]; (ii) in addition to the policy to increase the use of plastics announced in the 11th Five-Year Plan, a transformation from export-led economic revitalization to domestic demand expansion was announced in the 12th Five-Year Plan launched this year. This will further accelerate the use of plastics in China [8][9]; and (iii) in 2008, tax reduction measures were set forth to promote the use of waste plastics, and last year, it was approved to import waste PET bottles in the form of bales [10]. This enables direct import of bales to mainland China, which used to be imported through Hong Kong, and reduces transportation costs. According to the observation analysis report of China Plastic On Line "Plastics Market" [11], in the future 5 to 10 years, the demand for waste plastics is expected to grow at 10% to 20% annually.

4. ENVIRONMENTAL ISSUES ASSOCIATED WITH TRANS-BOUNDARY MOVEMENTS OF WASTE RESOURCES

4.1 Basel Convention and cross-border flow of waste plastics

Trans-boundary movements of waste resources such as scrap iron, waste plastics (excluding part of polyvinyl chloride (PVC)), waste textiles, waste rubber, etc. are not subject to the regulations of the Basel Convention. Polyvinyl chloride is also permitted for export if the percentage of lead content is 0.1% or less by weight [12]. For the past 21 years from 1988 to 2009, Japan exported PVC to 28 countries such as China, South Korea, Taiwan, and the U.S.A. When exported to contracting states such as China, a preliminary inspection is conducted based on the domestic law in Japan as an exporting country corresponding to the Basel Convention. In the same way, an inspection is also conducted of the trading partner based on its domestic laws. In the case of China, inspections are conducted based on the "Environmental protection control standard for imported solid wastes as raw materials - Waste and scrap of plastics" as well as the standards of the Basel Convention. The status of conformity to the standards of the Basel Convention and the domestic laws in China for waste plastics imports in China can be summarized as follows.

4.2 Cases of non-conforming waste plastic imports rejected by China

According to the materials released from the General Administration of Quality Supervision, Inspection and Quarantine of the People's Republic of China, the number of waste plastics imports which failed to meet standards has been on the rise, as waste plastics imports by China have increased.

According to the report from China's Waste Resources Import Management Symposium held in Tokyo in 2008, the total number of lots of recyclable resources (scrap iron, waste paper, waste plastics, etc.) imported by China in 2007 totaled 287,602 [13]. As a result of random checks, 735 lots of waste resources failed to meet the "Environmental protection control standard for imported solid wastes as raw materials - Waste and scrap of plastics," which was approximately 0.26% of the total lots. Of the 735 non-conforming lots, 409 lots were waste

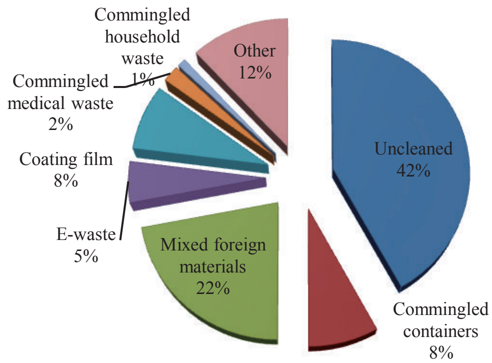

Fig. 5: Breakdown of 409 Lots of Non-conforming Waste Plastic Imports in 2007
Source: General Administration of Quality Supervision, Inspection and Quarantine of the People's Republic of China[14]

plastics, which accounted for 56%, the largest percentage of the total.

As shown by the breakdown of reasons for the rejection of waste plastics imports in Figure 5, the number one reason for the lot being rejected was uncleaned plastic waste (42%), followed by mixed foreign materials (fibers, papers, etc.) (22%), coating films unremoved (8%), commingled containers (8%) (until restrictions on the import of waste PET bales were lifted in 2010, only the import of waste plastic scraps (flakes) were permitted), commingled electric and electronic parts (E-waste) (5%),

Table 2 Some Cases of Rejected Waste Plastic Imports

Importer	Year	Exporter	Reason for rejection
Shandong	2003	Japan	Commingled household waste
Liaoning	2004	South Korea	Radioactive materials in excess of standards
Liaoning	2006	South Korea	Commingled medical waste
Guangdong	2007	Hong Kong	Commingled medical waste
Shandong	2007	Japan	Mixed foreign materials in excess of standards
Guangxi	2008	Unknown	Commingled E-waste
Zhejiang	2009	U.S.	Commingled E-waste

Source: General Administration of Quality Supervision, Inspection and Quarantine of the People's Republic of China[14]

commingled medical waste (2%), commingled household waste (1%), etc. Imports from the U.S. contained the largest number of non-conforming waste plastics totaling 150 lots, which was followed by 70 lots imported via Hong Kong, and 54 lots imported from Japan. The major non-conforming cases are shown in Table 2.

5. TRANS-BOUNDARY MOVEMENTS OF WASTE RESOURCES AND ENVIRONMENTAL POLLUTION

According to the Chairman's Summary Report of the Senior Officials Meeting on the 3R Initiative held in March 2006 in Tokyo, it was asserted that for the establishment of rules of trans-boundary movements of hazardous waste agreed in the international community (the Basel Convention), additional rules to restrict trans movements of recyclable resources were necessary [15].

However, obligatory restrictions should be left to each country. In addition, according to "Invisible Flow" and a Study Report on Recycling and Exports by Atsushi Terazono (2007), although the Basel Convention restricts trans-boundary movements of hazardous waste, it is currently easy to export such waste as long as there is an agreement between the seller and the buyer. It was also pointed out that even if a problem occurred, it would be difficult to ask who was responsible, and to what extent, for the problem [16].

The Basel Convention designates E-waste, PCB, residual agricultural chemicals, waste oil, medical waste, lead batteries, etc. as critically restricted items; however, it imposes no restrictions on waste resources which are not subject to the regulations of the Convention such as waste plastics, and the waste resources are being exported to many developing countries. Furthermore, in the recycling process of resources such as waste plastics, not a few countries may not have adequate technologies and economic capacities for environmental protection, which cause concerns about environmental pollution. Therefore, regarding such waste items mentioned above whose trans-boundary movements are increasing at a rapid pace, it would be desirable to inspect whether or not the Basel Convention is functioning effectively for the prevention of environmental pollution. In order to promote environmentally sound recycling of waste resources on an international basis, it must be said that exporting countries are required to thoroughly control their quality, and developing countries as well are also required to have a certain level of management ability as importing countries. When we visited an independently-operated small plant in Zhejiang Province, China in (August) 2010, where PVC pellets were recycled and processed, they had a low awareness for measures against environmental pollution. Sufficient environmental measures have not yet been implemented in the recycling and processing of waste plastics in China compared to Japan. In addition, adverse effects of environmental hormones such as plasticizers, including phthalates and bisphenol-A have been pointed out by many scientists of the world since 1990s. Although the scientific evaluation of their effects on human health has not been completed, the use of such substances for children's toys, etc. is restricted in Europe and other countries, and it has been pointed out that such restrictions may have an impact on the export of plastic products from China. In addition, there are some experts who point out the issue of "precocious babies" in China in recent years [17]. From the viewpoint of promoting environmentally-sound 3R policies on an international basis, an examination is considered to be necessary to prevent effects of such scientifically uncertain chemical substances on human health and ecology. In addition, administrative efforts will be increasingly important in the future to ensure that environmental regulations are properly implemented at recycling sites of waste plastics.

6. SUMMARY

i) Reason for the rapid increase in demand for waste plastics in China

(a) Due to reasons such as rapid economic growth in China and economic disparities between Japan and China, as well as the promotion of 3R policies in Japan, the outflow of waste plastics from Japan to China has been rapidly increasing in recent years, especially after 2000. China has been importing waste plastics not only from Japan but also from all over the world.

(b) Chinese government's circular economy promotion policies are serving as an underlying cause of the increase in the demand for waste plastics.

ii) Changes in waste plastics recycling in Japan

(a) Due to the obligation to separate and collect waste by citizens and municipal governments under the Containers and Packaging Recycling Law, material recycling of waste PET proceeded smoothly for a while after enforcement of the Law. However, the outflow of waste plastics to China has been putting pressure on the management of waste plastic recycling business operators in Japan and pressure to rationalize their management. As a result, some operators have gone bankrupt or closed business.

(b) The amount of material recycling of waste plastics generated in Japan is only 20% of the total, and more than half is recycled by thermal recycling. Moreover, the portion of material recycling set aside for exporting has risen year by year, and currently only 25 percent are for domestic use and 75 percent are exported to China and processed there.

(c) With the increase in demand from China, exports of waste plastics to China have been increasing. Although Japan exports 20% of its waste plastics imported by China at present, when the market size of Japan is compared with that of China, Japan's supply capacity of waste plastics is already reaching its limit.

iii) Basel Convention and concern about environmental pollution

(a) The Basel Convention prohibits trans-boundary movement of hazardous materials; however, it is questionable if it effectively functions to address the environmental pollution caused by the trans-boundary movements of resource materials which are not subject to the Convention such as waste plastics. Thus, it is necessary to further study the environmental pollution involved with the recycling process of waste plastics.

(b) Some specialists point out concerns over the effects of environmental hormone substances on human health, which requires a separate scientific study, in particular.

Abstract

With rapid development of urbanization and industrialization, resources seem to be more and more important. All over the world, every country are paying more attention to resources conservation and recycle. At the same time, China and Japan, two large countries in Asia, share many similarities and have many differences. This paper, from the angle of sustainable development, compares various aspects of waste disposal and recycling in both China and Japan, including technologies, administrations, CSR (Corporation Social Responsibility), public attitudes and so on. By SWOT analysis, we can get to know merits and demerits of two countries' waste disposal and recycling, so as to better understand the differences between China and Japan and provide deeper suggestions to international resources recycling cause.

Keywords

International Resource Recycling, Waste Products, Comparisons, China and Japan

1 INTRODUCTION

Accompanied by ever-increase of international recycling development and the need for resources, resources recycling have been a hot-spot issue in contemporary society promoting ever-frequent international trade in this field. As to the issue of international resources recycling, not only does cooperation be indispensible, but deep understandings of different recycling systems in counters are also quite necessary. As a result, this paper, focusing on comparisons and analysis of waste disposal and recycling systems in China and Japan, aims at providing useful information to international resources recycling.

2 WASTE DISPOSAL AND RECYCLE SITUATION IN CHINA AND JAPAN

2.1 Solutions of waste disposal and recycle technologies in China

China enacted the Law of Prevention and Control of Environmental Pollution by Solid Waste in 2005. In the law, the definition of waste law was explicitly stipulated. As a result, according to the law, "waste" is a kind of product that coming from human daily life, manufacturing process, and natural environment as well. "Waste" itself contains solid and semi-solid two forms, and can be divided into three categories: industrial solid waste, municipal solid waste and hazardous waste. In many cases, this definition has the highest authority.

At present, the most common ways of urban waste disposal is land filling, occupying 70% of total quantity. The second way is high-temperature composting, which contains 20%. Very rare waste is disposed by incineration. By the end of 2006, there are 23 household waste disposal facilities in Beijing, including 6 household waste transferring stations, 13 landfill sites, 2 high-temperature composting sites and 2 incineration plants. The overall designed processing capacity is 15710t/d[1]. Since land filling sites are so important in end disposal that their operational state should be carefully detected. Though a large number of wastes are disposed by land filling, incineration has had more and more influences and effectiveness. More and more plants or factories prefer to use this method when handling waste disposal and recycle problems.

Land-filling

Land-filling is the cheapest way of waste disposal, as in China, the price for land-filling 1 ton of waste is about 40 RMB, much lower than any other technologies. That's why over 70% of household waste was handled that way.

However, despite its cost advantage, land-filling has many problems. A case in point is about land. In china, land is so expensive that it has already brought a series of problems, such as high cost, low benefit and consumers' heavy burden. While land-filling covers so large an area, making previous expensive lands much more expensive. Moreover, this method will also bring smelly to filled sites, especially in summer when temperature is a little bit higher than average. Dust, smell, bacterium and percolate will do great harm to human and surrounding areas,

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_47,

threatening people's life and health. As a result, the problems of landfill sites have become a tough issue over recent years.

High-temperature composting

Household waste when giving enough heat, they can be made into fertilizer, which can be used in agriculture. It indeed is a good way to dispose waste and realize recycle at the same time. But this method also has some inextricable problems. When household waste is made into fertilizer, it must be provided with enough heat, of which the process is difficult to control. It is the temperature that prompting this fermentation process. But usually the temperature is too hard to control and how to test the most suitable temperature is also a big question. Even if the temperature is suitable for fermentation, there is still one question left unsolved, that is low efficiency of fertilizer. Once the efficiency is very low, it cannot be easy to use in agriculture. Besides, how to fix a price is also a problem.

Incineration

Nowadays incineration seems to be the most effective way to handle waste disposal problems on one hand, and on the other hand, realizing the goal of recycle.

The merit of saving a lot of places is the most apparent and most remarkable one. By incineration, the average volume is greatly reduced. According to statistics, after incineration process, the reduction of volume is about 80% comparing to previous one[2]. Consequently, a landfill sites designed for 10 years' longevity can prolong its lifetime into 80 years. This is a very excited method when considering waste disposal. At the time of saving places, this method also will decrease the virus quantity of waste. What's more, heat energy released during incineration process is perfectly fit for generating electricity. This form of electricity generating way is considered to be pollution-free, high efficiency, environmental friendly, clean and sustainable approach.

As to the demerits, it is quite apparent—cost. Compared with domestic waste disposal method, incineration seems to be a little bit high than them, probably about 150 RMB/ton, almost 3 times than that of land filling. The second is CO_2 emission, which is much higher than land filling.

2.2 Solutions of waste disposal and recycle technologies in Japan

According to Japan's Waste disposal Law (enacted in 1970 and revised in1991), in Japan waste is defined as that "Waste is stuff that human needn't, usually is exited in the form of solid and liquid (Radiation substances are excluded in this definition.)" Waste in Japan can be divided into two main categories, common waste and industrial waste. Common waste is some household waste and office waste; industrial waste is usually very large, for example, things like construction waste, electric waste, household appliances and something existed during industrial processes all belong to this category.

Currently, Japan did very well in waste disposal and recycle. Most of the times, recycling plants have exceeded government in recycling rate, and qualifying rate. Under the background of CO_2 reduction, many plants are taking this into consideration when doing recycle. So, coming to the problem of CO_2 reduction rate, near every plant will save a lot of energy, achieving reduction quantity and rate.[3] In Japan, waste disposal and recycle are made according to their categories. Different kinds of waste have a different disposal way for recycle.

Electric waste

As we all know, electric waste are different from other waste in compositions and in contents that restored in them. First, Electric parts are made by Al, Fe, Ti, Zn, Pb and etc, which are hard to degrade in natural environment. On the other hand, these materials will cause serious problems to human health. If left uncontrolled, they will become hazardous waste as well. As a result, all electric waste disposal and recycle plants are trying to refine metals from electric waste, and strive to make them more and more purified. Second, electric parts are usually computer accessories, such as hardware, software, main board or other kinds of data storage parts, so electric waste themselves are not only metals, but also face the problems of information security. Out of safety reasons, all plants should have permits in order to dispose electric waste, and the acquirements of these permits are also selected one in a hundred.

Construction waste

Construction waste is certain kinds of waste, such as large stones, cartons, packaging bags, ropes, plastic substances and something like that. One of apparent characteristic of construction waste is non-flammability. In most plants, after manual sorting, construction waste will be put into shatters, grinding and finally, be made into plaster.

Household appliances waste

Household appliances waste usually contains 4 pieces: refrigerators, TVs, air-conditionings and washing machines. Compared with other kinds of waste, household appliances also have some points which differ from other waste. That lies in component parts. Household appliances usually composed of plastic casing, kinescope, electric lines, metals and glasses as well. As a result, the first step of disposal is to disintegrate them according to categories, after that, different kinds of waste will be disposed separately.

Household waste

Household waste usually means living waste, which is related with everyone's daily life, such as food waste, plastic bags, waste paper, cottons and something like that. According to the law, household waste can be divided into two categories, one is flammable, and the other one is inflammable. Flammable waste will be incinerated, and heat can be used to generate electricity. Inflammable waste can also be shattered and made into other products, so as to realize recycle.

3 COMPARISON AND ANALYSIS BETWEEN CHINA AND JAPAN IN WASTE DISPOSAL AND RECYCLE

China and Japan, two large countries in Asia and the world, have different national conditions, such as different policies, different cultures and history; as a result, they share many in common and have many differences too. Considering comparisons in waste disposal and recycle, there are mainly 4 similarities and differences, and they are listed as follows.

3.1 Law

Similarities

a.Legislation: Both China and Japan are sharing the same legislature. The laws are made by national government and have highest potency comparing with other regulations.

b.Management: Two countries' management is nearly the same, which is "Up-to-bottom". By this way, government saves many time and energy in coping with different benefit groups, which is significantly different from that of western countries.

Differences

a.Contents: (1) Comparing with Japan, China's waste disposal and recycle laws are just in its beginning stage, which are either comprehensive or practical. While on the other hand, Japan's waste disposal and recycle system is mature enough, that one can easily find what they want in the law system. (2) Two countries' waste disposal and recycle law systems have different focuses. In China, the laws are mainly focusing on policies, while in Japan, laws are more related to practices. (3) Considering the objects, differences also exist. Japanese waste disposal laws not only provide legal basis for government, but also regulate corporations and public. While Chinese waste disposal laws mainly concentrate on the former.

b.Maneuverability: Japanese waste disposal and recycle laws are easy for people and corporations to follow, while Chinese laws are difficult to understand, let alone practice.

c.Regulation and punishment: Japanese laws are very restricted, as a result, under this law system, there are very little people crossing the law. However, the punishments in Chinese laws are a little bit weak, so that it seems a little common for people to obey the laws.

3.2 Definitions/ Classifications

Similarities

The same place is that whatever China or Japan, the definitions of waste are in accordance with law. So it is the law that regulates definition as well as classification.

Differences

In China, waste is a certain kind of substance that comes from daily life, industrial production and other ways, and it can be divided into 3 categories, industrial waste, municipal waste and hazardous waste. Right now, large number of municipal waste and small portion of industrial waste is disposed. While in Japan, wastes are mainly two categories, one is industrial waste, the other one is common waste. Industrial waste can be divided into construction waste, electric waste, household appliances waste and food waste in supermarket. Common waste is daily life waste and small number of office waste. Moreover, in Japan, all kinds of waste can be disposed and recycled.

3.3 Economic situations

Similarities

Though China and Japan, one is developing country, the other is developed, but considering GDP issue, they are almost the same. Moreover, two countries are all on the road of rapid development, and more or less, they have the ability to put enough money to handle waste problems.[5]

Differences

a.GDP: Same GDP, but different population triggers the differences in waste disposal and recycle. Japan's per capital GDP is much higher than that of China, and as a result, Japan has more money to handle waste disposal and recycle problems. That's why in China, only household waste can be well treated.

b.Cost: The costs of China and Japan in waste disposal and recycling have large differences. In China, average cost of waste disposal is around 1300 Yen/ton, while in Japan, it is about 7000 Yen/ton, 6 times higher than that of China.

3.4 Public awareness

Similarities

Environmental education seems more and more important in both China and Japan. Nowadays, people are willing to learn about environmental protection methods, and are getting used to environmental protection behaviors.

Differences

Japan's environmental education started much earlier than China, consequently, Japanese nowadays have already formed the good habits of protecting environment, which in China environmental education is just at its infancy stage. For example, in the last food waste disposal supermarket, I saw a lady put all of used plastic packages into supermarket's trash box, and all of the packages have been washed and dried, which is nearly impossible in today's China. However, after several years' environmental education, I'm confident that public awareness toward environmental protection will be raised.

3.5 SWOT analysis between China and Japan

SWOT stands for Strengths, Weaknesses, Opportunities and Threats. This analyzing method is specifically designed for enterprises. It mainly adopted to analyze a company's competing Strengths, Weaknesses, opportunities and threats. And perfectly linked a company's inner and outer resources, and is very useful for a company's future development. As a result, SWOT analysis can perfectly suit for waste disposal and recycle plants[4].

Strengthen

China: (a) Low cost. Compared with Japan, the cost of waste disposal and recycle is much lower and cheaper. This can be explained by cheap manual power, low price of raw materials and products. (b) Large areas. Considering the issue of waste disposal and recycle, large areas means low requirements of treatment technologies and not very strict assortment procedures. (c) Up-down system. China's political system belongs to the "Up-to-Bottom" system, so it's easier for government to make comprehensive management over waste disposal and recycle issues, meanwhile, it's also a way to save time, money and energy.

Japan: (a) Mature law system. Japan has a very comprehensive system of waste disposal and recycling, every process in this system is in accordance with laws, so it is pretty easier for companies and people to follow. (b) CSR. Japanese companies to some extent, has a higher responsibilities, so that government doesn't need to spend time and money persuading corporations to follow recycling laws or regulations. (c) Technology innovation. There's no doubt that Japan's technology is always ranking first three places in the world, especially in electric products and humanize design. The products or production lines maintain both high efficiency and low energy consumption. (d) Public participation. After many years' education and practices, Japanese people nowadays have already formed environmental protection awareness.

Weakness

China: (a) low recycle standard. Considering overall situation in China, nowadays' waste disposal and recycle process is not modern and advanced enough, so the recycle rate is much lower when comparing with Japan's. (b) Recycle products are things like tiles, even can't meet intermediate standards. (c) Smell control problem. (d) Small quantity. Right now, there are very limited numbers of disposal plants using incineration way to handle waste problem.

Japan: (a) Cost. In Japan, the cost for disposing 1 tons household waste is about 7000 yen. And in almost every disposal companies, manual operation cannot be replaced by mechanical operation. Because in every kinds of waste, there is too much other waste, mixed together, as a result, very difficult to pick out, the corporations themselves have no choice but to hire more people. (b) End products. In almost every corporation, the end products are very simple and lacking varieties, such as raw metals, Al, Fe, Zn, Pb, and Cu, much cheaper than processing materials.

Opportunity

China: (a) further treatment over waste disposal and recycle. There's a big market in China waiting to be discovered. This also means we can further contracting the volume and mass of waste products, further reducing threats brought forward, further improving our environment and further enriching our end products. (b) On the basis of previous, our country can develop its trade with other fields or other countries. (c) Prompting technological innovation and scientific researches.

Japan: (a) Cost reduction. Cost is too high in Japan. Companies can do something to cut their cost, as previously mentioned, cost is too high in Japan. (b) Diversity of products. Because at present, the products of recycling are very simple, only some raw materials like Al, Fe, Zn, something like that. Raw materials are usually very cheap, maybe they can be made into some other end products.

Threat

China: (a) Limited land resources. Nowadays in China, due to rare land, the price of purchasing land or house is very high. If the situation continues, it's hard to image or expect that over 10 years, when there's no other land for land filling, what we should do to deal with our waste, and how high it is our housing price will be. (b) Limits in technology. Nearly all kinds of waste disposal and recycle plants are using Japanese or European's technology, so it will constrain our country's own development.

Japan: (a) High cost, low benefit will bring many threats to a company. (b) Too much emphasizing on recycling. As a matter of fact, recycling is not everything; it is only a way to solve waste, at the same time enhancing recycling rate. However, Japanese corporations pay too much attention on waste disposal and recycle, which is of course not the core essence; as far as I am concerned, trying to improve environmental design is a better choice.

4 BETTER SUGGESTIONS TO INTERNATIONAL RESOURCE RECYCLING

4.1 Policymaking system

In light of the fact that China's law system of waste disposal and recycle is not mature and comprehensive, the top priority for Chinese government should be legislation. By setting up various laws and enriching whole law systems, all levels of governments, corporations and individuals can restrict themselves in accordance with laws.

Meanwhile, internationally, all countries should work together to establish new law systems specifically for resources recycling. Modern countries have the rights and responsibilities to provide support to developing countries. By these efforts, global society can strive a balance between international resources recycling and economic development.

4.2 Environmental standard system

Over the international world, there are no other countries can advocate that the criteria system in their own country is complete and perfect, as a result, the first step is completing criteria system so as to maintain the resources recycling within the country safety and in good condition. Meanwhile, global world should work together to set up a whole system of ccriteria to evaluate and set restrictions to regulate their behavior, so as to better promote global resources recycling.

4.3 Industrial structures optimization

There's no doubt that developed countries do better than developing countries in their industrial structures optimization process. Since international resources recycling need input and output chains, global world should pay special attention to provent pollution industry shift, which will definitely do harm to developing countries. In view of present situations, international world should strengthen this industrial chain, protecting the rights of the weak parties.

4.4 Technological innovation and cooperation

Since policies are difficult to establish and be revised, maybe corporations can do something to update their disposal machines and production lines so as to increase profits. And also through cooperation with other countries, the corporations themselves will sure benefit. Meanwhile, global world should encourage the innovation of technology, and work in cooperately to handle and conquer difficulties. While developing countries, should make sure of technological patents, so as to make international technological transfer unimpeded and smoothly.

4.5 Environmental education

It is quite true that public environmental awareness in developed countries have nothing to blame, while, in developing countries, it is in need effort to enlarge and upgrade public awareness toward environment. This kind of education should exist not only in nature environment, but also in daily life as well. For example, from daily garbage classification to resources saving, from protecting water resources to full use of resources. By these approaches, environmental friendly society can be shaped and prolonged.

5 CONCLUSIONS

a) Due to different national conditions, law systems and economic situations between China and Japan, there are separated ways of waste disposal and recycle.

b) Waste disposal and recycle should meet the needs of a country's development. Recycling only for recycle cannot be a good choice.

c) Considering the issue of waste disposal and recycle, technological innovation should always be put into effect.

d) International cooperation will act as stipules in technological innovation.

e) As for international resources recycling, substantial suggestions have been made in order to promote this process.

Post-Modern Engineering Science: Current Trends and Shortcomings of IT use in Knowledge Generation

Harald E. Otto
Department of Mechanical Engineering, Università Politecnica della Marche, Ancona, Italy

Abstract
Traditional ways of producing knowledge, solving problems, conducting business and making policies are undergoing a drastic change in both theory and practice. Major driving forces providing a multi-dimensional impetus for such a change stem from the post-modernism movement, newly shaped scientific paradigms, rapidly developing scientific instruments and technology, and the concept of sustainability. Despite this development, work on the role and impact of information technology on knowledge generation and concomitants influencing the way research is conducted has been quite neglected. In this paper the potential and shortcomings of current trends in knowledge generation based on data-intensive scientific discovery are analyzed and discussed.

Keywords:
engineering knowledge, know-how, simulation modeling, computational discovery, data mining

1 INTRODUCTION

Current forms of post-modern knowledge production feature a problem-solving methodology, in contrast with modern science, which is influenced mostly by the approaches and methods of empiricism and logical positivism. This problem-solving methodology is much broader and can be placed in an interdisciplinary social and economic context. Here, knowledge is acquired in a more exploratory way in the context of application, providing a strong problem-driven and practice-oriented approach. Various actors and stakeholders from different disciplines and fields of expertise provide a participative mode of knowledge production within a heterogeneous network that extends to various locations beyond the limits of the familiar and traditional institutions of higher education and research. Within this scenario, scientific activity becomes increasingly interrelated with and dependent on data provided by instruments and their proper analysis and interpretation. Here, advanced information technology (IT) in the form of computing machinery, software, and networks represents a key technology, which today is employed in every science and engineering field and discipline.

The remainder of the paper proceeds as follows. In section 2 the nature of engineering science and technological knowledge is briefly discussed. Section 3 provides some background on work in data-driven scientific discovery. In section 4 the trends and shortcomings of current approaches are presented and discussed, and these are summarized in the final section.

2 ENGINEERING SCIENCE AND KNOWLEDGE

2.1 The nature of science

Engineering science, either as an activity to generate engineering/technological knowledge or as a body of knowledge in itself, is different in nature from other sciences, though it also contains some elements to be found in most scientific disciplines. Perhaps its pragmatic orientation is what makes engineering science different from other sciences. Engineering science aims at generating knowledge and technology to modify the real world according to our needs, while other sciences seek knowledge about reality as it was and as it is. Since engineering knowledge is generated with the goal of producing an artifact or service aimed at serving a predetermined purpose, the pre-conditions of the problem-solving process are different from those in other scientific disciplines. In engineering science, problem solving is usually a task-oriented process, which has a defined beginning point and a specific goal. However, in other sciences, whether they be, for example, social science, life science, or natural science, scientific research has no such defined points, telling us exactly where to start and what to investigate. Although the problem-solving aspect in itself is in many cases not characteristically different in engineering science from that in other sciences, the termination criterion surely is. In the case of the former, problem solving ends when an acceptable solution, being verified and tested, is found. However, in the case of the latter, research continues by asking ever deeper-reaching questions, either to unearth further knowledge to increase

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_48,

insight and understanding of the subject of investigation or to find an example to falsify a current hypothesis or theory.

2.2 The nature of knowledge

Since both engineering science and engineering practice are strongly bound to technology and applications which need to work with as well as in the complex concrete reality encountered in the real world, the knowledge itself is different from that in other sciences, even though it also comprises concepts that have been derived from other sciences (cf. [1]). Hence, engineering is not just a form of applied natural science, as suggested in [2] and popularized in the 1960s and 1970s in philosophy and science and technology policy making. Due to its pragmatic orientation, knowledge in engineering science is usually more specific, being related to particular situations of application that cannot automatically and easily be transferred to other situations or even generalized. On the other hand, knowledge in other sciences, for example life science or natural science, tends to be universal, i.e. theories and models provide the same contents and outcome, independent of any particular situation or context. Engineering knowledge, sometimes used synonymously with technological knowledge in the literature, represents a body of different kinds of knowledge, with some not to be found in other scientific knowledge. Technical skills and knowledge about how artifacts or processes are to be operated and how they function, in the literature referred to as *know-how* (for original early work see [3,4]), are such examples. Note that this sort of knowledge is inculcated in the sense that one is able to supplement and perfect partial know-how and remedy misunderstandings, a typical exercise in developing competence. Engineers also possess knowledge about norms, i.e. know the character and properties of functions related to artifacts and processes. Normative knowledge, which can handle propositions about, for example, effectiveness and efficiency, is unable to deal with assertions of truth, and thus does not exist in other scientific disciplines. Knowledge represented in graphical forms such as diagrams, sketches and drawings, sometimes referred to as *visual knowledge* (cf. discussions in [5]), also represents a typical part of engineering knowledge. Declarative and procedural knowledge in the form of numerical data, formulae, and other formal or informal notations, in the literature also referred to as *knowing-that* and *propositional knowledge*, can be found across all academic disciplines from engineering and science to humanities and economics. Perhaps it should be noted here that this sort of knowledge is imported in nature, i.e. one knows that or not, in contrast to know-how, where individual subjects of knowledge and skills are usually in certain stages of development. The discussion above has outlined some characteristics of engineering knowledge, though it did not provide any specific details on its contents, which would go beyond the scope of this brief introduction. However, an overview and better understanding on this issue can be obtained by studying the taxonomies and critical comments given in [6,7,8].

3 DATA-INTENSIVE KNOWLEDGE DISCOVERY

Considering science as a problem-solving activity, knowledge can be generated by means of searching a space of possible solutions. Nowadays, vast amounts of data are available from different sources ranging from sensors that provide extensive environmental data throughout the year to immense data collections, sometimes in the range of petabytes, obtained through complex simulations and experiments. When these are combined with an advanced IT infrastructure, in most if not all scientific and engineering disciplines only semi-automatic data analysis and information representation approaches are feasible. Those approaches, which use computational tools, can be divided roughly into two groups, namely digital modeling/simulation and computational scientific discovery, and data intensive approaches referred to as knowledge discovery in databases (KDD).

3.1 Digital modeling and computational discovery

Employing models to either develop or test hypotheses, theories or designs is a common approach used in any science. Models created for this purpose are always an approximation of the real world representing a pre-defined set of properties of an artifact, process or phenomenon. However, models can also serve as a representation of events and things that are contrived. Particularly in engineering science, it is sometimes quite difficult to strike a balance between idealizing and abstracting as used in modeling and the need to produce concrete knowledge to solve a problem related to some application in the real world. Modeling always involves analogies in that a model is analogous to reality in only certain aspects. Different types of analogies relating to properties such as shape, structure and function are employed to create different types of models having a physical, graphical or notational (mathematical/logical) nature. To improve efficiency and reduce the time required to produce a physical or graphical model, especially in engineering science, various sub-disciplines, such as rapid prototyping and computer-aided drawing, evolved along with advances in technology. With advances in both computer technology and software engineering and the increasing need to quickly produce models that could easily be interrogated, analyzed and modified, and could grow in complexity as rapidly as the complexity of problems in post-modern science and engineering was growing, notational models translated into programs and implemented in digital form on computers gained in popularity on a scale unprecedented in history. Since mathematical models quickly tend to become quite complex, analytical solutions presenting precise mathematical proof are of limited use. Hence, approaches to solving the equations used in notational models have to resort to numerical methods, with the understanding that errors and uncertainty are almost always present in such numerically obtained solutions. This situation has led to computer simulation, or what is nowadays also referred to as *simulation modeling* or *modeling and simulation*. An overview of basic principles, individual process steps as related to design, implementation, execution, and verification/analysis of the digital model, including views from current practice, are given in [9,10].

The approach of computational discovery aims at producing knowledge that is in a standard scientific structure and notation such as reaction pathways, structural models and numeric equations [11]. This approach is somewhat complementary to the approach of knowledge discovery in databases, where, depending on the technique employed, either descriptive or predictive models are generated in the form of rule sets, decision trees or neural networks. Although knowledge discovery is not very communicable, computational discovery, on the other hand, seems to be capable of overcoming many hurdles in the communication of knowledge in various scientific and engineering disciplines. Work on computational discovery aims basically to design and develop computer systems that are capable of producing scientific discoveries similar in nature to those made by human scientists. Since science is a remarkably complex intellectual endeavor, with discovery being perhaps the most creative part, efforts to automate it even partially seem audacious and far-fetched at first. However, by approaching this goal through a heuristic search while focusing on small, well-defined tasks, some initial progress could be made, as suggested in early work in the 1960s [12]. Research based on this approach translated in the 1970s and 1980s into computer software [13,14], which was based on data-driven induction of descriptive laws. At that time, employing those first computer programs in experimental work on historical examples provided not only promising results, but the first compelling evidence that computational scientific discovery is possible. Recent examples of progress in this field, including the establishment of models of dynamic systems based on ordinary differential equations, the automated discovery of quantitative laws (expressed in the form of equations) in collections of measured data, and the formulation of equation-based models and laws from observed data, are presented in [15]. Computational scientific knowledge discovery is still in its infancy, with work in progress and successful applications in practice lagging far behind other approaches such as data mining, discussed elsewhere in this paper. Nevertheless, the work and results in this field are a valuable contribution to the ongoing and rapidly growing body of research on computational tools and techniques for post-modern technology- and data-driven knowledge discovery.

3.2 Knowledge discovery in databases

The methods and techniques developed and applied in KDD are aimed at making sense of data sets and, considering the rapidly growing volumes of data being collected and stored digitally, it is preferable to target huge data sets. Classical methods of data analysis in science and engineering are no longer either practical or feasible, since they involve the use of statistics for manual probing of the data by individual domain experts quite familiar with that data. A drastic scale-up of human analysis capabilities by utilizing information technology is what is required to deal with the data overload generated by today's advanced technology. Although the basic methods and techniques developed in KDD are related to research in artificial intelligence, pattern recognition and machine learning and are used for such problems as summarization (high level viewing of a data set), prediction (regression) and classification (discovery) of patterns in data, they are similar in nature to those in statistics. However, techniques such as neural networks and decision trees, used in the inference process, tend to be more robust to noise and uncertainty in data, while at the same time less dependent on analysis skills and the subjectivity of individual domain experts. However, basic issues regarding clean and consistent data, well-defined analysis targets and prevention of data/model overfitting are as important for data mining as they are for classical statistics if one is to generate robust and sound results. Knowledge discovery in databases is an interactive and iterative process involving numerous steps ranging from data cleaning and pre-processing, through data reduction, selection of particular data mining methods, and determination of model and hypothesis employed in the exploratory analysis, to the interpretation of mined patterns and translation into knowledge [16]. Results from the actual data mining step within KDD depend on the method and model selected and can be represented, for example, as decision trees, classification rules or networks. Perhaps the last mentioned are the most difficult to interpret due to their hidden internal nodes and their complex models being captured by link weights. On the other hand, in the case of decision trees, rules can be translated into any natural language, such as English, to explain why a prediction was made for a particular entity. An overview and more details on classic and advanced methods and techniques of KDD can be found in [17]. Early work on KDD evolved with a highly interdisciplinary nature because of the intersecting research fields involved, such as knowledge acquisition from expert systems, pattern recognition, machine learning, database systems, data visualization, and statistics, to name but the most prominent. An overview on research issues and applications in science-related data mining in the 1990s is given in [18]. KDD is comprised of a set of individual processes developed into a methodology aimed at covering the entire process of massive data-based knowledge discovery ranging from how data is stored and accessed to models and algorithms that can be scaled to datasets ranging in size from terabytes to petabytes, thus encompassing methods and techniques reaching beyond the scope of their disciplines of origin. Progress made in KDD, in particular methods and techniques for data mining which have resulted in next-generation data mining systems covering various application fields including natural science, engineering science, social science, finance, and medicine, are discussed in [19].

4 DEVELOPMENT IN THEORY AND PRACTICE

It is the nature of engineering knowledge that it is technology-related, application-oriented and a problem-solving process. Engineering is itself strongly biased towards solutions that are not only feasible in practice, but also effective, and wherever possible efficient as well, in contrast to, for example, natural science, where problem-solving is more problem-centered. Therefore, discussions in the following focus on three particular directions, namely approach-, technology-, and application-related issues.

4.1 Approach-related issues

Some of the shortcomings, which still prevail in data-centric approaches to knowledge discovery can be attributed to the way in which data, with their values and properties, are abstracted and formalized. In our lifeworld (cf. [20]), concepts are formed by the human mind, while reflection upon the environment is subject to experience through the human senses. In science and engineering, concepts can be seen as epistemic capacities, or as cognitive or abstract units of meaning that can be used in the development and testing of hypotheses and theories. In digital models and sets of data stored in information systems, in most cases data entities and their relationships are structured using concepts within a system of categories forming an ontology, which acts as a kind of formal explicit specification of knowledge representation related to a particular domain. As post-modern problem solving demands interdisciplinary and multidisciplinary solutions to problems with ever-increasing complexity, data entities of databases, data repositories, and data warehouses from different domains and disciplines need to be considered and analyzed. However, data modeling and value definition are strongly domain specific, so misunderstandings and misinterpretations arise if systems and experts have to deal with data sets which are not within their domain and expertise respectively. Such problems mainly occur due to misunderstandings regarding entity value semantics and concept/category relationships. For example, in the case of the former, the property of being easily set on fire might be related to the term *flammable* in one domain, while within another domain the term *inflammable* might be used instead. This is a situation which, at the current level of system development, can be remedied only by human intervention. The latter, though discussed in a philosophical rather than technical context, has been referred to as *category mistakes* [3] and is not addressed in practical approaches or in any available software system.

Another source of concept-related misinterpretation of data sets is the changing of data distribution characteristics, i.e. the instability of statistical properties of the target variable within a data set, to obtain a correct predictive model. This phenomenon is inherent in many data streams subject to analysis, though most prominently in those related to biological, socioeconomic, product life cycle, and environmental processes, and is commonly referred to as *concept drift*. Data streams, in contrast to traditional static databases and data warehouses, are comprised of an ordered sequence of entities that arrives in timely order. Due to the increasing interest in and availability of data streams both online and offline, this issue has received considerable attention in the research community in both academia and practice, with many solutions partially overcoming this problem for techniques and algorithms used in knowledge discovery and data mining. An overview and further details on basic and current approaches, such as periodic retraining, also known as model refreshing, weighted ensemble classifiers and cluster models, as well as sliding window based classification, to name but a few, are provided in [21,22]. Current international research in progress addressing approach-related issues regarding time-changing data streams to capture the dynamics of patterns, i.e. how they evolve, grow and decrease, seems to be promising. However, technology-related shortcomings such as parallel computation (in distributed systems) to keep the mining process up with the high-speed characteristics of the data streams, and frequent encounters of local low data storage and transmission capacity in current imbalanced IT infrastructures, still impose considerable limitations on those solutions.

4.2 Technology-related issues

Hardware-related technological shortcomings can be attributed to the increasing imbalance of IT infrastructures regarding the development of the capacity to generate, store and process data compared to the capacity to access and transfer data. Taking a brief look back some three decades from now, hard disk based storage capacity was in the range of 30 megabytes for a regular single device at around a quarter of a million dollars of cost for one gigabyte of storage capacity. Within only three decades, hard disk based storage capacity of single devices has increased in the magnitude of 10^5, while costs have dropped in the magnitude of 10^6. A similar trend has taken place with the development of computational capacity and control processing unit (CPU) technology. Compared to those feats in computation and storage technology, developments in interface standards and technology seem to pale. For example, even after three decades of innovation and development newly introduced standards such as the serial advanced technology attachment (SATA), are only able to support a data rate at 3 gigabits per second. With current trends in data-intensive scientific discovery utilizing data in the terabyte and petabyte range, access and exchange technology poses a severe bottleneck. Until technology in this field can catch up with developments and facilitate adequate data bandwidth, new strategies, such as bringing the processing and analysis to the data, need to be pursued as interim solutions.

One of the soft technology-related shortcomings which is still most prominent can be attributed to the representation of mining models. Since data mining models usually generate results which were previously unknown, it is important that they are represented in a form that facilitates understanding and trust in respect to the domain context, so that this information can in turn be translated by human experts into new domain knowledge. Considerable progress has been made in information visualization technology, providing interactive, multi-dimensional information displays where users not only view results dynamically, but also interact with the visualization in various ways. Thus, analysis and understanding of a wide range of mining models has been achieved. However, currently available KDD systems still do not take full advantage of advanced visualization technology, nor do they provide sufficient interfacing with other computer-aided data representation, analysis and decision tools.

4.3 Application-related issues

Current approaches such as simulation modeling, knowledge discovery and data mining are not only data-intensive, but also data-centric, due to the focus on their structure and values during the knowledge generation process. Accordingly, the quality of data is of utmost importance, though in research practice, when these approaches are applied, the scale and extent of this fact does not always seem to be taken into account fully. Data quality in the literature is usually related to attributes such as consistency, completeness, accuracy and precision, and timeliness [23]. However, aspects of data deficiencies related to their representation and interpretation still do not get the attention they deserve. In particular, data representation deficiency, seen as the difference between how an observer infers a view of a phenomenon from data provided by a system and the view that an observer obtains by directly observing the same phenomenon in our real world, is a problem in the case of technology-driven natural science and engineering science. This situation is in contrast to other disciplines, where, for example, socioeconomic phenomena can be observed almost directly without much necessity for the mediation of technology in the observation itself. Technology-mediated observations of phenomena (cf. [20]), or even technology-generated phenomena, contain considerable amounts of technology-related knowledge on how the observation was performed, i.e. how the data were generated. However, today, in almost all databases, data warehouses, and data streams, this sort of information, which is actually an important element of data quality, perhaps on a higher level than the data quality attributes outlined above, is not available. Of course, for the domain experts and data analysts who also created the data subject to knowledge discovery, a great deal of knowledge is available on how those data were created and which technologies and methods were employed. Hence, interpretation and proper selection of discovery and mining techniques, along with appropriate predictive models, can be employed to translate the endeavor of data-intensive knowledge discovery into a successful scientific activity. The trend to consider what is referred to in the literature as *data provenance* (see also [24]) is surely a step in the right direction, but it is still far from capturing all the information related to this 'how-knowledge' along with the data, and describing the context and conditions relating to how the data were generated, i.e. how the observation was executed, using what technological means and in which way. Perhaps this issue is a problem that should be considered within ontology engineering, a sub-field of knowledge engineering, where development, life cycles, and building the tools of ontologies are at the center of research (cf. [25]). This is in contrast with classical approaches to ontology, originating in metaphysics, which were concerned only with fundamental categories in regard to what exists in our natural world.

Another shortcoming, in particular of data mining models, is the fact that they can reveal connections between data entities and their attributes, but do not necessarily identify a causal relationship. In some applications this may be contributed to by so-called *latent variables*. As opposed to observable variables, latent variables relate to phenomena that are either abstract and not observable (hypothetical) or simply not explicitly present (hidden) in the data model. The latter case represents a typical example of the problem many applications are facing today, namely that the data sets subject to analysis were not designed for the purpose of data-centered knowledge discovery, and thus feature a data structure less appropriate for this type of inquiry.

5 SUMMARY

Current trends have been discussed, together with a selection of problems of an apparently perennial nature regarding major knowledge generation approaches in science and engineering that are moving toward being computational and data based. Due to the nature of engineering knowledge, discussions were sub-divided into approach-, technology- and application-related issues. The more science and engineering are embedded in technological infrastructure, especially that which is IT related, the more that infrastructure is likely to drive them. Indeed, work pursuing scientific and engineering understanding through the use of advanced computing technology, and involving vast amounts of data, is increasing dramatically. In fact, this tremendous impact of IT on theoretical and experimental research has even begun to cause signs interpreted as the rise of a fourth data-driven and data-intensive science paradigm. However, at the current level of development, this data-intensive scientific knowledge discovery should not be mistaken for an attempt to automate creative modeling and the synthesis of new domain knowledge. These highly intellectual capabilities of human experts are still far out of the reach of any computing machinery.

Creating Sustainable Emotional Value through Personalized Design

Yu-Shan Tseng (1)[1], Ming-Chyuan Ho (2)[1]
[1] National Yunlin University of Science and Technology

Abstract
In addition to visible sustainability issues like materials and alternative energies, the sustainable emotional value between consumers and products is also important in sustainable design. Products emotional value comes from the meaning products to consumers. Personalized products and personal emotion are closely related, so put forward to explore the personalized product design strategy to improve the consumers' emotional value to products. In this study, through related literature and case analysis, we conclude that sustainable design emphasizes the value creation of the design, which must be durable and amicable to the environment. Personalized commodities also create value, a kind of sustainable emotional value. From the standpoint of sustainable design, the higher the consumers' emotional value to products is, the longer the product's service life is, leading to a stronger intention to recycling and reuse.

Keywords:
Sustainable design, Personalized design, Emotional design

1 INTRODUCTION

In the past, we did mass manufactures, mass consumptions and also excessive wastes. Gradually, environmental protection and environmental sustainability issues had been highly discussed. We started to rethink what we can do to the damaged environment. So are thinking about how to make the earth healthy and sustainable regardless of in sociology, economics, environmental engineering or other fields. So, since the destruction is caused by human, we think it from human, from the point of design, to change consumers' concept to sustainability. By designing, we put sustainability into a force. If the product is perceived to be irreplaceable, other products in the market cannot convey a similar meaning to the owner. Replacing and disposing of such a product is thus perceived as a loss of its special meaning. As a result, the experience of attachment to a product is likely to last over time, resulting in product longevity (Mugge et al. 2005).

1.1 Research Background and Motivation

1.1 Paper title and authors

With each country's policy and consumers' attention to environmental issues, the society who did the mass production and mass consumption causing excess substances past has gradually realized the importance of environmental protection. From the concept of environmental protection, recyclable resources, production process and materials must not harm the earth ecosystem; alternatively, old things can be redesigned and reused through regeneration design; all these is one of the many aspects of sustainable design. So to promote sustainable design is an important trend in design community. In addition to visible sustainability issues like materials, alternative energies, the sustainable emotional value between consumers and products is also important in sustainable design. It is common among people that they will especially love and cherish certain commodities, for which, even if damaged, they would still unwilling to discard but will be willing to do the repair or to redesign for reuse. This is all because the goods have high emotional value to people. By improving consumers' emotional value, the products will emerge some kind of meaning to consumers and thus be more cherished and used and have prolonged life; or an old but meaningful item will be given a brand-new look.

1.2 Research Purpose

Personalized design start from consumers' demand, different from the products mass manufactured. To consumers, personalized design meets their psychological needs of pursuing being distinctive and unique, so as to demonstrate their personal style and taste. It takes "difference design" strategy, personalized products designed through which not only have functions meeting different customers' needs, but also satisfy consumers' wish to create their self images and taste through products. Therefore, if the personalized merchandise appeals consumers to have emotional causes, the emotional value of products will be enhanced.

The purposes of this study: 1. Discussion on personalized design and how to enhance the emotional value of products. 2. The increase of the emotional value will influence consumers' sustainable practices.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,

2 RELATED LITERATURE

2.1 The value of personalized design

In the past age of the mass production, products satisfy consumers' pursuit of "excellent quality and reasonable price" by means of low cost and considerable quantities. But in this era of the ever-growing individual consciousness, the pursuit of consumers is out of the ordinary goods. For them, to meet the self realization of personalized products is unique. The mass production of the sense of value is far lower than the customized product. According to theory of hierarchy of needs proposed by Maslow in 1970, human demand level is divided into five levels. Once basic physiological needs are met, people will continue to pursue to a higher-level demand. Similarly, after consumers' basic needs are satisfied by mass production of goods, a higher hierarchy of needs will be pursued and product development and production mode must change according to market demands. From current limited design goods or tailor-made goods emerging in consumptive market, it can also be seen that belongingness needs, esteem needs and self-actualization needs increase as economic ability and social status enhance.

As shown in Figure 1, positioning of personalized design is obvious after comparing Maslow's hierarchy of needs theory and Hancock's hierarchy of ergonomics needs with transformation mode of manufacturing. So, value of personalized product lies in its uniqueness that is different from mass-manufactured goods. After understand consumers' demands through communicating with them, designers can design the goods to meet consumer expectations, such as specific function, modeling, image..... Nowadays, customers not just pursue product function and aesthetic feeling, but the more important is to convey their self image. People utilize various ways such as: clothes, food, cars or entertainment style to create the image of who they are and their unique features. These external materials preferred by consumers can reflect their self image, personality and taste, and personalized merchandise is in response to this trend. Personalized design takes strategy of differentiation design, because when spiritual need rather than mass production is pursued, products should be able to express consumers' unique tastes, preferences and personality in addition to having functionality. Therefore, personalized design has its value and a position in the market.

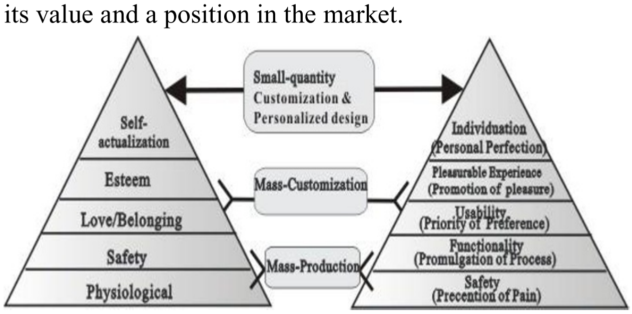

Fig. 1: Production mode

2.2 Emotional Design

Human emotion is the most abundant, including happiness, anger, grief, joy and other mental activities. Emotion has its particularity and presents different personal traits. Integration of emotions into products can improve product difference. As Normand (2005) said, emotional value is a valuable target in terms of product design. Excellence in design is about more than the product itself is. It is about creating positive, rich and meaningful user experiences. Consumers are ever mindful that the products we surround ourselves with and engage with during our daily tasks need to satisfy needs beyond the functional (Deana McDonough a; Howard Denton B; Jonathan Chapman, 2009).

Modern product design is also an activity about emotion activity, and an emotional design process, rather than the development of early simple appearance modeling process. With the wealth of material, and the ever-accelerating pace of life, people's demand on spiritual satisfaction becomes more pressing; people's requirement of product is no longer only on the material surface, but deep emotional appeal is more important. Emotional design language or design elements should make people feel, well, so will stick, and resonance also arises spontaneously.

2.3 Personalized Design, Sustainable Design and Consumption

Sustainable design takes into account environmental, economic and social impacts enacted throughout the product (Bhamra, Lofthouse.2007). So when product development model for groups gradually converts into personalized design mode, the product manufacturing processes have also been changed. Mass-manufactured products are lack of affection, because they are readily available. Therefore, such products have shorter life cycles and are eliminated quickly. The application of sustainable design strategies can greatly reduce lifecycle impact (Lewis et al., 2001). The designer's role is to head to the sustainable design thinking to shape consumer behavior to make it towards the sustainable direction. In addition, in terms of consumer behavior, mass production and mass consumption in past cheap-supply market generates too many disposable products, which bring burden to environment and threats to human safety. So, in policies calling for being environment friendly, the appeal of "sustainable consumption" is also important. User Consumption has been a long-standing concern for sustainability (Ann Thrope, 2010). The concept of sustainable consumption emphasizes that individual, corporate, government, and other units should be responsible to consider the future as a life or the existence way owned by people now; humans and other species should share ecological resources to survive and ensure that people's needs will be met both at present and in the future.

Stewart Walker(2006) said in "Sustainable by Design": product design should not value dazzling appearance and continuous replacement; it is better to focus on product performance that can be used for many years and make consumers have more time to feel the inner spirit of the product. Product personalization is an interesting strategy to stimulate long-lived product attachment and, thereby, contribute to a sustainable society, because consumers may perceive the personalized product as irreplaceable. So, personalized design is to enhance value and significance of product in consumers' minds. When the item is unusable, consumer will wish to recycle and re-create product value. Thus, consumers not only change

3 DISCUSSION OF DESIGN CASES

Taking a look at the concept of the sustainable design, we can find a lot of practical design cases. Some designers collect the recyclable materials, transform them and then sell them, while some other designers are entrusted to design and transform. For example, in the year 2009, an activity named "You bring it, we pimpin it" was held by a group of Dutch designers in Hong Kong. "Pimpin" means "beautification" in Dutch, so a lot of people brought the things that is meaningful to them for transformation. Turning the old objects totally into new ones is not only relevant to the environmental-friendly issue, but also helps those old things find a new place in the hearts of their original owners.

Table 1 :Redesign and Reuse Cases

Objects	Why to redesign ?
	1.The cups that are stored up for long and seldom used. While the owner is unwilling to discard them, so they are transformed into lighting decoration.
	2.「Wool Filler」Wool Filler's favorite sweater is worn but he is reluctant to throw it away, so he has the designer to redesign it.
	3.Empty bottles are usually used as vases. Why not change the stereotype to make it a lamp.
	4.This pair of wooden duck is a wedding souvenir. Because there are a lot of damages, the designer transformed it into a pair of door stops. This transformation not only retains the object, but also makes it more functional. (www.fangstudio.com)
	5.The owner's old pictures and files are already dead with the computer in its hard drive. However, the designer decorated the hard drive with glossy materials and makes it look like a book, which means the reunion of him or her with the memories. (www.fangstudio.com)
	6.The iron chair, even though is old and broken, but being used for years, the owner still cannot bear to discard it. Being transformed, it is more comfortable to sit on with a cushion. The old stuff is given a brand-new look and can be used longer. (www.fangstudio.com)

4 GENERAL DISCUSSION

This study observed and analyzed the current transformation and redesign of the products and found that many people are willing to transform their old products. And this willingness of re-use is caused by the emotional link with the products. So to prolong the life cycle by enhancing the sustainable emotion link from the customer to the products, we recommend these psychological impacting suggestions:

(1) Personalized design strategies

The use of personalized design has a high sentimental value to the consumers. This method, by customizing appropriately seizes the sentiment level of the consumer mentality. When thinking of the personalized design strategies, the customers past experiences can be taken into consideration on the one hand, because one's past memories and experiences are the most distinguishing differences. On the other hand, you can also start from one's five senses, which is disparate from person to person. For example, the familiar colors, sound, smell, texture and so on, can all serve to promote the customers' sentimental value so as to prolong the products' life cycle and further raise up its added value.(Fig.2)

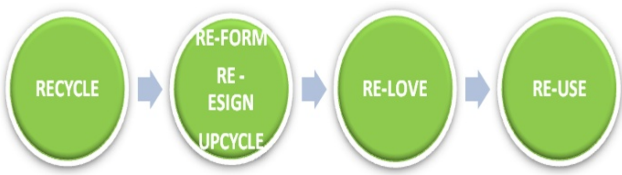

Fig. 2 : The lifecycle of Personalized design products

(2) Customer Co-Design:

Companies become interested in moving from mass-orientation to an individualization of offerings. A promising strategy is to offer consumers a role in the product development process through product personalization (Ruth Mugge, Jan P.L. Schoormans, Hendrik N.J. Schifferstein, 2009).The most intimate objects are the ones that we made by ourselves (Norman, 2005). There are a lot of ways for the consumer involvement in the design: offer of the idea for the design or do it yourself. What we are talking about here is the offer of the concept, the story, and the memory and so on. By communicating with the designer, a personalized product is accomplished. For the consumers, the involvement in the design itself is already a satisfaction of self-fulfillment. As a whole, the consumer participation is needed in the personalized design; the extent of the consumer involvement (like the provision of the information) will affect the degree of the product personalization.

5 CONCLUSIONS AND SUGGESTIONS

Since all designs will have an impact on the environment from the design phase, we should apply recyclable materials and consider how to prolong the products' life cycle in designing to reduce wastage of the resources. Therefore, promoting the sentimental value is one of the sustainable designs. Nowadays, the consumers turn from intelligent consumption to perceptual consumption, their subjectivity become stronger and the demands for the products are varied, differentiated and personalized, so their patterns of consumption are controlled by their emotional feelings. Therefore, from the perspective of the emotional value, the personalized design strives to make meaning of the products to their owners. This strategy is to promote the emotional value of the products, make the consumers love their products and improve the situation of ecological damages caused by the bad habit of wasting. The promotion of the sentimental value arouses the interests of consumers' future "redesign" and "re-use" to achieve the value creation emphasized by the sustainable design. Truly living sustainably and develop sustainably on this beautiful planet. This study suggests that an emotional magnitude of value should be made in the future so as to test the factors that affect the intensity of emotional value. It is already put into use in the personalized design and promotes the sustainability of the products' emotional value.

A consumption based LCA tool for housing management

Riikka Kyrö (1)[1], Jukka Heinonen (2)[1], Seppo Junnila (3)[1]
[1] Aalto University School of Engineering, Helsinki, Finland

Abstract
The housing sector accounts for roughly 30% of the total annual energy consumption in the developed nations. Notwithstanding, sustainable housing management has not received sufficient attention previously, even though the role of housing managers can be considered significant in reducing the energy consumption of existing residential buildings. This study proposes a concept for a comprehensive and consumption based carbon management tool for professional housing managers. The tool employs a tiered hybrid life cycle assessment approach to evaluate all emissions derived from housing company activities. This paper explores the attitudes and ideas of the housing managers themselves. Based on the interviews, it appears the managers and their clients would benefit from the easy-to-use, quick and non-labor or data intensive tool.

Keywords: housing management, IO-LCA, energy consumption, greenhouse gas (GHG) emissions

1 INTRODUCTION

The built environment accounts for roughly 40% of the total annual energy consumption in the developed nations. Furthermore, the housing sector alone accounts for approximately 30% of the same, and a significant share of global greenhouse gas emissions derive from activities associated with housing [1]. Fortunately, the building sector also has a lot of potential for reducing said emissions. To exploit the potential, much research in the field is needed.

Building characteristics naturally have a significant effect on the energy consumption, and consequently, greenhouse gas emissions of buildings. The amount of greenhouse gases also depends heavily on the energy production mode. However, it is often disregarded that housing managers, through their practices and policies, have direct influence on the environmental performance of buildings, including the energy consumption. A previous study by the authors suggests that in multi-family apartment buildings with a district heating system, individual occupants have limited potential to influence the energy consumption of the dwellings [2]. In fact the housing management company controlling the heating system will inevitably have a higher impact on the overall energy consumption. The role of managers have previously been studied for both commercial buildings, i.e., facility management [3-5] and housing [6-8].

The background to this study is a multiple case study of several different types of housing companies from the Helsinki Metropolitan Area, Finland. The case study utilizes a hybrid LCA method for greenhouse gas emission estimation. The data sets comprise annual economic inputs retrieved from the financial statements of the housing companies as well as metric consumption data reported by housing management. During the course of research, the idea of the possibility to share the calculation tool utilized by the researchers with housing managers, as managers readily hold the data required. The idea emerged, that the input-output based LCA method, which is relatively quick and simple to use, could in the future be easily utilized by housing managers to estimate the carbon efficiency of the housing companies they manage. The purpose of this paper is to investigate the attitudes of the managers towards such a tool. The main motivation is that housing managers could develop the environmental efficiency of their practices and thereby take part in the challenging task of reducing the environmental effects of the built environment.

The remainder of the paper is structured, as follows. The next Section describes the Study design describing both the GHG calculation tool and the case study with interviews. The results of the qualitative study are then presented in two phases in the following Section. The final Section discusses the findings, and draws conclusions regarding the future use of the tool.

2 RESERACH DESIGN

2.1 The employed model

The tool introduced in this study estimates annual carbon dioxide equivalent (hereinafter CO2e or GHG) emissions for housing companies with an application of a tiered hybrid LCA method. The method has been previously employed by Kyrö et al 2011 [2]. The method is based on the Carnegie University’s Economic Input-Output Life Cycle Assessment Model (EIO-LCA) [9]. However, the most significant processes producing carbon emissions are replaced with local process level data.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_50,

In other words, the strengths of the two traditional LCA methods, process LCA and input-output LCA (IO-LCA) are combined. Thus, the truncation error inherent to all process LCAs is somewhat reduced and accuracy compared to direct IO-LCAs slightly increased [10-11].

The main data needed to use the tool comprises annual reports and financial statements of housing companies. Typical housing company related activities are divided into the following nine (9) cost categories:

1) Management and Administration
2) Cleaning and Maintenance
3) Repair
4) Water and Wastewater
5) Heating
6) Communal Electricity
7) Waste Management
8) Insurance
9) Real Estate Tax

In addition to the financial data, annual reports compiled by housing managers provide consumption data for the two categories producing the most GHG emissions, namely, Heating and Communal Electricity. For these two categories, the production phase emissions are replaced with either national or local process data. The calculated national average "g/kWh" emissions for district heating, electricity and oil may be utilized as appropriate. Employment of the method within a case study from the Finnish capital Helsinki is described in detail in Kyrö et al 2011 [2].

2.2 The case study

A multiple case study of housing companies from the Helsinki Metropolitan Area, Finland was the basis for this paper. Several different types of housing companies (condominiums, townhouses) with different demographic structures from the Helsinki Metropolitan area are included in the case study. The case study enables demonstrating both the utilization of a hybrid LCA method for GHG emission estimation, and the possibility to use the tool for carbon management.

In field research and in management studies in particular, understanding activities and phenomena that are less established benefits from the use of qualitative data and research methods [12]. In order to obtain insight on the management policies practices of the housing companies included in the study, interviews of the housing managers were conducted. The interviews also aimed at learning about the manager's general opinions and attitudes towards energy management, and potential interest towards the tool. The interviews were conducted as semi-constructed interviews.

The 25 housing companies were managed by 9 different Finnish housing management companies in 2008, the year of the data. All nine were contacted with requests for interviews. Two of the managers were no longer managing the housing companies in question or had gone out of business. The remaining seven all agreed to be interviewed either in person or via telephone. At the time of writing this paper, five interviews had been conducted in September 2011. The five interviewees manage 12 of the 25 housing companies, i.e. represent 48% of the housing companies included in the sample.

The interviewees were asked about their views on their own potential to manage GHG emissions, as well as what they thought of the possibility to using the described tool. The responses and ideas were transcribed to form an understanding of the overall usability of the tool, as seen by the managers.

3 MANAGEMENT INTERVIEWS

This section presents the findings of the management interviews. Illustrative data, i.e. excerpts from the interviews are used to provide better perceive the managers attitudes. The data are grouped around a few central points which emerged from the interviews.

Overall, the managers had a positive attitude towards the utilization of the tool. The attitude mostly stemmed from the rise of the eco-conscious views in society in general, as clearly stated my one manager:

"I think a lot of people would be interested as these things are becoming more and more popular, especially with the younger, more conscious residents. People would like to know their own carbon footprints."

When asked whether managers would consider using the tool themselves, the most critical factor seemed to be the fear of an increasing work load. The managers maintained that the tool should be made as simple as possible, so that using it would not be time consuming.

"Where would we [managers] find the time? Depends on how quick and simple it would be."

"The tool should be easy and simple to use. It could also encourage managers [to behave more eco-efficiently]."

"…it appears things are going into the direction of housing managers taking care of everything… but I guess that's okay."

With regard to the positive effects of the tool, proper communication of the results was considered essential. Some managers expressed particular concern for the potential misinterpretation of the results.

"The results would need to be communicated well to the residents, so that the numbers are not misunderstood by your average Joe. We would not want anyone to move out,

because they thought the CO2 emissions were too high. You would have to be careful with that."

"…communicating the results properly would be the most important thing."

One manager suspected that, although a good idea, this type of tool would only attract a limited clientele. The manager in question managed properties lower income level areas and did not see the tool as useful to his clients.

"…I think it would really be of interest only to something like 5% of housing companies, the ones with an eco-conscious resident base, or the ones with a long term strategy which includes environmental goals."

Indeed, it has been stated before [8] that environmental goals are not a priority for managers and financial issues are favored over the environmental ones. Discouragingly, similar ideas emerged from the interviews as well:

"Using the tool would be more of a 'nice-to-know' thing… in the end it is the Euro that counts!"

The profitability of using the tool was clearly seen as an issue. The interviewees pondered over the commercial potential and marketability of the tool.

"I'm not sure how we would sell it to the client [housing company]."

"We would need to see a demo version, have someone else use it first in their annual report."

Interestingly, even though all interviewed managers considered the tool a viable idea, no one expressed a desire to be a forerunner in the issue. One interviewee considered the possibility of the government making CO2e emissions calculations mandatory, similar to energy certificates.

4 DISCUSSION AND CONCLUSIONS

The purpose of this study was to explore the possibility to use a tool developed by the authors for carbon management of housing companies. As housing managers readily hold both financial information and metric consumption data of the activities of the housing companies they manage, an input-output based hybrid LCA technique, which is relatively quick and simple to use, could in the future easily be utilized by housing managers. With the tool, housing managers could develop the environmental efficiency of their own practices and thereby take part in the challenging task of reducing the environmental effects of the built environment. Engaging housing managers to this type of proactive involvement would be of essence, as a previous study by the authors suggests [2], that housing management may have a more significant impact on the energy consumption buildings than individual occupants.

The tool is currently in MS Excel format and, although relatively simple to use, a more user-friendly interface would be needed prior to introducing the tool to professional managers. Moreover, housing managers will need help in promoting the tool to their clients, the housing companies. It should be emphasized how the tool will enable comparisons between housing companies from different eras, house types, and technical standards. A further advantage to managers is the possibility of scenario building and benchmarking.

Energy efficiency in logistics – Potentials and limitations

Doris Gierlinger[1], Friedrich Starkl[1]

[1] University of Applied Sciences Upper Austria, Steyr, Austria

Abstract

New modes of production call for new modes of distribution. Just-in-time or just-in-sequence manufacturing for example presuppose more frequent information, freight, transport and vehicle flows. Particularly in connection with transport and logistics negative impact and pollution occur when emissions exceed assimilative capacity. Transport has a number of environmental side effects. These impacts arise through the emission of pollutants, through land-take for new roads for example and as increases in noise levels. Nevertheless, many instruments introduced in the transport system failed to reach their target since gains in global environmental efficiency have not been enough to cope with the consequences of the obvious transport growth. For all that, within the large body of work referring to globalization, internationalization or free trade agreements, transport is not regarded as an important issue, it is rather taken for granted. Classic trade theory for example neglects the role of transport and logistics. In the paper, the scope of interference regarding an enhancement in energy efficiency and carbon dioxide efficiency, which implies an emission reduction, is analyzed. It is tried to get to the bottom of the impact of the configuration of economic activities on traffic flows by an extensive and structured literature review and content analyses in the field of New Economic Geography. The degree, to which logistics principles and requirements are becoming decisive for organizational and location decisions is scrutinized. It is assumed, that political and market-based instruments determine the nature of transport and logistics and therefore hold appropriate potential for alteration in this field. An enumeration of adequate instruments in regard to the demanded energy efficiency in logistics will be given. The aim of this paper is to identify potentials and limitations for an energy efficiency enhancement in logistics and transport by applying principles of the New Economic Geography in a logistics context.

Logistics, Energy efficiency, New Economic Geography

1 INTRODUCTION

The frequently cited globalization comes along with a modification and reconfiguration of freight transportation due to dynamic material, goods and information flows. The impact and emissions respectively caused by transportation are obvious. Taking a closer look at the transport sector within the EU-27 clearly shows that road transport was the most energy consuming mode throughout the last decade. Its share amounts at 81 % of the total in 2008. It is followed by air transport with a share of 14 %. Inland navigation and rail transport consumed around 2 % of the total. Furthermore air transport was the fastest growing sector between 1998 and 2008 with 33 % overall increase for the EU-27. Road transport experienced an increase of 12 %, while energy consumption by rail and inland navigation declined by 3 % and 11 % respectively. [1]

The following picture shows the final energy consumption by the different modes of transport:

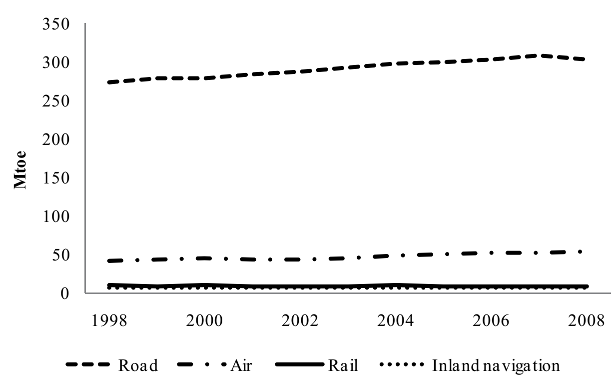

Fig. 1: Final energy consumption by mode of transport

In addition, the European Union certifies the transport sector a potential of 26 % regarding the reduction of energy consumption. The transport sector both depicts a major environmental risk due to its greenhouse gas emissions and a significant factor for the dependency on fossil fuels. [2] A macroeconomic point of view clearly outlines the relation of an economy and the efficiency of

transport systems. It goes without saying that an appropriate capability of a transport system, depending on various geographical influences and determinants, is an essential prerequisite for an adequate fulfilment of the demand given, the higher division of labour and increased competition respectively in the domestic market as well as in foreign trade. Conversely economic prosperity entails an increase in the need for transport services. [3] New modes of production call for new modes of transport. Just-in-time and just-in-sequence manufacturing for example presuppose an increased exchange of information, freight transport volume and therefore augmented vehicle flows.

Consequently, transport flows are indispensable connected with economic activity levels in the production and household sectors. This linkage offers a first insight into the New Economic Geography (NEG) literature, whose models and findings are at the moment primarily theoretical. Particularly transportation interacts for example with urban development via real income effects, housing demand and mode choice. [4] Anyway its worth having a closer look on the propositions made within this framework concerning the configuration of economic activities and the transport flows resulting from these allocations.

2 THE NEW ECONOMIC GEOGRAPHY

2.1 An overview

New Economic Geography is the second among neoclassical agglomeration theories. It tries to get to the bottom of agglomerations at meso and macro levels. It scrutinizes the formation of agglomerations and the conditions required to keep their setup. As a matter of principle it is assumed, that agglomerations observed do not result from inherent differences of locations but can rather be attributed to so-called circular causality and cumulative processes. [6]

2.2 Key features of the New Economic Geography

Geographical economics takes as its starting point the fact that economic activities are, clearly, not distributed randomly throughout space. Taking a closer look at any map immediately shows that the clustering of people and firms is the rule and not the exception. Geographical models are often hard to analyze analytically, due to the fact that its approaches rely to a large extent on simulations which are supposed to determine the distribution of economic activity across space.

Trade theorists are mostly interested in how market structure, production techniques and consumer behavior interact. Factor and commodity prices resulting from these circumstances are supposed to determine the pattern of international trade flows. Location is, at best, an exogenous factor and is not regarded as significant. On the other hand, regional and urban economics take market structure and prices as given and try to figure out which allocation of space is most efficient. The behavior of consumers and producers, which is of core relevance in trade theory, is less important. [5]

New Economic Geography models describe how spatial distribution of economic activities changes as transportation costs slowly decline. The slow decline aims at mirroring the actual decline in transportation costs observed throughout the last years. With falling transport costs companies are able to increase their exports while being less dependent on immobile factors as sources of profit. [7]

The first key feature in the New Economic Geography models is the so-called home market effect. This effect describes the net effect of market expansion and market crowding. An exogenous change in the location of upstream demands provokes a more than proportional change of downstream supplies in the same direction. Importantly, the intensity of the home market effect is dependent on the level of trade freeness. Since trade freeness weakens the market crowding effect more than the market expansion effect, lowering trade costs intensifies the change of downstream supply which is induced by a shift in upstream demand.

Secondly in NEG models agglomeration forces are referred to as self-enforcing, which is called circular causality. This circularity should point out the feedback relations between economic activities. It is characteristic for NEG models that the strength of the circular causality depends on the level of trade barriers.

The third fact worth mentioning is the fact that the relations between the strength of circular causality and trade freeness show up as so called “hump-shaped agglomeration rents”. Taking a long-run outcome into account where all companies are located in one specific region, agglomeration rents are defined as the loss a company would have to face when relocating to another region. The hump shape shows that the agglomeration rents are a concave function of the trade freeness.

Endogenous asymmetry is also induced by circular causality. The assumption is that two symmetric regions with trade barriers face regional asymmetries when gradual increases in trade freeness take place.

The importance of the extent of trade freeness becomes obvious when talking about agglomerations. Therefore the way in which endogenous asymmetry emerges is extraordinarily discontinuous and is called catastrophic agglomeration. Once a certain point in trade freeness is reached, a small increase causes so called catastrophic agglomeration due to the fact that the only long run outcome is agglomeration.

Additionally local hysteresis is worth mentioning. It arises when the level of trade freeness brings multiple long-run outcomes forward. In an initial situation almost all firms would be in the same region. If in case of a shock a number of firms moved to another region, all firms would suddenly cluster there. A removal of this first shock would not cause a reversal of its effects. This is called hysteresis or path-dependency, which means that transitory shocks have permanent impediments.

The last core element of NEG gets obvious when dispersion and agglomeration effects are both long-run outcomes. To outline this means that the shared belief that firms will cluster in specific regions is self-rewarding and self-fulfilling. [8]

2.3 Krugman's core-periphery model

Paul Krugman launched the New Economic Geography as a subfield of the broader field investigating the location of economic activities. His core-periphery (CP) model forms the basis for the analysis of regional divergence, the formation of regional clusters as well as the impacts of regional policy among others. NEG holds reasons for the existence and persistence of sizable regional disparities at various spatial scales.

The core-periphery-model has two similar regions, two sectors and two factors. One factor is inter-regionally mobile while the other is not and every factor is specific to one sector. The so-called constant elasticity of substitution (CES) differentiated good makes use of the mobile factor and is produced under increasing returns to scale which are internal to the firm. The homogenous goods sector employs the immobile factor under constant returns to scale. Both goods can be traced while the CES differentiated goods trade is impeded by iceberg transport costs and the homogenous goods trade is costless. Therefore two types of equilibria exist: Agglomeration of the CES industry in a single region when transportation costs are low, even dispersion of this industry across the two regions when transportation costs are high. Both equilibria are stable for intermediate transportation costs. [9] It is obvious that this is a very stylized model, which is established in order to enable further research in this field.

2.4 Transport and New Economic Geography

The so-called iceberg transport cost function is distinguishing for New Economic Geography. It was first developed by Paul Samuelson in 1952. Again this contribution is more methodological than practical but facilitates modeling trade costs. It is based on the assumption that two markets exist. A home market *H* and a foreign market *F*. When producing good *x* in the home market *H* with a value of *VXH* and some of the good is consumed by the act of shipment, the value of the good arriving in the foreign market is denoted as $\tau x VxH$, where $1 - \tau x$ is the proportion of the good *x* consumed by the process of transportation from *H* to *F*. For determining the relative prices of the goods in the home market *PXH* and in the foreign market *PXF*, it is crucial to consider that the value of the good in the home market *VXH* is the result of a multiplication of the domestic price per ton of the good *PXH* and the tonnage of good *x* being shipped from the home market *MXH*. In international shipment, although the price per ton of *x* paid by the foreign customer to the domestic producer is *PXH* for each ton purchased at *H*, the overall weight of good *MXF* actually arriving in the foreign market F is only *MXH* tons. To put it differently, the foreign price per ton PXF actually paid by the foreign consumer is displayed as

$PXF = PXH\ (MXH/MXF) = PXH/\tau x.$

Correspondently, the same can be formulated for a foreign-produced good y of the price *PYF* per ton in the foreign market, the home market price of good *y* is denoted as

$PYH = PYF/\tau y$

τy represents the proportion of the good *y* which is not consumed in the process of transportation from *F* to *H*. The iceberg formulation describes transportation costs as stepwise discontinuity between home and foreign prices of any goods. The degree of discontinuity is dependent on the value of τ. [10]

2.5 Iceberg transport costs and New Economic Geography

Krugman spurred on the former works on new international trade and developed and integrated the geographical space in his research work. One of the major achievements was the formulation of iceberg transport cost functions as a continuous distance function. He redefined Samuelson's iceberg function into an explicitly geographical distance-related function. Krugman defines iceberg cost functions as $V_d = V_0 e^{-\tau D}$, where V_0 is the value of the good at the origin location, τ is the iceberg decay parameter, D denotes the haulage distance and V_d is the quantity of the good actually delivered at its destination. Here, τ represents the remaining quantity of the good which tips-off on each kilometer of transportation. In Krugman's elaborations concerning the iceberg model the level of the distance-delivered price convexity increases with the value of the good shipped. Consequently the price of the delivered good rises with distance at a greater rate for goods with higher origin prices than for goods with lower origin prices. [10] Verbal as well as mathematical models make use of abstraction. This means that certain key features of the system of interest are selected and represented in the model, which should display the real world. In NEG reference to so-called "real-world" phenomena is made. Anyway, this abstractions and formalizations are oftentimes subject to debates. Like all economic models, NEG models are surrogates. The focus of theorists is put on the representation, which is the abstract, formalized and simplified landscape in the modeled world. [11] By all means, transportation costs play an important role in NEG models. Notwithstanding, modeling these transport costs is one of its weakest parts and many authors complain about the restrictions that come along with iceberg transport costs assumptions. Furthermore, hardly any progress seems to have taken place in this field throughout the last years. By all means, transport costs are prices which are set in imperfectly competitive markets and which respond to demand and supply shocks. Another important component of the NEG has to deal with the asymmetry of transport and trade costs, since freight imbalances apparently affect transport costs to a large extent. These imbalances evoke strong effects on the spatial structure of the economy. [12]

2.6 Agglomerations and networks

Major transport nodes abet industrial agglomerations. These nodes and transshipment points within transport networks exhibit a favorable location for cost-optimizing or -minimizing companies. Examples therefore are nodes in cities which are located close to road infrastructure such as highways or railroad stations. The co-occurrence of agglomerations and transport nodes stems from the reciprocal reinforcements among them. One of the most important points is the fact that companies want to save transport costs by locating around such nodes. In 2004 an estimation conducted by the researchers Anderson and van Wincoop [13] illustrates that the tax equivalent of trade costs in industrialized countries accounts for 120 %. This number can be split into transport costs (21 %), border related trade barriers (44 %) and local retail as well as distribution costs (55 %). Additionally time related aspects have to be considered concerning transportation. Close contact to suppliers and customers is essential anyway. One more reinforcement aspect is the fact that transport nodes and their efficiency respectively are meliorated by increasing agglomeration tendencies. In this context scale economies assume an important role in this context. The development of large-sized and high-speed carriers, such as container ships or bullet trains, contributed to economies of scale which serve as incentive for collective transportation and consequently bring trunk-routes and hub-and-spoke processes forward. Once again circular causation comes into place. Whenever frequent transport services are available on demand, a large number of shippers will be attracted to this link which again entails the offering of more frequent transport services. This positive feedback again leads to the endogenous formations of trunk links and transport hubs. Whenever scale economies of transportation dominate, certain transport advantages of locations enable the spontaneous emergence of major transport nodes at any place having a large demand such as the existence of industrial agglomeration. Fujita and Mori call this mechanism "economies of transport density" which are primarily present in air, railroad and maritime transportation. [14]

3 INTERCONNECTION BETWEEN NEG AND ENERGY EFFICIENCY

The explanations concerning NEG offered so far are of theoretic nature and call for a transfer to aspects related to real life. Numerous scientists are engaged in abstractions. In this paper and in the project work at the University of Applied Sciences Upper Austria it is tried to figure out, where interconnections between NEG and energy efficiency in logistics can be derived and transferred via specific projects to praxis. Nevertheless, the research work done so far has still to be called work in progress and a lot of theoretical as well as empirical research studies have to be conducted.

Potentials to enhance energy efficiency in freight traffic are numerous. As mentioned in Chapter 1, transport flows are indispensable connected with the economic activities of a country. Therefore mobility and traffic are induced by industrial locations and transport nodes, which are built around these locations respectively. Therefore it is assumed that the competition among industrial locations will increase over time. Nevertheless, whenever companies make decisions concerning the establishment of local operations they do not take the related traffic into account. Conversely, infrastructural measures are oftentimes not oriented towards a strategic, long-term location planning. Consequently, an elaborated strategically oriented and integrated location and land use regulation as well as an adequate transport policy can contribute to a minimization of transportation distances. Again, the previously featured circular causality comes into place at this point. Furthermore, decisions concerning the modal choice can influenced positively and freight as well as individual traffic could be bundled. Altogether it is expected, that these measures contribute to the enhancement of the attractiveness of a location. In the next chapter some practical examples concerning potential contributions in logistics to enhance energy efficiency will be given.

4 ENERGY EFFICIENCY IN LOGISTICS

4.1 Logistics concepts and their impact

Best practices in logistics call for the integration of environmental management with day-to-day operations. [15] Logistics in particular is the process of planning, implementing and controlling the efficient, cost effective flow and storage of raw materials, in-process inventory, finished goods and related information from point of origin to the point of consumption for the purpose of meeting customer requirements. [16] Logistics and supply chain management focus on the adequate configuration of process chains while at the same time tracking an increase in efficiency as well as effectiveness. Hence, overcoming distances (transport, handling) and time (storage) are the core elements of logistics which necessitate accordant energy consumption. In addition to time and cost aspects, questions concerning energy efficiency come into force. (Freight) Traffic will – besides energy supply, feeding and farming as well as building and living – be one of the most fundamental scopes of action, which have to put the principle of sustainability into practice. [17] Generally, there are two domains of different actors, which can contribute to achieving environmental improvements. One is the macro domain, where actions are taken by the governments and legislative authorities. The other domain is the micro-domain, where companies set priorities in regard to environmentally friendly processes. In the macro domain it has been widely recognized that transport is among the main sources of environmental pollution.

Measures taken in the past are numerous but unsatisfactory due to their inability to keep pace with the growing transport volumes.

4.2 Potentials for a more sustainable transport sector

Improving sustainability within the transport sector requires a comprehensive and integrated transport and environment policy approach which combines legislative and economic instruments in a capacious way across all traffic carriers. A few examples for potential contributions to a more sustainable transport sector will be mentioned at this point: In general logistics can follow three approaches within transport policy in order to minimize negative impact on the environment. The first approach would be a realization of modal shift. Secondly, reducing the demand for transport services and thirdly, reducing the impact of transport processes on the environment. In the micro domain a shift in the processes of enterprises has to take place, more precisely a process restructuring is necessary. [18] A survey conducted at the University of Applied Sciences in Steyr [19] tried to get to the bottom of own-account transport operations in Austrian companies. To specify the question was how many companies operated own-account transports and the reasons therefore. 49 % of the companies surveyed operated own-account transports and the essential reasons given where supposed cost savings as well as quality aspects. The following picture illustrates the capacity utilization of the truck fleets of the particular companies:

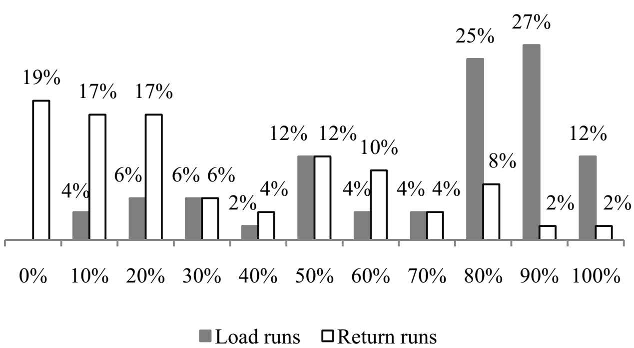

Fig. 1: Utilization of truck fleets

This figure outlines the fact, that companies hold great potential concerning so called freight hold utilization. Especially in the return runs, the figures exhibit a clear tendency towards low utilization. A synergetic increase of freight hold utilization and the avoidance of empty drives respectively contribute exceedingly to a reduction of carbon dioxide emissions. In this context so called logistics pooling systems have to be mentioned. Within such systems truck use (sometimes even warehousing) is planned and optimized company-wide. The physical transport of goods with trucks of the manufacturer or carrier is accomplished in the course of a collectively planned optimization of transport capacities. This can be realized by the minimization of empty drives or rather by the shared utilization of one truck by several manufacturers when supplying a retailer. On the grounds of technical and organizational conditions each carrier processes definable advantages. Road haulage scores with its flexibility, almost infinite interconnectedness and organizational simplicity. Rail transport is especially shows advantages especially on long distances and when carrying bulk load. Transports by plane on the other hand are characterized by speediness over long distances. Concerning the modal shift mentioned before, it has to be said that an intelligent combination of specific carriers according to their advantages to intermodal transport chains has to be realized. Consequently these transport chains can be designed more efficient. At least in Europe certain mental barriers seem to exist and hinder a comprehensive utilization of intermodal transports. Anyway it would lead to a relaxation on the roads in case a successful shift of the main leg from the carrier road to the carrier rail or inland waterway and keep this track as long as possible. The simple principle is, the longer the main leg and the distance travelled, the more environmentally friendly the transport. Another example for potentials in freight traffic is related to a project conducted again at the University of Applied Sciences Upper Austria, which is called "time4trucks". Within this project traffic forecasting data of infrastructure operators are combined with data of shippers in order to unload neuralgic road sections, primarily in urban areas. Hence traffic congestions, time losses, costs and planning uncertainty as well as additional carbon dioxide emissions can be avoided. The consolidation of data allows for influencing traffic conditions. Consequently this leads to improved fuel efficiency and fuel consumption respectively. [20]

5 SUMMARY

It has to be said that in the actual application of NEG models it is important to distinguish two types of impediment to trade in space. In more detail it is about transport costs for goods and communication costs for doing business over space. It is for example suggested to focus on transport costs for goods and communication costs among business units which exert different effects on the spatial organization of economic activities. Comprehensive studies on the nature and modeling of transportation activities have to be a central concern for any further development of the NEG. [14] In practice, potential contributions in logistics to enhance energy efficiency in freight traffic are numerous. In general it can be stated, that ecological strategies contribute to the requirements of customers concerning environmentally friendly and sustainable products. Logistics holds a prominent position in this context, due to the fact that companies can contribute significantly to the reduction of environmental pollution when applying adequate strategies. It is necessary to not only identify different strategic, tactical and operational decisions influencing the environment. Furthermore, it is inevitable to relate them to each other in order to be able to foresee their consequences on the environment. [21] Three main steps have to be considered when designing new logistics structures. First the total costs and the delivery service of the existing structure have to be calculated. In comparison to that, alternative structures and their costs have to be analyzed and calculated respectively. The third point is the calculation of dimensions and size of facilities, which have to be established. [18] Improved planning and organization of logistics processes provoke an increase of the ecological as well as logistical efficiency. The significance of environmental aspects within logistics will continuously rise. A number of reasons, such as rising commodity and energy prizes, increasing integration accompanied by further negative environmental impacts, contribute to this relevance. Additionally it can be expected, that so-called external costs will be increasingly assigned to the respective polluters instead of being borne by the general public.

Ecolabelling and Design for Environment in Building Transportation Systems

Asko Koskimäki[1], Hannele Tonteri[1], Claudio Donghi[2] and Hanna Uusitalo[2]

[2]KONE Corporation

Abstract

There is a growing need for indicating the environmental performance of products partly due to legislation set by governments and partly to gain an advantage in the markets. For quite some time companies have used life cycle assessment (LCA) to address the environmental issues related to their products. LCA results can be communicated with Environmental Performance Declarations, but these are not as visible as ecolabels or energy performance labels and thus remain generally unknown by the public. The aim of the study is to provide designers useful information about material choices from the environmental point of view by looking at the findings of past LCA studies and seeing how these could be used to rate and indicate the environmental performance. The goal was to provide elevator designers a sketch of a visually easy to understand and a fast to interpret chart to use in material comparison. This chart should indicate a few of the environmental performance indicators that were found necessary by a literature review in the sector of building material performance.

elevator, life cycle assessment (LCA), material rating, environment

1 INTRODUCTION

A growing concern of the environmental issues in all the sectors of industry has set a new challenge to product designers of incorporating environmental issues at a very early stage of the design process. There are several guidelines for ecodesign of which the most relevant for this case study was the ISO 14062 [1]. The ISO 14062 is divided into six stages: planning, conceptual design, detailed design, testing / prototype, production / market launch, and product review. As it has been noted that more than 80% of the environmental impacts are determined at the early stages of product design, the scope of the study performed focuses on the planning and conceptual design stages of the ecodesign standard.

The planning stage of the design for environment process includes such aspects as gathering the information, align with organizational strategy, consider the environmental impacts, and making an environmental analysis of the product. The second stage of the design is the conceptual design, where environmental aspects such as conducting life cycle oriented analyses, formulate measurable targets and meeting environmental requirements are considered. [1] These two stages were the main driving forces in further analysing the material choices in the design stage of a product.

2 APPROACHES AND METHODS

The study uses an example elevator as the case product, but the same kind of study could be conducted on a variety of products. In case of elevators, many manufacturers have presented their environmental product declarations (EPD's), which all indicate that materials are the second largest contributor to the environmental impacts caused by elevators, as presented in an EPD of a KONE example elevator in Figure 1. Often it seems that most effort is concentrated on the use phase and too little effort is put to the material choices. [2, 3]

The literature review looked at different labelling schemes as well as different legal obligations around the world that need to be included when thinking about the design for environment of an elevator. The labelling schemes included in the study covered both green building labelling schemes and product labelling schemes. The reviewed green building labelling schemes included LEED from the United States [4], BREEAM developed in the United Kingdom [5], Green Star currently growing in the Southern Hemisphere originally developed in Australia [6], and CASBEE from Japan [7]. Of these LEED and BREEAM received the most attention as they are used in the largest scale around the world. Product specific labels to indicate the environmental performance of elevators tend to focus on the energy performance of elevators and exclude the material choices made. This is understandable as the energy consuming use phase dominates the life cycle environmental impacts; good example being the example elevator presented in Figure 1. Product specific labels included the energy performance guidelines under development by the International Organization for Standardization [8] and the energy

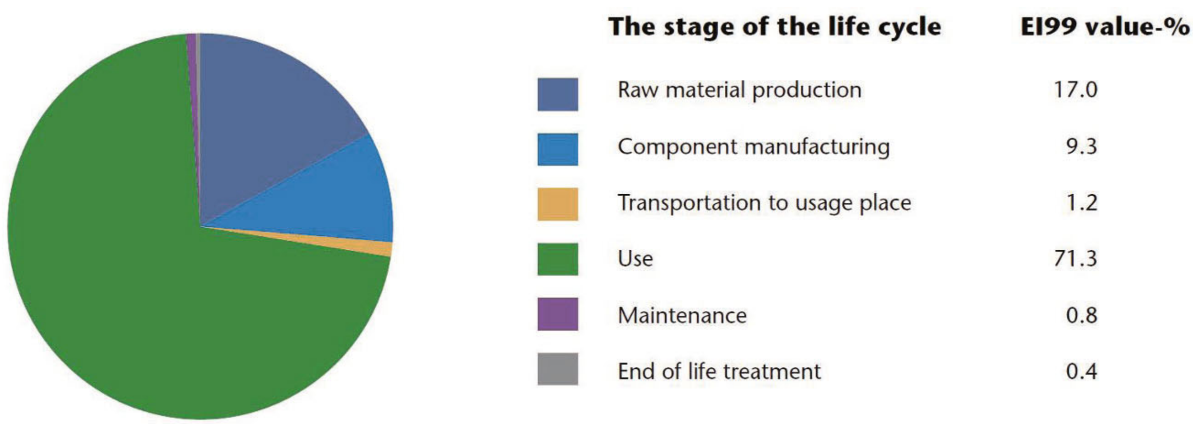

Figure 1 - The shares of different life cycle stages on the environmental impacts of a KONE example elevator

efficiency rating guidelines of Verein Deutscher Ingenieure [9]. As there seems to be no well recognized environmental label to communicate the environmental performance of the material choices in elevator design, the study resulted in presenting the environmental performance of different materials on a 'Material Environmental Radar Chart' as presented in Figure 2. The process of identifying the relevant environmental performance indicators (EPI's) for different materials used in an elevator is a demanding task. This could be performed via a full life cycle assessment, but this is often seen as a daunting task by companies. Thus, finding a simpler way of identifying and visually presenting the relevant EPI's for different materials would be a welcome addition to the choice of tools for designers.

3 TOOLS FOR DESIGNERS

A wide set of tools are available for designers dealing with material choices, but as the environmental issues are often more complex to measure than traditional material properties such as tensile strength or elastic modulus, these tools are often highly indicative and therefore give no exact values. The uncertainty of these tools is possibly the biggest reason for many companies for not having incorporated these tools to their design portfolio in a larger scale. Two tools were tested in this study: the LCA software KCL-ECO developed at VTT Technical Research Centre of Finland and the Cambridge Engineering Selector (CES) with the EcoAudit Tool.

The LCA software KCL-ECO has been developed since 1992 with the version KCL-ECO 4.1 currently in use. KCL-ECO version 5 is currently under development at VTT to integrate knowledge and data from various sources within a company and from external sources. KCL-ECO 5 will have the well-known, highly visual and easy-to-use features from the previous versions with new and improved user interface that helps the user to perform fast, reliable and easily understandable LCA's. KCL-ECO 5 is being built on the Simantics platform to synchronize different software systems such as Balas[1], Apros[2] and CAD.

The EcoAudit Tool is an add-on tool to the CES Selector, which helps the user to address such issues as the carbon footprint, energy usage, waste and emissions produced or the manner of disposal. The EcoAudit takes a two stage approach to ecodesign; the first stage being ecoauditing and the second being optimization of the process to minimize the environmental burden. The latest version of the software is the CES Selector 2012 with an extended ecodesign tool and a wider data selection. The CES tool uses a bill-of-materials fed by the user and associates these materials to a wide database gathered from literature. Nevertheless the amount of processes and materials in the CES Selector is impossible to fully cover, so estimates have been made to present values for materials that have no direct data source. This brings about the error margins of about 20%. [10].

4 IDENTIFYING RELEVANT EPI'S

One of the most important aspects for an elevator manufacturer is the green building rating schemes mentioned earlier. It is worth noticing that each of the green building rating schemes has a degree of rationality in it. This rationality presents itself as non-uniform set of categories in which credits can be obtained and as different weighting factors for these categories, e.g. the Green Star puts more weight on water consumption whereas the CASBEE might focus more on structural aspects such as earthquake resistance. This presents a dilemma for multinational companies as focusing on a single green building rating scheme might result in scoring a lower result in other regions of the world. Gathering the most important credits or points from different green building rating schemes might set clear guidelines for EPI's used in rating elevator materials, but often elevators, escalators and moving walks are explicitly excluded from the material categories. Possibly the most important contribution the green building rating schemes have in the scope of this study is the amount of recycled material used. For example CASBEE awards credits for the use of recycled materials as structural framework materials or as non-structural materials. [11]

Two very important EPI's for an elevator manufacturer are embodied carbon dioxide equivalent emissions (CO_2-eq) and embodied energy. These two EPI's are often seen as very comparable, even though this might not be the case. This was noted by Dixit et al. [12] as it was noted that one problem arises from the different system boundaries used in the studies. For an elevator manufacturer the system boundary of interest in material choices is a cradle-to-gate, i.e. from raw material extraction to the gate of the production plant, where as a building constructor might include building demolition as well. The same problem may arise when looking at the CO_2-eq. emissions. A transparent way of reporting these emissions, such as the one presented by the World Resource Institute and the World Business Council for Sustainable Development [13], should be chosen.

A rapidly growing EPI that cannot be omitted is the water consumption. Water footprint methodologies are currently developed by many different parties. The different water footprinting tools and methodologies can roughly be divided into two mainstreams: accountancy schemes (e.g. GRI indicators [14], and Water Footprint Network [15]) and schemes for assessing, certifying and communicating sustainable water use (e.g. Global Water Tool by WBCSD [16] and Water Sustainability Tool by GEMI [17]). No single method is yet widely accepted and as methods are being developed further, the mixing of accountancy and response schemes will further increase. In the sector of water footprinting, the hopes are that the upcoming ISO 14046 will unite and clarify the methodology currently in use and under intense discussion. For this reason this study takes focus only on the water consumption or water withdrawal.

Finally it is seen as a necessity to make a note about the legal obligations of the materials, such as the RoHS Directive, the WEEE Directive and the REACH Regulation. Again the literature review raised the problem faced by a multinational company of having to deal with different criteria in different parts of the world. Nevertheless in this case this problem can be solved by setting the company requirements according to the tightest legislation in the world. This final point in this set of example EPI's can score either zero or one, depending on whether the legal requirements are met or not.

5 RESULTS AND DISCUSSION

At the very early stages of the study, it was the ambition of all persons involved to find an ecolabel for elevators. This, soon after, took the form of making a feasibility study of possible ecolabels for elevators and different materials used in elevators. In the end all parties agreed that at this stage the best and most usable result would be to draft a 'material environmental radar chart' (see Figure 2). This could be used by designers to easily assess the environmental performance of different material options by visually being able to compare associated environmental performance indicators. During the study it was also noted that it would be good to tie elevators to the green building rating schemes also in other areas than energy consumption, as elevators are becoming an increasingly important part of the growing cities.

Further results shall be presented at the 7th International Symposium on Environ-mentally Conscious Design and Inverse Manufacturing (November 30th-December 2nd, 2011), Kyoto City, Japan.

6 ACKNOWLEDGMENTS

This research was performed in close co-operation between KONE Corporation and VTT Technical Research Centre of Finland and was partially funded by the European research project Solutions for Managing Organizations' Environmental Performance Indicators (OEPI, 748735).

New global warming indicators, CEWN, CETN and s-CETN based on removal rate of GHGs from the atmosphere

Akira Sekiya (1)[1], Sayuri Okamoto (2)[1]

[1] National Institute of Advanced Industrial Science and Technology (AIST), Central 5, Ibaraki, Japan

Abstract

A new indicator, the CETN (Carbon Dioxide Equivalent Temperature Change Number), is proposed as an alternative to the GWP (Global Warming Potential). CETN is a metric where the temperature change by the emission of gases is compared at the same degradation rate. There are two types of CETN, CETN and s-CETN, depending on the way of standard setting of degradation rate. They are obtained from simple calculation and the comparative evaluation in equivalent amount becomes available by unifying the removal rate of each gas from the atmosphere. They are realistic and novel global warming indicators as the lifetime of each gas is reflected.

Alongside already reported CEWN, in which RF (radiative forcing) is compared at the same degradation rate, there are three indicators, CEWN, CETN and s-CETN, ready. For these indicators, the removal rate from the atmosphere is set at 75%, at the same time, modifications, such as change of the base year setting of atmospheric carbon dioxide to preindustrial time, inclusion of warming due to degradation products, are made, thereby CEWN_2 (75-pi), CETN_2 (75-pi) and s-CETN_2 (75-pi) are calculated and proposed as actual indicators.

Using these three indicators, LCCP analyses for semiconductor cleaning and blowing agent of polyurethane insulation are carried out, and the results are different from the results with existing GWP.

Keywords:

GWP, CEWN, CETN, s-CETN, global warming indicator

1 INTRODUCTION

The countermeasures against global warming are urgent issues. The quantified emission reduction is assessed by the basket system under the Kyoto Protocol. The idea of the system is that the number which indicates the warming intensity is given to each warming gas and then the total sum of the emission of each warming gas multiplied by its respective number is controlled. Under the Kyoto Protocol, the GWP (Global Warming Potential) is used for the calculation. However, its arbitrary property of being used with a 100-year time horizon and the fact that the relation between the GWP and the climate impact is not clear are acknowledged as problems of the GWP. Under the circumstances, the GTP (Global Temperature Change Potential) which makes clear the relation between the emission of greenhouse gases and global-mean surface temperature has been proposed [1]. However, the GTP_P represents the temperature change due to a pulse emission of a gas after a given period of time has elapsed, thus it does not evaluate the integrated warming. In addition, the fact that the value differs greatly depending on the length of the given period in most cases is also the issue. Meanwhile, the GTP_S is scarcely applicable to the other emission scenarios as it represents the integrated warming based on its own scenario where the emission increases by 1kg every year during the given period. We have developed the CEWN (Carbon Dioxide Equivalent Warming Number) with the view to establish a fair warming indicator and encourage the proper usage of fluorinated gases [2]. The CEWN calculates the warming by the emission of greenhouse gases in the similar way of the GWP, but with the removal rate of each gas from the atmosphere unified. It has provided the fairer comparison values of the warming for various greenhouse gases.

This paper proposes the CETN (Carbon Dioxide Equivalent Temperature Change Number) where the global temperature change, which complies with the GTP, by the emission of greenhouse gases are compared by unifying the removal rate of each gas from the atmosphere. It is thought that the CETN is the comparison values of the greenhouse gases which maintains the fairness of the CEWN and has clearer relation with the climate impact. In addition, as CEWN, CETN guides selection of better technology by being applied to technological assessment.

2 EXPERIMENTAL

2.1 Calculation of CETN

The equation used for the calculation of CETN is as follows:

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_53, © Springer Science+Business Media Dordrecht 2012

Equation 1: CETN calculation

$$CETN(X) = \frac{ACETN(X)_A}{ACETN(X)_C} = \frac{\int_0^{t_{XA}} AGTP(t)_A\, dt'}{\int_0^{t_{XC}} AGTP(t)_C\, dt'}$$

$$= \frac{\frac{A_A \alpha_A}{C}\left\{\tau\left[1-exp\left(-t_{XA}/\tau\right)\right]-\frac{1}{\left(\tau^{-1}-\alpha_A^{-1}\right)}\left[exp\left(-t_{XA}/\alpha_A\right)-exp\left(-t_{XA}/\tau\right)\right]\right\}}{\frac{A_C}{C}\left\{a_0 t_{XC}\tau - a_0\tau^2\left[1-exp\left(-t_{XC}/\tau\right)\right]+\sum_i a_i\alpha_i\left[\tau\left(1-exp\left(-t_{XC}/\tau\right)\right)-\frac{1}{\left(\tau^{-1}-\alpha_i^{-1}\right)}\left[exp\left(-t_{XC}/\alpha_i\right)-exp\left(-t_{XC}/\tau\right)\right]\right]\right\}}$$

When the elapsed years, after 1kg of gas A and 1kg of carbon dioxide are emitted at the beginning until X% of their emission is removed from the atmosphere are denoted by t_{XA} and t_{XC}, respectively, CETN (X) of gas A is given by Equation 1, where C is the heat capacity of the system, A_A and A_C are the radiative forcing due to a 1kg change in gas A and carbon dioxide, respectively, and τ is a time constant for the climate system and equals to λC where λ is a climate sensitivity parameter (here, 0.8 K(W m^{-2})$^{-1}$ is taken). The equation for each AGTP is quoted from Shine 2005 [1].

The coefficients for the above equation, which are the same as IPCC 2007 [3], are as follows:

$$a_0 = 0.217,\ a_1 = 0.259,\quad a_2 = 0.338,\quad a_3 = 0.186,$$
$$\alpha_1 = 172.9\ years,\quad \alpha_2 = 18.51\ years,\quad \alpha_3 = 1.186\ years$$

Both CETN and s-CETN are calculated as the ratio of integrated temperature change of gas A to integrated temperature change of carbon dioxide. In CETN case, temperature changes of gas A and carbon dioxide are both integrated until X% of each emission is removed from the atmosphere, while, in s-CETN case, though carbon dioxide as the denominator is the same as CETN, temperature changes of gas A is integrated until the ratio of integrated temperature change to infinitely integrated temperature change becomes X%.

Some examples of CETN and s-CETN in the case where the removal rate of carbon dioxide from the atmosphere is fixed at 75% are shown in Table 1.

2.2 Base year fixing of atmospheric carbon dioxide at preindustrial time and introduction of carbon dioxide environment number (CO_2 EN)

The base year of atmospheric carbon dioxide is fixed at preindustrial time, that is, year 1750. Based on the formula in IPCC 2001 [4] along with the preindustrial atmospheric carbon dioxide concentration of 278ppm, the radiative forcing per kilogram of CO_2 is calculated and fixed at 2.45×10^{-15} W m^{-2} kg^{-1}. Additionally, the following is defined as the carbon dioxide environment number (CO_2 EN) in year Y.

$$CO_2\, EN_Y = RF_{CO2,\,Y} / RF_{CO2,\,1750}$$
$$\approx C_{CO2,\,1750} / C_{CO2,\,Y}$$

where $RF_{CO2,\,Y}$ is the radiative forcing per kilogram of CO_2 in year Y [W m^{-2} kg^{-1}], $C_{CO2,\,Y}$ is the atmospheric carbon dioxide in year Y [ppm]. The examples of CETN and s-CETN where base year is fixed at preindustrial time are shown in Table 2.

2.3 Inclusion of warming effects due to the degradation to carbon dioxide

The CETN(X) of gas A including the warming effects of carbon dioxide, which is a degradation product of gas A, is calculated and denoted by CETN_2 (X). When every carbon atom included in gas A degraded is assumed to change into carbon dioxide, as the CETN is the value relative to carbon dioxide, the CETN attributable to the degradation product, CO_2, is simply derived from the carbon number of gas A and the ratio of molecular weights of carbon dioxide to that of gas A, and the CETN_2 (X) is given by

$$CETN\_2(X) = CETN(X) + C_A \times \frac{M_C}{M_A} \times \frac{X}{100}$$

where C_A is the carbon number of gas A, and M_C and M_A are molecular weights of carbon dioxide and gas A, respectively.

The examples of CETN and s-CETN in both cases of excluding and including the effects of the degradation products, which are denoted by _1 and _2, respectively, are shown in Table 2. Further, new indicators including the effects of the degradation products for selected gases are compiled in Table 3.

2.4 Inclusion of effects due to degradation to trifluoroacetic acid and its dissolution in water

Some fluorine compounds are known to be degraded to trifluoroacetic acid (TFA) in the atmosphere. Therefore, for gases whose TFA yield rates have been known, inclusion of the warming effects attributable to CO_2 as the degradation product is reduced at that rate. These results are shown in Table 4. In the case of trifluoroethanol, as shorter lifetime considering the wet deposition through uptake by cloudwater and rain has been reported [5], the case of shorter lifetime is also listed.

2.5 Comparison of LCCP analyses by CEWN, CETN, s-CETN and GWP

The LCCP data of semiconductor cleaning gases and blowing agent for polyurethane insulation are as previously reported [6] [7]. The evaluation results using new indicators are shown in Fig. 1 and Fig. 2.

3 RESULTS AND DISCUSSION

CETN is based on the ideas below.

The equation of the temperature change at a given time due to a pulse emission of a greenhouse gas, which Shine proposed [1], is applied with the coefficients quoted from IPCC 2007 [3] and the integrated temperature change over the period leading up to a given time is characterized as the warming amount leading up to that time due to the emission of the gas. This value is different from the warming amount of GTP_P which is the value at a given time, and also, this integration and the integration in the emission scenario of GTP_S differs in meaning.

3.1 CETN

The warming by each greenhouse gas is integrated leading up to the time when the removal rate of each gas reaches to a given rate as is the case in CEWN, and compared each other. This realizes an equivalent quantity evaluation with taking the lifetime into account, which is called CETN.

3.2 s-CETN

The warming by each greenhouse gas is integrated leading up to the time when the ratio of integrated temperature change to infinitely integrated temperature change becomes a given rate, and compared each other so that it may realize another equivalent quantity evaluation with taking the lifetime into account. This is called s-CETN.

3.3 The setting of the removal rate from the atmosphere

The higher setting of removal rate from the atmosphere is more likely to have higher reliability of evaluation as a larger part is evaluated. However, the overhigh setting enhances the uncertainties of evaluation, since long-term evaluation is required. In particular, in the case of carbon dioxide, the change in concentration is complex and the error grows over time. Although it is supposed that carbon dioxide behavior is predictable up to 500 years after, in reality, 100 years of time, which corresponds to 63 % of removal rate, is used in many cases. In addition, if the evaluation term is too short, the difference between the atmospheric models becomes large, then, 75% of removal rate, which corresponds to about 350 years of time in carbon dioxide case, has been employed. Some examples are shown in Table 1.

3.4 The base year fixing of atmospheric carbon dioxide

The concentration of atmospheric carbon dioxide has been increasing year by year. It is known that the radiative forcing (RF) per unit weight has been decreasing with this concentration increment. Despite the persistent decrease in RF, in the case of GWP calculation, carbon dioxide is always used as a reference (= 1), accordingly, the calculated warming due to the other gases becomes large even though it stays unchanged. In addition, the fact that the GWP value of carbon dioxide is always 1 as a reference as well as the increase in GWP value of the other gases is likely to give a false impression that the warming attributable to the other gases has grown. Further, the regular correction is inevitable for GWP values.

Therefore, in the case of CEWN, CETN and s-CETN, the base year of atmospheric carbon dioxide concentration is fixed at preindustrial time, year 1750.

The change in carbon dioxide concentration is decided to

Table 1: CETN and s-CETN for some GHGs in the case where the removal rate of each gas is 75%

Common Name	Chemical Formula	Lifetime [years]	CETN_1(75)	s-CETN_1(75)
Years until CO_2 decreases by the given removal rate			356	356

n-Pentane	C_5H_{12}	0.010	2.30	2.29	3.06	0.04

The radiative forcing per kilogram of CO_2 used for the calculation is y1750 value for CEWN, CETN and s-CETN and y2005 value for GWP.

The coefficients for concentration response function of CO_2 are the same as IPCC 2007.

The lifetimes and GWP values are quoted from IPCC 2007 [3] except for hydrocarbons whose lifetimes are quoted from IPCC/TEAP 2005 [8] and whose GWP values are calculated in the same way of direct GWP in IPCC 2007.

a) The values of CEWN, CETN and s-CETN of methane have been multiplied by 1.4 to account for the indirect forcing following GWP of methane in IPCC 2007 [3].

b) The indirect forcing like effects on tropospheric ozone, CH_4 and CO_2 is not included in any values of hydrocarbons. In IPCC 2007 [3], it is reported that in direct GWP values of Ethane, Propane and Butane are 5.5, 3.3 and 4.0, respectively with uncertainty range of -50% to +100%.

be shown as the carbon dioxide environment number, which is defined as the ratio of RF in a year to RF in year 1750.

3.5 The warming effects due to the degradation product, carbon dioxide

Carbon-containing greenhouse gases are decomposed to produce carbon dioxide in many cases. Assuming that every carbon atom in each gas changes into carbon dioxide, CETN_2 and s-CETN_2, in which the warming effects due to carbon dioxide as a degradation product is added, are also proposed.

The amount of carbon dioxide produced until the given removal rate of 75% and until the ratio of integrated temperature change to infinitely integrated temperature change becomes the given rate of 75%, in the case of CETN and s-CETN, respectively is calculated, and then

Table 4: CETN (75-pi) and s-CETN (75-pi) for gases which produce trifluoroacetic acid (TFA) as degradation products

Common name *Chemical formula*	Lifetime [years]	TFA yield	CEWN_2 (75-pi)	CETN_2 (75-pi)	s-CETN_2 (75-pi)	GWP_{100}
HFC-134a	14	no TFA correction	308	197	315	1,430
CH_2FCF_3		13.0% [10]	308	197	315	
HFC-227ea	34.2	no TFA correction	732	641	749	3,220
CF_3CHFCF_3		100% [10]	732	640	748	
HFO-1234yf	11days [9]	no TFA correction	1.68	0.87	1.98	3.8 [a]
$CF_3CF{=}CH_2$		91% [11]	0.89	0.08	0.93	
Trifluoroethanol	0.5 [4]	no TFA correction	13.2	1.16	13.7	59 [a]
		30% [12]	13.0	0.96	13.5	
CF_3CH_2OH	0.3 [5]	no TFA correction	8.21	0.84	8.60	35 [a]
		30% [12]	8.01	0.64	8.34	

The radiative forcing per kilogram of CO2 used for the calculation is y1750 value for CEWN, CETN and s-CETN and y2005 value for GWP.
The coefficients for concentration response function of CO2 are the same as IPCC 2007.
The lifetimes and GWP values are quoted from IPCC 2007 [3] unless otherwise indicated.
a) Calculated in the same way of direct GWP in IPCC 2007.

the integrated temperature change corresponding to the carbon dioxide produced is added to CETN_1 and s-CETN_1 to calculate CETN_2 and s-CETN_2, respectively. Thus, the given rate of 75% is applied to the additional warming as the degradation product, as well. CETN_2 and s-CETN_2 are simply calculated by adding the carbon dioxide production equivalent to the given rate as they are relative values to carbon dioxide.

3.6 Comparison between CEWN, CETN, s-CETN and GWP

These new indicators and conventional GWP are shown for comparison in Table 3.

As is noted from the table, the values of new indicators are large in the long-lived gases case and small in the short-lived gases case. They are equivalent quantity evaluations and it is thought that they show realistic values with the evaluation fairness ensured.

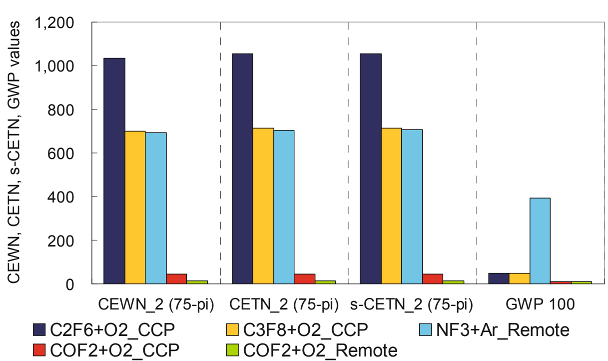

Fig. 1: LCCP analyses of CVD chamber cleaning by new indicators and GWP

Cleaning objects : SiO film
(pre-depo 200nm + depo 600nm (60sec.) on φ8" wafer)
abatement of exhaust gas : on
DEP for abatement --- CF_4 : 0.95, others : 0.99
gas leakage at prod. --- C_2F_6, C_3F_8 : 2.38%, NF_3 : 16.0%

3.7 Correction to hydrosoluble gases

It is known that stable trifluoroacetic acid (TFA) is produced as the degradation products. As TFA is a strong acid with a high affinity for water, it is removed from the atmosphere readily dissolved in the water without being decomposed into carbon dioxide. Trifluoroethanol is hydrosoluble itself and the lifetime becomes short due to

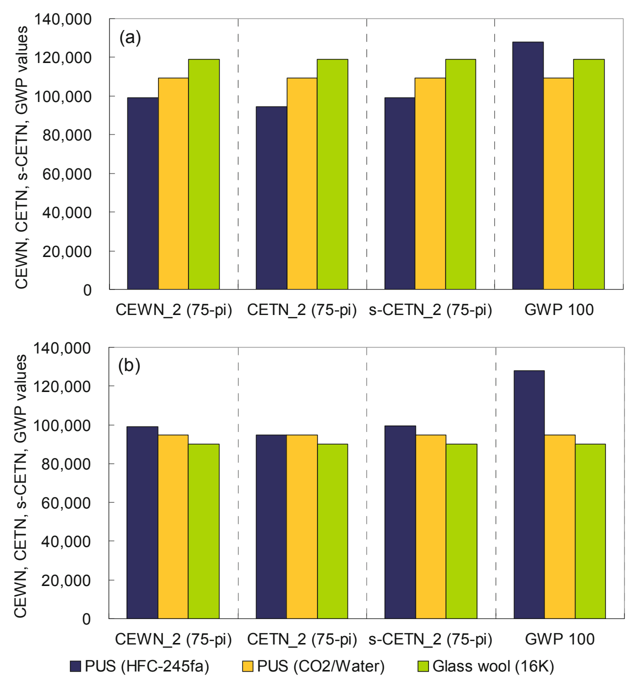

Fig. 2: LCCP analyses of wooden house insulations by new indicators and GWP in the case of (a) equal thickness of insulations and (b) equal heat transfer resistance of wall / ceiling / floor

blowing agent recovery after the 50-year use : no
HDD, CDD data : Japan, national average (2002)

Table 5: Features of CEWN, CETN, s-CETN and GWP

	CEWN, CETN	s-CETN	GWP_{100}
concept	integrated warming values until a given removal rate from the atmosphere is reached	integrated temperature rise until a given ratio to the infinitely-integrated temp. rise is reached	integrated warming values up to 100 years after the emission
evaluation period	lifetime-dependent		100 years
evaluation amount	The residual rate of each gas during a period of evaluation is the same.	The ratio of evaluation to the infinitely-integrated temperature rise is the same.	long-lived gases : partial short-lived gases : total
long-term evaluation	Longer evaluation is possible within the range where the behavior of CO_2 is clear		impossible due to uncertainty over long-term behavior of CO_2
point (years, rates) settings	Higher rates/years are desirable. Progress of CO_2 research can be reflected.		“100 years” is arbitrary
relationship with climate impacts	strong		weak
characteristics of evaluation	Sustainability is evaluable.		one-sided evaluation
warming value of "CO_2 = 1"	fixed (preindustrial value) or settable		changing by time
CO_2 as degradation products	Simple addition is available.		not included

the wet deposition [5]. Trifluoroethanol dissolved in the water becomes TFA without being decomposed into carbon dioxide.

As shown in Table 4, the correction of TFA production and wet deposition is applied to CETN_2, s-CETN_2 as well as CEWN_2 for gases whose TFA yield rates or wet deposition rates have been reported.

3.8 Comparison of LCCP analyses by CEWN, CETN, s-CETN and GWP

The LCCP analyses by CEWN, CETN, s-CETN and GWP on semiconductor cleaning gases and blowing agent for polyurethane insulation are carried out. The results are shown in Fig. 1 and Fig. 2. The results by new indicators are substantially different from the GWP results. In the case of cleaning gas evaluation, long-lived cleaning gases have a huge effect on the environment. In the case of blowing agent evaluation, it is clear that HFCs have a better outcome than non-fluorine series blowing agent.

4 CONCLUSIONS

New global warming indicators, CETN and s-CETN, are presented. The difference between these new indicators as well as previously reported CEWN and existing GWP is summarized in Table 5.

It is expected that these new global warming indicators, as metrics which show new direction of technology development, will make a contribution to future Eco design by changing conventional one-sided evaluation into multi-sided evaluation.

New Life Cycle Assessment Process for Strategic Reduction of Environmental Burdens

Shigeki Nitta[1], Yoshihisa Moriguchi[1]
[1] Mazda Motor Corporation, Hiroshima, Japan

Abstract

The purpose of this study is to develop a new Life Cycle Assessment (LCA) process that will enable us strategically to reduce environmental burden due to products. This is achieved by combining scientific knowledge on burdens caused environmental problem, the database on burden by material manufacture and product assembly, and sales portfolio of the product.

According to previous popular LCA process, analyzed burden items are assumed as main factor of environmental impact regardless of product category before amount of burden items by the product life cycle are calculated (life cycle inventory analysis). Next, the life cycle inventory analysis and impact assessment are carried out. The impact assessment depends on the initially-assumed burden items. New LCA process does not require the initially-assumed burden items, and enable us to carry out the comprehensive impact assessment.

Keywords:
LCA, new process, comprehensive assessment, strategic environmental improvement

1 INTRODUCTION

Many results of LCA to assess the environmental burdens due to products in life cycle were reported. In these LCA process, analyzed burden items, e.g. CO_2, NO_x are assumed as dominant factors of environmental impact e.g. global warning, photochemical oxidant, before life cycle inventory analysis.

In this study, previous LCA reports on global warming impact assessment were reviewed. Fuluhashi Environmental Institute (2009) carried out LCA on production of cardboard box [1], also Yasuhara Plamics (2009) on production of composite resin[2], and Bluetech (2009) on production of fixation agent for ground improvement[3]. These reports defined three environmental burdens, CO_2, CH_4, N_2O, as global warming gases and carried out life cycle inventory analysis, and environmental impact assessment on global warming with IPCC2001 GWP100. Although there are many kinds of global warming gas, e.g. Dichromethane, Halon,Methyl bromide, Perfuorobutane, Sulphur hexafluoride other than CO_2, CH_4, N_2O, they limited the three items depend on the assumption that the three items emitted by these products were dominant on global warning. The assumption was not validated by them.

Yamato, M (2002) carried out LCA on a Minivan with hybrid engine [4]. In the life cycle inventory analysis, only CO_2 was analyzed. The assumption that CO_2 was dominant global warming gas emitted by the minivan was not validated.

Similarly, Nitta,S., Moriguchi, Y (2010,2011) carried out LCA on passenger car [5] [6] based on the same assumption without validation.

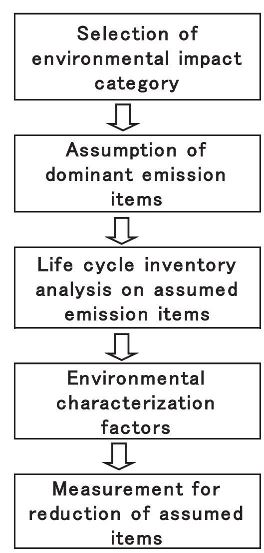

Fig.1 Previous Process of LCA

The previous process of LCA study is shown in Fig.1. In the Previous process of LCA, environmental burden items were assumed as dominant factor of environmental problem regardless the kind of products before lifecycle inventory analysis. The amount of emission of the assumed environmental burden items was calculated. The environmental impact assessment was carried out with the assumed environmental burden items. Whether the assumed environmental burden items was dominant global warming gases was not validated.

A reliability of environmental impact assessment depends on whether early assumption is appropriate or not. The previous process may be necessary to proper man-hours for LCA when the sufficient database on environmental

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_54, © Springer Science+Business Media Dordrecht 2012

burden items emitted by production was not build.

The new process of LCA that does not require the early assumption was developed with recent database for LCA necessary. Amount of emission of all environmental burden items in the database were calculated. And dominant environmental burden items caused the environmental impact are identified. Strategic measurement to minimize the environmental impact is possible by focusing reduction of identified environmental burden items.

2 METHODOLOGY

2.1 New process of LCA

New process of LCA that will enable us to measure the strategic reduction of environmental impact is achieved by combining a scientific knowledge on environmental burden items cased environmental impact, a database on environmental burden items emitted by material production and product production process and a database on sales portfolio of the product. Fig.2 shows the new process of LCA. Each steps of the process are explained as follows.

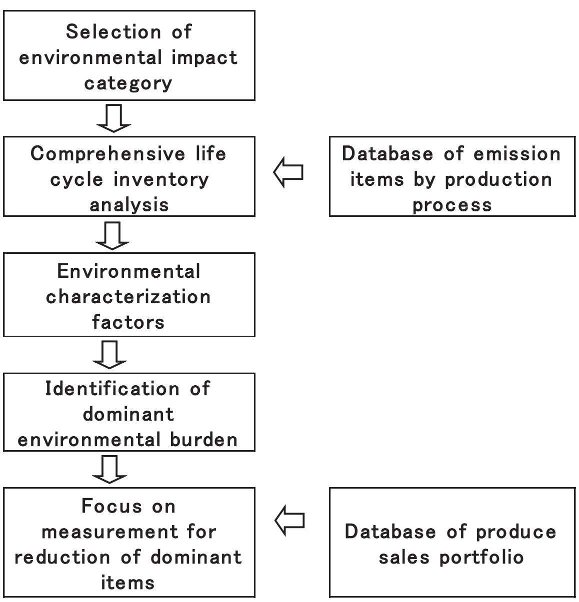

Fig.2 New Process of LCA

Selection of environmental impact category to assess

First, environmental impact category to assess should be selected. There are global warming, acidification, photochemical oxidant, etc. as environmental impact category. In this step, environmental burden items should not be limited to a few items. Global warning impact was selected in this study.

Comprehensive life cycle inventory analysis

Environmental burdens were calculated on each five phases consist of material production, product production, product use and disposal in life cycle. Life cycle inventory analysis on all environmental burden items in the selected environmental impact category was carried out based on the database of emission items by material production and product production process. The amount of all environmental burden items included in the database should be calculated.

Database of emission items by production process

Gabi4 [7] was used as database of emission items by material production process. The database of emission items by parts and product assembly production process was built by a investigation of Mazda factory. The database of sales portfolio was built by Mazda marketing data.

Environmental characterization factors

As for global warming impact in this study, environmental characterization factor is called Global-warming potential (GWP). GWP is a relative measure of how much heat a global warming gas in the atmosphere. It compares the amount of global warming by a certain mass of the gas in question to the amount of global warming by a similar mass of CO2. A GWP is calculated over a specific time interval, commonly 20, 100 or 500 years. GWP is expressed as a factor of CO2 whose GWP is standardized to 1. The GWP 100 years was popular and used in this study. Specifically, CML2001 by Leiden University[8], e.g. CH_4; 23, N_2O; 296, NMHC; 16, was used as GWP.
CO2 equivalent mass was calculated by Formula (1). A contributing rate of each emission gas was calculated by dividing CO2 equivalent mass of each emission gas by Formula (1)

$$CO2_{equivalent} = \sum_{j=1}^{n} GWP_{a,j} \times m_j \quad (1)$$

where,

$CO2_{equvalent}$:CO2 equivalent mass total
GWP_j: Global warming potential of emission gas j for years.
m_j : Mass of emission gas j (kg)
a: Suffix of the time horizon years over considered
j : Suffix of the kind of emission gas

Identification of dominant environmental burden items

The identification of dominant environmental burden items enable us strategically to minimize the environmental impact.

Mazda announced that all customers who purchase Mazda cars are provided with the joy of driving and excellent environmental and safety performance under slogan of “Sustainable Zoom-Zoom” long-term vision for technology development.

Based on the vision to provide all customers with the joy of driving and excellent environmental and safety performance, LCA of passenger car was carried out for not only special grade installed with improvement device of fuel efficiency but also for sales volume-weighted average LCA of all grade. Taking dominant environmental burden item, the process of LCA is shown in Formula (2).

$$LE_{aveage} = \sum_{i=1}^{m} LEi \times V_i \Big/ \sum_{i=1}^{m} V_i \quad (2)$$

Where,

$LE_{average}$: average envionmental burden of sales portfolio,

LE_i :Life cycle of envionmental burden of *i* car grade,

V_j : Sales volume of *i* car grade

i : Suffix of car grade number 1- m,

Focus on measurement for reduction of dominant items

The process mentioned above enable us to focus on the reduction measurement for the dominant environmental burden items on selected environmental impact category.

2.2 Analyzed Products

The analyzed product was new Mazda Demio shown in Fig.3. The goals of this analysis were to compare environmental performance between new Mazda Demio and its predecessor before miner change, and to identify issues for environmental improvement.

New Mazda Demio was refined on the exterior and inertia appearance, installed the new engine; SKYACTIV-G, i-stop, i-DM and lightweight seats, and improved the air resistance coefficient; Cd. The "i-stop" was designed for

Fig.3 New Mazda Demio

restarting the engine through combustion by injecting the fuel directly into the cylinders while the engine is stopped and igniting it to generate the force necessary to push down the piston by taking advantage of the features of the direct injection system. The i-DM was the Intelligent Drive Master system which would help drivers improve their driving techniques so that the drivers could enjoy driving, offer a comfortable ride to passengers and consequently reduce the fuel consumption. As for safety improvement, New Mazda Demio was installed DSC (Dynamic Stability Control) and 3 point seatbelt of rear center seat. Fuel consumption of New Mazda Demio achieved 30km/l (10-15 driving modes).

2.3 System Boundary s

The system boundary is shown in Fig.4 [5]. The life cycle of car is defined as five phases, material production, car production, use, maintenance and disposal from raw material extraction to disposal.

The durations of car use was set as ten years, and life cycle driving distance was set as 100,000 km by Japanese JC08 driving mode.

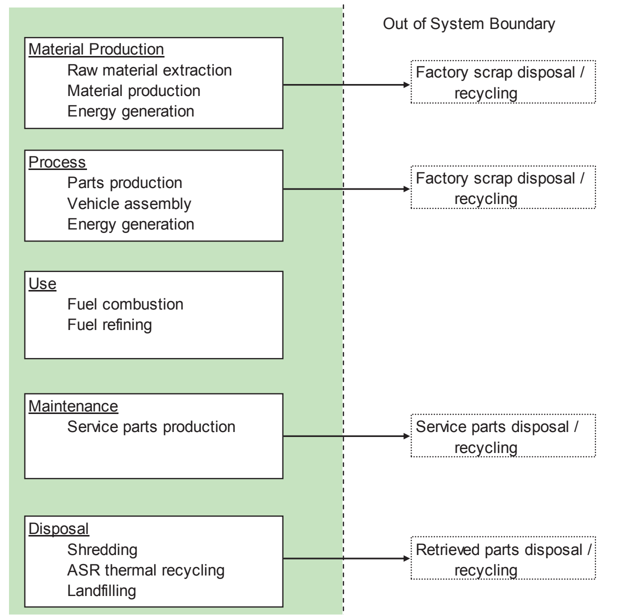

Fig.4 System Boundary[5]

3 RESULTS OF ANALYSIS

3.1 Global warming impact assessment

The masses of global warming gases emitted by the best selling grade of New Mazda Demio in lifecycle were calculated. Fig.5 shows the CO2 equivalent mass component rate of each global warming gases emitted by the New Mazda Deimo in life cycle, CO2:96.897%, CH4; 2.529%, N2O; 0.331%, NMHC; 0.1242% and others: 0.001%. CO2 was identified as the dominant environmental burden item in Fig.5.

The dominant environmental burden items in global warming gases emitted by the car were validated. In term of the results, the dominant environmental burden items were same as previous LCA processes..

3.2 CO2 emission

LCA of New Mazda Demio and its predecessor are carried out according to Formula (2) to reflect diffusion status of each grade into account. Each grade sales volume were indicated as the past record and plan respectively. Fig.6 shows CO_2 emissions by 10000 km driving distance of a unit of Mazda Demio in sales portfolio. In Fig.6, CO_2 emission of the predecessor by 10000 km driving distance indicates 1.0 as a relative scale.

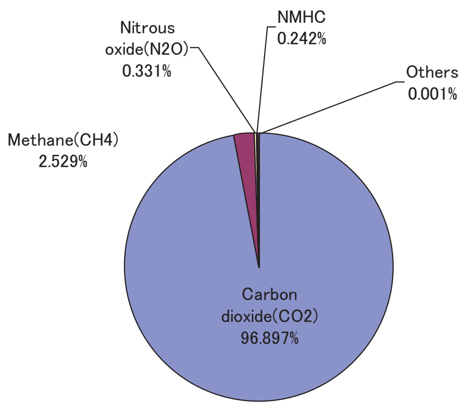

Fig.5 Comparison of global warning potential among greenhouse effect gases due to New Demio life cycle

CO_2 emission of new Mazda Demio decreases by 11% than predecessor. The environmental performance depends on improvement of fuel consumption with new engine SKYACTIV-G, i-stop and air resistance improvement. CO2 emission by production process also decreases by increased production efficiency and energy saving.

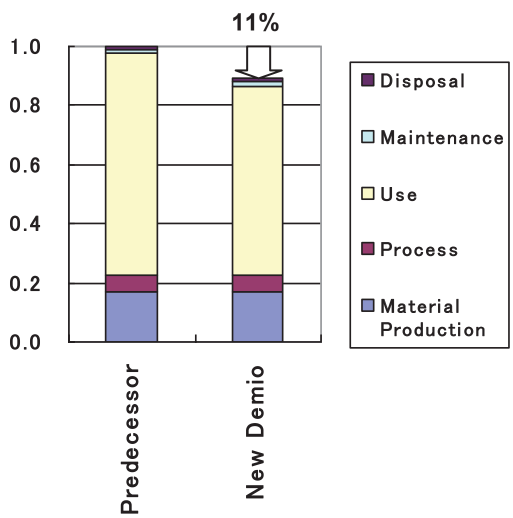

Fig.6 Comparison of CO2 emissions between predecessor and new Demio

4 CONCLUSION

In this study, new process of LCA for strategic reduction of environmental burden was developed, and was validated to be feasibility.

First, amont of all kinds of global warming gases emitted by new Mazda Demio in life cycle were calculated. Second, contribution rario of these gases were calculated with GWP100(CML2001). Third, it was validated that CO2 was the dominant gas on global warming becase of 97% contributing rate. The amont of CO2 emitted by New Mazda Demio in life cycle decreased by 11% than its predecessor.

In term of the results, the dominant environmental burden items were same as previous LCA processes. However, persons in charge of environmental improvement are able to tackle reduction of environmental burden with conviction by the new process of LCA.

Further study is nessesary to expand other environmental impact categories,e.g. acidification, photochemical oxidant, etc. Additionally, new scientific knowledge on burdens are necessary to be reflected in to the databases.

Integrated LCA for Printing Service in an emerging country

Hirokazu, SHIMIZU[1], Katsuya NAGATA[2], Aran HANSUEBSAI[3], Pradya KIENGPRAKONG[3]

[1] Shimizu Printing Inc., Tokyo, Japan

[2] Graduate School of Environment and Energy Engineering, Waseda University, Tokyo, Japan

[3] Department of Imaging and Printing Technology, Chulalongkorn University, Bangkok, Thailand

Abstract

In most of emerging countries in Asia, such as Thailand, Printing Service LCA is not organized, so schematization and localization of practical methodology is transferred thanks to the joint research project by Shimizu Printing Inc. and Chulalongkorn University. Printing Service LCA developed in Japan is focusing not only on $LCCO_2$ but also on Integrated LCA. It has strong possibility to take root even in emerging countries for environment-conscious Printing Services.

Keywords:

LCA, $LCCO_2$, Integrated LCA, Environmental Load Point, Printing Service

1 INTRODUCTION

Quantification of environmental load for Printing Service is well organized in Japan [1], namely Printing Service LCA is precisely schematized in the forms of $LCCO_2e$ [2] and Integrated LCA [3]. But, printing industries in many emerging countries in Asia do not have clues of quantitative assessment method yet and feel rushed to establish calculation method since some of their business model can work out only by exporting related business.

Thailand which is located in the center of Southeast Asia is covered here to validate Printing Service LCA to show possibility of localizing calculation method fitting in Thai printing industry.

In order to promote diffusion of Printing Service LCA, joint research study is conducted with an academic organization. Chulalongkorn University (CU) which is a top national university and the most influential printing related academic institution is selected to be a counterpart.

Carbon centered evaluation method for environmental load might not be perfect even in emerging countries, so Environmental Load Point (ELP) which is Integrated LCA method developed by Nagata Laboratory at Waseda University should be verified its effectiveness in Thailand.

2 ANALYSIS

2.1 ELP quantification method

ELP is based on evaluation of nine different impact categories. Outstanding feature is that order of priority for environmental load is decided by questionnaires from variety kinds of interest groups.

This idea is based on preference order about impact categories which should be determined by people's concern about environmental issues.

Weighting for each impact category is called "category importance"; it is a critical factor when consolidating environmental loads as an integrated indicator. For ELP, questionnaire such as Analytic Hierarchy Process (AHP) is utilized primarily to specify category importance for a specific group. Table 1 indicates an example of AHP explaining how to determine category importance ratio.

Table 1: Category importance determined by AHP

ELP 9-category		B: 1.Energy drain	2.Global warming	3.Ozone depletion	4.Acid precipitate	5.Resource consumption	6.Air pollution	7.Ocean & water pollution	8.Problem of waste disposal	9.Ecosystem effect	Multiplication of 9Cs*1	Category importance*2	Category importance ratio*3

ELP has over 185 of consumption/emission items such as crude oil, coal, iron ore, CO_2, landfill and others categorized in nine impact categories, but items are narrowed down for light version here since inventory data are simplified by the use of CO_2 calculator named "Simple LCA" created by Japan Environment Management Association for Industry and some items are uncollectable ones statistically in Thailand. Weight coefficients for all items in impact categories should be organized by related references; it is summarized in Table 2.

Table 2: Weight coefficients of items in impact categories

Impact category	Item(number of items for full version and light version)	Reference to fix weight coefficient for items in impact category
1 Energy drain	Cruide oil, coal..(5, 5)	Low calorific value/Reserve production ratio (Crude oil=1)*2
2 Global warming	CO2, CH4,CFC..(38, 3)	GWP100*1 (CO2=1)*2
3 Ozone depletion	CFCs..(24, 0)	ODP (CFC-11=1)*2
4 Acid precipitate	NH3, SOx..(7, 2)	AP (SOx=1)*2

Consumption or emission in one year for each item should be investigated from statistics in the specific country since target product is produced domestically here. Annual load is led from multiplication of weight coefficient and consumption or emission, and then summed up for each impact category. Calculation is done as Environmental Load Factor (ELF) for each item, and then is multiplied by inventory data to calculate ELF which is emission factor for ELP. Inventory data for Thailand is not well organized yet, so the one in Japan is utilized instead. Table 4 shows actual calculation of ELF for each item and ELF for each process. Paper is illustrated by an example.

Table 4 ELF for items and specific process (e.g. Paper)

Impact category	Item	Annual load A=C×TQ	ELF C*AHP/Total of A*10^16	1.Paper Inventory data	1.Paper ELF(ELF *Inventory data)
Energy drain	oil	4.91E+10	1.98E+04	2.20E-01	4.35E+03
	coal	3.55E+09	2.18E+03	2.43E-01	5.29E+02
	natural gas	2.41E+10	1.52E+04	2.27E-02	3.46E+02
	uranium ore	9.63E+07	2.93E+05	3.72E-06	1.09E+00

Ecosystem influence	Dioxin	0.00E+00	0.00E+00		
			Total ELF:		1.71E+04

At the end of ELP explanation, practical quantification steps are summarized below.

(1) In order to calculate annual load for each item in each impact category, weight coefficient which is fixed by the reference for item in category (Table 2), is multiplied by annual consumption or emission for item (Table 3) and summed up as annual load for each impact category.

(2) Category importance determined by AHP (Table 1) in each impact category is multiplied by weight coefficient which is fixed by the reference for impact category, and then divided by sum of annual load in impact category for normalization. Total of each item's consolidated coefficient is summarized as ELF for each process; it is basic element, namely emission factor to calculate ELP. (Table 4)

(3) ELP is led by multiplication of ELFs for processes and total inputs or emissions for processes.

Mathematical formulas for three steps are shown below in concert with explanation.

$$A_j = \sum_k (C_{j,k} \times TQ_k) \quad (1)$$

$$ELF_k = \sum_j \left(C_{j,k} \times W_j \big/ A_j \right) \quad (2)$$

$$ELP_i = \sum_k (ELF_k \times Q_{i,k}) \quad (3)$$

ELP_i: Integrated indicator

A_j: Annual load in j impact category

$C_{j,k}$: Weight coefficient for k item in j impact category

TQ_k: Annual consumption or emission for k item

ELF_k: Integrated coefficient for k item

Wj: Weight coefficient (category importance) from questionnaire in j impact category

$Q_{i,k}$: Total consumption or emission for k item in i process

Suffix I: Process or product

Suffix j : Impact category

Suffix k: Item in impact category

ELP evaluates environmental impacts with sufficient balance. It is an Integrated LCA approach illustrating environmental load from wide range of standpoints.

2.2 Survey by AHP for different groups

As mentioned above, ELP is started by AHP to know environment conscious level (category importance) by impact category for specific group.

For this study, people inviting questionnaires in two groups besides CU students and personnel are defined. One is “Printers” (40 interviewees) from Printing Association and the other is “Housewives” (40 interviewees) having strong influence on buying behavior. Both are key groups to know category importance of nine impact categories for further research.

Latest AHP from three groups in Thailand are summarized and compared with the one from “Printers” in Japan. For CU students and personnel, “Resource consumption” is ranked first, “Ecosystem effect” stands second and “Global warming” sits third. Their focus is mainly on scarcity of resources, global warming issue is not paid attention as number one issue.

For Printers and Housewives in Thailand, “Global warming” is ranked first, “Energy drain” stands second and “Air pollution” sits third, two groups shows exact same tendency. Definitive reasons for the results are not known, but it could be considered that Global warming issue also gets a lot of media attentions in Thailand.

For Printers in Japan, they are 30 interviewees from Japan Waterless Printing Association and carbon calculation operators. Namely, they are at the edge of printing industry from the viewpoints of environment conscious, so the result could be the most ideal among imaginable ones. They view “Global warming” as first priority and “Energy drain” as second priority, their way of viewing is all the same as Printers and Housewives in Thailand. Even though their bases of daily activities are different, importance of first and second impact categories they pay attention are all the same. It is shown in Figure 1.

Impact Categories	Printers 40-interviewee JPN	Chula Univ. 100-interviewee THA	Housewives 40-interviewee THA	Printers 30-interviewee THA
1.Energy drain	0.142	0.098	0.142	0.152
2.Global warming	**0.161**	0.134	**0.168**	**0.156**
3.Ozone depletion	0.114	0.129	0.109	0.117
4.Acid precipitate	0.079	0.084	0.083	0.096
5.Resource consumption	0.098	**0.168**	0.089	0.087
6.Air pollution	0.106	0.100	0.112	0.130
7.Ocean & water pollution	0.118	0.082	0.110	0.103
8.Problem of waste disposal	0.059	0.067	0.089	0.071
9.Ecosystem effect	0.122	0.138	0.098	0.088

Reference: Nagata Lab. at Waseda Univ.

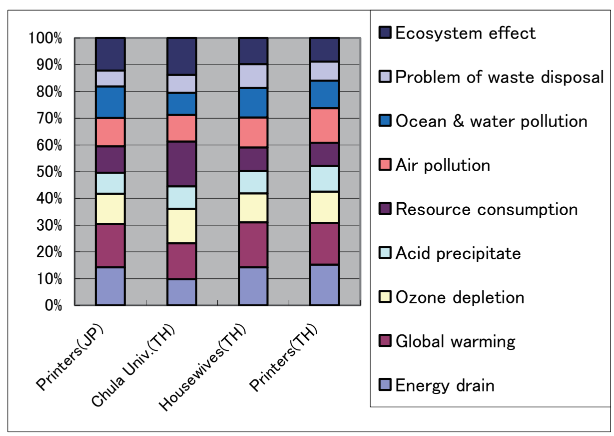

Fig. 1: AHP results in Thailand and Japan

As a result of AHP in Thailand and Japan, it is clear that people who are deeply involved in printing related and buying activities, that is to say that suppliers and consumers are very conscious about “Global warming” and “Energy drain”, but contrastingly do not care almost nothing for “Problem of waste disposal”.

On the other hand, people in academic field are trying to look straight at the current environmental problem. They consider “Resource consumption” as top priority, it means that drawdown of mineral resources in the near future is worried more than a little.

So on that point, in order to speed up people to shift their mood to environment conscious, "Global warming" is definitely critical factor, but people in academic field never be misguided by media and try to keep the ideal balance of environment conscious.

2.3 Case study specification for ELP

Case study here is a textbook for students at Department of Architecture at CU, its specification is summarized in Table 5.

Table 5: Specification of a textbook for case study

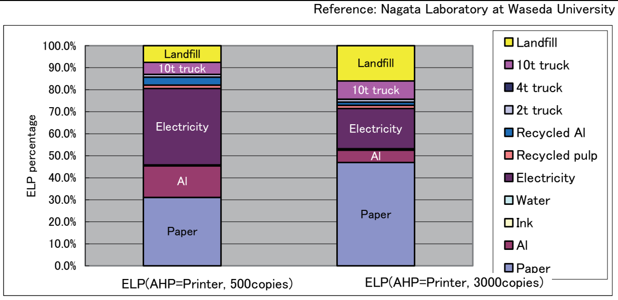
Title:	The beginning of Siam Architecture Arts
Author:	ML Prateep Malakul
Size:	190mm*260mm*6mm
Copies:	500
Pages:	Cover 4P + Text 128P

2.4 ELP results by different production lots

Questionnaires to know category importance of impact categories by AHP are conducted for CU, Housewives and Printers separately in Thailand, but ELP based on one category importance only by Printers but different production lots is verified at first. Figure 2 indicates the difference of ELP by 500 and 3000 copies of a textbook.

Process	Case study-1(500 copies)				Case study-2 (3000 copies)			
	ELF	ELP(AHP=Printer)			ELF	ELP(AHP=Printer)		
		Input	ELP			Input	ELP	
1. Paper	1.71E+04	276.210 kg	4.73E+06	31.1%	1.71E+04	1,058.750 kg	1.81E+07	46.9%
2. Al	2.18E+05	10.000 kg	2.18E+06	14.3%	2.18E+05	10.000 kg	2.18E+06	5.6%
3. Ink(Polyurethane)	5.88E+04	1.033 kg	6.07E+04	0.4%	5.88E+04	4.276 kg	2.51E+05	0.7%
4. Water	9.95E-01	2.580 kg	2.57E+00	0.0%	9.95E-01	10.691 kg	1.06E+01	0.0%
5. Electricity	4.25E+03	1,243.908 kWh	5.29E+06	34.8%	4.25E+03	1,655.352 kWh	7.04E+06	18.2%
6. Recycled pulp	1.57E+03	149.351 kg	2.35E+05	1.5%	1.57E+03	374.659 kg	5.89E+05	1.5%
7. Recycled Al	5.44E+04	10.000 kg	5.44E+05	3.6%	5.44E+04	10.000 kg	5.44E+05	1.4%
8. 2t truck	4.38E+03	41.208 tkm	1.80E+05	1.2%	4.38E+03	114.936 tkm	5.03E+05	1.3%
9. 4t-truck	3.52E+03	2.843 tkm	1.00E+04	0.1%	3.52E+03	2.843 tkm	1.00E+04	0.0%
10. 10t-truck	2.98E+03	278.549 tkm	8.30E+05	5.5%	2.98E+03	1,069.382 tkm	3.19E+06	8.3%
11. Landfill	7.42E+04	15.477 kg*1	1.15E+06	7.6%	7.42E+04	83.459 kg*1	6.20E+06	16.0%
		Total ELP:	1.52E+07				3.86E+07	
		Total ELP/book:	3.04E+04				1.29E+04	

Reference: Nagata Laboratory at Waseda University



*1: Weight of products*Landfill ratio(12.2%)

Fig. 2: ELP of 500/3000 copies

ELP for 3000 copies is 2.5 times as much as the one for 500copies when number of copies for medium-run is six times as many as the one for short-run. ELP per book is cut downed to more than half when production lot is changed from 500 copies to 3000 copies.

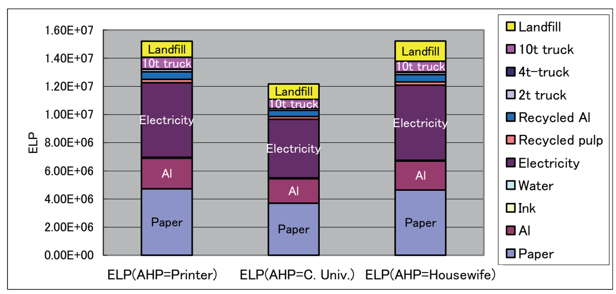
For short-run job, "Electricity" is the highest load because it occupies more than one third of the total. Yet, for medium-run job, "Paper" is the most influential factor since it almost reaches half of the total load. Breakout of environmental load per book depends on lots; it is exactly the same as cost performance.

2.5 ELP result comparison of CU students, Printers and Housewives in Thailand

ELP result is compared among three different groups such as Printers, CU students and Housewives in Thailand to know how category importance determined by AHP influence ELP results. It is summarized in Figure 3.

Process	Input	Printer (THA)		CU (THA)		Housewife (THA)	
		ELF-1	ELP	ELF-2	ELP	ELF-3	ELP
1. Paper	276.210 kg	1.71E+04	4.73E+06	1.34E+04	3.70E+06	1.68E+04	4.64E+06
2. Al	10.000 kg	2.18E+05	2.18E+06	1.74E+05	1.74E+06	2.05E+05	2.05E+06
3. Ink(Polyurethane)	1.033 kg	5.88E+04	6.07E+04	4.38E+04	4.52E+04	5.72E+04	5.91E+04
4. Water	2.580 kg	9.95E-01	2.57E+00	7.93E-01	2.04E+00	1.01E+00	2.59E+00
5. Electricity	1,243.908 kWh	4.25E+03	5.29E+06	3.36E+03	4.18E+06	4.28E+03	5.33E+06
6. Recycled pulp	149.351 kg	1.57E+03	2.35E+05	1.24E+03	1.85E+05	1.58E+03	2.36E+05
7. Recycled Al	10.000 kg	5.44E+04	5.44E+05	4.34E+04	4.34E+05	5.14E+04	5.14E+05
8. 2t truck	41.208 tkm	4.38E+03	1.80E+05	3.39E+03	1.40E+05	4.11E+03	1.69E+05
9. 4t-truck	2.843 tkm	3.52E+03	1.00E+04	2.74E+03	7.80E+03	3.27E+03	9.29E+03
10. 10t-truck	278.549 tkm	2.98E+03	8.30E+05	2.32E+03	6.46E+05	2.76E+03	7.70E+05
11. Landfill	15.477 kg*1	7.42E+04	1.15E+06	7.01E+04	1.08E+06	9.31E+04	1.44E+06
	Total ELP:		1.52E+07		1.22E+07		1.52E+07

Reference: Nagata Laboratory at Waseda University



*1: Weight of products*Landfill ratio(12.2%)

Fig. 3: ELP of Printer/CU/Housewife

ELP for Printer and Housewife is almost the same since the same trend is seen in category importance by AHP for both groups, so compare Printer with CU only here.

ELP for CU is about 20% less than the one for Printer. The reason is that Printer's ELFs which are emission factors for ELP are much higher than CU's ones. Two major influential factors are Paper and Electricity, those ELFs for Printer are around 1.3 times as much as the ones for CU because Printers weights more on Global warming which has almost 50% affect on paper and 60% affect on electricity individually. This is a case study showing different environmental load based on different category importance even though calculating same specification of a printed matter.

Category importance in impact category which is weighted highly for inventory data influences ELF and leads ELP higher even though production lot is the same.

2.6 ELP result comparison of Thai printers and Japanese printers

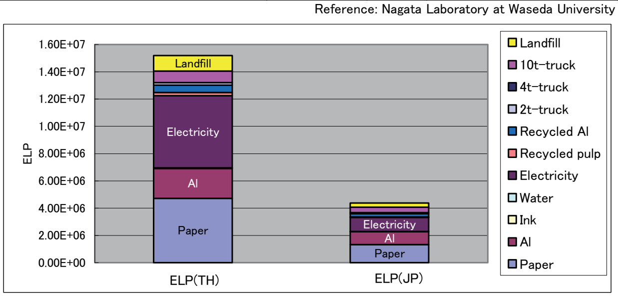
Cross-border comparison of ELP between Thailand and Japan is done based on Printers' category importance in each nation. The result is shown in Figure 4.

ELP in Thailand is almost 3.5 times as much as the one on Japan, namely environmental load in Japan is less than one third. The reason is that the most influential ELF which is Electricity is 5.2 times as much as the one in Japan. Additionally, second highest load which is Paper is 3.6 times as much as the one in Japan. ELFs of two major factors are obviously different on a grand scale.

In addition, Thai ELFs for each item such as oil/coal/natural gas for Energy drain and CO_2/N_2O/CH_4 for Global warming in impact categories are much higher compared with Japanese ELFs for same items after normalization considering item's category importance by AHP and sum of annual load in impact category.

Process	ELF(TH)	ELP (Printers, THA)			ELF(JP)	ELP (Printers, JPN)		
		Input	ELP			Input	ELP	
1. Paper	1.71E+04	276.210 kg	4.72E+06	31.1%	4.75E+03	276.210 kg	1.31E+06	30.0%
2. Al	2.18E+05	10.000 kg	2.18E+06	14.3%	9.62E+04	10.000 kg	9.62E+05	22.0%
3. Ink(Polyurethane)	5.88E+04	1.033 kg	6.07E+04	0.4%	1.49E+04	1.033 kg	1.54E+04	0.4%
4. Water	9.95E−01	2.580 kg	2.57E+00	0.0%	1.93E−01	2.580 kg	4.98E−01	0.0%
5. Electricity	4.25E+03	1,243.908 kWh	5.29E+06	34.8%	8.21E+02	1,243.908 kWh	1.02E+06	23.4%
6. Recycled pulp	1.57E+03	149.351 kg	2.34E+05	1.5%	3.02E+02	149.351 kg	4.51E+04	1.0%
7. Recycled Al	5.44E+04	10.000 kg	5.44E+05	3.6%	2.36E+04	10.000 kg	2.36E+05	5.4%
8. 2t truck	4.38E+03	41.208 tkm	1.80E+05	1.2%	1.86E+03	41.208 tkm	7.66E+04	1.8%
9. 4t−truck	3.52E+03	2.843 tkm	1.00E+04	0.1%	1.68E+03	2.843 tkm	4.78E+03	0.1%
10. 10t−truck	2.98E+03	278.549 tkm	8.30E+05	5.5%	1.42E+03	278.549 tkm	3.96E+05	9.0%
11. Landfill	7.42E+04	15.477 kg*1	1.15E+06	7.6%	1.96E+04	15.477 kg*1	3.03E+05	6.9%
		Total ELP:	1.52E+07				4.37E+06	

Reference: Nagata Laboratory at Waseda University

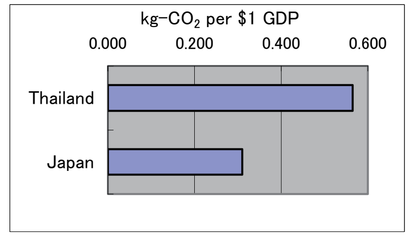


*1: Weight of products*Landfill ratio(12.2%)

Fig. 4: ELP of Printers in Thailand and Japan

This result might be suspicious because the result differs greatly when comparing. Figure 5 could show comprehensive idea and backup the difference of the result in some way since it shows relation nature of environmental factor and economical factor.

Year	2007
Scale	kg−CO_2 per $1 GDP
Thailand	0.565
Japan	0.310
JP/TH	54.9%



Reference: United Nations Statistics Division

Fig. 5: CO_2 emission per GDP 1$ in Thailand and Japan

This data shows that CO_2 emission to generate $1 of GDP, the number in Japan is nearly half of the one in Thailand. It means that efficiency of production and service is down to the half level in Thailand. If focusing only on manufacturing except for service related activities, this difference is easily imagined that CO_2 emission to generate $1 of GDP in Thailand can be much worse than current figure.

3 CONCLUSION

Integrated LCA for Printing Service ranging from primary data collection at production site to secondary data collection by bibliographical survey is established in an emerging country without any serious obstacles. Though there is limited condition such as no statistical data for some items in impact categories, the comparison of environmental load by the scale of ELP can be performed to know the difference between an emerging country and an advanced country. Comparison of the same printed matter based on different category importance in the same nation cannot show any significant meaning, but comparison based on different category importance in different nation can show valuable match-up. This is the way for ELP to be utilized.

Carbon centered evaluation method is viewed with skepticism in advanced countries since many believe that other environmental influences should be considered in some way, it also happens in emerging countries. Surveys for different groups of people mostly show that Global warming is top priority among impact categories, but it does not stick out and other impact category such as energy drain is also considered to be important as well. Therefore, the demand for Integrated LCA such as ELP is expected to be stronger and stronger from now on; the method should be schematized and utilized in other emerging countries in the future even though it has minor limited condition regarding consumptions or emissions of items in impact categories. ELP is the one to be transitioned and localized in different countries in a short span of the time since only questionnaires of category importance and investigation of consumption/emission of item are necessary things to do.

Taking all of these results above into account, ELP for Printing Service can be established even in emerging countries with minimum level of effort.

4 DISCUSSION

Primary data collection is not so difficult since printing related facilities which are utilized all over the world are all the same though mixture of old and new should be considered. But, secondary data collection sometimes meets obstacles because of pending arrangement in national database which is supposed to be organized by government institutions in emerging countries. For the case study here, secondary data of paper occupying majority of the load is not prepared in Thailand for years and is misappropriated to Japanese secondary data. Data for paper is one of the most important one for Integrated LCA, so inventory data for two different kinds of paper which are coated paper and coated cardboard should be well prepared as soon as possible.

Many people especially in academic and industry field in emerging countries feel that Carbon Footprint of Products (CFP) cannot show real environmental load and try to develop comprehensive Integrated LCA approach, but it is not successful yet. When most of people in town cannot understand CFP perfectly, it is presumed that comprehension of Integrated LCA result must be much more obscurity. The time might not be ripe to go on to the next step right now. It is too straightforward for Integrated LCA to utilize for Business to Consumer basis, but it might be much easier for Business to Business basis to start utilizing Integrated LCA as consolidated indicator in the streamline of supply chain.

Finding out the solution for the problem of getting the concept of Integrated LCA across is a great challenge and a near-future agenda.

Research on Environmental Innovation Strategy that intends High Performance Enterprise in Uncertain Age

Yoshinori Ito (1)[1], Katsuya Nagata (2)[2]
[1] IBM Japan, Ltd., [2]Waseda University, Tokyo, Japan

Abstract
The purpose of this content is to clarify the characteristic in the source of the corporate value creation based on empirically analysis of the environmental strategy that intends a high performance in an uncertain age of recent years. Various proofs has already been performed about the Porter hypothesis that the environmental control stimulates the technical improvement and the competitiveness of the company rises inside and outside the country, and financial data of the eco management investigation and the listed company intended for the domestic manufacturing from 2005 to 2010 is used here. The relation between an environmental performance and a financial performance was analyzed by various cuts, and the grasp of a basic theory for modeling and the further validation of the hypothesis by the double check were tried from the trend and the pattern of each enterprise. In a domestic enterprise, it is clear to have to consider the CSR whole that exceeds the environmental range and the viewpoint named ESG as an area expansion and non-financial index to the foreign company when application to the business is considered though a constant tendency was able to confirm the hypothesis. It is thought that the result of the trend analysis clarified here is useful in the meaning of supplementing a part of essential information to make the position of the enterprise in the sustainable society that should be aimed in near future.

Keywords:
evaluation, CSR, ESG, strategy, innovation

1 INTRODUCTION

The company is pressed for various correspondences for continuation while many uncertain factors, such as economy by the global financial crisis or a newly emerging country seen rarely, change of population structure, or a correspondence demand to the social responsibility for which the environmental problem that is progressing steadily although it is not rapid, and a company are asked, occur in recent years. Probably, the action which a sustainable company should take in such a situation must be based on the information gathering more scientific basis, and suitable decision-making. The correspondence although what depends many of former corporate value on an economical result was in the mainstream, non-social acts, such as a scandal, lead to a large drop in share prices also in the viewpoint of compliance, these theme neglect will be impossible. Although financial performance and an environmental performance generally have a relation of a trade-off, It is thought that the Porter hypothesis that environmental regulation stimulates technical innovation and business competitiveness increases is verifiable by clarifying the characteristic of the fountainhead of corporate value creation from analyzing positively the situation of the environmental strategy in which the high performance companies. Although various actual proofs have already been made in and outside about this theme, The financial statistics of the eco management degree investigation for the domestic manufacturing from 2005 to 2010 and a listed company are used here, The relation between an environmental performance and financial performance was analyzed at various cut ends, and re-verification of the hypothesis by the grasp and supplementary examination of basic theory which are turned to modeling from the trend and type of each company was tried. Below, in Section 2, the outline of related precedence research is checked and a hypothesis, the model for verifying it, and data are explained with Section 3. Section 4 shows the contents and the result of empirical analysis, and last Section 5 has stated the implication towards future deployment and practical use in business as a conclusion.

2 THE OUTLINE OF PRECEDENCE RESEARCH

2.1 Relation between regulation, environment policy, and corporate value

The Porter hypothesis is supposed that technical innovation which will bring about expense saving and improved quality if environmental regulation is designed appropriately is stimulated, and business competitiveness increases. Although it receives and the report of the actual proof is carried out one by one from around 1995, The company by Parmar etc. pursues profits to the last at the beginning, and it applies from 1999 in 2002 from a view negative about the synergistic effect by the new technology of an environmental measure, Some reports of

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_56, © Springer Science+Business Media Dordrecht 2012

bringing good influence to financial performance by secondary effects, such as not only the technical innovation by an environmental measure but transparency of decision-making and improvement in reliability, are shown. Moreover, report by the domestic data in 2004 and afterwards the measure for the environment of a company changing from recognition of a cost factor to positioning as one of the most important strategies, and, it seems that the correlation is becoming more clear with progress of time, such as showing the conclusion whether a high environmental performance also come to evaluate the market side simultaneously as a factor which raises a corporate value.

Table 1 : Number of evaluated companies by year

Industory / Year	2005	2006	2007	2008	2009	2010	Total
Food	25	30	31	31	33	36	186

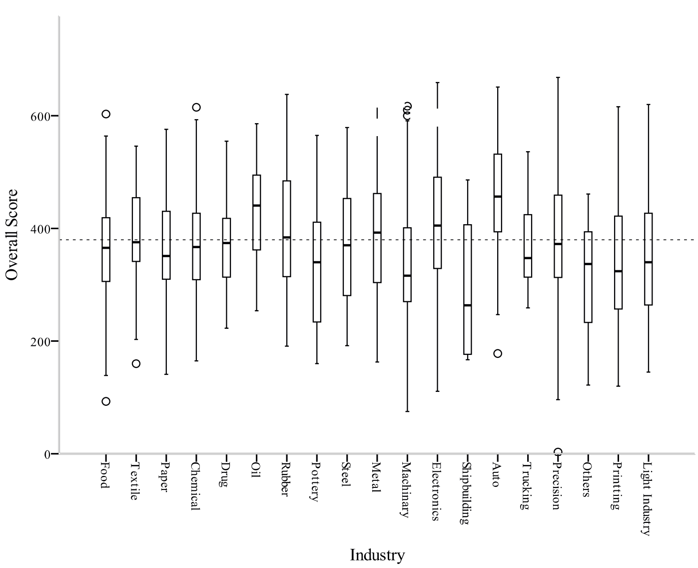

Fig. 1 : Over-all sore by industries (2005-2010)

2.2 Uncertainty of reformist investment

About innovation investment, from the skeptical thing that it may be promoted by the emissions-rights sale profit motive of Alpay in 2001, there is a report of Ambec, Mohr, etc. to which it is supposed that an effect fixed about investment for research and development is seen in 2002 and afterwards. In the situation where environmental regulation is performed by Popp D. in 2005, it is higher profits to perform investment for research and development, and when there is no regulation, in the way which does not perform investment for research and development, the average of profits becomes high. Moreover, if a possibility of gaining such high profits that research and development expenditure being innovatively large scale is high, it will collect, in henceforth the domestic reporting, if the virtuous circle of the environment and economy of what is not necessarily made clear as economic theories, such as evaluation to the inefficiency or environmental conservation activities in a company, is brought about and the possibility of a policy is not denied simply, it is collected.

3 A HYPOTHESIS AND ACTUAL PROOF MODEL

3.1 Verification design outline

Some of the contents already clarified by precedence research, although the concrete verification hypothesis was set up along with five verification themes, the each outline will be explained below. 1 check of relevance of result, 2 classification by synthetic index, 3 classification by degree of similar, 4 check of causal relationship between factors, and 5 predict future from past data as optional.

3.2 About the check of the relevance of a result

The relation between basic environment and financial factor is checked the correlation analysis and discriminant analysis which carried out the focus are given to the holdings company etc. that plan global business and a strategic investment with large size of business and characteristic of a company, for example, an overseas sales ratio, and the following hypotheses are verified. Hypothesis 1: a. Environment and financial factor have

Table 2 : Descriptive statistics

	N	Minimum	Maximum	Mean	Std. Deviation
Overall	2085	3	668	379.84	109.286
Management	2085	7	100	62.61	18.157
Poution	2085	9	100	68.29	20.825
Recycling	2085	10	100	68.76	17.080
Product	2085	10	100	63.28	19.378
GHG	2085	5	100	57.91	21.703
Sales	1992	1642	26289240	705006.80	1769282.100

Valid N	1575				

positive correlation, b. A size of business and an environmental indicator have positive correlation, and c. A holdings company and global business show higher performance from a strategic intention.

3.3 About the classification by a synthetic index

Principal component analysis extracts the two main ingredients from the synthetic target index this time, and it tries the pattern type according to company. Moreover, a part is verified based on the influence of a related event. Hypothesis 2: The group of the company which raises a corporate value without damaging value by strategic action also in a company with a large size of business and high environment assessment exists.

3.4 About the check of the causal relationship between factors

A financial indicator and an environmental indicator are taken to each dependent variable, the remaining variables are taken to an independent variable, and a multiple regression model is derived by the multiple linear regression analysis by a stepwise procedure.

4 ESTIMATION RESULT IN ACTUAL PROOF

4.1 Data and a sample

Sample data set the listed company which can obtain financial statistics and stock price data as the main objects out of around 400 companies of domestic manufacturing in Japan market which has been the target of the Nikkei eco management degree investigation about six years of 2005 to 2010. Scoring of the result investigated by the contents the evaluation criteria of eco management degree investigation were indicated to be in Table 1 is carried out by environment overall score for each industries. Financial statistics and stock price data collected the corresponding data of the fiscal year from Nikkei NEED-FAME. Moreover, it supplements with attribute dummies, such as a size of business, global business, and a holdings company, in analysis.

4.2 The characteristic of data

The selected company of business environment degree investigation is classified into the industry of 19, and distribution of the comprehensive mean score of each type of industry through 2005 to 2010 shown in Fig. 1. If an overall average is seen, a car, electrical machinery, etc. are positioned by the higher rank. Moreover, the amount of descriptive statistics of the data for analysis is shown in Table 2. As an index of financial performance, it learns from precedence research, and is using the logarithm of the Tobin's Q minus 1 as one of the indices showing the corporate value computed from a stock price. The outline of the business environment of a period by which investigation was conducted is shown inFig. 2. At the financial crisis in 2009, the fall of the corporate value and returns are confirmed in almost the companies.

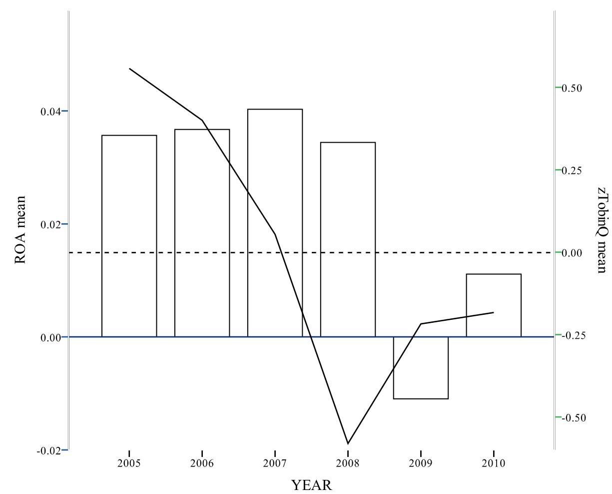

Fig. 2 : Overview of the business environment

4.3 The relation between environment and a financial factor

The investigated correlation between an environmental indicator and each financial statistics described in Table 3. First, although the significant result was not seen for a short period of time for one year in the relation between

*. Correlation is significant at the 0.05 level (2-tailed).

ROA and an environmental synthesis rank which shows short-term financial performance, if six years are seen from the mid- and long-term viewpoint, a mutually related tendency will appear. About the item which requires investment, such as countermeasures against pollution and greenhouse gas, especially, negative correlation is shown as what spoils short-term profits. When it sees about the foreign sales ratio and environment assessment, a coefficient is 0.2 set, but positive high correlation is shown relatively and the environmental measure consciousness of global business is imagined. Although ROA which shows profits about a research and development cost versus sales ratio and environment assessment gives impact by negative correlation, it is considered to contribute to improvement in environment assessment, and although it affects profits similarly about a capital investment pair sales ratio, it is raising evaluation of countermeasures against pollution, the measure against a product, and the measure against resource circulation. It is in the tendency which shows a high rank generally in a relation with the consolidated sales and the number of employees showing the scale of a company, it is thought that this comes from the business structure which can be equal to a minimum measure investment. Also it seems that investment contributes to the improvement in the value of a relation with a corporate value, correlation of minus is shown in sales or profits. About environment assessment, variation is seen by items.

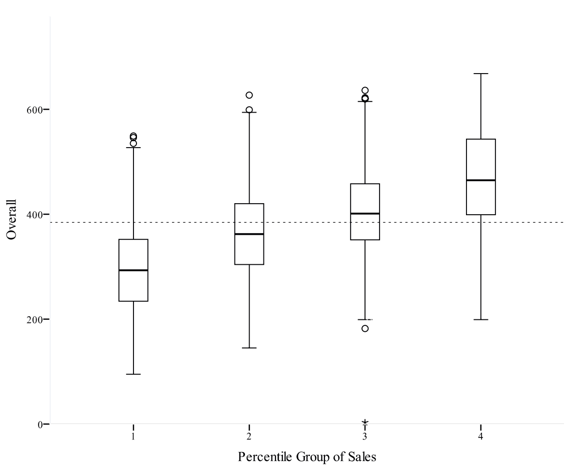

Fig. 3 : The environment-assessment tendency by a size of business

4.4 Trend analysis by a size of business

It divided into four from the higher rank as a size of business from the average of the consolidated sales of a company, and verified the relation with overall environment score. First, the result of having authorized the difference of each index between groups (sales rank) analysis is shown in Fig. 3. Positive correlation is found by a size of business and the environmental indicator from on a graph, and the tendency for the higher rank company to raise environment assessment compared with the market value (equipment and investment for research and development are included) is seen. In another test, the environmental indicator, the big difference was seen especially by the measure against warming and countermeasures against pollution between the groups of a sales scale. This is considered to be a result of being in the environment which is easier to cope with it as a major company compared with small and medium-sized enterprises.

4.5 The characteristic of a holdings company

The result analyzed by the time series about 16 holdings companies among 424 candidate companies shown inTable 4. The environmental comprehensive evaluation of that in which holdings are unexpectedly less than the corporate value from the teble can read the tendency which a holdings company exceeds generally.

Table 4 : Relation between holding companies and environment assessment

		Overall	Management	Poution	Recycling	Product	GHG

4.6 The type of the pattern according to company

The result of having conducted principal component analysis in order to carry out the type of what kind of the tendency and characteristic being according to each company and to extract the factor that it is likely to be the most influential from each index shown in Table 5. The two main ingredients of environmental comprehensive evaluation, a size of business, the 2nd rank, an environmental synthesis rank, an eco management rank, which consist of the 1st consolidated sales, number of employees, etc. were extracted from this result. The result of having mapped these two main ingredients in the graph Fig. 4. The inside where a large number exist in the 2nd quadrant (upper left) if a graph is divided by four quadrants, There is a company county considered to have aimed at the improvement in a corporate value strategically, carrying out an environmental consideration effectively by mega industry like the company of the 1st quadrant (upper right), and although an environmental consideration is carried out by mega industry like the 4th quadrant (lower right), it can read that the company group which has damaged the corporate value also exists. The graph shows which sampled some companies from the food industry and checked the transition by the time series, and it is being checked whether based on the strategy trend of each company, the position is moving at a given fiscal year. The portion which transition based on a strategy can see is considered that the people in general of a certain thing need to conduct detailed analysis by industrial classification from now on since the factor currently influenced by the economic trend is also considered greatly.

Table 5 : Component matrix a

4.7 Determine of a multiple regression model

The result of having taken the Tobin Q minus 1 and the eco management degree evaluation synthesis degree score which show financial performance to each dependent variable, having taken the remaining variables to the independent variable, and having carried out multiple linear regression analysis by a stepwise procedure described in Table 6. Each multiple regression type was drawn from these results as follows.

Financial performance (Tobin Q) =
+ 3.340 ROA
+2.927 R&D investment
+0.347 overseas sales ratio
+0.904 capital investment
-0.006 pollution score
+0.001 overall score
-0.003 environment management score
+0.002 recycling score
-0.437 constant

The correlation coefficient R which is applied although verification by real data was also performed, and expresses a degree is not so high as 0.534, and the coefficient-of-determination adjusted R square showing prediction ratio, it is 0.281 and a still low model, and it is thought that the elaboration according to industrial classification and fiscal year is future still more nearly required.

5 CONCLUSION

The motive of this research has begun from an awareness of the importance of not only a company but what kind of stakeholder throat the characteristic like contributes to construction of sustainable society. If it is economical activity, the role which a company plays will be large, and about a global subject, such as what is called an environmental problem, it will become positioning also with an important national policy. Advanced nations specifically create an effective innovation further, and it is thought by these days that a bigger effect is brought about by enabling application to a newly emerging country with great influence. Although ISO26000 was published as a framework of social responsibility as an international system, it is important to establish the foundation of the production of common structure which each stakeholder recognizes each one of responsibility systematically, and can visualize the direction which should be aimed at. The research would be raise accuracy more by using the domain expansion to an overseas firm, corporate social responsibility results of an investigation, the event information on a time series, etc. by using the framework of this analysis as a base.

Although this subject of research is construction of a strategy making support assessment system, it is still required advancing continuously detailed analysis and examines to clarify a necessary minimum and more effective factor efficiently utilizable in business.

Abstract

Environmental load assessment has been used for a variety of purposes, such as the promotion of environment-conscious products through the environmental disclosure. For example "carbon footprint labeling system" as a model project by The Economy, Trade and Industry Ministry and "Ecoleaf" as an environmental labeling program by The Japan Environmental Management Association for Industry. However, both are limited application to only a small part of many products and services. Making further contribution to the construction of environment-friendliness society, these environmental information systems incorporated into existing distribution systems are required.

In this paper, the development of the possible environmental information system incorporated into existing automobile recycle parts distribution system, called "Green Point System (GPS), is explained. GPS provides the environmental information based on the environmental load reduction effect quantified by E2-PA which we have developed.

Automobile recycle parts used as replacement parts of the accidental damage have some problems, such as "product awareness", "reliability", and are low penetration. Providing the environmental information through the GPS is designed to build recognition and expand with the spread of automobile recycle parts.

Keywords:

LCA, potential assessment, automobile recycle parts, environmental information system

1 INTRODUCTION

The aim of this study is to suggest measures which manufacturers and users have to take for environment-friendliness society through the quantification of design for environment.

In recent years, for building the zero-waste economy/society, the consideration to 3R(Reduce, Reuse, Recycle) at the design phase of various products. At the same time, the method of quantitative assessment of products, services and social systems become important.

Before now, there were cases of quantitative assessment with LCA(Life cycle Assessment) ,however, Existing LCA (Life Cycle Assessment) has been pointed out of "subjective view", "complex and tangled of data collection" and so on.

The Eco-Efficiency Potential Assessment, E2-PA, which solves problems in existing LCA, has been developed [1]. Introducing the concept of the "potential" evaluating maximum environmental load of materials and design factors, one of the features of the E2-PA is to be able to assess the environmental load only by the data on the design phase of products and services.

Environmental load assessment being used for a variety of purposes, such as the promotion of environment-conscious products through the environmental disclosure. As a part of its ways, The Environmental Labeling, as shown in Table1 [2], [3], [4], is used. Especially, the Type Ⅲ has the Environmental Load quantitative data as its central feature. For example, in Japan, there are "carbon footprint labeling system" as a model project by The Economy, Trade and Industry Ministry, and "Ecoleaf" as an environmental labeling program by The Japan Environmental Management Association For Industry. Recently accelerating efforts to provide environmental information. However, both are limited application to only a small part of many, many products and services. Making further contribution to the construction of environment-friendliness society, these environmental information systems incorporated into existing distribution systems are required. In this paper, we mention the development of the possible environmental information system incorporated into existing automobile recycle parts distribution system, that we call "Green Point System (GPS). GPS provides the environmental information based on the environmental load reduction effect quantified by E2-PA.

Automobile recycle-parts used as replacement parts of the accidental damage have some problems, such as "product awareness", "reliability", and "low penetration" [5]. Providing the environmental information through the GPS

DOI 10.1007/978-94-007-3010-6_57,

is designed to build recognition and expand with the spread of automobile recycle-parts.

2 DEFINITION OF THE AUTOMOBILE RECYCLE PARTS

In Japan, the automobile recycling law enacted in Jan.1 2005, ELVs (End-of-Life Vehicles) enforced proper treatment for automobile parts as shown on the Fig. 1 [5]. First, Automobile dismantlers retrieve reusable parts from ELVs. Secondly, scrap metal processors pick up recyclable metals and plastics from the rest. Finally, The ASR (automotive shredder residue) has wound up in landfills and recycled.Reusable parts from ELVs retrieved by Automobile dismantlers in this process are called “automobile recycle-parts”, composed of the “reuse-parts” and the “rebuilt-parts” [6].

3 EVALUATION OF CO2 REDUCTION EFFECT IN RECYCLE-PARTS BY E2-PA

3.1 Purpose of evaluation

Now, in Japan, recycle-parts accounts for only 5-6 percents of the aftermarket, on the other hand, 40 percents in USA [5]. So, the recycle-parts market in Japan has some room to grow. In other words, it is required to replace the new parts with recycle-parts in some of aftermarket.

Table 1: Classifications and features of the Environmental Labelings

Number and name of ISO Standards	ISO14024 Type I third-party certificate	ISO14021 Type II Self-declared environmental claims	ISO14025 TypeIII Environmental Load quantitative data
Case	Eco Mark	Recycle Label	ECOLEAF
Operator	Japan Environment Association	Ricoh	Japan Environmental Management Association for Industry
Symbol mark			
Number	120 companies, 8000 products (As of May 2011)	limited to part of products	468products (As of Sept. 6 2011)

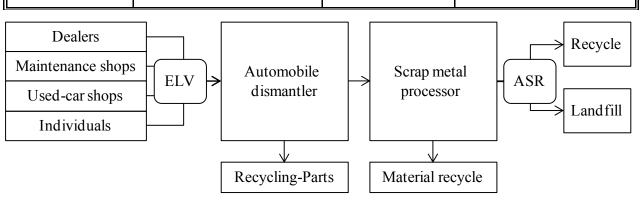

Fig.1 : Process flowchart of ELVs

The reasons why the recycle-parts are not prevalent are because of “quality control and clarification”, “differences between the U.S. and Japanese ways of business practice”, and “lack of awareness of its”. With this background, the aim of our study is to build recognition and expand with the spread of automobile recycle-parts through providing the quantified environmental information.

In this paper, the CO2 reduction effect of recycle-parts are quantified by comparing to new parts.

3.2 Precondition of evaluation

3.2.1 Evaluation scenario of reuse-parts

Fig.2 shows the process of new parts and reuse-parts manufacturing.

The ELVs are trucked to Automobile dismantlers to be dismantled. They retrieve trouble-free parts and market after quality checking. In this reuse part manufacturing process, transportation fuel and energies in dismantling are consumed. Meanwhile, in original system, a new part manufacturing, new resources in new materials and energies in part manufacturing are consumed.

Therefore, the CO2 reduction effect of the reuse part is given by the following equation;

$$R_{X\,reuse} = (E_V + E_M) - (E_T + E_D) \qquad (1)$$

where CO2 reduction effect of a reus-epart X is expressed as R_{Xreuse}; CO2 emissions from producing virgin materials is expressed as E_V; CO2 emissions from parts manufacturing is expressed as E_M; CO2 emissions from transport is expressed as E_T; CO2 emissions from dismantling an ELV is expressed as E_D.

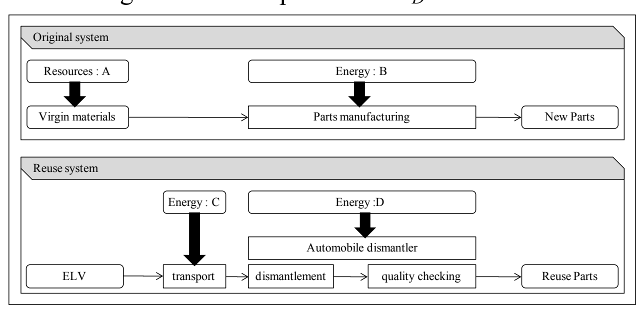

Fig. 2: Process of new and reuse-parts manufacturing

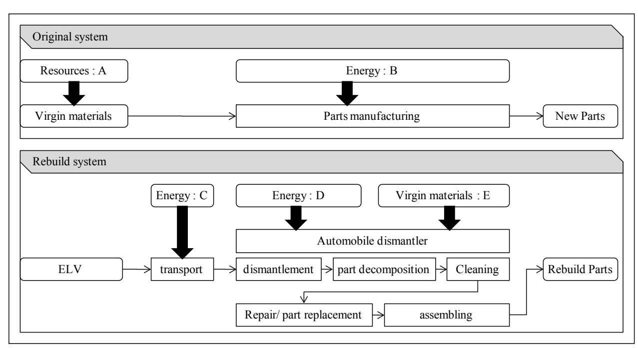

Fig. 3: Process of new and rebuilt-parts manufacturing

3.2.2 Evaluation scenarioof rebuilt-parts

Fig.3 shows the process of new parts and rebuilt-parts manufacturing. The ELVs are trucked to Automobile dismantlers and trouble-free are retrieved. The parts needed locally-repaired are torn down, cleaned, replaced to new parts, and assembled once again. The original sysytem is the same as mentioned.

Therefore, the CO2 reduction effect of the rebuilt-part is given by the following equation;

$$R_{X\,rebuilt} = (E_V + E_M) - (E_T + E_D + E_L) \qquad (2)$$

Where CO2 reduction effect of a part X is expressed as $R_{Xrebuilt}$; CO2 emissions from producing a locally-repaired part is expressed as E_L

3.3 Inventory data

3.3.1 Virgin Materials

To calculate the CO2 emissions from materials which compose parts, data about construction materials of the parts should be revealed.

It is next to impossible to collect these enormous quantities of data from parts manufacturers. So, in this study, we dismantled the ELV, listed in Table.2, to get the data about construction materials of the parts.

The data are classified into 475 parts depend on JAPRA system which automobile recycle-parts distribution system and into 7 kinds of materials, listed in Table.3. Also, the CO2 emission coefficients of them from raw materials taken from the earth to producing virgin materials are listed in Table.3 [7]. Due to limitations of space, the data of construction materials of the parts are omitted.

3.3.2 Parts manufacturing

Energies and resources are needed in the process of parts manufacturing., listed Table 4 [7], [8] .

3.3.3 Transport

The transportation fuel, listed in Table.5 is consumed in the process of transport of ELVs from the auto dealers to automobile dismantlers.

3.3.4 Automobile dismantler (Reuse system)

Meanwhile new materials are not consumed in reuse system, energy, listed in Table.6 [7], to dismantle ELVs is needed.

3.3.5 Automobile dismantler (Rebuild system)

In rebuilt system, new materials are consumed for replacing wear-out parts to new one in addition to dismantling ELVs. In this study, we have explored the ratio of new parts and energies in the rebuilt system by conducting hearings with rebuilt makers, listed in Table.7.

3.4 Result of the CO2 reduction effect

3.4.1 CO2 reduction effect of Reuse-parts

Due to limitations of space, full details of 475 parts cannot be included. So Fig.4 shows the CO2 reduction effect of 10 parts which are widely available in significant quantities. As is evident in the figure, CO2 emissions from reuse system are exceedingly-small compared to from original system. So, using the recycle parts produce over 99% CO2 reduction effects than new parts.

3.4.2 CO2 reduction effect of Rebuilt-parts

Next, Fig.5 shows the reduction effects of rebuilt-parts. They produce 33%-97% (78% on average) CO2 reduction effects than new parts. The reason why there are differences in CO2 reduction effects among each part is because the ratio of new parts in the rebuilt system differs depending on each part.

4 CONSTRUCTION OF ENVIRONMENTAL INFORMATION SYSTEM

As previously mentioned, existing environmental information systems have an issue that they are limited application to only a small part of many, many products and services. The reason for this is that focusing too much on elaborating evaluations that makes it very difficult to collect data necessary. There are about 4000 parts on delivery to the assembly maker and more some tens of thousands of types of vehicles [9]. Therefore, about Automobile recycle parts, it is very difficult to evaluate CO2 reduction effects of each part from the viewpoint of correcting the data. Afterwards, the aim of providing the environmental information should be defined. It helps consumers to select environment-conscious products and as a result, promote moves to develop and sell them. So it is not important to evaluate environmental loads of products too exactly on elaborated data, but to evaluate within the range got across to consumers. Therefore, in this study, we have tried to quantify the CO2 reduction effects of recycle in such a way as to the ratio by weight of a base car.

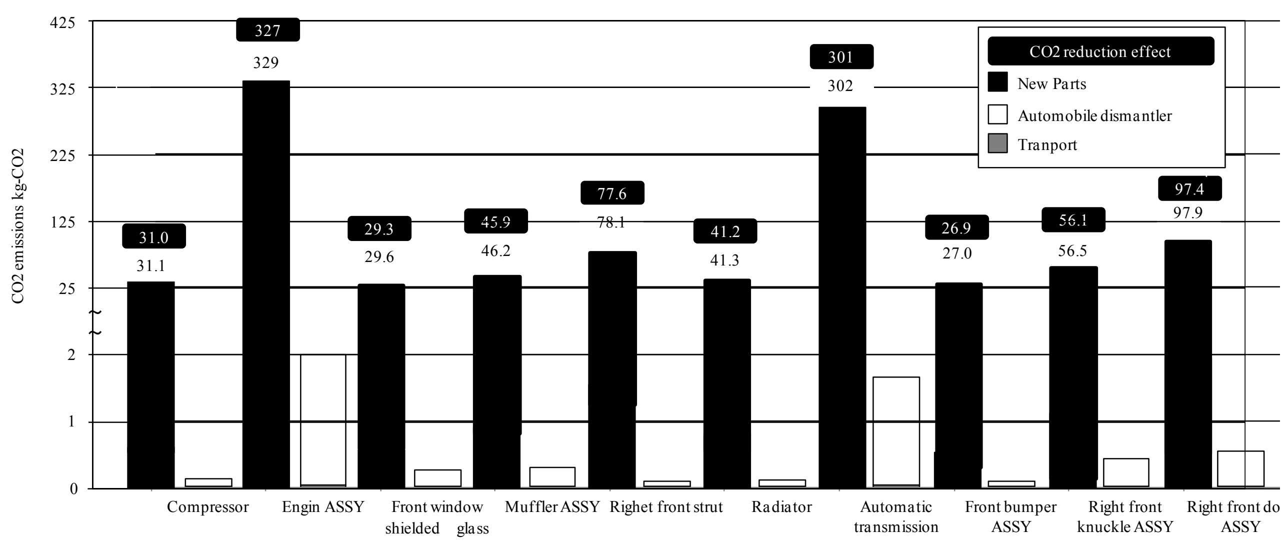

Fig. 4: CO2 reduction effect of Reuse-parts

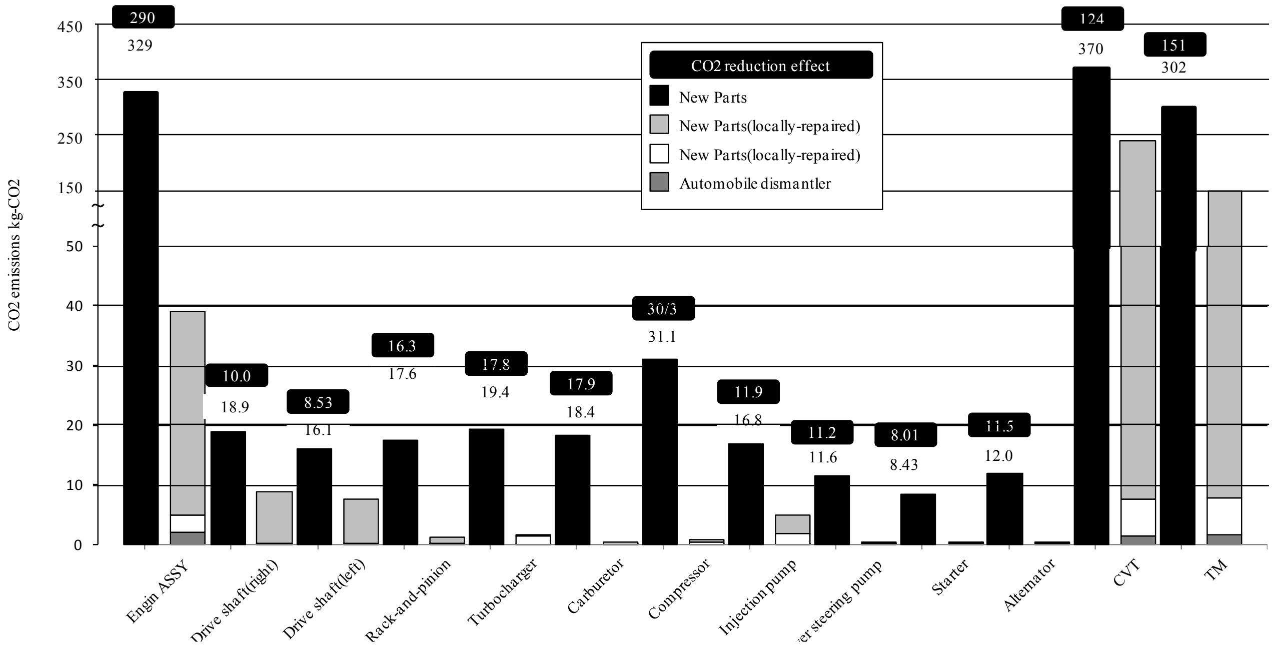

Fig. 5: CO2 reduction effect of Rebuilt-parts

4.1 Concept of the CO2 reduction effects database

There are two ways to evaluate the CO2 reduction effects of recycle parts on the differences in types of vehicles. One is to dismantle and make a survey of each car. The other is to multiply the weight of a car, which is existing data in recycle parts distribution system, by the basic units on a base car. From a viewpoint of integrating the environmental information into existing distribution system, the aim of our study, it is necessary to be ease of maintenance. Therefore, we have made a study on the way of calculating the CO2 reduction effects of various cars by data easy to get. Existing recycle parts distribution systems have data such as “Car Type”, “Year” and “displacement”. So the database to be able to calculate CO2 reduction effects on them is easier to be integrated into existing distribution systems.

4.2 Construction of CO2 reduction effect database

Fig.6 shows the way to assemble a database of CO2 reduction effect.

4.2.1 SUNNY Original Database

As mentioned above, the CO2 reduction effect data of each parts composed of the SUNNYare classified into 475 parts depend on “JAPRA system”, which automobile recycle-parts distribution system.

4.2.2 CO2 reduction effect Unit Database (Based on SUNNY)

The CO2 reduction effect Unit of each parts are given by the following equation;

$$U_X = \frac{E_X}{W_0} \tag{3}$$

4.2.3 Weight of Vehicle Database

Existing recycle parts distribution systems have data such as “Car Type”, “Year” and “Displacement”. So we have estimated the Weight of Vehicles from the displacement.

“Japanese Motor Vehicles Guidebook” [10] has the data of “Car Type”, “Year”, “Displacement” and “Weight of Vehicle”. By the multi-regression analysis, Weight of Vehicle Database has been constructed.

4.2.4 CO2 Reduction effect Database

The CO2 reduction effect of each parts on “Car Type”, “Year”and “Displacement” are given by the following equation;

$$E_{X'} = U_X \times W_X \tag{4}$$

where the CO2 reduction effect of part X on “Car Type”, “Year”and “Displacement” is expressed as $E_{X'}$; the weight of a vihecle is expressed as $W_{X.}$

The database has been applied to the Green Point System (GPS) run by the “Green Point Club” (GPC). GPC promotes the GPS which has been jointly developed by WASEDA University Environmental Reserch Institute and Japan Automobile Parts Recyclers Association and pursues the goal of market extension of recycle parts. Now, 257 automobile recycle suppliers use the GPS. Some use the system for point system between car repair shops.

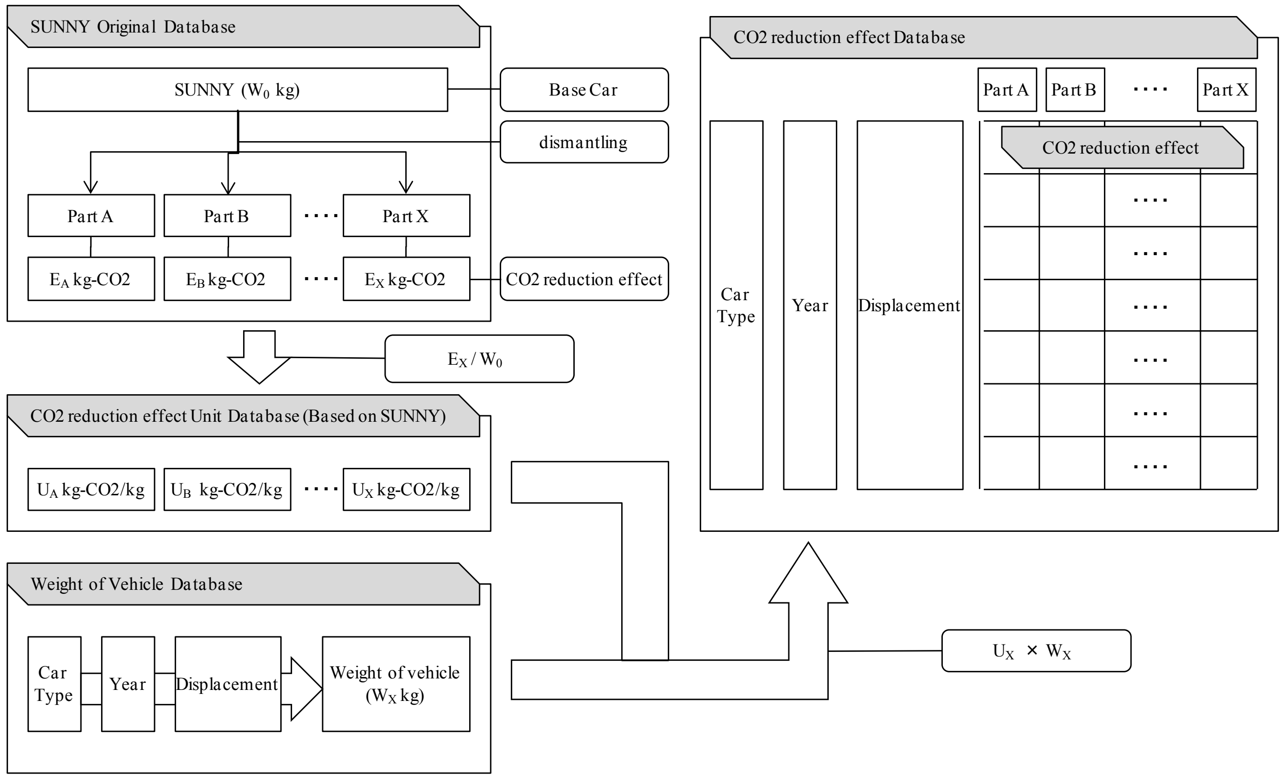

Fig. 6: Structure of CO2 reduction effect database

5 CONCLUSIONS

The present paper has proposed the method of constructing the environmental information system incorporated into existing distribution systems. The results discussed here are as follows.

(1) The important thing for the construction of environmental information system is not to evaluate environmental loads of products too exactly on elaborated data, but to evaluate within the range got across to consumers.

(2) The CO2 reduction effects of recycle-parts are evaluated on the construction materials got through dismantling the ELV.

(3) Constructing the CO2 reduction effects database, the environmental information system, called as “Green Point System”, has been incorporated into existing distribution system.

ACKNOWLEDGMENT

A part of this study was supported by Japan Automobile Parts Recyclers Association and many reuse and rebuilt makers. The authors express their deep gratitude.

Abstract

"Green IT" is expected to become the key to reduce greenhouse gas emissions. Introducing the Green IT can reduce the "total" greenhouse gas emissions. However, attention is required to the fact that the reduction of the "total" greenhouse gas emissions consists of "increase" and "decrease". For example, shifting to use energy-saving home electrical appliances reduces greenhouse gas emissions in consumer category. On the other hand, it increases in industrial category, such as manufacturing energy-saving home electrical appliances. If the way to return the merit of the Green IT, which contributes the reduction of total greenhouse gas emissions, to suppliers is not structured, it is possible to hinder promotion of the Green IT. Therefore, evaluation method of supplier's contribution to Green IT is needed.

In this study defines the Green of IT and Green by IT, which are the composition of Green IT. Green of IT means "improving energy conservation itself" and Green by IT means "reducing greenhouse gas emissions by replacing existing systems with IT". In addition, this study proposes the concept of evaluation method of supplier's contributions to Green IT and evaluated the energy-saving home electrical appliances, as an example for the Green of IT and the paperless stock office, as an example for the Green by IT.

Green IT, inter-industry relations table, supplier's contributions,

1 INTRODUCTION

The aim of this study is to develop the evaluation method through the quantification of environment-friendliness design to be shifted to environment-friendliness society.

Japan is the world's fifth greenhouse gas emission country, and the Kyoto protocol obliges Japan to reduce greenhouse gas emissions by 6% during the first commitment period, taking the 1990 figure as a baseline. The fact, however, greenhouse gas emission is increasing especially in other sectors (the business establishments and the residential sector), as shown in Fig. 1 [1]. Therefore, "Green IT" is expected to become the key to reduce greenhouse gas emission in its categories. Being yet to be clearly defined, "Green IT" includes the concept of "design for environment", such as the reduction of hazardous substances, recyclability and energy-saving. Especially "energy-saving" is now gaining attention as a measure against global warming. It is predicted that introducing the Green IT can reduce the "total" greenhouse gas emissions [2]. However, attention is required to the fact that the reduction of the "total" greenhouse gas emissions consists of "increase" and "decrease". For example, shifting to use energy-saving home electrical appliances, one of the Green IT, reduces greenhouse gas emissions in consumer category. On the other hand, it increases in industrial category, especially in electronic devices sector, such as manufacturing energy-saving home electrical appliances, as shown in Fig. 2 [3]. Until now, manufacturing companies, mainly in industrial category, have made an effort to enhance energy efficiency in manufacturing under the Rationalization in Energy Use Law. And in the near future, it is possible to be introduced the stricter regulations, the cap-and-trade system, than ever before, which means the total volume control of greenhouse gas emissions.

If the way to return the merit of the Green IT, which is expected to contribute the reduction of greenhouse gas emissions totally, to suppliers is not structured, it is possible to hinder promotion of the Green IT. Therefore, evaluation method of supplier's contribution to the Green IT is needed.

In this paper defines Green of IT and Green by IT, which are the composition of Green IT. Green of IT means "improving energy conservation itself" and Green by IT means "reducing greenhouse gas emissions by replacing existing systems with IT".

In addition, this paper proposes the concept of evaluation method of supplier's contributions to Green IT and the energy-saving home electrical appliances, as an example of the Green of IT and the paperless stock office, as an example of the Green by IT have been evaluated.

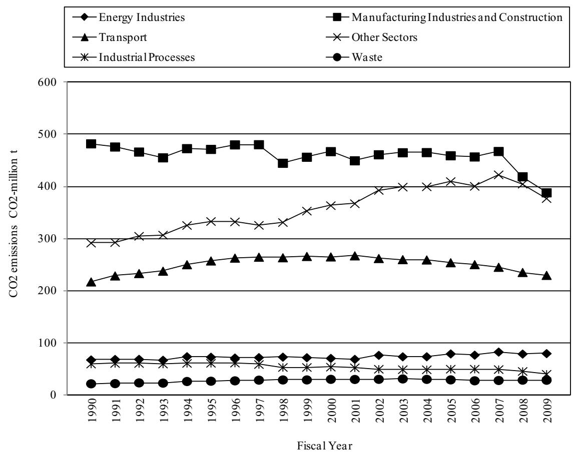

Fig. 1: Changes in sectoral CO2 emissions in Japan

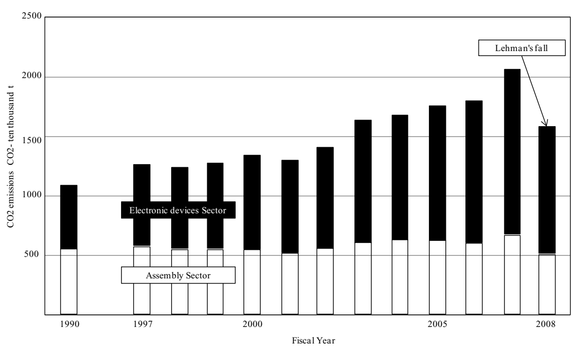

Fig. 2: Changes in sectoral CO2 emissions in the electrical and electronic industry

2 DEFINITION OF THE GREEN IT

In response to a growing worldwide interest in global warming, Therefor, we have defined the effect of Green IT as the CO2 reduction. It is classfied into the Green of IT and Green by IT, being defined as shown in Table 1. The examples of the Green IT are shown in Table 2 [4].

3 TREND OF INCENTIVES

As a measure against global warming, it is important to promote the Green IT. Technological developments leading to save enery and replacing existing products and services with enegy-saving ones are needed, however, there are higher prices and lack of awareness than existing ones. Therefore , providing incentives are needed. Table 3 shows the trend of incentives in Japan [5], [6], [7], [8], [9]. Incentives for suppliers are mainly regulatory ways, such as CO2 reducing obligation, attainment criteria and so on. On the other hand, Incentives for consumers are mainly economic ways, such as the tax reduction, the subvention like the Eco-Point and so on. Therefore, it makes easy for consumers to buy the energy-saving products and services. But the more they are sold, the more CO2 emissions from suppliers are increased. In other words, there is a possibility that the spread of the energy-saving products are hampered because regulatory ways work on suppliers while they manufacture energy-saving products. Therefore, it is needed to clarify whether the supplier's contributions to the CO2 reduction influence the result of economic incentives and construct the way to return the merit of the Green IT to suppliers.

In this study, the evaluation method of supplier's contributions to Green IT is developed.

4 CONCEPT OF CO2 REDUCTION EFFECT AND CONTRIBUTION

We have organized the concept of CO2 reduction effect and contribution to them for evaluating the supplier's contributions to the Green IT.

Table 1: Definition of Green of IT and Green by IT

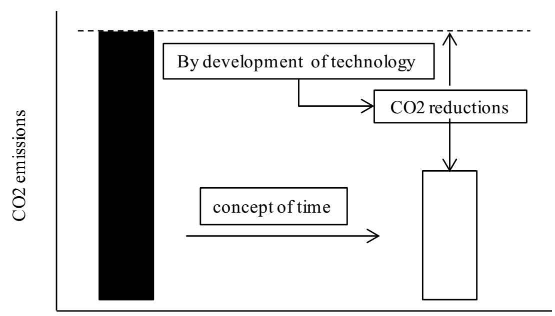
Item	Green of IT	Green by IT
Definition	Energy saving in use of its own products and services	CO2 reduction effect by replacing the existing products and services with new ones.
CO2 reduction effect		

Table 2: Examples of the Green IT

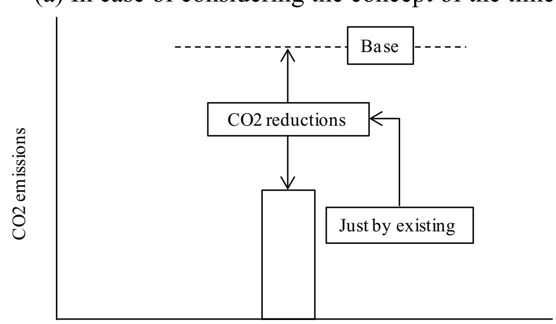
Classification	Case	Notes
Green of IT	Light bulb	Bulb-type fluorescent lights and LED bulbs consume less than the power of incandescent bulbs.
	LCD TV	The brightness control and LED backlight reduce the power consumption.
	Datacenter	Introducing Energy-saving IT devices and air conditionings and devising layout of them reduce the energy consumption of datacenters.
Green by IT	Paperless meeting	CO2emissions from paper manufacturing, printing machines and so on are reduced.
	Music distribution service	CO2 emissions from CD manufacturing, transport to the stores and so on are reduced,
	Telemedicine service	The telemedicine service facilitates sharing of information among doctors and between doctors and patients. CO2 emissions from transport are reduced.

Table 3: Trend of incentives in Japan.

Incentives	Notes
Energy Saving Act against the factories and business establishments.	Obligations as follows are imposed on factories and business establishments more than 1500kL (crude oil equivalent) of annual energy consumption. (1) Selection of the energy manager. (2) Regular report of the status of energy consumption. (3) Submission of the medium and long term plan(limited to more than 3000kL)
Energy Saving Act against the machinery and appliances.	Attainment criteria for energy efficiency are imposed on products of the regulation.
Emissions trading system	The institution for CO2 reduction through the market mechanism. In Japan, JVET-CO2S has been started in 2005.
Act on Promoting Green Purchasing	Act on promoting products which reduce the environmental loads. Public agencies taking the initiative in buying environment-conscious products has been described.
Eco-point system	The Eco-point system was introduced to stimulate the economy and raise public awareness of global warming on May.2009 by The Ministry of Economy, Trade and Industry. The Eco-Points can be exchanged for various products and services.
Green taxation plan	Tax incentives for the spread of vehicles with low-fuel consumption, low-gas emissions which meet certain standards.



(a) In case of considering the concept of the time



(b) In case of not considering the concept of the time

Fig. 3: Concept of the contributions to the Green IT

4.1 Case of considering the concept of the time

On the concept of the time, the effect of CO2 reduction is achieved by (should be rephreased) the developing technologies for energy saving. For example, replacing fluorescent backlight with LED backlight makes the power consumption of the LCD TV lower.

In case of considering the concept of the time, It can be considered that components of the product already exist and contributions to the CO2 reduction effect are provided to the technologies which reduce the energy consumption. Taking a bulb as an example, when the CO2 reduction effect of the bulb-type fluorescent light, compared to the incandescent bulb, has been achieved mainly by the improvement of the fluorescent lamp and electronic ballast, the bayonet cap exists in common. Therefore, the contribution is not provided to it.

4.2 Case of not considering the concept of the time

The effect of CO2 reduction, which is not the concept of the time means that the product which meet a certain energy-saving standard at some point is the energy saving product and the difference between the standard and the energy consumption of the product is considered as the CO2 reduction effect. The leading runner approach is taken as an example of a certain energy-saving standard.

Unlike the CO2 reduction effect on the concept of the time, It can be considered that the product itself which meet a certain energy-saving standard contributes to the CO2 reduction effect. therefore, In case of not considering the concept of the time, contributions to the CO2 reduction effect are proveided to the all components of the product, not only the technologies which reduce the energy consumption.

Taking a bulb as an example, Setting 'The power consumption of bulb must be under 25W' as the standard, the bulb-type fluorescent light is the enegy saving product, but incandescent bulb is not. At this point, the comparison between them have disappeared and it can be considered that the bulb-type fluorescent light itself contributes to the CO2 reduction effect. In this case, all components of the bulb-type fluorescent light, including the commodity parts, such as a bayonet cap, contribute to the CO2 reduction effect.

4.3 Concept of the contributions to the Green IT

Fig. 3 shows the concept of the contributions to the Green IT. In case of considering the concept of the time, as levels of technology improve, CO2 emmisions are decreased. Therefore, it can be considered that technology improvements reduce the CO2 emmisions. On the other hand, in case of not considering the concept of the time, the product itself which meet a certain energy-saving standard generates the CO2 reduction effect.

The former is suitable for continuous product development and the later is suitable for discontinuous.

Taking a energy saving of LCD TV as an example, the existing is modified by LED bucklight. Therefore the concept of the existing product is given and the case of considering the concept of the time is applied to the Green of IT. On the other hand, the paperless services replace the existing paper services, therefore, there are no services for comparison to the existing because the technologies of papereless services are completely different from ones of , paper services. Therefore the case of not considering the concept of the time is applied to the Green by IT.

In this study, it was evaluated that the supplier's contribution to the Green IT, taking a LCD TV as an example of the Green of IT and a paperless stock office service as an example of the Green by IT.

5 DEVELOPMENT OF THE EVALUATION METHOD OF SUPPLIER'S CONTRIBUTIONS TO THE GREEN IT

5.1 Example of evaluation of the Green of IT

Taking the LCD TV as an example, the evaluation method of supplier's contributions to the Green of IT is explained.

The data needed for the evaluation have been got by the hearing investigation to a certain supplier. Products listed in Table 4 were evaluated.

As previously mentioned, the contributions are provided to the the technologies which reduce the energy consumption. The hearing investigation revealed that the breakdown of the energy consumption reduction of the units and parts, listed in Table 5, are known to some extent. Therefore first, the contributions of them were provided according to each energy consumption reduction by the following equation.

$$C_x = \frac{R_x}{R_{LCD}} \tag{1}$$

$$C_{xy} = C_x \times \frac{R_{xy}}{\sum_y R_{xy}} \tag{2}$$

where the contribution of the unit x is expressed as C_x; the energy consumption reduction of the LCD TV is expressed as R_{LCD}; the energy consumption reduction of the unit x expressed as R_x ; the contribution of the part y of the unit x is expressed as C_{xy}; the energy consumption reduction of the part y of unit x is expressed as R_{xy}.

Secondly, contributions of each suppliers are needed to be evaluated for the aim of this evaluation. For evaluating the supplier's contributions, it is needed to reveal the supplier's contributions to each components' contribution. However, it is very difficult to evaluate the their contributions by the data, such as the energy consumption reduction, because various suppliers are engaged in development activities. It is also difficult to get the data, such as R&D investment and development period.

In this evaluation, supplier's contributions to to each components' contribution have been revealed by the panel method. Specifically, 100 points have been provided to them by questionnaires. Therefore supplier's contributions are calculated by the following equation.

$$C_{xyz} = C_{xy} \times \frac{R_{xyz}}{100} \tag{3}$$

$$C_z = \sum_x \left(\sum_y C_{xyz} \right) \tag{4}$$

where the supplier 'z ' contribution to the pats y of the unit x is expressed as C_{xyz}.; energy consumption reduction of the LCD s expressed as C_z;the supplier 'z ' contribution to the part y of the unit x is expressed as R_{xyz}; the supplier 'z ' contribution to the energy consumption reduction of the LCD s expressed as C_z.

Fig. 4 shows the result of supplier's contributions to the energy saving of the LCD TV. As shown in the figure, the contribution of parts manufacturer is the highest and one of assenmly manufacturer is second highest.

The adequacy of the results differing from the persons who answer questionnaires is reviewed.

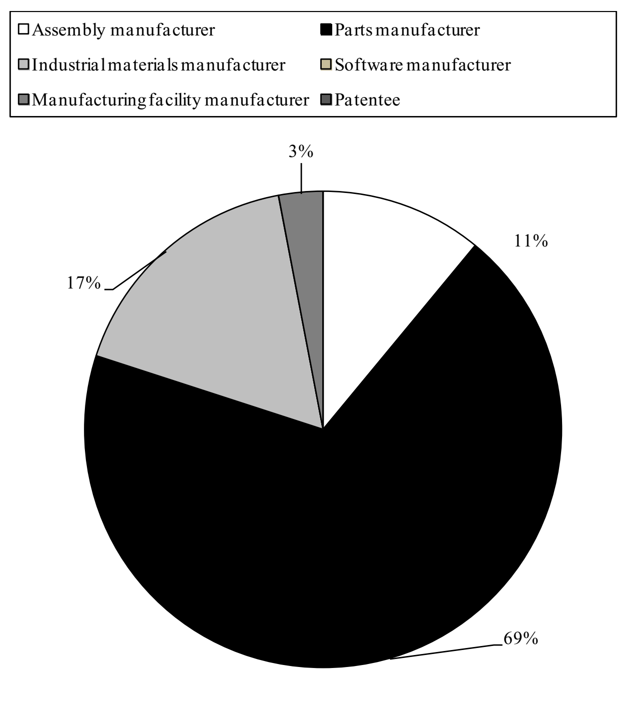


Fig. 4: Result of supplier's contributions to the energy saving of the LCD TV

Table 4 : Spec of evaluated LCD TVs

Item	Unit	Base (old model)	Comparative (new model)
Release year	-	May 2007	May 2009
Screen size	inch	32	32
Electricity consumption reduction	kWh/y	30

			Standby power circuit	kWh/y	1
Signal processor unit	kWh/y	12.5	Tuner circuit	kWh/y	1
			Audio circuit	kWh/y	1
			Image processing circuit	kWh/y	6
			Double speed processing circuit	kWh/y	3
			System control circuit	kWh/y	3

5.2 Example of evaluation of the Green by IT

In case of the evaluation of the Green by IT, It is considered that the product itself contributes to the CO2 reduction effect. Therefore, supplier's contribution to the system itsself is needed to be revealed.

The effect of the Green by IT is achived by consumers selections. At this time, they pay forit. Therefore, it can be considered that the price represents the utility of the product or servicce. If each supplier's components of the price could be revealed, the contribution of each suppliers who deliver value to consumers can be evaluated.

However, it is very difficult for suppliers to disclose the components of the price because they are confidential information.

Therefore, in this study, the contributions of each suppliers were evaluated by how the payment prrice of consumers rippled through the suppliers economically by means of the the inter-industry relations table.

The paperless stock office was taken as an example of the Green by IT. This service can reduce the space for paper documents by putting them on a scanner.

In this paper, we evaluated the supplier's contribution to the service introduce into the office of 200 workers. Table 6 shows the expected introductory price .

In this paper, the supplier's contibutions to the paperless stock office have been evaluated at annualized rate.

First, the contributions of the components of the system were provided according to each price by the following equation.

$$C_x = \frac{P_x}{\sum_x P_x} \quad (5)$$

where the contribution of the component x is expressed as C_x.; the price of the conponent x is expressed as P_x.

Secondly, contributions of each suppliers to the contributions of the components were provided by the inter-industry relations table by the following equation.

$$C_{xz} = C_z \times \frac{R_{xz}}{100} \quad (6)$$

$$C_z = \sum_x C_{zz} \quad (7)$$

where the supplier 'z ' contribution to the component x is expressed as C_{xz}: the ratio of the ripple effect through the supplier z of consumer's payment price to the component x is expressed as R_{xz}: the supplier 'z ' contribution to the paperless stock office is expressed as C_z.

At this time, the correspondence relations between the conponents of the system and 190 indutries on the inter-industry relations are shown in Table 7.

Table 6 : Expected introductory price

Component	Price Yen	Useful life Year
Scanner	249000	5
Software	2362500	5
Support	37800	1
Server	460000	5
Personal computer	800000	4

Table 7: the correspondence relations between the conponents of the system and 190 indutries on the inter-industry relations

Component	Corresponding to the inter-industry relations table
Scanner	Office appliances
Software	Electronic computer and ancillary equipments
Support	Electronic computer and ancillary equipments
Server	Information services
Personal computer	Information services

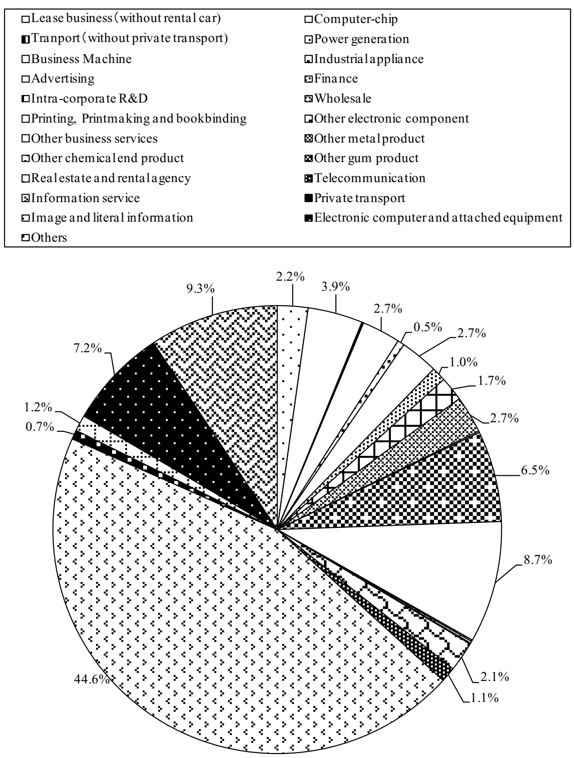

Fig. 5 : Result of the supplier's contribution to the paperless stock office.

Fig. 5 shows the result of the supplier's contribution to the paperless stock office.

As shown in the figure, the contribution of information service industry is the highest and one of other business services which includes worker dispatching service is second highest.

6 CONCLUSIONS

The present paper has proposed the development of the evaluation method of supplier's contributions to the Green IT. The results discussed here are as follows.

(1) The spread of the energy-saving products are hampered beuause regulatory ways work on suppliers while they manufacture energy-saving products. Therefore, it is needed to clarify the supplier's contributions to the CO2 reduction effect in use as the result of economic incentives and construct the way to return the merit of the Green IT to suppliers.

(2) The evaluation method of supplier's contributions to the Green IT differs by introducing the concept of time or not. IT. In case of considering the concept of the time, as levels of technology improve, CO2 emmisions are decreased. Therefore, it can be considered that technology improvements reduce the CO2 emmisions. On the other hand, in case of not considering the concept of the time, the product itself which meet a certain energy-saving standard generates the CO2 reduction effect.

Large scale product carbon footprinting of consumer goods

Saori Smith[1]
[1] Environmental Resources Management, UK

Abstract
This paper describes the evolution of a large scale product carbon footprinting programme and lessons learned from its implementation across a wide and varying range of consumer products. The learnings from this process provide valuable insight on key issues arising in different supply chains and product categories. Tesco's carbon labelling programme demonstrates that large scale carbon footprinting is possible, but the supply chain needs support and data need validation to be consistent. The cost of carbon footprint measurement reduces significantly the more it is undertaken – through familiarisation, scale and gathering transferable data. The Tesco case shows us that product carbon footprinting can be achieved to a credible and recognised standard on a large scale. The success of its product carbon footprinting programme was helped by a well considered scoping process and carefully nurtured supplier engagement.

Keywords:
product carbon footprinting, supply chain, consumer goods

1 INTRODUCTION

This paper describes the evolution of a large scale product carbon footprinting programme and lessons learned from its implementation across a wide and varying range of consumer products. The learnings from this process provide valuable insight on key issues arising in different supply chains and product categories.

Over recent years, interest in the greenhouse gas emissions from individual products has gained momentum as consumers, companies and governments alike strive to reduce their impact on the environment. Words such as 'carbon footprint,' and 'food miles', which were once considered environmental 'jargon,' are now commonplace in our everyday language. A better understanding of the greenhouse gas emissions across a product's life cycle helps companies to identify how and where efforts should be focused to minimise them. Publication of product carbon footprint results in the media provides consumers with the information to make their own purchasing decisions. An understanding of impacts incurred during the use phase of products can help consumers to identify ways that they themselves can influence the carbon footprint of a product. The cumulative impact of small changes made from any one of these potential outcomes could be considerable if realised on a large scale.

The emergence of different methods to standardise an approach to product carbon footprinting is an optimistic development to enable wider product carbon footprinting initiatives and to allow for product comparisons. If the ability to compare the greenhouse gas emissions of different products is what is desired, it follows that product carbon footprinting should be undertaken on a large scale. There are challenges to product carbon footprinting on a large scale, including time constraints and barriers to data collection. However, experiences from a large scale product carbon footprinting programme undertaken by Tesco in the UK shows that, for the most part, these can be overcome. The Tesco case highlights the importance of a well planned process and, perhaps more importantly, identifies the significant role that suppliers play in ensuring successful data collection for the product carbon footprint calculations.

The Tesco product carbon footprints were calculated according to the *Publicly Available Specification for the assessment of the life cycle greenhouse gas emissions of goods and services* (PAS 2050) [(1)]. However this paper is not intended to promote any particular approach for the assessment of product greenhouse gas emissions.

2 THE TESCO CASE

Early in 2007, Tesco announced an ambition to calculate the total carbon impacts of the products that it sells, including both their direct and indirect emissions. As a part of meeting this objective, the carbon footprints of over 1000 Tesco consumer items across more than 40 different product categories have been calculated, following the PAS 2050 method. The key objectives of the work were to inform consumer communications and to identify hotspots in product supply chains, with a view to a longer term goal of reducing supply chain emissions.

The product carbon footprinting initiative began with a pilot project, which investigated the experiences of suppliers in collating the data needed for the calculations. Suppliers were supported in calculating carbon footprints and their experiences informed recommendations for

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_59,

future footprinting efforts. Key findings, such as how suppliers responded to the data request, were used to inform the structure of the ongoing carbon footprint work.

The first phase of work was undertaken as part of a product labelling trial and calculated the carbon footprints of thirty products across six product categories. The footprints were calculated to what was then the draft PAS 2050, drawing on ISO standards on life cycle assessment. The thirty product carbon footprints subsequently underwent a verification process by the Carbon Trust, a not for profit company dedicated to supporting companies in reducing their greenhouse gas emissions. As a result of the verification process, twenty products were certified which were labelled and promoted in Tesco stores. The labels were present on product packaging and displayed the greenhouse gas emissions associated with the total life cycle of the product. To date, over 1000 PAS 2050-compliant carbon footprints have been calculated for Tesco own-brand products across a range of categories, from light bulbs to milk and from toilet paper to plastic food containers.

The process for calculating the Tesco product carbon footprints typically followed a standard process, as follows:

- identification of products to be footprinted (on the basis of sales volume, visibility, interest, ease);
- product/supply chain characterisation and mapping;
- data scoping – identification of primary and secondary data needs;
- primary data collection – supplier meetings, issue of questionnaires, data checking;
- secondary data collection – emission factors and supporting activity data;
- development of footprint model (Excel-based); and
- reporting and analysis.

3 KEY TRANSFERABLE FINDINGS

The calculation of over 1000 product carbon footprints across such a diverse range of products was met with a number of challenges and has provided valuable lessons for future work of this type. Lessons learnt from the Tesco case can be transferred to anyone wishing to undertake footprints of multiple products.

3.1 Scoping

When calculating the carbon footprints of multiple products at the same time, scoping is invaluable both in terms of the individual product footprint and the programme as a whole.

How successful the carbon footprint is depends on more than just a number at the end. For a company undertaking the calculations, how efficiently the process is completed and ensuring that the results provide information to meet the requirements of an end goal are key aspects of an outcome that is useful and value for money. Identification of the end goal is one of the first decisions to be made as this will frame the scope of the calculations and the data that are required for them. Whether the goal is for communication of results to an external audience or for internal purposes only, it should be ensured from the start that the calculations are undertaken with sufficient rigour to enable the required level of assurance.

For Tesco, where external communication was a key element of the end goal, it was essential that the product carbon footprints were calculated to a credible and recognised standard. The *Publicly Available Specification for the assessment of the life cycle greenhouse gas emissions of goods and services*, or PAS 2050, was chosen. Further assurance was provided by undergoing the Carbon Trust verification process to attain certified product labels.

Part of the scoping process should be a ‘go’/’no-go’ decision: is it possible to calculate the carbon footprint of the product given timescales and other resource constraints? In order to make this decision and to frame the wider scoping exercise, it is useful to know as much as possible about the whole life cycle of the product, from raw material, through production to use and final disposal at end of life. The life cycle should be mapped out in relation to the specific supply chain for each product, including identifying geographic location and when key materials are sourced from multiple suppliers. Understanding the full supply chain helps to identify what data are needed for carbon footprint calculations and allows for some assessment of the potential for obtaining it. A good understanding of the supply chain will provide an indication of whether primary data collection from suppliers will be possible. It will also help to identify when a certain supplier is present in the supply chain for more than one product and thus when data collection efforts can be combined. This kind of planning streamlines data collection and supplier liaison to result in a better value carbon footprinting process.

For the Tesco carbon footprints, suppliers were approached as early on in the process as possible. This meant that key information, as described above, was obtained to determine whether the footprinting of that product was a practicable option. In some cases, it was found at this stage that the supply chain extended to several small producers in multiple geographic locations, which would significantly increase the time and effort required to obtain a representative dataset for the product carbon footprint calculations. In cases such as this, when the time and effort required to complete the footprint calculations to the required standard would not produce a reflective number of product carbon footprints, the decision was often made to not proceed further. Identifying these cases early on in the process allowed for this time and effort to be focused elsewhere, on a product supply chain that could be expected to provide a more certain outcome. This kind of approach, coupled with the identification of high-volume products, meant that the footprinting programme resulted in enough carbon footprints to enable comparison and for the selection of products that were of interest to the consumer.

3.2 Supplier engagement

The Tesco case generally saw a high level of engagement from suppliers, which facilitated the scoping and data collection exercise and was instrumental to the efficiency of the process. This high level of supplier engagement is possibly a reflection of the close relationship that Tesco has fostered with its first tier suppliers.

Primary data are always preferred for carbon footprint calculations, although not always essential. Suppliers who are engaged in the process are more likely to provide primary data for their operations, to maximise the primary data available for the product carbon footprint. As noted above, where suppliers are found to be present in the supply chains of more than one product, the cross-over should be reflected in the way data collection is handled, as there is likely to be significant cross-over in data needs.

For the Tesco carbon footprints, data were collected via data collection templates, which were tailored as much as possible to the specific supply chain for the product being assessed. Based on detailed discussion with the suppliers, it was possible to structure the templates to suit the exact processes involved and limit confusion on the part of the supplier in terms of what information should be provided and in what format. Again, this upfront investment in time saved significant effort further along in the process, as a clear data collection template minimises the need for follow up questions on the information provided. Data collection is typically the most time consuming part of any product carbon footprint and poses the biggest risk to completion of the calculations. A well-designed template assists suppliers in knowing what is required of them and ultimately saves time down the line.

Increasingly, suppliers in a variety of industries and in different geographies are knowledgeable in carbon footprinting data requirements and have experience in the process. However, it is to be expected that there will be hugely varying levels of knowledge and expertise. For suppliers that have no experience of product carbon footprinting, it is likely that they will need guidance and assistance in understanding the aims of the work and in providing data. This further emphasises the benefit of a complete understanding of the supply chain and early supplier engagement, in order to adequately plan for different levels of assistance to be provided.

The benefit of a large scale programme is that, with each phase of work, there is a good chance that data will be required from the same suppliers, who will already have been engaged in the process and are more likely to be able to provide data with minimal assistance. It is therefore a beneficial investment of time to provide guidance to suppliers on carbon footprinting data collection, where needed, as well as to facilitate a wider understanding of the aims of the programme in general. Indeed, offering to share the product carbon footprint results with suppliers might provide a valuable incentive to encourage cooperation and collaboration.

A further benefit of a large-scale carbon footprint programme is that, with each phase of work, a larger database of information is gathered on a variety of different products and supply chains. More often than not, data collected for a previous phase of work can be useful to estimate the likely impacts of a different product. For example, with data collected for the production of an orange juice product, it might be possible to make some reasonable estimates with regard to certain aspects of the supply chain for apple juice. This bolsters any scoping calculations and provides confidence on where to focus data collection efforts. It also serves to identify the presence of any significant issues.

4 BENEFITS OF A LARGE SCALE PROGRAMME

4.1 Putting product carbon footprint values into context

A large scale product carbon footprinting programme enables more widespread comparison of product greenhouse gas emissions to provide greater context and meaning in terms of an individual product carbon footprint as well as the combined indirect emissions from an entire product range. To the consumer, or to an inexperienced eye, a lone carbon footprint value for a specific product is meaningless, as it cannot be determined whether the number is high or low, good or bad, or how it compares to a similar product. A well thought out large scale programme will identify product categories that are of interest to the audience (eg high retail volume products or product life cycles that have an interesting story) and that can be contextualised by comparing with each other and previously footprinted products.

4.2 Increasing awareness

A large scale carbon footprint programme, that provides footprint values for comparable products, will help to raise awareness of products or processes that result in higher emissions and subsequently identify where efforts should be focused for reduction. Should the product carbon footprint results be communicated to an external audience, consumer awareness will be raised, enabling meaningful comparison of similar products to assist in decision making. Of particular relevance to the consumer are impacts that occur during the use phase. Wider understanding, from large scale exposure of results, of how consumers themselves can influence the carbon footprint of products could have a significant impact in tackling overall emissions.

4.3 Continued supplier engagement

Having engaged suppliers during the product carbon footprint calculation process, this can be continued by sharing and discussing the results of the carbon footprint assessment. The results provide an ideal opportunity to continue working with suppliers in order to initiate efforts for emissions reduction and process improvement. Whilst a product carbon footprint will provide useful information on where the carbon 'hotspots' are in the supply chain, it is a further step to identify realistic and practicable options for reducing emissions. By working with suppliers, an impact that occurs at one stage of the product life cycle (for example disposal of packaging at end of life) can be tackled at another (for example, by working with the supplier of packaging materials). Through continued engagement of the supply chain, the product carbon footprint results can be interrogated to identify opportunities to reduce energy, minimise packaging, use alternative materials and other emissions reduction options. The benefit of a large scale programme is that, as the same supplier is often involved in many different product supply chains, it is possible that working with one supplier will have relevance for several different products.

4.4 Focusing emission reduction efforts

Carbon footprinting on a large scale means that the cumulative impact of a specific product on total company emissions can be identified. By identifying emissions from high consumption products, the actual impact of a product type on a company's emissions or on a country's emissions can be seen. This identifies which products or product categories should be focused on to make an actual difference to total carbon emissions.

The nature of a large scale carbon footprinting programme means that there will be significant cross over between different product categories. This lightens any potential burdens and encourages knowledge sharing where a certain process has significance to a number of different products. An example is chilled transport, which will be used for several different products and often incurs considerable impacts due to refrigerant emissions and increased energy consumption. Focused effort from different areas for a common purpose has the potential to be of greater influence to identify opportunities for carbon reduction or efficiency.

5 NEXT STEPS: FACILITATING LARGE SCALE PRODUCT CARBON FOOTPRINTING

The Tesco case shows us that product carbon footprinting can be achieved to a credible and recognised standard on a large scale. The success of its product carbon footprinting programme was helped by a well considered scoping process and carefully nurtured supplier engagement.

Experiences from the Tesco programme indicate that greater success in data collection is likely with a supply chain that is engaged with the process and that is provided with information to give an understanding not only of the aims of the carbon footprint, but also practical details on process. For suppliers that had prior understanding, the data collection experience was considerably less ominous and was achieved within much shorter timescales. To facilitate large scale product carbon footprinting, encouraging wider understanding of product carbon footprints and the process is a worthwhile investment in order to foster future cooperation in any footprinting initiative.

Data collection is one of the most crucial stages of any product carbon footprint. In order to attain a high level of primary data, which is always preferred for product carbon footprints, it is typically the most resource intensive. Any efforts to streamline this process to make it more efficient would benefit a large scale programme. Further to the points raised above in relation to the benefits of an engaged supply chain, it follows that increased knowledge and experience will enable suppliers to undertake more of the data collection activities unaided.

6 SUMMARY

This paper summarises the evolution of a large scale product carbon footprinting programme and lessons learned from its implementation across a wide and varying range of consumer products.

Abstract

Recently, with the technology level is increasing, not only our ecology environment is destroyed, but also the global climate is changed. Many governments are forced to rethink the sustainable issues. Among these issues, the impact of carbon dioxide (CO_2) should be the most serious problem. Therefore, the manufacture industries begin to calculate and disclosure the CO_2 emission and then to reduce it. In the past, the manufacturers need to spend a lot of time and cost to get the product's carbon footprint. In this research, the information communication technologies (ICT) framework is constructed that could collaborate with suppliers to get the life cycle data very easily. The ICT is the new concept to integrate the information and communication technology. Finally, a case study is conducted and analyzed to demonstrate the model...

1 INTRODUCTION

United Nations Environment Programme reported that the significant environmental impacts over the past 20 years include global warming, clean water supply, agricultural land, and biodiversity, while all of which have been confirmed as major menaces to human life. McKinsey (2008) global questionnaire found that senior managers of enterprises generally suggest that there is a need to be responsible for environmental protection and implement in-plant carbon management activities. In other words, current enterprises have to disclose carbon information of various in-plant activities and gradually establish carbon footprint system for products to evaluate the carbon footprint of each product, and further find approaches to reduce carbon emission to achieve the purpose of carbon neutralization. Carbon footprint is defined as the direct (on-site, internal) and indirect (off-site, external, upstream, downstream) CO_2 equivalent, CO_2e, emission of a product or service in its life cycle (Wiedmann and Minx, 2008). Carbon footprint may be viewed as a hybrid, deriving its name from “ecological footprint” and conceptually being a global warming potential indicator (Wackernagel and Rees, 1996). Here, ecological footprint refers to the biologically productive land and sea area required to sustain a given human population expressed as global hectares (Pandey *et al.*, 2011).

Because the competition among “companies” has been transformed to that among “supply chains versus supply chains,” many enterprises also agree that carbon management has become an important issue (Hult *et al.*, 2007) in supply chain management, and thus, requested suppliers to cooperate and assist in investigations. For example, retailer Walmart（2009）provided the criteria for supplier sustainability assessment to request suppliers to disclose carbon information and life cycle information. Rizeta *et al.*（2010）assessed the GHG efficiency of several supply chains of the same product marketed through different types of retail systems in Europe. Lee (2011) integrated the carbon footprint into the automobile supply chain, Hyundai. Fleten *et al.* (2010) analyzed the optimization of carbon storage in supply chains.

The observation of enterprises' past footprint inventory of products showed that, owing to the limited cost and resources, most of these investigation were conducted as special project for target products, were seldom comprehensively conducted, and were not integrated with existing internal management system or information system of enterprises. Due to the lack of system integration, it was time-consuming to conduct these inventory and the data quality could not be ensured for the guidelines, such as PAS2050 specifications (e.g., relevance, completeness, consistency, accuracy, and transparency) (BSI, 2008). In addition, the developmental life cycle of current products are shorter. Therefore, the data obtained from the inventory may only be the carbon footprint of a product or in-plant fragment information, which cannot be reutilized for further data processing, such as the carbon emission reduction of material use/components or manufacture system.

2 LITERATURE REVIEW

Carbon footprint is a measure of a product's impact on the environment, in terms of greenhouse gases (GHGs) emitted along its supply chain (Finkbeiner, 2009; Wiedmann and Minx, 2008). Thus, it is a subset of the data covered by the more comprehensive life cycle stages, which takes into account the consumption of resources and all the impacts associated with a product's full life

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_60, © Springer Science+Business Media Dordrecht 2012

cycle, from raw material, manufacture, transportation through use and maintenance, to final disposal. Busch and Hoffmann (2007) indicated in the study on supply chain that heat (carbon) flux implies a company's carbon emission and carbon constraints in its supply chain, which will affect its financial status. Current enterprises have gradually attached importance to carbon information disclosure of products. If an enterprise only discloses its carbon emission, it is impossible to assess its performance of carbon reduction. The stage of maximum GHG emission cannot be found unless the supply chain carbon inventory of product is obtained. With constant improvements, low-carbon products can also be developed. Many scholars have indicated that in the design of current supply chain, in addition to quality, delivery date, and cost, it is also necessary to take into account carbon emission and include carbon emission into the assessment criteria for suppliers.

Carbon footprint inventory is established based on the methodologies of GHG inventory and life cycle inventory. To conduct consistent carbon footprint inventory, the environmental science and engineering community have developed several systematic methodologies or guidelines for the detailed characterization of the environmental impacts of chemicals, products, and processes.

(1) The Greenhouse Gas Protocol Initiative (GHG Protocol):
(2) ISO started developing an international standard ISO 14067 on Carbon Footprint of Products (Part 1: Quantification, Part 2: Communication) .
(3) The Intergovernmental Panel on Climate Change (IPCC) has developed guidelines for reporting on GHG emissions from a number of industrial processes and activities.
(4) A GHG accounting guidelines. It has published carbon footprints for some food products (ADAS, 2009).
(5) The British Standards Institute developed the PAS 2050 Specification for assessment of the life cycle GHG of goods and services.

Besides the above methodologies and guidelines, there is an established tool, Life Cycle Assessment (LCA), for evaluating environmental outcomes of products or services through their lifecycle. It has broad international acceptance in science as a means to improve environmental performance of products or services (Ortiz et al., 2009). According to ISO 14040, an LCA study essentially consists of four interconnected steps/phases: goal and scope definition, inventory analysis, impact assessment, and interpretation. LCA is an objective process to evaluate the environmental burdens associated with a product or activity by identifying and quantifying energy and materials used and wastes released to the environment; to access the impact of those energy and material used and released to the environment; and to evaluate and implement strategies to affect environmental improvements.

3 METHOD

This study used ICT tool and referred to the existing international references and guidelines and existing methodologies for carbon footprint inventory in an attempt to simplify data collection and inventory procedures, to establish standard procedures, and to establish a tool for calculating carbon footprint of apply chain inventory, as shown in the Figure 1. Figure 1 shows the framework of the carbon footprint disclosure system. This system is based on current carbon footprint inventory technique with the aid of information system. The descriptions are as follows.

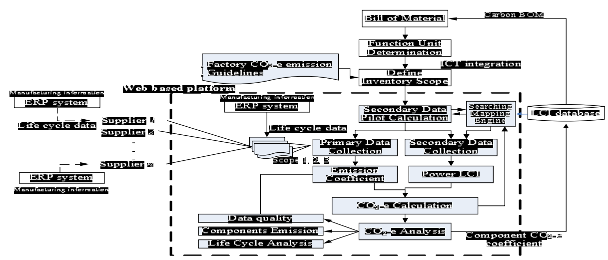

Fig. 1: Framework of the carbon footprint disclosure

3.1 Data form and secondary data collection

During the analysis on carbon footprint, it was necessary to collect all the relevant in-plant information and activity data concerning product manufacture. However, because the inventory data were unavailable, secondary data were used to replace primary one. As for the reason that the data of actual plants could not be collected, the reason was that some techniques did not belong to enterprise, suppliers intended to protect trade secrets, there was a lack of information system in the existing system. The explanations about primary and secondary data are given as follows (Torcellini and Deru, 2004).

- Primary data were those obtained from specific facilities
- Secondary database were those included in the product system life-cycle inventory that have been obtained from published sources.

The quality classification of secondary data varied with the scope of life cycle, and could be divided into: (1) the national emission factor obtained by a certain country using existing data; (2) the emission factor of industrial data obtained by a specific industry using its existing data; the emission factor obtained by a certain enterprise using its internal data.

3.2 Product life cycle primary data collection and input

After function unit was determined, the data of product could be collected according to the stages of life cycle, including stages such as raw material input, product manufacture, transportation, use, and waste. The explanations about them are given as follows:

(1) Raw material input stage: the direct materials are the main raw materials and packaging materials of product. In general, main raw materials are those which will be retained on the product. The data at this stage usually were obtained from supplier inventory form. Therefore, suppliers were requested to directly complete the form according to the materials required by unit product.
(2) Product manufacture stage: the data on energy and resources used in product manufacture stage, auxiliary materials used during processing, such as cutting fluid and cleaning agent, air, water and waste pollutants emitted, and in-plant transportation were respectively collected according to the regulations and criteria of ISO14064 and PAS 2050. In general, these data had to be used to calculate materials used by unit product according to allocation principle.
(3) Transportation and retail stage: the data at this stage were those delivered from manufacturer to retailor and they also included the CO_2e emission of retailers.
(4) Use stage: the data at this stage referred to the air pollution, water pollution, and wastes produced when end-users used the product.
(5) Waste stage: the data at this stage referred to the air pollution, water pollution, and wastes produced by product at waste stage.

3.3 Carbon footprint calculation of full product and carbon BOM establishment

The primary data were combined with the secondary data and were analyzed to calculate the overall carbon emission, namely, the carbon footprint of product. The formula is as follows.

Carbon footprint= $\sum \{all\ CO_2\ emissions\ of\ life\ cycle\ stages\}$

3.4 Analyses and assessments

Relevant analyses and assessments included: (1) data quality; (2) analysis on carbon BOM; (3) assessment on life cycle; (4) other data-related analyses:

(1) Data quality: data quality could be assessed based on the proportions of primary data and secondary data of carbon emission. *DCH* indices could also be used to represent it, including:
- *D*: Direct measure, such as collecting and obtaining data by directly using measuring instrument;
- *C*: Calculation or estimation, such as obtaining data by using electric power receipt to calculation manufacture distribution;
- *H*: Scenario hypothesis: if the scenario of users cannot be actually understood, virtual scenario can be used to calculate carbon emission.

(2) Analysis on carbon BOM: the components of higher carbon emission could be understood based on BOM data, and thus the enterprise could negotiate with suppliers about making improvements. The data on carbon emission of the same components at different plants could also be assessed and analyzed in Carbon BOM to find out the direction for improving production.

4 SYSTEM IMPLEMENTATION

4.1 AS-IS and TO-Be model

(1) AS-IS model

End-user enterprises assisted suppliers in collecting their on-site Material BOM and relevant resource data. The contents of Material BOM should include information such as processing conditions, product materials, assembly proportions, weights, and amount used during manufacture process. Moreover, the data collected were filled in the inventory form one by one, and an e-mail was sent to confirm the accuracy of data with enterprises. After the confirmation of data, data were artificially input into life cycle assessment software, SimaPro v7.2, for assessment of emission. After the analysis, the result of CO_2e emission was artificially backfilled to the inventory tool, and an e-mail was sent as the reply to the enterprise. However, during this series of analysis, it was more difficult for the enterprise to comply with the five principles of PAS2050:

(1) Relevance: the enterprise had to spend more costs to complete the inventory and data collection. The specific project-based management had to consume a large amount of cost and time.
(2) Completeness: the Material BOM of suppliers was a trade secret. Therefore, it was uneasy to obtain it. Suppliers tended to conceal their ingredients. Therefore, carbon emission might be overestimated or underestimated.
(3) Consistency: because the carbon footprint inventory was conducted as a specific project, it was hard to effectively compare the carbon information to that of past years.
(4) Accuracy: because the data were artificially input, there might be artificial mistakes such as double key in or input errors of weight unit, assembly proportions, and amount. Therefore, the accuracy of carbon emission would be significantly reduced.
(5) Transparency: the enterprise failed to immediately and explicitly know the carbon information of various suppliers.

(2) TO-Be model

In this system, the enterprise could integrate the production information (Master Production System, production time, etc.) of in-plant enterprise resource planning (ERP) system with bill of material information (materials, assembly proportions, weights, and amounts), relevant in-plant energy and resource consumption information, or supplier information. Moreover, it could search for relevant materials of LCI (life cycle inventory) database through data inventory form and functions of Searching Engine, Memory Database, and Power LCI Engine. I n this system, memory database was established to record the corresponding materials used by various suppliers, and the purpose was to reduce the time and manpower to re-search the corresponding materials of life cycle assessment software and to maintain the consistency of materials in use. The contents of complete inventory form should include the information such as corresponding product materials, assembly proportions, weights, and amounts of the LCI. The complete form after mapping was input and transformed into the file mode readable by LCI calculation software to calculation CO_2e emission. Moreover, data accuracy was also enhanced and potential artificial input errors were excluded. After the calculation was completed, the CO_2e emission was backfilled into the original inventory form to enable the enterprise to clearly find out the components/parts of higher risk through material flow data and Life Cycle Assessment and to choose suppliers for cooperation from the perspective of environmental improvement. The system is shown in Figure 1. The AS-IS and TO-BE models are also shown in Figure 2.

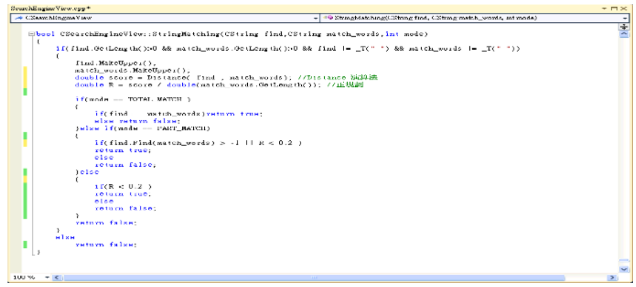

Fig. 3: Searching Engine

4.2 Searching Engine for secondary data

During the citation of secondary data, Simapro, was mainly used. However, it was restricted by regional data. To ensure that appropriate secondary data were cited, some data, including name and coverage of life cycle, might not be directly corresponded. In addition, international database could only be used. Therefore, mapping and searching engine were established to assist the enterprise in establishing its own Carbon BOM to backfill the data it had searched to the database, which reduced the difficulty in searching, ensured the consistency of data, and reduce the amount of data to be inventoried. By using the search engine, the secondary life cycle data could be easily found by using the keywords.

Fig. 2: As-Is and To-Be model for case study system

4.3 POWER LCI Engine

During the inventory, because the names of chemical materials were different, some mistakes were made when citing the secondary data, resulting in the significant difference in data. Therefore, this study used C++ software which could rapidly input the data of life cycle inventory and exchange that with the data of inventory form through the functions of import and export to reduce the occurrence of artificial mistakes. The life cycle data could be exchanged by using this engine very easily. Thus, this engine could reduce the human typos and enhance the data input speed.Each figure and each table must have a caption. Initially capitalize only the first word of each figure caption and table title. Figure captions are to be *below* the figures. Table titles are to be *above* the tables. Captions should be centered. Place the figure or table on the text page as close to the relevant citation as possible, ideally at the top or at the bottom of a column. If a figure or table is too large to fit into one column, it can be centered across both columns at the top

Fig. 5: Carbon footprint of Taiwan EPA

or the bottom of the page. Make sure that it does not extend into the page margins. Do not wrap the text around the figures.

5 CONCLUSIONS

As the issues concerning GHGs have gradually attracted the attention of enterprises, carbon footprint disclosure has become more and more common. In Recent years, Environmental Protection Agency in Taiwan has aggressively encouraged enterprises to disclose product carbon information, to apply for cable label in Taiwan, and to promote enterprises' disclosure of product carbon emission at each stage of life cycle, in order to propose carbon reduction policies. To date, approximately 80 B to C products have applied for carbon label. For the carbon label in Taiwan, please visit the website: http://cfp.epa.gov.tw/.

Fig. 4: Power LCI Engine

Faced with such a change in industrial demand, although enterprises had developed some techniques and accumulated experiences concerning carbon footprint inventory, these techniques and experiences still fail to meet the need. The main reason is that enterprises hope to use a simple and rapid inventory tool to assist them in finding the direction for carbon reduction. This study used ICT technique, referred to guidelines and methodologies of carbon footprint inventory, and specifically integrated the information required by suppliers to establish carbon footprint inventory system. The development of this system included determining function unit, analyzing product BOM information, inventorying enterprises' primary and secondary data, feeding back product carbon BOM to the designer, and assisting in design and development of system. The results showed that this system could indeed reduce enterprises' investment in manpower and resources of carbon footprint inventory, reduce the time of inventory, and enhance data accuracy. Because previous studies seldom investigated the establishment of product carbon footprint system, the data were provided by ERP and were not obtained from the design stage. Therefore, many aspects of this study can be improved, such as integrating this study with the laws and regulations and guideline principles of carbon footprint inventory, integrating this study with CAD system at R&D stage, performing in-depth analysis on quality of carbon footprint data, and developing energy saving and carbon reduction methods by connecting the data obtained from this system with production system.

Abstract

Recent studies indicate that global warming is worsening, tremendously affecting our environment. Hence, reducing CO2 emissions is one of the most pressing issues in environmental protection. Among the natural resources, water is one of the most vital. Having a clean and secure water supply, as well as a water distribution system, is crucial for modern society. From a life cycle perspective, a complete water supply system is complicated and contains substantial, embedded carbons, which comprise infrastructure, as well as purification facilities and related processes. Assessing the total carbon footprints of a complete water supply system would present numerous benefits. Such evaluation covers the examination of water supply efficiency and identifying opportunities for carbon emission reduction after a thorough inventory. In addition, calculating the carbon footprints of products has become increasingly important for global enterprises. Determining the carbon footprint of unit of water (i.e., in $kgCO_2$ e/m^3) is necessary for the calculation of a product's carbon footprint.

In view of the above-mentioned issues, several countries, including Scotland, the UK, USA, Japan, and Italy, have studied the carbon footprints of water supply systems. In Taiwan, previous studies conducted to determine the carbon footprints of water supply systems were not based on a life cycle perspective. Commissioned by the Water Resources Agency of the Ministry of Economic Affairs, this study calculated the carbon footprints of five water supply systems, each with different characteristics in terms of topography, scale, raw water quality, and purification process. The water supply systems studied included a traditional purification plant, a purification plant with high-turbidity raw water, a multi-process purification plant, an advanced purification plant, and a desalinization plant. The scope of inventory and assessment includes the intake, the purification, and the distribution stages, as well as the infrastructure and the chemicals used that are associated with these stages. Carbon footprints are calculated based on the unit water sold (m^3). The calculation is performed in accordance with the standards set by the Taiwan Carbon Footprint Calculation Guidance for Products and Services. Preliminary results show that the carbon footprints of the traditional purification plant, the purification plant with high-turbidity raw water, the desalination plant, the advanced purification plant, and multi-process purification plant are 0.1768, 0.2646, 9.6249, 0.4969, and 0.1942 kg CO_2e/m^3, respectively.

Keywords: Water supply system, global warming, carbon footprint, life cycle perspective

1 INTRODUCTION

Recent studies indicate that global warming is worsening, greatly affecting our environment. According to the Intergovernmental Committee of Experts on Climate Change (IPCC), average temperature is rising and this would seriously affect our environment [1]. Hence, the reduction of CO_2 emissions is one of the most important issues we need to address to protect our environment. Among our natural resources, water is one of the most vital resources. Water is the new oil and carbon is the currency that drives the water industry to make significant changes by reducing its carbon emissions [2].

In Taiwan, there is abundant rainfall every year, but most of the rainfall is rapidly lost to the ocean because of strips of populous areas, abrupt geographical features of Taiwan's mountains, and heavy downpours. In addition, rainfalls in Taiwan tend to cause zonal or seasonal droughts very easily because of the unequal distribution of rain in certain areas and during certain seasons [3].

In the past few years, political actions and media reports on climate change issues and carbon footprints were brought into the spotlight. On account of its importance, several countries, such as Scotland, the UK, USA, Japan, and Italy, have studied carbon footprints of water supply systems. Taiwan also conducted some studies on the calculation of carbon footprints of water supply systems. However, those studies did not focus on the life cycle perspective. In this study, based on Taiwan Carbon Footprint Calculation Guidance for Products and Services, experience from other countries, extended literature

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_61,

review, and expert consultations, the boundary and scope of carbon footprint calculation of water supply systems was decided [4].

Currently, five water purification plants with different characteristics (i.e., traditional treatment, advanced treatment, plant with high turbidity treatment, multi-process treatment, and desalination plant) are being applied to do inventory and to calculate carbon footprints. The results will be used in the future as estimates and reference materials for Taiwan's carbon footprinting of its water supplies.

2 LITERATURE REVIEW

The concept of the carbon footprint came from the ecological footprint assessment created by Wackernagel [5], which considers humanity's energy and resource throughput and converts these data into area units. The ecological footprint and the carrying capacity can then be directly compared because they are measured using the same units. Carbon footprint can be defined as a measure of the exclusive total amount of carbon dioxide emissions that are directly and indirectly caused by an activity or are accumulated over the life stages of a product [6]. Thus, reducing energy consumption and carbon emissions entails committed action through sustainable management practices based on a life cycle perspective.

The Life Cycle Assessment (LCA) methodology enables the calculation of environmental burdens in a systematic and scientific way by regarding all inputs and outputs of a system [7]. LCA is mainly used for assessing systems and identifying options for improvement and, in some cases, for developing sustainability indicators [8]. It is a systematic tool used in analyzing and assessing environmental impacts, as well as energy use, over the entire life cycle of a product, which generally includes raw material extraction, manufacture, product use, recycling, and final disposal [9][10] .

Current international guidelines for calculating carbon footprints include ISO 14067, World Resources Institute (WBI), World Business Council for Sustainable Development (WBCSD), PAS2050, and TS Q0010. In 2010, the Environmental Protection Administration (EPA) made an announcement about calculating the carbon footprints of Taiwan in a study entitled, "Taiwan Carbon Footprint Calculation Guidance for Products and Services" (Taiwan's Product Category Rules [PCR]). Taiwan's PCR are founded on CNS 14040 and CNS 14044, which established the LCA methods and the reference PAS 2050 in step with the spirit of carbon footprint assessment [11]. For consistency in calculating a product's life cycle's greenhouse gas emissions, they have detailed specifications on products and services.

The Global Type III Environmental Product Declarations Network (GEDNET), founded in 1999, is an international non-profit association of type III environmental product Declaration organizations and practitioners. "Water Distribution Through Mains, Except Steam and Hot Water PCR Draft" was published by GEDNET. This document provides PCR for the assessment of the environmental performance of UNCPC class 6921 water distribution through mains (except steam and hot water), and the declaration of this performance by an environmental product declaration (EPD). This PCR document was developed by the Emilia-Romagna Development Agency (ERVET) [12]. The water supply boundary is shown in Fig. 1.

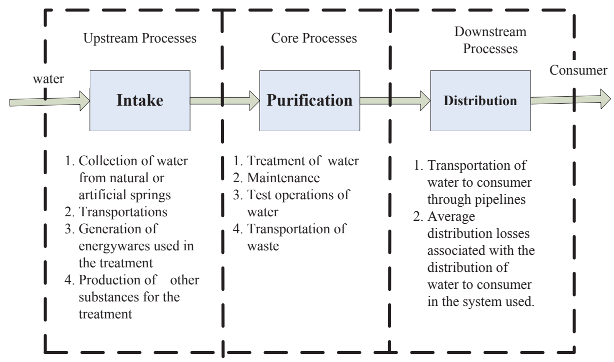

Fig. 1 : Water distribution through mains, except steam and hot water PCR draft

According to the PCR of ERVET, experience from other countries, extended literature review, expert consultations, and Taiwan's PCR in Fig. 2 [13][14][15][16][17][18][19] have decided the boundary and the scope of assessment, including intake, purification, distribution, chemicals, consumables, transportation at each stage, and infrastructures.

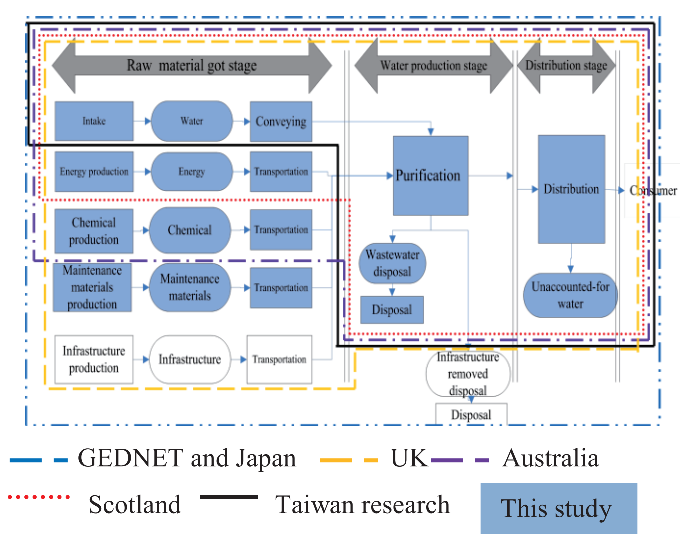

Fig. 2: Water supply system boundary of each country researched

3 RESEARCH METHODOLOGY

The goal of this study is to assess the life cycle greenhouse emissions of five plants in Taiwan through expert consultation. Table 1 shows details about the five plants. This research uses a "cradle to gate" approach, where the functional unit is defined as the global warming potential of 1 cubic meter of water production.

Table 1 The five supply system

	Gongguan Purification Plant	Panhsin Water Treatment Plant	Kinmen Seawater Desalination Plant	ChengChingHu Water Treatment Plant	FongYuan Water Treatment Plant
Operations management	Taipei Water Department, Xindian River System	12th Branch, Taiwan Water Corporation	Kinmen County Waterworks	7th Branch, Taiwan Water Corporation	4th Branch, Taiwan Water Corporation
Headspring	Xindian River	Three-Gorge Dam, Shihmen Reservoir	Sea off Kinmen	Kaoping River	Ta-chia River, Shih-Kang Dam
Intake	Turbidity current	Pumping	Pumping	Pumping	Pumping
Capacity (tons per day)	520,000	680,000	2,000	450,000	600,000
Notes	1.Traditional purification plant 2.Photovoltaic (PV)	1.Traditional purification plant 2.High-turbidity raw water	1.Reverse osmosis system	An advanced purification plant: (1)Pre-ozonation system (2)Crystal softening system (3)Post-ozonatoin system (4)Biologically activated carbon filter pool	1.Traditional purification plant 2.Two purification plants

The system boundary of the LCA method consists mainly of three stages, namely, intake, purification, and distribution stages. This study's results have two parts; one includes infrastructure and another does not include infrastructure. Emissions from the production of capital equipment, including building, pipe infrastructure, and machinery, are in the system boundary of the LCA analysis. Fig. 3 shows the boundary and the inventory of one treatment plant whose inventory time is one year (in 2010).

4 RESULTS AND DISSCUSSION

This study chose the Simapro 7.2.3. Its database is from Eco-invent, and the model used is IPCC 2007 GWP 100a. The electricity coefficient is 0.612 kg CO_2/m^3, which is from the Bureau of Energy, Ministry of Economic Affairs. Fig. 4 and Table 2 show greenhouse gas emissions from different stages, including intake, purification, and distribution stages, for every 1 m^3 of water produced by each treatment plant.

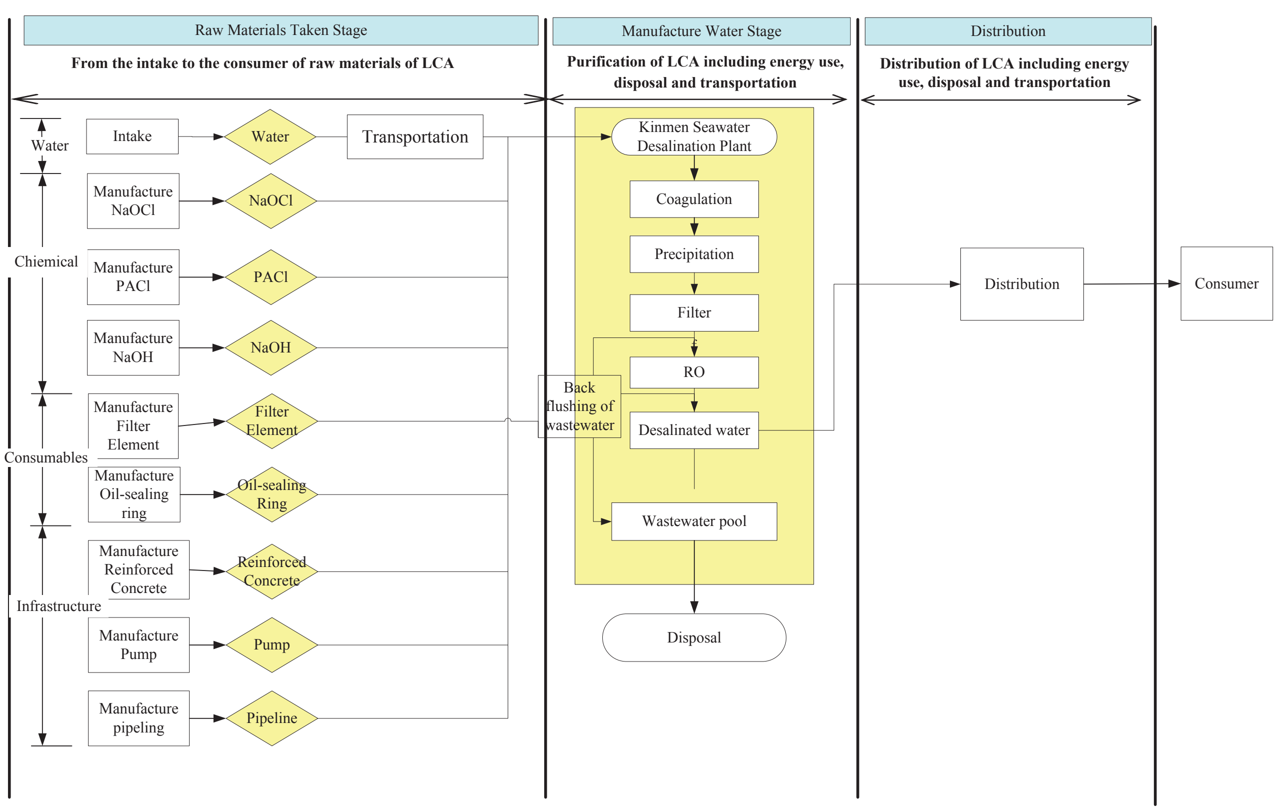

Fig. 3: Boundary and inventory of the Kinmen seawater desalination plant

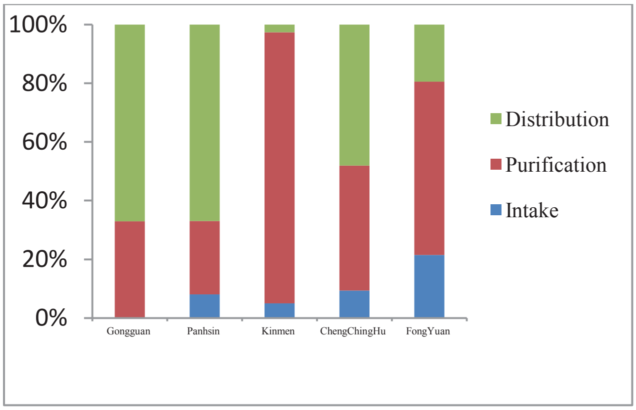

Fig. 4: Greenhouse gas emission percentage of each plant

Table 2: Greenhouse gas emissions of each plant

	Gongguan	Panhsin	Kinmen	ChengChingHu	FongYuan
Intake	0	0.0213	0.4816	0.0464	0.0417
Purification	0.0582	0.066	8.896	0.2117	0.1148
Distribution	0.1186	0.1772	0.2473	0.2387	0.0377
Total	0.1768	0.2646	9.6249	0.4969	0.1942

Unit :kg CO_2 e/m^3

This paper includes the study of boundaries, infrastructures (including construction [steel and concrete]), mechanical and electrical equipment (motors), and pipelines into the calculation scope. The lifetimes of infrastructures are assumed to be 58, 12, and 38 years [20], respectively. To collate data, the calculations of the each plant's carbon emissions are as follows:

(1) Gongguan Purification Plant. The intake stages contain distribution wells. The purification stages contain reinforced concrete pools and mechanical equipment. The final distribution stages contain two parts, namely, mechanical equipment and cast-iron pipes. The total carbon emission is 0.1833 kg CO_2e/m^3.

(2) Panhsin Water Treatment Plant. The intake stages contain mechanical equipment. The purification stages contain reinforced concrete pools and mechanical equipment. The final distribution stages contain mechanical equipment, PVC pipelines, and cast-iron pipes from the 12th branch of the Taiwan Water Corporation. The carbon emission is 0.2689 kg CO_2 e/m^3.

(3) Kinmen Seawater Desalination Plant. The intake stages contain reinforced concrete storing cisterns and mechanical equipment. The purification stages contain reinforced concrete pools and mechanical equipment. The final distribution stages contain mechanical equipment, PVC pipelines, High-density polyethylene (HDPE) pipelines, and ductile iron pipelines. The carbon emission is 10.6734 kg CO_2 e/m^3.

(4) ChengChingHu Water Treatment Plant. The intake stages contain mechanical equipment. The purification stages contain reinforced concrete pools and mechanical equipment. The final distribution stages contain mechanical equipment, PVC pipelines, and cast-iron pipelines from the 7th branch of the Taiwan Water Corporation. The carbon emission is 0.6032 kg CO_2 e/m^3.

(5) FongYuan Water Treatment Plant. The intake stages contain reinforced concrete storing cisterns. The purification stages contain reinforced concrete pools and mechanical equipment. The final distribution stages contain mechanical equipment, PVC pipelines, ductile iron pipelines, and cast-iron pipes from the 4th branch of the Taiwan Water Corporation. The carbon emission is 0.2832 kg CO_2 e/m^3.

On the overall, carbon emissions in the consumption of electricity are the best emission sources. For example, electrical consumptions at the Gongguan Purification Plant, the Panhsin Water Treatment Plant, and the ChengChingHu Water Treatment Plant are about 67.39%, 67.27%, and 48.19%, respectively. In the purification process, the different processes have different results. For instance, carbon emissions of chemicals in the Gongguan Purification Plant, such as PAC, NaOCl, and NaOH, are about 84%. Carbon emissions of electrical consumptions are about 16.15%. The best carbon emissions are from such chemicals as PAC, NaOH, and liquid chlorine from the Panhsin Water Treatment Plant, which are about 83.75%. Carbon emissions from the reverse osmosis system is the best emission source in the Kinmen Seawater Desalination Plant, whose electrical consumption in the purification stages is about 99.75%. In the ChengChingHu Water Treatment Plant, chemicals, such as NaOH, $Al_2(SO_4)_2$, liquid chlorine, H_2SO_4, and others are the best sources of emission, which are about 67% in the purification stages. Carbon emissions of electrical consumption are about 33%. Finally, in the FongYuan Water Treatment Plant, carbon emissions of chemicals used, such as PACl and liquid chlorine, are about 62.73% in the purification stages. Carbon emissions of electrical consumption are about 36.99%. The solar PV electricity generation systems of Gongguan Purification Plant would reduce about 0.0017kg CO_2 e/m^3 in 2010.

5 CONCLUSION

The equivalent of 0.1768, 0.2646, 9.6249, 0.4969, and 0.1942 kg CO_2e would be emitted from the production of 1 m3 of water from a traditional purification plant, a purification plant with high-turbidity raw water, a desalinization plant, an advanced purification plant, and a multi-process purification plant, respectively. Reverse osmosis contributes significantly higher greenhouse gas emissions than other purification processes during the life cycle of water production. On the overall, the generation of electricity for pumping and for water delivery accounts for a large proportion of greenhouse gas emissions during the life cycle of 1 m^3 of water production.

Korea*– Japan**
International Cooperation on Type I Eco-Labeling
- Analysis of Its Performance & Future Directions –

Jong heon Park (1)[1], Ju yeong Kim (2) [1]

[1] Korea Environmental Industry and Technology Institute, Seoul, Republic of Korea

Abstract

Korea Environmental Industry and Technology Institute(KEITI) has established Type1 ecolabelling system based on ISO 14024 and managed it since 1992. KEITI has also cooperated with other organizations abroad which is operating ecolabelling system so that ecolabelling system cannot be the barrier to international trade. KEITI has concluded MRA with Japan Environment Association(JEA) and cooperate actively such as developing common criteria. KEITI will increase common criteria, share recent environmental information and finally make our relationship(KEITI-JEA) last and strong.

Keywords:

Type 1 eco-labelling, International cooperation, Japan Environment Association(JEA), Mutual Recognition Agreement(MRA), Common criteria

1. TYPE I- ECO-LABELING SYSTEM

Environmental labelling are the designs or indications adhered and provided to products and service media with the purpose for delivering economical information for products and services to the consumers. The environmental labelling system solves the economical problems that occur due to consumption of products or services and furthermore, devised to expedite sustainable consumption and production. Moreover, the purpose of environmental labelling is to induce eco-friendly consumption patterns by providing economical information for the overall process of products and services(phases of production, distribution, usage and disposal) for consumers and enabling the producers to develop and manufacture products that correspond to the eco-friendly consumption patterns.

International Organization for Standardization(ISO) has classified environmental labelling into 3 types and has regulated the conditions for each type of the environmental labeling in the 14020 series. Among the conditions, Type I Eco-Labeling signifies the method where a 3rd person validates the eco-friendly products by sorting products with smaller environmental influence when compared to other products of same usage over the product's lifecycle including manufacture, distribution, usage and disposal.

Since its initial enforcement in Germany during 1979, the Eco-labeling system has been successfully enforced in 48 different regions including the European Union, Northern Europe, Canada, the U.S. and Japan. The nation of Korea introduced Eco-Labeling system by establishing the "Laws on Development and Support for Eco-Labeling" in 1994 and the national contest for environmental cover designs in 1990. From then on, the grounds related to the system operations for "Laws on Development and Support for Eco-Labeling" were found in 1994 to establish the Eco-Labeling Association(present, Korea Environmental Industry & Technology Institute, KEITI) to revitalize Eco-labeling system.

The Eco-Labeling system of Korea is generally operated through the following phases.

A. Select subject product group as the category for subject of certification

B. Determine criteria for evaluating the eco-friendliness for selected product group

C. Verify the appropriate certification standards for subject product group when a corporation is to request certification and approve certification for product appropriate to certification standards according to result of deliberation

D. Surveillance check for the certified product to inspect whether the product is consistently satisfying certification standards during the certified period

All nations or organizations that enforce the Type I Eco-Labeling program operate with the similar forms of the system as stated above.

* Korea Eco-labeling organized by KEITI (Korea Environmental Industry & Technology Institute)

**Japanese Eco Mark organized by JEA (Japan Environment Association)

2. INTERNATIONAL STANDARDIZATION AND MUTUAL RECOGNITION ARRANGEMENT OF ECO-LABELING SYSTEM

The international society's debates on the Eco-Labeling system are accomplished largely by the international organizations including the World Trade Organization(WTO), the International Standardization Organization(ISO) and the Eco-Labeling Operational Institution Conference Group including the Global Eco-Labeling Network(GEN). Major issues include the international standardization for Eco-Labeling system to harmonize with free trade principles for removing irrational trade barrier effects for export products of each nation while expediting developments and supply of eco-friendly products.

WTO supports conclusion of the Mutual Recognition Agreement(MRA) amongst nations so that the conformity evaluation system for the purpose of environment, safety, health, consumer and protection does not act as Technical Barriers to Trade(TBT). Moreover, the Global Eco-Labeling Network(GEN) is actively encouraging the Mutual Recognition Agreement(MRA) to progress the international standardization of Eco-Labeling system.

The Mutual Recognition Agreement(MRA) is the agreement concluded to recognize the "Conformity Assessment" by the agreed nations for regulated products determined by each nation for safety, health, environment, consumer protection. Here, the Conformity Assessment" implies the test, evaluation and judgment of whether the product, process or service satisfies the standards, average or technical regulations. Moreover, "recognition" is recognizing that the results from the opposite side's conformity assessment and the person involved are equivalent.

The process and method of mutual agreement for Eco-Labeling have the need for the following approach. As the 1st phase, 'Mutual Recognition for True Nature of Both Nations' speaks of the mutual recognition that recognizes the opposite nation's eco-friendly products by verifying the true nature of the Eco-Labeling system between the nations and concluding the memorandum of agreement. KEITI has concluded the 1st phase MRA with Nordic Swan, the Eco-Labeling organization of 5 Nordic nations. As the 2nd phase, 'Mutual Agreement of Environmental Examination Methods for Products and Examination Organizations' standardizes the recognition process and evaluation methods for examinations in the nation's Eco-Labeling institutions to assign the official evaluating organization in each nation to mutually recognize the test results. KEITI has concluded the 2nd phase MRA with Taiwan, Thailand, Australia, China and New Zealand.

The 3rd phase 'Mutual Recognition by Common Recognition Standards' is the method of unifying the Eco-Labeling certification standards of a nation to recognize that the certified product has the same eco-friendly excellence as the products certified in the agreed nations. At the present time, the common standard agreement taking place between Korea and Japan can be considered as a good example of this phase. Lastly, the 4th phase 'Unification of Eco-Labeling System amongst Nations' is the method of unifying the different systems of each nation to operate by unifying the operational institution, certification process and test evaluation in one organization. This corresponds to the European Flower system enforced among the member nations of EU or the Nordic Swan that is enforced among the Northern European nations.

3. Korea-Japan Mutual Recognition Agreement

KEITI and Japan Environmental Association(JEA) have recognized the system of both nations in 2003 and concluded MRA that recognizes the official test evaluation results. Since then, the two have consistently progressed the cooperation business for developments of common standards on personal computers(2007) and the multifunctional devices(2010). Since the conclusion of MRA in 2003, when a Korean corporation desires to apply for Japan's Eco-Mark, the preparations of verification report and test evaluations are deputized by KEITI and when a Japanese corporation desires to acquire the Korea's Eco-Mark, the reports and test results from the JEA side are recognized.

The common standard developments between Korea and Japan began as the needs to standardize the 3 nations Eco-Labeling certification standards were brought up at the '5th Korea-China-Japan Environmental Industry Round Table(RTM)' in 2005. At the 3rd working-level meeting in 2007, personal computers were selected as the subject product for development of common standards and in the same year, the Partial MRA was concluded by RTM for the operation of common standard for 'personal computers.' When recognized from the certification organization of one's own nation that the corporation applying for the opposite nation's Eco-Labeling is satisfying the common standards through the same MRA, the opposite nation must also recognize this corporation and the corporation that received their nation's certification for product was enabled to use the opposite nation's Eco-Label just after receiving the verification for the non-common standards of the opposite nation. Based on the conclusion of the Mutual Recognition Agreement, the discussions for common criteria amongst the 3 nations was more actively progressed and at the 5th working-level meeting in 2008, the common certification criteria for personal computers were finally determined.

At the 8th Korea-China-Japan Round-table Meeting(RTM) in 2008, the 'multifunctional devices were selected as the next item for development of common standards and through discussion, the common/uncommon standards amongst Korea, China and Japan were finally completed in December of 2009. Due to the position differences on China's side, the common standard development agreement was not ultimately concluded among the 3 nations and in 2010, only Korea and Japan concluded the agreement. Through the working-level meeting held in Korea, the detailed processes that were left out in the agreement while progressing with mutual recognition and the agreement for operational regulations were additionally completed to enable a more articulate progression of tasks. KEITI and JEA agreed on all items with the exclusion of forced standard and independent operational standards within one's own nation for the multifunctional devices(8 items including quality and consumer information).

The working-level meeting held in 2010 involved not only KEITI and JEA but also the attendance of various persons concerned including the president of Korea's Business Machine Association and the secretary-general of Japan's Business Machine Industry Association(JBMIA). They visited the major test institutions of Korea to observe the testing process for 'noise' and 'discharge of harmful material including VOCs' to serve as a great opportunity to widely notify the high reliability and clear task executions of Korea.

4. Effects of Korea-Japan's Mutual Recognition Agreement

The mutual recognition of the Eco-Labeling system has the advantage of reducing projected costs related to certification since the test, analysis and evaluations can be received within the corporation's own nation when desiring to acquire the Eco-Label of an opposite nation. Moreover, there is the effect that the time consumed for testing is reduced since the tests are progressed in domestic institutions. This system also reduces costs for acquiring foreign Eco-Labels to induce corporations with high dependence on exportations to acquire the Eco-Label as measures to secure the foreign markets and this will soon become the opportunity to revitalize the corporate participation in the Eco-Labelling system.

5. Future Plans

The 3 nations of Korea, China and Japan are annually holding the RTM and working-level meetings to place efforts for increasing items of development for common standards and strengthen cooperation. Henceforth, the agreement for mutual recognition process amongst 3 nations will be derived. Moreover, there are plans to review the development items for new certifications standards and drafts of common standards for the DVD players.

The Korea-Japan Eco-Labelling cooperation is being evaluated as a model example of cooperation in that it has concluded the cooperation in detail such as preparing detailed processes of mutual recognition and operational regulations and that is under direct operation of the agreement. It is suggested to KEITI and JEA that the detailed certification standard data system for each Eco-Label product is constructed. Through this, Korea and Japan will be able to further understand each other's certification standards and also provide help in developing the common criteria. KEITI also desires to share the information on recent trends of foreign regions with JEA. For example, Korea will be able to inform JEA about their experiences on recognition of the GENICES(Global Ecolabelling Network's Internationally Coordinated Ecolabelling System). KEITI will spare no efforts in cooperating with JEA to make the Korea-Japan common criteria as Asia's Eco-Labelling standards.

Current status of Japanese pilot project of Carbon Footprint of Products

Ken Yamagishi, Masayuki Kanzaki (1)[1]

[1] Japan environmental management association for industry (JEMAI)

Abstract

The Japanese national pilot project of Carbon Footprint of Products (CFP) have mainly two purposes. One is to provide GHG communication information to consumer. The other one is to find processes with great GHG emissions by CFP assessment for companies and further reduce GHG emissions by identifying points of GHG emissions reduction. JEMAI has involved as the secretariat of CFP project. In this paper, I introduce the history, the basic structure, current situation and experiments of Japanese pilot project of CFP.

Keywords:

LCA, Carbon footprint, Product category rules

1 INTRODUCTION

In fiscal year of 2008, 30 companies joined preliminary pilot project of CFP to individually provide case studies of their own products' CFP without basic guideline document and Product Category Rules (PCR). From which key issues have been extracted and a guideline document of CFP was generated [1].

In fiscal year of 2009, the Japanese government has launched pilot project of CFP. The first step for each business field was PCR establishment, and 45 PCR and corresponding 99 products were certified by the committee of pilot project [1].

In fiscal year of 2010, the guideline document and PCRs were updated by these two years' experience and public comment. Some experiments such as reduction quantification, system certification scheme, verification by verification bodies, rules for diversification of labeling, validation method of service category and broadly-applicable PCR were launched under the project. Through the experiments, additional rules were established. And generic database for CFP quantification is opened to public [1].

In fiscal year of 2011, some of experiments, CFP verification and PCR certification have been continued.

2 BASIC STRUCTURE

2.1 Basic rules

The basic concept of the project is based on ISO14040-44 and ISO14025. From which the two main guideline documents are established. One is "Basic Guideline of the Carbon Footprint of Products". It provides basic frameworks for CFP quantification, communication and other schemes regarding the project. Another is "Guide of establishing product category rules". It provides principles, criteria and process for establishing PCR in accordance with the guideline.

Through the project experiments, additional rules were established such as "Application rules for reduction quantification (provisional)", "Application rules for referencing a existing PCR & CFP " and "Application guideline for PCR & CFP of services"[1].

For the program operation, three operational guidance are established such as "Rules concerning the registration of draft PCR development plan and approval of PCR", "Rules concerning the verification of CFP calculation results and labeling method" and "Specifications of CFP label and displaying other information "[1].

2.2 PCR

PCR defines the criteria for CFP quantification and labeling method for a certain product category. PCR makes clear to consumers and businesses, how the declaration quantified.

Companies (or industrial circles) develop PCR. To begin the development of PCR, companies shall register the PCR developing plan; let the interested parties be involved in the discussion.

Range of the PCR is difficult to arrange. Typically, companies would want to develop a PCR only for their product which they want to evaluate. Then, the range of PCR tend to become narrow. The narrow range PCR is easier to develop. However, for whole CFP program, a number of PCR is needed. With a wide range PCR, more companies can participate in the CFP program. However, it is difficult to develop PCR, because of many participants' consensus. And also it is difficult to clarify

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_63, © Springer Science+Business Media Dordrecht 2012

the requirements.

PCR certification procedure contains 5days public comments, review by an independent reviewer(s) and then examination by PCR review panel for certification.

2.3 CFP quantification and verification

The companies quantify their products' CFP pursuant to the certified PCR and receive CFP verification. CFP verification is conducted by a third-party verifier(s), and then PCR verification panel examines. CFP verification checks evidences and validity of adopting the quantification methods. If the result is considered appropriate, companies can market their product with the CFP label.

Quantification and verification of CFP strongly require LCA expertise to the companies and verifiers. However, each companies and each verifier have difference of LCA expertise competence. It is very hard to participate CFP program for the beginner companies and verifiers. PCR, other basic rules, past case studies, common examples, common CFP application format and guidelines for verifier are useful to participate CFP program. In many cases, the most important key to improve thier LCA expertise is experience. So far, the appropriate training with actual case study was effective to improve LCA expertise.

2.4 Establishment of generic database

To support CFP quantification, generic database for basic materials is opened to public. On the database, more than 1000 GHG emission factors are listed. The coverage is agriculture, forestry, fishery, mining, food, chemical, oil industry, ceramics, machinery, utility supply, transportation etc. [1] .

The Secretariat and the industrial associations developed each GHG emission factor data to pursuant to GHG emission factor data criteria. Then the data was reviewed by the data validation panel.

3 EXPERIMENTS

3.1 Reduction Quantification

Application rules for reduction quantification has been established, as requested from participants. Basic concepts are based on ISO14044 and ISO14025.

Requirements are [1],

-The same PCR shall be used for calculations.

-Product from other company shall not be compared.

-The function shall be the same or similar. (less - functional product, which is old, can be compared)

-Data shall be collected in the same manner.

- Comparison shall be done between verified results, and Information on comparison shall be disclosed.

3.2 Experiments on system certification

To make verification cost down, some experiments on verification scheme has held.

System certification is management system certification including CFP quantification, internal independent verification and declaration. In fiscal year of 2010, system requirements for CFP quantification was developed. And also formats for system certification were developed. In fiscal year of 2011, some companies have been trying to establish the system under support of the Project.

3.3 Experiments on verification by verification bodies

In the project, the individual LCA/CFP experts who assigned by the CFP program examine verification of the CFP application from companies. By this experiment, the feasibility of product-by-product verification by verification bodies has been studied.

3.4 Other Experiments

Some other experiments are carried out under the project.

Examples are [1],

-PCR certification method and CFP validation method in service category

-broadly-applicable PCR

4 CURRENT SITUATION AND PROJECT SCHEDULE

On September 2011, 65 PCR were certified and 345 CFP labeled products were verified. Some of CFP labeled products will be exhibited at Eco-Products Exhibition in December 2011. Then, the acceptance of CFP application will be suspended.

To prepare privatization of CFP program, the essential result of the three-year pilot project will be reported till March 2012.

Since fiscal year of 2012, private organization is going to operate the CFP program. The program also is based on ISO 14067 in future.

Design for Sustainable Behaviour Research Challenges

Casper Boks
Department of Product Design, Norwegian University of Science and Technology (NTNU), Trondheim, Norway

Abstract
This paper reviews the current state of Design for Sustainable Behaviour, and concludes that so far, the body of literature mostly presents, explains and structures possible design strategies, proposes design solutions based on these strategies, and presents case studies that evaluate the acceptance and effectiveness of such designs. In order to advance the field, three main research challenges have been identified. These are establishing a common terminology, more formalized research protocols for user centred research to better inform design solutions, and selecting target behaviours

Keywords:
Design for sustainable behaviour, user centred design, case study research, research design

1 INTRODUCTION

Partly because of growing attention for sustainability in design, design researchers increasingly acknowledge their role that through design they can have a profound influence in altering users' behaviour into more sustainable behaviour and consumption patterns [1]. As a result, fuelled by dedicated conference sessions, international workshops and other ways of scholarly cooperation, in recent years a 'design for sustainable behaviour' research community has developed. In the earlier phases of ecodesign research, attention for the use phase has mainly focused on using technology to increasing resource (mostly energy) use efficiency. Now it is understood that by understanding user behaviour, and using that in design solutions including shapes, colours, affordances, 'nudges', up to 30% energy consumption reduction may be achieved [2]. Research into Design for sustainable behaviour strategies aims at exploring design strategies for reducing behaviour-related environmental impacts of product and systems, although they have also been proposed for more general applications to persuade users into more socially desirable behavioural patterns [3].

This 'design for sustainable behaviour' community embraces insights from a various relevant scientific fields, such as social psychology, persuasive technology, sustainable consumption, industrial ecology, stakeholder analysis and interaction design. Also within these fields, interest in looking at design as a possible source for solutions is growing, creating a mutual cross-fertilisation of ideas and concepts.

On-going research focuses on exploring relevant concepts and disciplines to provide an understanding of relevant user, product and system aspects that need to be studied and incorporated into design strategies for sustainable behaviour – ultimately to facilitate the successful application thereof. Attempts to conceptualize, frame and structure research constructs, influencing factors, and strategies are abundant, but results thereof are not established yet as a common language that facilitates research progress. In recent years also several case studies have been published focusing on the collection of relevant data for designing solutions that inform, persuade or force sustainable behaviour. Still, this process of selecting, generating and exchanging case study data is observed to be rather unorganized and ad-hoc.

These observations are by no means meant as critique, and are largely unavoidable consequences of an immature research area trying to mature. Therefore it is essential to periodically reflect on how this 'subfield' of sustainable design could or should evolve in the next years; do we continue to randomly select interesting case studies because of a certain perceived improvement potential in changing environmentally-relevant behaviour, or can this process be better structured and motivated? Do we continue to do case studies on a standalone basis, or do we find ways to integrate case study results to facilitate cross-case study analyses? This paper aims to sketch and motivate the need for the selection, collection and exchange of case study results, and to discuss formats for doing so, implicitly advocating the need for a common understanding, and use, of relevant terminology.

2 AN INVENTORY OF RESEARCH CHALLENGES

One of the commonly agreed upon research challenge in design for sustainable behaviour research is to overcome the lack of understanding of when to apply what type of behaviour-changing strategies. It is understood that

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_64, © Springer Science+Business Media Dordrecht 2012

particular ways of influencing are more appropriate than others in particular situations [1,4], and that a thorough understanding of human–product interaction would be required to select the right strategy to induce the desired sustainable behaviour [5].

Ideally industrial designers should be equipped with a decision-making tool, enabling evaluation of alternatives in order to choose the [design for sustainable behaviour] strategies best suited for each project [6]. Also, more research into how users might experience persuasive technologies has been advocated, as well as addressing ethical issues related to removing freedom from users by using such technology [1,7].

In 2009, based on a survey among scholars active in design for sustainable behaviour research, Pettersen and Boks presented a reflection on the main priorities, challenges and opportunities for future development of the field [6]. The study demonstrated a strong connection between research into design-led influence on behaviour and fields linked to interaction design and consumption studies, where deep knowledge about human behaviour and how to influence was considered fundamental, along with issues regarding the development of design interventions. The survey participants saw the development of the field as following a certain path; it was, suggested that first, through theoretically and design oriented research, research should focus on how to understand, assess and analyse influences on and consequences of interaction and how to design influential interventions. A next step would be to study how to fit it all into a company context. Still, with integration into industrial product development rated as the most important research topic, but simultaneously questions concerning stakeholder, managerial and organisational issues seemingly put on hold, some concern was expressed about the risks of creating an island and walking into the same trap of 'classic ecodesign': lack of momentum after decades of tool development.

The above considerations leave us with both a notion of actual progress, and further needed progress in this field. However, taking this starting point of identifying research challenges in existing literature shows that scholars are so far mainly concerned with a content perspective, without addressing the more pragmatically oriented questions posed in the introduction of this paper. The next sections continue therefore with exploring these questions one step further, and are concerned with three main perspectives: 1) developing a common terminology, 2) developing research protocols and frameworks that allow for cross-case analysis, and 3) selecting target behaviour.

2.1 Developing common terminology

One of the key understandings needed to develop and successfully apply design for sustainable behaviour strategies has been found to be a certain categorization of mechanisms that can be used to influence user behaviour. This is widely acknowledged in the design for sustainable behaviour research community. Earlier research focuses on creating prompts [8] or scripts [9,10] to induce environmentally preferred behaviour, and such mechanisms are often used as starting point for developing such a framework. One of the first categorisations was made by Lilley et al. [11], defining three types of product-led interventions: (i) Scripts and behavioural steering – based on definitions by Jelsma and Knot [10]; (ii) Eco-feedback – products informing users of the impact of their behaviour, hoping to induce attempts by users to minimise that impact; (iii) 'Intelligent' products and systems – products circumventing the user's decision making process by ceding the decision making to the product. Wever et al. [5] used a similar categorization using eco-feedback, scripting and forced-functionality as mechanisms to trigger the desired behaviour. Also similarly, Elias et al. distinguished Consumer education, Feedback and User Centred Eco-Design, the latter being defined as "creating products where the most intuitive and comfortable way of using and interacting with a product or system is also the most environmentally friendly" [12]. Bhamra et al. [13] elaborated the distribution by Lilley et al. further by splitting it up into seven parts. Figure 1 is an attempt to an overview of the distributions as proposed by various authors, based on the description of how the strategies will affect the behaviour of the user. On the left side of the figure the use of a spectrum is suggested reflecting a continuous distribution of control where the user has complete control on one end and has no control on the other. Tromp et al. distinguish four types of influence that designers can exert (coerce, persuade, seduce or decide), and add another dimension, namely salience; a design can exert influence that can vary from an implicit to a more explicit manner (salience). In an article yet to be published, Zachrisson [14] explores this additional dimension further by introducing obtrusiveness, using Jelsma's 'force' property of the script, described as "restricting the opportunities for undesired use, or strengthening the stimuli for desired use" [15], thus creating an 'obtrusiveness-control landscape.

Clearly, developing a joint terminology is still an on-going process, and the near future may see additional dimensions to be proposed for characterizing design for sustainable behaviour strategies.

2.2 Choice of methods - towards cross-case analysis

Social psychology literature has a tradition for carrying out experiments using a wide range of methods, with the aim of identifying and understanding behavioural patterns. As this very understanding is often the main goal in this field, there is no tradition in this field to take findings further towards designing solutions that alter behavioural patterns. In design literature most available studies focus on explaining mechanisms that may affect user behaviour, and on translating these mechanisms to suggest design strategies that may convert user behaviour towards more sustainable or socially acceptable patterns.

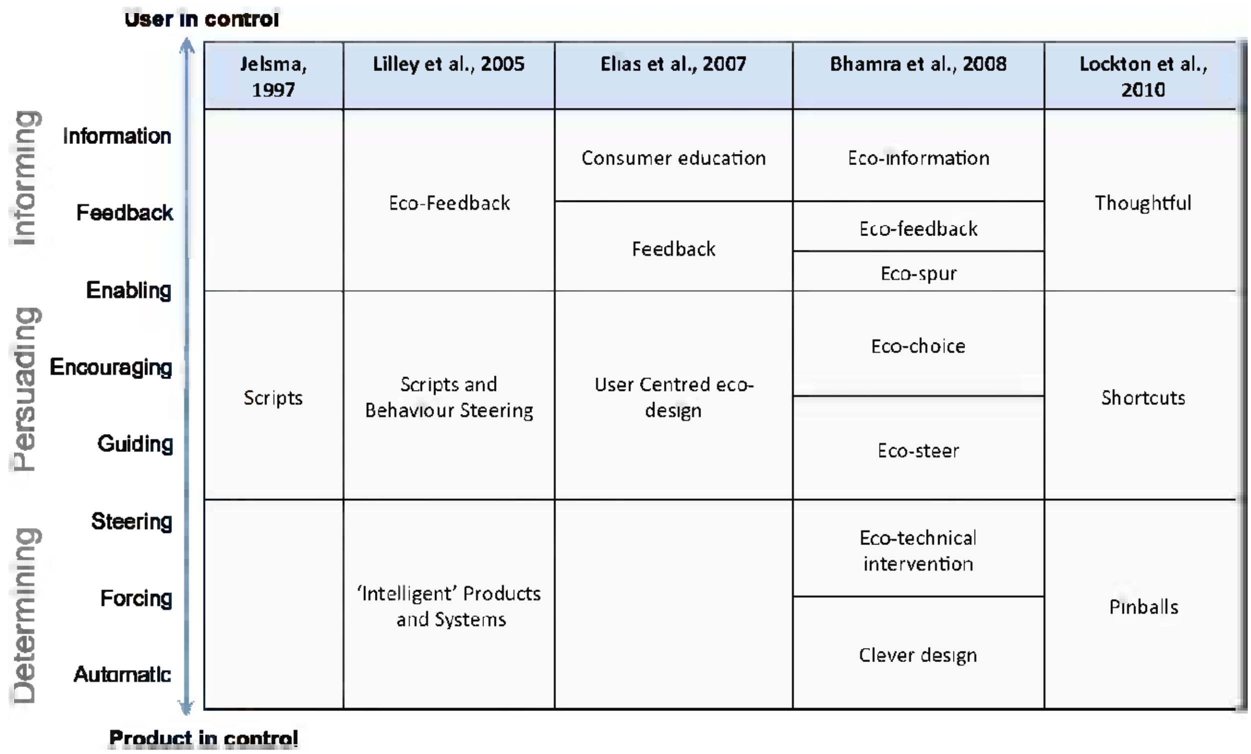

Figure 1: Comparison of design strategies for sustainable behaviour

Such case studies often include the testing of a priori designed solution concepts, and refrain from a substantial collection of user data before such solution concepts are generated. Only a minority of publications seem to rely on a priori data collection on aspects of user behaviour, or report in any detail on research protocols used to collect user data. Among these, Elias [16] reports on using video observation studies to collect raw data which was converted into times and frequencies of particular behavioural patterns related to the opening of refrigerator doors, thus identifying a top 5 of highest energy impact behaviours. A case study on investigating littering behaviour in public spaces largely depended on direct observation and counting littered products in various spaces [17. Lilley gathered behavioural data of mobile phone users based on live data collected on the use of the phone using 'context-aware' technologies such as Bluetooth, GPS and motion sensors [18]. Laitala et al. collected quantitative information on consumers' experiences and opinions concerning clothing consumption habits, including buying, maintenance and discarding behaviour, together with qualitative data from user interviews, wardrobe observation, and laboratory tests to study a range of relevant aspects [19,20]. Papantoniou et al. report on participatory approach followed applying conventional ethnographic methods such as interviews, observations, probes and focus groups in order to gain insights on what people "say, think, do and know" about energy consumption in their day-today practices [21]. An on-going study on oral healthcare practices applies several user-centred-design research methods including interview, overt observation, covert observation (video recording), cultural probing, survey, generative sessions and a blog analysis to collect a rich base of information concerning how oral health care is conducted in order to identify various factors that affected this behaviour. Structuring and analysis of this data is used as input for generating design solutions with the intention to create more sustainable oral healthcare practices, such as reducing water consumption [22].

Even though case studies based on empirical data are limited, the above examples suggest a considerable variety in research protocols used, both in terms of aim of the study, in terms of which variables data was collected on, and in terms of conclusions drawn.

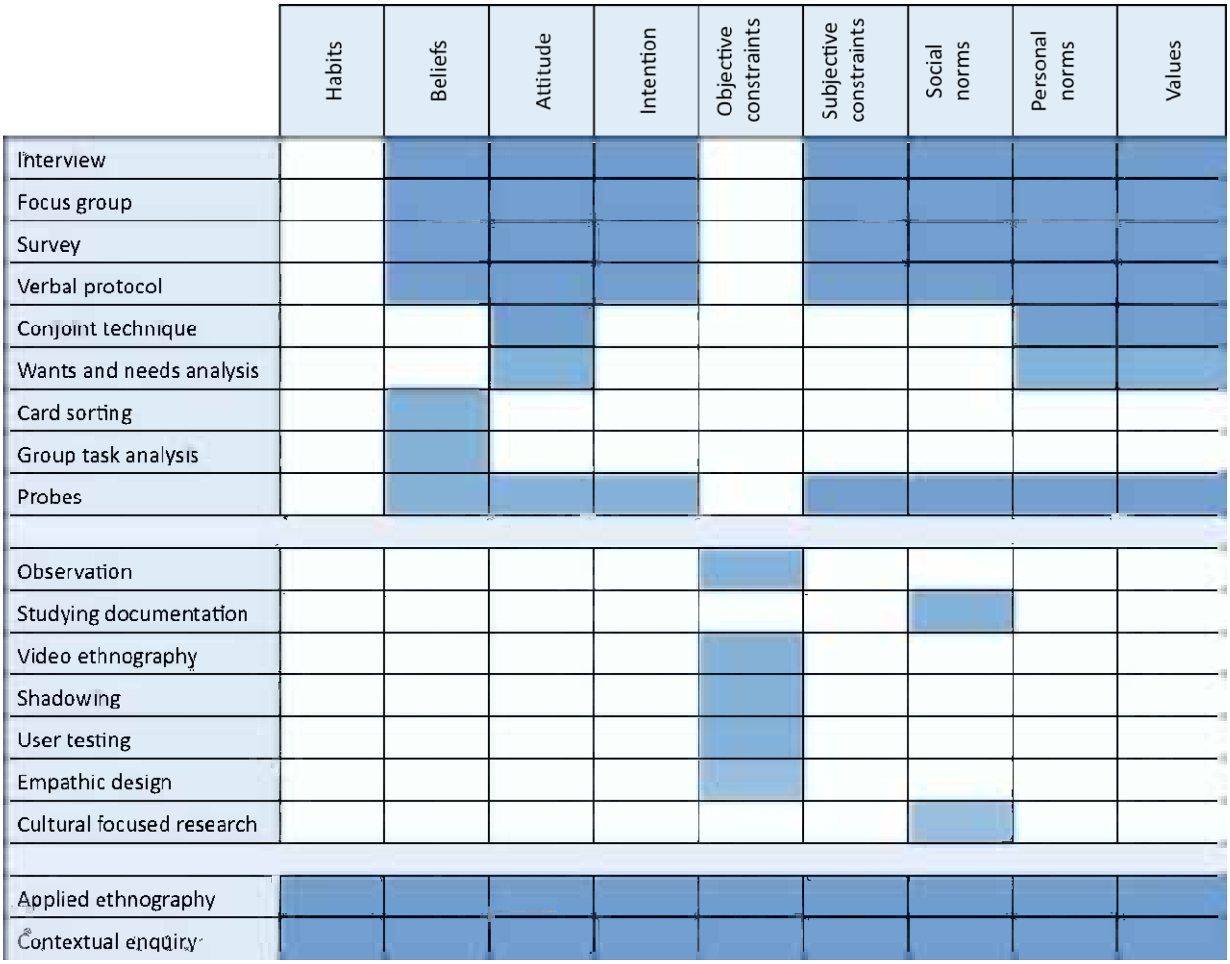

Figure 2: Matching behavioural aspects and suitable user data collection methods

Taking this one step further, Figure 2 presents a matching of various aspects of behaviour that may be relevant to study, with data collection methods that may be most appropriate for that purpose [23]. This table may be relevant future reference for choosing appropriate data collection methods in research protocals for future design for sustainable behaviour case studies.

In time, a better understanding of which data collection methods to use to research which aspects of relevant behaviour may also lead to more standardised research protocols. This in turn would in theory allow for creating databases in which empirical data from different but compatible case studies could be collected. Data collection on individual product-related practices, but in a compatible format, may thus facilitate future meta-analysis of consumer practices, studying broader routines or parts of life styles. For example, integration of separate case studies on the use of kitchen appliances would allow addressing behaviour-related aspects of kitchen-routines in a synergetic way, just as separate case studies on different interfaces for heat, ventilation and air conditioning in different areas of buildings would provide a more complete understanding of how dwellers could be stimulated into more sustainable behavioural patterns for operating these interfaces [24]. At the same time, this may leverage the academic standing of design for sustainable behaviour research, and fuel the integration of design research with and socio- psychological research.

2.3 Selecting target behaviour

So, even if we would have a framework available for systematically collecting relevant data from cases, which cases should we select? Why did Elias select the opening of refrigerator doors as a target behaviour for one of the first main case studies based on empirical data? Would the large project on design for reduction of littering in public space have been carried out if it were not for an NGO contacting the Design for Sustainability Research Group at Delft University of Technology, as they did? Would on-going case studies in woodstove use and littering behaviour in cinemas have been selected if external partners would not have approached the design for sustainable behaviour research group at NTNU as they did?

One logical starting point for selecting appropriate behaviour could be the size of the potential reduction in environmental impact through altering user behaviour. Theoretically, selecting relevant case studies would not be a problem, if all user behaviour that impacts sustainability through the use of products and systems would be systematically listed, if extensive life cycle assessment studies would be done to classify these behaviours according to their impact; the ones that would come out ranking highest could then be identified as target behaviours. This is however a highly impractical and time consuming activity. Moreover, additional relevant considerations would be missing, such as related to the magnitude of the behavioural component, and the improvement potential from a designerly perspective. Designing solutions at both ends of the spectrum depicted in the left side of Figure 1 (providing information leaving the user in full control, or making certain behaviour impossible, leaving the product in control) may require less designerly competence and creativity than creating solutions on the middle end of the spectrum, where users are to be enabled, encouraged or even seduced towards desired behaviour. In additional, the complexity of the situational context may be a relevant aspect to consider in selecting target behaviours.

Within the sketched literature field, this issue has so far remained unaddressed, but as early in the mid-nineties, methods have been proposed to identify target behaviours most suitable for policy measures aiming for reduction of environmental impact [25]. Relevant considerations may include the 1) potential for impact on the environmental problem, 2) the existence of approximations to the ideal behaviour, 3) compatibility with cultural norms or current practices, 4) costs, and 5) complexity. Scoring on these parameters would help understand which behaviours have the most potential for impact on the specific environmental problem and which are feasible. It is also argued that using a scoring system based on these considerations would facilitate a participatory, detailed analysis of the environmental issue and the ideal behaviours, which permits all of the principal concerns from the variety of disciplines and perspectives to be discussed systematically.

Although providing a starting point for solving the question how to select target behaviours to be changed by design for sustainable behaviour strategies, the approach may be less relevant in this very context. Firstly, applying these considerations appear close to the theoretically flawless but highly impractical approach sketched above: doing a detailed analysis and then targeting the one with the highest potential; which is not what we are after. Secondly, the approach appears to target those behaviours that are easiest to change, which might neither be the ones with the highest improvement potential, nor the ones with the most interesting design challenge; as such, the proposed method is highly compromising.

Then, should we instead depend on gut feeling? Interestingly, in 2005 Gardner and Stern [26] presented a short list of target behaviours, for which action would be most effective based on the estimated percentage of total US individual/household energy consumption that can be saved by 27 actions. These actions were selected based on an informal survey of books and articles that offer individual advice to citizens, mostly in the form of unranked list of actions, on how to reduce their energy consumption. This list appears very attractive, though not very detailed for design case studies purposes, and suggests that a heuristic method for selecting target behaviour can provide meaningful results. From a design for sustainable behaviour perspective, some interesting aspects can be derived. First of all, this list by and large suggests that energy consumption can be reduced most significantly by changing citizens' behaviour in a way that is either related to 1) purchasing behaviour of major items that are bought only few times in someone's life, such as a house, car, or major appliances, and 2) installing of and choosing initial settings on systems such as heat, ventilation and air conditioning, that citizens only do few times or year, or perhaps only at the moment of purchase. Changing behaviour related to product use that is more frequent has, according to list, less of an impact on total energy consumption. Moreover, several of the items in the list are of a yes/no nature such as shifting to energy saving lamps or low-resistance tires yes or no, or participating in a carpool yes or no. The list essentially includes only three items that have an everyday behavioural component: driving behaviour, daily setting of a thermostat, and clothes washing. From a design for sustainable behaviour perspective again, these might be the most interesting to focus on, in the context of the desire to focus on the middle end of the aforementioned spectrum. And indeed, these items have been received scholarly attention, though so far limited in the context of design for sustainable behaviour.

It should be noted that Gardner and Stern's list focuses on energy consuming behaviour and does not feature any actions that are based on consumption of other resources, such as water or firing wood, which do have environmental implications as well, and do also provide interesting designerly challenges.

3 CONCLUSION

Design for Sustainable Behaviour is an emerging research area, which is gradually gaining momentum and a critical mass of scholars focusing on this topic. So far, the body of literature mostly presents and structures possible design strategies and to what designs the application thereof may result in, and presents standalone case studies that evaluate the acceptance and effectiveness of such designs. In order to advance the field, three main research challenges have been identified; establishing a common terminology, the use of user research to better inform design solutions allowing cross-case analysis, and selecting target behaviours with high potential for both environmental improvement potential and contributions from design thinking. .

Case-based Design Aid for Sustainable Behavior and Lifestyle

Li-Hsing Shih[1] and Yi-Hsien Chang[1]
[1]Dept. of Resources Engineering, National Cheng Kung University, Tainan, Taiwan

Abstract
This study proposes two approaches to facilitate design for sustainable behavior and lifestyle based on a case library containing existing product designs that lead to behavior change. For each case, expected behavior change, design patterns and technologies used are analyzed and recorded in the cases library. In the first approach, relationship between target behavior, design pattern and technology used is constructed based on the cases. With tables presenting the relationship, designers can find suggestions of design patterns and technologies for a given target sustainable behavior. In the second approach, sustainable Kansei descriptors are chosen to describe customer feelings for each case so that relationship between Kansei description and design patterns and technologies used can be established. After sampling measures of multiple Kansei description via a questionnaire survey, statistical correlations between Kansei description and design patterns and technologies used are obtained. Designers can find useful design patterns and technologies for intended feelings with Kansei descriptors.

Keywords:
Case based reasoning, design with intent, Kansei, sustainable behavior.

1. INTRODUCTION

In the past decades, design for lower environmental impact in manufacturing stage has caught more attention than in use stage. Recently, focus may have turn to environmental impact occurring in use stage. Bhamra et al [1] stated that a great potential of lowering environmental impact exists in household energy use. Herring and Roy [2] suggested that a "rebound effect" appeared when energy saving produced by energy efficient products is taken back in the form of higher consumption. Many consumers, knowing that products (e.g. light bulbs) now costs less, are less concerned about turning them off, or even leave them on all night. Thus these behaviors 'take back' some of the energy savings by the green products. Because of these phenomenon, design for sustainable behavior (DfSB) was discussed most anxiously recently. Eco-design has to not only adopt green materials or energy efficient technology but also change consumer's behavior in the use stage. Consumers' decision and behavior should be incorporated in design stage so that eco-design could lead consumer to a sustainable way of living.

There are many literatures working on design that can lead to behavior change, although they could be presented in different terms. For instance, Lilley [3], Elias et al [4], Lockton et al [5], Wever et al [6] and Pettersen and Boks [7] worked on "design intervention" emphasizing that designers should take responsibility of user behavior. If applied to DfSB, design and technology should persuade or guide users to sustainable way of using products. Design intervention was categorized into three types: educational intervention, technological intervention and product-led intervention. In product-led intervention, designers can adopt concepts of behavior steering, eco-feedback and intelligent product or systems to guide consumers. Jelsma [8] worked more on the design philosophy "behavior steering". Wever et al [6] suggested to involve users in the design stage and used the term "user-centered design" where designers should collect information, identify needs of users and invite users to involve, evaluate and test the product design. Lockton et al have had a series of studies and developed methodology called "design with intent" (DWI) ([5][9][10][11]). They presented three ways to influence user behavior: enabling, motivating, and constraining behavior. Wever et al [6] integrated the concepts mentioned above and suggested more work could be done in "design for sustainable behavior" area. To summarize, there are several ways to influence user behavior including

(a) Eco-feedback

(b) Educational intervention

(c) Scripting, enabling behavior

(d) Forced functionality, intelligence system

Locton et al presented useful DWI method with 11 target behaviors and more than 101 design patterns and 8 lenses that can be adopted to achieve target behaviors. They [9] mentioned that DWI method can also be used in design for sustainable behavior. In this study, target behavior and design pattern are included as major elements of domain model of case based reasoning.

On the other hand, technology should also be developed for changing people behavior instead of simply

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_65, © Springer Science+Business Media Dordrecht 2012

fulfilling their needs (Verbeek et al [12]). Fogg [13] started research on "persuasive technology" that focuses on how technology could persuade or influence people. Jager et al [14] used persuasive technology to raise awareness of energy consumption of household devices. Midden et al [15] suggested using persuasive technology to encourage sustainable behavior. Midden et al [16] summarized four ways in which human and technology interact with respect to sustainability. The four roles technology can play are (1) as intermediary, (2) as amplifier, (3) as determinant, and (4) as promoter of environmentally significant behavior.

This study aims at helping designers find useful design patterns and technologies for DfSB. Existing cases of DfSB were collected to form a case library so that experience can be extracted. Concepts of case based reasoning (CBR) such as setting domain model, retrieve, and reuse of cases are adopted to facilitate DfSB.

2. DESIGN FOR SUSTAINABLE BEHAVIOR WITH CBR

This section discusses how to extract information of past cases and find useful suggestions for designers. In light of the above literatures, design patterns and technology used are found essential for leading to behavior change. For example, DWI provides 11 target behaviors and 101 related design patterns. Using the idea of DWI, existing cases are analyzed and coded with a domain model that consists of target behavior and design patterns.

In addition to design patterns and target behavior, authors suggest that domain model should include: (1) technology used in DfSB products and (2) emotional or Kansei descriptors that are used to describe the feelings and affective influence of users (see Figure 1). The second idea is from Kansei engineering approach that builds relationship between design parameters and Kansei descriptors so that design parameters can be properly controlled to have a design reaching users' emotional expectation (Nagamachi [17]).

Target behaviors and users' feelings represented by Kansei descriptors could be seen as expected results of DfSB while design patterns and technologies are means to behavior change. Hence, a domain model is proposed to describe past cases containing:

(1) target behavior that are adopted from DWI method,
(2) design patterns that are adopted for DWI method,
(3) Kansei descriptors to describe the feelings of users for each case product, and
(4) technologies used in the cases.

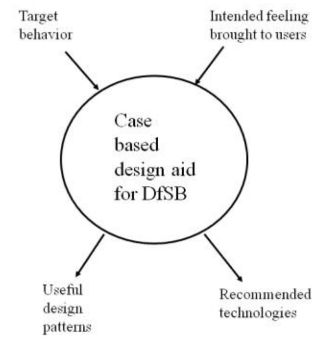

Fig. 1: Scheme of case based design aid for DfSB

With the domain model, cases of products with DfSB were written into a case library. To demonstrate the approach, fifty household products with DfSB were collected, analyzed and coded based on the domain model. The cases are collected from websites of large companies (like Philips), platforms of green products, and descriptions of intelligent house, and meet three conditions: (1) leading to sustainable behavior, (2) household use excluding personal mobile devices, and (3) applying information and communication technologies (ICT). Since there are only fifty cases, limited number of design patterns and target behaviors out of DWI are found. Table 1 shows six target behaviors while Table 2 contains fifty design patterns. Numbers of target behavior and design patterns should increase as the number of collected cases increases.

Table 3 shows examples of 20 Kansei descriptors that are collected from literature describing sustainable lifestyle. Table 4 shows some examples of 23 ICTs found in the cases. Two approaches that start from target behavior and intended feelings to facilitate DfSB using the case library are presented in the following two sections.

Table 1: Target behaviors for DfSB for household ICT products

User-system interaction	
S1	User follows a process or path, doing things in a sequence chosen by the designer
S2	User follows a process or path that's optimized for those particular circumstances
S3	Decision among alternatives: a user's choice is guided
S4	Only certain users/groups of users can use something
S7	Users only get functionality when environmental criteria are satisfied
User-user interaction	
U2	Users (and groups of users) do interact with, and affect each other while using a system

Table 2: Examples of the fifty design patterns adopted from DWI

index	Design patterns

e	voice record
f	alarm clock/stopwatch/timer
…	…
u	automation
v	remote control
w	sensor that detects circumstance

3. DfSB STARTING WITH TARGET BEHAVIOR

After the case library of products with DfSB is built, cases with intended target behaviors could be retrieved. To use this approach, premise is that designers know what behavior DfSB intends to lead to. Once designer has an idea of intended behavior, cases with the specified target behavior could be retrieved and therefore design patterns and technologies adopted in the cases can be found. Since multiple cases that have the same target behavior may be retrieved, number of times that design patterns and technologies appear is used to reflect strength of suggestion. Design patterns and technologies with more times of appearance are considered highly related to the target behavior.

Table 5 shows design patterns recommended for various target behaviors where design patterns on the left are highly recommended because they appear more times than others in the retrieved cases. Indices representing design patterns are shown in last section. In other words, the number of appearance of the design patterns in retrieved cases decreases from left to right. Similarly, Table 6 shows technologies recommended for various target behaviors where technologies on the left are strongly recommended.

Designs could refer to these recommended design patterns and technologies for conceptual design of DfSB. Combination of multiple design patterns and technologies could be acquired from these tables. Since these recommendations are based on past cases, users may be more convinced as the number of cases increases.

Table 5: Recommended design patterns for various target behaviors

Target behavior	(Strongly Recomm) (weakly Recomm)
S1	A12, I6, M7, P8, …..C10, M14, S3

U2	I6, I8, A12, L1,….. M3, M11, S2, S3

Table 6: Recommended technologies for various target behaviors

Target behavior	(Strongly Recomm) (weakly Recomm)
S1	a, b, o, p, f, j, ……., s, w, g, k, v
S2	o, a, o, j, u, b, ……. k, c, e, l
S3	a, o, b, h, j, p, c….., m, q, w
S4	a, c, g
S7	U, v, t, b, f, j
U2	a, o, d, b, ………... l, r, u, v

4. DfSB STARTING WITH INTENDED FEELINGS OF USERS

Designers conducting DfSB may start with intended feelings that a new design would bring to users. Kansei (emotional) descriptors were selected to describe feelings of potential users with respect to each case. In a questionnaire survey, consent/dissent of using Kansei descriptors to describe feeling for each case is collected from each respondent. More than 30 respondents were asked whether they would use each of the twenty Kansei descriptors for each case. For each case, we can collect 20 normalized scores (ranging from 0 to 1.0) with respect to 20 Kansei descriptors. If the score is 1.0, it means that all respondents used the descriptor to describe the case.

With the survey results, correlation coefficients between scores of Kansei descriptors and appearances of design patterns and technologies are hence calculated. Tables 7 shows design patterns with positive correlation with Kansei descriptors. Table 8 shows technologies with positive correlation with Kansei descriptors. To achieve intended Kansei descriptors in DfSB, design patterns and technologies with highly positive correlations are recommended. Contrarily, those negatively correlated design patterns and technologies are not recommended. Designers could certainly start with multiple Kansei descriptors and thus find more suggestions using the information in Tables 7 and 8.

Table 7: Examples of design patterns with positive correlation with Kansei descriptors

Kansei descriptors	Design patterns Highly positive corr	Design patterns Positive corr
Energy saving	I8, A11, I6, P2, P14	A9
Env. protection	A11, P2, I6, P14	A9, I8
Good looking	I6, I8, P2, P14	C6, A11, L1, L7, L10, P12, S2, S5, S6

5. CONCLUSIONS

Two approaches to facilitate DfSB are proposed with concept of case based reasoning. Cases of existing DfSB are collected and expressed with a domain model that includes target behavior, Kansei descriptor, design pattern and technology used. In the first approach, relationship between target behavior and design patterns and technologies used is established via statistical analysis based on the fifty cases. Designers can start with target sustainable behavior and find suggestion of design patterns and technologies using the tables provided.

In the second approach, Kansei descriptors for sustainable lifestyle are chosen to describe customer feelings for each case so that relationships between Kansei sustainable description and design patterns and technologies used are established. For each case, measures of multiple Kansei description from customer opinion are collected via a questionnaire survey. Designers can start with intended Kansei descriptors and find useful design patterns and technologies based on the correlation analysis.

Both approaches would provide recommended design patterns and technologies that could be basis for conceptual design of DfSB. Two approaches could be adopted simultaneously, starting with both target behaviors and Kansei descriptors and obtaining multiple suggestions of design patterns and technologies using the tables resulted from statistical analysis.

Packaging: Sustaining cultures and meeting new imperatives

Rudi Meyer

NSCAD University, Halifax, NS Canada

Abstract

Managing the 'waste' generated through what is seen as excess packaging is not a simple technological problem. The social and cultural aspects of using packaging and wrapping must be considered in any strategies that aim to reduce our consumption of packaging materials.

Keywords:

3Rs, packaging, wrapping, social dimensions, culture

1 INTRODUCTION [1][1]

Packaging, the wrapping of goods and materials, indeed "wrapping" in even its widest sense, is integral to human exchange and interaction. There are of course direct functional reasons for both personal and commercial packaging: physical protection, including barrier protection; containment or agglomeration, with the potential for portion control; security; information transmission, including marketing or advertising, and, of course, for general convenience, to name but a few.

Most or all of these criteria are considered when packages, and their contained products, are designed. Concerns about the environmental and ecological impacts of packaging have now, finally, been added to the list of criteria that must be considered when packages are created. Great strides have been made: the adoption of "cradle to cradle" thinking in developing sustainable products; new materials, e.g. truly biodegradable plastics made of starches, cellulose, and polylactic acid, etc., and the implementation of strategies like the "3 Rs" (Reduce, Reuse, Recycle) in waste management hierarchies.

The latter strategy is significant in light of the social aspects of ecological design. Without minimizing its importance, it is, I think, important to understand that a strategy that asks people to reduce, reuse, and recycle may be at odds with cultural uses of packaging, e.g. a package as package may have an emotional, or communicative, or symbolic import that is integral to a social group; hence, the pragmatic exhortation to change a social norm, even if recognized as a common good, is likely to encounter difficulties.

An important challenge for ecodesign is the reconciliation of social customs with ecological concerns. Given the importance and long traditions associated with packaging and wrapping in Japanese culture, along with the technological, design, and aesthetic sophistication of their manufacture, use, and appreciation, it seems to me only natural that a close study of past, present, and potential future developments in various cultures can result in a significant contribution to resolving at least some of the ecological challenges that we face today. Japan, with its long history of traditional packaging practices, continues to revive and develop strategies that satisfy both ecological responsibility and the cultural importance of packaging. This paper is a sketch of an ongoing body of research, focused on paper packaging and wrapping, that will result in tangible and practical design solutions to a dilemma faced by all of us.

2 BACKGROUND

Japanese wrapping and packaging using both paper and other traditional materials occupy a distinguished position in the world, and their presentation, dissemination and popularization have had profound influences on packaging design. Various Japanese design associations publish annual collections of commercial packaging designs, however, the explicit cultural importance of packaging in Japan was perhaps first introduced to a wider Western audience with the translation of Oka Hideyuki's *How to wrap five eggs* (1967)—a work produced in affiliation with a traveling exhibition that was staged over 100 hundred times—, continued in a subsequent volume, *How to wrap five more eggs*, in 1972, reprised in some measure in a series of Canadian exhibitions in 1988: 'The Art of Japanese Packages' [2]. In these texts and exhibitions the aesthetic elements, and their inextricable relationships with other cultural values inherent and underlying the designs are explicitly and implicitly emphasized. A hands-on approach was published Ekiguchi Kunio with his *Gift-Wrapping: Creative Ideas from Japan* in 1985 [3]. This book introduced Western readers to the ineffable

---

Proceedings of EcoDesign 2011 International Symposium

DOI 10.1007/978-94-007-3010-6_66,

haptic and temporal qualities that inhere in making and opening gifts and packages. Ekiguchi explains carefully the important spiritual and cultural role of packaging in Japanese day-to-day living. Together, the publications make clear and the exhibitions make manifest the close connections between aesthetics and their relation to cultural and spiritual expression. Joy Hendry too has noted the elegiac tone in Oka's writing, particularly in the 1988 'The Art of Packages' catalogue [4]. He mourns the loss of the spirit of 'care' in the wake of industrialization while Ekiguchi celebrated the continuing importance of careful wrapping in present-day Japan. Both sentiments were discernable in the exhibition, 'Tsutsumu: Traditional Japanese Packaging' staged at the Meguro Museum of Art, Tokyo this past winter. The exhibition re-presented many of the types of packages highlighted by Oka almost fifty years ago, including Oka's eponymous 'five eggs'.

It is also noteworthy that in the printed interviews with designers in other published collections of Japanese package designs—e.g. *Wood package : Keiko Hirohashi, Toshio Sugimura, U.G. Sato, Kozo Okada, Ryo Arai, Akiko Arai, Shigeru Akizuki* (1987), *Package Design in Japan* (1989) [5]—that the creators of the packages invariably mention the cultural implications of packaging, e.g. animistic ideas about packaging protecting the 'being' of the contents, the importance of care for both the contents and the recipient, and the nature of the communication conveyed by the package and the circumstances of exchange. These dimensions are bound up with the aesthetic elements, indeed, as Saito Yuriko [6] has elaborated in numerous publications, the one is almost synonymous with the others.

Anthropological studies of gift-giving, and by extension packaging, in English, have also kept pace. For instance, Befu Harumi published "Gift-Giving in Modernizing Japan" in 1968 [7], almost at the same time as Oka's work was being translated. It is, however, Joy Hendry's 1993 book, *Wrapping Culture: Politeness, Presentation and Power in Japan and other Societies*, has had the longest-lasting effect [8]. Indeed, Hendry's use of 'wrapping culture' as a descriptor, in her careful study not only of gift wrapping and packaging, but also of social 'wrapping', was and has become an accepted metaphor under which to discuss Japanese culture, e.g. Eyal Ben-Ari's et al 1990 *Unwrapping Japan: society and culture in anthropological perspective* [9], or, from a design perspective, Ekuan Kenji's 1998 *The aesthetics of the Japanese lunchbox* [10]. Ekuan draws metaphoric parallels between Japanese lunch boxes—wrapping, containment, beauty, and its 'spiritual precision'—and approaches to product design in Japan. Two recent, important additions to the literature on packaging and its social implications are Katherine Rupp's 2003 *Gift-giving in Japan: cash, connections, cosmologies* [11] and Inge Daniel's 2010 *The Japanese House: Material Culture in the Modern Home* [12]. Both Daniels and Rupp engaged in an exhaustive fieldwork in which they examined and recorded the social ramifications and uses of gifts and their wrappings in daily Japanese domestic life.

3 3Rs

Against the background of these investigations, it is illuminating to revisit the seeming pragmatic strategies to manage our strained resources in efforts to address our ecological dilemmas. For instance, a wonderful case in point: Reduce, Reuse, Recycle, or the 3Rs— a striking, poetic, self-reflexive illustration of its own message—succinctly outline one of the strategies for promoting environmental responsibility and ecological balance in a world of limited resources. This collective strategy enjoys widespread, in fact global, acceptance and increasing implementation. A global 3R initiative for waste management was first proposed at a G8 summit in 2004; this was formalized in a meeting of G8 environment ministers in the 3R Kobe Action Plan in 2008. (Earlier warnings of a need to address the issues have of course been issued over the last 40 years, e.g. the Club of Rome's 1972 *Limits to Growth Report* [13] and the Brundtland Commission's 1987 *Our Common Future* [14], to name only two.)

Under the banner of each of the 3Rs, multiple efforts are under way, but even straightforward proposals to use less stuff are (much) debated and even potentially contentious. One simple proposal is to reduce paper weights and alter standard sizes—Japanese businesses use a lighter weight than both America and Europe for their day-to-day uses, although Japan adheres to ISO paper standards—; another, of course, is to ask people to refrain from printing digital texts. It is noteworthy that this latter advice has in the main gone unheeded. The vaunted "paperless" office has not materialized, in fact, paper use has increased exponentially with the introduction of computers and inkjet printers. I surmise that the reason for this is our need for a material or substantial "proof" of our records and actions: the haptic experience of texts is somehow comforting. Michael Braungart, the co-author of *Cradle to Cradle: remaking the way we make things* (2002) with William McDonough [15] , has argued for what he has termed "rematerialization" by which he means making things properly first and foremost, not smaller or fewer of them; the quantitative for him should be a secondary concern. He is speaking about more technologically complex manufactured components, not simple wrappings and packaging, nevertheless, his arguments are indicative of the issues. He sees efforts at dematerialization as part of a destructive, linear, production system that aims to simply amend an existing system without making necessary fundamental changes [16]. His observations offer a glimpse of how vexed the issues can quickly become.

Reuse also seems self-explanatory. Things are reused, e.g. shipping containers, cartons, and so on are either reutilized for their original purpose, or repurposed in some way. In North America at least, shoeboxes, at one time, enjoyed an almost iconic significance as a repository for personal photos and correspondence. Braungart has also proposed a "technical circulatory system"—an additional closed, parallel system within the 'natural' ecosystem—in which components are part of an "intelligent materials pool"; they are reused in the next generation of goods, rather than being "downcycled" and used for something else [17]. This proposal is in essence the creation of an exclusive system that is completely self-referential. It would seem, at first glance, that the social and cultural import of such systems are not a consideration, except in the widest sense.

Among the three Rs, recycling seems to have enjoyed particular popular attention and appeal, perhaps because, once systems are in place, everyone can easily participate in recycling programs, and in fact, not insignificantly, it takes minimal effort for a concomitant, substantial emotional reward. In an odd way, the act of recycling on a domestic level—the separating of 'waste' into coloured boxes and bins, or into transparent plastic bags, for display on the street before collection—is a repurposing of the discarded materials for communicating ecological and social concern.

Like other countries, Japan has instituted legislation to promote recycling: the law for the promotion of sorted collection and recycling of containers and packaging (1997); the home appliance recycling law (1998); construction material recycling law (2000); law for the promotion of effective utilization of resources (2000), to name only some. Japan also put forward another domestic plan to meet the challenges: Japan's New Action Plan towards a Global Zero Waste Society, in 2008.

Indeed, on the whole, Japan's efforts are remarkable. The Japanese Paper Recycling Promotion Centre reports that in 2008 Japan recovered about 22. 75 million tons of paper of which 3.5 million tons were exported and 0.o6 imported, leaving about 19 million tons of which 99% were used to re-make paper [18].

The reuse of paper—cellulose—fibers is unfortunately limited. The recovery and use of fibers from already-made paper presents technical challenges in their recovery and reconstitution, and their suitability for continuous reuse is limited. New fibers must be added to make new paper. Similarly, cellulose from material other than trees: straws, hemp, etc. is also challenging. One difficulty, for instance, is the amount of silica in the material that must be removed with new processes that risk causing further harm to the envirionment. Japanese paper (*washi*), made from non-hardwood pulp, the sole paper source in Japan before the Meiji era, and uniquely strong and appropriate for a host of uses, has now become a fine craft enterprise, rather than a commercial source of paper.

3 SOCIAL IMPLICATIONS

What is worth noting, at the risk of belabouring a point, is that all of these efforts to manage paper use are in essence technological fixes that seem not to pay any attention to the cultural and societal dimensions of the problem of over-use of a limited resource, and it is these that I think important to at least outline briefly. Japan's traditional paper packaging culture offers a particularly illustrative case study.

To state the obvious, packaging is the lynchpin of any functioning economic or supply system. It is absolutely necessary, in some form, for almost any kind of trade. In fact, some goods or products could not be distributed without some sort of packaging. Two examples, both ubiquitous, at least in North America, are portion-controlled, take-away coffees in paper or styrofoam plastic cups and drinking water in plastic bottles. Japan is unique in the world for its sophisticated network of vending machines that provide drinks of all kinds, both hot and cold, in metal cans, plastic– and glass bottles. It is safe to claim that almost all exchange goods are in some way, or at some time packaged, and almost one-half of all packaging is made out of paper.

In economic contexts, packaging has a number of clearly defined purposes. First and foremost, packaging is designed to protect something from its environment: from temperature, from humidity, from mechanical shock, and so on. Packaging must also be designed to be secure, i.e. to tamper proof, or, failing that, to make any interference immediately noticeable in some way. Visible evidence of a package's protective powers may be of great symbolic importance., e.g. visible protection of the physical 'object' and its spiritual qualities.

Packaging is also meant to conceal, or to partially obscure. Saito, in her essays, writes of miegakure (now you see it, now you don't) and the aesthetics of the attraction of the concealed. In the same context, Saito also elaborates the importance of the temporal aesthetic inherent in the acts of wrapping and unwrapping. One of the small pleasures for visitors to Japan to discover is the ease with which one can open packages once one has found the (hidden) key: the little notch from which to start a tear, the small tab or the discreet string to pull, or the initial fold that when undone opens all the others. The starting point of the process also literally gives pause, elicits pleasure, and preserves the wrapping. The rich tradition of white paper packets and envelopes closed with elaborate knots, themselves indicative of a sentiment or meaning is a uniquely Japanese development. Some knots are not meant to be untied; they signify permanence. This is diametrically opposed to the Western practices of impatient, destructive unpacking.

One of the other practical demands on packaging is its use to containand and to agglomerate: liquids have been mentioned already, but powders, granules, and similar materials are usually gathered in one package. This allows not only for portion control and convenience in distribution, but also, importantly, the ability to give shape while protecting otherwise amorphous goods: *onigiri* and *inari sushi* come to mind. This kind of packaging raises another interesting dimension to the relationship between the contents and their wrapping. In the case of both, one can eat the wrapping, raising the question where does one begin and the other end. As well, the two together elaborate the gustatory aesthetic involved in the consumption of the two. A Western equivalent can be seen in wafers used as substrates for baked goods, in fact, a German-language variant is known as *Esspapier*: eating paper.

Small packaged goods are themselves often collected in a secondary package, which in turn may be arranged within a still larger tertiary package (and so on). This adds convenience—there have been efforts to revive the use of furoshiki in day-to-day use as a replacement for plastic bags. Collections of smaller packages in a larger one allow for specific arrangements within the package, again to reflect cultural symbols and identifiers, e.g. the number of items in a package may be relate to numerology, lingusitic homonyms, and the like. The ensuing layers of wrappings or packaging also may also have social import: The layers of wrapping may be associated with layers of meaning and hierarchies of importance.

Imparting meaning, or in a more prosaic sense, communicating is another key function of wrapping. W are all intimately aware of the function and power of branding. In some instances the package—the brand—is more important than its contents. As noted earlier the kinds of knots used to tie packing string (*mizuhiki*), the colour of the string, their orientation all convey a message and its sentiment. The number of layers also convey emotional messages: the message is directed at the recipient through the packaging, and to its contents. An example of pragmatic communication can be seen on seasonal gifts—*chūgen-seibo*—sent to people at the appropriate times of the year and on which the outer wrapping bears important information: the name of the store, the location of the store, and the costs involved: All of these data are important in determining degrees of obligation for reciprocity. Once this layer is removed, the next layer of wrapping carries additional meanings that reflect other aesthetic concerns. Again, the aesthetic is not to be separated from the meanings.

4 SUMMARY

These very few illustrations—formal constraints prohibit greater elaboration—of the profound importance of packaging as a means of cultural exchange and communication illuminate, I hope, in some measure the care that must be taken and the sensitivity we must exercise as we address our ecological concerns. Failure to do so will make our collective task that much more difficult: *Mottainai*.

Abstract

The aim of this paper is to highlight possibilities for designers to change their products towards showing a better energy performance during their usage. To this end, the paper offers them a simplistic methodology, which supports the consideration of the most important aspects of energy saving. This methodological support is needed since not only electronic household products, but also consumer behaviors have become more complex over the years. In this research we are focusing on saving by adding extra smart energy saving functions. Product equipped with some level of intelligence are able to perceive their environment, can be aware of the presence of people and other agents, and can respond smartly to the needs of these agents. The proposed methodology has been developed to support designers in using these ubiquitous controllers to optimize energy consumption. Because it seems to be not obvious to find the energy saving controller or combination with the highest gains. The ubiquitous energy controllers are nonetheless additions to the original product and the trade-off between the extra gains and the costs of adding a control function must be made.

Keywords:

Ubiquitous controllers, smart energy saving, design for energy efficiency, trade-off calculation

1 INTRODUCTION

The principal question of our research is why designers do not develop electronic household appliances that provide optimal energy performance?

Energy consumption and their environmental problems are becoming a heavy concern all around the world. Several studies pointed at the fact that many household appliances have a strong environmental impact due to their high energy consumption and especially because of the amount of energy that is wasted during this consumption. Contrary to the efforts, the progress to reduce this amount of waste is not optimal. Still plenty of electronic household appliances are inefficient in terms of energy consumption.

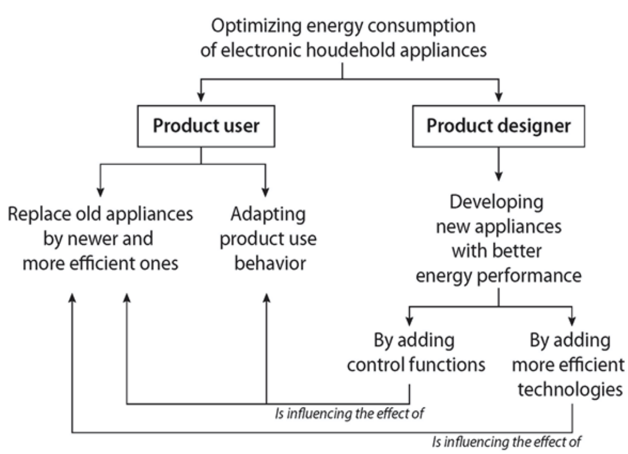

Fig. 1: optimizing the energy consumption of electronic household appliances

The ways of energy saving which could be found in literature (through the product designer and through the product user) are visualized in Figure 1, and are useful to argue why it is important to develop energy intensive products, that designers must do this, and consequently how they must do this. This paper we will investigate what the related difficulties are in the design process and how to apply control functions in the design of electronic household appliances with the purpose to save energy.

In Figure 2 we present a graphical representation of a model to reason about all aspects that are related to this energy efficiency problem with the focus to develop a methodology to support designers in using ubiquitous controllers to optimize energy consumption. Some of the research areas had to be further decomposed due to the different relevant issues and their complexity.

The research started in the domain of the energy efficiency problem. In Section 2, we are considering the energy efficiency problems that are appearing in the design process. Next, in Section 3, the saving possibilities that can be used by designers were examined. And lastly, in Section 4, we are focusing on the trade-off calculations that must be done to achieve an energy efficient product. In addition to this research, in Section 5, the research is discussed and some concluding remarks were made.

2 ENERGY EFFICIENCY RELATED PROBLEM IN THE DESIGN PROCESS

2.1 Difficulties and influencing factors in design activities

In order to reduce consumption and impact, product designers have to use environmental friendly technologies and must fulfill environmental specifications and legislative norms. Nevertheless, these activities are not yet *embedded in designers' daily activities*. This is because achieving optimal energy performance with electronic household products needs a wide ranging search for optimal solutions, as well as a complicated multi-criteria optimization process and decision-making, The process of designing for optimal energy performance features complexity that is caused by the fact that designers should consider not only the operational functions and the actual energy consumption related to them, but also the type of usage of the products, the user behavior, and a lot of other intangibles[1]. In addition, it is rather resource and time consuming to take all influencing parameters into account simultaneously.

Designers are no technology engineers nor can they educate people in how they have to behave with electronic products [2]. On the one hand, a designer is generally not supposed to get engaged with designing more efficient technologies, but to make the most out of possible technology combinations or adaptations by including them during design. This obviously implies that they should be aware of what technologies exist, what functionality they are able to realize, and what are the best ways of their application. On the other hand, as Crosby and Taylor did, we should make a distinction between consumer 'information' (e.g. specific information attached to a given product) and consumer 'education' (e.g. more generic data or training as how to judge the performance of a product form its stated characteristics) [3], since designers can only inform users of their energy consumption through the design of the appliances but cannot educate them.

2.2 Introducing energy efficiency in the design process

Towards involving energy efficiency in the design process, two major considerations have been proposed. Firstly, we have to be aware of the fact that energy efficiency should be seen as *just one of the requirements* to which the future product should come across. A general household product has multiple requirements that must be fulfilled. Thus designers must pay attention to all of them. In contrast, this research is only considering the effectuation of the requirement of having an optimal energy performance during the product use.

Secondly, considering this accomplishment we also have to realize in which *stage in the design process* the execution of energy efficient actions should be accomplished. We considered some common used models to structure the new product development process, to think through the most important phases for designing energy efficient products. [4-6]. As already mentioned above, crucial to energy efficient design is the phase in which the product specifications and requirements should be defined. Often this is step two in the design process, following the ideation step and prior to the concept development. During the definition of the product requirements, it is important to adjust the requirement of energy efficiency, in order to be able to spent time designing the product having an optimal energy performance. The actual design action appears during the concept development phases of the product. In this phase designers have to implement all requirements into their product.

2.3 User behavior influence on energy saving

While reading literature we noticed that much effort is put into the motivation and education of users to change their behavior concerning energy savings, in contrary to this effort, we also notice that not all household appliances are designed to support users in this environmental behavior. Products often suffer from some sort of secret energy consumers, such as a clock or a light, and they cannot be turned off completely. So even if consumers want to reduce their energy consumption, it is not easy to do so.

Obviously, this also means that designers can support users in receiving optimal energy consumption. A typical consumer is influenced by a variety of factors, including where and how the specific information is provided, and the exact format in which it is presented. Mansouri argued that the general conclusions are that end-users tend to apply energy-thrift actions if (1) they understand the benefits, (2) they are motivated, and (3) appropriate information–feedback techniques are applied [7, 8]. To reduce household consumption designers need methods of encouraging the adoption and use of energy efficient technologies. In these methods, socially and culturally sensitive research should be combined with technically proved technologies [3].

2.4 Automated vs. user driven control to save energy

Often in literature [9-12] there is also discussion on the level of automation. Energy consumption can be reduced by people‘s decisions or by machine’s decision, and the whole range between.

If the responsibility is given to the user, designers must engage users in the design of control systems that they like in order to allow them to create the comfort conditions they want and which will support them, through using auxiliary technology, to reduce their energy consumption. In contrast, if users do not have any intention to reduce their energy consumption, automatically adapting the energy consumption is also a possibility. One of the challenges of designing for sustainable behavior is that users’ actions can be difficult to predict as they are driven by a complex array of internal and external influences. To minimize unpredictability and ensure compliance with energy saving goals it is possible to design highly autonomous systems which minimize or eliminate the need for human intervention completely or use constraints to prescribe actions [9].

However, by taking the decision making capability away from the user to prevent ‘unsustainable’ actions, we separate cause and effect. Some authors fear that without feedback on cause and effect users may be less likely to learn from, and adapt, their behavior accordingly. In addition, some authors say that users may perceive automation as a lack of choice and this may reduce acceptance [9, 13-15]. We can conclude that there are different views on it, but also that further research is needed to determine where automation of actions is acceptable and where choice is preferred.

3 ENERGY SAVING POSSIBILITIES OF SMART, UBIQUITOUS CONTROLLERS

3.1 Domestic energy consumption

The electricity consumption of the total amount of appliances in a household is determined by two main factors: the type and number of electrical appliances in the property; and the use of these appliances by the members of the household. The family members influence the electricity use of a dwelling both by their purchase of electrical appliances and through their use of these appliances [1, 16, 17]. Considering the duration of use of these products, we see that time actually means three different things: (i) duration of usage, (ii) frequency of usage, and (iii) product lifetime [15]. Longer use duration, larger use frequency, and longer lifetime mean larger total energy consumption.

Another difference between household appliances is the power consumption level [18]. We can differentiate low-powered and high-powered products. Typical examples of low-powered products are mobile phones, shavers, toothbrushes, clocks etc. Typical examples of high-powered products are heating systems, air conditioners, washing machines, etc. considering this difference, we conclude that if a product implements a critical energy conversion process (e.g., converts electric energy to thermal energy) and consumes a large amount of energy, we can expect a relatively higher saving by reducing the energy saving opportunities in comparison to low-powered products [19]. This assumption is also underpinned by the fact that, typically, these products also feature high stand-by power consumption [1]. Besides, most low-powered products are battery-powered today. As the energy provided by batteries is limited, the energy performance of this kind of products are usually optimized [20], and various technologies are used to improve the energy performance [21].

3.2 Energy saving principles

Based on the energy-related characteristics (usage and power characteristics) of electronic household appliances we can distinguish three general energy saving opportunities: (i) the useless operation time, (ii) the useless operation, and (iii) the overload of power. Useless operation time can be found in products that are in active power but that are not used for a certain period of time e.g. light that is left on in the toilet when there is nobody there, a television that is playing in the living room when the family is eating in the kitchen. Useless operation is when a product does something that is not needed by the user. Often this occurs as heating or lighting e.g. the light of a power button shining red when the appliance is switched off, the heat production of products components such as in a notebook. Overload of power can be located when a product is ‘working harder’ then needed. For instance a vacuum cleaner that sucks harder than necessary to suck the substance.

After locating the energy saving opportunities, it is also important to know how to reduce them. In contrast to designers, engineers can develop new less energy intensive product technologies, and powering and materialization solutions to eliminate this useless energy consumption [22]. Designers on the other hand should be aware of these advanced solutions and use and combine them in an efficient way to make consumer products. If we suppose that they are using the most efficient technologies, designers can only save additional energy by adding auxiliary functions to control the products energy consumption and reducing the saving possibilities. Control can be achieved, as discussed above by human control or automatically and can vary from low intelligent functions, such as switches and buttons towards more complicated and context aware controllers.

3.3 Ubiquitous energy saving technologies

The term ‘context-aware ubiquitous technologies’ describes a class of (still emerging) technologies that are everywhere and anywhere present to seamlessly assists us in our daily tasks, i.e. many functions are intelligently automated, and can significantly contribute to the quality and sustainability of life [23]. The idea of using ubiquitous technologies as enablers of smart energy saving functions has emerged during the last decade.

Products equipped with some level of intelligence are able to perceive their environment, can be aware of the presence of people and other agents, and can respond smartly to the needs of these agents [24]. Ubiquitous controllers can contribute to optimization of energy consumption based on this kind of extra context information. [25]. Information displays, computing, sensing and communication will be embedded in everyday objects and within the environment's infrastructure [23]. For example, motion sensors can be used to increase energy efficiency: (1) for indoor and outdoor lights (the lights turn off once they stop sensing motion), (2) motion sensor alarm: when it is triggered by activity, it activates a camera, (3) use motion sensors to start music when you enter a room and stop it if you leave, and so on [26].

4 TRADE-OFF CALCULATION

The main problem with smart control devices is that they are added extras. Though ubiquitous devices are becoming smaller in size, cheaper to manufacture, more powerful and multi-functional, application of complex control subsystems typically goes together with non-ignorable additional costs. energy saving must be calculated. In certain situations, the extra costs of applying ubiquitous controllers to improve the energy performance of electric household appliances can be higher than the actually attainable savings. Obviously, the ubiquitous controller must not consume more electricity than it allows users to save. Accurately there is a balance between how much energy additional controllers can save and how much it will cost energy wise. In other words, a trade-off must be reached between the gains of the smart energy saving controllers on one side and the extra costs of these controllers on the other side.

In addition to the tangibles, which can be expressed in terms of financial means, we consider the user acceptance as an intangible, which is critical from the aspect of the appreciation of the product. In this calculation, we assume the users to be rational and so neglect the quantification of the intangibles and consider only the product cost or, from the perspective of the user, the selling price of a new product, and the energy cost as determining parameters.

To estimate the trade-off, we should compare the total costs characterizing a product which is not equipped with a ubiquitous controller with the cost and appreciation of the product equipped with ubiquitous controller. From now on, we refer to the product not equipped with ubiquitous energy saving controller as original product, and to the one equipped with this as extended product. It should be assumed that the information about the possible energy waste and energy saving possibilities are known before the trade-off estimation. The financial trade-off for an extended product can be expressed mathematically as an optimum finding problem:

$$TO = \max(G_1, G_2, \dots, G_n) \qquad (1)$$

Where:

TO is the trade-off result that takes the value of the maximum of financial gains which is determined by comparing the particular gains obtained for each considered extended product variant.

G_i is the financial gain (or saving) that can be achieved in the case of a particular product-controller combination (i) in comparison with the original product. The gain can be calculated as:

$$\mathrm{G} = \mathrm{TPC_O}\text{-}\mathrm{TPC_N} = (\mathrm{PP_O} + \mathrm{EC_O})\text{-}(\mathrm{PP_N} + \mathrm{EC_N}) \qquad (2)$$

Where:

G is the achievable financial gain (or saving) in the case of a new product equipped with ubiquitous energy saving controller in comparison with the initial product

TPC_O is the total product cost of the original product

TPC_N is the total product cost of the new extended product

PP_O is the product (sale) price of the original product

PP_N is the product (sale) price of the extended product

EC_O is the energy cost of the original product

EC_N is the energy cost of the extended product

To calculate the gains, we also need information about the sale prices of product variants (product costs). There have been many papers published both on quantitative estimation and on numerical calculation of sale price. Typical quantitative cost estimation methods assume that detailed design of a product has been completed [27]. Cost estimation tools to support early design are scarce and rough. However, various methods, such as case-based reasoning, decision support mechanisms, and analogical reasoning techniques have been successfully applied in a quasi-numeric or qualitative estimation of product price [28]. Typically, these techniques make use of past data to predict the costs of a new product without requiring precise information on the product itself. Literature shows that calculation of product cost is a complicated summation with multiple unknown variables. What it means is that we can consider and use the selling price of the product as a substitute of the actual product cost. It is a frequently applied simplification [29] and this has in fact been considered in above Equation (2). In the case of an extended product, the total cost of the original product needs to be appended by the cost incurred by the applied ubiquitous energy controllers. The additional product cost components include the market price of the controller, the additional embedding cost, and the implementation cost.

Literature was investigated to see what software tools are available for energy cost calculation. What we found is that the currently available tools typically require very detailed information about the embodiment (manifestation) of the product. On the other hand, the need for supporting energy consumption and estimating the various costs in the early phase of product development has also emerged. In fact, some first steps have been made in this direction [30]. A proper energy saving calculation should consider the hours of being in operation and in standby mode [1]. In order to make reliable estimations, we need detailed use scenarios and user behavioral patterns [31]. The most obvious measure is cost and this explains why everything is expressed in terms of money in our calculation scheme. In practice it means that the calculated energy consumption is converted to money by considering the energy prices. The energy consumption of the original product can be calculated as:

$$E_O = (OH_A \times NP_A) + (OH_L \times NP_L) + (OH_Z \times NP_Z) \times 365 \qquad (3)$$

Where:

E_O is the energy consumption of the original product (expressed in kWh/year)

OH is the number of operation hours in a day for the original product

NP is the nominal power required for the operation of the initial product (expressed in kW)

A is the index of the active power mode

L is the index of the low power mode (stand-by)

Z is the index of the off or zero power mode

Furthermore,

$$\sum OH_i = 24h \qquad (4)$$

For the original product, the energy consumption cost can be calculated as:

$$EC_O = E_O \times \sum(TU_p \times EP_p) \qquad (5)$$

Where:

EC_O is the energy consumption cost of the original product

TU is the time in use (expressed in years)

EP is the energy price per kWh consumption

P is the time period in which the EP is unchanged

E_O is the aggregated energy consumption of the original product,

It can be assumed that equations for energy cost and energy consumption calculations remain the same for the original and the extended product only in incidental cases. Therefore, the above Equations (3) till (5) must be adapted to and specialized in terms of the descriptive variables and their relationships.

Obviously, when the physical manifestation of a new product remarkably differs from the original product the variables, and consequently the respective equation will be partially or completely different. These changes may require a comprehensive redefinition of the workflow of computation and the descriptive equations [32].

5 DISCUSSION AND CONCLUDING REMARKS

The objective of this paper was, firstly to highlight possibilities for designers to change their products towards showing a better energy performance during their usage, and secondly, to develop a new methodology to supports the consideration of the most important aspects of adding auxiliary ubiquitous controllers for energy use optimization. This support is needed since the complexity of electronic household products has increased and consequently consumer behavior has also become more complex over the years. Some authors even argued that reductions up to 10-20 % of the products annual energy consumption can be achieved.

5.1 Advancements and limitations of the research

The scientific novelty of the research can be found in the commonsensical approach towards the development of the methodology in which we strive after converting theoretical behavior into a practical means of assistance. Also did we considered the problem from the side of the designer and was the focus of energy optimization entirely limited to the use phase of the appliances. The research was narrowed to the category of electronic household appliances to make the whole manageable. We have to indicate that in addition to the possible implications of the methodology, the methodology is still basic and does not take following aspects into consideration: (1) consumer acceptance, intangible influencing factors and therefore irrational consumer decisions, and (2) the flexibility or irrevocability of the controllers.

5.2 Interpretation of the result

The intention of our work is to convert the existing theoretical knowledge into a computer oriented practical means. Parallel with the methodological investigations, we are studying the requested functionality and possible implementations of the computer tool that can assist designers in selecting and designing smart energy saving controllers. Our interpretation is that more support is needed to assist designers in making a decision on smart energy saving. The methodology remains too complex and extensive to let designers work with it. Moreover, designers are already overloaded with all kinds of methods to optimize the design process. To get a new methodology or tool launched and accepted it must fulfill a number of extra requirements.

Abstract

This paper investigates the life-span of cork products, and how the knowledge from use enables to learn about the material. This is accomplished through a longitudinal approach with users; several cork products are being used, and interviews are performed. In general, users are satisfied with the products, and the specific appreciation of aspects such as performance, quality and aesthetics is also good or very good. Main differences observed are dirt and other visual changes, and at this moment (three months) the life-span of the cork products is good, and the use of the material can be considered appropriate.

Keywords: Sustainable consumption and production; life-span and use(r); cork products and materials

1 INTRODUCTION

1.1 Cork – origin, materials and applications

Cork is a renewable resource, the outer bark of the cork oak tree, and can be removed periodically from the tree stem without endangering vitality. The cork oak forests occur in the Mediterranean region and provide multiple important functions, such as preventing soil erosion and the protection of biodiversity [1] [2]; therefore the production and use of cork contributes significantly to the sustainability of these ecosystems and regions.

Cork is namely a light material, rather impermeable, resistant to wear, and has high friction. Wine cork stoppers are the main cork application, and others include construction materials, floating devices, and for aeronautics [3] [4]. More recently its use has also been increasingly explored in the field of design [4] [5]. Currently there are already several cork materials, such as: white agglomerates, black agglomerates, rubber-cork, cork gel, CPC - cork polymer composites, cork wool, cork paper, cork textile/ skin [3] [4] [5] [6] [7].

1.2 Product life-span and materials use

The durability of products is generally acknowledged as a requisite for sustainability [8], and lifetime extension is in general environmentally desirable, except for energy consuming products [9]. Succinctly, it enables to reduce resource use and the subsequent outflows to the environment. From a resource perspective, this is particularly important in the case of cork since the production is limited – slow growth in a specific region. The relevance of addressing product longevity has been more recently presented by Cooper [10], as well as a clarification of related designations: while *life-span* (or lifetime, longevity) are acknowledged as broader concepts, by including multiple influencing factors, *durability* refers mainly to product intrinsic characteristics. In this paper, durability is referred to in the title since most of the issues arising so far are product intrinsic aspects, and also due to the material focus; although, it should be noted that the general scope of the research is broader – at life-span.

Materials are a specific product feature influencing the life-span of products; how they age is directly related with the materials they are made of. Even though some properties in databases provide an indication on how materials withstand use, such as hardness, there is generally no specific information on the issue available to the designer. Following, two examples of research in the field are succinctly introduced.

Within *Eternally Yours* [11], one of the projects addressed plastic materials; a *Proud Plastics Survey* was performed to collect information about plastic products, originating in a *Plastic Experience Guide* and production experiments to enrich the aesthetic quality of plastics. And Fisher [12] investigated how plastic materials age with use and gather dirt in ways perceptible by users; this may elicit strong feelings and promote the disposal of products.

1.3 Research aim and questions

From the above, this work aims to investigate the life-span of cork products, and how the knowledge from use enables to learn about the material, through the following Research Questions:

RQ1 – How is the life-span of cork products?

RQ2 – What can be learnt about the material?

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,

2 METHODOLOGICAL ASPECTS

2.1 Study setup

Several cork products are being used: at specific moments, interviews are performed with the users, and photographs are taken to register changes in time. Here, results from the three months moment are presented.

Planning: currently, the planning of the moments to collect information is (in months): [0m], 3m, 8m, 16m, 24m, 36m.

Products: 18 cork products for household (bath, kitchen) and personal use (leather market, stationary) were selected and acquired, and different cork materials were contemplated. Some scale was also introduced: with few exceptions, a minimum of three units of each product is being used.

Participants: there are 31 participants, and approximately half are related with research on cork or wood; the study is being performed in Portugal.

Interview: the interview is semi-structured, including open and closed questions coherently organized. This was considered appropriate for the explorative scope of the research.

2.2 Contents of the interview

A – Use of the product (general characterization)

The 1st group of questions aimed to characterize the use conditions: confirm if the product is being used (use of the product); how the product is used (context of use); and, how often it is used (intensity of use).

B – Product appreciation (general)

In the second part the aim was to accomplish a general appreciation of the products, and users were inquired namely about likeness (if they like using the product), and satisfaction (if they are satisfied and would recommend the product).

C – Product evaluation (specific keywords) – five aspects

To accomplish a more specific appreciation and evaluation of the products, five aspects were selected for exploration and assessment in the study. These are: performance (e.g. functionality), quality (technical or broader concept), durability, aesthetic appreciation, and attachment.

At this moment only qualitative appreciations were requested; these were transported to quantitative [1-5] and objective [Y/N] scales to enable comparisons. The correspondences are presented in the table below.

Table 1: Scales for qualitative appreciations

Performance, quality and durability	Excellent; entirely	5			Aesthetic appreciation and attachment
	Very good; good	4		Yes	
	Sufficient; moderately positive	3		Yes but	
	Insufficient; moderately negative	2		No	
	Bad; very negative	1			

D – Comparison/ others (several)

The last group of questions addressed some other aspects: comparison with new – observed differences in time; required maintenance/ cleaning; and, possibility to offer as a gift (answered in B).

2.3 Products – a selection

Table 2: Products being studied – a selection

Household	Personal use
	
(a) PC – Soap dish [White agg. (small)]	(c) PN – Wallet men [Skin/ Textile (dark)]
	
(b) PD – Coaster bk [Black agglomerate]	(d) PR – Pencil case sm [Cork-wood mix]

3 RESULTS

3.1 Use of the product (general characterization)(A)

Use of the product

In general the products were effectively being used, and therefore the implementation of the study was successful. Although, a few exceptions occurred, and which have slightly affected the sample size: PD – Coaster bk, PJ – Keychain, PO – Notebook.

Context of use

With regard to the context of use of the products, in a general way it was possible to characterize them; users have described it appropriately, and at least with the information that seems necessary so far. This is relevant to characterize the circumstances of use, and interpret aspects that may arise; exemplifying, while two soap dishes are used in the sink, for washing the hands, another is used for the bath.

Intensity of use

Similarly, the intensity of use is also relevant 'background' information to characterize the use of the products; it describes how often a product is used, and should be balanced with time. Accuracy is difficult to obtain in this issue, and it also depends on the kind of product. Exemplifying also with the soap dish, use intensity is different if used frequently by four people, two or one, and some users also wash their hands more often than others.

3.2 Product appreciation (general) (B)

In general the appreciation of the products is good. With regard to likeness, with few exceptions responses were favorable [Yes], participants like using the products; there were only three negative situations and five [Yes but]. Users were also in generally satisfied with the products, and willing to recommend them; there were also three negative cases, and four positive but with observations [yes but].

When asked if the product would be suitable to offer as a gift, there were five negative situations and four doubtful ones. Additionally, and since several users have multiple products, some were not mentioned; in general these were household products, and the least mentioned ones were basic or plain (coaster wt, pan base, and place mat wt – all made of white agglomerate).

Table 3 - Exceptions to the general positive appreciation

	Yes but	No
Like Use	Soap dish Fruit bowl Place mat bk Notebook Pencil case sm	Place mat bk Keychain notebook
Satisfaction/ Recommend	Bath mat dry Soap dish Fruit bowl Pencil case sm	Place mat bk Notebook (2)
Gift	Soap dish Fruit bowl; Pen Pencil case sm	Place mat bk (2) Keychain Notebook (2)

3.3 Product evaluation – specific five aspects (C)

Following, participants were asked to more specifically evaluate the products according to five aspects: performance, quality, durability, aesthetic appreciation, and attachment. Following responses are presented, and from the individual charts, a general comparison one was made to visualize aggregated results.

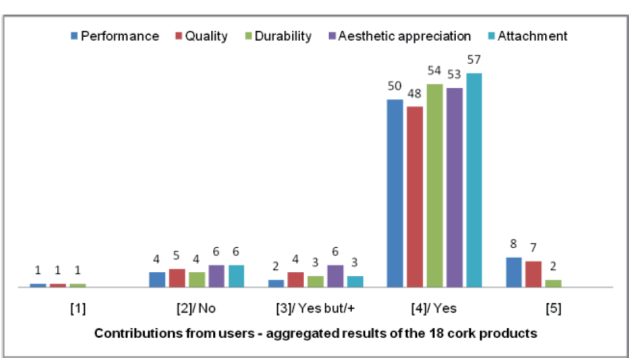

Figure 1: General comparison of the five aspects

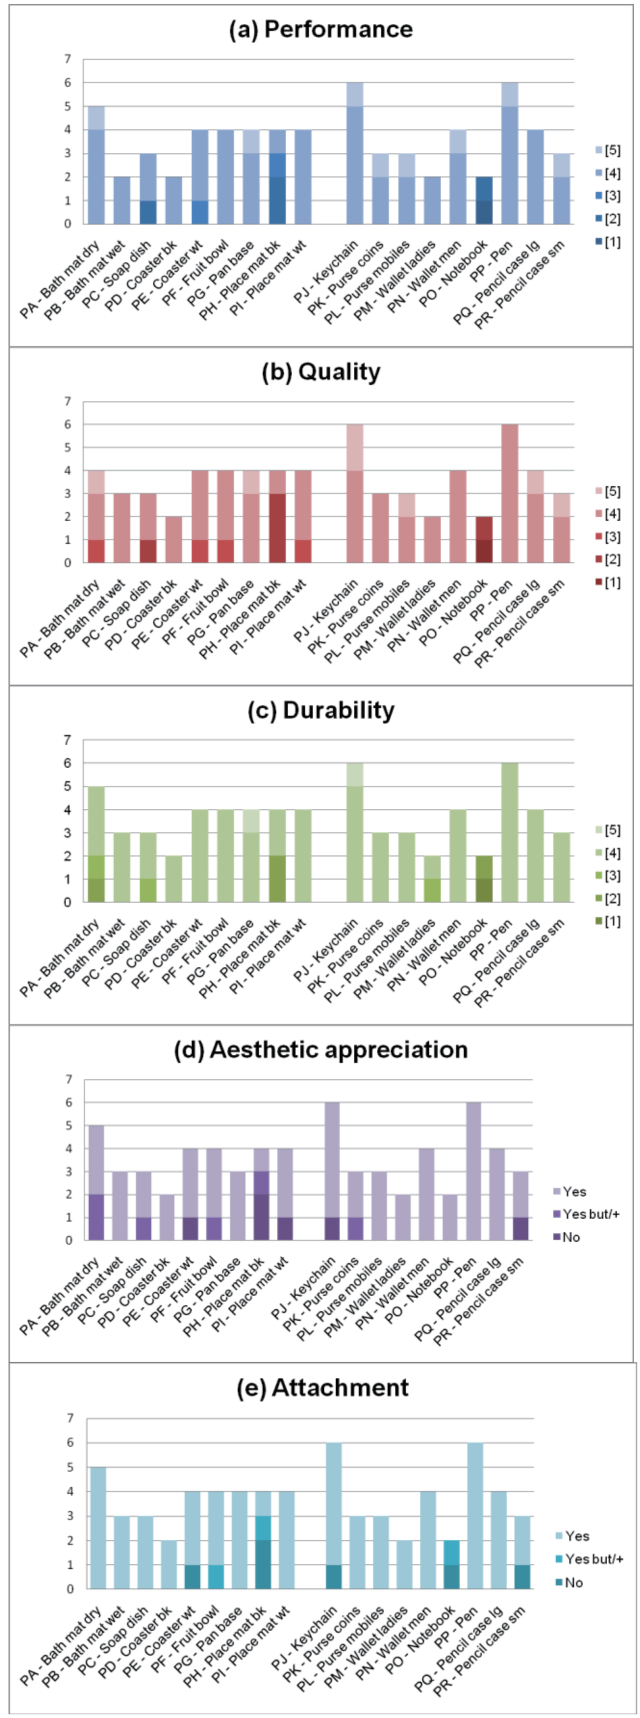

Figure 2: Product evaluation of the five aspects

As can be observed, in general, the evaluation of the five aspects is good or very good [4/ Yes] for most product-user situations. By observing the comparison chart, it can be noticed that the results are relatively similar: in one hand it is still early (3m) and therefore a good appreciation is natural; on the other hand, even though these are all different aspects, they appear correlated – one issue that occurs has sometimes repercussions in some of the five aspects, even if not up to a negative assessment. Following, the few cases for which negative evaluations occurred are succinctly described.

PA – Bath mat dry: in this case there was one negative product-user evaluation in a household with higher use intensity; there is slight damage in a corner/ edges and which is perceived as happening too soon; dirt was also noticed.

PC – Soap dish: in this case, with one of the users with higher use intensity, there is already some slight surface material deterioration, and a usability issue was noticed – the soap gets too attached to the soap dish, which is lifted together.

PH – Place mat bk: with this product several issues were pointed out by different users: fragility – in a household the products got broken and were returned (end of life-span); smell – this dark cork material has a peculiar smell; the fact of being dark for the function of eating; and, little bits of the material get loose.

PO – Notebook: in this a binding problem was found by both users, and sheets get loose easily (products returned).

PE – Coaster wt and PI – Place mat wt: in each case, one user indicated to have no aesthetic appreciation (or indifference) for the products; the fact that these are relatively simple and common cork products and material (white agglomerate) may justify that.

PJ – Keychain and PR – Pencil case sm: in these cases also one user in each declared to have no aesthetic appreciation of these products and materials, and the reasons provided were personal taste.

3.4 Comparison/ others (several) (D)

Differences in time

With regard to changes identified in the products, succinctly and from an aggregated perspective, in 41% of the product-user situations no differences were identified. The chart in Figure 3 presents the three main categories of differences observed.

The main single aspect arising is related with dirt (general or stains), and this accounts for 45% of the situations. Another significant category (22%) includes some visual changes – getting darker, color change, ageing of material, or evidence that it has been used (excluding dirt). Other aspects are grouped in a larger category (33%) and among examples are damage or slight changes in shape.

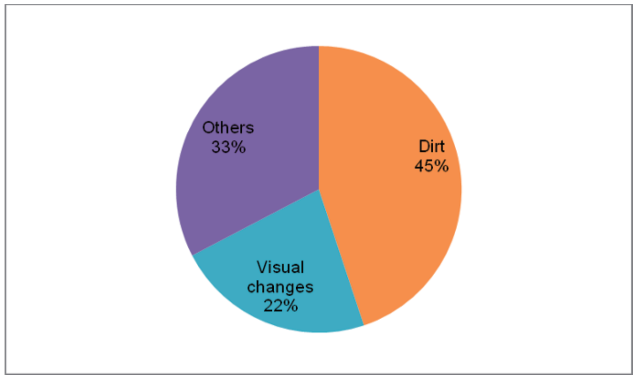

Figure 3: Main differences observed – aggregated results

From a product perspective (Fig.4), it can be noticed that the opinions and experiences of different users are relatively diverse; this may result from distinctive use intensities.

Only three products have entirely no differences observed (coaster bk; coaster wt; and pan base), and the pen is an example in which mainly that is observed, although 2 users mentioned it seems to have become slightly darker; in the bath mat wet, 2 users mentioned that the colour became lighter (lost ink). Mixed examples are e.g. the fruit bowl and the keychain: while some users acknowledge dirt, others have noticed it got darker, and others observed no differences. In other situations some kind of aspect was found by one user, such as in the bath mat dry: dirt by 4 of the users, evidence of use by one, and damaged corner by another. With regard to the two main products with problems, the notebook and place mat bk, besides the specific issues (binding and fragility, mainly), their visual appearance was in most cases similar.

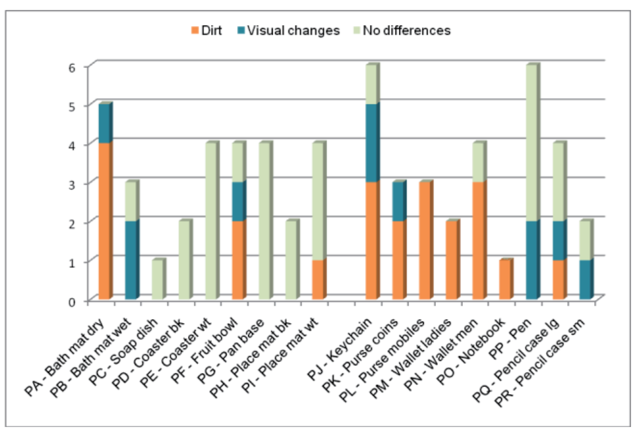

Figure 4: Main differences observed – per product distribution

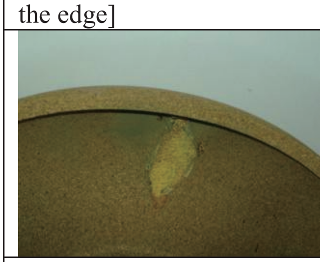
For 11 of the 18 cork products a few other aspects occurred, and are succinctly presented in Table 4.

Table 4: Differences observed – Other aspects (33%)

Product	Other aspect
Bath mat dry	damaged corner (1)
Soap dish	Soap in surface and slight deterioration; slight soap residue in surface, but not well washed. (2)
Fruit bowl	Rot orange peel merged with cork itself; fruit that rots a bit makes cork darker. (1)
Place mat bk	corners are broken (2); deformation with pan (heat); residues and smell intensity decreased. (4)
Keychain	small scratches in metal (1)
Purse coins	Very slightly breaking, crack, rip or tear; Softer: more malleable and smooth. (2)
Purse mobiles	Shape: more flat or flexible; less perfect. (1)
Wallet men	Softer: in body of wallet, but corners still stiff; shape: curved to one side – use in trousers back pocket. (1)
Notebook	binding problem (2)
Pencil case lg	pen marks (1)
Pencil case sm	has extended - is larger (more pens) (1)

Additionally, it should be noticed that the dirt observed is not necessarily a negative issue. Differences acknowledged have a visual emphasis but a few exceptions were observed: residues and smell in the place mat bk, and a more malleable and smoother material in the purse coins. Bellow a few images of used products situations are presented.

Table 5: Images of used products

Household	Personal use
	
(a) PA2 – Bath mat dry [dirt and slight damage on the edge]	(c) PJ6 – Keychain [ageing, darkening (not dirt)]
	


(b) PF2 – Fruit bowl [residues of orange peel]	(d) PK1 – Purse coins [Dirt or ageing]

Maintenance

For personal use products no maintenance was necessary, including cleaning, and only one user mentioned to 'shake off' dust or dirt in a purse mobiles. Although, three users of different cork skin products mentioned the need to clean, or that it would look better if so. One of the products was cleaned by the researcher and user, with a wet cloth; it was simple and the result was good.

In contrast, for the household products, some kind of cleaning operation was reported by about half of the users. For most of these products cleaning was performed with a wet cloth, and was generally considered normal or simple. A few exceptions were also observed: fruit bowl – product was cleaned by researcher with user – better overall aspect but main spot remained, where the orange peel merged with the cork material; perhaps it could be removed entirely, but with even more effort – moderate to difficult effort. Place mat bk – cloth got dirty with residues. Place mat wt – still dirty, grease (but no soap used).

4 DISCUSSION

Concerning the general methodological approach, and considering that similar studies were not available, it is interesting to point out the successful implementation of the study, and that the results are appropriate for the two scopes of the study – life-span and material.

With regard to the characterization of the use of the products, context and intensity of use are difficult issues to measure in a precise way, and there are other differences in how people use the products. These are not simple aspects but so far the objectives were well accomplished.

The evaluation of the five aspects is good, but it should be noticed that this is still an early moment; later results will provide more relevant contributions. Additionally, situations with sufficient evaluation ([3]) can be regarded as opportunities for improvement, and negative assessments ([2], [1]) should be regarded as problems.

And about differences in time, even though some can already be observed in several products, most are slight or moderate, and do not constitute a problem.

5 CONCLUSIONS

With regard to the characterization of use, the products are being used indeed, and it was possible to successfully characterize the context and intensity of use.

Concerning the general appreciation of the products, with few exceptions, responses were positive; participants like using, are satisfied, and consider most products appropriate to offer as a gift.

About the specific appreciation of the products with the five aspects – performance, quality, durability, aesthetic appreciation, and attachment – the evaluation of most products was good or very good [4/Yes]. Additionally, responses for these five aspects are not precisely the same, but there are only slight differences.

With regard to the differences observed in the products, these were mainly dirt related or visual changes. Other aspects were also noticed but are mostly product specific or not mentioned often. And about maintenance, no specific operations were required besides cleaning.

RQ – How is the life-span of cork products?

For the moment, the life-span of the cork products is good. There is a general positive appreciation, and the evaluation of the five key product aspects is also generally good or very good [4/ Yes]. Several issues were already identified as differences in time, but few were explicitly acknowledged as problems by the users.

With regard to the products for which the life-span ended, only a few were returned due to specific problems: the notebook, in which a binding problem was identified by two users, and both units were returned; and the place mat bk, in which some fragility was noticed in one of the households – the products got broken and were returned.

RQ – What can be learnt about the material?

Considering the general positive appreciation, and good or very good evaluation of the products, for the moment, the use of the material in these applications can be considered appropriate.

Most issues that can be learnt directly about the material arise mainly from differences in time. The two large categories identified are dirt and visual changes, observed in several products. As such, the material may be considered somehow delicate or susceptible to visual changes.

From this, as a suggestion with regard to material developments, future research in surface finishing's and engineering seems relevant.

ACKNOWLEDGMENTS

We gratefully acknowledge the PhD grant attributed to the main author by the Portuguese Foundation for Science and Technology (FCT), enabling this work (FCT reference: SFRH / BD / 46646 / 2008). Furthermore, this would also not be possible without the collaboration of all participants, and who were available without any specific retribution. Thank you!

Product Subjective Sustainability: Analysis of the Japanese Users' *Kansei* Evolutions over their Short/Long-lived Products' Lifetimes

Seyed Javad Zafarmand (1)[1], Fumio Terauchi (2)[2], Hiroyuki Aoki (3)[2]
[1] Faculty of Art and Architecture, Shiraz University, Shiraz, Iran
[2] Deign Science Div, Graduate School of Engineering, Chiba University, Chiba, Japan

Abstract
Focusing on the subjective side of product sustainability and considering the lack of a wide expression to encompass product subjective issues that contribute to products' longevity with regard to sustainability values, the present work proposes the concept of Product Subjective Sustainability (PSjS) to particularly indicate 'the emotional, affective and/or aesthetical capability of a product to satisfyingly and pleasantly last during its expected long/short lifetime'. Aiming to expand this concept experientially by using the *Kansei* Engineering approach, this paper presents the process and results of an analytical study on the evolution of Japanese users' *Kansei* toward their short/long-lived product during its entire lifetime. The specified short and long lived product types for this analytical study are, respectively, mobile phone, private passenger car and Japanese handicraft or traditional furniture. As the main outcome of this analysis, the *Kansei* structures and the trends of PSjS are drawn and compared between these products.

Keywords:
product longevity, psychological lifetime, mobile phone, passenger car, handicraft

1 INTRODUCTION

Although the importance of subjective aspects of sustainability has been reinforced within some scientific debates [1-5], most studies about sustainability have focused on its objective aspects (such as recycle-ability, renewability, eco-material, green energy and so on), whereas its subjective side have not been observed adequately [6-7]. The key challenge of "subjective environmental aspects of products and processes" has been discussed in design research since the last years of the 20th century [8]. Nevertheless, the importance given to the subjective issues of sustainability within design research is increasing theoretically and empirically [9]. Practically, the focus of design research concerning such issues is on 'lifetime optimization of products' [10]. Nes and Cramer proposed five design strategies for product longevity among which 'product attachment' seems to be the most directly related to the product's psychological or subjective lifetime [11].

As emotional bonding may increase a product's lifetime [12], extending the psychological lifespan of durables and increasing the degree of consumer-product attachment could be instrumental in reducing both the demand for scarce resources and the rate of solid waste disposal and may contribute to a more sustainable society [13-16]. The strategy of enhancing product attachment, however, brings many challenges and is the most uncertain as to whether it actually enhances longevity [10]. A product, even a very personal one like a mobile phone, could be emotionally pleasurable, aesthetically appealing and/or functionally comfortable during its expected short/long lifespan while there might be a very weak user-product attachment. Therefore, the durability of users' satisfaction and emotional pleasure regarding a product and its appeal do not necessarily eventuate to attachment. According to the findings of our previous researches, there are at least two other effective trends than just product attachment that could be used for extending the psychological lifetime of such short-lived product as mobile phone [17-18]. In fact, user-product attachment is one of the important subjective issues about a product, which include the user's total attitude, feeling, affection, emotion and/or appreciation. Such subjective issues could be professionally called *Kansei* [9, 19-20] rather than any other term like emotion.

As user-product attachment seems to be not the only means for extending or optimizing the psychological or subjective lifetime of products, there is room for an open concept or wide expression (such as product subjective sustainability) to comprehensively encompass product subjective issues that contribute to products' pleasurable longevity when considering product sustainability.

The term 'subjective sustainability' has been used as a versatile and wide concept in the literatures of various fields such as social sciences [21] public policy [22], forest management [23], urban design [6-7, 24-25] and package design [26]. Nonetheless, the definite territory of

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_69,

'subjective sustainability' has not been identified clearly or explained well within the literature.

In this research, we have named "a product's capability of being pleasing, appealing and satisfyingly enduring during its expected long/short lifetime" particularly as 'Product Subjective Sustainability' (PSjS). The word 'sustainability' in this concept is not only meant to imply a fair durability but the imperative application of such durability in terms of product sustainability. Nevertheless, PSjS could be expanded to generally embrace all subjective issues of how a product reflects or affects sustainability values [27]. This concept was first proposed at IASDR 2009 [17] and then expanded at EcoDesign 2009 [18] by the authors.

2 APPROACH

Focusing on the particular concept of PSjS, we have used the evolution of users' *Kansei* toward their short/long-lived products over the entire lifetime of products as a framework to clarify the concept. To cover all subjective issues together, the analysis of such an evolution is based on the *Kansei* Engineering approach [19-20]. The entire lifetime of the product from the user's perspective is here divided into three main lifecycle stages: Purchase (P); Keep or Use (KU); and end, throw away or Replace (R). This framework is to approach PSjS experientially and expand it analytically.

Considering the following points, mobile phone, private passenger car and Japanese handicraft or traditional furniture are designated, respectively, as the short and long-lived product cases for this analytical study. The subjective issues of mobile phone are more considerable than other kinds of products due to the users' very close/personal relationship with it despite it being a short-lived product [28-29]. A user's emotional attachment to a mobile phone – rather than other kinds of products – has been reflected in numerous scholarly works [30-33]. There is also a considerable level of attachment between a user and his/her own car [15]. Private passenger car is an approximately long-lived product in Japan [34]. As a private passenger car registers its owner's individual character and social class, a user may have a personal relation with his/her car. But the traditional furniture or handicraft is definitely long-lived product, which are very valuable and respectable for the owners of such objects considering their rich cultural aspects. Nevertheless, these three kinds of products completely vary when considering their function, technology, mobility, status, background and scale beside the user. Within our previous research, the patterns of three groups of Japanese users' *Kansei* evolution over the lifecycle stages of their mobile phone, car and handicraft/furniture were extracted separately and compared between these products [35]. But, here, to comparatively show the trends of PSjS between the short/long-lived products, the responds of these three groups of subjects are analyzed all together.

3 METHOD

To gather the data required for this study, three groups of Japanese subjects (as user/owner of mobile phone, passenger car and handicraft) are investigated through the definite and descriptive questionnaires. The subjects are questioned about their feelings, emotions, images and/or attitudes – namely, their *Kansei* – regarding their products (mobile phones, cars or handicrafts) in each of the three lifecycle stages (P, KU and R) separately in three different questions.

The first group of subjects, as the users of mobile phone, ranged from 15 to 24 years old, were 31% female and 69% male and consisted of 32 students at Chiba University and 17 high school students living in Chiba. The second group of subjects, as the owners of private car, ranged from 49 to 74 years old, were 29% female and 71% male and consisted 18 students' parents or professors of Chiba University. And the third group of subjects, as the owners of handicraft, ranged from 38 to 74 years old, were 33% female and 67% male and consisted of 15 students' parents or professors of Chiba University.

The descriptive words that the subjects used to describe their *Kansei* about their products in the lifecycle stages are summarized into *Kansei* items through the KJ Method [36-37]. The *Kansei* items based on the subjects' responses are processed by using Quantification Theory Type III (QT3) [38] to show their distribution in X, Y and Z dimensions and, accordingly, their major trends. This number of axes for the spatial data derived from QT3 has been decided on the basis of the resulting Eigen values which were more than 0.500. The distribution of the subjects' *Kansei* statuses in the three lifecycle stages of their products would be another output of this QT3 process. To show the trends of the subjects' *Kansei* evolutions over their short/long-lived products' lifetime, the Centers of Gravity of the spatial data relevant to the subjects' *Kansei* statuses in the three lifecycle stages of their products are used as the indictors. Finally, the resulting trends are compared between the short and long lived products.

4 RESULTS

4.1 *Kansei* items distribution

In total, respectively, 626 Japanese *Kansei* keywords (including 278 for the P stage, 212 for the KU stage and 136 for the R stage), 430 Japanese *Kansei* keywords (including 135 for the P stage, 163 for the KU stage and 132 for the R stage) and 269 Japanese *Kansei* keywords (including 119 for the P stage, 90 for the KU stage and 60 for the R stage) were derived from the subjects' responses regarding their *Kansei* about their mobile phones, cars and handicrafts/furnitures in the different lifecycle stages of these products. All of these keywords were summarized into 73 *Kansei* items or descriptive keywords through the KJ method. The subjects' responses about their *Kansei* regarding all three lifecycle stages of their products were adapted to these 73 *Kansei* items and processed by using QT3. The overall output distributions of the *Kansei* items are shown as X-Y and X-Z graphs in Figure 1. Considering the context and distribution of the *Kansei* items in the graphs, the three axes of X, Y and Z are, respectively, named '*Passive Affection – Active Emotion*', '*Pain – Pleasance*' and '*Subjectivity/Attitude – Objectivity/Value*'. The *Kansei* items, their resulting dimensions and frequencies in each lifecycle stage and product type are presented in Table1.

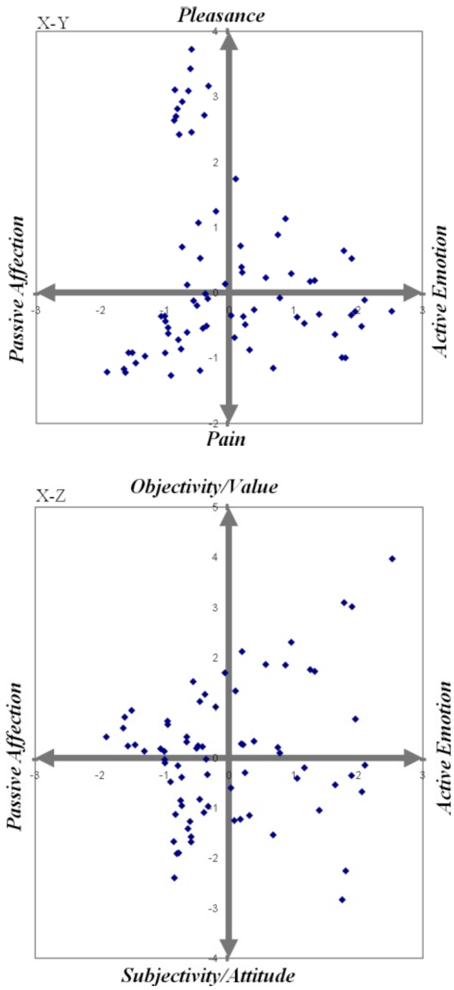

Fig. 1: Distribution graphs of the resulting *Kansei* items

4.2 *Kansei* evolutions over the products lifetime

In addition to the *Kansei* items' dimensions, the other result of this analysis is the spatial data representing the subjects' *Kansei* statuses during P, KU and R lifecycle stages of their products. As the spatial data relevant to the resulting *Kansei* items and the one representing the subjects' *Kansei* statuses are the "sample score" and "category score" derived from of QT3 analysis on the same input data, the same names could be given to the axis directions of their distributions graphs.

Table 2: The *Kansei* items and their dimensions and frequencies in each lifecycle stage and product type

Here, the averages of the X, Y and Z dimensions relevant to the subjects' *Kansei* statuses in the three lifecycle stages of their products are considered their Centers of Gravity. The graphs shown in Fig. 2 are built on the basis of the resulting Centers of Gravity to indicate the trends of subjects' *Kansei* evolutions over the lifecycle stages of their products.

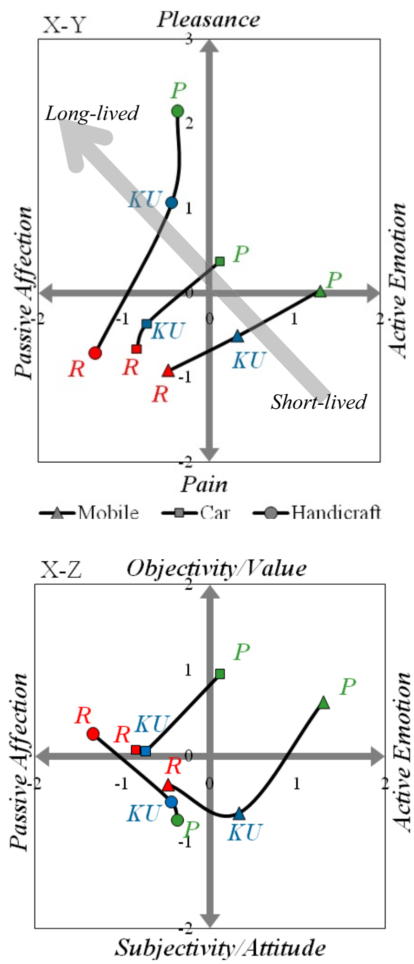

Fig. 2: Trends of *Kansei* evolutions over the lifecycle stages of mobile phone, car and handicraft

5 DISCUSSION

5.1 Trends of *Kansei* evolutions

Comparing the trends of subjects' *Kansei* evolutions between mobile phone, car and handicraft/furniture beside the axes directions of the graphs (Fig. 2), the subjects' *Kansei* statuses in stage R tend to the *Passive Affection* and *Pain* directions regardless to the product type. Regarding all product types, the subjects' *Kansei* statuses roughly evolve from *Active Emotion* and *Pleasance* in stage P to *Passive Affection* and *Pain* in stage R. The subjects' *Kansei* status regarding such short-lived product as mobile phone in stage P tends to *Active Emotion* and borderline of *Pain–Pleasance* directions, while such a status regarding the long-lived products is gradually tending to *Passive Affection* and *Pleasance* directions. Accordingly, the gray arrow highlighted in X-Y graph in Fig. 2 is considered product lifetime scale to indicate the total tendency of users' *Kansei* evolutions in short and long lived products. The subjects' *Kansei* statuses in KU and R stages of their car are so close, probably due to the users' reasons and intentional circumstances of replacing private cars, unlike the other products.

Looking at X-Z graph, the subjects' *Kansei* statuses regarding such definitely long-lived product as handicraft/furniture evolve from *Subjectivity/Attitude* to *Objectivity/Value*, while such trend is reverse in private car. Regarding mobile phone, the subjects' *Kansei* evolution from P to KU stages follows the same trend as car, while such evolution from KU to R stages is reversely following the same trend as handicraft/furniture. The reasons of such dual trend might be the similarities of purchase circumstances between mobile phone and car and replace circumstances between mobile phone and handicraft/furniture. The subjects' *Kansei* statuses in P and KU stages of their handicraft/furniture are so close; probably, because a user's attitude toward such a cultural/traditional object might have no drastic change in these two lifecycle stages.

5.2 *Kansei* structure

The structure of the *Kansei* items from product lifetime and lifecycle viewpoints is visualized into a diagram shown in Figure 3. Overall, considering the *Kansei* items' frequencies in the product types and lifecycle scales, (shown in Table 1) they could be laid in five different levels indicating the state of their generality/particularity. Some of the most frequent *Kansei* items belonging to each level are shown as instance in the diagram.

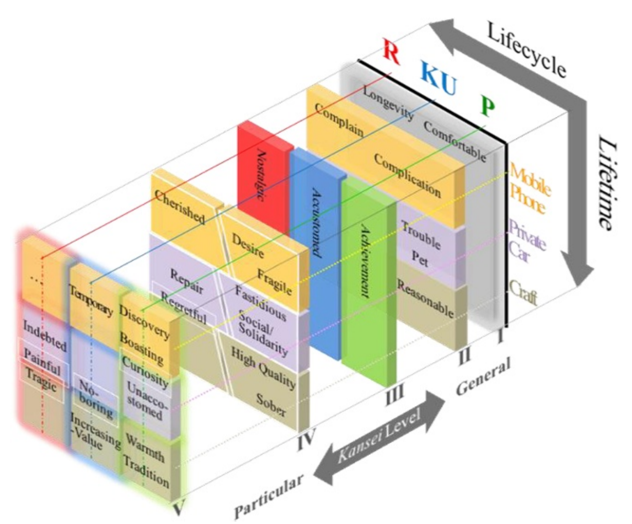

Fig. 3: The levels and structure of the *Kansei* items

The most general *Kansei* items such as Comfortable and Longevity, which a user may have about a product regardless to its lifetime and lifecycle, are placed in the level I. The other *Kansei* items, which are general in the lifecycle stages of more than one product type, could be also laid in this level. The *Kansei* items of level II (such as Trouble and Pet) are specified for a product type (like car) but common in all its lifecycle stages. But the *Kansei* items of level III (such as Achievement or Accustomed) are specified just for a lifecycle stage (such as P or KU) regardless to the product type. Level IV involves those *Kansei* items (such as High Quality and Sober) that a user may have regarding a product (like his/her handicraft) during two close stages of its lifecycle (like P and KU). However, some of the *Kansei* items laid in level IV might be the same for two product types. The *Kansei* items of level V (such as boasting and Discovery) are the feelings that a user may particularly have about a product (like mobile phone) during one of its lifecycle stages (like P).

6 CONCLUSION

The results of this study show that the subjects have had different *Kansei* statuses during the lifecycle stages of their short/long-lived products. Consequently, PSjS is indeed the issue of a user's overall pleasure, satisfaction and/or attachment regarding his/her product by which he/she may experience various/alterable emotions, feelings or moods that evolve from being mostly good, pleasant or dynamically positive to affectively becoming mature throughout the product's expected lifespan. Depending on the product type and its replacement circumstances, such a *Kansei* may evolve from *Subjectivity/Attitude* to *Objectivity/Value* or vice versa.

The *Kansei* structure (Fig. 3) that we arranged could be an initial instrument of guideline for product lifetime management from *Kansei* viewpoint. As those *Kansei* items that are placed in levels IV and V belong to the particular products studied within this research, they could be applied specifically for such products or a similar one to each of them from both lifetime and status points of view. But for a new product in general, the *Kansei* items of level III could be applied. In order to expand such a guideline and its applicability for promoting PSjS, our future research will focus on the design factors associating with each level of the *Kansei* items.

Using a guide to select design strategies for behaviour change; Theory vs. Practice

Johannes Zachrisson, Gøril Storrø, Casper Boks

Institute of Product Design, Norwegian University of Science and Technology, Trondheim, Norway

Abstract

In recent years there has been an increased focus on researching the potential environmental benefit from altering the way users interact with products. A number of strategies for how products may be designed to affect the behaviour of the user have been identified. However, there is a need for a guide that may help designers make informed decisions about which strategies to apply.

An ongoing research project at the Norwegian University of Science and Technology is aiming at creating such a guide. The initial phase of the project focused on identifying insight from social psychology regarding the factors that may affect the behaviour of a person. This is used as a framework for suggesting when different behaviour changing design strategies may be most promising. The preliminary result was a set of guidelines, proposing how information about the user or the context may give an indication of which design strategies to apply. This paper is based on the experience of working with the guidelines in a practical design project. The aim of the project was to reduce the environmental impact of behaviour related to oral healthcare, in collaboration with Philips.

Sustainable behaviour, Design guide, Case study

1 INTRODUCTION

In recent years there has been an increasing attention for the environmental consequences of consumption and the need to reduce these [1, 2]. Literature suggests consensus about the large potential for achieving environmental benefits from altering users' behaviour through the way they interact with products [3-7]. Brezet and van Hemel [8] even state that if a product consumes energy, it is the use phase of the product that has usually the largest environmental impact. Within the product design domain, strategies for affecting user behaviour and limiting the environmental impact have been proposed. One example of this is the "Design with Intent" card deck, where 101 behaviour changing design patterns have been collected and printed on cards in order to make them suitable for idea generation [9]. This research has shown the potential and identified design strategies, but there has been limited discussion in literature about when and in which context the different strategies are most likely to be effective. "Ideally industrial designers should be equipped with a decision-making tool, enabling evaluation of alternatives in order to choose the strategies best suited for each project [10].

At the Department of Product Design at the Norwegian University of Science and Technology (NTNU), ongoing research aims at providing designers with a means of making informed decisions about which design principles to apply, to achieve less environmental impact from the usage of products. In an earlier phase of this project, preliminary guidelines for selecting principles have been proposed [11-14]. These guidelines propose a way of translating information about the user and the context to recommendations of design principles. However, these preliminary guidelines have been derived from literature and theory, and have not yet extensively been tested in practical design projects. The project described in this paper, is the first case study where the guidelines have been applied in an actual design project. The focus was on the evaluation of the format of the guidelines and how they fit in with a designer's way of working, and not on evaluating the recommendations from the guidelines. The structure of the paper is as follows: first the preliminary guidelines are presented. Secondly, the case study is briefly described and the challenges regarding the use of the guidelines are pointed out. Finally these challenges are discussed and possible solutions to them are presented.

2 PRESENTATION OF THE PRELIMINARY GUIDELINES

In 2010 a set of preliminary guidelines for selecting "design for sustainable behaviour" strategies was proposed [11]. The basis for the guidelines is a combination of insight about human behaviour, mainly from the social psychology literature, and insights on how the design of products may affect the behaviour of the user, mainly from literature focusing on design for sustainable behaviour. The starting point is an understanding of the different factors that may affect the behaviour of the user. This can be seen as a central topic in psychology and has been widely described in the literature [4]. The Comprehensive Action Determination Model (CADM) by Klöckner and Blöbaum [15] was selected as a promising entry point to this vast bulk of knowledge (Figure 1). This model describes how human behaviour is affected by a combination of factors categorized as habitual, intentional and situational influences, and in addition indirectly affected by normative processes. Each of these can be divided into a number of sub processes.

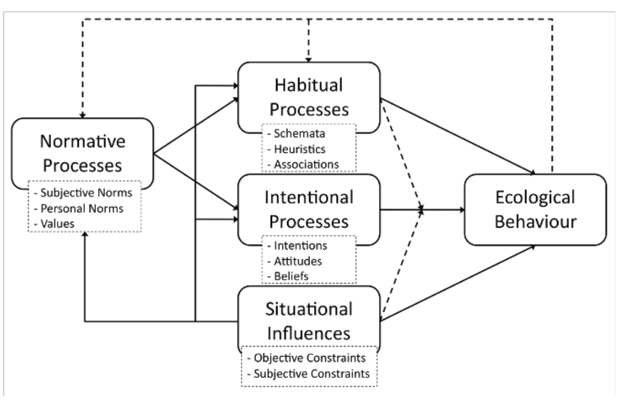

Fig. 1: The Comprehensive Action Determination Model

The theoretical basis for the guidelines is built up by analysing how factors identified by the CADM might be connected to different principles for behaviour change through design. A few common properties of the different design principles were used to enable a comparison between them. The most important of these properties, and also the one most commonly described in literature [16-18], is the distribution of control between the user and the product (Figure 2). At one end of this spectrum there are principles leaving the user in complete control. The user decides if and how the behaviour should be changed. At the other end, the user has no control, and the product forces the user to behave a certain way or causes the behaviour automatically. Between these two extremes, there are many variations of enabling, encouraging, guiding, seducing and steering towards the desired behaviour.

Fig. 2: Distribution of control

Based on the particular factors affecting a user's behaviour, recommendation may be given to how much control this user should have, to achieve a particular behaviour change. Similar recommendations can be given for other properties of the design principles. These recommendations can be combined in a set of preliminary guidelines encompassing the majority of the factors identified by the CADM (Figure 3). The guidelines consist of a number of statements regarding the effects different properties of design strategies can have on the behavioural factors. These statements are accompanied by graphs illustrating the relation between properties of the design principles and the behavioural factors.

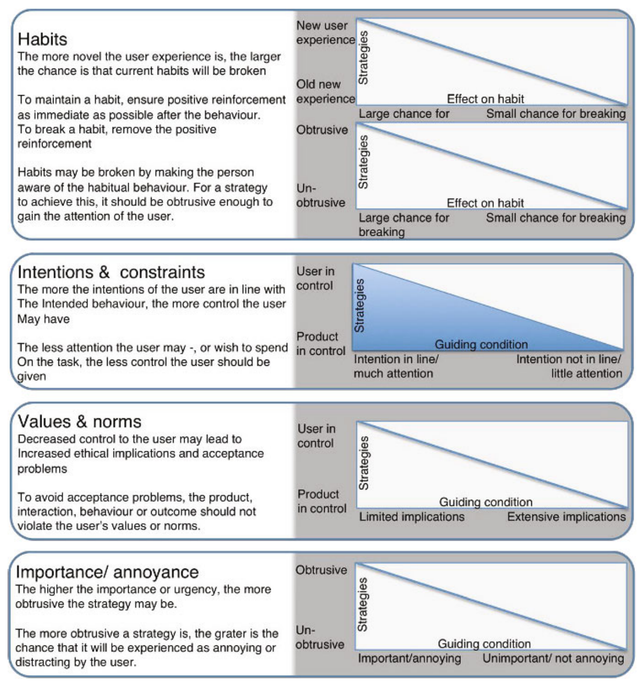

Figure 3. Summary of the preliminary guidelines.

The statements and illustrations are results of a combination of psychological theories and logic deduction. As an example we may consider the first statement of the 'Intentions & constraints'. The statement says that 'the more the intentions of the user are in line with the intended behaviour, the more control the user may have'. This is based on the ABC theory [19] and the following logic deduction: For a user to be willing to make the effort to change his behaviour based on information or feedback, which is the 'user in control' end of the control spectrum, the user should have some motivation to do so. If we move down towards the middle of the control spectrum, we find that the intended behaviour is the easiest or it is more difficult not to behave that way. We can then expect that not only users who find it easy to do what they wish may behave the desired way, but also those how have no strong opinion about the matter. Why should they make the extra effort of behaving differently, if they have no motivation to do so? However, users who have an opposing intention to the desired behaviour, may make that effort, and thus can we not expect to see any behaviour change among this group. If we consider the end of the spectrum where the user has no control, all users are being forced to behave the desired way, and we can expect the desired behaviour change for all users. However, as stated in some of the other guidelines, there may be other complications related to leaving the user completely without control.

3 THE CASE STUDY

As the guidelines so far had a purely theoretical basis, a project was initiated to test their practical application, in order to validate whether they actually are capable of pointing out promising design principles and to make sure the way the guide is presented accommodates the needs and desires of the designer. The focus of this paper is on the latter; i.e. to investigate the user friendliness of the guidelines. This order is useful, as improving the format of the guidelines will not only improve the usability of the guide, but will also enable easier and more extensive application in future design projects, when the quality of the recommendations will be tested. However, as this paper only describes a single case study, the results should rather be considered as input to the development process than as final results.

The project described in this paper is a master thesis project at NTNU, in collaboration with Philips Research in Eindhoven, The Netherlands. The topic of the project was sustainable behaviour in the context of oral health care.

In this project the oral health care practices of a target group of Norwegian or Dutch citizens within the age of 25-35 and 50-65 was investigated by using a combination of several user-centred-design research methods: interview, overt observation, covert observation (video recording), cultural probing, survey, generative sessions and a blog analysis. This resulted in a rich base of information concerning how the oral health care was conducted and the various factors that affected this behaviour. Structuring and analysis of the data could then be used as the input for the guidelines and should enable the identification of the type of design principles that would be most likely to have the intended effect. The scope of the project made it suitable to evaluate the structure of the guide, as it included an extensive user research and aimed to translate this into behaviour changing design solutions.

The exercise of structuring the data and applying the guidelines identified a number of problematic aspects of the guidelines. These are summarized in the following list of challenges, which will be more extensively discussed in section 4. However, it should also be noted that the guidelines did provide valuable support during the project and did show a potential encouraging future improvements.

3.1. The process.

Early in the project, it became apparent that it was unclear where in the process of designing for behaviour change, the guidelines were supposed to be applied. This became particularly clear when preparations were made for a creative workshop to generate ideas for design solutions. Either, the guide could be used to limit the selection of possible design strategies before generating ideas, or it could be used to evaluate the ideas and identify their potential after they had been generated. The advantage of limiting the solution space before generating ideas could be to have a more focused idea generation process and avoid a lot of time and energy being spent on ideas that easily could have been dismissed beforehand. On the other hand, such a narrowing of the solution space could exclude the potential of promising concepts being inspired by ideas that originally were unsuitable. In this project, the guide was primarily used to evaluate the ideas after the workshop. However, the overview of the different factors that may affect behaviour was used as a checklist during the user studies and preparation of the workshop, to make sure that all the factors had been investigated. This may perhaps also be a third way of using the guide, which might prove to be valuable also in future versions. To ease the use of the guide, there is a need to explain where it is intended to be used in a design process. Possibly, suggestions should also be made for tools or methods focusing on other parts of the process, which the guidelines may be combined with.

3.2. The factors.

The behavioural factors identified by social psychology, as for instance presented in the CADM, can be difficult to grasp for designers within the limited time they normally have at their disposal. One of the primary reasons for this is probably the level of detail and distinction between different concepts that are unfamiliar for designers. For instance, it cannot be expected that designers are familiar with the difference between the different forms of habits: schemata, heuristics and associations. Such distinctions may be unnecessarily complicated, as the guide also does not distinguish between the different types. Rather than trying to distinguish between attitude, beliefs and intentions, it might be sufficient to figure out the intentional factors, or “what the user wants”. After all, the factors are connected in a hierarchical structure where intentions are affected by attitudes, which again are affected by beliefs [20]. It might, however, be useful to distinguish between these three when analyzing how a particular intention may be changed. The understanding of the hierarchical relation can help understand that addressing the underlying attitude may change an intention, and similarly between attitudes and belief. A simple explanation of these relations should be included in the guide.

In addition to experiencing difficulties with structuring the information according to all the individual factors identified by the CADM, the format of the recommendations given by the guide was experienced as unclear and a bit hard to grasp. In particular the illustrations were not clear and should be presented in a simpler manner.

3.3 Conflicting factors.

As the guidelines identify promising design strategies according to specific information about the user or the context, the recommendations will vary depending on the target group and which factors one identifies as the steering once. There may be variation in which part of the behaviour it is relevant to address and which factors affect the behaviour the most. The designer will have to select the most important once and use these as the input to the guide.

Also, in some cases the suggestions by the guidelines may be in conflict. This can be illustrated by a case from the project. A group of users was characterized by their value of having to control the world around them. According to the guide, this indicates that the designer should strive to find solutions where the user is in control. However, within this group a number of users believed that they should rinse their mouth thoroughly with water after brushing their teeth, to improve the oral healthcare. This is a misconception, as it actually is desirable to leave the remains of the toothpaste in the mouth to gain maximum benefit from the fluoride. As the user therefore wants to do the opposite of the desirable behaviour, the guide suggests design principles where the user does not have much control. The two suggestions from the guide are in conflict as the designer is recommended to make sure the user is in control, and take away the control of the user.

4 DISCUSSION

As the designer experiences these problems as obstacles for applying the guidelines it is essential to solve them. Not only to enable future testing of the validity of the guidelines, but also to accommodate for the use of the guidelines in real projects. In the following section, each of the problems identified in the project will be addressed and possible solutions will be suggested.

4.1 The process.

To ensure that it is clear which part of the process of designing a behaviour change the guidelines are meant to address, an overview over a design process with the relevant areas highlighted could be accompanying the guidelines. Two versions of such overviews have been presented [12, 14]. However, one primarily focuses on the logic behind the guidelines itself and the other only looks at how the guidelines may be integrated with one other framework. A more holistic overview including a greater part of the design process and suggestions to supporting frameworks would be valuable. Figure 4 presents a suggestion to a process of designing a behaviour change.

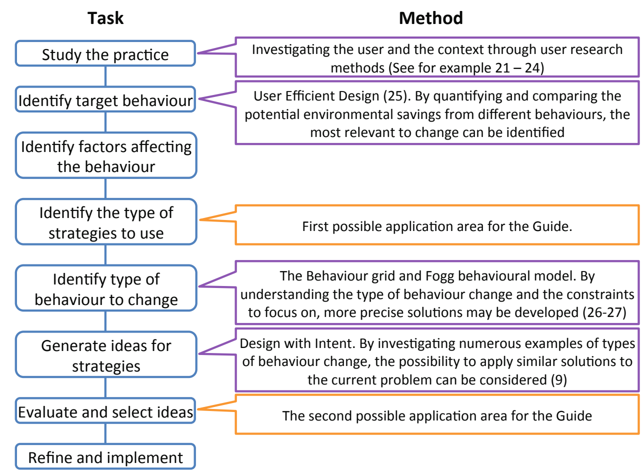

Figure 4. A sketch of a design process with suggested additional methods [9, 21-27]

4.2 The factors.

Both the amount and names of the factors in the preliminary guidelines are imported from the CADM model. These are selected to describe the reasons for behaviour in the best possible way, and not to accommodate a design project with strict time limitations. The number of factors and naming was know as a potential problem, but was not addressed particularly in the preliminary guidelines, as this had to be documented first. In addition, if the number of factors is reduced, there is a risk that valuable nuances between the factors are being lost. One way of coping with this might be to maintain the distinctions of the CADM, but only consider the factor categories instead of the individual factors. After all, as described in the CADM the factors in each category are closely related. This has to a certain degree already been done, as can be seen in figure 3, where for instance there is no distinction between the three different types of habits. However, as no distinction between the three is made in the recommendations found in literature regarding how to address habits, a distinction in the guide will not enable any additional recommendations. Thus may such a distinction only increase the complexity without providing any benefits, and should rather be left out of the guide. And after all, product design has a long tradition of simplifying methods from other disciplines to accommodate the needs of the industry. It is more important to get quick answers rather than precise ones [22]. This will have to be considered further when reviewing the results of future case studies.

As for the naming issue, this can be the subject of improvements through all the iterations of the development process. It is crucial that the designer feels comfortable with the terminology, at the same time as it is important to maintain the distinctions and the precision of the original terms. This might be achieved by using more everyday language and possibly substitute single words with short, descriptive sentences. An alternative presentation of the guide could be as following, with added explanation of the terms, simplified illustrations and reformulation of the recommendations:

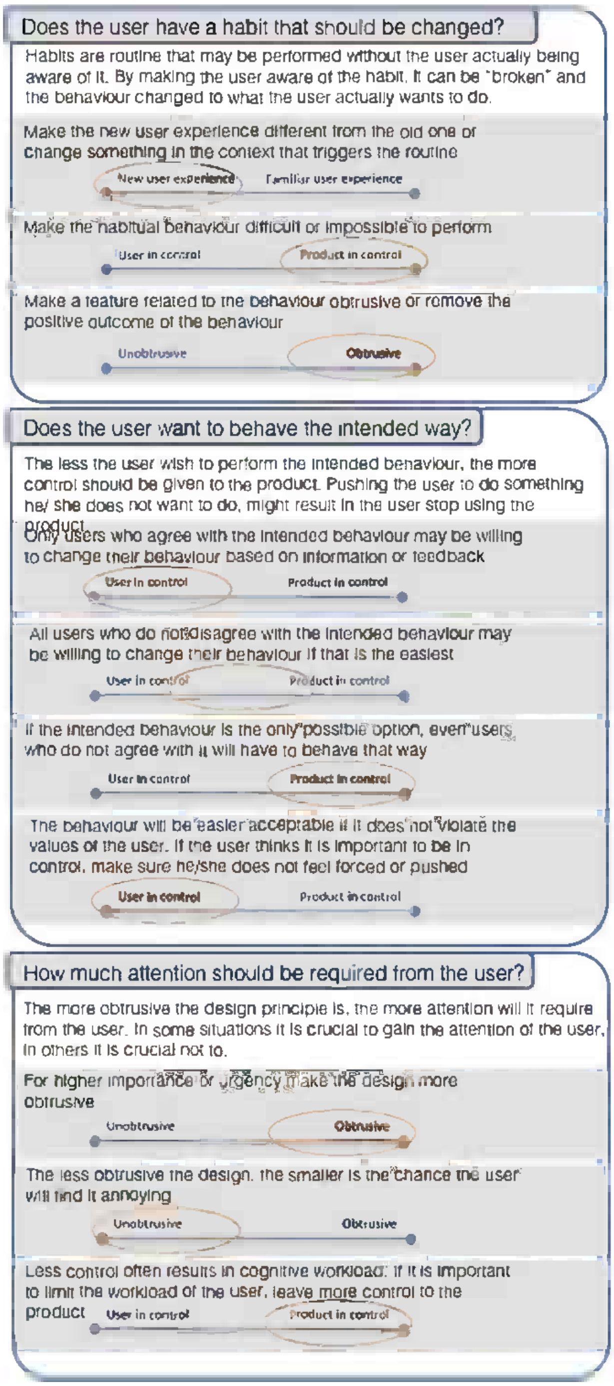

Figure 5. An alternative way to present the guidelines

4.3 Conflicting factors.

Based on this one case study, it is impossible to predict how great a problem conflicting factors may be. If future case studies uncover that this is a frequently occurring problem, it might require radical changes to deal with it. Perhaps is it necessary to develop some system to navigate between the conflicting factors, or change the entire structure of the guide. However, before any such measure can be motivated or informed, substantially more experience is required.

For the specific problem described in the example from the project, there is a difference in the types of factors that causes the problem. The wish to control the world around oneself is a value or norm, whereas the wish to rinse the mouth to improve the oral health care is based on the belief that this is the right thing to do. As norms and values are stable over time [28], it may be difficult to change the wish to control the world. However, the belief that one should rinse the mouth thoroughly may be possible to change, and may be both desirable and ethically responsible, as it is a misconception. This could be addressed by providing evidence that the belief is erroneous. This will not only remove the conflicting factor, but also make the user more willing to change their behaviour.

5. CONCLUSIONS

The project described in this paper, was primarily used to improve the usability of the guide. If it is easier to apply the guide in design projects, there may be fewer barriers to gaining more experience from other case studies. Thus will it be both easier to test the validity of the recommendations, and the testing will be more reliable, as there is a smaller chance of interference from usability issues. The guide, and the improvements suggested in this paper, should also be presented in a format that is easy to work with and provide an overview. Considering the amount of information and diversity of topics, a small booklet might be a suitable format. This could include both the guide, explanation to the process, instructions of how to use the guide, examples of design principles and introductions to other methods the guide could be combined with.

The development of the Design Behaviour Guide will need to go through several iterations to improve the quality of the recommendations and user friendliness of the guide. This paper describes the experiences from one case study, based on a single master project. The identified problems and the suggested solutions should thus be considered as input and a single iteration, and not as final by any means.

System Design of Maintenance Service for Distributed Production Facilities

Hitoshi Komoto[1], Nozomu Mishima[1]

[1] System Functional Design Research Group, Advanced Manufacturing Research Institute, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Ibaraki, Japan

Abstract

Maintenance is fundamental service for the manufacturing industry to increase the performance of production facilities from both economic and environmental perspectives. This paper proposes a simulation-based method that supports maintenance service design of distributed production facilities from a system-level perspective. The simulation result shows relations between the productivity of distributed facilities and total maintenance service cost considering system constraints such as the availability of maintenance engineers. The paper shows how the simulation model is developed on a Service CAD integrated with a life cycle simulator.

Keywords:

maintenance, system design, simulation

1 INTRODUCTION

Manufacturing is one of the most energy and resource intensive processes in the global economy. Sustainable manufacturing is a crucial concept for the decrease of environmental impacts created in life cycles of products [1]. Various systematic methods for sustainable manufacturing have been proposed, which include reconfiguration of manufacturing systems [2] and design of closed-loop flows of products and reusable modules [3].

For the manufacturing industry, systematic design and management of innovative service offerings in product use stage (e.g., pay-per-function and product sharing) have gained attentions [4]. Among these service offerings, especially for production facilities such as machine tools and industrial robots, maintenance service plays a crucial role in the decrease of cost and energy usage in the life cycles as well as the increase of quality of products [5].

Recent studies analyzing maintenance service from a life cycle perspective focused on single production facility (e.g., [5]). These studies considered systemic aspects in the analysis such as trade-off relations between the cost of maintenance service and that of other activities in life cycles of products (e.g., operation). However, product and process models used for the analysis could not sufficiently deal with constraints on maintenance service for multiple facilities such as the availability of maintenance engineers and spare parts. Such constraints often appear when the number of production facilities is large relative to that of the service resource owned by service providers. This is why maintenance service design considering such constraints seems to be useful for small-middle enterprises (SMEs) of machine tools and industrial robots with limited resources, which are installed on distributed production plants of diverse manufacturers.

Traditionally, supply chain logistics including system-level constraints have been modeled and studied with such techniques as mathematical programming (e.g., [6]) and material flow analysis (e.g., [7]) for the analysis and optimization of resource flows. However, these techniques could not deal with complex behavior of production facilities in the use stage.

Life cycle simulation (LCS) is a technique to simulate the behavior of a large number of products in a market [3]. LCS can deal with a variety of product-related service (e.g., maintenance and upgrade) offered by manufacturers and service providers. System-level constraints can be included in LCS in order to apply LCS to the design of maintenance service from a system-level perspective.

This paper analyzes maintenance service system design for distributed production facilities. The analysis is conducted with a modeling tool for LCS called Service CAD integrated with life cycle simulation (ISCL) [8]. ISCL is equipped with a service modeling technique to build discrete event simulation of the life cycle of production facilities. The simulation model includes a system-level constraint representing the number of maintenance engineers. With a case study, the paper analyzes how the constraint and related parameters of maintenance service influence the productivity of production facilities, while simulating the occurrence of physical deterioration of distributed production facilities and the shortage of maintenance engineers.

DOI 10.1007/978-94-007-3010-6_71, © Springer Science+Business Media Dordrecht 2012

The rest of the paper is organized as follows. Section 2 clarifies the concept of maintenance system design discussed in the paper. Section 3 proposes a maintenance system model based on the concept and describes the procedure to build the model on ISCL. Section 4 presents a simulation model developed for a case study and its results. Section 5 summarizes the study and draw conclusions.

2 MAINTENANCE SERVICE SYSTEM DESIGN

In order to clarify the maintenance service system discussed in the paper, it assumes an enterprise that offers maintenance service for a large number of distributed production facilities. The main constituents of the model of a maintenance service system are system performance indicators, deterioration behavior of production facilities, maintenance options, and maintenance resource as constraints on the system.

System performance indicators

System performance indicators are necessity to evaluate the performance of a maintenance service system offered by the enterprise from a system-level perspective. This means that system-level performance should be dependent on the performance of individual production facilities. The average of productivity, energy usage, and life cycle costs of all production facilities are examples of system performance indicators.

Deterioration behavior of production facilities

Accidents such as breakdowns and failures of production facilities are causes of system performance deterioration. These accidents happen to individual facilities at different timing in their lifetime. The influence of these accidents on the performance of facilities can be defined by the magnitude of performance deterioration due to the occurrence of accidents. Given these accidents as stochastic events, the occurrence of accidents can be defined with probabilistic variables. The accidents introduced here is similar to risk of an event defined in terms of its probability and effect.

Maintenance options

This study focuses on the fundamental aspect of maintenance service that it improves the performance of facilities. Maintenance service can be classified into two types regarding execution conditions. First, preventive maintenance is performed following given schedules. Second, corrective maintenance is performed when the performance of facilities is deteriorated.

Resource constraints

The enterprise may not be able to distribute maintenance resources such as skilled maintenance engineers to each production facility. The number of these engineers is regarded as capacity of the enterprise. This is why a maintenance service system has to be designed considering such resource constraints.

3 MODELING AND IMPLEMENTATION

3.1 Modeling procedure

This section explains the model of a maintenance service system based on the concept introduced in Section 2. The model is implemented on ISCL and simulated with LCS.

Product facility model

A production facility is regarded as a discrete system, whose behavior is characterized with performance deterioration due to usage and performance recovery as a result of maintenance service. In this study, it is assumed that the performance is measured with respect to several major failure modes, and the modes are defined before this modeling procedure. The state of a production facility k is defined by a set of performances with respect to failure modes.

$$s_k(t) = (p_1(t), \dots, p_i(t), \dots, p_M(t)) \tag{1}$$

Where, p_i is the performance measured in terms of failure mode i, and M is the number of given failure modes.

Performance deterioration model

Performance deterioration is dynamic behavior occurred to individual production facilities with respect to failure modes. Events causing performance deterioration such as failures and accidents are defined by the probability of occurrence r_i and its effect d_i with respect to a failure mode i. The effect indicates the magnitude of performance deterioration.

$$p_i(t+1) = p_i(t) - d_i \; [if\; r < r_i] \tag{2}$$

Where, r is a random variable between 0 and 1.

Maintenance service model

Maintenance service is defined by the condition and consequence of the occurrence. The condition is defined by the performance of production facilities with respect to failure modes (for corrective maintenance) and/or given maintenance schedule (for preventive maintenance). The consequence of maintenance service is described by the recovery of performance m_i and the increase of maintenance service cost, which depends on the total number of maintenance service n_i. Equations 3 and 4 formalize the consequences of an occasion of maintenance service with respect to failure mode i.

$$p_i(t+1) = p_i(t) + m_i \tag{3}$$

$$n_i(t+1) = n_i(t) + 1 \tag{4}$$

Performance model

In this paper, productivity of a set of production facilities at a system level $P_{SYS}(t)$ and the total maintenance service cost $C_{SYS}(t)$ are regarded as the performance indicators of a maintenance service system.

First, $P_{SYS}(t)$ is defined by the average productivity of individual facilities $P(t)$. The relation is formulated in Equation 5.

$$P_{SYS}(t) = \sum_{k=1}^{N} P_k(t)/N \tag{5}$$

Where, N is the number of production facilities.

The productivity of a production facility $P(t)$ is defined by the product of $p_i(t)$, i.e., the performance of the facility with respect to failure mode i.

$$P(t) = \prod_{i=1}^{M} p_i(t) \quad (6)$$

This formulation assumes that failure modes are independent one another. The system-level productivity at specific period T is defined by the time average of $P_{SYS}(t)$.

$$P_{SYS,T} = \sum_{t=1}^{T} P_{SYS}(t)/T \quad (7)$$

Second, the maintenance service cost $C_{SYS}(t)$ is the sum of maintenance service cost for each facility $C(t)$.

$$C_{SYS}(t) = \sum_{k=1}^{N} C_k(t) \quad (8)$$

Maintenance service cost for a production facility is the inner product of unit maintenance service cost c_i and the number of occurrences of unit maintenance service n_i with respect to failure mode i. In case of preventive maintenance, the product of the cost of a visit to facilities and c_p the number of visits n_p is added to the maintenance service cost.

$$C(t) = \sum_{i}^{M} (c_i \cdot n_i(t)) + c_p \cdot n_p(t) \quad (9)$$

This formulation asusmes that unit maintenance service cost is a constant, but that the number of the occurrences of maintenance service is a dynamic variable. The total maintenance cost accumulated during specific period T is defined in Equation 10.

$$C_{SYS,T} = \sum_{T} C_{SYS}(t) \quad (10)$$

A resource constraint

As a system-level constraint in the propose model, the number of maintenance engineers R is introduced. The constraint is described with the following inequality relation.

$$\sum_i e_i(t) x_i(t) \leq R \quad (11)$$

Where e_i is the required number of engineers for maintenance service for failure mode i, and x_i is the number of facilities, to which the maintenance service is offered. Due to the constraint, the priority of maintenance service types should be defined. For instance, maintenance engineers are first delivered to facilities suffered from severe accidents then delivered to those suffered from light accidents.

3.2 Implementation on ISCL

Fig. 1 shows the implementation of the model on ISCL, which is used in the cased study described in Section 4. The model consists of Entities, Attributes of entities, Activities, and Scenes.

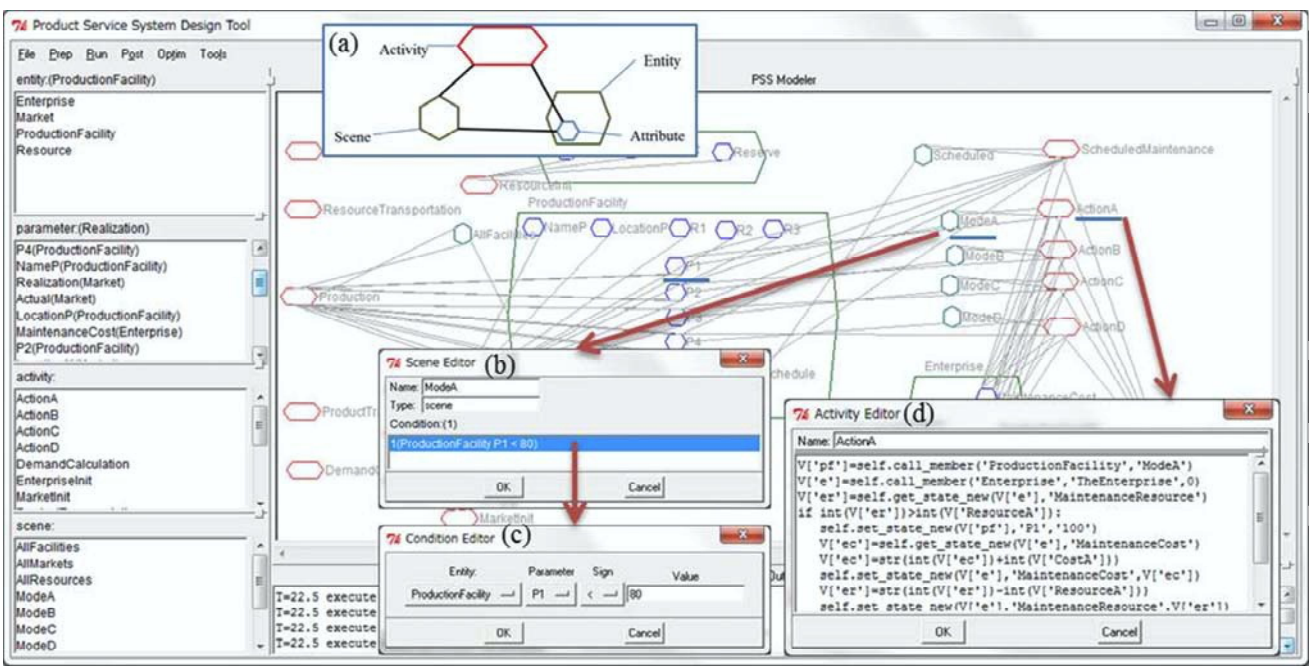

Fig. 1: Implementation of a maintenance service system model on ISCL

Entities are physical elements in the model. This study focuses on two entities in Fig. 1, *Production facility* and *Enterprise*. In the simulation, instances of these entities are created. In the case study, 500 *Production facility* instances and an *Enterprise* instance are created.

Attributes of *Production facility* define the state with respect to failure modes (i.e., *P1* in Fig. 1) and other parameters assigned to each failure mode (e.g., condition of the occurrence and effect). Individual *Production facility* instances have their own state.

Activity represents all kinds of processes in the life cycle of *Production facility* (ex. manufacture, use, maintenance, other services etc.). As a result of executing these processes, *Production facility* instances are created (removed) and the state of individual instances is updated. Each activity is described by its condition and consequence. Quantitative and probabilistic information is supplied to the definition of consequence. The condition is defined with Scene explained below.

Scene is defined by the partial state of *Production Facility* as execution condition of Activities. For instance, there is a link *ActionA(Activity) – ModeA(Scene) – P1(Attribute)* in Fig. 1. *ModeA* is defined by an inequality relation about *P1* (i.e., *P1*<80) and it is connected with *ActionA* (see Fig. 1 (b) and (c)). This is interpreted as "Maintenance service A is offered for all production facilities, whose performance *P1* is lower than 80".

Fig. 2 shows relations between model elements on ISCL. Table 1 details these relations. Relations 1 and 2 correspond to the definition of Scene, Relation 3 to the condition of Activity, and Relations 4-8 to the consequence of Activity. Visible relations on ISCL are generated based on the model description defined either with dialogs (e.g., Fig. 1 (b) and (c)) or programs on text boxes (e.g., Fig. 1 (d)). Parameters and performance indicators are defined with a separate window shown in Fig. 3. With ISCL, the users of the simulation model do not need to look at the detail of the simulation model developed by the modeling experts.

Table 1: Meaning of relations defined on ISCL

	Relation	Connected when
1	Scene-Entity	Scene includes all instances of Entity
2	Scene-Attribute	The value of Attribute is included in the definition of Scene
3	Activity-Scene (1)	Scene is regarded as the execution condition of Activity
4	Activity-Entity (1)	Activity creates instances of Entity
5	Activity-Entity (2)	Activity deletes instances of Entity
6	Activity-Scene (2)	Activity refers to an instance of Entity specified by Scene
7	Activity-Attribute (2)	Activity gets the value of Attribute
8	Activity-Attribute (3)	Activity sets (changes) the value of Attribute

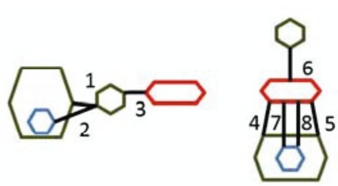

Fig. 2: Relations between models elmeents on ISCL

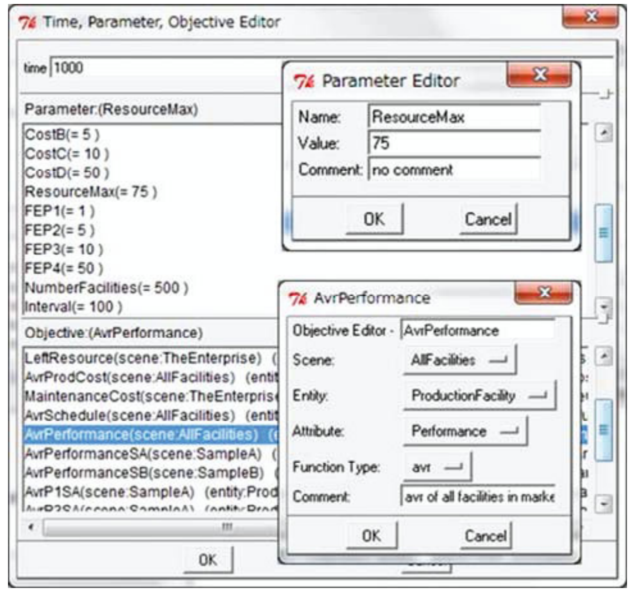

Fig. 3: Windows to define parameters and performances

4 A CASE STUDY

4.1 Simulation settings and assumptions

This study assumes production facilities with four independent failure modes (i.e., *M*=4) and four types of accidents I-IV. Table 2 shows the parameter values of individual accidents explained in Section 3. It is assumed that the cost of visiting production facilities for preventive maintenance is 1 regardless of the state of facilities.

The attributes of production facilities representing the performance with respect to the failure modes are named *P1-P4* in Fig. 1, which corresponds to accidents I-IV. The initial value of these performance is 100. The value may decrease at the occations of accidents at production (i.e. use of production facilities) and recovers at maintenance service, each of which is named *Action A-D* (for corrective mainteannce) and *Scueduled Maintanance*. The activation conditions of maintenance service is defined in Table 3 and the interval of preventive maintenance as one of the simulation parmeters in Table 4.

Table 4 shows 10 scenarios simulated in the case study. These scenarios are defined by three critaria, (A) whether corrective mainteanance is offered or not, (B) whether preventive mainteanance is offered or not and the interval of priventive maintenance (if it is offered), and (C) the number of maintenance engineers as a system-level constraint. The selected values of the interval (100 and 200) were calculated based on the average decrease of perforamnce 0.05 (the product of r_i and d_i) and the difference bbetween the initial value (i.e., 100) and thersholdes defining the conditions of maintenance service in Table 3 (i.e., 80 and 90). The number of facilities is 500. The number of simulation steps, which characterizes the specific interval of the study *T*, is 1000.

Table 2: Parameters of accidents and recovery

i	r_i	d_i	e_i	c_i
I (very light)	1/20	1	1	1
II (light)	1/100	5	5	5
III (modest)	1/200	10	10	10
IV (severe)	1/1000	50	50	50

Table 3: Activation conditions of maintenance service

Description	Condition
Corrective maintenance	$p_i(t) \leq 80$
Preventive maintenance	$p_i(t) \leq 90$

Table 4: Simulated scenarios

Index	A	B	C	Index	A	B	C
1	Yes	No	100	6	Yes	100	75
2	Yes	No	75	7	No	200	100
3	Yes	200	100	8	No	200	75
4	Yes	200	75	9	No	100	100
5	Yes	100	100	10	No	100	75

4.2 Simulation validation

The simulation model has been tested for model validation. The test model excluded preventive maintenance, and the threshold of corrective maintenance was set to 100. This means maintenance service is immediately offered at the occurrences of accidents regardless of the failure modes. Under the situation, the expected value of maintenance cost of a production facility was 0.2 (0.05 for each failure mode calculated by the product of $\boldsymbol{r_i}$ and $\boldsymbol{c_i}$ in Table 2). Since the total number of production facilities is 500, the total maintenance cost per time step is 100. Fig. 4 shows the progress of total maintenance cost (Y-axis) with respect to simulation step (X-axis) as a simulation result of the test model. The simulation result showed the validity of the developed model.

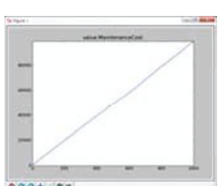

Fig. 4: Validation of the simulation model

4.3 Simulated behavior

Fig. 5 and Fig. 6 show the performance (Y-axis) with respect to simulation step (X-axis) under the scenario 3. They show deterioration and recovery of the performance of a production facility (individual) with respect to failure modes I and III, and that of the average of 500 production facilities, respectively. They show the timing of periodical maintenance (P) and corrective maintenance (C). In Fig. 5, two occasions of preventive maintenance were found. In Fig. 6, several occasions of both corrective maintenance and periodical maintenance were found. The average behavior of 500 production facilities seemed to converge with simulation progress.

Fig. 7 shows the number of maintenance engineers (Y-axis) after allocating them to production facilities at every simulation step (X-axis). The number was always bigger than 0 during the simulation. This is why the number was sufficient to offer maintenance service under the scenario.

Fig. 8 shows the productivity of a specific facility and that of the average of 500 facilities with respect to simulation step (X-axis). Fig. 8 shows performance deterioration at all failure modes I-IV.

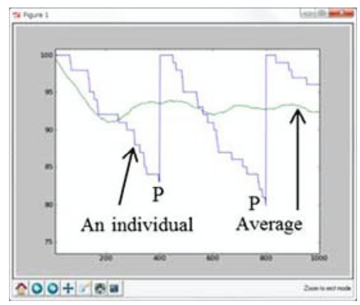

Fig. 5: Performance of a production facility and the average of 500 facilities (failure mode I)

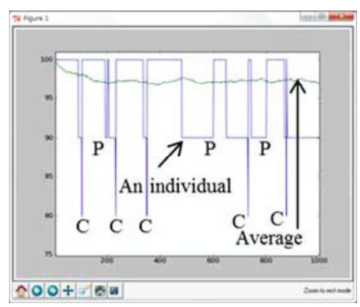

Fig. 6: Performance of a production facility and the average of 500 facilities (failure mode III)

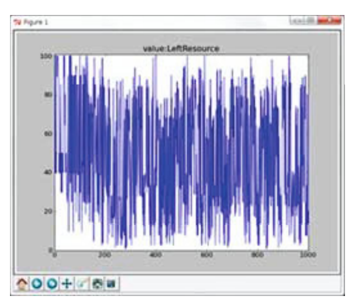

Fig. 7: The number of maintenance engineers left

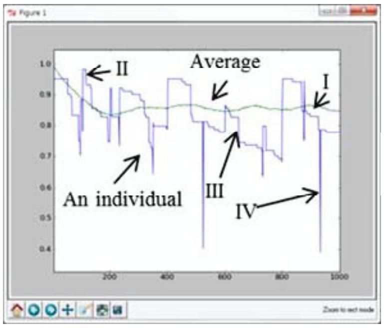

Fig. 8: Productivity change with simulation progress

4.4 Simulation results

Table 5 shows the simulation results of 10 scenarios in Table 4. In Fig. 9, C_{SYS}, (i.e., the average of the cumulative maintenance service cost) and P_{SYS} (i.e., the time average of the average performance of production facilities) are plotted on X-axis and Y-axis, respectively.

In general, the maintenance service cost increases as the productivity increases. The productivity is higher and less sensitive to the number of maintenance engineers when corrective maintenance is included (comparing pairs 1-2, 3-4, 5-6 with pairs 7-8 and 9-10). The shorter interval of maintenance service leads to higher productivity, when predictive maintenance is included (comparing pairs 5-6 and 9-10 with pairs 3-4 and 7-8). However, a ratio of the productivity over the maintenance service cost is higher with longer maintenance service interval.

Table 5: Simulated results

Index	$C_{SYS,T}$	$P_{SYS,T}$	Index	$C_{SYS,T}$	$P_{SYS,T}$
1	5.32	86.1	6	5.63	87.9
2	5.25	85.2	7	4.34	78.5
3	5.14	86.1	8	3.96	75.2
4	5.11	85.3	9	5.64	84.8
5	5.92	88.9	10	5.10	80.1

$C_{SYS,T}$:Maintenance service cost [10^4],

$P_{SYS,T}$: Productivity [%],

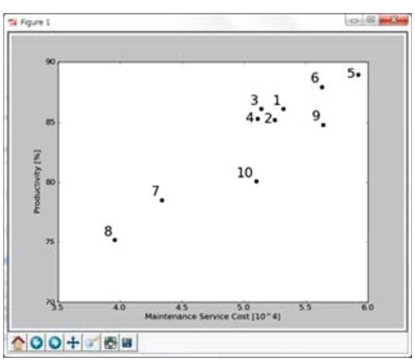

Fig. 9: Maintenance service cost vs. productivity

5 SUMMARY AND CONCLUSIONS

This paper has proposed a simulation-based method that supports maintenance service design of distributed production facilities. The simulation result has shown relations between the productivity of distributed facilities and total maintenance service costs, while considering physical deterioration of facilities and availability of maintenance engineers. With the method, providers of maintenance service can qualitatively assess and design a maintenance service system with higher productivity with lower maintenance service cost. It has shown the procedure to build the simulation model on ISCL and shown how a service modeling technique is used with a specific simulation-based method for the service design in life cycles of products such as LCS. Simulation-based design of a maintenance service system like one presented in this paper is crucial for the early assessment of product-related service from a system-level perspective.

Abstract

This paper presents an approach to Ecodesign based on the management of environmental business risks, which are defined as 'stakeholder responses to environmental impacts with the potential to cause harm to business objectives'. Case studies are used to demonstrate the approach, with a particular focus on the management of critical materials. The paper concludes that by using risk, environmental considerations can be integrated into design decisions at Rolls-Royce, although the method contains significant uncertainties. In particular, the paper highlights the complexity of both assessing the supply risk of a material and how this could translate into an impact on the business. The paper also discusses how the risk model could be expanded to address other environmental business hazards.

Keywords:

critical materials, risk, environmental risk, life cycle management

1 INTRODUCTION

Rolls-Royce provides power systems and services for use in the air, on land and at sea, focusing on four main markets: civil aerospace, defence aerospace, energy and marine. Predominantly, although not exclusively, Rolls-Royce's products are based on the gas turbine engine.

The nature of Rolls-Royce's products present several unique barriers to the implementation of ecodesign approaches:

1. Environmental impacts from the 'in-use' phase dominate over the product life cycle. Understandably this is the focus for addressing environmental impacts, although this also means that environmental impacts from other phases of the life cycle can be overlooked.
2. Rolls-Royce's products are designed to have an operational life of up to 50 years. Environmental problems can change significantly in this time and it is difficult to foresee what the next problem might be.
3. Rolls-Royce's products are technically mature. There is very little design freedom to make non-use phase environmental improvements.
4. Due to the safety critical nature of Rolls-Royce's products, the company uses rigorous design systems to verify product designs against well defined requirements. At the present time, non-use phase environmental impacts are not comparable within the traditional design space, which means they are largely ignored.

Risk management is used within the Rolls-Royce design system to identify hazards that can impact on design and other business objectives. By translating environmental impacts into an assessment of business risk, barriers to ecodesign can be overcome and non use-phase environmental impacts considered within the design process. This paper presents two case studies that test an approach to ecodesign based on the management of environmental risks. The case studies focus on the use of critical materials, which is linked to the abiotic resource depletion environmental impact category.

As risk is a broad term, the paper first defines what is meant by 'environmental business risk'. Materials criticality is then introduced as a significant risk, using an approach developed by the European Commission to highlight materials that are of concern. Based on knowledge of where these materials are used in Rolls-Royce's products, case study risk assessments are then presented, which show how the risks posed by materials criticality can be incorporated into standard design decisions. The paper discusses the practicalities of the risk based approach, in light of significant uncertainties that will be inherent in any system that seeks to look into the future. The paper also discusses how the risk model could be expanded to address other environmental business hazards.

2 ENVIRONMENTAL RISK MANAGEMENT

Environmental risk management adopts a business risk perspective, concerned with identifying hazards that can impact on business objectives [1]. It is based on the

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_72, © Springer Science+Business Media Dordrecht 2012

observation of a cause-effect cycle between the environmental impacts of a business' operations and products and stakeholder responses to these impacts (whether they are actual, potential or perceived) which seek to reduce them and can impact on business objectives [2]. The stakeholder responses to environmental impacts, with the potential to cause harm to business objectives, are defined as 'environmental business hazards'. The environmental business risk is a product of the likelihood of a hazard occurring and the impact it would have on business objectives if it did. There are many sources of environmental business hazard, regulation being a primary example.

Business risk is assessed against objectives, which are generally based upon the provision of products and services and the revenue this provides. It follows that, to assess the risk posed by environmental business hazards, it is necessary to understand how hazards impact on the ability of the business to make and sell products. Risk can be assessed by connecting some feature of the hazard with a feature of the product. Appropriate mitigating actions can then be implemented.

3 CRITICAL MATERIALS: A SIGNIFICANT ENVIRONMENTAL BUSINESS HAZARD

A significant environmental business hazard that has been the subject of recent attention is 'critical materials'. The phenomenon is concerned with constraints being placed on the accessibility of material commodities as a result of geological, political and economic factors. Whilst it is not purely an environmental problem, the depletion of abiotic resources is a common impact category within life cycle impact assessment [3], and it falls within the definition of an environmental business hazard.

There are two *"dimensions"* of materials criticality [4]:

1. Supply risk: identifying and applying factors that can be used to assess the risks to the supply of a material.
2. Economic importance: an assessment of how important the use of a material is in meeting economic goals, which can be also be assessed at a business level e.g. restrictions in the availability of materials can also restrict the ability of a business to make a product.

A material is referred to as critical when it has a high supply risk and is of high economic importance.

The two dimensions of materials criticality need to be applied to understand the business risks posed. These can be achieved through the:

1. Identification and application of a method for assessing supply risk, which identifies materials of concern.
2. Connecting these materials with uses in products to evaluate the risk posed to business objectives.

3.1 Assessing supply risk

Several different methods have been developed to assess supply risk [5] [6] [7]. Due to the use of a transparent methodology with available data, this paper focuses on an approach developed by the European Commission (EC) [7]. The EC method applies four metrics to assess supply risk:

1. Monopoly supply: materials that come from few sources are assumed to be higher risk.
2. Governance indicators: materials that are sourced from politically unstable regions are assumed to be higher risk. Governance indicators are merged with the monopoly supply index to highlight where a material's supply is dominated by unstable producing countries.
3. Recycling rate: based on the assumption that the availability of recycled sources lowers risk.
4. Substitutability: materials that are substitutable are likely to be more flexible to changes in demand, reducing risk.

Monopoly supply is measured using the Herfindahl-Hirschmann Index (HHI), which is the sum of the squares of the supply percentages (S) of producing countries (c) for a given material (i), as shown in Eqn. 1:

$$HHI_c = \sum_c S_{ic}^2 \qquad \text{(Eqn. 1)}$$

The equation produces a figure between 0 and 10000, a higher number signifying higher risk.

World Governance Indicators (WGI) produced by the World Bank were merged with the HHI to highlight where supply was dominated by an unstable producing region. The WGI scored countries according to 6 categories (including political stability, control of corruption and rule of law), producing a result between 0 and 10. These scores were merged with the HHI as shown in Eqn. 2:

$$HHI_{WGI} = \sum_c S_{ic}^2\, WGI_c \qquad \text{(Eqn. 2)}$$

The result produces a score of 0 to 100000, which was scaled to a value of between 0 and 10.

The recycling rate used for a material i (ρ_i) applied the ratio of current demand met by old scrap. Data on recycling rate is given in the EC report [7].

Substitutability (σ_i) for a material i was measured using an index developed through expert judgements (Table 1).

Table 1: Substitutability indices [7]

Score	Substitutability
0	Easily and completely substitutable at no additional cost.
0.3	Substitutable at low cost.
0.7	Substitutable at high cost and/or loss of performance/
1.0	Not substitutable.

All of the metrics were merged into the final equation for supply risk, calculated by material (i):

$$SR_i = \sigma_i (1 - \rho_i) HHI_{WGI} \qquad \text{(Eqn. 3)}$$

The term (1- ρ_i) is used as a higher recycling rate will reduce supply risk. The result of the supply risk calculation will produce a score of between 0 and 10 by material, with a score of 10 representing the highest possible risk.

SR scores were calculated for 41 materials, 14 being highlighted as potentially critical (Table 2). Both of the highest scores were attributed to materials that have relatively few sources (monopoly supply).

Table 2: The EC 14 (SR scores in bold) [7]

Rare Earth Elements (REE) **[4.9]**	Indium **[2.0]**
Platinum Group Metals (PGM) **[3.6]**	Tungsten **[1.8]**
Niobium **[2.8]**	Fluorspar **[1.6]**
Germanium **[2.7]**	Beryllium **[1.4]**
Antimony **[2.6]**	Graphite **[1.3]**
Magnesium **[2.6]**	Tantalum **[1.1]**
Gallium **[2.5]**	Cobalt **[1.1]**

The 14 critical materials highlighted from the EC report and the method for assessing SR solve the first problem of identifying materials that are of concern. To understand the risk, it needs to be identified where these are used in products.

3.2 Identifying uses of critical materials

Product data is required to understand the uses of critical materials. Basic data on product content is provided by a standard engineering Bill of Materials (BoM). A BoM is unlikely to be sufficient to identify product features related to all environmental business hazards. Hazards can relate to any impact over the product life cycle, requiring a life cycle view. However, a BoM is sufficient for identifying uses of critical materials as an initial approach.

There are two perspectives on the problem of identifying critical materials in products. One approach could be to use a list of critical materials (for example the EC 14) and compare these with all product BOMs to identify any matches i.e. where a BoM lists a material of concern. This is necessary to identify all uses of critical materials within existing products, and is called the existing product perspective.

The opposite approach would be to start with a BoM and compare it with a list of critical materials to determine if any are used in the product. This is called the design perspective, where only those critical materials in the product being designed are of interest. The next sections focus on assessing the business risks posed by the use of critical materials approaching the problem from both the existing product and design perspectives.

4 CASE STUDY 1: ASSESSING RISKS TO EXISTING PRODUCTS

The following steps summarise the process for assessing the risks posed by critical materials to an existing product:

1. Identify at risk elements (the EC 14).
2. Identify if those elements are present in a product (required in order to understand the risk).
3. Complete a product based risk assessment by combining the measure of supply risk for the materials in question with the potential impact on business objectives from using the high risk material. To be relevant to existing design processes, the risk assessment has to be completed using the appropriate risk management criteria within Rolls-Royce.

PGMs were identified as having a high supply risk from the EC report. One particularly rare PGM is used as an alloying element within turbine blades on one of Rolls-Royce's large civil aero-engines. Using an alloy with this PGM maintains high creep strength within blades that operate at very high temperatures and pressures [8].

When designing a component, several business objectives are set against which risk can be assessed. One of the main objectives is a target unit cost for the parts and engine. Risks to unit cost of using the PGM in turbine blades can therefore be assessed. Rolls-Royce applies 5x5 risk matrices combining measures of likelihood and impact to assess risk. The unit cost risk matrix relevant to the product being analysed is shown in Fig. 1.

Likelihood	V. Low (< 3)	Low (3 to 5)	Med (5 to 25)	High (25 to 50)	V. High (>50)
V. High	9	14	19	24	29
High	7	12	17	22	27
Med	5	10	15	20	25
Low	3	8	13	18	23
V. Low	1	6	11	16	21

Impact (unit cost £K)

Fig. 1: Risk criteria case study 1

Likelihood

Assessing risk using the matrix in Fig. 1 requires the likelihood assessment method from the EC report to be translated into the scoring scheme applied, using a scale of v. low to v. high. Based on the actual SR scores given in Table 2, Table 3 outlines how the SR translates into an assessment of likelihood consistent with the risk matrix.

Table 3: Translating SR scores into the risk matrix scale

Likelihood (L)	SR score
Very high	SR ≥ 4
High	3 ≤ SR < 4
Medium	2 ≤ SR ≤ 3
Low	1 ≤ SR < 2
Very low	SR < 1

PGMs having a SR score of 3.6 translates into a high likelihood from Table 3.

Impact

To assess the impact, a breakdown of unit cost is required to understand how much of the total cost of turbine blades the materials account for. Illustrative cost data is presented in Table 4.

Table 4: Illustrative unit cost breakdown

Element	Cost (£s)
Casting	600
Material	60
Coating	250
Machining	150
	1060

An estimate of the potential cost increase of the material cost fraction is required, which is a function of:

1. How much the cost of the PGM could increase.
2. The PGM fraction of the whole material cost.

It is impossible to predict what the future cost of a material might be with any degree of certainty. To give an indication of the potential cost increase, the price volatility of the material is used. From company data the historical price volatility of the PGM in question is approximately 20 (calculated by dividing the maximum market price by the minimum taken over a 10 year period). For illustration, the PGM fraction of the cost of the material is estimated to be 1/3. Thus the impact can be calculated by multiplying 1/3 of the material price by 20, shown in Table 5.

Table 5: Impact on unit cost

Element	Cost (£s)	New cost (£s)	
Casting	600	600	
Material	60	**460**	
Coating	250	250	
Machining	150	150	
	1060	**1460**	
			Engine unit cost change
	Change	400	**45600**

As over 100 turbine blades are used in the engine, the total impact on unit cost of approximately £45000, which represents a high impact on the scale shown in Fig. 1.

Risk assessment

Combining the high likelihood from Table 3 with the impact calculated above produces the risk assessment result in Fig. 2.

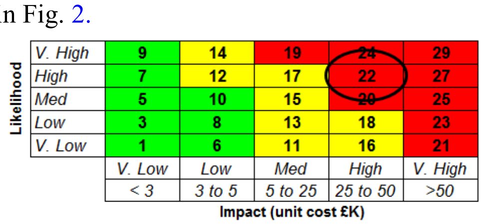

Fig. 2: Risk assessment result

Being the top right of the risk matrix this risk is deemed unacceptable and will require mitigating actions.

Mitigating actions

One mitigating action would be to take the PGM out of the blade. However, this will have an impact on specific fuel consumption (sfc), which is another design objective. Risk criteria for assessing risks against sfc is shown in Fig. 3.

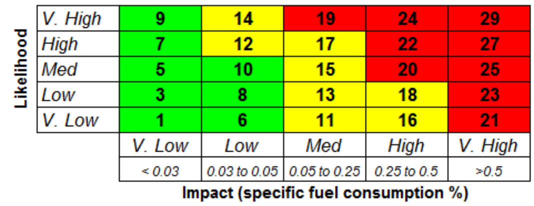

Fig. 3: Risk criteria for sfc

The impact on sfc of taking the PGM out of the blade is estimated to be between 0.1-0.2%, from internal engineering data. An sfc reduction of this magnitude translates into a medium impact using the x-axis scale in Fig. 3.

As the impact on sfc will only occur if an alloy not containing the PGM is used, which is dependent on the likelihood of the PGM becoming unavailable, the likelihood result from the unit cost assessment is used. Combining this with the sfc impact produces the risk assessment result shown in Fig. 4.

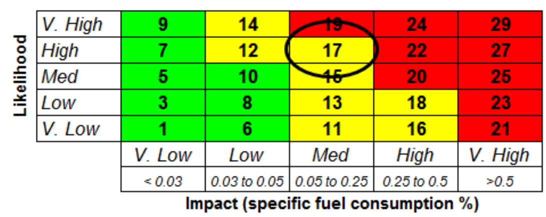

Fig. 4: Risk assessment result for sfc

As the risk to unit cost is higher than for sfc, on balance it is likely that the PGM would be removed and a different alloy used.

5 CASE STUDY 2: ASSESSING RISKS TO NEW DESIGNS

The following steps summarise the process for assessing the risks posed by the use of critical materials to new designs:

1. Select a BoM for a new design.
2. Identify critical materials used within the a BoM for a new design, by comparing it with the EC 14.
3. Complete product based risk assessment, using risk criteria relevant to the product in question, by multiplying the likelihood (supply risk) by the impact on business objectives.

A BoM for the outer liner of an annular combustor used on a small military turbofan engine is used for this case study, which is being re-designed to meet new customer requirements. Two uses of at risk elements were found in the new design:

1. Cobalt within the combustor alloy.
2. Yttrium (a REE), used within the thermal barrier coating applied to the combustor.

As with the previous example, the case study will focus on the impact on unit cost objectives. The risk criteria taken from the relevant business risk management plan is shown in Fig. 5.

Likelihood					
V. High	9	14	19	24	29
High	7	12	17	22	27
Med	5	10	15	20	25
Low	3	8	13	18	23
V. Low	1	6	11	16	21
	V. Low	Low	Med	High	V. High
	< 0.6	0.6 to 1	1 to 5	5 to 10	>10

Impact (unit cost £K)

Fig. 5: Risk assessment criteria

Likelihood

From Table 2, the SR scores for cobalt and yttrium are 1.1 and 4.9 respectively. These scores translate into a low likelihood for cobalt and very high likelihood for yttrium using Table 3.

Impact

The unit cost breakdown for the component is required to assess the impact on unit cost objectives. Illustrative cost data is given in Table 6.

Table 6: Illustrative unit cost breakdown

Element	Cost (£s)
Casting ops	2500.00
Material	500.00
Machining	1250.00
Coating	250.00
Remaining ops	1500.00
	6000.00

As with the previous case, to understand the impact on unit cost, an estimate of the potential cost increase of the material cost fraction is required, which is a function of:

1. How much the cost of the cobalt and yttrium could increase.
2. The cobalt and yttrium fraction of the overall material and coating costs.

From company data, the historical price volatility of cobalt is 6 (max. price/min. price over 10 years) and for yttrium is 7. For illustration, cobalt is estimated to represent 20% of the total material cost and yttrium 3% of the coating cost. The impact is calculated by multiplying 20% of the materials cost by 6 (volatility of cobalt) and 3% of the coating cost by 7 (volatility for yttrium). The overall impact on cost is shown in Table 7.

Table 7: Unit cost impact

Element	Cost (£s)	New cost (£s)	
Casting ops	2500.00	2500.00	
Material	500.00	**1100.00**	
Machining	1250.00	1250.00	
Coating	250.00	**302.50**	
Remaining ops	1500.00	1500.00	
	6000.00	**6652.50**	
			Engine unit cost change
	Change	652.50	**652.50**

The impact on unit cost of £600 for cobalt represents a low impact on the scale shown in Fig. 5. Impact on unit cost of £52.50 for yttrium is very low using the same scale.

Risk assessment

Combining the low likelihood and impact for cobalt produces a low risk (Fig. 6). Combining the very high likelihood with a very low impact for yttrium also produces a low risk (Fig. 6). Aggregating the scores of impact and likelihood for both cobalt and yttrium gives a total materials criticality risk towards the centre of the risk matrix in Fig. 6. A risk of this magnitude is unlikely to be of concern, not requiring mitigating actions. Being towards the centre of the risk matrix it may require monitoring to ensure the risk does not become unacceptable.

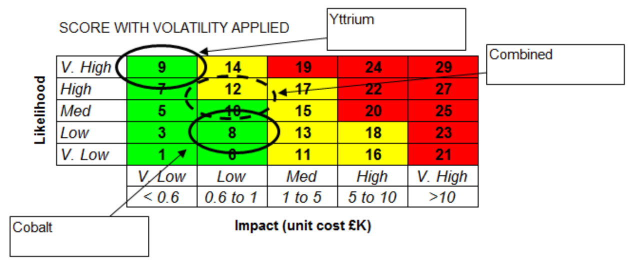

Fig. 6: Risk assessment result

6 DISCUSSION

The two case studies show how the risk based approach can be used to consider a complex environmental issue in a format that is consistent with standard engineering design decisions at Rolls-Royce. However, the approach is challenging for a number of reasons, discussed below.

There are significant uncertainties within all parts of the assessment. Firstly, assessing supply risk is not a simple task. The EC method was applied as it provided a transparent methodology and developing a bespoke approach was outside of the scope of this work. However, in reality there are many metrics that can be included within the assessment which were overlooked, for example risks related to materials produced as co-products or future changes in material demand. Adding both of these might have identified some of the 14 materials as being not critical, or highlighted at risk materials which have been overlooked. The method could be improved by selecting metrics that are relevant to the context (Rolls-Royce), or even better using a dynamic modeling approach instead of relying on proxy metrics as representations of dynamic material supply systems [9].

Another area of uncertainty is in the product cost data used within the assessment. In a company with an extended supply chain, quite often a lot of the costs related to raw material inputs are not readily available. For the purposes of this paper illustrative costs were used. Although in practice cost data is difficult to get hold of. Costs can be estimated by comparing raw cost data from the purchasing function with cost breakdowns for parts. Engineering judgement can then be used to estimate what fraction of the cost of, for example a forging on a BoM, might be related to raw material inputs. Greater accuracy, and thus confidence in the results, could be obtained if the BoM (or other system) clearly outlined what costs elements were related to raw materials.

The most obvious area of uncertainty is predicting how a risk to supply may translate into an impact on cost. It is impossible to try and predict material prices. To obtain defendable estimates historical price volatility was used, although this must go with the caveat that relying on historical trends is a very poor means of estimating what might happen in the future [10]. For example, the price volatility for cobalt and yttrium were quite similar. Although the current price trend for cobalt is stable, while the shape of the yttrium curve is exponential. If this trend continued using past data is a very poor estimate of the future impact. This problem is not likely to be resolved; there are always going to be uncertainties in predicting the future.

A final source of uncertainty is in the business objectives themselves. Risk can only be assessed against objectives. If the business alters the criteria used for the risk assessment (the scales of impact, likelihood and acceptability of risks) the risks presented here could be more or less acceptable. Assessing risk is inherently subjective.

Acknowledging these uncertainties, the paper has shown how the risk based approach is useful. One classic problem in ecodesign is determining how to trade-off between environmental impacts. Using the framework of business objectives, the first case study successfully demonstrated how this can be achieved.

7 EXPANDING THE RISK BASED APPROACH

A final consideration is how the risk approach could be expanded to include other environmental business hazards. Building from the two perspectives described in Section 3.2, this could be achieved by defining more features of environmental hazards (for example the use of hazardous substances). This would also require more detailed product data containing features of products that could be connected to these hazards, with a life cycle view (for example, a life cycle inventory). Ways of measuring the likelihood of different hazards will also be required.

8 CONCLUSIONS

This paper has presented an approach to ecodesign based on environmental risk management, in conclusion:

- The risk based approach successfully demonstrates how a complex environmental problem could be considered with standard engineering decisions. It has also shown that by using business objectives, environmental impacts can be traded off with each other.
- However, whilst the method was successful, there were significant uncertainties. In particular assessing supply risk and how this translates into an impact on material price.
- The risk based approach could be expanded to include other environmental business hazards. This requires more detailed product data.

Building Sustainable Product Service Systems between SMEs

Ricardo Javier Hernández Pardo[1], Tracy Bhamra [1]

[1] Loughborough Design School, Loughborough University, Loughborough, UK

Abstract

Product Service Systems (PSS) can help small and medium enterprises (SME) to become environmentally and socially responsible. However, there few examples of PSS developed by SMEs and even less sustainable PSS. Design and Information and Communication Technologies (ICT) are the main areas in the development of PSS and their integration can be used to encourage the adoption of sustainable PSS in SMEs and make them more suitable for these small businesses. Additionally, considering the development of sustainable PSS not only on an individual basis but also on an industry-wide basis can be one way of involving SME in larger systems. A case study with 16 SME is presented exploring this approach.

Keywords: Product service systems, design, sustainability, ICT, SME

1 INTRODUCTION

Industrial development during the last fifty years has been growing at an accelerate rate without considering all possible environmental and social impacts produced [1]. In consequence the planet has shown strong signals of deterioration in environmental terms and large inequalities in social aspects have emerged [2]. Facing this reality during the last thirty years different calls have been made asking for profound changes and searching for a new business paradigm [3] [4].

In that search, concepts with potential to contribute to achieving sustainable businesses such as cleaner production, recycling, ecodesign and product service systems (PSS) have been deployed [5], [6]. In the case of PSS and despite its potential contribution to develop sustainable businesses there are not many successful examples implemented by small and medium enterprises (SMEs), they have been limited mainly to medium and large firms. It is then interesting to explore this lack of examples in SMEs especially if it is considered that nearly 80% of the world's firms are SMEs [7]. Some of the reasons given in the literature that could explain this difficulty to develop a PSS in SMEs have to do with the internal and external barriers to develop a PSS in any firm such as costs, organizational resistance and regulatory context [8] [9] but also with particular problems of this type of firm.

However it is the hypothesis of this research that it is possible to consider developing sustainable PSS in SMEs based on the integration of design and ICT as the main areas in the development of a PSS. It is also considered the development of sustainable PSS between different stakeholders and not only on an individual basis. ICTs could play an important role in this kind of large PSS articulating the relationships between SMEs, suppliers, clients and other stakeholders. In this paper first the concept of sustainable PSS is presented, then the potential contributions of ICTs to develop sustainable PSS, and then the analysis of thirty-six commercial PSS is deployed as basis of four types of PSS characterized by the relationships between ICT and design. Finally, an overview of a case study with sixteen Colombian Manufacturing SMEs from the leather industry is presented and three alternatives to develop a sustainable PSS proposed.

2 BACKGROUND

2.1 Sustainable PSS

PSS are defined as "a system of products, services, supporting networks and infrastructure that are designed to be: competitive, satisfy the customers' needs and have lower environmental impact than traditional business models" [10]. These kinds of systems can also help companies to become more socially responsible [11]. In this case where there are environmental and social benefits PSS are considered as sustainable PSS. However, PSS are not necessarily sustainable, they have to be designed and implemented to achieve environmental and social benefits [9]. Examples of PSS already in the market are Auto-Share from Car Sharing Network Inc., Xerox Document Services by Xerox and Reuse System Housing by Sekisui Chemical between others. Some of the benefits mentioned in the literature coming from a PSS are increment of customers' loyalty, better strategic position for companies, reduction of materials and energy used implementing innovative usages, and encouragement to create collaborative networks [9], [10], [12-14].

Despite the benefits PSS is not a concept massively developed in the market and less so in SMEs [15]. General barriers such as lack of infrastructure, lack of mentorship,

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_73, © Springer Science+Business Media Dordrecht 2012

poor communication channels between stakeholders, and difficulties to access financial capital are part of the reason why innovative solutions such as PSS could be too demanding for SME [16]. Additionally, lack of knowledge of environmental legislation, lack of awareness of their impacts and general difficulty to embed the concept of sustainability make even more unlikely the development of sustainable PSS in SME [11] [17].

2.2 ICT potential contributions to sustainable PSS

The rapid evolution of ICT during the last decades has opened opportunities to contribute to sustainable development [18]. Between these opportunities there are for example the development of smart green products, virtualization, better communications between stakeholders, e-commerce and servitization [19]. The development of these opportunities can facilitate and improve environmental and social industrial performance.

In relation to SMEs, ICTs can also act as generators of change in the way these firms design and develop their products [20]. The adoption and use of technologies change how firms design their products and services and those changes could result in a greater disposition to innovate and a more flexible and inclusive design process. Finally, previous studies have suggested a possible contribution of ICT to make PSS more practical and operable [21] or to develop indicators of performance for these systems [22]. However little has been done in a structured way about the potential contribution of ICT to PSS and less to sustainable PSS. Also little is known about the relationship between ICT and design.

In this sense new approaches to address the challenges to develop sustainable PSS in SMEs are needed. Using insights from the literature and from a scoping study developed at the beginning of this research a reference model was built to direct the research. In this model design and ICT are considered as the main areas in the development of sustainable PSS. The integration of these areas can give the structure needed to make more operable the concept of sustainable PSS in small businesses. The opportunities mentioned earlier where ICT can contribute to develop sustainable business could be oriented to develop sustainable PSS and in the same way concepts already developed around design for sustainability can be used as a basis to ensure sustainable results. Considering that the possible relationships between design and ICT in a PSS are not defined yet in the literature, the first stage addressed in this research to formalize the integration of these two areas was to explore these relationships in different PSS.

3 DESIGN AND ICT IN PSS

3.1 Analyzing PSS on the market

In parallel to a case study with a group of Colombian Manufacturing SMEs a set of 36 examples of PSS were analyzed. The objective of this analysis was to establish possible relationships between design orientation and use of ICT in these PSS. To select the PSS previous literature, research projects and technical reports were reviewed. The PSS selected in this revision fulfilled two conditions: first they were examples developed by companies and second they claimed to have some environmental or social benefits or both. The assessment of the PSS to determine how well the benefits claimed were achieved was not part of this analysis. The analysis instead was oriented to review each PSS trying to understand how design and ICT were related to each other.

The selection of PSS did not try to have a statistical representation, however the intention was to select a variety of examples coming from different sectors. Along with the information reviewed in each PSS a general description of the offer, the country or countries where the PSS was offered, the orientation of the PSS to customers, to businesses or both and finally the industrial sector was included. In the end the analysis of the PSS was reduced to four types of PSS according to the relationship between design and use of ICT. This typology is described in the next section.

3.2 Four types of PSS

The four types of PSS defined by the relationship between design and use of ICT were:

1. Design based
2. ICT based
3. Design and ICT as supporters
4. Design and ICT integrated

Design based, PSS where products and services are designed specifically to fulfill the purpose of the PSS. ICT play mainly a commercial role establishing relationships with customers and as means to deliver the offer. Products and services in this kind of PSS could demand the use of innovative materials or especial production processes.

ICT based, ICTs are the element that articulates the PSS and enables its existence. Products and services are not necessarily designed for the PSS, it means it is possible to find the same products and services which are not part of a PSS. Some technologies could be embedded in the products of the PSS but demanding just slight modifications in the product design in comparison to a standard product.

Design and ICT as supporters, in these PSS design and ICT are part of the PSS but not directly attached to the main value delivered by the offer that is usually convenience. Products and services are not designed particularly for the PSS and ICT are used with commercial purposes.

Design and ICT integrated, the relationship between design and ICT is stronger and more balanced than in the other cases. Products and services are designed specifically for the PSS and ICT enables the delivery of the value of the offer and the interaction with the customers. ICT play a very important role connecting consumers with the products and the services of the PSS.

The importance of identifying these relationships and to characterize a PSS with them is to understand how the actual design process and use of ICT in a company can be oriented in one direction or another towards a PSS. Depending on the initial conditions of a company one type of PSS is more deployable than others. It means for example that a company with highly differentiated products could be more suitable to consider a design based PSS rather than an ICT based one. The four types of PSS according to the relationships explained are presented in Fig. 1.

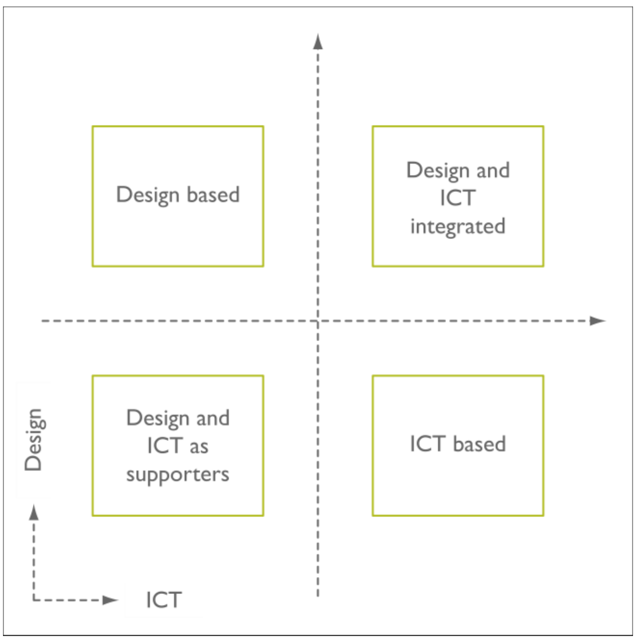

Fig. 1: Types of PSS defined by the relationship between design and ICT

Understanding a PSS in terms of the relationships between design and ICT can also be useful when PSS are thought of on an industrial basis rather than on an individual basis. If the PSS is developed by the articulation of different actors in an industry the integration between design and ICT can be established by competences developed by different stakeholders and they do not need to be present in just one.

In the next section an overview of a case study with 16 Colombian Manufacturing SMEs belonging to the same industry is presented. In this case study possibilities to develop sustainable PSS supported by design and ICT between different stakeholders are explored. In this sense the four types of PSS characterized in this section are used as part of a framework to define opportunities according to the findings in the case study.

4 CASE STUDY

4.1 Overview

16 Colombian Manufacturing SME belonging to the Leather Industry mainly shoemakers were approached to develop a case study. The data was collected through semi-structured interviews with the owners of the SME. Additionally documents from the companies and previous studies about the industry were included and analyzed. All the SMEs involved in the case study were previously participants of an ICT implementation project supported by the Colombian Ministry of ICT.

The research question behind the case study was to find out how design and ICT could be integrated to contribute to develop sustainable PSS in SMEs. In this sense the interviews were especially focused on exploring the design process and how the use of ICT have changed that process. In the next two sections the characterization of the actors in the industry and current practices and dynamic around design and use of ICT in relation to the actors identified are presented.

4.2 Identification of actors in the industry

Part of the analysis done during the case study was related to identifying the actors involved in the industry and to defining their roles. The objective to do this identification was first to understand better the dynamics of the industry and second to recognize gaps that could suggest opportunities to develop sustainable PSS in an individual or in an industrial basis. The actors identified were:

SMEs, small factories dedicated mainly to produce shoes and some leather accessories, usually with 20 to 30 full time employees. Their production is mainly for national market. Their clients are from small shops to large distributors and shop chains. They do not have direct sales to final customers and in some times of the year with high production levels they have to outsource parts of the production process to small satellites composed by three to four people working from home. Their financial capital is very limited, their main resource is their production capacity. The use of ICTs is limited to commercial purposes and in general is limited to very basic technologies such as email and web search. They do part of the design process internally and other part is subcontracted externally to model makers.

Model Makers, they are professionals usually with some training in design or with large experience in the industry. Their job is to translate photos and basic drawings of concepts (shoes) to soft models in cardboard. Their job is mainly manual and assisted by traditional techniques such as the use of the pantograph. Their work with the factories is based in long-term relationships.

Associations, they are industrial bodies dedicated to support the SME's operation. That support is manifested mainly in the organization of commercial fairs during the year. It is during these commercial fairs that the SME show their products to potential clients. Additionally Associations also prepare courses and seminars on topics such as commercialization, production techniques, and money management between others. These Associations also offer assistance on themes related to fashion and new commercial trends but this service is not clear and widely accessible according to the SME. All these services are offered to the SMEs on a membership basis.

Suppliers, there are mainly two large group of suppliers in this industry one are direct producers of the materials and the other are distributors and resellers. It is more usual that SME are approached by suppliers of the second group for materials like glues, soles and synthetics. In the case of leathers the suppliers are in general the tanneries directly. Suppliers play an important role in the diffusion of new production techniques, machinery and materials. They also push new concepts such as the use of ecological glues that was in force during the case study development.

Clients, they are small shops, large distributors and chain shops. They are the ones to define the guidelines for the factories' production including trends, materials and styles. With a large offer of shoes coming from the SME they are a powerful actor in the industry able to define commercial conditions including price.

Satellites, they are small and informal workshops based in the workers home. They are usually composed of three to five people who meet to undertake specific production tasks that don't require a factory. These satellites work on a temporal basis during the year.

After the actors in the industry were identified and described, a map was produced to show the main connections between these actors, (see Fig. 2). This map was used later during the case study in the analysis of the opportunities to develop sustainable PSS.

4.3 Design and ICT functions of the actors

Design in the SME was usually defined not as separate function; it was described as part of the production process. Even if some activities related to the design of the shoes are done internally in the SME the recognized designers in the industry are the model makers. In this sense the design process is divided into internal and external activities. The internal activities are carried out by the owner who decides the initial concept, materials, colours and combinations for final models while the model maker does the external tasks. Despite the fact that design is considered important for the SME they do not create value through design. In general when they decided to develop a new concept they start with products already on the market produced by other companies in other countries, then design is used to make slight modifications to models being more followers than leaders in the industry.

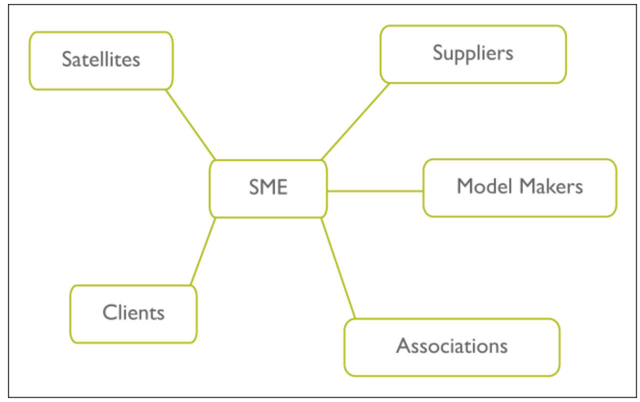

Fig. 2: Actors identified in the case study

The relationship between design and the clients is almost strictly related to the final assessment of the models during the commercial fairs. Clients in general do not intervene in the design process until that point when they can reject the models or accept them with or without some final changes. These design changes in the final samples are just small modifications. According to the SMEs one of the reasons why clients do not intervene in the design process is because the offer of samples at the commercial fairs in much larger than the demand. It means that for clients it is easy to choose the models without being involved in a collaboration process of design with the factories. Finally Associations give some advice on themes such as trends and fashion; however they were only mentioned by two of the SMEs interviewed. In a review of the Associations websites programs of support on themes such as design and commercialization were found but these programs are not widely accessible for all the SMEs in the industry even when all the SMEs involved in the case study were members of at least one of these industrial bodies.

In terms of ICT, there is a general lack of knowledge about the possible technologies that can be used in the design process. Owners in the internal design activities and model makers in the external ones do not use ICT to support the design process. In general design is manual and there is some resistance to consider replacing the manual process for activities that involve the use of ICT. This resistance is not because SMEs do not like the idea of using technologies it is more because they consider the use of ICT difficult and not suitable for the kind of task that they need to do to design a shoe. Currently the main use of ICT in the design process occurs at the beginning of the process when the Internet is used to search for models from other countries and markets. The main output of this search are photos and drawing used later by the model maker. In this sense the current use of ICTs in the design process is limited and not the most appropriate to develop competences such as innovation.

4.4 Development of sustainable PSS between SMEs and other stakeholders

Taking into account the general analysis of the industry, the findings about design and ICT in the SMEs involved in the case study and the characterization of the actors presented, it was concluded that the idea of developing sustainable PSS was more suitable in this case on an industry-wide basis. It means that according to the general definition of a sustainable PSS and the types of PSS defined by the relationships between design and ICT, the SME involved in the case study did not have the conditions to develop a sustainable PSS. Even, if the competences required to build a sustainable PSS could be developed in these SMEs, the analysis of the case study showed that the opportunities to develop the concept was in considering the integration of different stakeholders in the industry and not on an individual company basis.

The opportunities identified were mainly related to current practices in the industry that could be improved by the concept of sustainable PSS. During the case study it was found that different activities give value to the final offer but because the industry is strongly product oriented these activities are not valued and opportunities to improve the operations of each SME and the industry on a sustainable basis are missed. Using the map of relationships between the actors of the industry three subsystems were identified (see Fig. 3). Each subsystem represents one opportunity to develop a sustainable PSS integrating two or more actors and transforming some of the activities currently done by these actors. These sustainable PSS are supported by design and ICT and explained in part in relation to the types of PSS presented in section 3.2.

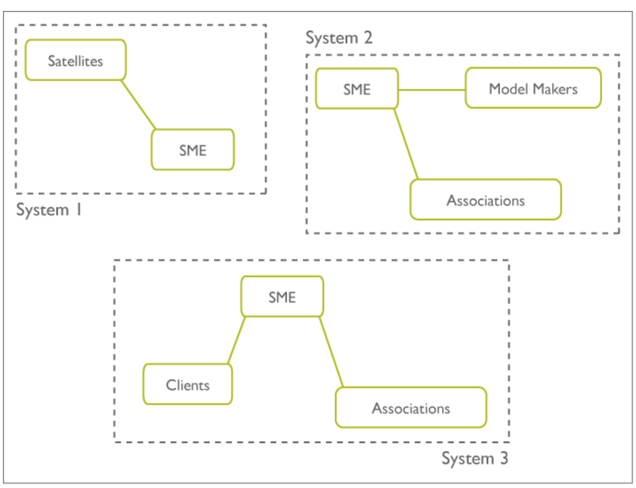

Fig. 3: Possible systems between actors

System 1, the first possible option to develop a sustainable PSS is related to the relationship between SME and production satellites. In this case the production capacity of the satellites is the main service associated to the system. If the production tasks are coordinated through the system that is supported by ICT there could be benefits associated to better production planning, traceability of materials, management of design and production standards, coordination between satellites and reliable deliveries. In a seasonal industry such as the leather industry with low and high periods of production a system that helps to coordinate factories and satellites could contribute to solve current problems such as lack of personnel in some periods of the year, work force instability, unfair wedges, delays and reprocesses. These improvements in terms of design could represent better use of resources, the possibility to sustain satellites work through out the year working for different factories in a better schedule

System 2, in this case the opportunity could be oriented to develop a sustainable PSS with *design and ICT integrated* according to the types of PSS presented in section 3.2. Currently design is a competence divided between SME and model makers. Associations give some advice but it is not widely exposed. Changing current manual practices of design into a design process supported by ICT could improve the interaction between SMEs and Model makers allowing also the participation of the association. A collaborative design platform between these actors could enrich the process of design reducing times to market and number of iterations between SME and model makers changing the current manual interchange of photos into a systematic process of collaboration from concept to detail design leaving register of the whole process. If SMEs and model makers design in a virtual platform the dynamic of the process could change from producing physical samples to producing virtual collections. These kind of collections could reduce significantly the use of resources used currently especially for the commercial fairs in terms of materials, energy and time. Additionally a system with these characteristics could improve themes such as traceability of design models, development of new trends and possibility to support large productions between SME to satisfy international markets where design standards have to be fulfilled by different factories. In terms of the associations this system could be used to improve and make more accessible their services.

System 3, based on a similar platform to the one presented previously as system 2, could be developed as a sustainable PSS between SMEs, clients and Associations. This third system could be an *ICT based* type. Basically the interaction between SMEs, clients and associations could be improved supported their communication process by ICT. This improvement could be reflected in a new assessment process based on virtual collections and the possibility for clients to suggest and see in real time modifications to the final samples during the commercial fairs. Additionally this system could also affect current problems such as commercial safety, payments and lack of cooperation between SME and between SMEs and associations. In terms of benefits the assessment of the samples could be more efficient, communication between stakeholders more fluent, it includes the interchange of information about design, orders, sales, payments, claims, suggestions and new events between others. Under this scheme of cooperation new services can be developed between SME and clients such as models repositories, e-commerce, visit arrangements and the main collaborative design.

These opportunities identified as subsystems in the industry are a preliminary result of the analysis of the case study. The final objective is to transform the logic used in this case to propose the three sustainable PSS into a final framework that can give structure to the idea to develop sustainable PSS in SME.

5 CONCLUSIONS

Design and ICT are the main areas in the development of sustainable PSS and the identification of the possible relationships between them in current PSS is a first step to formalize the integration of these areas. Considering the develoment of sustainable PSS between different stakeholders enlarges the amount of possibilities and can make operable the concept of PSS for SMEs. The three PSS proposed in this paper were the result of the thematic analysis of the interviews and document analysis collected during the case study, this procedure has to be refined and transformed into a generic framework that can be used in a systematic approach with similar industries. That final framework is the next stage of development of the research.

Integrated Product Service Engineering - Factors influencing environmental performance

Sofia Lingegård[1], Tomohiko Sakao[1] and Mattias Lindahl[1]

[1] Department of Management and Engineering, Linköping University, Sweden

Abstract

This paper aims to lead theoretical discussion regarding which IPSE (Integrated Product Service System) factors are expected to increase environmental performance of a life cycle compared to a traditional product sales business. Existing theories such as theory of product development, transaction cost theory and theory for risk management are used and the paper theoretically analyzes and identifies the following crucial characteristics; complexity of the product, uncertainty of offering, control of product operation, asymmetric information and scale of economy.

Keywords: PSS, environmental performance, information asymmetry, economies of scale, risk

1 INTRODUCTION

In society today there is increased awareness about environmental problems and this in combination with concern about future shortages of natural resources has resulted in increased pressure to find innovative strategies that can tackle these problems. During the last two decades, industry and academia have proposed and tried to implement several strategies and solutions. In much of the manufacturing industry today, numerous companies' business offerings are a combination of physical products and services. From academia, these include Functional Economy [1] and the Integrated Product Service Engineering (IPSE) concept, also often called Product/Service Systems (PSS) (e.g.[2]). PSS is defined, for instance, as "a marketable set of products and services capable of jointly fulfilling a user's needs" [3]. The proposal of a "life cycle-oriented design" [4] highlights an important step for the "product and technical service design processes" integration. Additionally, some specific engineering procedures and computer tools have been developed and validated with industrial cases (e.g.[5]).

However, the research in this area is still in its infancy and a number of questions remain unanswered. Specifically, a general weakness in existing literature is that even though a large number of authors have stressed PSS' environmental and economic potential (e.g.[6]), very few studies have proved PSS' potential for changing environmental performance. There are two main questions to consider. One is under which conditions PSS is a suitable offering and in general, PSS approaches seem to work well for e.g. products with high costs to operate or maintain, complex products and long life products [2]. Theoretical investigation has also begun: For instance, property rights have gained attention as a key for PSS to be meaningful [7]. Yet, all these literature are insufficient, especially from scientific viewpoints. The other main question is which PSS factors influence the environmental performance in comparison with traditional product-sales type business. Very few e.g. [8] have attempted to analyze the relation between PSS types and their influence on environmental impact.

2 REDEFINING IPSE

Our research group at Linköping University and KTH (The Royal Institute of Technology) in Sweden has developed what is termed Integrated Product Service Engineering (IPSE) [9]. IPSE looks at combinations of products and services and is a type of engineering, which is different from PSS per se. In addition, it attempts holistic optimization from the environmental and economic perspectives throughout the life cycle. IPSE also consists not only of design as the most influential activity, but possibly other engineering activities such as maintenance, upgrade, remanufacturing, etc. Therefore, IPSE has to deal with the time dimension of the life cycle. Figure 1 depicts different interesting processes for IPSE, obviously showing various disciplines and different aspects to be addressed. An IPSO (Integrated Product Service Offering) is an offering that consists of a combination of products and services that, based on a life cycle perspective, have been integrated to fit targeted customer needs. This often creates close contact between the supplier and customer. Further, IPSO means that products and services have been developed in parallel and are mutually adapted to operate well together in contrast to traditional product sale.In many cases, the service provider retains responsibility for the physical products in the IPSO during the use phase, e.g. the customer only uses the machines and pays for the manufactured volumes; then, when the customer does not need them anymore, the supplier takes back the machines. Such cases increase the provider's interest to ensure that the customer uses machines installed as long as possible and

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_74,

that any disturbances, such as the need for repairs, are reduced. This could lead to a product lifetime extension.

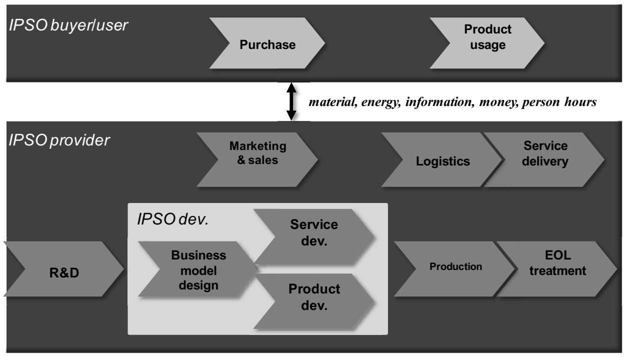

Fig. 1 : Processes of IPSE's interest [10]

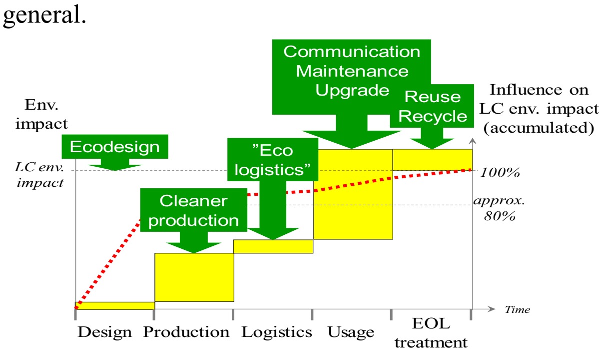
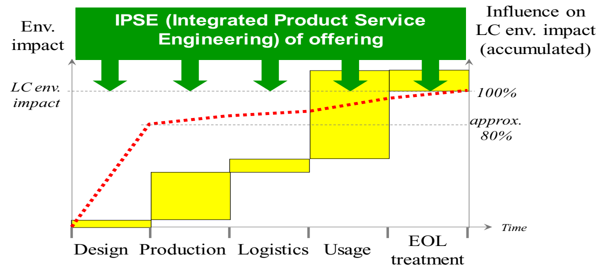
Based on [11], IPSE is explained in comparison to Ecodesign (environmentally conscious design) due to some commonality with Figure 2 (a) and (b), where different types of engineering activities are put on the identical graph. The graph depicts the environmental impact of a certain type of product with high impact from its usage phase, which holds true in many cases. The horizontal axis represents the time dimension on the life cycle. Bars represent the environmental impact from each phase such as production and usage (scaled with the left vertical axis). A dotted line represents the accumulated influence of the activity at each phase of the life cycle's environmental impact. It is shown that the design phase has by far the highest ratio, which is generally known. As seen by the dotted line, Ecodesign is obviously crucial, since it is the design activity with the dominant influence. However Ecodesign is not sufficient since it leaves out control after the design phase. This is why IPSE is more effective, including the possible employment of other engineering activities such as maintenance.

In this paper the following characteristics are to be paid particular attention. The first is its length of the usephase which be long, e.g. more than 20years. Therefore IPSE has to address much of this time dimension with design and especially effective design since the earlier a certain action is taken the more effective its outcome is in general.



(a) Various Eco-activities



(b) IPSE

Fig. 2 : Comparison of IPSE and other activities

Note: The environmental impact (shown by bars) is a rough estimation of active products. EOL and LC stand for end-of-life and life cycle, respectively.

Then, what is design? A seminal work by [12] states "design is an engineering activity that … provides the prerequisites for the physical realization of solution ideas" (originally in [13]). This mainly concerns processing information about needs and wants from stakeholders and through the product life cycle, as well as about function and structure of the product. Effective processing of information plays a central role in IPSE – this is the second characteristic.

Then, design of what? This is the next relevant question as discussed in [14], which points out an artefact, i.e. an object to be designed, is today "integrated and systemic product-services linked in a high-level user experience". Also acknowledging co-creation of value by a provider and a customer/user is a strong idea behind the servicizing (see e.g. [15]), a provider cannot get rid of influence from its customer/user to create the intended value. Thus, a provider can design something contributing to its value, but cannot design the value itself. This means that control of risks of the value creation process is crucial. Thus, this risk is the third characteristics.

In sum, IPSE can be defined as an engineering activity controlling risks of value creation through dealing with information originating from a wide window on the time dimension.

3 PRODUCT DEVELOPMENT

According to ENDREA [16], product development is defined as: "all activities in a company aiming at bringing a new product to the market. It normally involves design, marketing and manufacturing functions in the company". The current business model for many products the focus is normally on cutting down the cost for manufacturing and delivering and little focus is placed on later phases of the product's life cycle. At the same time, life cycle cost studies and life cycle assessments have shown that for many products, it is during the use-phase where the major costs and environmental impact for the product occur. Figure 2 shows, in a basic way the environmental impact accumulation over the product's life cycle.

When developing IPSO, the basic principal is to consider all life cycle phases in order to optimize the offering from a life cycle perspective. The idea is to get the lowest total cost for the offering possible, not only to get the lowest cost for product. Costs are often associated with the use of materials and energy, which in turn provides a negative environmental impact, implying that more cost-optimized products usually have less environmental impact. Figure 2 also illustrates the different phase's impact on the total environmental impact and how important the design phase is, especially the early part of it where the product specification is defined.

At the same time, the initial product specification sets up boundaries for potential actions in the later phases which is often referred to as the "design paradox". The paradox, Fig 3., is that when the general design information is needed, it is not accessible, and when it is accessible, the information is usually not needed. Costs for later changes increase rapidly, since earlier work must be redone [17]. Figures 2 and 3 illustrate the importance of the design phase as well as getting in relevant requirements as early as possible in the development process. It also shows the problem with traditional product development where often little care is taken in product development (and in its specification) for future services, maintenance, and end-of-life-treatment. Traditionally, the initial focus is on developing the physical product and subsequently a possible service (intangible product) is developed, but this is hindered by the limitations set up from the physical product. When developing IPSO, the development is accomplished in an integrated and parallel approach.

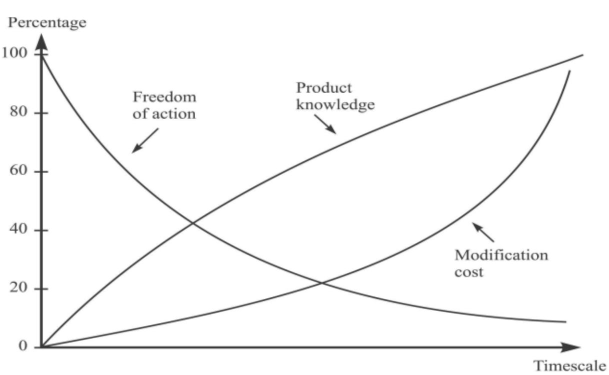


Fig. 3. The relation between "Freedom of action", "Product knowledge" and "Modification cost" is shown [18].

The rate of market and technological changes has accelerated in the past decade implying that companies must be pro-active and rapidly respond to fluctuations in demand [19]. A way to handle these challenges is to do more of the product development in a more parallel and concurrent way in order to e.g. shorten the calendar time (from start to stop) and increase the collaboration over competence disciplines. One concept in line with this is Integrated Product Development (IPD), whose basic idea is to increase the efficiency in product development by more parallel activities and a higher degree of co-operation between functions, levels and individuals in an enterprise [20].

However, if a business model is changed from selling products to providing a function via IPSO, this also changes the conditions for development. When selling products, there is a need to constantly sell new ones or new models in order to survive. This implies that a company should want to split technical improvements between several versions in order to be able to sell more products over time. However, if a company sells IPSO, this is changed since the company wants the customer to use it for as long a time as it is economically interesting. The company will implement the best technique at once instead of taking it in steps leaving more time for developing more optimized offerings - offerings that are more cost-efficient and effective, and therefore in general give a lower negative environmental impact. Nevertheless, it will still be relevant for shortening the calendar time (from start to stop).

4 INFORMATION ASYMMETRIC BETWEEN A PROVIDER AND A USER

In general, environmental impact of a product life cycle is determined by product characteristics themselves and processes on the product. The former includes the type and amount of materials in a product, while the latter includes how to treat the product at EOL (end of life). Thus, the environmental impact of a product can be decreased by changing either its characteristics or its processes. However, one has to own and apply appropriate information to do so. There are different types of such information about a product itself or processes along the life cycle phases such as design, manufacturing, usage, and EOL. In addition, the information may not be documented in such a way that it is easily transferrable to another actor.

Who owns the information on how to improve the environmental aspect of the product and processes at different stages of the life cycle? Information asymmetry exists in many cases between the OEM, who in many cases designs a product, and the user. For instance how to attain the best energy performance for the product in practice may be more hidden to a user than to a designer – the user simply does not know how to operate the given product for the best performance, or the provider has more knowledge of the best available technologies at the moment. There can be various reasons for this, such as a lack of user education in spite of the existence of the necessary information, or the strategy of a user as a company not to get the competence.

Note that information asymmetry in the "market for lemons" addressed by [21] is not the main issue of this paper. In that case, the information possessed by a provider is about a product at a point of sale and is unchanged after the sale of the product, as it is based on a product-sales type business and the provider has no access to the product afterwards. This is shown with gray lines in Figure 5: the information of a user about the product increases along time and can surpass that of a provider. Note that variation of speed of the increase along time is not considered in this graph. In IPSE, on the other hand, a provider can obtain more information with access to the product during usage, and could maintain superiority regarding product information over the user. This is drawn as Cases 1 and 2 in Figure 5, to refer to the same and a higher speed as compared to the user, respectively. In Case 3, due to the lower speed than the user, the provider is surpassed by the user.

Information asymmetry can be a weapon for a provider to obtain payment in IPSE and makes IPSE meaningful as a business. For example, in the case where an OEM owns more information about usage or EOL of a product, there is potential for the OEM to provide IPSO so that the environmental impact is less than would be for product sales. It is also often reasonable for an OEM to be able to provide maintenance or upgrade service of its product. From the viewpoint of environmental performance, on the other hand, information asymmetry is a hindrance to improvement, since it is costly to transfer information to an actor who needs it.

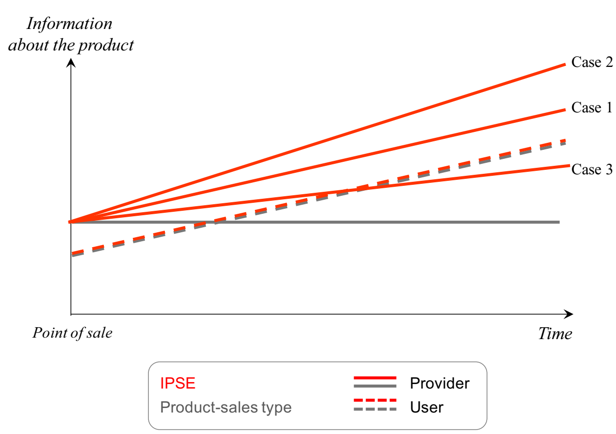

Fig. 4. Transitions of amount of information about a product after sales

5 ECONOMIES OF SCALE

Economies of scale are the result of an increased number of units produced or distributed, making it possible for the unit price to decrease [22]. An IPSE provider has the possibility to attain economies of scale through several different aspects. To provide IPSE is, in some cases, equal to being responsible for all the life cycle costs of the offering, which provide incentives to optimize the total cost as well as to realize economic development, and potentially environmental development [2, 9]. The provider would be able to gain economies of scale for both the products and the services. Leverage in production and administration could be created by offering the same services to different customers [23]. Another way of decreasing costs and achieving economies of scale could be realized when answering customers' demands by constantly configuring the same technology and skills in different ways [24]. For a certain industry the market capacity is limited, which means that a single company may not reach its scale of economy since its market share is relatively fixed for a certain period of time. It is not possible to realize large-scale effects with only a few customers, since much information is needed before, during and after the delivery which results in high transaction costs [25]. If a number of companies outsourced their processes to one organization, this would aggregate the volume and the production efficiency would increase [26]. This would also bring down the transaction costs, since they were created when transferring goods and services [22]. If the transactions occur frequently they are better handled within one single organization, since hierarchical governance facilitates administrative control and coordinated adaptability [27]. Furthermore, customers want to benefit from the knowledge of the supplier, and are reluctant to do business with several suppliers if they want an integrated and global offering [28]. However, the number of actors should be enough to make sure all the components of the offer are delivered by experts [29].

Apart from reduced transaction costs new costs for complementary products may also appear for the provider in the beginning, but will benefit from economies of scale after the transition [30]. Even though IPSE offerings imply customized solutions to achieve economies of scale, they have to be combined with well-defined modular structures at the component level [31-32]. This could also be useful when considering remanufacturing, since parts that are worn out quickly or require frequent upgrading should be placed in an accessible way [33]. Additionally, the IPSE approach would provide the manufacturer with the knowledge of how many products that are entering the process, as well as when they would do so, which would provide the IPSE provider with a remanufacturing plan that is easier to manage [33].

Furthermore, the IPSE provider can economically afford a high level of specialization and technological features due to economies of scale, and can thereby optimize resource consumption and waste production, leading to better eco-efficiency for the company [34]. The provider also often gains a competitive advantage over the customer when it comes to experience and knowledge concerning the product. With information, such as knowledge of how the equipment is repaired across their whole customer base, the provider can optimize maintenance routines and thereby minimize the cost as well as to increase availability and reduce product failures [30, 35]. Economies of scale can also emerge when the provider is in charge of the operations at the site of the customer, when the expertise of the provider in running the equipment can provide reduction in lead time and scale affects [36].

6 RISK

There are various types of risk, namely possible negative consequences from the environmental viewpoint. Reasons for this include an actor's lack of necessary information due to another actor's possession of the information, which was already discussed in the section on information asymmetry. There is another reason as well – non-existence of information.

Whether a product is better from an environmental standpoint for a given need is not necessarily certain at the time the product is first used. Different factors for this originate from the environment (not in the meaning of sustainability) and users. The former includes the speed of progress of the technology used in the product (or product generations) (see e.g. [37]). If a new product is more energy efficient than the original one, and it becomes available before the end of usage, it may be better environmentally to switch to the new product. The user factor includes his/her discontinuity with the need for the chosen product. For instance, a change in demand causing a user to stop using a product after a short time, and owning another product in addition, generates additional environmental impact.

How can these different types of uncertainty be better handled? A provider could do this. If a provider promises a user in a contract that the "best" available technology is provided within the contract period, the user can avoid the uncertainty of the technology progress. For the user's discontinuity of the need, a provider could give an option to a user so that the user can return the product to the provider after a certain period of time. By doing so, a user can shorten the time of holding that risk. The "trick" behind this is scale of economy that enables a provider to cancel different types of risks arising from its users. Thus, variety of the needs by a group of many customers is cancelled.

7 CONCLUDING DISCUSSION

This paper endeavoured to lead theoretical discussion regarding which IPSE factors are expected to increase environmental performance of a life cycle compared to a traditional product sales business. Four aspects from theory were discussed and their relevance was pointed out. In the theory of product development, information about a product is pointed out to be a crucial parameter, although the theory is to be adapted according to the nature of the offering – IPSO as opposed to a physical, traditional product. Then, asymmetry of the information about a product between a provider and a user was identified as a key for IPSE to be meaningful also through comparison with the product sales type business. Economies of scale were brought into the discussion and this remains to be an important issue for IPSE but with different characteristics from the product sales type business. Finally, risk was discussed and pointed out to be a crucial parameter to be controlled after sale and economies of scale were shown to be an enabler to control the risk in a better way. As shown in these four sections, these aspects are interlinked with each other and need to be further investigated. Nevertheless, the paper has provided a first theoretical cornerstone regarding conditions for IPSE to be a meaningful business style and IPSE's influential factors on environmental performance.

Further research is needed and the authors aim to continue to clarify and model the aspects discussed in this paper to more thoroughly explain the environmental advantages with IPSO in comparison to traditional sales.

Current state of the art on repair, maintenance and serviceability in Swedish automotive industry – a virtual product realization approach

Andreas Dagman (1)[1], Rikard Söderberg (2)[1]

[1] Institution of product and production development, Chalmers Technical University, Gothenburg, Sweden

Abstract

Sustainability with its three aspects, economy, ecology and social, is gaining more and more attention in industry as well as in academia. One way of increasing sustainability is to increase the life length of a product as well as ensuring performance by making it easy to maintain and repair. The consumer trends are moving towards a more positive attitude to buy a function rather than the product itself. By having this approach aspect such as maintenance, service and repair (MSR) is put in a different light. This paper presents a interview study with the intention to investigate the state of the art regarding maintenance and repair in four different Swedish automotive manufacturing companies with emphasis on how virtual product realization is considered and implemented. It was stated during the interviews that the use of simulation and analysis methods with emphasis on MSR differs and that it sometimes can be troublesome to make impact in project discussions etc. due to their difficulty in delivering hard figures e.g. cost, weight, CO2 emissions etc.

Keywords:

Maintenance, service, disassembly, virtual product realization

1 INTRODUCTION

Sustainability with its three aspects, economy, ecology and social, are gaining more and more attention in industry as well as in academia. It is no longer high status to park a huge SUV at your driveway, your neighbors will rater pat you on the back if you park a hybrid or electrical vehicle there. The consumer trends are going in a direction towards a more positive attitude to buy a function more than the product itself. This is the core message of Product Service System (PSS) which is a combination of physical products and services, [1]. In PSS the traditional manufacturer-vendor-user relationship is rearranged, in order to deliver environmental and (for the company) economical benefits. By having this approach, aspects such as Maintenance, Service and Repair (MSR) is put in a different light since the companies will take care of the cost during the life time of the product also. MSR may be defined as, "the combination of all technical, administrative and managerial actions during the lifecycle of an item intended to retain or restore it to a state in which it can perform its required function [2]. Design for maintenance as an important topic for a good design was raised in the early days as for example stated in Asimows "Introduction to design" [3]. Though it has not been explored to a very large extent [4]. The area has been explored but focus has been on maintenance intervals, mathematical models etc. rather than guidelines for design for maintenance and repair.

By maintaining the products and make them easier to repair, the life length will increase and most surely the total life cycle performance will improve too. This in turn will lead to more sustainable solutions. Putting more emphasis on MSR requirements during creation of designing solutions will make it easier to avoid the need of draining different fluids when repairing or decreasing the need of destroying parts a more sustainable product solution is achieved. To achieve these kinds of solutions there is a need for new tools and methods. By using computerized tools i.e. virtual tools it is possible to evaluate a vast amount of different solution, in a short time. By creating a virtual product realization process the need of prototypes is decreased which leads to higher sustainability. Here, virtual product realization refers to simulation, analyses, model creation etc. which is used in order to decrease the usage of expensive and time consuming physical models [5].

1.1 State of the art

MSR are one of the vast amounts of different product characteristics which need to be taken in consideration during the product development process. There are methods and tools which are tailor made for many of the different product characteristics. Under the label Design for X a wide collection of specific design guidelines are summarized. Each design guideline addresses a particular issue that is caused by, or affects the characteristics of a

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_75,

product. Design for maintenance (DfM) has not been in focus to a great extent in the design for X area [4].

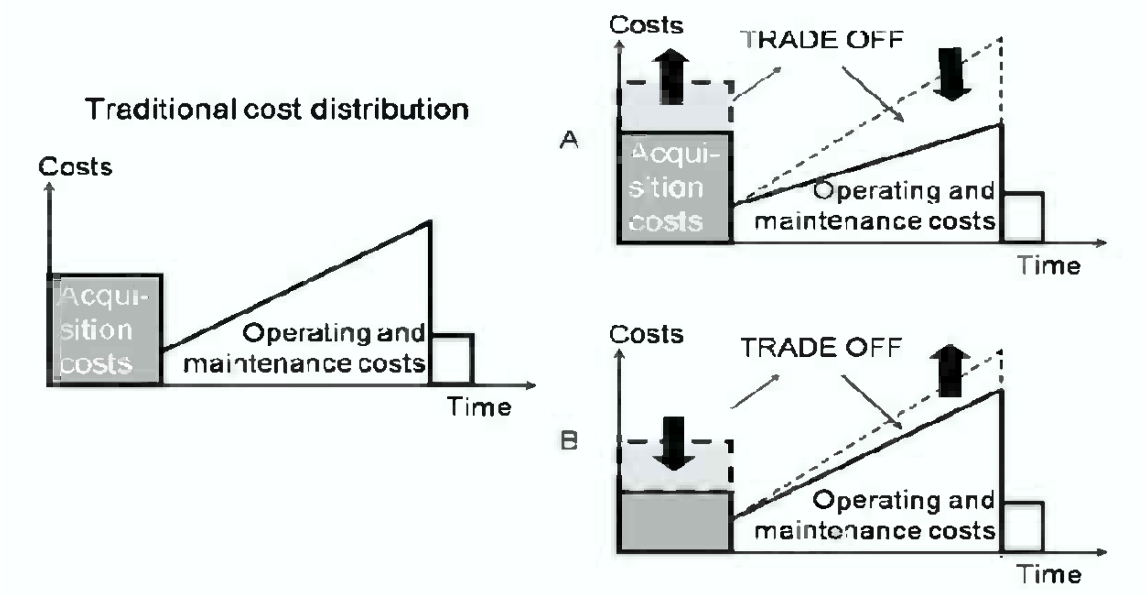

Fig. 1: Strategic courses of action to optimize a life cycle, from [6]

Though the focus has been on the mathematical side calculating maintenance schedules etc. and not emphasizing on the on the synthesis i.e. design for maintenance area [4]. Chiu and Kremer [7] made literature review with emphasis on investigation of the applicability of Design for X tools during design concept evaluation. According to this there are fairly numerous methods and tools present for disassembly and recycling but not for maintenance. A number of DfM guidelines has been proposed by Mital and Desai [4]. In generic design methodology books, DfM is mentioned but not extensively, usually 1-3 pages out of 200-300 pages. For example in "Engineering Design: A Systematic Approach" [8] it is mentioned as Design for ease of maintenance, in "The Mechanical Design Process" [9] it is mentioned as design for test and maintenance, in Product Design and Development [10] it is mentioned as "Ease of maintenance" (sorted as a specific branch of industrial design) and in Engineering design methods [11] mentioned as maintenance under the section "Improving Details". Design for disassembly, which can be considered a subset of maintenance, is a topic that covers several areas of the product life cycle. According to Westkämper [6] the disassembly aspects will influence both during the assembly process in order to repair and disassembly defects caused by assembly. Then in the usage phase there is the service and maintenance part that is of importance. Wübbenhorst [6] states that there is correlation between the acquisition of the product and the Assembly and disassembly operations, see Fig 1. Depending on how big your effort is in the beginning of the product life cycle the cost of operation and maintenance will also differ. He states that there is a correlation between the different aspects. Time is an important aspect when evaluating different maintenance as well as repair solutions and methods. In [12] a number of disassembly time evaluations for automotive industry is presented. There are different methods to come up with the standard times for different work procedures. One of the predetermined systems is the Methods-Time Measurement (MTM) [13].

There are quite numerous quality issues that are related to the positioning of parts i.e. that the part is not positioned as it is supposed to be [14]. In other terms the personnel do not know when the part is in right place/position or not.

1.2 Scoop of the paper

Maintenance and repair aspects of products are essential to ensure their performance as well as to increase the life cycle of the product. By supporting this area with methods and tools during the product development process the possibility to meet the above mentioned aspects increases. According to the Wingquist laboratory research process there is a need to identify both a research challenge as well as to indentify an industrial need [15]. Together they give rise to a research idea. In this paper we present an interview study with four Swedish automotive manufacturers. The presented interview study has two aims. The first one is to increase the knowledge regarding how MSR aspects are considered and treated in automotive industry in Sweden. The second aim is to identify an industrial need in this area. Since the research agenda within the research group, where this research has been carried out, aims at a fully virtual product realization process emphasis has been on how virtual tools are used.

2 METHODOLOGY

In this section the methodology used throughout this paper is instroduced.

2.1 The design of the study

The study was carried out by conducting semi structured interviews with personnel within the participating companies whose responsibility was service and maintenance aspects. Semi structured interviews has a formalized, limited set of questions. It allows for complementary questions during the interview if needed [16]. The approach was exploratory to its nature in order to gain knowledge how vehicle industry in Sweden are approaching MSR in the product development process. The scope of the questions had a twist towards how MSR aspects in particular are taken care of during virtual product realization. The length of the interviews was between 1-2 hours. The interview was performed in group constellations at the companies and not individually. The total number of interviewees was 11 distributed among the four companies. In the first company only one person was interviewed, at the second company there were two persons, at the third and forth company there were four persons interviewed. The interview study was planned in accordance to the methodology presented in [16]. One way, according to Kvale, to accomplish the interview studies is to follow a seven steps procedure, see table 1. These steps are developed for semi structured interviews but can also be used as base when designing the questionnaires. The same questions were posted at all of the interviews. Through the questions was not posted in the exact order during all of the interviews. The setup was more of a conversation where the questions were used as guidance.

Table 1. Seven steps for interview planning, [16]

1. **Thematize.** Conceive the aim of the study and describe the area for the investigation before the interviewing. The investigations *why* and *what* shall be clarified before the question about *how* is formulated.
2. **Planning.** Plan all the stages for the investigation, with respect to what knowledge that will be obtained and with the moral consequences for the investigation in consideration.
3. **Interview**. Accomplish the interviews according to an interview guide and with a reflective attitude to the requested knowledge and to the interpersonal relation due to the interview situation.
4. **Transcription**. Prepare the interview material for analysis, which usually means a transfer from spoken language to written language
5. **Analysis**. Decide from the investigations aims, subjects and foundation of the interview materials point of view witch analysis methods that suits the interviews.
6. **Verification**. Establish the interview results level of generalization, reliability and validity. Reliability assigns to the consistency of the result and validity to if a survey investigates what was meant to be investigated.
7. **Report**. Report the result of the investigation and use the methods in a form that corresponds to science criteria's, that takes the ethic aspects in consideration and leads to a readable product.

2.2 The planning of this study

The planning of this study is here presented.

1. Thematize

The presented interview study has two aims. The first one is to increase the knowledge regarding how MSR aspects are considered and treated in automotive industry in Sweden. The second aim is to identify an industrial need in this area. The study is explorative to its nature and not investigating a stated hypothesis.

2. Planning

The study as whole includes interviews as well a workshop with the participating companies. The workshop is planned to be executed in the middle October.

3. Interview

We were two persons at three of the interviews and one at the final one. An interview guide with the questions was used during the interviews. The questions were not necessary posted in the order written in the guide though it was used to not miss any questions.

4. Transcription

The answers from the interviews were written down in a condensed format during the interviews.

5. Analysis

The answers were clustered to find, if possible, a general opinion. It was considered to be enough documentation level for this kind of interview study.

6. Verification

Four companies within the same type of business are participating so the answers can be considered to be fairly generalized. The study is explorative to its nature why validity and reliability is not considered relevant.

7. Report

The outcome of the study is reported in this paper to in an as consistent way as possible.

3 RESULTS

In this section the results from the interviews are compiled together. The aim of the survey was not to pinpoint either of the companies working procedure in detail. The aim was rather to find a general picture of MSR aspects, with emphasis on virtual product realization, why the answers from all four companies have been clustered together.

The presentation structure of this section is the question posed is written in underlined style and after that a compiled answer based upon the answers from all four companies is presented. At some of the question a short introductions is posted in order to clear out the purpose of posting that question. There are two main areas that were investigated; *MSR aspects in the product development process* and *Information flow between the OEM and service stations*.

During the interviews we identified two diverse but closely connected activities i.e. job assignments, which were equal among all the companies. The first of the two main activities was to improve the design solutions regarding service and maintenance aspects. This activity is to its nature proactive. The second activity was to design and improve MSR methods for the service technicians. One special activity was the development and design of special tools used for the service operations. There are situations where there is a need to have special tools to be able to solve the MSR solutions.

MSR aspects in the product development process

How is your area promoted within the company?

MSR is considered to be an important area within the companies. It was consensus that it sometimes can be troublesome to make impact in project discussions etc. due to their difficulty in delivering hard figures e.g. cost, weight, CO2 emissions etc. This was also perceived among the interviewees to be one of the core issues in order to ensure that the product solutions are easy to maintain and repair. One of the reasons to the current situation has its origin in how maintenance and repair aspects are quite often taken care of within the companies. Since they need the entire model of the vehicle they gets it when it is more or less finalized which leads to a reactive approach rather than a proactive. The current trend within the companies is that MSR requirements are taken more into account during the early stages of the product development process. The introduction of different simulation tools has made this possible.

How is the disassembly and reassembly time calculated and when?

The companies are in general using two types of input for calculation of disassembly and reassembly time, namely standardized methods and laboratory tests. There are several standardized methods for estimating the disassembly time e.g. MTM [13]. The standardized time methods are used when the maintenance and repair methods are created. In the laboratory tests service technicians will carry out the service/repair method two times live in a laboratory workshop. The time of their actions is measured and these times are then used as a basis for the time estimation. These tests are done when the vehicle is in its final development stages. The disassembly and reassembly times are also used by the service stations when they shall do cost models for different service as well as repair jobs.

Which are the main issues with virtually testing and evaluation of MSR aspects?

It was stated during the interviews that the use of virtual tools, as support when developing and evaluating MSR aspects differed, quite much, between the companies. All of the companies did have CAD and PDM systems which they used in the product development process. There was differentiation between virtual tools to analyze and ensure efficient MSR solutions. The same pattern was also identified in the area of method MSR where technical drawings based upon the actual CAD-models are the basis for the creation of MSR methods for maintenance and repair. There are tools which converts the geometrical CAD-models directly into technical drawings or into vector format. These kinds of tools were not used by all the companies. The technical drawings, used for the repair and maintenance handbooks, were more or less performed by hand not using any of the available software's that exists.

The need of appropriate CAD models was also found as one of the core influencing aspects to be able to analyze and simulate maintenance and repair aspects as well as to do the maintenance and repair methods. Since the participating companies was OEM:s (Original Equipment Manufacturer) most of the development work is outsourced to the sub contractors an together with that the detailed CAD-models. In many cases there is a lack in the agreements between the OEM:s and the subcontractors regarding the CAD data. The subcontractors send, quite commonly, the data to the OEMS as a final assembly not including any individual parts. This gives the situation that the OEM:s does not have the CAD models in details which gives much work efforts. To sort this out the engineers at the OEM's, sometimes, needs to do the time consuming work to modeling the geometries from scratch.

Is virtual training used to educate the service and maintenance personnel?

Virtual training is currently not adapted to a large extent within the companies. They see advantages with using virtual tools in this are but they find it quite hard to do an adequate simulation. It is hard to come up with a virtually representation of the surroundings of the service station since it differs quite much. Maintenance and repair jobs at the service stations are not repetitive to its nature especially compared to the production line. It is thereby seen as a challenge how to do the ergonomically evaluations for example when the input parameters are such diverse. They see opportunities to use motion tracking systems to monitor how service personnel are working. The aim with using this device is rather to gain knowledge than using if or virtual training. The training of service personnel is today is carried out at the companies taught live next to the vehicle.

How do you set requirements regarding fasteners to allow for disassembly and reassembly?

There are vast amount of different types of fasteners used. Compared to the assembly line where easy handling of the fasteners, both physically and cognitive, the situation is a little different when disassembly. The disassembly process can incorporate both destructive and non destructive disassembly regarding fasteners, parts etc. The MSR divisions put requirements on different fasteners regarding type and how many times they should be able to disassemble and reassemble. Though there is balancing needed between fasteners used, disassembly time, destructive and non destructive removal. There were no general guidelines her but case dependent.

How do you work with directions and clearance when designing for service and maintenance?

To be able to reach the component when maintaining and/or repairing is essential for the technicians. Here there were quite different situations at the companies. The engineers at some of the companies did not have any special tools when checking directions and clearance in the product development process. It was rather based upon experience among the engineers from earlier MSR solutions from older models. Other ways of doing this was also to use the CAD-models and just move them around as stiff parts in the model to see whether they collided or not. At some of the companies they had access to a robot path planner which was used to automatically analyze and simulate the possibility of disassembly.

How is disassembly connected to ergonomic aspects?

The ergonomically aspects of service and maintenance work is rather unexplored throughout the companies. Compared to ergonomic simulations for production stations these work tasks are most commonly not investigated. Though there is a trend in the companies that these aspects are to be more considered and therefore also highlighted. One reason mentioned for this was that this is not as repetitive to its nature as for production for example.

How do you make sure that the parts are correctly placed and tightened when reassembled?

There are quite many quality issues that are related to the positioning of parts i.e. that the part is not positioned as it is supposed to be. The maintenance and repair methods were made as detailed as needed with use of figures and text to ensure that the service personnel did understand correctly. Within these instruction manuals there were for example torque rating included for screws when needed but not for all actions. According to the interviews most commonly the service technician ends the job with a test drive to ensure the functionality.

There was no use of haptic responses as a feedback to ensure right positions. All of the companies did have service centers where the service technicians were taught how to do the service and repair procedures. It was stated during the interviews that it was a great difference regarding how the different service stations carry through service and repair task. Even if the MSR-department had given them a manual of how to do it they did not follow this but found alternative ways of working.

Information flow between the OEM and service stations.

How do you collaborate with service stations and other customers regarding service and maintenance manuals etc.?

In order to get the service methods and service information out to the service stations and maintenance areas different IT-systems was used, with some low tech alternatives. The IT-systems did, in general, offer service and repair manuals, time standards, spare parts catalogue, communication interface, diagnostic fault tracing and software downloads etc. During the interviews the systems as such was not investigated why the core difference has not been investigated. There is a great difference between the technology levels at the service stations around the world why there is a need of low technology alternatives. Thereby paper copies of the service manuals as well as DVD-discs were still used. It was only pictures and text in the manuals. No movies or other type of interaction was used.

How is knowledge from the service personnel and customers taken care of and brought back into the organization?

The same IT systems used to deliver the maintenance and repair manuals were also used by to get feedback from the service personnel. Within these systems the service personnel had the possibility to give feedback and improvement suggestions back to the service departments. There are also customer complaint departments where customers can give their input to but also input from the service stations. It is not common that the complaints from service personnel as well as end customers are going directly to the product development departments.

4 CONCLUSION

By increasing the ease of maintaining and repair of the product solutions a longer life cycle is achieved which most surely leads to an increased sustainability. The consumer trends are going in a direction towards a more positive attitude to buy a function more than the product itself. This is the core message of Product Service System (PSS) which is a combination of physical products and services Maintenance, service and repair (MSR) aspects are considered of great importance for the companies according to the interviews. MSR will most surely gain greater impact in the organizations if it adapts to a PSS business models, which seems to be the trend today. It was consensus among the interviewees that it sometimes can be troublesome to make impact in project discussions etc. due to their difficulty in delivering hard figures e.g. cost, weight, CO2 emissions etc. If the companies will move more towards a PSS (Product-Service Systems) approach repair and maintenance will be of greater importance and the need to get numbers of these aspects will be highlighted and more focus will be put there.

It was stated during the interviews that the use of virtual tools, as support when developing and evaluating MSR aspects differed between the companies. But the use was on the low side in general. The trend was towards increasing the use of virtual tools in order to give feedback to the product development process before the product is finalized, proactive work.

The need of appropriate CAD models was also found as one of the core influencing aspects to be able to analyze and simulate maintenance and repair aspects as well as to do the maintenance and repair methods.

The following conclusions can be drawn from this study.

- It is of great importance to enable transformation of MSR requirements into hard facts such as cost, weight, CO2 emissions etc.
- There is a need of appropriate CAD-models both on part and assembly level.
- MSR is quite commonly treated in a reactive way than in a proactive way which leads to a situation where it is hard to influence the product solutions.
- Virtual training of service personnel has not been introduced but is seen as positive.
- The final conclusion of this paper is that there is a need to introduce simulation and analysis tools for MSR aspects.

By directing more focus to MSR the possibility to make the design and product more eco friendly and thereby more sustainable will increase.

Future work will be identification of key aspects of MSR that needs to ´be simulated and analyzed. Based upon this new virtual tools will be developed and introduced.

Supporting Maintenance Services by Utilizing Worker's Behavior Sensing and Visualization Based on Mixed-Reality Technology

Tomoya ISHIKAWA (1)[1], Masakatsu KOUROGI (2)[1], Takeshi KURATA (3)[1]

[1] Center for Service Research, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan

Abstract

This paper describes a novel approach to support maintenance services by utilizing mixed reality technologies. To use buildings, plants, and facilities for a long term is a one of the requirements needed to establish sustainable society. In order to manage life cycles of buildings and facilities appropriately, adequate maintenance is required. Not only the improvement of working efficiency but also the improvement of worker's satisfaction is an important issue. In order to solve the issue, we have researched and developed supporting technologies for maintenance services by utilizing worker's behavior sensing and visualization. In this paper, we describe the issues on operations of maintenance services and the supporting technologies to solve them.

Keywords:

maintenance service, mixed reality, behavior sensing, 3-D indoor modeling, visualization

1 INTRODUCTION

To use buildings, plants, and facilities for a long term is a one of the requirements needed to establish sustainable society. In order to manage life cycles of buildings and facilities and to keep safety, stability, and comfort, high quality maintenance services are required. The market sizes of building and plant maintenance services are currently about 3 trillion yen (investigation by Japan building maintenance association [1]) and about 860 billion yen (investigation by Japan institute of plant maintenance [2]) respectively, and the importance of the services is increasing increasingly.

Typical operations in maintenance services are mainly inspection, full equipment, repair, and cleaning. Most of the operations are manually provided by workers and labor-intensive operations except for networked remote monitoring of operational status of devices and facilities, and so most of them are compensated by experience and intuition of workers.

Worker's operations and work contents are written down in work reports, daily reports, notes for handover of operations, and so on. By accumulating work histories and know-hows, the work analysis and redesigning of service processes can be dealt from engineering point of views. It also prompts standardization of workflow and information sharing. Additionally, the standardized workflow can be used for the development of human resources for keeping pace with globalization of maintenance services caused by oversea transfer of manufacturing industry. However, the enforcing to record work histories strictly gives high workload to the workers. Moreover, in building and plant maintenance services, the repetition of move and work occur frequently, and thus recording operations on the site and comprehending states of other workers are often difficult. These are common issues in labor-intensive industries. One of the significant differences compares to arterial industry is the difficulty of comprehending situations in service fields since the ratio of human power is much higher. In addition, the variation of qualities of workers' skill makes strongly difficult to design optimal service processes and its applications.

To present the solution to these issues, firstly visualization of worker's behavior measured objectively and quantitatively in service fields and virtualization of their work spaces are effective in the first place. Based on the service analysis by the visualization, redesigning services and applying the redesigned services to the service field can be possible for running the service optimization loop a.k.a. plan-do-check-action (PDCA) cycle.

For measuring worker's behavior, time study that records time to operate, places to work, and etc. using stopwatches by investigators who track the workers has been applied [3] in large indoor environments such as buildings and plants. But, the method requires much time and human resources for measuring many workers exhaustively. Furthermore, it is difficult to record the detailed information such as moving trajectories of workers in service fields, places in which workers need actions of high workloads, and frequency of the actions. In terms of the visualization of the measured information, managers and analysts cannot understand the meaning of the behavior if the information is not visualized with the service field.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_76,

In this paper, we describe a novel approach to improve service quality, working efficiency, and employee satisfaction by applying worker's behavior sensing and visualization technologies based on mixed-reality technology to service fields. This paper is organized as follows. Section 2 describes the concept of the maintenance service supported by mixed-reality technology, and Section 3 explains about the technologies of the worker's behavior sensing and virtualization of service fields. The operative examples and the summary of this paper are presented in Section 4 and 5.

2 MAINTENANCE SERVICES SUPPORTED BY MIXED-REALITY TECHNOLOGY

We aim at achieving improvements of both working efficiency and employee satisfaction of maintenance services by measuring worker's detailed behavior which is difficult to be obtained by conventional methods and by visualizing it for service analyses and designs. As the measurement and visualization technologies to achieve that, we employ sensor / data fusion [5] and 3-D indoor modeling [6] technologies based on mixed-reality technology [4] that prompts information circulation between real and virtual worlds. These technologies synergistically realize precise measurements of worker's behavior in service fields and creation of high-quality 3-D models of service fields at low costs (Fig. 1).

Based on the workers' information measured and visualized by the technologies, managers of workers can consider effective assignments of human resources and rapidly direct to workers in a broader perspective. For the workers, they can receive appropriate appraisal to their works by evaluating the workload as objective and quantitative indicator by using the measurement technology. Recently, maintenance services are becoming outsourced, so that comprehending positions in which place facilities to be maintenance in the service field are often difficult for the workers who do not well know the service field. In such situation, the workers can work effectively by an indoor navigation based on the real-time worker's behavior sensing and the visualization of the service field. Additionally, the measured data that are places and time to work can be evidences as work histories of workers, and so to measuring worker's behavior enables to support input of work logs. To accumulate these work logs and histories prompts standardization of workflows, and they are used as documents for developments of human resources.

As described above, maintenance services can be improved by utilizing the worker's behavior sensing and visualization technologies, and we believe service innovation that improves working efficiency and employee satisfaction.

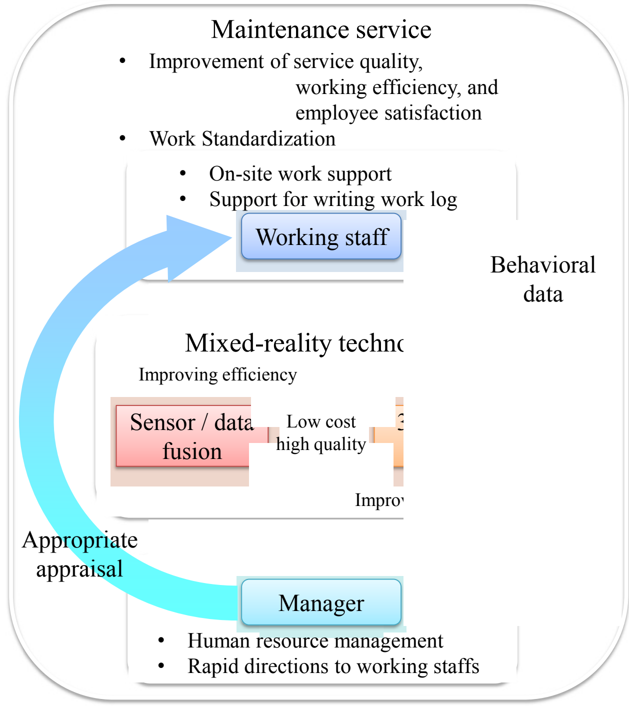

Fig. 1: Conceptual diagram of maintenance service supported by mixed-reality technology

3 MIXED-REALITY TECHNOLOGY FOR WORKER'S BEHAVIOR SENSING AND VISUALIZATION

In this section, we describe the sensor / data fusion for measuring worker's behavior and the 3-D indoor modeling for virtualizing service fields and visualizing the 3-D models of the service fields with the measured data based on mixed-reality technology for supporting maintenance services. The technologies can distribute the costs and realize high-quality functionalities by cooperating each other. The cost distribution makes installation of the technologies to service fields easy [4]. Remains of this section give the explanations of the sensor / data fusion and the 3-D indoor modeling technologies.

3.1 Sensor / data fusion

The sensor /data fusion (SDF) is a measurement technology that estimates worker's position, orientation, and action continuously in large indoor environments where global positioning system (GPS) cannot work [5]. SDF can estimates the worker's position, orientation, and action accurately by probabilistically fusing the relative displacement estimated by the pedestrian dead-reckoning plus (PDRplus: PDR with action recognition) [7] from sensor data of the sensor module (consists of gyroscopes, accelerometers, magnetometers, and a barometer) equipped by the worker, the absolute position estimated by the infrastructures placed in the service field such as active radio frequency identification (RFID) tags, surveillance

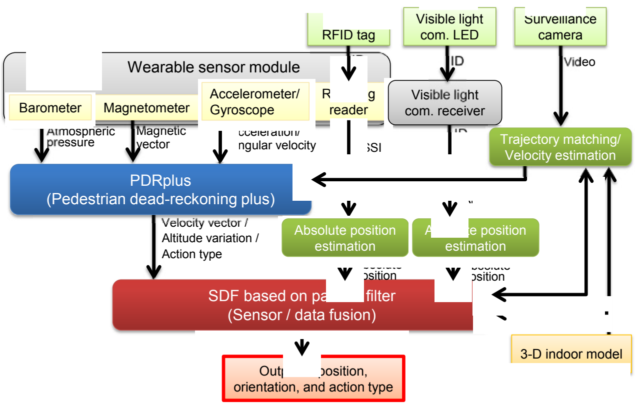

Fig. 2: Configuration of sensor / data fusion

Fig. 3: 3-D indoor model created from photographs

cameras, and LEDs with visible light communication which emit unique IDs, and the 3-D indoor model to be used for visualization. Fig. 2 shows the configuration of the SDF.

The SDF continuously estimates detailed movements by accumulating the relative displacement from PDRplus and corrects the accumulative errors by using the information from the infrastructures in the service field. By this configuration, the infrastructures do not have to be placed densely in the environment, and we can reduce the installation and running costs for the infrastructures. Since, RFID tags and surveillance cameras are often used in service fields for security reason, they can be also used for SDF. Moreover, not only the worker's position and orientation but also the worker's action such as standing up, sitting down, and so on can be estimated by PDRplus, and so we can quantitatively obtain the amount of movements and workload based on the estimated actions.

The SDF based on the particle filter [8] estimates the state of the worker's position and orientation by approximating a set of samples of the state vectors as the probability distribution. If the SDF can have the 3-D indoor model used for visualization etc., the SDF can correct the probability distribution to the one that consists with the actual worker's movement by restricting the distribution on the floor regions in the 3-D indoor models. The map-matching algorithm enables the SDF to track the worker precisely by diverting the 3-D indoor model.

The positioning and the action recognition can work in real-time by transferring sensor data via wireless network remotely from the sensor module equipped by the worker to the SDF server. Off-line processing is also possible by storing all the sensor data in the memory card such as micro SD cards in the module.

3.2 3-D indoor modeling

The 3-D indoor modeling technology [6] allows the user to interactively create photo-realistic 3-D models from multiple photos that capture the real environment effectively. In this 3-D modeling, the user can create 3-D models only from photos captured by an ordinal digital still camera. Therefore, the user can create 3-D models at low cost compared with the other method using specialized devices such as laser-range finders. The time occupying the environment for capturing photos is also comparatively short.

The modeler program utilizing the 3-D indoor modeling technology supports the user to effectively create 3-D models by exploiting geometric constraints estimated from each photo. Additionally, by cooperating with the SDF, the modeler supports to integrate 3-D models and to reduce texture shortages. This cooperation contributes to effective and low-cost 3-D modeling.

Fig. 3 shows a 3-D indoor model of an office environment (floor space: about 1000 m^2) created from 57 photos for about 10 hours. The images in Fig. 3 bottom are the views rendered from parts of the3-D model not photos. From the visualization, we can see the details of the office environments easily and intuitively.

4 SUPPORTING TECHNOLOGY FOR MAINNTENANCE SERVICES

This section presents operative examples of supporting technologies realized by the technologies described above.

4.1 Remote monitoring and workload measurement

To comprehend the worker's behavior and workload during the maintenance service has been difficult in the past. In addition, generally managers do not comprehend the details of each service field where the workers work. Therefore, the consideration based on the meaning of the worker's behavior derived from the service field for improving working efficiency has been difficult.

By utilizing our technologies, the managers can visualize and comprehend the workers' behavior in the service field in real-time. Fig. 4 shows the examples of the remote monitoring of the worker's position and orientation. We can confirm that the worker's position and orientation are precisely tracked by utilizing the 3-D indoor model and the state in the service fields is comprehensible. According to the assessment of the worker's situation by the visualization, the managers can optimize the human resources. For example, the manager effectively directs a worker who had finished tasks to support the other worker who had not finished.

Fig. 5 presents the visualization of the worker's trajectory with the 3-D indoor model. From the visualized trajectory, the managers and analysts can intuitively understand where the movements frequently occurred and how the worker moves in the service field. Furthermore, from the estimation of the SDF, they can obtain the statistical information such as time to work in each workplace, where high-workload tasks occurred in, and the frequency. According to the statistical information, the managers and the analysts can consider that optimal places where equipment used for cleaning should be for reducing the movements of the worker, assignments of human resources for high-workload tasks, and giving appreciation to the worker who is assigned high-workload tasks for improving working efficiency and employee satisfaction.

4.2 On-site work support

In maintenance services provided by outsourcing, the worker also does not well comprehend the service field and where the facilities to be maintained are. This is the one of the reasons that decreases the working efficiency. In our approach, the working efficiency can be improved by navigating the worker to the workplace in which the facilities to be maintained are by using the real-time SDF and the 3-D indoor model. Fig. 6 shows the appearance of the worker who is navigated to a facility to be maintained by the displayed guidance controlled by the worker's position and orientation. The worker can see the bird's-eye or first-person views selectively and can easily make correspondences between the real service field and the virtualized service field. Thus, by following the guidance, the worker can move to the workplace effectively.

The histories of the worker's movements can be used for the evidence of the work. For example, if a system of work reports can automatically input where the worker works in and how long is it, it can contribute to reduce the labor hours and to prevent forgetting reports.

In future, the detailed operation support such as displaying procedures of operations by augmented-reality technology

Walking in corridor

Cleaning sink

Cleaning toilet

Fig. 4: Remote monitoring of worker's behavior (Colors present orientations of samples.)

Fig. 5: Visualization of worker's trajectory

Fig. 6: On-site work support by real-time tracking and visualization (left colum : appearance of a worker, right colum : displayed guidance)

intuitively can be possible by combining our technologies and more precise tracking technology [9] using a camera equipped on the handheld devices. We consider that it can be effective for supporting less skilled workers and for developments of human resources.

5 SUMMARY

In this paper, we describe a novel approach to improve both working efficiency and employee satisfaction in maintenance services by utilizing worker's behavior sensing and visualization technologies based on mixed-reality technology, and we present the supporting technologies which have been developed for maintenance services. Our supporting technologies enable managers and analysts to objectively and quantitatively comprehend the worker's behavior that had been difficult to measure so far. Therefore, we believe that our technologies have strong impact not only on managements of human resources but also on worker's operations and designing services.

As the future works, we need to research and develop more feasible technologies for maintenance services based on feedbacks from actual managers, analysts, and workers in the service fields. Besides, to evaluate effectiveness and worker's workload before and after installation of the supporting technologies is required. By collecting such evaluation data in actual service fields, it is possible to create a cost-benefit model of the supporting technologies, and the model can be useful for spreading them to service fields.

Battery Life Cycle Management for Automatic Guided Vehicle Systems

Takehito Kawakami[1], Shozo Takata[1]
[1] Department of Business Design and Management, Waseda University, Tokyo, Japan

Abstract
Battery management for automatic guided vehicle (AGV) systems is important to reduce costs and increase the efficiency of the AGV systems. Valve-regulated lead-acid (VRLA) batteries, which are generally used in AGVs, should be charged at appropriate time intervals, to avoid the deterioration of batteries and to extend their lives. On the other hand, frequent charging affects the efficiency of AGVs. The cost of chargers, which determines the charging time of the batteries, should also be taken into account. It is not easy to select a proper battery management strategy that considers all these factors. To solve these problems, a battery management simulation is developed for evaluating battery related costs under various AGV operation modes and for designing battery management strategies. To verify its effectiveness, the simulation is applied to a body in white at the finishing line of an automobile manufacturing plant.

Keywords:
automatic guided vehicle (AGV), valve-regulated lead-acid (VRLA) battery, battery management, simulation

1 INTRODUCTION

In recent years, automatic guided vehicles (AGVs) have been widely used to improve the efficiency of material handling in flexible manufacturing systems. AGVs usually employ valve-regulated lead-acid (VRLA) batteries because of their high reliability and low cost. Although VRLA batteries are inexpensive, as compared to other types of batteries, battery related costs of AGVs account for a significant part of their operation costs. The lives of batteries vary depending on their operation mode such as timing of charge. Therefore, to reduce battery related costs, life cycle management of batteries is important.

Although battery management is important for AGVs, limited researches have been carried out on AGVs, according to Le-Anh et al. [1]. Ebben [2] has proposed a cost trade-off analysis to assist AGV system designers in selecting the proper battery type as well as the number and position of battery stations. In addition, he proposed determining the locations of battery charging stations, to minimize effects of charging parameters such as charging time on the efficiency of the system. However, he did not take into account the deterioration of the batteries. On the other hand, Kaiser [3] proposed a cost-efficient battery management system for stand-alone renewable power supply systems (RESs) with a photovoltaic generator, in which the battery life can be extended by taking battery deterioration into account and using a different charging method. However, operation modes of the batteries for RESs are quite different from those of AGVs.

The goal of this study is to develop a methodology for planning a battery management strategy that minimizes battery related costs to increase the efficiency of AGVs. For this purpose, we developed a simulation for evaluating battery related costs in a given AGV operation mode. This simulation system can be used to determine the appropriate battery management strategy.

In Section 2, we discuss the framework of a battery management system for AGVs. In Section 3, Schiffer's model [4] is introduced to evaluate the battery deterioration induced by AGV operation. In Section 4, the planning method for the battery management strategy is proposed and the simulation used for evaluating battery related costs based on the state changes of the batteries during AGV operation is explained. Finally, in Section 5, a case study is presented by considering a body in white at the finishing line of an automobile manufacturing plant as an example.

2 BATTERY MANAGEMENT OF AGV SYSTEMS

Battery management is important for the efficient operation of AGVs. AGVs usually employ valve-regulated lead-acid (VRLA) batteries because of their high reliability and low cost as compared to other types of batteries. The life of a VRLA battery depends on its usage. The best way to use VRLA batteries is to avoid over-discharge and insufficient charging. Thus, to avoid

Proceedings of EcoDesign 2011 International Symposium

battery deterioration and consequently reduce battery related costs, it is important to manage the timing of charge. In addition, battery deterioration affects the efficiency of AGVs. Frequent charging owing to a decrease in the capacity due to deterioration interferes with the AGV operation and reduces the efficiency of the AGV. Therefore, to minimize the total cost, it is necessary to prevent battery deterioration and increase the efficiency of the AGV by determining the appropriate battery management strategy. Fig. 1 shows the relationship between these factors and a battery management strategy as well as battery related costs. As shown on the left-hand side of the figure, the following items should be considered in the battery management strategy.

(a) Charging methods

According to Ebben [2], there are three types of charging methods: battery swapping, using a charging rail, and recharging inside the AGV. In the battery swapping method, a discharged battery is swapped with a charged one and then charged outside the AGV. Using the charging rail, the batteries are charged by running the AGVs under a charging rail. Although this method is effective, it cannot always be used to full charge the batteries. In the case of recharging the battery inside the AGV, the AGV cannot be used while it is being charged. Therefore, AGV systems with heavy usage cannot be charged using this method.

(b) Number of chargers and batteries

It is necessary to have a certain number of batteries and chargers to full charge the batteries. Thus, a limited number of batteries and chargers accelerate battery deterioration.

(c) Timing of charge

Timing of charge is important in battery management, because, on one hand, frequent charging extends the battery life, while on the other hand, it restricts the AGV availability.

(d) Timing of battery disposal

From the viewpoint of cost of batteries, batteries should be used for as long as possible. However, in the case of deteriorated batteries, the number of charging occurrences increases because of their reduced capacity. In addition, there is a risk of AGV stoppage due to energy shortage. Therefore, the timing of battery disposal is an important factor to be considered in battery management.

With regard to cost, the following items should be considered in battery management for AGVs.

(a) Initial cost of batteries and chargers

This depends on the charging method, number of batteries, and number of chargers.

(b) Battery replenishment cost

This is the cost of disposed batteries that must be replaced.

(c) Losses due to AGV stoppage

Improper management of batteries may cause AGV stoppage. Losses induced by AGV stoppage are evaluated by considering the costs incurred to recover the production losses.

(d) Labor cost for charging

This cost is incurred when battery swapping is adopted as the charging method. It is evaluated in terms of the time required for battery swapping.

3 MODELING CHARGE-DISCHARGE AND DETERIORATION CHARACTERISTICS OF LEAD-ACID BATTERIES

3.1 Attributes of VRLA batteries

As indicated in the previous section, identifying the state of batteries is essential for battery management. The state of batteries is represented in terms of state-of-charge (SoC) and state-of-health (SoH). These terms are defined as follows:

(a) SoC: ratio of residual capacity to nominal capacity.

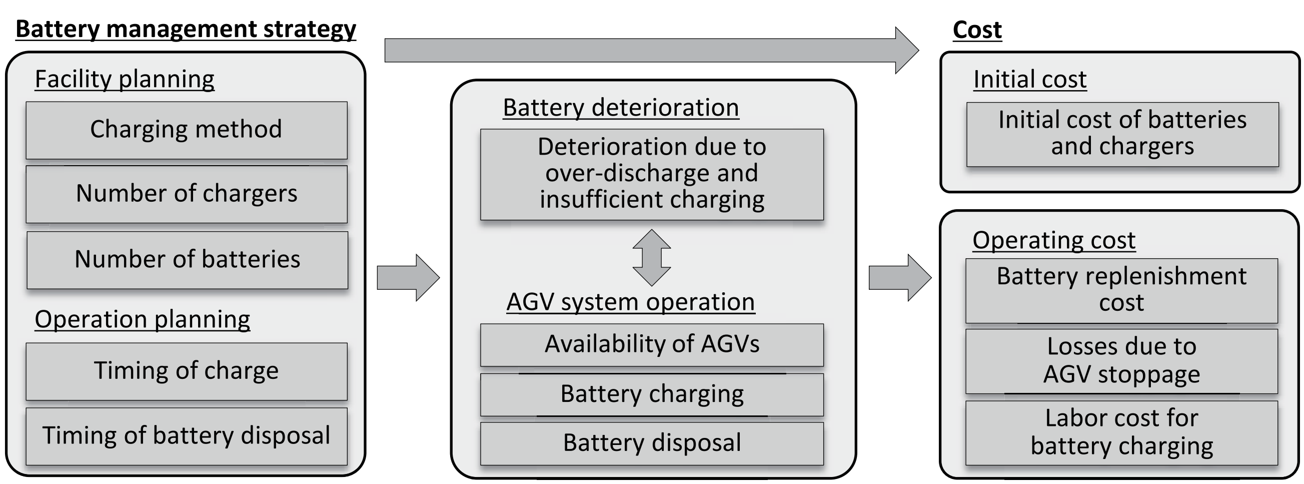

Fig. 1: The relations between battery management strategy and cost

Residual capacity is the stored electrical charge. It decreases as the battery discharges.

(b) SoH: ratio of available capacity to nominal capacity. Available capacity is the actual capacity of a full charged battery. It decreases as the battery deteriorates.

Battery deterioration affects the efficiency of AGV systems and vice versa (here, the efficiency of AGV systems includes that of batteries as well as that of AGVs). These relationships are shown in Fig. 2. Depending on the operation mode of AGVs, the batteries are charged and discharged. The changes in SoC induced by the charge and discharge operations affect the progress of battery deterioration. Decrease in SoH due to battery deterioration affects the way a battery charges and discharges. Typically, low SoH results in frequent charges, which disrupts the AGV operation and restricts the availability of AGVs. On the other hand, excess deterioration of SoH results in the disposal of the battery, as shown in Fig. 2.

Hence, for efficient AGV operation and cost-effective battery management, it is important to estimate the SoC and SoH of a battery.

3.2 Model for estimating available capacity of battery

To evaluate the SoH and SoC of a battery, we used Schiffer's model [4]. With this model, we can evaluate the progress of deterioration of a VRLA battery due to improper battery usage, such as insufficient charge, varying rates of discharge, and varying times between full charging. A simplified flow diagram of the model is shown in Fig. 3. In this model, the following dominant deterioration modes of VRLA batteries are taken into account.

(a) Grid corrosion

Grid corrosion is the main cause for deterioration of backup batteries. This effect is also non-negligible in case of cycle-use batteries, such as those used for AGV. The progress of grid corrosion proceeds with time, and is accelerated with high temperature and high terminal voltage.

(b) Degradation of active material

In the case of batteries used in AGV systems, the main cause for deterioration is the degradation of the active material. As batteries repeat cycles of charge and discharge, the composition of the active material changes, which causes deterioration of the batteries. The cumulative amount of discharge during a battery's life-cycle has a deciding effect on the deterioration of active material. This effect is further divided into two modes: sulfation of active materials and fining of active material particles and adhesion defects. The rate of deterioration of the former mode is accelerated when the batteries remain for long periods in a discharged condition. On the other hand, the rate of deterioration of the latter mode is accelerated when the battery over-discharges during charge and discharge cycles.

Using the model, at each point in time we can calculate the battery's SoH and SoC by setting battery-dependent parameters and inputting operation data such as charging and discharging current and ambient temperature. Battery-dependent parameters can be determined from the battery specifications and operating experiences.

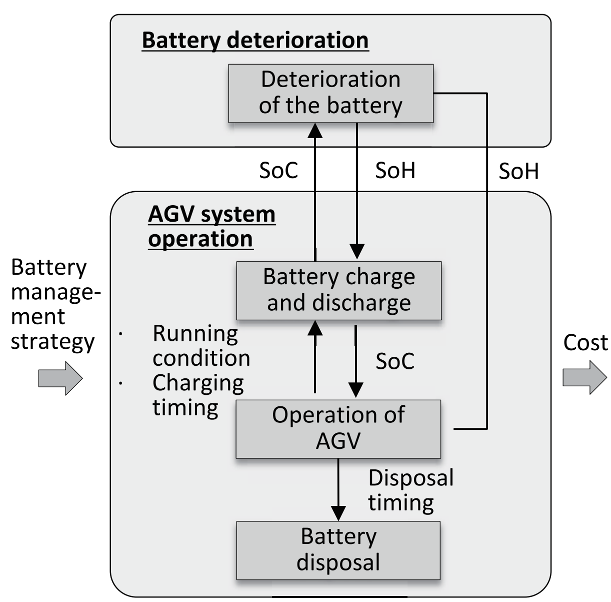

Fig. 2: Relationship between battery deterioration and AGV system operation

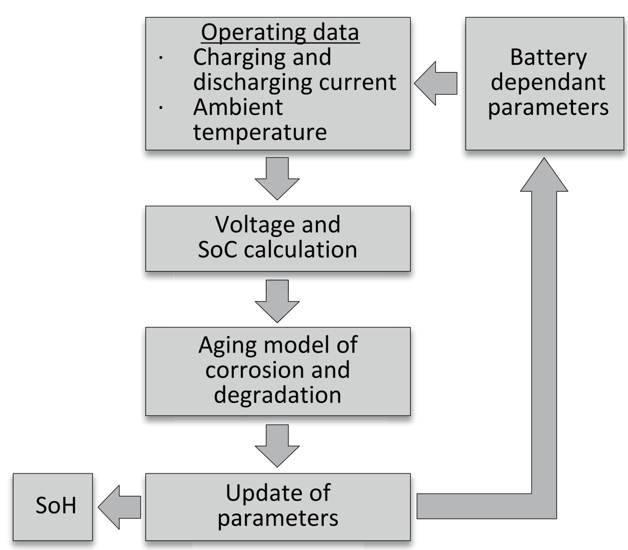

Fig. 3: Simplified flow diagram of model [4]

4 BATTERY MANAGEMENT STRATEGY PLANNING FOR AGV SYSTEMS

4.1 Simulation-based planning of battery management strategy for AGV systems

In planning the battery management strategy, we try to minimize the battery related cost, consisting of:

- "Battery acquisition cost" = "battery unit price" × "number of batteries",
- "Battery charger acquisition cost" = "battery charger unit price" × "number of battery chargers",
- "Losses due to AGV stoppage" = "number of AGV stoppage instances" × "influence rate per AGV stoppage",
- "Labor cost for battery charging" = "number of charging instances" × "labor cost per charging".

The influence rate per AGV stoppage is calculated as the overtime charge required for recovering the losses induced by the AGV stoppage.

The above cost items, except for the battery charger acquisition cost, vary depending on the AGV system operation, which is affected by the SoH of each battery. For example, the charging of a battery may be stopped before being full charged, when another battery on board becomes empty and requires charging. Therefore, it is not easy to analytically estimate the battery related cost. To cope with this problem, we adopt a simulation based approach in determining the battery management strategy.

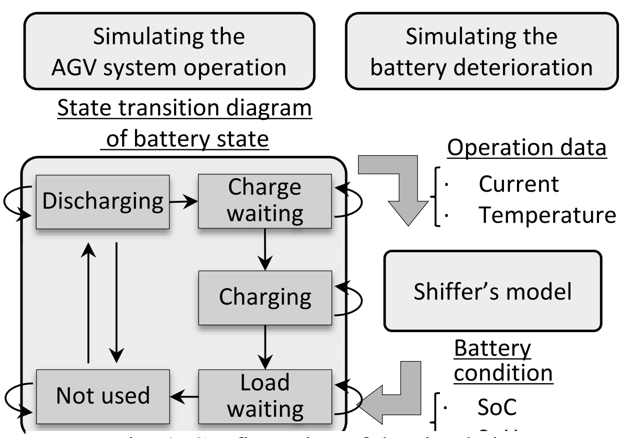

Fig. 4: Configuration of the simulation

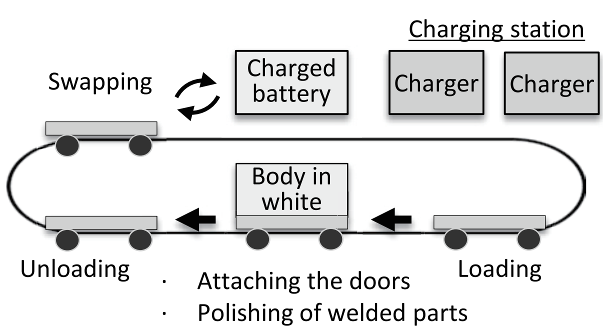

Fig. 5: Outline of the AGV system

4.2 Simulation system

In the simulation, the state of the AGV operation, including battery usage and the state of each battery, is calculated at each point in time. By running the simulation over an evaluation period, we can obtain the number of disposed batteries, number of charging events, and number of AGV stoppages. The configuration of the simulation consists of two modules, as shown in Fig. 4. The module on the left side of the figure is for evaluating the AGV system operation. In this module, the state of the AGVs and batteries are determined from the state transition diagram. The charging and discharging current at each point in time is estimated depending on the states of batteries. The module on the right side of the figure is for calculating the battery conditions. The conditions of batteries, such as SoC and SoH, are estimated using Schiffer's model, by getting from the left-side simulation module the charging and discharging current, as well as the ambient temperature. The state transition is determined by considering the battery state and the AGV location.

5 APPLICATION OF SIMULATION TO AGV SYSTEM IN ASSEMBLING LINE OF AUTOMOTIVE MANUFACTURING PLANT

5.1 AGV system for body in white at finishing line

To demonstrate the effectiveness of the proposed planning method, we take as an example an AGV system used in an automotive manufacturing plant. Fig. 5 shows the outline of the AGV system for a single-loop-type finishing line. In this line, 50 AGVs are used to transport the body in white, while doors, bonnets, and trunk lids are attached to the body in white, and the welded parts are polished. Production is carried out in 2 shifts. It takes approximately

Table 1: AGV system operating conditions

Items	Values
Number of vehicles production in a day	800
Number of shifts	2
Number of AGVs	50
Time of AGV to rotate the line	45 minutes
Battery swapping time	1 minute
Amount of electricity to rotate line	3.6 Ah
Battery type	VRLA battery
Nominal capacity of the battery	65 Ah
Time of full charging	about 6 hours
Location of battery chargers	end of the line

Table 2: Values for cost calculation

Items	Values
Battery price per unit	38,000 yen
Battery charger price per unit	78,000 yen
Influence rate per AGV stoppage	500 yen
Labor cost per charging	100 yen

50 minutes for an AGV to rotate the line. Battery swapping is adopted for charging the batteries. The discharged batteries are unloaded from the AGV and the charged batteries are loaded using a first-in, first-out strategy at the charging station. It takes approximately one minute to swap a battery.

5.2 Execution of battery management simulation

The simulation is executed using the AGV system operating conditions listed in Table 1. The parameters of Schiffer's model used for calculating the battery state are determined primarily based on the values used in Schiffer's paper [4]. They are modified based on the battery specifications and operating experiences. The changing pattern of the discharged current, when the AGV makes a circle in the line, is assumed to be identical, because each AGV rotates in the same loop.
In the simulation, the following set of conditions is chosen as the baseline condition.

- SoC at which the battery is charged: 0.4
- SoH at which the battery is disposed: 0.8
- Number of battery chargers: 100

Each condition is changed from the base line condition, that is, SoC in the range of 0.2–0.5, SoH is set in the range of 0.6–0.9, and the number of battery chargers in the range of 30–150. The evaluation period is set to 10 years. The costs of the various items are indicated in Table 2.

5.3 Results and discussions

The simulation results provide useful information in determining the proper battery life cycle management strategy.

Fig. 6 shows the changes of battery related costs for varying SoC, which is the criterion for charging the battery. The figure shows that the larger the SoC is, the lower the acquisition cost of the batteries becomes. This result is reasonable because larger SoC values are preferable for the battery life. On the other hand, as seen in the figure, the labor cost for battery charging increases as SoC increases. This is because frequent battery charging is needed to achieve larger SoC values. Therefore, to minimize battery related costs, we need to select the proper SoC value as the charging criterion.

Fig. 7 shows the changes of battery related costs for varying SoH, which is the criterion for battery disposal. The figure shows that large values of SoH, which means early disposal of the battery, lead to increased battery acquisition cost. On the other hand, small SoH values indicate that the battery is used even in a deteriorated condition. Since in this condition frequent charging is required, the smaller the SoH becomes, the larger the labor cost for battery charging becomes, as seen in Fig. 7. Therefore, to optimize the timing of battery disposal, we also need to select an appropriate SoH value.

Fig. 8 shows the changes of battery related costs, for a

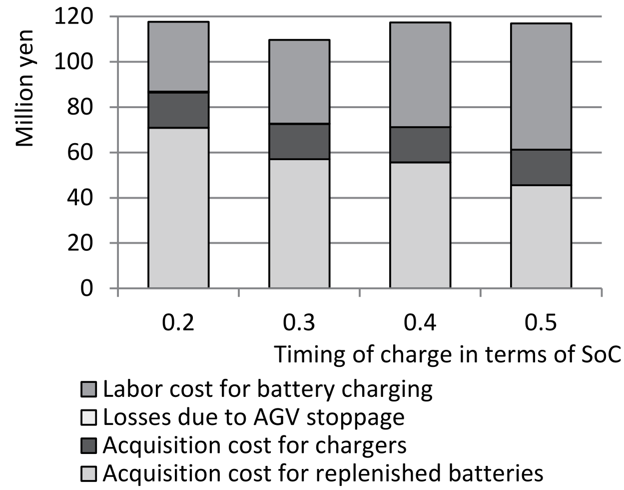

Fig. 6 : Changes in battery related costs with changes in timing of charge

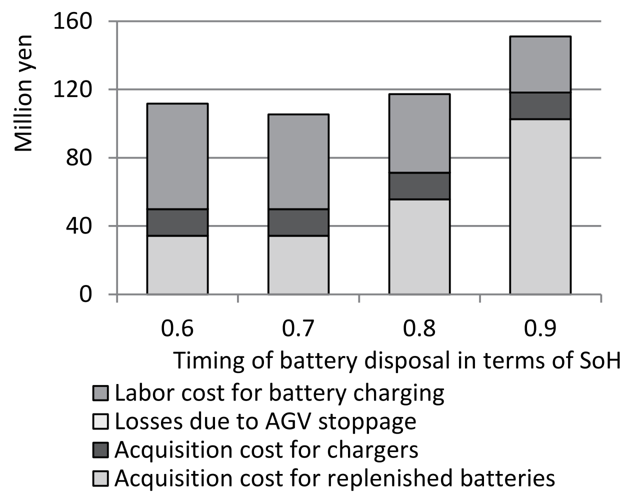

Fig. 7 : Changes in battery related costs with changes in timing of battery disposal

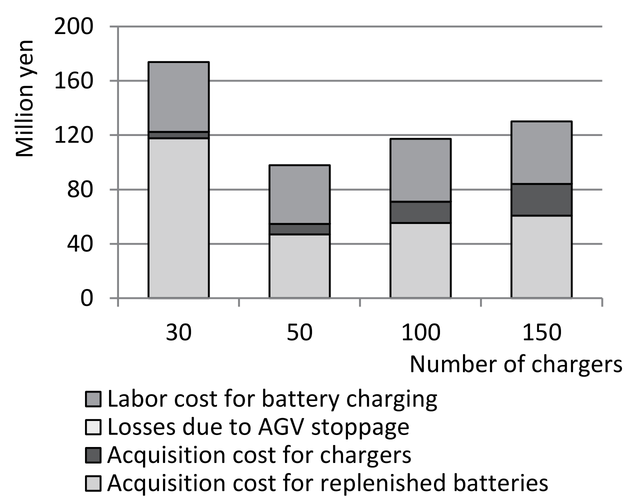

Fig. 8 : Changes in battery related costs with changes in number of chargers

varying number of battery chargers. The figure shows that a small number of chargers lead to an increase of the battery acquisition cost. In this example, the number of batteries is set to the sum of the number of the AGVs and the chargers. Therefore, the smaller the number of chargers means the smaller the number of charging batteries. Since the demand rate of charged batteries is constant, when the number of AGVs in operation is constant, the smaller number of batteries in the charging station results in shorter charging time, which could accelerates battery deterioration. On the other hand, excess number of battery chargers, results in the increase of the acquisition cost of replenished batteries. Because, in this setting, the total number of batteries increases proportionally to number of chargers, the total amount of deterioration due to grid corrosion, which progresses with time, increases. Therefore, to minimize battery related costs, we also need to select the proper number of chargers.

6 CONCLUSION

We have developed a battery management simulation to evaluate battery related costs, in a given AGV operation mode and to plan appropriate battery management strategy. In this simulation, the deterioration of VRLA batteries is calculated using the Schiffer's model. The effects of the battery management strategy on AGV system operation are evaluated by calculating, at each point in time, the states of each AGV and battery. This simulation can be used to plan a battery management strategy that minimizes the battery related costs, which include the initial cost of batteries and chargers, battery replenishment costs, losses due to AGV stoppage, and labor cost for battery charging. To verify its effectiveness, the simulation is applied to a body in white at the finishing line of an automobile manufacturing plant. The simulation results show that to determine the optimal battery management strategy, we need to take into account complicated relationships. For example, in determining the timing of charge and timing of battery disposal, the trade-off relationship between the acquisition cost of replenished batteries and the labor cost for battery charging should be considered. It is also necessary to consider different deterioration modes of batteries in determining the number of batteries. A small number of batteries accelerate the sulfation of the active material. On the other hand, an excess number of batteries induce a large amount of grid corrosion.

Because it is challenging to optimize the battery management strategy when considering these complicated relationships, the next step in our work will be to develop an optimization method for computing battery management strategies.

[1] Fraunhofer Institute for Reliability and Microintegration (IZM), Berlin, Germany
[2] Technical University of Berlin, Berlin, Germany

Abstract
Over the past years a new concept has evolved to combine eco-optimization with reliability aspects. As a short phrase we have coined the word eco-reliability, which we would like to explain and explore in the following paper.

Keywords:
eco-reliability, trade-off analysis, multi-criteria optimization

1 INTRODUCTION

In a nutshell the accurate life time of a product is an underrated and often diffuse influence on the environmental performance of a product. On the other hand the reliability optimization of a product can lead to an over-use of resources, if an unrealistically long or harsh use time is targeted.

For both domains – the environmental and the reliability aspects – and for the resulting economic implications a better understanding and analysis of the "correct" life time is required. In consequence, there is a need to optimize such situations with domain-spanning trade-off tools, which are not yet available.

Compared to the previous conceptual paper [1] we would like to give more details on the trade-off mechanisms and the directions for devising practical tools in the future.

2 LIFE TIMES AND OBSOLESCENCE DRIVERS

Increasingly, the different concepts for life times of electronic systems are recognized as major influences on the environmental performance. Yet, most assessments have to be limited to one highly aggregated and averaged use case, where the actual expected active use and the ecoefficient life time is determined by such diverse factors as reliability, accidents, technical progress and fashion (see Table 1).

Life times in environmental assessments are usually condensed and averaged use patterns, which are assumed uniformly over the life time. Only in very specific cases are different user groups, or differing sequential use patterns distinguished (such as household or company internal re-use cycles). The life time ends when disposal or recycling is initiated to destroy the shape of the product, although most often inactive shelf storage is not counted as part of the life time. This is most often the case when there is a preselection to investigate energy use rather than material use. When material flows are in the focus of an analysis, especially in the form of dynamic material flow analysis, the model to capture life time is completely rebuilt compared to a standard life cycle assessment.

In the reliability domain we are in contrast dealing with probabilistic life times, which are often based on mixed

Table 1: Obsolescence drivers

Domain	Obsolescence effect
Reliability	Fail due to ageing
Reliability	Fail due to overstress / accidents / misuse
Technical progress	Technical obsolescence due to incompatibility with new standards or e.g. new software requirements
Technical progress	Efficiency obsolescence, when efficiency gains are high enough that early scrapping of equipment is preferable even when including all life cycle aspects
Economics	Economic obsolescence, when total cost of ownership is lower through earlier replacement
Economics of consumables	As a special case, when consumables are either not on the market anymore (see "incompatibility") or when buying a new product costs less than a set of consumables for the old product
Economics of bundle contracts	When a new contract with bundled hardware is more economic for the user, the old hardware is usually obsolete
Fashion	Obsolescence due to changes in fashion or design expectations, while product may still be fully functional

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_78, © Springer Science+Business Media Dordrecht 2012

load mission profiles or on cyclic laboratory load profiles. If a reliable use time in years is defined at all it is by necessity a conservative assumption, based on many boundary conditions about load types, load times and load strengths. In addition, reliability by its main definition means that selected performance or degradation parameters stay within predefined ranges. Out of range values are then classified as fail, and the reliable life time ends. Nevertheless products may still be functioning and in active use, even when the internal parameters declare the product a statistical fail.

In summary terminology for use time and life time is very diffuse and sometimes ambiguous, and we do not intend to set new definitions at this point across all domains involved. For the discussion of eco-reliability approaches and even more so for actual investigations the awareness for the potential mismatch of "life time" concepts in the different domains is an essential factor, however.

3 THE QUESTIONS TO ASK

At the core eco-reliability is a trade-off analysis spanning multiple design domains. A selection of design domains or partial models affected are depicted in Fig. 1.

A conventional trade-off involves sacrificing one result or parameter in order to improve another aspect of the system under investigation. The underlying assumption is therefore that one key performance indicator is improved to the detriment of one or more other performance indicators. In a wider sense, however, the performance parameters do not always have to be at cross purposes, and understanding and quantifying any correlation or linkage – irrespective of signs – constitutes a trade-off analysis. The result of the trade-off is then a better understanding of the mechanisms involved and a subsequent multi-criteria optimization to determine one feasible compromise solution.

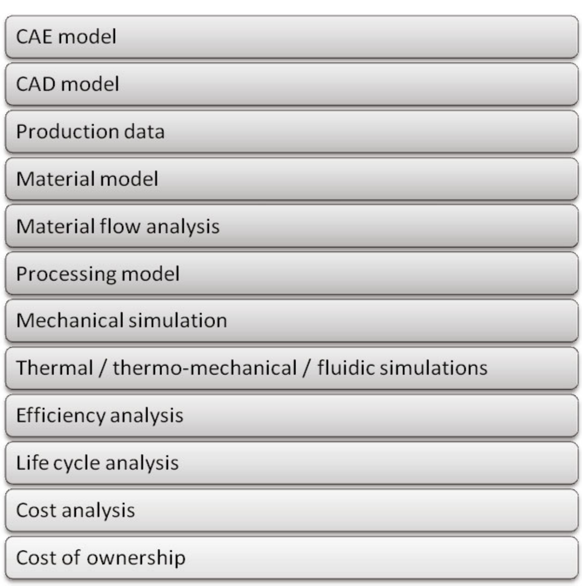

Fig. 1: Example design and modeling domains

Note that the scale directions are not always unambiguous, hence an increase in one parameter and a decrease of another parameter may be an improvement in both cases rather than a traditional trade-off situation. Replacing energy usage with energy efficiency will for example invert one scale of the problem and therefore completely change the optical interpretation without changing any facts.

Where a conventional trade-off would occur within the frame of one modeling approach or in very few cases combining two modeling domains, in the future more complex linkage between various models – and potentially still separate tool environments – will be necessary.

Provided that the software complexity and the data exchange can be solved – what would be the questions which could be answered additionally, more fully or more precisely than before? The following list gives a first impression, which is then referenced in the following case discussions:

- Toxicity vs. energy use
- Production resources vs. use energy
- Reliability vs. resource consumption
- Better sensitivity on life time assumptions
- Better sensitivity on user averaging
- Inclusion of efficiency trajectories

4 MORE DETAILED CASE DISCUSSIONS

4.1 Starting Simple: General Lighting

Energy efficient lighting presents various trade-offs relating to eco-efficiency. With the option of compact fluorescent lamps (CFLs) additional toxic potential has been introduced when compared with conventional light bulbs. But the improved energy efficiency was considered to outweigh the added toxicity, hence leading to the staged phase out of incandescent lamps in the EU under the Ecodesign directive [2][3].

This has been confirmed many times in retrospect: conventional light bulbs emit more mercury via the conventional energy generation mix than could be released from the replacement CFLs by breaking all CFLs at end of use. Therefore despite introducing additional toxicity in products the total toxic potential is reduced. This is a trade-off between differing environmental impact categories – a still contentious topic in the life cycle assessment community, as in the end it is often a societal or political decision, rather than a scientific decision.

The favorable balance for CFLs rests on another key parameter: the expected average life time of each technology. For general lighting the relevant life time is the cumulative use time, sometimes to be analyzed in conjunction with the number of switch cycles. If the difference between average maximum use times of the competing technologies were smaller than the current factor of ten then the amortization of higher production expenditure (for CFLs) and additional toxicity would not be quite as favorable. This is a case of trade-off between the reliability of the product versus its key environmental performance. In reality, however, some CFL products did not reach the declared life time, while some incandescent light bulbs far outlive the test standard of 1000 hours active use.

Hidden behind the average technical life time is the complexity of actual use times. For many lighting situations use times are so low and non-uniform that the mercury emission amortization will never occur. Nevertheless, the average must by definition be a solid base for political decision making, as other replacement bulbs will obviously have to have even better return on invest in terms of energy, mercury emissions or energy costs. This is a case where a more complete inclusion of use cases would bring better understanding of (local or individual) adverse effects of the technology change.

Even though ecoefficiency and eco-reliability are in favor of CFLs compared to incandescent lighting, there remains a potential draw back regarding dissipative use of valuable resources. This trade-off is still not straightforward to evaluate quantitatively, as to some degree a higher use of resources should be permissible to achieve longer life times together with higher efficiency. The root problem here is that resource loss is even more difficult to trade-off against toxicity or energy in one modeling approach. If CFLs were recycled to a large degree then resource loss would not be a problem. However, recent reports have shown that in Germany many CFLs are simply crushed to go into underground special waste sites. If this continues and is done similarly in other parts of the world, then the trade-off between lower energy use and higher environmental burdens in production, toxicity and resource losses would come to the foreground once more.

With the next technology wave of light emitting diodes in general lighting the possibilities for improvement are even better. Toxic materials are drastically reduced and critical resources appear only in small amounts. Nevertheless, these trace amounts should in the future be recovered at end of life.

An LCA comparison of Osram dating from 2009 showed that in a life cycle assessment perspective the LED component and module production has less environmental impact than the production of the aluminum cooler [4]. So even though LEDs are continuously improving in luminous efficacy, the remaining waste heat is still considerable and occurs concentrated in very small areas, leading to high effort for sufficient cooling under all operating conditions.

The current trade-offs are therefore more closely related to the reliability and lighting quality for retrofit, bulb-shaped LEDs. If the thermal design is not sufficient or is not stable over the life time then the lighting efficiency and the technical life time will decrease. Thus, at the current state of LED efficiency and of the power conversion, resource use for the cooling cannot be minimized without compromising the other key performance parameters.

The comparative equivalence of LED compared to CFLs in the production phase once more rests directly on the assumed technical life time. In the Osram LCA study 25000 h were assumed for the LED version, compared to 10000 h for the CFL and the standard value of 1000 h for incandescent bulbs. With these values one LED bulb is slightly better than 2.5 CFLs regarding primary energy consumption, and equal or slightly worse for the environmental impact categories covered. Both are in the same range as the equivalent 25 incandescent bulbs for most impact categories, and score slightly better regarding in terms of global warming potential and primary energy demand. Changing the life time assumptions for example to 20000 h for the LED or to 15000 h for the CFL would change the manufacturing comparison from "roughly equal" to a clear advantage for the CFL technology.

In all cases the use phase by far dominated the total life cycle result, so overemphasizing the differences of the production phase is unfair. Nevertheless this is an example of trade-off between different life cycle phases, and by extension between the different players in the life cycle.

At the 2009 technology generation analyzed in the report LEDs could be shown to just draw equal to the environmental performance of CFLs, both far surpassing the incandescent bulbs, but as mentioned with the potential to improve LEDs further and faster that the alternatives.

This is not a prime example for the importance of efficiency trajectories mentioned above, but it will be worthwhile to investigate at some point, whether replacement of early generation LEDs in high use profiles before they actually fail would be a net environmental benefit.

If so, should they be recycled as fast as possible to replenish the resource base, or should they be kept in storage until the recycling efficiency for certain elements has increased (another efficiency trajectory), or should they be employed for less intensive use cases, where newest technology does not pay off? The questions never end, and so far there are no adequate tools to answer these questions.

4.2 A Look at Energy Harvesting

Mobile and non-mobile local power supplies are another area for making eco-reliability investigations. While not reaching the visibility and the global environmental impact of lighting, consider that these are product types sold in millions in many countries of the world.

Once more, realistic use times and life times are key parameters for comparing established technologies (in particular primary and rechargeable batteries) with new options (such as fuel cells and energy harvesting).

In current work to be presented in a separate paper at EcoDesign 2011 the focus is set on comparing differing energy harvester solutions against the longer term use of batteries for distributed sensor nodes. To put this into perspective, also these products are projected to reach multi-million markets in the next years.

The basic trade-off is between the up-front technology and resource investment for the energy harvester, which then needs no additional energy resupply and – in the best scenario – no further maintenance at all. Batteries in comparison need to be replaced when looking at use cases over multiple years, leading to requirements of accessibility, constant maintenance planning, and either the production of the replacement batteries or the energy conversion for recharging in case of rechargeable batteries.

For now the focus is set on comparing the secure energy availability over a specified time against the environmental concerns such as potential toxicity and use of scarce resources.

For future investigations the reliability of the micro harvesters (technical life time limitations) will be of interest, as will be the trajectory combinations of the batteries and harvesters on the supply side and the sensor or microsystems on the energy demand side.

4.3 General Application Areas

Note that the general lighting examples are the "simplest" examples to introduce eco-reliability as a concept. Much more interesting, but also much more challenging, are similar trade-offs in mobility, alternative energy, industrial electronics and ICT (see Fig. 2).

Life time variation (technical product realization, but also influence of the operating conditions), use time variation (involving overlays of the different kinds of obsolescence, but also a spread of different use cases) and the time dependency are the key parameters to bring together. The resulting base data or scenario variations can then be coupled with any environmental assessment procedure.

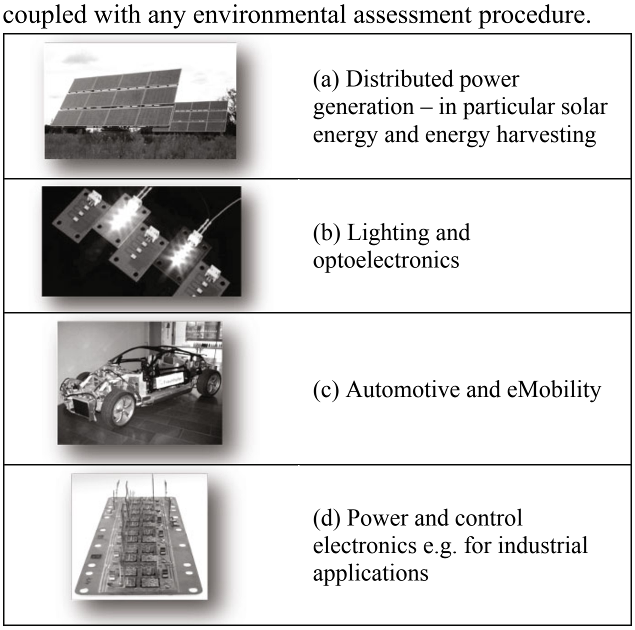

Fig. 2: Application areas for eco-reliability

5 SUMMARY

Seen within the framework of ecodesign of electronic products there are two main configurations where eco-reliability can serve as guidance. The main route of investigations concerns products and systems, where extending the life time or the factual accumulated use time is beneficial for the overall resource balance. These are systems, where additional resources during the generation phase might be justified by the very long use times or by multi-life-cycle concepts.

On the other hand there are systems, where the life time in effect need not be extended, because some form of obsolescence will occur before the technical life time is ever achieved. Reasons for obsolescence can be intentional one-time use, fashion, changing technical standards, or an efficiency race condition. For these systems the optimization path should be to minimize the value of materials used, and to ensure product take back and high grade recycling.

There are many system types between these extremes, where it is necessary to determine trade-offs and conflicting requirements already during the design. Models for parameterized trade-off analysis are therefore the core of the approach. But the modeling still needs to be very specialized depending on the application field, such as lighting, decentral energy generation, electro-mobility or industrial power electronics, and no uniform tool approach can be predicted at this stage.

The new combination of reliability and environmental assessment provides the basis to better distinguish, when to invest scarce resources intentionally, and when to limit their use unless proper recovery management is in place. In the end often a balance between energy efficiency over the whole life cycle and resource efficiency has to be determined, and the reliable life time has a major influence on the overall cost and environmental balance.

Sustainable design strategies in practice and their influence on business models

Elli Verhulst [1, 2], Casper Boks [2]

[1] Department of Design Sciences, Artesis University College Antwerp, Antwerp, Belgium

[2] Department of Product Design, Norwegian University of Science and Technology, Trondheim, Norway

Abstract

Developments towards sustainable product innovations receive a growing attention in business as a result of several driving forces. Incorporating strategies for sustainable product innovations in a firm takes a longitudinal implementation trajectory. During and after the implementation of strategies for sustainable design, sustainable business models can emerge. This paper describes insights from practice – based on an empirical study in business cases- on how the implementation of sustainable design strategies in practice may contribute to business models evolving into sustainable business models. The results suggest two trajectories: sustainability can be added to the standard business model leading only to limited changes, or the implementation of the strategies lead to the development of a new business model that delivers more sustainable outcomes. The influence on the business model is indicated in the study to depend on the choice of strategy for sustainable product innovations and on the maturity of the firm.

Keywords: sustainable design strategy, business models, case study

1 INTRODUCTION

A growing number of firms realises that action is needed in order to follow current developments towards sustainable product innovations. Several types of pressure from various stakeholders thereby make them take action within product design, development and manufacturing [1]. However, incorporating sustainability in a firm asks for a long term transition in order to make product innovations sustainable. Different scholars motivate the importance of studying the implementation process of a strategy for sustainable product innovations, emphasizing that the main challenge of applying sustainable product innovations is not (just) in the development and formulation of a sustainable strategy and vision, but in the implementation of this new strategy in a firm [2], [3], [4]. During this implementation process, the theoretical strategy needs to be translated into practice. Also during, or as a result from the incorporation of sustainable product innovations, sustainable business models are found to emerge in practice. The introduction of such a strategy in the firm -by the occurrence of different activities- can grow in time and finally result into an (un)intended (sustainable) business model [5]. Zott and Amit [6] emphasise that the order of developing and implementing a product strategy or a business model can be interchanged. This paper explores the emergence of these business models during the implementation of strategies for sustainable design. First, literature on (sustainable) business models is briefly described, subsequently followed by the results of a qualitative study that provides empirical insights on the emergence of sustainable business models in practice. This paper thereby aims at linking theoretical and empirical insights on the implementation of sustainability criteria on a product development level, with a higher level in the firm that focuses on business innovation.

2 INNOVATION THROUGH (SUSTAINABLE) BUSINESS MODELS

In comparison to past and recent product innovations that often occur on a technical level, innovation of the business model focuses on a higher level in the firm and aims at adding value for all departments in the firm. Business models therefore link technical inputs and economic outputs of a firm, in other words converting new technology into economic value. The value of products and services forms a crucial element for firms [7]. The creation of value therefore forms a central element in a business model. A business model is defined as a depiction of the content, structure and governance of transactions designed so as to create value through the exploitation of business opportunities [6]. The value thereby refers to the total value that is created in the transactions, regardless of whether it is the firm, the customer, or any other participant in the transaction who appropriates that value. Content, structure and governance are described as the three constructs of a business model [6]. Several other authors consider four main areas in business that need to be covered in a business model: infrastructure, value proposition, financial viability and customer interface. These areas are sometimes further divided into six to ten attributes [8], [9], [10].

A sustainable business model (SBM) can 'tell the story of sustainability' within a firm by showing how sustainability is imbedded in the four main areas, related to content, structure and governance of a firm and its partners. In this

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_79, © Springer Science+Business Media Dordrecht 2012

sense, the incorporation of sustainability criteria in a firm's business model is mentioned as another way to support eco-innovations [11]. However, until now, few theoretical frameworks and empirical cases serve as an example for the development of sustainable business models.

The incorporation of sustainability criteria in the business model is seen by some authors as adding separate attributes next to the four main attributes: social and environmental costs and social and environmental benefits form two supplementing attributes [12], [13]. However, this view of separately adding these attributes might restrict a full integration of sustainability criteria in the business model and thus also in the firm. Traditional approaches are often restricted by such a partial integration [14]. An example is corporate social responsibility (CSR) where environmental and social issues often get relegated to the margins of company activity, stay unrelated to the core activities of the company (such as product design, development and manufacturing), and as a result these issues are not seen as an integral part of the business. More holistic approaches are proposed by other authors. One is proposed in the form of a conceptual framework of business model eco-innovation [5]. The business model canvas of Osterwalder and Pigneur [9] is thereby incorporated in a broader framework that includes the development side of marketable eco-innovations, the incorporation of economic, ecological and social aspects in the model as well as marketing and successful implementation of the eco-innovations. Another holistic approach proposes a system-based sustainable business model that is based on two company cases, in which both the socioeconomic as well as the natural environment are included [15]. The sustainable value framework [16] on the other hand combines sustainability drivers and opportunities with four basic components that create value for the shareholders, which are mapped according to two dimensions: time and activity boundaries (internal versus external). The four components are innovation and repositioning, cost and risk reduction, growth trajectory, and reputation and legitimacy. The availability of these, mostly conceptual, models and frameworks are of great value, although they need further development and verification in practice.

3 INSIGHTS FROM PRACTICE

This paper describes the results of an empirical case study in which eight business cases provide qualitative data and profound insights on the emergence of sustainable business models during the implementation process of sustainability issues in product innovations. In order to select appropriate business cases three criteria have been used. The eight business cases were selected on basis of a) being actively involved in product development and related activities, b) being in the process of integrating sustainability criteria in the firm and in product development, and c) being geographically situated in Belgium (Flanders) or the Netherlands. This geographical boundary limits differences in legislation and national culture, whilst it simultaneously increases the accessibility of the sites to be visited.

A combined set of qualitative data from different sources set [17] is used to analyse and study the business cases: interviews, archives and documentation and observations, of which the interviews form the main data source. In each business case, employees were addressed that are related to both product development and the process of implementing sustainability criteria in product development or in the firm. The analysis of the empirical data has been done in two main stages, of which the first has a descriptive nature, whereas the latter is explanatory. In a first step, different topics that have been touched in the data set were coded and subsequently clustered. A second part of this step contained the description of the phenomenon under study, i.e. the emergence of sustainable business models during the implementation process of sustainability in product development, subsequently followed with an analysis of each case. In a last step, a cross-case analysis between the different business cases has been made. Table 1 presents an overview of the business cases studied.

Table 1: Overview of cooperating firms

Case	Product	Product sector	Firm's size	Experience with sustainability issues
Case 1	creation of durable working, learning and living environments	Furniture	Large	Experienced Since 1990
Case 2	display and visualisation solutions	Electronics	Large	Starter Since 2009
Case 3	ergonomic office chairs	Furniture	Medium	Experienced Since 1997
Case 4	space-saving, functional and modular furniture	Furniture	Medium	Starter Since 2007
Case 5	sheets and films	Chemical industry	Large	Starter Since 2007
Case 6	electronic consumer goods	Consumer goods	Large	Experienced Since 1994
Case 7	quality aluminium systems for external use	Construction industry	Large	Starter Since 2006
Case 8	public lighting systems	Lighting equipment and traffic signalisation	Large	Starter Since 2008

In the study, fourteen people cooperated from eight different firms, in total spread over sixteen interviews and observations during work sessions. Five of the firms have their headquarters in Belgium; the three other firms are situated in the Netherlands. The functions of the respondents vary within the different firms: as a coordinator of Corporate Social Responsibility (CSR), coordinator of quality, health and environment, communication manager, or R&D manager. The business cases do not necessarily have the same maturity level of implementing sustainability in their business innovations; a distinction is made between starters and experienced firms. The starters are considered as firms that recently started their explorative trajectory, trying to find out what fits best to the firm and its products, which should lead them towards more sustainable products. The 'experienced' firms have been mostly incorporating and reporting on sustainability aspects for more than ten years. This does not mean that all the work has been done, as all of them are currently working on improvements in order to reach a higher level of maturity when it concerns sustainability.

4 EMERGENCE OF SUSTAINABLE BUSINESS MODELS

This paper forms a part of a broader study that entails a study of the complete implementation process. In this paper however, we do not go further on the description or analysis of the implementation process of sustainable design in the cases businesses due to space boundaries. This paper is limited to the study results on the emergence of sustainable business models.

4.1 Sustainability in the business model

The empirical data have been ordered according to the four main areas of a business model [8] and thus represent how different aspects related to strategies for sustainable product innovation influence the business model of that firm. In order to limit the space used, Table 2 shows how this is the case for two of the eight firms that cooperated in this study. The complete table points out a selection of findings according to the elements of a business model as described in section 2, suggesting how the implementation of the sustainability strategies influences the content of the business model.

A first indication that comes forward is a variation in impact on the business model between the business cases depending on the strategy and the experience of the firm, e.g. firms that incorporate a product-service system (PSS) versus firms that focus merely on material improvements, eco-efficiency or legislation. Product-service systems are indicated in the data set to occur in business cases 1 and 3 and were indicated to have a larger impact on the sustainable business model –i.e. on customer interface, infrastructure and financial viability- than is the case with e.g. eco-efficiency in product design.

The data also indicate a difference in impact on the business model between cases that have a common vision on and framework for sustainability and cases that do not have this common view on sustainability. In several of the cases that recently started the incorporation of sustainable design, a general vision was indicated to be lacking, whereby adaptation on sustainability occur on an individual project level. In this group of firms, adaptations in the sustainable business model stay limited to the margins of the company activity (e.g. cases 2, 4 and 7). This corresponds with the indication in literature on restrictions of traditional approaches [13].

As an example, the integration of sustainability in business case 4 leads to an improved value proposition and an adaptation of the key activities. On the other hand, the empirical data indicate that in firms with more maturity on sustainability, and where a general vision on sustainability is present -such as in business case 3- the changes that took or take place in the firm concerning sustainability issues seem to affect the value proposition, customer interface, infrastructure and financial viability of the business model. All four areas and the adaptations that

Table 2: Adaptations of the four main areas of a business model through the integration of sustainable design strategies

	Value proposition	Customer interface	Infrastructure	Financial viability
Case 3	Creation of leasing system for office chairs Ensuring closed-loop of products (leasing, take-back and recycling)	Leasing and take-back services for products	Sustainability network - sustainable suppliers - recycling companies - knowledge and research institutes Key activities and resources - take-back system - leasing system - sustainable marketing - ecodesign quality products - eco-efficient development and production - disassembly line	Leasing system Take-back system Material reduction for new products Eco-efficient production and infrastructure
Case 4	Light-weight, space-saving and modular furniture	-	Sustainability network - external experts - knowledge and research institutes Key activities and resources - projects in cooperation with partners from network	Cost-efficiency

occur in the empirical data are discussed below for each area.

Value proposition. It was found that the integration of a strategy for sustainable product innovation led to a new and (more) sustainable value proposition in all the business cases studied. This adaptation or change of the value proposition however does not equally influence the value creation in the different transactions in the other main areas of the business model (i.e. infrastructure, customer interface and financial viability) or towards the different stakeholders (firm, customer, other partners) [6].

Customer interface. The data from the different business cases indicate a low attention for the customer interface. In some of the cases, sustainability is not considered to add value to the customer. In other cases, some elements related to sustainability are identified that can support and strengthen customer relations and customer channels. This occurs mostly in the business cases that changed to offering PSSs, or in allready customer-oriented business cases. These insights suggest that, so far, the customer side of the (sustainable) business model is barely influenced by the implemented strategies, or rather, that the current strategies for sustainable product innovations insufficiently take account of this customer side.

Infrastructure. Cooperation in sustainability networks is mentioned in all firms, independent of the experience of the firm. External experts on sustainability occur in many of the cases, mostly in those that have only little experience with sustainability issues. In-house expertise on the other hand is indicated to occur only in firms with significant experience. A similar situation applies for cooperation with universities and research institutes, and for influence in the supply chain. The data suggests that the business cases that do not have a common vision and framework for sustainable product innovations mostly cooperate with external experts and partners in order to assemble and gain knowledge on sustainability issues. On the other hand, sustainability experts form an asset in the key resources of the other firms. Also in these cases, a sustainability network is indicated to rather have a strategic function with the aim to find allies on the same sustainability level. More and different partnerships thus arise as a result of the integrated strategy for sustainable innovation.

In all cases, key activities are indicated to become affected by the implementation of sustainability criteria in product innovations, next to a larger number and a different type of key partners.. Other, new activities occurred in some of the business cases, such as the development of new in-house expertise, the development and management of leasing and take-back systems, etc.

Financial viability. The data suggests that, especially in the early stage of implementing strategies for sustainable product innovations, low revenue streams are present in the business cases. The incorporation of sustainability criteria thus does not immediately lead to direct revenues for a firm, but it might already lead to cost reduction and efficiency from the start. This type of financial viability was indicated most often in the business cases. This cost-efficiency can also be considered as a part of the value proposition. As a remark, it should also be noted that the data in this study only provided limited information on the financial viability as an aspect of the emerging sustainable business models from the integrated strategies.

4.2 An example of an emerging sustainable business model: business case 3

This section gives an example of an emerged sustainable business model, based on business case 3 of this study. This firm followed an interesting trajectory towards sustainable product innovations, whereby different strategies were applied consecutively: starting from a focus on design for disassembly, the firm broadened their sustainable activities to an own internal disassembly line and a corresponding take-back system. However, in order to complete and ensure the closed material loop of their products, a new strategy was introduced: the leasing of their products. Although leasing is not new as a concept, i.e. for cars, it is an innovative approach in the furniture sector. The four main areas of a business model and how they are influenced by the implementation of sustainable design strategies are described subsequently for business case 3.

Value proposition. In this business case, the value proposition changed significantly by the introduction of a system to lease their products. The company switched from offering a product, i.e. office chairs, towards a product-service system (PSS). For both the firm as well as the customer, this created interesting opportunities, but also a new way of working, selling, distributing, maintenance and usage. For the company, it closes the material loop, because by offering the products as a service, the firm is guaranteed to receive all the leased chairs back. These can subsequently be disassembled, reused (parts) or recycled (materials) and manufactured into new chairs or other products. However, it also demands new methods and approaches for the sales department, as well as for distribution, maintenance and take-back.

Customer interface. Significant changes are indicated above to occur in the customer relationships, whereby much energy and time needs to be invested by the sales department to explain the new product-service combination to possible customers, the benefits of the system for the customers, the environmental gains from the system, and an explanation on the pricing of product and service that shows the financial consequences of the system in comparison to the traditional way of buying office chairs. However, the company did not approach new sales channels nor did it change focus towards other customer segments. The latter can be explained by the aim of the firm to be a frontrunner in a niche market. Entering other markets would mean that the leading position of the firm might get lost or threatened. The choice for using the current sales channels stems from the availability of multiple sales channels that differ depending on the country. This specificity of sales approach could get lost with the development of a new and uniform sales mechanism.

Infrastructure. The infrastructure of the business case was also indicated to have become affected significantly, as substantial changes were needed in the key activities, key resources and the key partners. New key activities were linked to the leasing and take-back system, whereby the sales, maintenance and service and collection of the products needed to get organised well. Moreover, the disassembly of the products happens in-house, which makes that the infrastructure has been adapted (assembly line), but also the employees needed education on the purpose and the procedure to follow. New partners entail recycling companies, suppliers of recycled materials and other sustainable materials, as well as other partners with which the business case cooperates in research and other projects concerning sustainable innovations.

Financial viability. All these changes also have repercussions on the financial viability, in which leasing contracts create constant and long-term revenue streams, as well as a strong and long-term connection with the customers. Moreover, the collection and recycling of materials saves (new) material costs, as well as an eco-efficient production and infrastructure lowers costs. On the other hand, the organisation and fulfilment of the leasing system with extra maintenance and collection asks for an adapted cost structure in which additional efforts and investments are needed for personnel, infrastructure and education. However, in this business case, the financial advantages were indicated to be merged with the other advantages that are created for the customers, the firm and the environment, which makes it a viable and attractive sustainable business model.

In this company, the integration of the applied strategies for sustainable product innovations clearly led to a new and sustainable business model that strengthens their approach and the value they create throughout the complete value chain.

5 CONCLUSIONS

The aim of this paper was to link theoretical and empirical insights on the integration of sustainable design on a product development level, with changes in the business model of that firm, which most often gets developed on a higher level in a firm. The business case data in this study suggest that initial implementation of sustainability in product design and development generally lead to changes in a firm's business model. However, changes range from a limited effect, where sustainability is a mere add-on in the periphery of business activity, to the development of a genuinely new business model. The difference in type of sustainable business model seems to depend on the chosen strategy for sustainable product innovations. The data suggests that focusing on product and process related activities do not lead to substantial changes in business models, whereas developing activities that span beyond products and processes, such as developing product-service systems, have a considerably larger impact on the business model and can thus lead to well-integrated sustainable business models, as shown in the example case. The incorporation of sustainability issues was indicated in all the business cases to lead to a new value proposition, a change in key activities and more and new key partners. Acquiring external experts as new partners seem to occur more regular in inexperienced firms, whereas more in-house experts are present in the more experienced firms. The customer side of the business model is indicated to be underexposed in several of the business cases and merits more attention in order to raise the total value creation of the business.

This study provides valuable insights on how sustainable business models emerge during the implementation of strategies for sustainable design, based on a qualitative study of eight business cases. Further research is recommended that focuses on a larger sample of business cases, whereby common strategies and approaches for sustainable design can serve as a starting point to study how the application of these strategies affect the firms' business models. Quantitative research can provide valuable insights and simultaneously measure the impact of certain aspects on the development of sustainable business models, which on its turn can support the integration of sustainable design in business.

Design for Remanufacture: Organisational Factors Influencing Successful Integration into the Design Process

Gillian D Hatcher[1], Winifred L Ijomah[1], James FC Windmill[2]
[1]DMEM, University of Strathclyde, Glasgow UK
[2] Centre of Ultrasonic Engineering, Electronic and Electrical Engineering, University of Strathclyde, Glasgow, UK

Abstract
Remanufacturing, the process of returning a used product to a like-new condition with a warranty to match, is widely recognised as an environmentally preferable end of life strategy for many products, being both an energy and material saving solution. How the product was designed can have a significant effect on how easily it may be remanufactured, and it is from this understanding that the concept of 'design for remanufacture' (DfRem) has emerged. The aim of this research is gain an understanding of the organisational factors that enable the successful integration of DfRem considerations into a company design process, through a series of case studies in the mechanical/ electromechanical sector. This paper presents the findings from case studies of two companies currently remanufacturing their products- one that is involved in DfRem, one that is not. A comparison of the two case studies has revealed that factors such as customer demand, remanufacturer communication and business priorities may have a significant effect on DfRem integration.

Keywords:
Remanufacture, design for remanufacture, organisational factors

1. INTRODUCTION

Remanufacturing is now widely recognised as an environmentally preferable end-of-life strategy for many products, being both a material and energy-saving process as well as reducing waste to landfill. The process involves returning a used product to original specification or better through inspection, disassembly, cleaning, reprocessing, reassembly and testing; and therefore much of the value from original manufacture is retained (Figure 1). A remanufactured product may be sold at a reduced price yet with a warranty that is equal to or better than a newly manufactured equivalent [1]. Products that are suitable for remanufacture can typically be described as durable (able to withstand the remanufacturing process plus multiple lifecycles) and of high value to ensure that remanufacture is profitable. There of course must be customer demand for the product once it has been remanufactured, which is most likely when that product is technologically stable. Examples of commonly remanufactured products include automotive parts, photocopiers and off-road equipment.

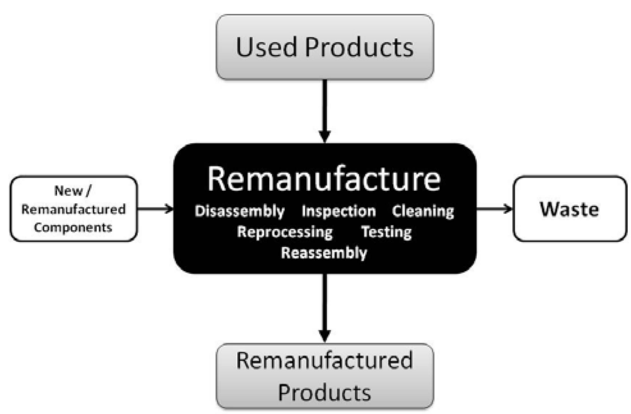

Fig. 1: The remanufacturing process

Previous research has indicated that the efficiency and effectiveness of the remanufacturing process can be greatly influenced by product design features and properties such as material choice, durability and ease of disassembly. It is from this understanding that the concept of 'design-for-remanufacture' (DfRem) has emerged, a design activity focused upon facilitating the various remanufacturing steps, thus promoting less

waste and more component reuse. However, very few products are currently designed for remanufacture, often limiting a producer's potential to maximise their gains from end-of-life processing. The reasons behind this lack of DfRem activity have yet to be fully explored, in particular organisational issues, the focus of this paper.

2. RELATED LITERATURE

DfRem has been a fairly popular topic in remanufacturing research over the past 15 years or so, and it is now widely recognised that there are certain product properties that can have a positive or negative effect on the remanufacturing process, depending upon how that product was designed. For example, if a product is designed to be more easily disassembled without damage this will improve remanufacturing efficiency, and if more durable materials are selected the product will be more likely to survive multiple lifecycles [2, 3]. Much of the previous research in DfRem has focused upon design methods and tools developed specifically for remanufacturing issues, either quantitative metrics and calculations [4, 5] or more qualitative design aids [6]. Others have proposed the use of existing methods and tools to enhance remanufacturability, such as modularisation [7] or QFD [8]. These papers offer new or innovative ways to consider remanufacturing during the design phase, however they do not consider how such methods and tools could be integrated into a complex company design process. Indeed it has not been considered whether the provision of DfRem methods and tools alone is sufficient for successful integration.

Similar research in the field of 'design for environment' or 'ecodesign' would suggest that organisational factors could also have a significant impact on DfRem integration into the design process. McAloone [9] found that designer and management enthusiasm were key factors in ecodesign integration success, as well as the timing of environmental decisions. Boks [10] focused upon the 'socio-psychological' factors of integration and concluded that issues such as cooperation and organisational complexities could be more important than technical issues such as tool development. Ammenberg and Sundin [11] emphasise the importance of having ecodesign as a prominent fixture in the design process, and propose greater inclusion of product design considerations in a company's environmental management system. Johansson [12] compiled a list of success factors based upon ecodesign integration literature, which included organisational concerns such as management, the development process and competence. These papers provide a framework for identifying the organisational factors that affect DfRem integration. However, although DfRem is often considered to be under the wide umbrella of design for environment issues, it cannot be assumed that research findings for ecodesign are mutually compatible with DfRem. Studies have shown that most companies will choose to remanufacture primarily for profit, and a company is extremely unlikely to remanufacture for environmental reasons alone [2], thus making the incentives and goals of DfRem different to that of ecodesign.

3. INVESTIGATION

Considering the current state-of-the-art in DfRem research and the indications provided by research conducted in similar fields, the focus of this study is upon understanding the *organisational factors* that impact upon DfRem integration into the design process. What kind of organisation can successfully integrate DfRem, and how may this be achieved? Answering this question involves viewing DfRem not as an 'add-on' task but as part of a wider system that incorporates management and business operations as well as individuals' attitudes and motivations.

The investigation is following a multiple case study methodology with OEMs producing mechanical/ electromechanical products, one of the most mature remanufacturing industry sectors in the UK [13]. Interviews with engineering management, design engineers, aftermarket engineers and remanufacturing personnel are being used to map the organisational conditions that will enable successful design for remanufacture, either to enhance current remanufacturing activity or effectively prepare for remanufacturing activity in the future. Interview data was also supplemented with observations of company manufacturing and remanufacturing processes, and access to documentation such as environmental policy and checklists.

4. FINDINGS

Two case studies have been carried out to understand the organisational factors that affect DfRem integration within OEM-remanufacturing companies: OEMs (original equipment manufacturers) which are currently remanufacturing their own products (as opposed to contract or third party remanufacturing). Previous work has found that this business scenario is the most likely to involve DfRem, as the OEM has a direct incentive to reduce remanufacturing costs [14]. Company A manufacture diesel engines for the off-road and power generation market, Company B manufacture pumps for the oil and nuclear industry. Both these product types are naturally suited to remanufacture, and it has been found to be a profitable aftermarket solution for both businesses. However, Company A is actively involved in DfRem, whilst Company B is not. Interviews were conducted to determine the drivers and barriers to DfRem within each organisation, utilising within-case and cross-case analysis. Figure 2 illustrates the relevant factors and the relationships between them, as identified through this research.

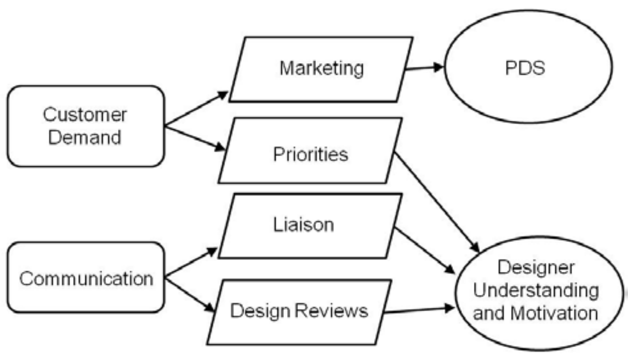

Fig. 2: Identified factors affecting DfRem integration in the case study companies

Customer demand was identified as a key driver to DfRem. If there is customer demand for remanufactured products- or low cost spares- the research found that **marketing** are most likely to be in support of remanufacture. As design specifications are typically written in collaboration between engineering and marketing, this means that the interests of remanufacturing will be included in the product design specifications (PDS) documentation. This finding would concur with similar findings in the field of ecodesign integration [15]. Commitment to DfRem at this early stage, when few design decisions have been made, is of significant importance for successful integration. This enables DfRem to become a natural part of a designers' every day work: the PDS documents of Company A contain DfRem specifications, and interviewed design engineers did not consider DfRem to be a particularly difficult or troublesome task, it was simply viewed as one of the many considerations to be made when developing a new engine. This somewhat contradicts popular views in the literature that DfRem requires specialist tools and that designers' lack of DfRem knowledge is a barrier [2]. Customer demand would appear to be one of the more striking differences between Company A, who design for remanufacture, and Company B who do not. Whilst Company B remanufacture their products, their customers in the oil and nuclear industry do not specifically demand remanufacturing- they have demanded a high speed service that Company B have chosen to address through remanufacturing. Because the customer is not concerned with the specific benefits of remanufacturing, DfRem is not highlighted as a key design feature when developing specifications.

Whilst customer demand may increase incentives to design for remanufacture, these case studies have found that customer demand and other pressures such as legislation may have the opposite effect, even simultaneously. For example, the increasing pressure of emissions regulations upon design engineers working for Company A means that remanufacturing issues are often discarded due to a conflict of **priorities** in which remanufacturing is most often considered least important. Similarly, the bespoke nature of Company B's products comes hand in hand with very specific customer demands, leaving little room in the design process for DfRem considerations. Designers are under great pressure to meet these demands; if it is a case of compromise between DfRem and another, greater priority, DfRem considerations are most likely to lose out.

Furthermore, this research has found that DfRem understanding and motivation amongst designers, whilst influenced by priorities, may also be reinforced by standards of **communication** between the remanufacturer and OEM design engineering. Both companies in the study cited communication as an area that could be improved to enhance DfRem activity. Without effective communication between both business sectors, there is little opportunity for the remanufacturer to provide design-related feedback that will inform designers of the potential to enhance remanufacturability. Without this communication, designers will remain uninformed and unmotivated with regards to DfRem, and remanufacturing issues will remain low priority in the design process, even in instances where the benefits of DfRem are high. Similarly, a company that solely relies upon historical and experience-based remanufacturing knowledge may fail to address the most relevant and challenging DfRem issues of the day. Both companies in the study designed their products based on historical knowledge and data on remanufacturing: Company A make use of long-established standards and guidelines and design management at Company B felt that because their current products are based on a long-established pump design, there is no longer a need to consider remanufacturability.

To expand upon the communication factor, key considerations are 'who' and 'when'. *Who* communicates will have an impact on how effectively DfRem feedback can be integrated into the design process: their background, their expertise and their relationships with both remanufacturing and design engineering. Company A have a **'remanufacturing liaison'** who is able to pass information between both parties and raise DfRem issues during product development, however it is possible that direct communication between designer and remanufacturer would be most effective. *When* communication takes place is also of significance because there is a short window of time during which DfRem design changes will be feasible: after a certain point in the design process significant changes are considered too costly and time consuming [15]. Therefore, the earlier in the design process this communication can take place, the more influence remanufacturing concerns may have on the final product design. Early **design reviews** were identified to be a strong opportunity for improved OEM-remanufacturer communication: one of the differences between Company A and Company B is the attendance of aftermarket representatives at design reviews.

5. DISCUSSION

This paper has presented some of the key factors affecting an OEM-remanufacturing organisation in the integration of DfRem into the design process, namely customer demand (market support and prioritisation) and communication. Whilst external factors such as customer demand and legislation have a strong control over designers' priorities, they are mostly outwith the control of the design engineer. However, this is not to say that an OEM that does not have strong customer demand for DfRem or an OEM that has other critical issues to prioritise could not benefit from more remanufacturable products. For example Company B in this study did not have specific customer demand for DfRem, yet improving the efficiency and effectiveness of their remanufacturing operations could have a high impact upon company profitability, as aftermarket is the company's main source of revenue.

The factor most within OEM control is communication. If OEM design engineering and remanufacturing can establish regular, responsive feedback between both parties, then the specific needs of the remanufacturer could be better understood. Whilst remanufacturing issues will most likely always struggle to compete with demands such as high performance and low cost, improved communication will increase designer awareness of DfRem issues, and having the direct voice of the remanufacturer will make their needs less easily compromised. This of course must be combined with an understanding of remanufacturing's role within the business and the benefits of improving remanufacturability. Based upon case study findings, one possible way to introduce this understanding is through design reviews, which could present an ideal opportunity for the remanufacturer to voice their ideas and concerns, at a time when design changes remain possible. In both case study companies, designers would most likely learn about company remanufacturing operations and DfRem through experience (such as attendance at design reviews where remanufacturing personnel are present) rather than formal training. The best approach to establishing effective communication between both parties remains unclear and will require further investigation- for example, is the use of a 'remanufacturing liaison' better than direct communication? There would appear to be advantages to a liaison (a dedicated member of staff) and disadvantages (a diluted sense of relevance and significance).

6. CONCLUSIONS

Previous research in the field of ecodesign has suggested that organisational factors, as well as the provision of specialised guidelines or design tools, could have a significant impact upon the integration of remanufacturing issues into the design process. This paper presents findings from a study that aims to result in an organisational roadmap towards successful DfRem integration, focusing upon two companies in the mechanical sector that are currently involved in the remanufacture of their products. Comparing the similarities and differences between these two companies has highlighted customer demand and communication as significant drivers for DfRem integration, as these factors will have an impact on both design engineer understanding and motivation, and the inclusion of remanufacturing issues in design specifications. Design reviews have been identified as a potential opportunity to enhance communication and therefore DfRem integration. However, to develop a true and relevant organisational map towards DfRem integration, further case studies are required that look beyond OEM-remanufacturer organisations. OEMs that use contract remanufacturers, and OEMs that are not currently involved in remanufacturing are likely to face different challenges, possibly more difficult to overcome.

Ecodesign Maturity Model: the Ecodesign Practices

Daniela C. A Pigosso (1)[1], Henrique Rozenfeld (2)[1]

[1] Department of Production Engineering, University of São Paulo, São Carlos, Brazil

Abstract

Ecodesign is essential to companies that have recognized that environmental product responsibility is vital to long term success. However, its application has not reached companies worldwide over the last decade. It is still not clear which ecodesign practices should be selected and how to manage the process of integration into the product development process and continuous improvement. The paper presents the Ecodesign Maturity Model (EcoM2), a model that aims to guide companies in the Ecodesign implementation, and focuses the discussion on the Ecodesign Practices, one of the EcoM2 components.

Keywords:

Ecodesign Maturity Model, ecodesign practices, guidelines, tools

1 INTRODUCTION

Ecodesign can be defined as a proactive environmental management approach that integrates environmental issues into the product development process in order to minimize environmental impacts throughout the product's life cycle (from raw material extraction and manufacturing to use and end-of-life), without compromising other essential criteria such as performance, functionality, quality and cost [1] [2].

The application of ecodesign is essential to companies that have recognized that environmental product responsibility is vital to long term success, since it promotes image improvement, cost and risks reduction, product innovation and development of new markets [3]. However, the application of ecodesign has not reached companies worldwide over the last decade mainly due to:

I. There are no systematization of the existing ecodesign practices;

II. There is an intense development of new ecodesign methods and tools in detriment of the study and improvement of the existing ones [4];

III. There is a lack of integration between ecodesign and the broad context of the product development process and product life cycle management [5][6][7][8];

IV. Ecodesign is poorly integrated into corporate strategy and management [4];

V. The Ecodesign implementation in companies is not supported by a roadmap for continuous improvement;

VI. The selection of ecodesign practices is not in accordance with the company´s current maturity level on Ecodesign.

Moreover, it is still not clear to companies which strategies, guidelines and techniques/tools should be selected and how to manage the process of integration into the product development process and continuous improvement. Consequently there is a need to propose models that help companies to implement ecodesign in their product development processes in an effective way.

In this context, it was developed, validated and tested the Ecodesign Maturity Model (EcoM2), which aims to guide companies into the effective implementation of ecodesign practices into the product development process in accordance with the organization´s strategic objectives and drivers.

The paper presents the concept of the EcoM2 and focuses the discussion on the Ecodesign Practices, which is one of the main elements of the model. It will be presented the methodology employed to collect and classify the ecodesign practices, the systematization adopted in the EcoM2 and also the interrelationship among the different practices and how they can be applied by companies.

The next section presents the goal and the elements of the Ecodesign Maturity Model (EcoM2): Ecodesign Practices, Ecodesign Maturity Levels and Application Method. Section 3 details the methodology employed in the development of the Ecodesign Maturity Model and in the systematization of the Ecodesign Practices. The Ecodesign Practices are detailed in Section 4. Summary and Outlook, Acknowledgments and References are presented in sections 5, 6 and 7, respectively.

2 ECODESIGN MATURITY MODEL (ECOM2)

The Ecodesign Maturity Model is a framework with an evolutionary approach composed by three main elements (Figure 1): Ecodesign Practices, Maturity Levels and Application Method. The goal of the Ecodesign Maturity Model (EcoM2) is to guide companies in the effective implementation of ecodesign practices into product

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_81, © Springer Science+Business Media Dordrecht 2012

development process and related processes in accordance with their strategic goals and drivers.

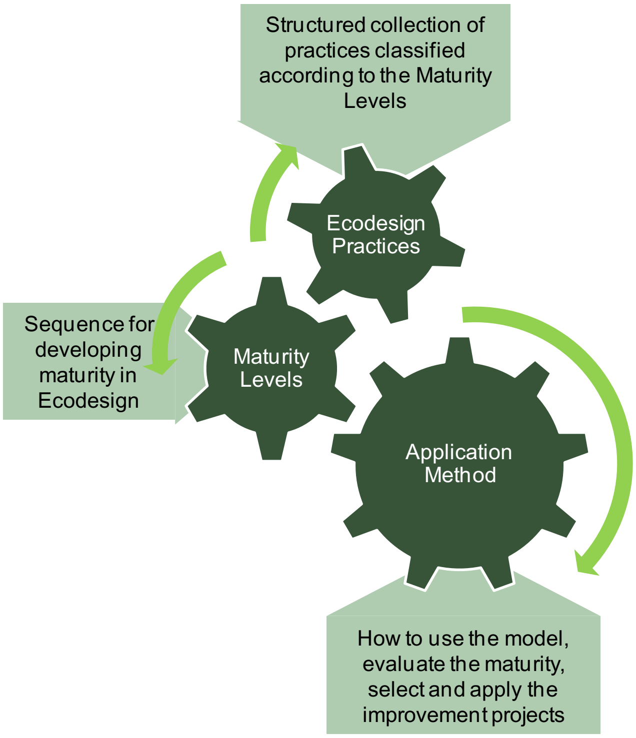

Fig. 1: Elements of the Ecodesign Maturity Model

The Ecodesign practices corresponds to the best practices currently developed and adopted by companies for the integration of environmental concerns into the product development process – it is composed by management practices and operational practices associated to ecodesign techniques and tools (see section 4).

The Ecodesign Maturity levels represent company evolution level in applying the environmental issues into the product development and related business processes. It is obtained by the combination of the evolution level of a practice and the capability level of its application. The evolution level on ecodesign can go from low knowledge and implementation levels, passing through pilot projects and process integration and culminating with the strategic consideration of ecodesign and exploitation of associated eco-innovations opportunities. The five capability levels adopted by EcoM2 assess the way in which a practice is applied by the company (incomplete, ad hoc, formal, control, optimize) (adapted from [9]). The ecodesign maturity levels defined in the Ecodesign Maturity Model can be summarized as follow:

- Level 1: Company has no experience on ecodesign and does not yet apply practices to improve the environmental performance of the developed products.
- Level 2: Company does the first moves in the application of Ecodesign, is already familiar with some practices and with the potential benefits. It is observed punctual and not consolidated approaches for the use of ecodesign practices.
- Level 3: Company recognizes the importance and benefits of Ecodesign by the application results. It is observed the technical integration with the first insertions of ecodesign practices into the processes and first steps to structure the environmental approach and common patterns.
- Level 4: The ecodesign practices are systematically incorporated into the product development process, since the initial phases (e.g. idea generation and portfolio management). Functionality analysis is now applied to conduct ecodesign.
- Level 5: There are the incorporation of environmental issues into company's corporate, business and product strategies. Environmental issues are considered jointly with technical and economic issues to support the decision making process.

The application method presents the way in which companies can use EcoM2 for process improvement. It contains a scheme for continuous improvement (like PDCA – plan, do, check, act) based on Business Process Management (BPM) approach [1]. It is composed by a method for diagnosis of current situation, development of an ecodesign maturity radar which presents the current profile of a company in the ecodesign application considering the capability level of the applied practices, identification of critical ecodesign subject for improvement, definition and prioritization of improvements projects, establishment of implementation roadmaps, development of the projects and assessment of obtained results by means of performance indicators.

The application of EcoM2 provides a benchmarking of ecodesign practices; an assessment of weaknesses and strengths concerning ecodesign practices application; a common language and a shared vision across the organization on ecodesign implementation; a guide for integrating ecodesign into product development processes; and a roadmap for improvement of product development process towards environmental sustainability.

EcoM2 was already theoretically validated by a set of 14 Ecodesign Experts from Europe, United States of America (USA) and Brazil and applied in large multinational companies of capital and consumer goods. The results of EcoM2 application were satisfactory and have led to the implementation of proposed improvement projects by those companies. This paper focuses on the Ecodesign Practices, a component of the EcoM2.

3 METHODOLOGY

The development of the Ecodesign Maturity Model (EcoM2) can be divided into three main parts: (1) Systematization of Ecodesign Practices, (2) Definition of Ecodesign Maturity Levels and (3) Development of an

[1] BPM IS frequently used to denote a software. In the case of this paper, it is an approach for improving business process based on an evolution of the PDCA cycle.

Application Method to support EcoM2 implementation into companies. As previously mentioned, this paper focuses the discussion on the Ecodesign Practices, which is one of the main elements of the model.

The Ecodesign Practices were obtained and classified. i.e. systematized, by means of a systematic literature review, the way by which the researcher can map the existing and previous developed knowledge and initiatives in a specific research area. Besides the analysis of previous discovery, techniques, ideas and ways to explore topics, the systematic review also allows the evaluation of information relevance to the issue, its synthesis and summarization [10] [11]. The main goal of the systematic review was the determination of the state of the art in ecodesign practices.

The phases carried out in the systematic review correspond to problem formulation (identification of the goal of the review, target and context, beneficed areas and expected results), data collection (identification of the relevant databases, keywords and strings), data evaluation (application of the inclusion/exclusion criteria for the selection of the relevant studies and representation standardization), data analysis and interpretation (synthesis of the studies and definition of the criteria for classification) and presentations and conclusions [10] [11].

Along the literature review, it was obtained 2145 studies (generic name attribute to papers, thesis, dissertations and books). It was performed an initial studies selection, which were then analyzed according to the inclusion/exclusion criteria (studies that presented relevant ecodesign practices). It was then carried out a review to certify that relevant studies had not been excluded. The valid studies were then analyzed in order to extract the relevant information about the ecodesign practices.

It was identified a huge amount of practices during the systematic literature review (more than 600). They were sorted out according to its characteristics into three groups: Ecodesign Management Practices (those that deals with ecodesign in the management of the product development process), Ecodesign Operational Practices (related to technical design issues during detailed design) and Ecodesign Techniques and Tools (artifacts that support the application of management and operational practices). Once the Ecodesign Practices were classified, the interrelationships and dependencies among each practice of a given group and also among the three groups by means of a correlation matrix were analyzed in detail.

The description of Ecodesign practices is presented in the section 4: Ecodesign Practices.

4 ECODESIGN PRACTICES

According to PMBOK [12], practice is defined as "a specific type of professional or management activity that contributes to the execution of a process and that employ one or more techniques and tools". Technique is defined as "a defined systematic procedure employed by a human resource to perform an activity to produce a product or result or deliver a service, and that may employ one or more tools" [12] and tool is defined as "something tangible, such as a template of software program, used in performing an activity to produce a product or result" [12].

Ecodesign Practice is the general label attributed to ecodesign activities that aims at integrating the environmental issues into product development process and which application can be supported by ecodesign techniques and tools. In the Ecodesign Maturity Model (EcoM2), the ecodesign practices were classified into two main groups: Ecodesign Management Practices and Ecodesign Operational Practices. These practices are interrelated among them (Figure 2), and are presented in detail in the next sections.

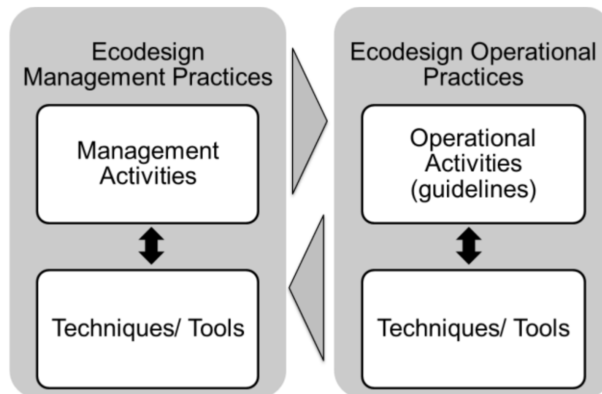

Fig. 2: Ecodesign Practices

4.1 Ecodesign Management Practices

The Ecodesign Management Practices are related to management activities of product development that addresses environmental issues and can be supported by ecodesign techniques and tools (Figure 2).

By means of a systematic literature review, it was identified and classified 75 Ecodesign Management Practices. It was performed an analysis to identify which ecodesign techniques/tools could support their application and the relationships among them were established.

It was assigned a code to each practice that gives information on the phases of a reference model for product development process [13] where the practice should be preferably applied (product strategic planning, project planning, informational design, conceptual design, detailed design, production preparation, product launch, product monitoring and take back of products). It includes also two support process: business process management for ecodesign (which application is essential to form the basis for Ecodesign implementation) and environmental impact assessment. The support processes, the phases of the reference model [13] and the associated codes are presented in the table 1.

Besides enabling the easy update and addition of new practices, the codification also enables the identification of the phase of the product development process and/or support processes where the practices should be applied.

Table 1: Code scheme for the classification of Ecodesign Management Practices

Code	Classification of Ecodesign Management Practices
100xx	Support Process - Business Process Management for ecodesign
200xx	Support Process - Environmental Impact Assessment of Products
300xx	Generic Activities
400xx	Product Strategic Planning
500xx	Project Planning
600xx	Informational Design
700xx	Concept Design
800xx	Detailed Design
900xx	Production Preparation
1000xx	Product Launch
1100xx	Product accompanying and monitoring

For example, one of the ecodesign management practices is “20001: Assess the environmental impact of products”. In order to support the application of this management practice, there are a set of 42 ecodesign techniques and tools that can be used, ranging from complex methods such as Life Cycle Assessment (LCA) [14][15][16][17] to more simplified and abridged ones, such as MET (Material, Energy and Toxics Matrix) [18][19] and MECO (Material, Energy, Chemicals and Others Matrix) [20][21]. The most suitable ecodesign technique/tool to be used can be obtained by the selection according to the company needs, current maturity level and the criteria used to classify the techniques/tools [12][22].

Other examples of ecodesign management practices includes “10011: Ensure commitment, support and resources to conduct the activities related to ecodesign”, “10015: Make ecodesign tasks a part of the daily routine for the relevant employees”, “10019: Formulate and monitor mandatory rules concerning environmental issues for the enterprise to comply with law/regulations”, “10023: Implement a life-cycle thinking in the company”, “30002: Clearly define the environmental indicators and the methodology to be used during the gates (phases assessments)”, “40013: Clearly define goals to improve products environmental performance (according to law, benchmarking, phases/aspects with higher improvement potential, etc.)”, etc.

It is important to note that it can be established relations of dependence among the ecodesign management practices, i.e., there can have pre-requisites for the application of certain ecodesign management practices. For example, in order to apply the practice “10002: Deploy and maintain an environmental policy for products” it is required to have previously applied the practice “10001: Formulate a company environmental policy”. The practice 20001 is also a pre-requirement for the application of the management practice “80001: Analyze and select the suitable ecodesign strategies according to the environmental goals and phases/environmental aspects of the product life cycle in which the environmental improvement opportunities are higher”, since it supports the identification of the environmental hot spots of the product under analysis. The application of ecodesign management practices can also be supported by the ecodesign operational practices (figure 2).

The Ecodesign Management practices are moreover classified according to the evolution level defined by EcoM2 (see section 2) and are used to assess the maturity level of companies in applying ecodesign, by means of the assessment of the capability levels of the application of each practice during the diagnosis. As a result, it is built Ecodesign maturity radar which guides the establishing of a roadmap for process improvement towards environmental sustainability.

4.2 Ecodesign Operational Practices

The Ecodesign Operational Practices deal with the technical issues of product design and is composed by ecodesign operational activities (guidelines) which can be linked to ecodesign techniques and tools (Figure 2).

The ecodesign operational activities were obtained by the consolidation of a summary of ecodesign guidelines for product design with more than 480 operational activities identified and systematized.

The guidelines were grouped on six ecodesign strategies: “Minimize Energy Consumption”, “Minimize Material Consumption”, “Extend Material Life Time”, “Optimize Product Life Time”, Select Low Impact Resources and Processes”, and “Facilitate Disassembly” – adapted from [23]). The guidelines of the strategy “Minimize Material Consumption”, for example, are: “Minimize material content”, “Minimize scraps and discards”, “Minimize or avoid packaging”, “Minimize materials consumption during usage” and “Minimize materials consumption during the product development process”.

In order to explicit the way in which the guidelines can be achieved, the EcoM2 also presents the design options, which provides more detailed ideas of product design (adapted from [23]). For example, some of the design options of the guideline “Minimize material content” are: “Dematerialize the product or some of its components”, “Miniaturize”, “Digitalize the product or some of its components”, “Avoid over-sized dimensions”, Reduce thickness”, “Apply ribbed structures to increase structural stiffness”, “Avoid extra components with little functionality”, “Reduce the material content by integrating functions”, etc. The Ecodesign Operational Practices should be customized by a company, according to the characteristics of the developed products.

Each guideline was also classified according to the phase of the product life cycle (pre-manufacturing, manufacturing, distribution and packaging, use and maintenance and end-of-life) and to the environmental aspects (material, energy consumption, solid waste, waste water and emissions) - adapted from DfE Matrix [24].

This classification indicates where the guideline can influence the environmental performance of a product and supports the selection of the most appropriated operational practices according to the characteristics of environmental impacts over the whole life cycle of the product under development. The guidelines are also associated to ecodesign techniques and tools that can support their application (Figure 2).

For example, if the hot spot [2] of a product under development is at the end-of-life of products, concerning to solid waste, the strategies “Facilitating Disassembly” and “Products Life Time Optimization” should be more adequate. Focusing on “Products Life Time Optimization” and assessing its guidelines, it can be concluded that “Facilitating Remanufacturing” is of higher importance. To support the application of this guideline, there are also a set of ecodesign techniques and tools such as EDIT (Environmental Design Industrial Template) [25], ELDA (End-of-Life Advisor) [26] and LCP (Life Cycle Planning) [27] that can support its application.

4.3 Ecodesign Techniques and Tools

Ecodesign Techniques and Tools can be defined as systematic means for the application of ecodesign that can support the application of both Ecodesign Management and Operational activities (Figure 2).

It was identified and classified 105 ecodesign techniques and tools. In order to support the selection of the most suitable ones for companies according to their needs and current maturity level, they were classified according to 6 criteria:

(1) Nature of the main goal (Prescriptive/Comparative/Analytic);

(2) Type of the tool used (Checklist/Guideline/Matrix/Software);

(3) Nature of input and output data (Qualitative/Quantitative);

(4) Product Life Cycle Phases (pre-manufacturing, manufacturing, distribution and packaging, use and maintenance and end-of-life),

(5) Application evolution (Theory/Experimental/Consolidated);

(6) Evaluation of Environmental Impacts (Yes/No).

The classification criteria used in the Ecodesign Maturity Model and the results obtained are presented in detail in paper [22].

Some examples of Ecodesign techniques and tools were presented previously in sections 4.1 and 4.2 in relation to ecodesign management and operational practices. The selection of the most suitable tool/technique to be used to the application of a specific activity must consider the current maturity level (see section 2) of the company and can be supported by the classification criteria.

2 The identification of the hot spots (most important environmental impacts of a product) can be performed by means of the application of the management practice “20001: Assess the environmental impact of products” using a set of different ecodesign tools and techniques.

5 SUMMARY AND OUTLOOK

The paper presented the general concept of the Ecodesign Maturity Model (EcoM2) and focused the discussion on the Ecodesign Practices, which were classified into two main groups according to their characteristics:

- Ecodesign Management Practices;
- Ecodesign Operational Practices;

and associated Ecodesign Techniques and Tools.

This work enabled the mapping of the state of the art and the classification of Ecodesign Practices. During the systematic literature review on ecodesign, it was identified 75 management practices for ecodesign (related to the management activities and tasks of product development process that addresses the environmental issues) and more than 450 ecodesign operational practices (related to technical design issues). These practices were interrelated among them and with the 105 identified ecodesign techniques and tools.

The classification of the Ecodesign Practices reinforces the importance of the consideration of strategic, tactic and operational levels when applying Ecodesign concept into companies. It is a result of a comprehensive bibliographical review and consolidates the knowledge on Ecodesign field.

The Ecodesign Maturity Model is inedited and aims to guide companies in the continuous improvement of their product development process with the incorporation of the environmental dimension striving for sustainability in their business. It considers the individual needs, drivers, characteristics, maturity levels and strategies of companies to support the product development process. Besides the contribution to companies, the Ecodesign Maturity Model should also contribute to the organization of the knowledge in the ecodesign and PLM (product life cycle management) research areas, structuring the practices and establishing interrelationships among them.

6 AKNOWLEDGMENTS

We extend our sincere thanks to the following experts on Ecodesign who agreed to participate in the validation of the Ecodesign Maturity Model: Ab Stevels, Aguinaldo Silva, Anna Hedlund-Åström, Casper Boks, Conrad Luttropp, Erik Sundin, Fabrice Mathieux, Han Brezet, Mark Goedkoop, Martin Charter, Mattias Finkbeiner, Mattias Lindahl, Tom Swarr and Tracy Bhamra. We also gratefully acknowledge FAPESP (Fundação de Amparo à Pesquisa do Estado de São Paulo) and CAPES (Coordenação de Aperfeiçoamento do Pessoal de Nível Superior) for their financial support of this work.

"Create Competitiveness In A Sustainable Society – Use Ecodesign, In Cooperation"

Anna Karin Jönbrink[1], Sandra Roos, Mats Sundgren, Eva Johansson, Birgitha Nyström, Peter Nayström

Swerea AB, Sweden

Abstract

This paper will describe a new methodology for the use of Ecodesign, where various competences are combined to obtain high quality results. The competences needed are: Environmental experts, who can evaluate the environmental performance of a product or service through Life Cycle Assessment, LCA, material- and process experts for the materials and processes in the targeted product or service, experts of the final product or service who can provide high quality data for the LCA. This cross functional team can develop new products or services, with high performance combined with low environmental impact, applying ecodesign when cooperating closely. Using this methodology is a feasible way to obtain improved competitiveness for the industry in a sustainable society.

Keywords:

Ecodesign, Life Cycle Assessment, Cooperation, Cross functional team

1 INTRODUCTION

As the understanding of the climate change increases, the quest for sustainable development has received widespread acceptance. At the same time, it is of great importance to have a competitive industry. Ecodesign is a way to create sustainable development and industrial competitiveness simultaneously, i.e. in ecodesign we minimize the environmental impact of a product while we maximize the performance/use of the product.

One common tool in ecodesign is Life Cycle Assessment, LCA, [1], [2] where the environmental impact from a product can be assessed over the life cycle (raw material, manufacturing, use, end of life, and transportation) in relation to a specific functional unit. Here is described how LCA in combination with product-, process- and material expertise is used to develop new products and processes with low environmental impact and improved performance.

2 SWEREA ECODESIGN, A PROJECT TO DEVELOP ECODESIGN METHODOLOGY

The Swerea Ecodesign is a project running from 2010-2012, where a methodology for creating optimal solutions is developed. "Optimal" is considered to solve environmental as well as other aspects of importance for the companies such as economical aspects, functionality of the products and processability. The methodology has shown to be successful because it combines all the necessary competences for the relevant materials and processes with competence on environmental analysis. Hereby optimal solutions can be obtained.

The ecodesign methodology is applied in some 10 case studies of different products and manufacturing processes in close cooperation with companies. The products and manufacturing processes will be assessed from the environmental perspective alongside with other perspectives such as technical performance, economical performance, safety etc. The environmental performance of current products and manufacturing processes is assessed with "screening LCA". Experts on the relevant materials and processes from companies and research institutes cooperate to gather the best available data sets. The result from the LCA can identify if a certain process, a certain material or substance has a significant detrimental environmental impact. Such processes/ materials/ substances are usually called "hot spots". The next step in the ecodesign process involves development work to improve the processes/materials/substances identified as hot spots. In order to improve the product or manufacturing process, the necessary expertise is used. A second LCA is performed to verify that the suggested redesign or process adjustment is improving the environmental performance of the product. Involvement of the companies ensures that economical viable solutions are developed, and hence the competitiveness is strengthened.

Ecodesign means integrating environmental issues throughout the usual product development process [3], in the following way:

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_82,

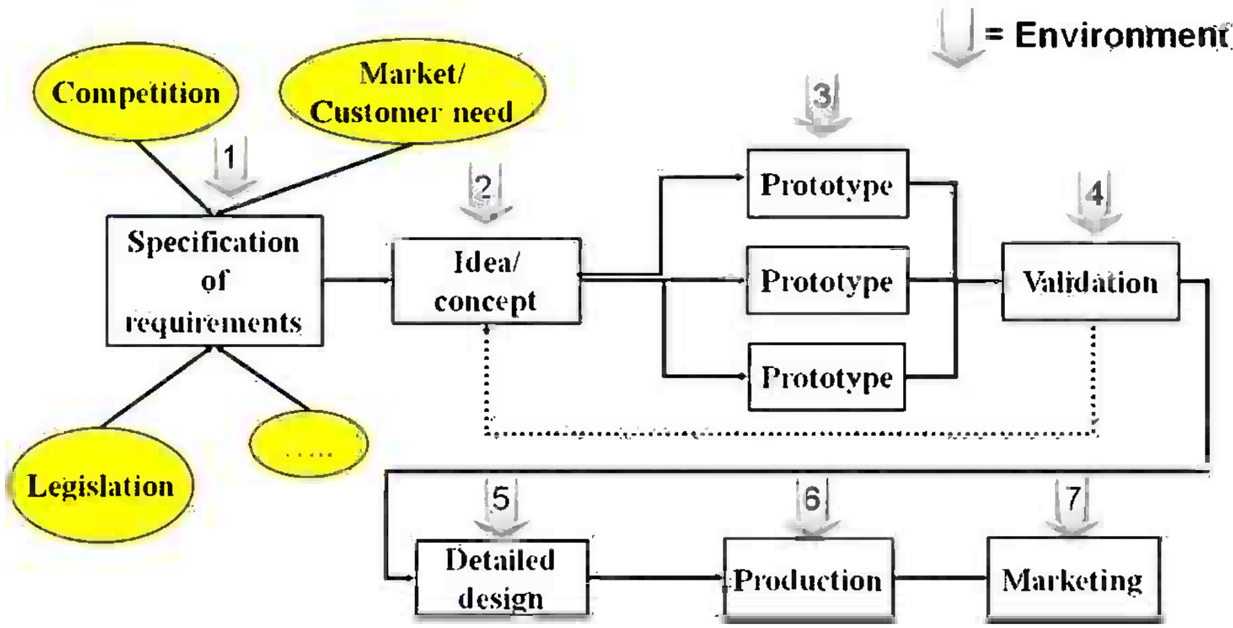

Figure 1 : Rough description of the ecodesign process

1. *Specification of product requirements.* Life cycle assessment, LCA, of ”existing” product to find out which life cycle phases and/or components and parameters are of greatest environmental importance overall. Legislative requirements and customer needs can involve single environmental issues. The results are fed into the specification of product requirements.
2. *Idea/concept.* The results of the first LCA can give lots of ideas on how to improve the environmental performance of the product, e.g. using brainstorming technique and cross scientific team of experts. These ideas are implemented in conceptual product designs.
3. *Prototype.* Prototypes are developed to fulfill environmental parameters decided in the earlier steps.
4. *Validation.* Validation (of the improvement) of the environmental performance of the different concepts. Since more data is available at the validation stage, the LCA calculations can be refined. This gives information to choose the best concept to continue with.
5. *Detailed design.* Detailed design of the chosen concept with due consideration to critical parameters and environmental aspects related to the product. The team is chosen in order to provide the needed expertise for that particular product, process or service. A second LCA is performed to verify that the suggested redesign or process adjustment is improving the environmental performance of the product.
6. *Production.* Management of environmental aspects related to production (compare with 4.4.6 Operational control in ISO 14001).
7. *Marketing.* May involve self-declared environmental claims (ISO 14021), environmental labeling (ISO 14024), environmental product declarations (ISO 14025), all of which requires verified environmental information about the product.

3 CASE STUDIES

The methodology has been tested in case studies of products and manufacturing processes. The different projects have identified different kinds of “hot spots”, and a methodology to find the best expertise for different kind of projects has been developed. In the case studies it was found that it is not enough that the cross functional scientific team work in the same project, everyone within his or her expertise, but the key to success is the close cooperation between the experts.

Some of the case studies are described below:

3.1 Substitution of SF_6 in high pressure die magnesium casting process

In the die casting process for magnesium, Mg, there is a need for gas covering of the melt. Today Sulphur hexafluoride, SF_6, is often used, but due to the high climate impact, the allowed use is limited to 850 kg/year and company in Sweden. Sulphur dioxide, SO_2 has been used as alternative but has caused explosions [4], and the industry is hesitant to use it due to the risk of injuries. The aim of the case was to find and investigate safe, cost effective and environmentally sound alternative cover gases.

To run the project, a group of experts from industry and the Swerea group was used. The project was lead by an expert of magnesium casting from Swerea SWECAST, research institute for Casting. Other members of the group came from the expertise of

- environment (running LCA)
- work environment (performing a work environment screening, including risk assessment and chemical risk assessment)
- metallurgy providing data and knowledge
- corrosion
- Experts from Mg die casting companies (providing data and knowledge about the processes)

Three different protective gases were tested with SF_6 and SO_2 as references.

The results of the project were that SO_2 can be used as a cover gas and that the risk for explosions can be reduced by using new materials in the crucible wall of the foundry oven. This solution was unexpected, and new, and was only possible due to the cross scientific competence in the project group.

3.2 Green office walls

Green office wall is the term used here to describe a vertical plant filled partition that can be used to divide a room. Studies have shown that these walls increase the well being of the personnel [5]. Whilst well being is difficult to quantify, green office walls have measurable positive effects such as improved air quality as the wall humidifies the air and reduces levels of certain types of VOCs such as formaldehyde which plants used in the green wall are known to absorb. The wall also provides sound absorption as it contains a thick layer of sound insulating mineral wool.

The aim of the project was to evaluate the environmental impact of this product and improve the overall environmental performance of it, if needed.

The functional unit was a 10 m^2 office space to reveal if the green office wall reduces the environmental impact of this functional unit or not. This was done by comparing the LCA of an office with a green office wall and an office with a set of systems that would achieve the equivalent air quality and sound absorption. This first comparison showed that over a 10 year period the office space with a green wall performs better than an office space without a green wall in terms of climate change (measured as carbon dioxide equivalents).

An option to go further and improve the overall environmental performance, was to compare the current type of green office wall made from steel and a new design of green office wall made from a bio-based composite material. The latter is derived from renewable resources, wood and grasses. Such materials store carbon dioxide which could make them a better choice than steel from an environmental point of view.

The second comparison showed that using a renewable bio-based composite material instead of steel does improve the environmental performance by 20%. In this product this results in a saving of 200kg of CO2 equivalent. Consequently the room with a biobased wall has a lower impact on global warming than the room without the wall after 7 years

The new bio-based composite materials that are used here present a number of challenges. The challenges lie in designing for these materials and manufacturing as well as the LCA. The LCA relies heavily on the whole team working together to clarify and estimate the necessary parameters.

However, although changing the material does have some impact on the environmental impact, it is important to note that the transportation needed for installation and maintenance has the single highest environmental impact during the product lifecycle. This is important information for the company selling the green wall and different solutions have been suggested for reducing the impact from transport. The company is now evaluating the use of a delivery firm that specialising in plants transport.

The new design of green office wall in bio-based composite material is being built and tested and will be on display at different fairs by the end of the year. This case study was performed in collaboration between Vegtech, the producer of the green wall, Amroy, producer of a pineoil based resin, APC, the composite manufacturing company producing the biobased composite wall structure, Swerea SICOMP and Swerea IVF. The study was financially supported by the involved companies and by FP7 project WOODY and the Eureka project Polywall.

3.3 Recirculation of steel casting residues in a roll casting company

There is a common problem in the casting industry regarding metal containing dust that leads to increased environmental impact and high costs for deposition. In addition the material has a value due to its high metal content which could replace some of the raw material in the process. Therefore there is a twofold possibility to decrease the environmental impact of these products, if recycling was possible. In order to enable recycling, a cross functional team of experts was composed. The represented competences covered metallurgy, steel casting, leaching, LCA, chemical risk assessment and regulations regarding deposition. Åkers, a company serving the global rolling mill industry was involved in the project, and a roll of 70 metric tons was used as an example.

The project started with mapping of energy and material consumption in all process steps within the manufacturing.

In order to get the right data, it was done in close cooperation with the company. To secure that the best solutions was found, and sub optimization avoided, the full life cycle was assessed in a LCA. The findings of the first study was that the raw material, and that the amount of fluoro components had a high environmental impact. Furthermore the energy consumption within the process showed to be quite high.

Development of a re-melting process focusing on solving the identified challenges started. Metallurgy combined with casting expertise, the company knowledge and process development expertise resulted in a re-melting process for the dust, feasible for the company, giving high yield and low environmental impact.

The quantified result showed savings of 1 ton of carbon dioxide, CO_2 and 5,6 MWh of energy per produced roll, in addition to the economic savings due to less need for raw material and for deposition.

In addition to the results regarding this specific product, the company have due to the analysis and work done, been even more focused on energy and toxic compounds.

3.4 Green Flagship

Sail yachts are considered environmentally friendly, due to the use of wind to create movement. Still there are possibilities to reduce the environmental impact from sail yachts. A cross functional team of experts was built, in order to improve the environmental performance of a sail yacht from Najad. The team included experts in the field of metallurgy, flow simulation, corrosion, casting, motors and fuel cells, solar panels, composite materials, textiles, LCA and environment.

As a first step a LCA was performed in order to find hotspots, life cycle stages and components of interest for improvement. The main environmental impact in terms of CO_2 was the use of diesel to run the main engine and the second largest was the use of diesel to run the second engine providing the boat with electricity during the life of the boat. Other things of importance in terms of photochemical smog were the use of solvents for composite materials in the production phase of the boat, and in terms of toxicity, the zinc which contain cadmium for the offer anodes.

The team started searching for solutions regarding diesel consumption for the main engine by looking at the geometric shape through flow simulation, and possible production methods for the keel. Other solutions tested for prototypes were cooling solutions to minimize the use of air conditioning and hence electricity during the use phase, new technologies to prevent corrosion by electric potential and bio composite materials to minimize the environmental impact of the composites. Ideas about how to implement and use solar cells and fuel cells to replace the main engine were developed and tested theoretically.

The results show that there are many feasible possibilities to improve the environmental performance of a sailing yacht.

4 SUMMARY

The Swerea Ecodesign project has developed a methodology where “traditional” Ecodesign methodology [6], [7] has been combined with a methodology to create successful cross functional teams. The methodology has been tested in some ten case studies, showing that cross functional teams of relevant experts together with experts from the companies involved, can create new, unexpected, technical and economical feasible solutions with improved environmental performance. In the case studies it was found that it is not enough that the cross functional scientific team work in the same project, everyone within his or her expertise, but the key to success is the close cooperation between the experts.

5 ACKNOWLEDGEMENT

We would like to thank all the different people involved in this project and case studies, making the results possible. In all the case studies, companies have been involved, making it possible to put the results in concrete form, and we would like to give them an acknowledgement for that.

Critical Analysis of Fair Trade Marketing in Japan

Shinichiro Terasaki[1], Shin'ya Nagasawa[1]

[1]Graduate School of Commerce, Waseda University, Tokyo, Japan

Abstract

This paper explores fair trade marketing in Japan by conducting a review of the historical development of the fair trade movement and its acceptance by consumers. Japanese fair trade marketing is illustrated through the evaluation of three case studies, deploying standard business analytical frameworks. This research shows that regional adjustments of marketing strategies are required to promote fair trade products in Japan. Corporate social responsibility is increasingly important to the advocacy of fair trade, particularly among powerful corporations.

Keywords:

liberalisation, sustainability, localisation, fair trade, nonprofit organisation, alternative trade organisation, transnational corporation, corporate social responsibility

1 INTRODUCTION

The forces of globalisation, industrialisation, and neo-liberalism have stimulated social inequality and environmental degradation, while also promoting important, new advocacies that aim to create a more socially and ecologically sustainable world [1]. Following this trend, increasing numbers of consumers are seeking to purchase ethical and eco-friendly products such as fair trade, organic, and Forest Stewardship Council-certified items.

This paper focuses on the growth of fair trade, induced by concern among consumers in the North. The purpose of fair trade, growing out of neo-liberal market principles, is to counter the practices of production that depreciate and exploit deprived people and the environment, especially in the poorer areas of the Southern hemisphere [2].

The fair trade movement was initially led by alternative trade organisations (ATOs) and non-governmental organisations (NGOs). Powerful companies, including transnational corporations (TNCs), normally considered the main actors in market liberalisation, have also taken up such advocacy since the late 1990s. Accordingly, marketing methods of fair trade products are also changing, provoking struggles between conventional advocates and TNCs that have differing perspectives on what constitutes fair trade.

This research explores the current promotional efforts of fair trade products in Japan. Few English-language academic journals referring to the Japanese fair trade movement are currently available. This paper will be the precious English-written research that deals with Japanese fair trade advocacy analysed from the perspective of marketing strategies.

Proceedings of EcoDesign 2011 International Symposium

2 LITERATURE REVIEW

2.1 Sales Growth of Fair Trade Products

Although fair trade items account for a relatively small share of the world market, the sales of such products continue to grow, restructuring conventional North-South linkages [2]. Since the 1980s, fair trade sales have accrued at a remarkable rate of 30% annually [3] owing to the labelling scheme and mainstreaming marketing fuelled by the scope of economies of fair trade products.

Despite the effect of the recent credit crisis, consumers paid 2.9 billion euros for fair trade certified goods in 2008 [4]. The estimates of the size of the Japanese fair trade market vary; according to scholars, fair trade has also expanded in recent years. Nagasaka [5] estimates the size of the Japanese fair trade market to be 52.3 million euros in 2007, the most recent year for which data are available.

This fast market growth derives from the mainstream market strategy of fair trade items. In Japan, Tsujimura [6] writes that fair trade coffee sales increased 13 times in volume between 2002 and 2005 owing to the sales effort of powerful retailers such as AEON and Starbucks. In the next section, we examine the pros and cons of the mainstream strategy from a historical perspective.

2.2 The Shift from Niche to Mainstream

Despite the fact that it originated in the ATO movement, fair trade products have been distributed via large, non-ATO channels since the early 1980s. European ATOs embarked on labelling fair trade items to enable their entry into conventional markets in the late 1980s. In 1997, a common labelling scheme was introduced under Fairtrade Labelling Organisation standards (FLO).

These labelling initiatives boosted the availability of certified items for consumers over the past two decades. In general, fair trade products are available through three major channels: dedicated retail outlets, supermarkets, and mail order. According to the European Free Trade

DOI 10.1007/978-94-007-3010-6_83,

Association (EFTA) [7], supermarkets have become indispensable sales channels for companies selling fair trade products. Supermarkets account for 33% of Tradecraft's total sales in the UK, 27% of sales by GEPA in Germany, and 24% of EZA's sales in Austria.

Although a mainstreaming strategy provides small producers with the chance to supply their products to the sector's powerful corporations, it may weaken the appeal of fair trade products as alternatives to corporate product offerings. There may be no need to go to third world shops any more to buy such products owing to the emergence of supermarket channels.

Despite these apprehensions, fair trade organisations actively began to look for business partnerships with powerful corporate actors to gain further market shares. Certainly, TNCs' participation in an alternative movement contributes to the increasing consumer awareness towards fair trade. However, we need to recognise the difference between ATOs and TNCs from the perspective of their objectives to pursue fair trade practices. Since TNCs must continually seek profit growth to satisfy shareholder interests, this may not lead to a reduction in the gap between the North and the South.

2.3 Fair Trade Consumer Portraits

2.3.1 Western Consumers

Recent surveys confirm strong positive consumer perceptions of the premise underlying fair trade and fair trade products. FLO's 2008 Consumer survey, conducted in fifteen countries, found that approximately half of the public recognises the FAIRTRADE Mark [4]. However, fair trade's positive image does not necessarily ensure its popularity across all sections of the public.

Blend and Van Ravenswaay [8] state that educated and wealthy consumers are more likely to buy eco-labelled items over ordinary ones. Further, Loureiro and Lotade [9] note that females with higher incomes and greater interest in environmental protection are more likely to choose differentiated goods such as fair trade, organic, and shade grown goods. In contrast, male and older consumers are less likely to buy such products [8], [9].

2.3.2 Japanese Consumers

Ikegami [10] notes that ethical consumption requires a relatively high living standard. In Japan, only 33.9% of people are willing to support ethical consumption, whilst in France, the proportion is 73% (ibid.).

This reflects the low fair trade recognition rate among Japanese consumers. According to a 2008 nation-wide survey of consumer perception towards fair trade in Japan, only 17.4% of respondents properly recognised that fair trade was a keyword associated with poverty and the environment [11].

As we confirmed in the previous section, Japanese fair trade customers also tend to be young females (mainly 30-49 years old) with at least a bachelor's degree and a slightly higher income than the average Japanese [12].

2.4 Summary

In Findings, we explore the actual marketing effort for the fair trade movement in Japan by examining three case studies to intensify the discussion.

3 FINDINGS

3.1 Overview

We explore three case studies of fair trade marketing in Japan. In each case analysis, theories of Ansoff Matrix [13] and Grant's sustainable competitive advantage (SCA) analysis [14] are applied where appropriate. At the end of this chapter, a brief summary of the findings is provided.

3.2 Case 1: Ministop

Although only a small number of fair trade items are available in Japan, increasing numbers of companies have taken up fair trade product development. The Ministop convenience store chain has grown its fair trade business, providing fair trade drinks and sweets in the past five years. Ministop decided to launch fair trade initiatives as part of its corporate social responsibility (CSR) initiatives, following the CSR policies of its parent company, AEON.

The uniqueness of Ministop's fair trade marketing comes from the astute market adjustability in product development. Although the market share of Japanese fair trade coffee in 2006 was only 0.04% [5], AEON's annual sales of fair trade products continues to increase rapidly due to the expansion of its product line to include ground coffee, drip coffee and canned coffee. A recent hit product in Ministop is fair trade canned coffee.

'Top Valu Fair Trade Canned Black Coffee' is the first FLO-certified canned fair trade coffee in the world. Ministop started to sell this item in 2006 at 137JPY/280g. The price of this product is approximately 8.3% higher than conventional canned coffee. Compared to other premium coffees such as 'Canned Starbucks Double Shot Espresso' (170JPY/140g), this canned fair trade coffee seems to be reasonably priced.

Overall, the marketing of canned fair trade coffee has been successful, although there are two key difficulties associated with further market growth. First, it takes time to diffuse the concept of fair trade; presently Ministop is just selling the canned coffee, ignoring the idea diffusion.

The second problem is that the coffee market is said to be led by males rather than females. In fact, 80-90% of canned coffees customers are males [15]. Since Japanese fair trade customers tend to be young and female, there is a significant mismatch between canned fair trade coffee and its prospective consumers.

According to Yomiuri Online [15], females prefer chilled cup coffee to canned one, and in 2005, the market size for chilled cup coffee was two twice the size it was in 2000.

Following this trend, all Ministop stores began to sell chilled cup 'Fair Trade Café Au Lait' in June 2009. This is the first FLO-certified product that is served in a chilled cup. This product was released onto the market recently, so sales data are not yet available. However, chilled cup fair trade coffee will have more marketing opportunity than canned type.

The Ansoff Matrix is now deployed to assess a series of Ministop's marketing strategy. Given that the fair trade market is a new market, Ministop first undertook market development strategies with conventional grind and drip fair trade coffee. They next embarked on diversification strategies with canned and chilled fair trade coffees.

Market Growth		Existing Products	New Products
	New Markets	Market Development Strategies Grind Fair Trade Coffee Drip Fair Trade Coffee	Diversification Strategies Canned Fair Trade Coffee Chilled Cup Fair Trade Coffee
	Existing Markets	Market Penetration Strategies N/A	Product Development Strategies N/A
		Product Growth	

Fig 1: The Ansoff Matrix with Ministop

Although market development strategies involve moderate risk because of new consumers' lack of unfamiliarity with the product, diversification strategies are far more risky, involving two unknowns: new markets and new products. In Ministop's case, the company diversified to deploy surplus productive capability that derives from the strong financial position of AEON group.

Although retailers need to lead consumers to new markets, such astute marketing strategies eventually become obsolete because consumption trends also change swiftly. For Ministop, it is still essential to undertake both market development and diversification strategies to spread the risks of fair trade business.

Through the lens of Grant's analysis, Ministop's high appropriability presents risks to the company's SCA, for it is dependent on the leadership of one individual. In addition, Ministop has experienced difficulties in ensuring the penetration of fair trade concepts among its employees, because most sales staff consists of part-time workers. This means that the loss of a particular corporate champion could affect the sustainability.

Durability comes from intangible assets such as corporate reputation as long as a firm sustains its innovative, productive, and high-quality features. While Ministop is recognised as one of the leading convenience chains in Japan, its reputation is largely derived from its conventional services and merchandising rather than from its fair trade initiatives. Accordingly, the durability of Ministop's fair trade business is not assured.

Furthermore, the low durability may allow new entrants to manufacture similar items, stimulating lower prices through competition and making fair trade products unprofitable. Other convenience store chains are able to follow the fair trade initiatives because of Ministop's high appropriability with low durability in fair trade business. The innovation of Ministop's fair trade marketing comes not from capabilities embedded in complex organisational routines, but from container changes on fair trade drinks that are relatively easy to replicate.

Overall, Ministop's fair trade marketing assumes a venture business character regardless of its mainstream status in Japanese retail markets. Its sustainability in the fair trade business depends on the longevity of CSR policy to support fair trade initiatives. It requires more involvement of corporate staff in Ministop, which will result in SCAs from the perspective of organisational learning in the fair trade business.

3.3 Case 2: People Tree

People Tree is a fair trade specialty brand, merchandising fashion items as well as conventional food products. People Tree was founded in Tokyo in 1995 by Safia Minney, and at present, the company has partnerships with 60 producer organisations in 20 countries throughout Asia, Africa, and Latin America.

While fair trade items in Europe are mainly FLO-certified foods and sundries, People Tree is renowned as a pioneering fashion-intensive clothes retailer. It sells such items not only in fair trade speciality stores, but also via mail order catalogue and internet channels. Currently, around half of company's sales come from fair trade clothes [5].

Since 2002, the turnover has grown at 3%-15% annually, reaching 0.7 billion in 2007. Minney [16] believes that fair trade clothing will become more prevalent if customers purchase it not because of its concept, but rather its cute design. This order is almost opposite to the historical development of fair trade popularity in Western nations.

At the outset of its efforts to sell fair trade clothes, People Tree faced obstacles because such clothes were not well aligned with Japanese preferences in design and size.

Currently, the company provides improved designs for the Japanese market, with local producers who maintain their indigenous techniques for apparel manufacture. To maintain quality and meet shipping deadlines, People Tree contacts local producers almost daily.

In the early days, indigenous suppliers sometimes resisted high product standards imposed by People Tree. The company's efforts including direct instruction on manufacturing techniques and annual invitations of local representatives to Japanese markets contributed to the decrease of such struggles [17].

Improved manufacturing techniques based on the high product standards imposed by People Tree could lead to the market expansion of fair trade garments to other developed nations. Moreover, since clothes manufacturing involves many processes such as weaving, embroidery and sewing, each process enables People Tree and the local producers to acquire experimental knowledge in clothes manufacturing to Japanese market.

Overall, People Tree's product development contributes to the promotion of fair trade fashion. Nevertheless, promotional efforts by advertisements are also indispensable for further penetration of such new markets.

In the last seven years, People Tree has placed advertisements in a variety of publications, as other fashion retailers do. Particularly, collaboration with Vogue Nippon in 2007 contributed to the expansion of People Tree's sales channels. People Tree's advertisements also revised conventional images of fair trade items among the readers of Vogue Nippon and people in the apparel industry as unfashionable.

In that collaboration plan, four designers from Foundation Addict, Bora Aksu, Richard Nicoll, and Thakoon provided designs for People Tree, and local producers in India and Bangladesh manufactured 100 clothes with organic cotton. Those clothes were sold at United Arrows in addition to the current sales channels in People Tree. Fair trade clothes in 'People Tree Collection 2008' were also retailed at Takashimaya. Following the success of the collaboration project, Bora Aksu, Richard Nicoll, and Thakoon continued to supply their designs to People Tree.

A series of promotional efforts did not emphasise the conceptual message of fair trade. People Tree first attracted the attention of young Japanese for its fashionable clothes. Then, the company shared the embedded messages of fair trade with local producers in the South. This strategy can be effective to draw attention of laypeople towards the fair trade movement, because many people tend to regard foreign loan words used in the context of civil society, for example, fair trade as alien.

From the perspective of the Ansoff Matrix, the marketing strategy of People Tree is mostly opposite that of Ministop: it moves away from diversification strategies toward market development strategies.

Market Growth		Product Growth: Existing Products	Product Growth: New Products
Market Growth	New Markets	**Market Development Strategies** Market-Adjusted Fair Trade Clothes Mainstream Sales Promotions	**Diversification Strategies** Ethnic Fair Trade Clothes Ethnic Fair Trade Handcrafts
Market Growth	Existing Markets	**Market Penetration Strategies** N/A	**Product Development Strategies** N/A

Fig. 2: The Ansoff Matrix with People Tree

The company continues to modify indigenous fair trade clothes towards 'mainstream' fair trade fashion, shifting the designs from ethnic tastes to Japanese preferences, and promoting them through 'celebritised' promotional efforts. Such modified fair trade clothes are considered comparable to other products sold in mainstream retail outlets.

This structural change of merchandising helps spread the monetary risks that are critical in the sustainability of small- to mid-size fair trade business, for, unlike Ministop, People Tree does not have the financial support of a large corporation. As a result, diversifying growth strategies is essential for the business sustainability of People Tree.

Grant's analysis, applied to the case of People Tree, reveals a contrasting approach compared with Ministop. Product development in People Tree derives largely from organisation-specific routines sustained by collaboration among local producers. In addition, most staff members are familiar with fair trade products, which can lead to stronger sales promotions and delivery of the conceptual messages of the fair trade movement. While mainstream retail outlets can facilitate advertisements such as posters and promotion boxes, these advertisements are less effective regardless of the staff members' passion for fair trade initiatives. These factors confer low appropriability, replicability, and transferability on People Tree's approach.

One possible weakness of People Tree comes from its low durability with respect to its reputation and business continuity. It may lose its corporate identity when the charismatic founder retires from the role of president. For People Tree, Minney is the greatest champion of fair trade fashion. Consequently, a key to the company's enduring success will be a smooth succession.

In conclusion, People Tree is now transitioning from a venture business to a mainstream retail outlet. People Tree will undertake market penetration strategies following the current two strategies to increase sales volumes through economies of scale when it has become one of the leading retailers in Japan.

3.4 Case 3: Choco-Revo

In the above case studies, we explored the various marketing strategies of private companies that sell fair trade items. This final case examines a Japanese NPO, Choco-Revo, which is a fair trade movement promoter.

Choco-Revo, established in 2006 by Tomoko Hoshino, engages in various activities associated with fair trade such as consumer surveys, CSR consulting, event hosting and advertisements. The demand for Choco-Revo's services, particularly among listed companies, is increasing because many companies e.g. SONY and Ministop seek to improve their CSR strategies. For instance, the reason Ministop decided to promote fair trade products originated in the conference, 'Exploring the Safety of Chocolates' supported by two Japanese NPOs, Choco-Revo and ACE. Those NPOs explained the human rights associated with chocolates production in the South.

Hoshino [18] believes that support of companies' 'something good' activities could satisfy the needs from business society on account of the increasing concern for CSR. People Tree [17] also explains that collaborations with companies in People Tree reflect the growing importance of fair trade as part of CSR strategies. As such, a company's CSR policy could boost fair trade movement, and the successful implementation of CSR depends on the deployment of fair trade-related NPOs.

Based on such embedded intentions, Takashimaya decided to collaborate with Choco-Revo to sell organic and fair trade chocolates named 'Zotter' during the St. Valentine's season in 2008. This marketing strategy was designed to build a strategic win-win relationship between Choco-Revo and Takashimaya. While the former could maximise its fair trade advocacy, the latter could retail 'something different' chocolates effectively. In 2009, other renowned retailers such as Odakyu, MUJI, Yurakucho Hankyu, and I.D.E.A also prepared for fair trade or organic chocolates recommended by Choco-Revo during the same season.

In addition to involvement with the private sector, Choco-Revo embarked on a collaborative relationship with public sector organisations such as the Japan International Cooperation Agency (JICA).

These collaborations led by Choco-Revo represent the organisation's optimal use of diverse strategic assets in the clients. Such collaborations with powerful actors allow Choco-Revo to acquire new sales channels, merchandising opportunities and reliability of its fair trade advocacy at low cost.

Choco-Revo's adoption of mainstream strategies may cause tensions with traditional and alternative market philosophies and practices. Ironically, it may be inevitable for fair trade NPOs to pursue the mainstream nature of fair trade movement due to the current lack of awareness about fair trade products in Japan. Hoshino [19] pointed out that environmental advocacy as a part of CSR strategies is generally more accepted by Japanese consumers than advocacies led by the government or NGOs.

On the whole, the tendency of adopting 'enlarged' mainstream strategies through collaborations will continue among powerful corporate actors as long as fair trade items are considered to be 'alternatives' of conventional commercial goods.

3.5 Summary

Each organisation discussed above has its unique marketing strategy of fair trade. In contrast with their Western counterparts, Japanese suppliers are required to produce more region-specific fair trade items.

Additionally, some NPOs began supporting such marketing efforts owing to increased concerns about CSR. This trend could accelerate the mainstream adoption of Japanese fair trade initiatives.

Because of the immaturity of the Japanese fair trade market, it remains hard to predict the future of Japanese fair trade marketing. It is clear, however, that the Japanese market will follow a different path from that observed in Western nations.

4 CONCLUSION

4.1 Major Research Findings

A short summary of the major research findings is presented in this sub-section.

4.1.1 Market Expansion through Product Development

These case studies demonstrate that localised products are required to expand the Japanese fair trade market. For instance, Ministop strives to adjust fair trade coffees to the local market through container and flavour development tailored to suit the Japanese market. Ministop has launched fair trade initiatives despite substantial financial risks, feeling such expenditures are necessary to support the company's CSR strategies.

In contrast, People Tree engages in fair trade as part of its core business. This leads to intense communication with local producers through the process of product development. Although People Tree exploits indigenous manufacturing technology, the organisation seeks to popularise its fair trade items with Japanese-specific clothes preferences.

4.1.2 Differing Relevance of Fair Trade Advocacy

Contrary to the West, the fair trade philosophy can be an obstacle to the fair trade movement. Since Japan is geographically and historically far from most local producers, few Japanese understand the importance of the concept. In fact, the consumer awareness of fair trade continues to be low despite its launch in the early 1990s. As a result, the laypeople in Japan tend to recognise fair trade not for its social relevance, but for the freshness of fair trade products promoted using Japanese-specific marketing strategies.

4.1.3 Enlarged Mainstream Strategies

Fair trade movement in Japan also shifts from 'grassroots' to 'mainstream', which is observed in its historical development in the West. In addition, Japanese fair trade suppliers increasingly seek to enlarge their mainstreaming strategies through collaborations with diverse actors such as the mass media, NPOs, governmental organisations, and major retailers.

4.1.4 Fair Trade Initiatives as Part of CSR

Since most 'mainstream' actors in Japan, are listed companies, they need to manage the growing concern for CSR imposed by various stakeholders such as shareholders and the global civil society. Nowadays, not only manufacturers, but also retailers take up fair trade businesses as part of their CSR strategies.

In addition, Japanese NPOs do not try not to pressure listed companies to adopt fair trade practices, but rather promote fair trade through the consultations of CSR strategies. In this sense, the relationship between fair trade

NPOs and listed companies in Japan can be described as cooperative rather than antagonistic.

4.1.5 Passionate Individuals Lead the Movement

In Japan, fair trade suppliers still suffer difficulties garnering public attention. Except for some speciality shops, most suppliers also remain unfamiliar with the idea of fair trade, even though they have already begun to develop fair trade items. Unlike the West, it is hard to imagine that laypeople in Japan have the competence to lead fair trade advocacy, irrespective of some passionate individuals, for example, Okamura (Ministop), Minney (People Tree), and Hoshino (Choco-Revo).

4.2 Future Predictions of Japanese Fair Trade

The present Japanese fair trade market is generally unattractive for mainstream actors given its market scale. In such a small market, fair trade businesses may not be profitable because companies cannot fully deploy economies of scale.

In contrast, corporations could pay the cost of such business when they regard it as the consideration of CSR that will contribute to the public penetration of fair trade concept. If powerful beverage makers were to perceive fair trade a part of their CSR activities, the Japanese fair trade market could become increasingly competitive, thereby driving mid-small roasters out of the competition.

Currently, Suntory contracts with Starbucks Japan to retail Starbuck's brand canned and chilled drinks at an approximately 50% higher price than conventional drinks. This implies that Suntory may develop fair trade drinks as part of value-added canned or chilled drinks. In reality, some companies began to consider fair trade coffees as value-added goods that may raise the total sales in the coffee category. However, if those companies seek sustainable profits from such items, fair trade coffees they will need to deliver high quality in addition to the humanitarian value. One of MUJI staff revealed that many customers recognise fair trade as an attractive brand, which eventually leads to constant purchase of fair trade drinks in the company [20]. As such, many fair trade actors will gradually look for the quality of fair trade products to promote repetitive purchase of such items.

A Cause-Related Marketing Strategy with a Character Brand –The Case Study of Projects at Solar Bear Fund, a Japanese Non-Governmental Organization

Yasuyuki Yamagiwa[1], Yurie Makihara[2], Megumi Harayama[1]

[1] Tokyo Zokei University, Tokyo, Japan, [2] Blekinge Institute of Technology, Karlskrona, Sweden

Abstract

Today's society is full of complexity and faces difficulties in inviting future generations to have discussions in order to move towards sustainability. Cause-related marketing (CRM) is a good tool for companies and non-governmental organizations (NGOs) to collaborate in order to improve society. A new CRM strategy with character brand is discussed here in order to investigate strategic possibilities and explore the key factors around how to design the strategy. This is done through a case study of the projects at Solar Bear Fund, a Japanese NGO, and the companies working with the NGO. Recommended discussions for the future are also provided.

Keyword

Cause-Related Marketing, CRM, Character Brand, Sustainability, Stakeholder Dialogue, Solar Bear Fund, Solarbear.jp

1 INTRODUCTION

1.1 Background

Society today is confronting ecological and sociological challenges that have affected the ecosystems and caused critical social problems [1]. On the one hand, in order to deal with these issues move society towards sustainability, efforts have been made to increase and enrich conversations among stakeholders [2]. On the other hand, challenges have been identified, two of which are described below. Firstly, the complexity in society has grown tremendously and the diversity of values among people has increased substantially [3]. It might therefore be difficult to share common goals and see how to reach those goals easily. Secondly, one of the key points in moving towards sustainability would be pursuing the satisfaction of our needs without compromising the next generation's [4]. However, for children, when it comes to understanding the ecological and sociological challenges and taking action themselves, it may not be clear how to satisfy their needs within the current society.

.

1.2 Cause-Related Marketing

Cause-related marketing (CRM) is generally known to be a marketing communication tool in order to put corporate social responsibility into practice [5]. CRM can function successfully only when consumers, business enterprises and non-governmental organizations (NGOs) collaborate. Consumers can indirectly contribute to social action programs simply by purchasing a product and service. For business enterprises, CRM is not only a way to contribute to social action programs, but it also brings two other possibilities. The one is that the sales of the product and service will increase and the other is that the stakeholders will value the company more highly. It might increase the brand value of the company in the long term. CRM also allows NGOs to raise funds in order to conduct social action programs and to communicate efficiently what they have has done to society [5].

For example, American Express has set up a program to donate money linked to customers' spending in order to restore the Statue of Liberty [6]. Kirin MC DANONE Waters Co.,Ltd has donated money to the construction of wells based on sales of Volvic water products in African countries [7]. The authors were inspired by the idea that benefits that the companies can obtain from CRM are so highly valued that cost intensive advertising can be less worthwhile [5]. The authors have started to investigate the possibility of CRM to overcome the two difficulties mentioned above, that is to keep simplicity without losing important factors to understand the issues and to provide the change to invite next generations into the conversation. Character brand could help convey the message more simply and intuitively in order to understand the issue and the goal. Investigating the case study of combining CRM with a character brand could provide some findings.

2 RESEARCH PURPOSE AND METHODOLOGY

2.1 Research Purpose

The aim of this research is to raise the authors' awareness of the issue by examining a CRM strategy of companies such as Sony Corporation, which is making use of character brand to support a Japanese NGO (the subject of this paper). Both expanding the possibility of this strategy and specifying what should be investigated and discussed in the future would also be included in the scope.

The research questions that would be addressed are:

1: How has a CRM strategy with a character brand been conducted in the real business case in Japan?

2: What would be the key factors to design a CRM strategy with a character brand to invite many stakeholders including children to discuss and to take action to move society towards sustainability?

2.2 Methodology

The process of the research includes conducting literature reviews and questioning via email a board member of the NGO. Firstly, articles, scientific journals, CSR reports and the websites of the NGO were researched.

3 RESULTS

3.1 A CRM Strategy with a Character Brand: A Case Study

Solar Bear Fund

The NGO has conducted educational activities to promote the increased use of renewable energy and to provide environmental education for children and do administrative work about license of the character of 'Solar Bear'[8]. As shown in figure 1, the character of 'Solar Bear' is displayed on the product and service of the companies that are taking a proactive step towards reducing carbon dioxide emissions in their marketing strategy. Part of the sales of the target products and services will be donated to the NGO, which provides solar panels to kindergartens or nursery schools and also provides sustainability education to children [9].

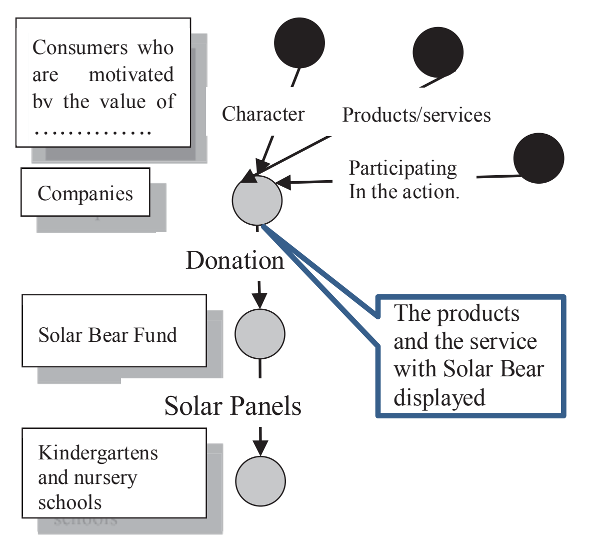

Fig. 1: The model of CRM with a character brand

Design-in the concept of the character at the advisory meeting

Founders of the NGO consist of directors of other NGOs and representatives from companies which support the NGO. As well as the board of directors, there is an advisory board, the representatives of which are supplied by the companies which support the NGO [10]. Based on these facts, it can be assumed that since the foundation of the NGO, the stakeholders have addressed important aspects, such as the concept that they aimed to create and whether the strategy was practically acceptable and applicable for Japanese companies.

It seems to be reasonable that if the NGO aimed to collaborate with Japanese companies to impact on society, understanding their needs and designing them into the concepts and services that the NGO would provide was crucially important. Therefore, the governance of the NGO has affected the CRM strategy.

Installation of the character

The symbol in this strategy is 'Solar Bear', which is developed by Mr. Shinji Katoh, the original creator, and Sony Creative Products Inc. This strategy uses the motifs of polar bears, which are threatened because of the impact of climate change, as shown in figure 2 [11]. The background of this story is that the brother polar bears were separated in childhood from their mother when the arctic glaciers melted due to climate change [12]. Solar is named after the sun that

© Shinzi Katoh

Fig. 2: The character Solar and Bear [14]

the NGO would like to disseminate with solar panels and Bear is named after polar bears [13].

Creation of Character Brand Recognition

When it comes to building this strategy, it is essential to create the character brand so that consumers easily recognize it. Constructing the easy recognition of the view of the world is a way to market the character brand. In order to do that, the publishing of the picture books 'Solar Bear' and DVD have been used [11][15]. In order to publicize the character brand to as wide an audience as possible, media such as newspapers and magazines have been utilized. Simultaneously, PR activities have been conducted at locations most attractive to customers. For example as shown in picture 1, the 'Solar Bear' monument has been installed and events have been held at Mediage, a shopping mall at Odaiba in Tokyo [16], as figure 3 shows.

Moreover, branding goods such as soft toys, kitchenware

Fig. 3: Solar Bear Monument

and groceries have added value to these products based on the license contract [9] [17]. These comprehensive approaches have contributed to an increase in reputation of the character brand.

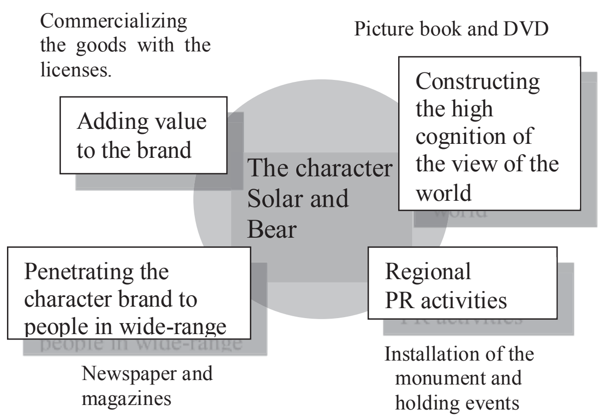

Fig. 4: Create of Character Brand cognition

Installation of solar panels and conducting educational activities

The NGO has installed solar panels in order to reduce carbon dioxide emissions (20 solar panels have been installed in schools in Japan based on donations to the NGO) and the electricity generated from them totals 29.715kWh and 8.65t-CO_2 emissions have been reduced excluding electricity sold as of December 2010. CRM is primarily a marketing strategy. At the same time, however, revenue from the marketing strategy is donated directly to reduce the impact on the environment [18].

The knock on effect of this strategy

The companies working with this strategy will now be discussed in order to see if any patterns emerge.

Sony Corporation donates a part of the revenue generated from the sales of batteries and battery chargers in packaging that display "Solar-bear" campaign characters [19] and the campaign message of 'Let's foster green electricity together' [9]. Sony Corporation also has a campaign to donate 100Yen for every VAIO™ customer in 2010 who has submitted the customer service survey [19].

Sony Life Insurance Co.,Ltd has allowed new policyholders to opt to obtain their policy guide on CD-ROM instead of in paper form. When they select the CD-ROM, Sony Life Insurance Co.,Ltd donates 10 Yen [19].

Sony Assurance has conducted a program to encourage a car-users' behavior change towards environmental conservation. The policy holders declare the estimated distance to be driven at the start or renewal of the contract. When policies are renewed, if the actual distance driven is below the estimated distance, Sony Assurance donates 1 Yen per kilometer to the NGO as a token of the contribution to environmental conservation [19].

Citizen watch Co.,Ltd has developed Eco-Drive, a wrist watch fitted with solar cells, so that users can use them without changing the batteries in order to decrease the environmental impact of using watches [20]. A portion of Eco- drive sales are donated to the NGO and character branded gifts such as key holders accompany the watches [9].

3.2 The pattern of the CRM with a character brand

The 4 key factors to design the content of the CRM strategy

By comparing the business cases as described in 3.2, some common characteristics about this strategy can be seen as shown in table 1. Some of them could be integral in designing a CRM with a character brand. It is not yet known if these characteristics are key or not.

1.Types of incentives

There are two types of incentives for consumers to participate in the program. The companies decide on the target products/services and donate a part of the revenue from the target product/service to the NGO. This shows very clearly and directly what percentage of the revenue would be donated and highlights the relationship between the consumers' and how much is donated. Alternatively, there is an indirect contribution. For example, in the campaign of Citizen Watch Co. Ltd, consumers do not know how much the company donates to the NGO when they purchase a watch. However, in the campaign of Sony Life Insurance Co. Ltd and Sony Assurance, it is clear that if a policyholder takes the agreed action in advance, a specific amount of money would be donated to the NGO.

2.Correlation of the products/services and the purpose of the NGO

One of the main aims of the NGO is to take action to decrease carbon dioxide emissions. To what extent the products/services provided in the campaign relate to the purpose of the NGO could be important to the campaign. For example, in the Sony Assurance campaign, the motivation to decrease using private cars would directly relate to the NGO's goal. In Sony Corporation's battery and chargers campaign of, the charger and rechargeable batteries would relate to the goal However, the campaign involves selling batteries, and their contribution to the NGO's goal is not clearly defined.

3.The extent to which children are invited to take actions in the campaign and to learn about sustainability

As mentioned in 3.1, regarding the creation of character brand recognition, some children know about Solar Bear and their story and some of them might want to take action to help them if presented with the opportunity. With this in mind, it could be crucial for the products/services to be displayed with a character brand that is tangible for children so that they question their parents about it. For example, in the campaign of Citizen Watch Co.,td, children might ask their parents to buy these watches because they want to have the accompanying Solar Bear key. In the battery and battery chargers campaign of Sony Corporation, a character brand can be located in-store that children can easily such as in front of the cash register. During the phase when those products/services are used, children can learn something around sustainability and how to take action. For example, in the campaign of Sony Assurance, they can learn how to decrease carbon dioxide emissions and how they can contribute to it by taking action themselves if their parents can explain the contract.

4.Whether the campaign promotes consumers' behavior changes beyond the campaign

The ultimate goal of the NGO should be to spread environmental education to people and collaborate with companies in order to accomplish the goal.

If people can continue to buy the products/services which have less impact on the environment thanks to a campaign, the campaign could be said to be more successful. For example, if a family tried to adopt the car usage in the campaign of Sony Assurance and change their lifestyle such as cycling or walking in their area instead of driving, even after the campaign, their behavior would continue. In the battery and battery chargers campaign of Sony Corporation, children who can learn to use a battery charger might opt for reusable batteries in the future.

The 4 factors to design the process of the CRM strategy

As this mentioned in 3.1 'design-in the concept of the character at the advisory board', it could be important to have 'stakeholder dialogue' from the earliest stage to build an understanding of needs between companies and a NGO and then to design them in to the concept, the process and the content of the campaign.

Table1: A Comparison of the examples

Company	Produce/Service	Types of incentives	Correlation of the products/services and the purpose of the NGO	To what extent children can understand the campaign.	The consumers' behavior changes more than the program
Sony Corporation	Batteries and battery chargers	Indirect	Some Clear: decreasing the waste material from batteries, which will decrease CO2 emissions The other Not really clear	Possible to contribute to the purpose of the NGO especially at purchasing the products	Possible
Sony Corporation	Personal computer	Indirect	-*1	-*1	-*1
Sony Life Insurance Co.,Ltd	Life Insurance	Direct	-*1	-*1	-*1
Sony Assurance	Auto insurance	Direct	Very Clear: Reduction of CO2 emissions from private cars	Possible to contribute to the purpose of the NGO especially at using the services	Possible
Citizen watch Co.,Ltd	Eco Drive (a wrist watch)	Indirect	Very Clear: Using Solar energy	Possible to contribute to the purpose of the NGO especially at purchasing	Possible

*1=the information is too limited to describe some conclusion here.

4 CONCLUSION

4.1 Summary

This is a case study that examines a CRM strategy that is making use of character brand. The process of designing-in the concept of the character and the process of the efforts to build the character brand in this CRM strategy have been described. It has helped to compare the case studies and come up with key components of this CRM strategy.

A CRM could be successful because of the benefits of CRM and character brand combined. CRM could be a bridging tool between companies and NGOs and a character brand could work to share the concept towards sustainability in a simple and empathetic way. It seems to function in the context and create the possibility to lead to both collaborations with future generations and to behavior changes today.

4.2 Areas for Further Research

This research is the first step towards understanding the business case of a CRM strategy with a character brand, and one of the contributions of this paper should be identifying the areas of further research.

First, a way to measure how the character brand directly contributes to increasing sales has not been established. Hence, the strategy should be investigated quantitatively. If this could be clarified and the validity of this strategy higher, more companies could decide whether to employ the strategy. Secondly, in this paper, building up the character brand has been the focus. However, a strategy to maintain the long-term value of the character brand is also necessary. Thirdly, this research has been done by literature review. Interviewing and/or conducting questionnaires of the companies working in this strategy and consumers would provide more information to scrutinize the authors' work. Sample questions could be:

- How has the character affected consumers' decision to buy the products/services?
- To what extent are children educated in the campaign?
- Has it caused a behavior change in consumers?

Fourthly, investigating the key factors that are described in 3.2 with more information and/or finding if there is a correlation between the key factors might be useful to expand a CRM strategy with a character brand.

Fifthly, there has been a framework for strategic sustainable development (the FSSD) developed in order to overcome the complexity without ignoring parts of reality [22]. Investigating where this marketing tool is located in the FSSD might be useful to the sustainability practitioners in the future.

Finally, we appreciate the generous support from Mr. Masahiro Ishino at Sony Corporation for providing and reviewing this information.

Business Strategy Planning Based on Sustainable Society Scenarios

Maki Hirosaki[1], Yusuke Kishita[1], Yuji Mizuno[1], Shinichi Fukushige[1], Yasushi Umeda[1]
[1] Department of Mechanical Engineering, Osaka University, Osaka, Japan

Abstract
Companies start to describe sustainability scenarios in order to make long-term strategies toward a sustainable society. However, the support in making such strategies is inadequate. In this paper, we propose a method for supporting planning processes of such business strategy scenarios. For this purpose, we formalize a business strategy scenario consisting of four parts and we take an approach to use existing sustainable society scenarios for describing environments surrounding the company. For verifying availability of the proposed method, a case study of solar panel business is carried out. As a result, it is revealed that planning of business strategy scenarios is efficiently supported by detailing an existing scenario.

Keywords:
scenario, sustainability, strategy, business, solar panel

1 INTRODUCTION

Companies have started to make long-term strategies toward enhancing their sustainability under many uncertainties in the real world. It is difficult to make long-term strategies because it is very tough to predict the future of environments around business. For dealing with this problem, describing scenarios is a promising approach for drawing a variety of futures and planning a variety of strategies in each future. Some companies have, in fact, described long-term strategies in the form of scenarios. For example, Ricoh [1] drew their visions and strategies in 2050 based on Emission Scenario written by Intergovernmental Panel on Climate Change (IPCC) [2].

Scenario planning [3] is a typical method for describing scenarios, helping to make strategies in the scenarios. The method of scenario planning is explained as follows: (1) a scenario writer selects some factors that have a crucial impact for business, (2) the writer draws some changes of the factors as scenario, and (3) the writer makes strategies based on the scenario. However, describing such scenarios is not well-supported.

The objective of this paper is to propose a method for supporting planning process of business strategy scenarios. Business strategy scenarios here refer to scenarios that describe business strategies based on various possible business environments. A business environment means an external environment around business. In this paper, we employ existing scenarios for helping to describe possible business environments. Additionally, we extend the stractual scenario description method [4] for representing business strategy scenarios.

2 CONCEPT OF DESIGN SUPPORT METHOD FOR BUSINESS STRATEGY SCENARIOS

2.1 Requirements for supporting design of business strategy scenarios

From our literature reviews on scenario planning methods we identify three requirements for supporting design of business strategy scenarios as follows:

(1) Various business environments should be described for examining uncertainties of future business environments.

(2) Business strategy scenarios should be formalized and gradually detailed in a stepwise manner so that the scenario writer can derive various business strategies based on various business environments assumed in the scenarios.

(3) The relationship between business environments and strategies should be clarified because the present situation will change in the future and, therefore, descriptions of business environment and strategies should be updated then.

M. Matsumoto et al. (eds.), *Design for Innovative Value Towards a Sustainable Society*,
DOI 10.1007/978-94-007-3010-6_85, © Springer Science+Business Media Dordrecht 2012

2.2 Approaches

In order to meet the above requirements, we take the following approach in this paper.

To meet the first requirement, a scenario writer employs one or more existing sustainable society scenarios in describing business environments. A sustainable society scenario means a scenario that shows visions of future societies toward sustainability. The method intends to help the writer to assume environments around business easily by reusing hypotheses and data in existing sustainable society scenarios. To meet the second requirement, we formalize a business strategy scenario consisting of four parts (see Fig. 1); *i.e.*, problem, vision of a company, future business environments, and business strategies. Details of this representation are explained in Section 3.1.

For the third requirement, we use the structural scenario description method [4] for expressing business strategy scenarios. The method has the advantage of representing logical relationship between descriptions in a scenario, thereby enabling to articulate the relationship between a business environment and associated business strategies.

2.3 Structural scenario description method [4]

To comprehend a structure of scenario, we define four levels to represent scenarios as follows.

- Scenario Level: shows the structure of sub-scenarios.
- Expression Level: shows the relationship between texts in a scenario.
- Word Level: shows the relationship between words in a scenario.
- Data Level: shows the simulations that underlie a scenario.

In each level, we express a scenario as a directed graph, using nodes and links. Nodes express an element of each level, while links express the relationship between two nodes.

3 METHOD FOR SUPPORTING DESIGN OF BUSINESS STRATEGY SCENARIOS

3.1 Basic structure of business strategy scenario

In this paper, we formalize a business strategy scenario in following way. For making strategies, we clarify targets that a company aims to achieve. For considering strategies easily, we distinguish a set of possible futures that the company cannot control from actions that the company may take. In other word, we divide descriptions in the scenario into external or internal descriptions. In this paper, we model a business strategy scenario as a combination of four elements; (1) Problem, (2) Vision and Target, (3) Business Environments, and (4) Business Strategies (see Fig. 1).

(1) Problem: setting about the business strategy scenario, such as topic and coverage about region and time horizon of a business strategy scenario. And it shows motivation of describing a business strategy scenario.

(2) Vision and Target: a goal of a company. It becomes a guide of business strategies in designing a business strategy scenario.

(3) Business Environment: the environment around business uncontrollable by the company, such as needs of consumers and competitors' actions.

(4) Business Strategy: sets of actions to achieve the target in various business environments.

We divide this business environment into two parts; namely, Sustainability Society Scenario and Detailed Business Environment. In sustainability society scenario part, the scenario designer uses existing sustainability society scenario as the outline of the business environment in order to help assume the future. In detailed business environment part, we add more information that is not described in sustainable society scenario (for example, competitors' actions and legislation).

3.2 Expression of business strategy scenario

We use the structural scenario description method [4] to express business strategy scenario. While this method is proposed for representing general structure of scenarios, the method does not express distinction between elements of a business strategy scenario. Thus, we extend this method for representing the scenario structure proposed in Section 3.1 by introducing Business Level. In Business Level, we express structure of business strategy scenario using nodes and links shown in Fig. 2. We define seven types of nodes (problem, vision, target, sustainable society

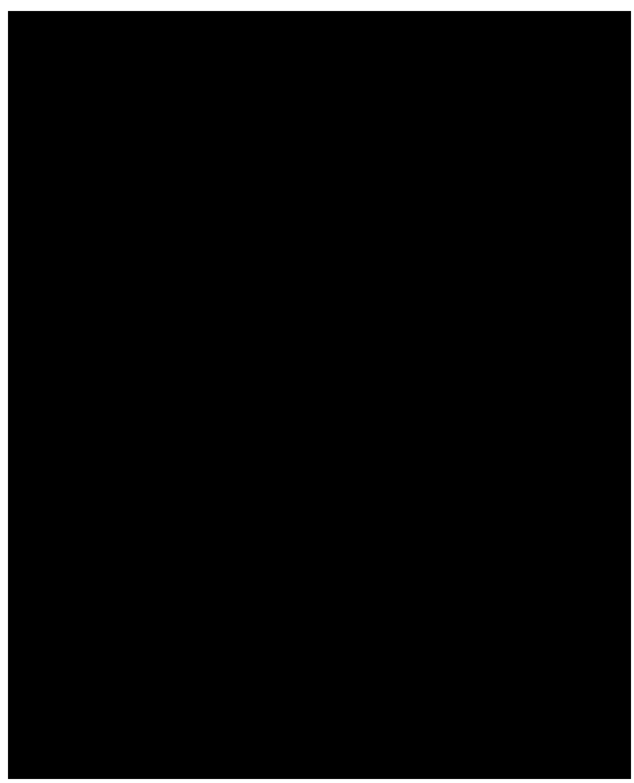

Fig. 2: Expression of structured scenario (Business Level)

Table 1: definition of Business Level

Type		Definition
Node	problem	A contents of problem setting
	vision	A goal that the company aims to achieve in a distant future.
	target	A mid-term goal that should be achieved to reach the vision.
	sustainable society scenario	An existing scenario used as a base of describing the business scenario.
	detailed business environment	A business environment deployed from descriptions of sustainable society scenario.
	business strategy	A set of strategies or actions that the company may take, under a business environment.
	conclusion	Conclusions that indicate final suggestions for the company, which are derived from the described business strategies.
Link	derive(A, B)	Node B is derived from node A
	detail(A, B)	Node B is a detailed description of node A.

scenario, detailed scenario, business strategy, and conclusion) and two types of links (detail and derive) in this level. Table 1 describes definitions of nodes and links of the business level.

3.3 Design process of business strategy scenarios

Along the basic structure of business strategy scenario as shown in Fig. 1, we describe a business strategy scenario in the following four steps.

Problem setting

For clarifying a topic and coverage of business strategy scenario, the designer describes a problem by defining seven items of Table 2. These items involve background, objective, actors of the business strategy scenario, region, and time horizon.

Vision and Target setting

In this step, visions and targets of the company are described. The designer describes a vision for clarifying a goal which a company wants to achieve in future (for example, reducing 30 percent of CO_2 emission in a company from 2010 to 2050). The designer then describes clearer targets to achieve the vision (for example, reducing 10 percent of CO_2 emission from 2010 to 2020).

Describing business environment

In this step, the designer describes environment around the business such as consumers' needs, competitors' actions, lifestyle, legislation, and so on. We divide this business environment into two parts; Sustainability Society Scenario and Detailed Business Environment. As the part of sustainability society scenario, the designer selects existing sustainability society scenarios.

Table 2: Problem description of a scenario

Item	Description
Title	Title of the scenario
Background	Motivation for describing the scenario
Objective	Objective for describing the scenario
Region	Targeted region in the scenario
Time horizon	Starting and end year of the scenario
Main Actor	Main stakeholders in the scenario
Actors	Stakeholders involved in the scenario, other than the main actors

In a detailed business environment part, we add more information that is not described in sustainable society scenarios (for example, competitors' actions and legislation). The designer describes a detailed business environment in two steps:

(1) The designer assumes changes about critical factors for the business, as a guide of describing detailed business environment.

(2) The designer details description of sustainable society scenarios along with the changes that are assumed in Step (1).

Describing business strategy

In this step, the designer describes business strategies, which the company may take based on each business environment described in the previous step. The designer describes business strategies in two steps:

(1) The designer makes a lot of business strategies based on each business environments.

(2) The designer organizes and selects business strategies to achieve the targets and visions.

4 CASE STUDY

4.1 Overview of the case study

For verifying availability of the proposed method, we carried out a case study of describing a business strategy scenario for a solar panel manufacturer. As an existing sustainable society scenario, we used Energy Technology Perspective 2010 (ETP2010) [5] because this scenario mentions dissemination of solar panels in the world until 2050. We described four detailed business environment based on the two sub-scenarios of ETP2010, and then derived various strategies from each business environment.

4.2 Problem setting

In this business strategy scenario, we defined main actor as a solar panel manufacturer. We assumed that the

Fig. 3: Business Level of the business strategy scenario

company produces two types of panels (crystalline silicon cell and thin-film sell). To consider long-term strategies in this company, we set problems as shown in Table 3.

Fig. 3 shows Business Level structure of the business strategy scenario. We expressed the problem setting described in Table 3 as a problem node (node (A)) in Fig. 3.

4.3 Vision and Target setting

We set a vision of this solar panel manufacturer as contributing to a sustainable society by providing solar panels. To achieve this vision, we set target that their products accounted for 10 percent of the world solar panel sales in 2020 and 15 percent of those in 2030. In Fig. 3, we expressed the vision of the company as node (B), the target in 2020 as node (B-1), and the target in 2030 as node (B-2).

4.4 Describing business environment

First, to describe business environment, we selected ETP 2010 as existing sustainable society scenario used in the business strategy scenario. In ETP 2010, two scenarios (Baseline scenario and BLUE Map scenario) are described, each of which differ in dissemination of energy technologies. While Baseline scenario assumes that governments introduce no new energy and climate policies, BLUE Map scenario examines the least-cost measures of achieving the goal that global energy-related CO2 emissions are reduced by half from the 2005 level by 2050 through the deployment of existing and new low-carbon technologies. In Fig. 3, we described the descriptions of Baseline scenario as node (C-1) and the descriptions of BLUE Map scenario as node (C-2).

Second, we described detailed business environment. We focused on changes of silicon prices as a critical factor in the solar panel business and make four detailed business environments based on the difference of silicon prices as shown in Table 4; that is, we created two detailed business

Table 3: Problem of the case study

Item	Description
Title	Business strategy scenario for solar panel manufacturer
Background	The solar panel market worldwide becomes more and more competitive as demand for solar panels is increasing due to pressures on global warming problems and energy security.
Objective	To plan long-term strategies for solar panel business.
Region	World (especially Japan, US, EU, China, India)
Time horizon	2010-2050
Main Actor	A solar panel manufacturer, which is based in Japan. This company deploys its business globally and produces solar panels with the two types of cells, i.e., polycrystalline silicon cells and thin-film cells.
Actors	other solar panel manufacturers, consumers, manufacturers of materials, governments

Table 4: setting in detailed business environment

		ETP2010	
		Baseline	BLUE Map
Silicon prices	Fixed	Any policy about solar panel is not introduced. Solar power is not so popular. Price of silicon is not changed.	A lot of policy about solar panel is introduced. Solar power is popular. Price of silicon is not changed.
	High	Any policy about solar panel is not introduced. Solar power is not so popular. Price of silicon is twice from now.	A lot of policy about solar panel is introduced. Solar power is popular. Price of silicon is twice from now.

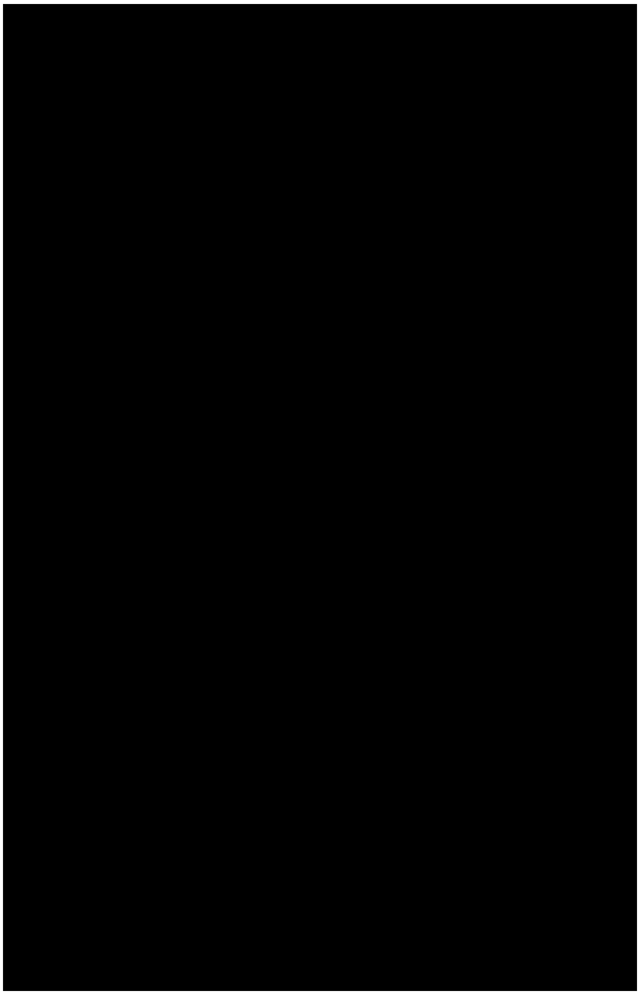

Fig. 4: Scenario description (BLUE Map)

environments for each of Baseline scenario and BLUE Map scenario. In Fig. 3, we created two detailed business environment (node (C-1-1) and (C-1-2)) based on Baseline scenario (node (C-1)), and two detailed business environment (node (C-2-1) and (C-2-2)) based on BLUE Map scenario (node (C-2)) There were two reasons we focused on silicon prices. First, silicon prices directly affect cost of crystalline silicon solar panel, which the company produces. Second, in the last decade, the share of solar panel manufacturers has been largely changed because of high silicon prices in the real world.

We detailed descriptions of sustainable society scenario by adding more descriptions as shown in Fig. 4, which is a part of description of the business strategy scenario. In Fig. 4, node (a) represents a hypothesis of ETP2010. The hypothesis represents that electricity generation by solar power in BLUE Map is 5 times as much as in Baseline. We assumed two different trends of silicon prices; *i.e.*, hypothesis (b) means that silicon prices remain unchanged from 2010-2050, while hypothesis (c) means that silicon prices will become 5 times higher in 2050 from node (a). Next, we estimated payback period with each materials of panels and describe in node (d). In this estimation, we used data in Solar Power Roadmap (PV2030+) [6] node (e)). Fig. 5 represents the result of the estimation. Fig. 5 tells that crystalline silicon costs as much as CIS-type solar panels (Fig. 4 node (f)) and that the payback period will become more than twice compared to CIS type (node (g)).

Fig. 5: Estimation of payback period by solar panel type, expressed as hypothesis (d)

4.5 Describing business strategy

From each of the four business environments, we derived various strategies. We described business strategies in each business environment as business strategy nodes (A-1-1, A-2-1, B-1-1, and B-2-1) in Fig. 3. A part of description of business strategies are shown in Fig. 4. Strategy (node (h)) that we continue to produce crystalline silicon solar panels is derived from description of business environment (node (f)). In the same way, strategy (node (i)) that we sell CIS-type solar panels when silicon price increase by 5 times is introduced from node (g).

From those strategies, we derived that we should sell CIS type when silicon prices become over twice higher as a conclusion (node (j) in Fig. 4). We described conclusions of the business strategy scenario in conclusion node (node (D)) in Fig. 3.

5 DISCUSSIONS

In this case study, a business strategy scenario was designed in the four steps (problem setting, vision and target setting, describing business environment, and describing business strategy).

Table 5 shows number of descriptions in the business strategy scenario. Table 5 indicates that about 60 percent of descriptions in the business strategy scenario are from the underlying scenario, ETP2010. In other words, we succeeded in employing the existing sustainable society scenario efficiently in designing the business strategy scenario. From this discussion, we achieve a part of the first requirement in Section 2.1 by using a sustainable society scenario, but in this method, description of business environment depends on contents of existing sustainable society scenario. On the other hand, about 25 percent of descriptions in the business strategy scenario

Table 5: Number of Expression Nodes in the business strategy scenario

Element		Number of Nodes	Percent age
Problem		9	1.3
Vision and Target	Vision	1	0.1
	Target	2	0.3
Business Environment	Sustainable society scenario	421	60.4
	Detailed business Environment	173	24.8
Business Strategy	Business Strategy	83	11.9
	Conclusion	8	1.1
Total		697	100.0

correspond to descriptions of the detailed business environment, where we added data and hypotheses about solar panel business. This means that, while the first requirement in Section 2.1 is supported to an extent, the main task of designing business strategy scenarios using our method is to detail business environments from existing scenarios.

By extending Structural scenario description method, we clarified the difference between each business environments. We also clarified relationship between business environment and business environment. In other words, we clarified the arguments of business strategies by using the method. For example, in this case study, we created four business environments. When comparing descriptions in detailed business environment nodes (Fixed silicon prices (BLUE Map) and High silicon prices (BLUE Map)), there is a difference about payback period between node (f) and node (g) (see Fig. 4). It is thus easy to follow arguments by following links. For example, in Fig. 4, arguments of node (h) are derived from nodes (a, b, d, e, and f). Therefore, the third requirement is achieved by clarifying the relationship between a business environment and its associated business strategies.

6 CONCLUSIONS

This paper proposed a method for designing long-term strategies using existing sustainable society scenarios. This paper also proposed a representation method for business strategy scenarios in order to clarify business environment and business strategies. In the case study, we created a business strategy scenario for a solar panel manufacturer. In this scenario, four business environments are assumed based on the existing sustainable society scenario IEA ETP2010 and various strategies are derived from each business environment.

Future works include developing support in describing detailed business environment part and describing business strategy parts.

[2] a-Socca, Inc

Abstract

As global environmental issues have become aggravated, "Eco" become one of competitive advantages in the business because of increasing consumers' environmental consciousness. However, it is difficult to lead eco-business to the success in both of environmental and economic aspects because of four features of eco-business; external economy, unrecognition of environmental value in the market, difficulty of evaluating, necessity of repeatedly reforming. For solving this problem, it is effective to support finding out eco-business ideas. This paper proposes the methodology that supports generation of eco-business ideas, which is developed through our investigation of eco-business. This paper also verifies its effectiveness through a workshop.

Keywords:

eco-business, business design methodology, idea generation, eco-innovation

1 INTRODUCTION

In order to achieve sustainable society, greater development in eco-innovation is required. Today, many firms are required by their stakeholders to maintain a high level of environmental consciousness and to take on a greater role in the continuing trend towards eco-innovation. For firms, operating eco conscious business has become vital, because "eco" has become one of the keys to a competitive advantage in business.

We can find several methodologies for supporting generation of new business ideas. 'TRIZ' is an inventive problem solving tool, by which new ideas are generated through six steps; problem analysis, problem definition, generating solutions, etc. 'The 9 building blocks[1]' is also one of these methodologies, by which new business ideas are investigate through nine perspectives: customer segments, value proposition, channels, etc. We can also find methodologies for supporting the development of environmental consciousness such as 'Life Cycle Assessment (LCA)' and 'Life Cycle Design[2].'

Furthermore, recently several concepts for eco conscious business are offered, such as 'Product Service System(PSS)[3],' 'Servicizing[4],' and 'Selling function[5].'. However, there has been a low incidence of success in both business and eco consciousness [6].

This study is to propose a methodology for supporting generation of new eco-business ideas for those that are in new project development and planning team in firms. We propose the methodology based on our investigation of existing eco-business. The investigation clarifies definitions, distinctive features and practical creation process of eco business. And we ran a workshop to verify its efficiency and to identify issues or subjects that need to be addressed.

2 FUNDAMENTAL MODELS

2.1 Investigation of existing eco-business

We investigated existing eco-business shown in Table 1 by literature review and interviews to business associates. For each business, we obtained summary of eco-business, customer needs, contents of service, way to provide service, profit model, sales promotion, triggers of starting the business, competitors, critical issues at the time of starting the business, and point of innovation.

Table 1 :List of investigated eco-business

No	Theme	Business	Company
1	Waste Management	Sub-critical processing technology	REMATEC Corporation
2		Solution business	AMITA HOLDINGS CO.,LTD.
3		Waste and re-resource electron dealings market	Recycle One, Inc.

2.2 Distinctive feature of eco-business

We here define eco-business as business that directly or indirectly reduces environmental loads to the society and, at the same time, makes economic profits.

The following four features distinguish eco-business from traditional business:

1) Existence of external economy

Eco-business provides value to various stakeholders, such as 'neighbors', 'nature', through the reduction of environmental loads, eg. a reduction of carbon emission, pollution and industrial wastes.

Therefore, in generating and evaluating eco-business, 'society' which includes 'neighbors', 'nature', and other stakeholders has to be taken into consideration.

2) Unrecognition of environmental value in the market

The environmental value eco-business provides to customers can be classified into the following four kinds: i) cost reduction, ii) avoidance of risks, iii) improvement of service quality, and iv) improvement of customers' image [7]. Much of these environmental value is not perceived as currency value in the market. For example, nobody buys "mitigating the risk of climate change that can happen in 50 years."

Therefore, we have to grasp the environmental loads to the society in generating and evaluating eco-business.

3) Difficulty of evaluating eco-business

It is difficult to evaluate eco-business, because companies begin eco-business are likely asked to restructure business models or supply chains. For example, in the case of 'No.16 lease of fluorescent lamp,' a company does not sell lamps, sells the service and changes a revenue model.

Therefore, a methodology for supporting generation of new eco-business ideas has to support not only to generate and build an eco-business but to evaluate it.

4) Necessity of repeatedly reforming

Through the investigation described in Section 2.1, we modeled the process of new eco-business development as show in Fig. 1. In the process of new eco-business development, repeatedly reforming an eco-business idea is needed to increase its feasibility.

The process can be divided into three phases. In the first phase, a core concept of eco-business idea is created and extracted from just ideas. In the second phase, an eco-business model is built and repeatedly revised by combining other ideas with the core concepts of eco-business ideas created and extracted in the first phase in order to improve the feasibility. We here define a business model as a mechanism generating profits, which consists of customers, a way to purchase/produce, product/service, price, a way to distribute, promotion.

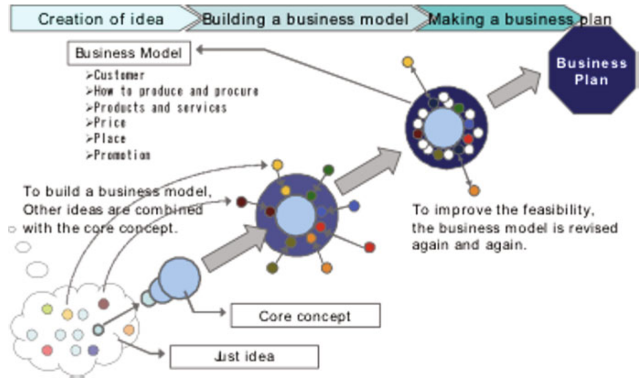

Fig. 1 : Process of establishing eco-business

And after superior's approval of an eco-business model, in the third phase, an eco-business plan is made, which contains the detailed plans and budgets showing how the operational and financial objective of a business.

Therefore, the methodology has to have a process of repeatedly reforming eco-business ideas and models.

2.3 Rules for eco-business idea generation

To succeed in business, 'value' provided to customer shall exceed 'cost' for customer as shown in Fig. 2. Through the investigation described in Section 2.1, in the case of eco-business, 'value' consists of 'environmental value' in addition to 'function' provided by the product or the service, and 'cost' consists of 'inconvenience' and 'risk' as well as 'price of product or service'.

We extracted 18 rules for designing eco-business by categorizing eco-business ideas according to Fig.2, which are derived from the cases described in Section 2.1. These rules can be divided into four types; i)Promoting environmental value, ii)Adding other function, iii) Lowering cost, iv) Changing market segment. And Table 2 describes these 18 rules.

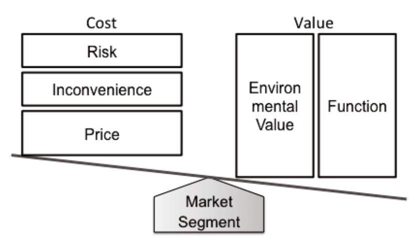

Fig. 2: Condition of the success for eco-business

Table 2 : Rules for designing eco-business

-Promoting environmental value	
1	Use of lower environmental loads materials (in production)
2	Introduction of lower environmental loads process
3	Expansion of product's life
4	Enhancement of product's environmental loads efficiency
5	Change to lower environmental loads utilities
6	Managing product usage and environmental loads
7	Managing life cycle of product
8	Use one more time
-Adding other function	
9	Receiving contracts for environmental loads
10	Combining various business values; e.g. function sale
11	Developing new service with knowledge
-Lowering cost	
12	Making environmental loads visible
13	Timesharing (of product); e.g. sharing and rental
14	Change revenue stream; e.g. lease, servicizing, and ESCO
15	Expansion of the business scale
16	Utilizing knowledge or technology in other fields
17	Financial support or charge from other stakeholders
-Changing market segment	
18	Change target segment of customers

3 PROPOSAL OF THE METHODOLOGY

As described in 2.2, in the methodology for supporting generation of new eco-business ideas, i) society has to be taken into consideration as one of stakeholders, ii) environmental loads to the society, such as waste and pollution, also has to be taken into consideration, iii) a process of repeatedly reforming eco-business ideas and models is necessary, iv) we support for building an eco-business model and evaluating it, .

Therefore, the methodology for supporting generation of new eco-business ideas has three features as below.

3.1 Divergent and Convergent process

The methodology has to have a process of repeatedly reforming eco-business ideas and models as described in Section 2.2. And we found eighteen rules for generating eco-business ideas as described in Section 2.3.

Therefore, we propose the 8 steps methodology shown in Fig.3. In STEP 1 – 3, the design team specifies the business, which is a starting point of generating eco-business ideas. STEP 4 is a divergent step, in which eco-business ideas are generated by applying eighteen rules to the business specified in STEP 3. STEP 5 – 6 are convergent steps, in which eco-business ideas generated in STEP 4 are combined into core concepts of new eco-business, and we evaluate these core concepts. STEP 7 is again a divergent step, in which we reform the core concepts by combining other ideas and build business model. And, finally, STEP 8 is a convergent step, in which we evaluate eco-business models and select them.

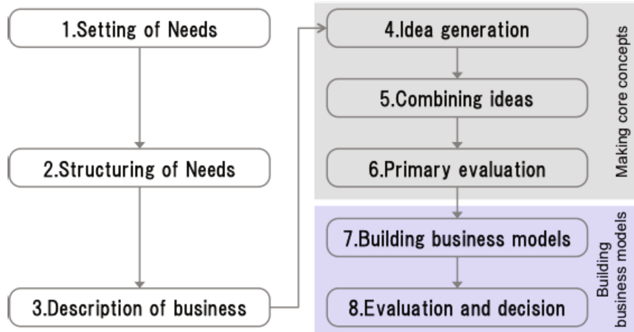

Fig. 3 : Eight steps for eco-business creation

In this methodology, we support the phases from creating core concepts to building business models in Fig. 1.

3.2 Modeling eco-business

For modeling eco-business, we propose the scheme shown in Fig. 4. As shown in this figure, we represent 'society,' and 'Eco-business provider,' in addition to the stakeholders of general business, such as 'Product provider,' 'User,' 'User's user,' as stakeholders of eco-business. 'Society' is defined as those who are affected by environmental external economy, and 'Eco-business provider' is defined as one who manages eco-business.

Also, we represent 'Waste/pollution', in addition to 'Product/Service' and 'Money', which are dealt between stakeholders.

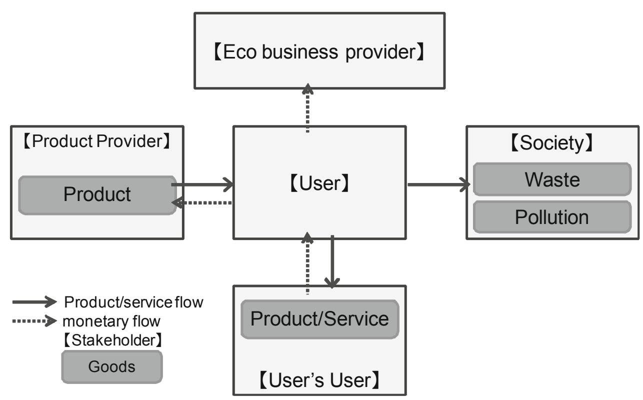

Fig. 4 : Structure model of eco-business

3.3 Evaluation of eco-business ideas

In STEP 6 in Fig.3, we have to evaluate core concepts of eco-business ideas created in STEP 5 not only from the point of view of its market attractiveness, from the point of views of environmental consciousness and company's suitability.

Therefore, for the evaluation, we combine the framework of 'Value portfolio [8]' and the 'BMO method [9].' 'Value portfolio' evaluates business ideas from the view points of the feasibility and the harmonization with company's vision. We evaluate the feasibility of eco-business ideas by using 'BMO method', in which 6 chapters of 'attractiveness' and 6 chapters of 'suitability' are given a full score of 10 points. In addition, in this methodology, as 'composition of vision', environmental consciousness is given a full score of 30 points.

4 CONSEQUENCE OF A WORKSHOP

4.1 Summary of the workshop

We ran a workshop for creating eco-business ideas starting with 'Production & Sales of air conditioners,' in which three experts on environmental issues participated. Within the time limitation of four hours, we were able to run through STEP 1- STEP 6 and created five core concepts of eco-business. The highest scored core concept was "managing the operation and selection of air conditioners by visualizing energy use and earning financial supports from an electric power provider by offering a peak time usage reduction."

4.2 Consequence of the workshop

In this Section the results of the workshop is shown step by step (in Fig.3)

1) STEP 1 Setting of needs

In this step, the design team sets the main requirements of upcoming business to satisfy customer needs. At first the design team gathers a list of needs by brainstorming, and then groups similar needs by using the KJ method [10].

In the case of 'Production & Sales of air conditioners', the design team gathered 'to make a room cool', 'to control humidity in a room', 'to save energy', etc.. And after grouping these needs, 'To make a room comfortable' is set as the main requirement.

2) STEP 2 Structuring the needs

In the workshop, we structured the needs as shown in Fig. 5 in order to find the needs, which another business satisfied.

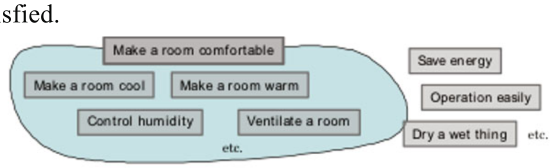

Fig. 5 : Setting of Needs

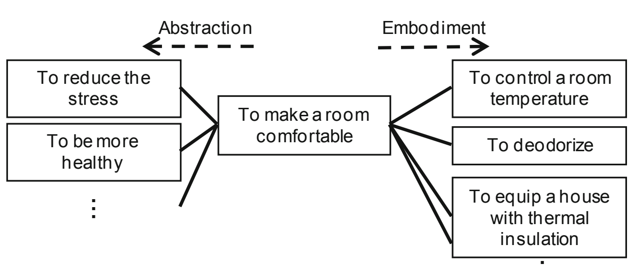

Fig. 6 : Structuring of needs

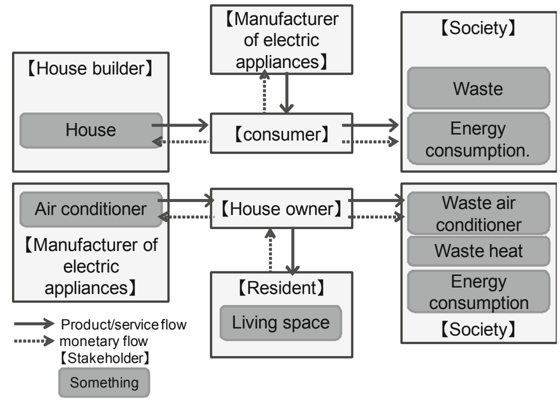

Fig. 7 : Description of existing business

3) STEP 3 Description of business

In this step, the design team selects the needs structured in STEP 2 and describes the business satisfies these needs according to the structure model of eco-business described in Section 3.2.

In the case, the needs "To control a room temperature" and "to equip a house with thermal insulation" are selected as the starting point of idea generation and modeled as shown in Fig. 7.

4) STEP 4 Idea generation

Eco-business ideas are generated by utilizing the 18 rules shown in Table 2. In other words, we combine these rules with the business description shown in Fig. 8 and generate ideas.

In the workshop, 25 eco-business ideas were generated in this step (see Table 3). For example, the idea, '(14) Rental of an air conditioner,' was generated by applying 'Rule13 Timesharing'.

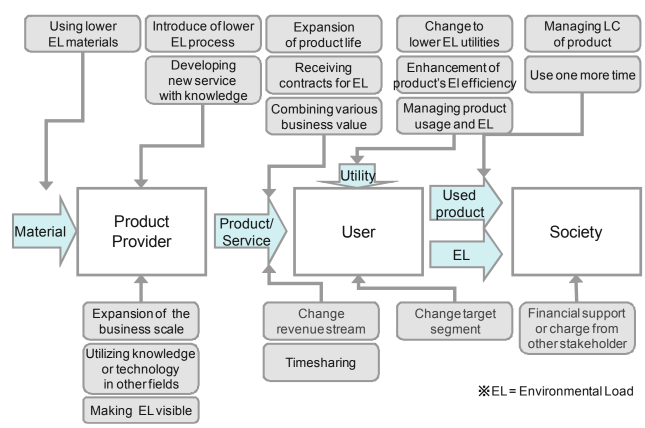

Fig. 8 : Application of Rules

Table 3 : eco-business ideas generated in STEP 4

№		Rules	Idea
-Production and sales of air conditioner			
(1)	1	Using lower EL materials	Using reusable parts
	8	Use one more time	
(2)	1	Using lower EL materials	Repairing and re-using of air conditioners
	8	Use one more time	
(3)	1	Using lower EL materials	Selling as a used product
	8	Use one more time	
(4)	3	Expansion of product's life	Expanding the life of product's parts
(5)	3	Expansion of product's life	Selling air conditioners designed for repairing easily
(6)	4	Enhancement of product's EL efficiency	Cooling a room in the morning and insulating it
(7)	4	Enhancement of product's EL efficiency	Selling air conditioners with high energy efficiency
(8)	4	Enhancement of product's EL efficiency	Managing operation and selection of air conditioners
	6	Managing product usage and EL	
	11	Developing new service with knowledge	
(9)	5	Change to lower EL utilities	Selling air conditioners with natural energy
(10)	6	Managing product usage and EL	Selling air conditioners contributing peak shaving.(Cooperation with electric power company)
	16	Utilizing knowledge or technology in other fields	
(11)	7	Managing LC of products	Using heat exhausted from an outdoor unit as a warm air
	8	Use one more time	
(12)	8	Use one more time	Magnets of motors are taken out for reuse
(13)	13	Timesharing	Sharing an air conditioner
(14)	13	Timesharing	Rental of air conditioners
	14	Change revenue stream	
(15)	18	Change target segment	Useing the air-conditioner outdoor unit as a drier
-Construction and sales of house			
(16)	1	Using lower EL materials	Using natural energy in a house
(17)	1	Using lower EL materials	Selling houses made of recycled resource
(18)	3	Expansion of product's life	Expanding the life of a house
(19)	4	Enhancement of product's EL efficiency	Selling houses with high insulation efficiency
(20)	4	Enhancement of product's EL efficiency	Sharing a room
(21)	4	Enhancement of product's EL efficiency	Sharing one air conditioner with several apartments
(22)	6	Managing product usage and EL	Managing energy use entirely on a house
(23)	11	Developing new service with knowledge	Advicing on energy saving in a house
(24)	13	Timesharing of products	Renting a room
	14	Change revenue stream	
(25)	16	Utilizing knowledge or technology in other fields	Selling the evaluation system for energy efficiency of buildings

Table 4 : Generated core concept in STEP 5

No	idea	Modified Idea
A	(2) (3) (12) (14)	Rental of air conditioners. Repair and re-use of air conditioner or reusable parts (e.g. magnets in the motor).
B	(3)(14)	Selling rented air conditioners as used products
C	(6) (8) (10)	Managing operation and selection of air conditioner by visualizing energy use. (e.g. Cooling down in the morning contribute peak shaving)
D	(11)	Selling the facility to dry laundry by the warm air exhausted from the air-conditioner outdoor unit in the veranda.
E	(13)	Sharing a big air conditioner between neighborhoods.

5) STEP 5 Combining ideas

The design team selects a couple of novel ideas and combines these with other ideas in order to create core concepts of upcoming eco-business.

In the case, five core concepts of eco-business were generated as shown in Table 4. For example, Idea B, 'Selling rented air conditioners as used products' was generated by combining '(3)Selling as a used product' and '(14)Rental of air conditioners'.

6) STEP 6 (Primary evaluation)

In this step, the design team evaluates the core concepts of upcoming eco-business ideas generated in STEP 5.

In the workshop, Idea C, 'Managing the operation and selection of air conditioners by visualizing energy use', was revised through the discussion in the evaluation, and was added the idea 'earning financial supports from an electric power provider by offering a peak time usage reduction'.

As a result, revised Idea C was scored the highest in evaluation (see Table 5).

Table 5 : Results of evaluation in STEP6

			Modified Idea No.				
			A	B	C	D	E
Contribution of the creation business value	Attraction	Market scale	3	4	6	2	3

4.3 Discussions

We evaluate this methodology through the workshop from the perspectives of 1) time efficiency, 2) novelty of ideas, and 3) effectiveness.

1) Time efficiency

In the workshop, we generated 25 ideas. We then created 5 core concepts based on these ideas, along with their evaluation, in a period of 4 hours. By directing the flow of the discussion, it was acknowledged that the participants were able to stay focused and productive in a short period of time. On the other hand, the process of structuring the needs (STEP 2), was pointed out to be low in time efficiency, because we just selected proper needs and business (STEP 3) in spite of taking a lot of time for structuring the needs.

2) Novelty of ideas

Participants pointed out that the 18 rules were effective for generating ideas. But they also pointed out that just proper existing business applied to 18 rules, 'Production & sales of air conditioners' and 'Construction & sales of houses', were described in STEP 3 and undermined the novelty of ideas.

3) Effectiveness

Several rules were not applied in STEP 4 in the workshop; they are '2. Introduction of lower environmental loads process,' '9. Receiving contracts for environmental loads,' '10. Combining various business value,' '12. Making environmental loads visible,' '17. Financial support or charge from other stakeholders.' Rule 12 and 17, among the rules not applied in STEP 4, were used in combining ideas (STEP 5). And other rules were supposed to have been applied, because several other ideas 'to use natural energy in the factory' related rule 2 and 'to sell the function of air conditioning' related rule 10 are conceivable.

Regarding the effectiveness of this methodology, participants pointed out improving the interface and the difficulty of evaluating environmental consciousness and business feasibility.

5 SUMMARY

This study is derived from investigation of existing eco-business and proposing a methodology for supporting of generation of new eco-business ideas. Through the workshop to generate eco-business ideas by using this methodology, we verified the feasibility, especially in generating eco-business ideas by 18 rules, combining with other ideas and evaluating it from three perspectives, such as market attractiveness, company's suitability, and environmental consciousness.

Abstract

Front End Innovation is a hot research topic, but there is still little research done in its relationship to design for sustainability. This paper explores the challenges of integrating environmental sustainability in this early stages of an innovation process and the design brief. The study is based on a content analysis of 35 design briefs from Belgian SMEs and multinationals, and a focus group with representatives from 14 Belgian companies. This study assumes a limited uptake of sustainability in Belgian design briefs. Furthermore, it argues that the use of certain strategies, such as front-loading, pushing sustainability upstream in the briefing process and sustainability opportunity identification in the front end, could help in greening the design brief.

Keywords:

Design Brief, Sustainable product innovation, Front End Innovation, New Product Development

1 INTRODUCTION

With an overpopulated planet, hungry for electricity and resources, sustainability will be one of the biggest challenges in the future. The challenges and opportunities for sustainable innovation are immense. And the time horizon is shrinking. Companies can play an important role in the transition process towards a sustainable and smarter world with an improved quality of life. Such a transition will likely require powerful new business models, with a rich playground for visionary ideas, products and services. Sustainability can be the ultimate fuel for long-term growth. Progress towards this goal will requires a multidisciplinary approach; political, social, economic and technical solutions must work in symbiosis to obtain sustainable development.

Staying competitive in an uncertain world is quite a challenging task. Companies must seek new ways of looking at products. The choices they make for which products to develop, and which targets to set for their sustainability performance will have a significant effect on the successfulness of our transition to a more sustainable world. The saying “don’t bring a sword to a gunfight” illustrates the problem of selling old products and services in a new world [1]. As the economist Joseph Schumpeter (1883-1950) put it, ‘innovation is a process of creative destruction’[2]. It both creates and destroys.

The very early phase in the innovation process, the so called front end of innovation, is often described as being the root of success for any company hoping to compete on the basis of innovation [3]. It is the phase with the largest impact on the end result of the project [3] [4] and the highest payback to one’s investments [4]. It is in this phase that businesses determine which development projects to start and which targets to set for those projects. The outcome of that process is reflected in the design brief. The decisions made in the design brief influences all the subsequent phases of the innovation process. It is a common sense that one can significantly improve products sustainability by focusing on sustainability already in the front end. This paper argues that sustainable design projects would be far more effective if commencing from an environmentally responsible brief, providing guidance to the design, engineering, marketing and management team.

Notwithstanding the logic behind integrating sustainability in the early stages of an innovation process and the design brief, in practice it is flawed. Front End Innovation is a hot research topic, but there is still little research done in its relationship to design for sustainability. There are a number of tools available to guide designers, engineers and managers in the design process after the specifications of the product or service are already set, but methods supporting goal finding for sustainable innovations are rare [6]. There is still little understanding on how to best bring environmental considerations into the design brief. Little guidance is given in literature how to effectively translate a sustainable commitment into project proposals that are both sustainable and make business sense [1].

The research in this paper aims at gaining understanding on how a design brief is established in the early stages of an innovation process and how environmental sustainability is integrated. The first part elaborates what is meant by a design brief, and how it is integrated in the early stages of an innovation process. The second part looks to the current practice of integrating environmental considerations in a design brief. Different research results are described and discussed in order to identify successful patterns for further research.

2 LITERATURE REVIEW

2.1 The Design Brief

In the past, briefing had been dominated by a highly mechanistic view of the design process, it seemed, that a good brief could turn design into something close to painting-by-numbers [7]. But the landscape changed. Today, every designer knows there is a intimate connection between briefing and design. Defining a design brief has become an integral part of the design process.

A design brief is a written description of a project that requires some form of design. It is an agreement, or contract between the parties involved in the project. Often times, it is also a point of transfer between different professionals, where the project is handed over from marketing to design, or from a product manager to an external design agency. It is also a road map and project-tracking tool, that defines the various steps that will be followed [8]. The role of a design brief is to provide the foundation to the entire design process in the shape of a functional document that can efficiently capture the information of a final product's attributes [9].

Ultimately briefing is the capture of knowledge of the user and the client, the expert, and the design and management team. Successful briefing is about clear and comprehensive communication and how information is structured [7]. It is important that the brief contains all the information and data necessary for every stakeholder in the process [8].

Previous research, based on data collected from major electronics multinationals in Japan and South Korea, has identified the use of environmental checkpoints, reviews, milestones and roadmaps as a most important success factor regarding the integration of sustainability considerations in the early stages of the product development process [10]. The design brief can play an important role in achieving this.

The focus of this paper is 'Industrial Design Briefs', briefs for the design of a new industrial product or a product-service system. Design is a broad term, with a variety of design disciplines (e.g. industrial design, package design, communication design). Each discipline requires different information in a truly useful design brief [8].

It should also be mentioned that design assignments are not always called 'design briefs'. There is a lot of diversification of terminology among literature and practice. People use a variety of terms, they also refer to them as new product development brief, creative brief, project brief, project sheet, innovation brief, or marketing brief [11] [8] [7].

Essential Elements of the Design Brief

When it comes to design briefs, there is no magic formula. If design is a problem-solving discipline, then design must start with a thorough understanding of the problem to be solved, which is best found in a design brief [8]. A single one-size-fits-all design brief format does not exist, but there are some key ingredients that any good design brief should contain. Kim Zarney [12] compares design briefing to stir-fry cooking, a rapid process that works best when you have all your ingredients ready before beginning to cook. It's helpful to start a design process with the information the design team really needs. Phillips [8] describes 8 essential elements of a design brief: (1) project overview and background, (2) category review, (3) target audience review, (4) company portfolio, (5) business objectives and design strategy, (6) project scope, timeline and budget, (7) research questions, (8) appendix. The '*project overview and background*' serves as an executive summary of the project, it clearly articulate the scope, the business needs, objectives, desired outcomes and ownership of the project in terms non-design business partners can understand. It contains all the essential information: what, why and who of the project. The '*category review*' refers to the industry in which the product or service is involved. Designers need to understand their audience before beginning the design process. This part is represented in the '*target audience review*'. The company and its activities is described as completely as possible in the '*company portfolio*' chapter. The section '*business objectives and design strategy*' provides a clear understanding of how design strategy is matched to business objectives. Time and budget requirements in every phase of the project are presented under the chapter '*project scope, timeline and budget*' in order to complete the project successfully. During the discussions with the design brief team, it is quite likely that a number of questions that are critical to the success of the design project remain unanswered. One can find these questions under the second last chapter. The '*appendix*' is an optional section and might contain documents that summarize research data, competitive analyses and visual material.

Insights

Doing a sustainable design project would be far more successful when starting from discussing and identifying sustainability opportunities in every chapter of the design brief. More research is needed how to best bring environmental sustainability in every section of a design brief.

2.2 Front End Innovation and the Design Brief

The innovation process may be divided into three areas: the front end, the new product development process, and commercialization [4]. The end result of the front-end area should be a written brief that links the creative objectives with the business objectives [12] [13].

Formulating a design brief in the front end of an innovation process is a creative, iterative and interactive process and is best developed in partnership [8]. Ultimately briefing does not progress linearly, the development shifts and jumps back and forth between different departments in a company and the design team.

Figure 10 shows the relationship between influence, cost of change, and available information during the innovation process. At the front end, the degree of freedom and influence on the project outcome is high, while little information is available and the cost of changes are low. At later points in the process one has more information available, but now the cost of change has increased.

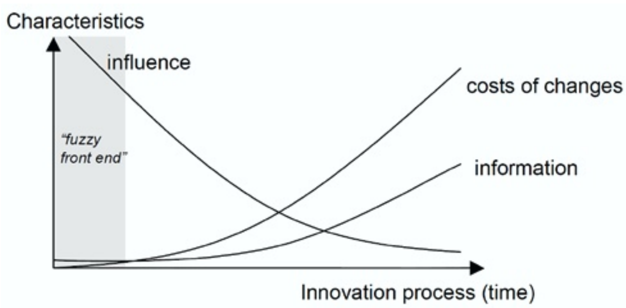

Fig. 1: Influence, cost of change, and available information during the innovation process ([15])

It is at this early stage and under this circumstances that the design brief is defined. Also quality, costs, and timings are mostly set during the front end [15]. Important decisions are made here, and will follow the product trough the project. Formulating a design brief has a lot to do with decision making in uncertain conditions and dealing with so called 'wicked elements'. One strategy to deal with this is 'front-loading', where one attempts to shift the information curve to the left. Front-loading is defined as "a strategy that seeks to improve development performance by shifting the identification and solving of problems to earlier phases of a product development process" [16]. By spending more energy in the front phase on analysis and strategic design one get more information while the influence is high and the cost of change low.

3 RESEARCH DESIGN AND QUESTIONS

The research in this paper aims at gaining understanding on how a design brief is established in the early stages of an innovation process and how environmental sustainability is integrated in the design brief and the front end. Based on the insights from literature and previous explorative studies [1] , [17] three main research questions has been formulated in order to address the research objective: Do companies take environmental parameters into consideration in their design briefs, and if so, how? And where is the focus placed? What are the drivers and barriers for companies for integrating environmental sustainability in the design brief?

To understand this phenomenon and the relationships between key elements, two exploratory studies has been conducted with a focus on Belgium SMEs and multinationals at varies industries.

In study 1, a focus group session was organized with representatives from 14 Belgium SMEs and multinationals in May 2011. Because relatively little research has been conducted regarding environmental parameters in a design brief, a qualitative approach has been chosen to get insights in themes and patterns which are relevant.

In study 2, a content analysis of 35 industrial design briefs from 35 Belgium based companies was used as research methodology.

Figure 2 [18] shows the different levels of knowledge using different research techniques. Talking to people provides insights in knowledge and thinking that is explicit to these people. This research technique was used in study 1. What people do can be observed. This was done in study 2 by looking at the design brief and the design brief process.

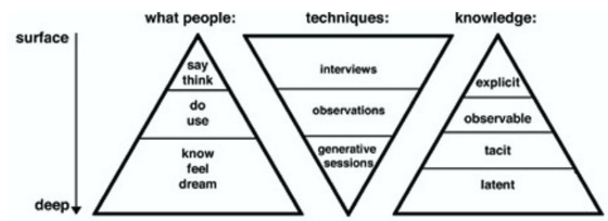

Fig. 2: Different research techniques access different levels of knowledge [18]

The grounded theory has been chosen as underlying strategy both for research and analyzing data.

4 RESEARCH

4.1 Focus Group

Research Background & Methodology

In order to get more insights in the drivers and barriers for integrating environmental sustainability in the design brief, a 3h focus group session was organized with representatives from 14 Belgium SMEs and multinationals in May 2011. All participants were members of VOKA, Flanders' Chamber of Commerce and Industry, and VOKA's Learning Network on Product Development and Design. All persons volunteered on the focus group after a call for participation sent by VOKA. Background of the participants ranged between senior management, project management, R&D, product design and engineering.

During the first part (1.5h) of the session a presentation was given on sustainable product innovation with a special focus on the design brief and integrating environmental considerations in the early stages of an innovation process.

The second part of the session (1.5h) was organized as a interactive group setting where participants were divided in teams of 4 to share their experiences and insights in integrating sustainability in the early stages of a design process and the design brief. Each team could make notes and schemes on big sheets of paper in order to visualize their thoughts to the other team members. Findings were summarized and presented plenary to the whole focus group at the end.

The second part of the focus group session was recorded with notes and partly with audio.

Analysis and results

The session and final presentation was transcribed chronologically by use of sentences, key words and statements. The relevant parts of the sheets of paper were analyzed and summarized.

Two general outcomes could be defined out of this focus group session. Firstly, integrating sustainability in a design brief is for many people a matter of 'want' and/or 'need'. Either you want to do it because you see opportunities (market demand, cost reduction, product differentiation, marketing), or you need to do it because it is required (legislation, retailer demands). 'What are the risks of this activity and what will be the return?' is a question often heard. Answering this question is not obvious, due to the characteristics of the front end phase as explained in Figure 1. Trying to have a clear view on this topics in the very early design brief stage (cfr Front-loading in chapter 2.2) can give a real boost to the integration of environmental sustainability in a design brief.

Secondly, there is a huge difference between a 'request for proposal', a strategic brief and the real design brief.

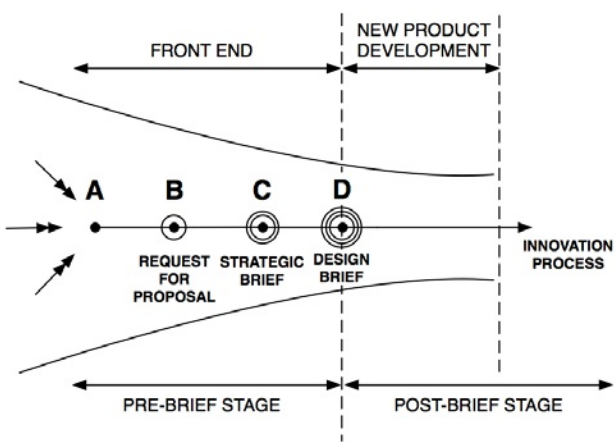

Fig. 3: The various stages of a design brief in an innovation process

The briefing process starts when someone in the company defines a business objective or need. This 'need' (A) can be a 'gut' feeling based on previous experience, a recommendation from a client or user, or a result of research. The need will be translated in a document, the '*request for proposal' (B)*, sometimes also called 'statement of need'. This document contains some basic information and goes to the management level in the organization where the team can decide whether it is worth pursuing, mostly decided after conducting a feasibility study. When the projects gets a 'go', the request for proposal will be upgraded into a '*strategic brief' (C)*. This document is usually created for the in-house design team or for an external design agency. The '*design brief*' (D) is developed and written in the next stage, in co-creation with the design group after considerable thought and discussion about the project. Figure 3 shows the various stages of a design brief at the front end of an innovation process. The different elements of the diagram does not represent actual time frames.

Pushing environmental sustainability upstream in this briefing process will result in a higher success rate on integrating sustainability into the design brief.

4.2 Analysis of 35 Design Briefs

Research Background & Methodology

A design brief is a crucial communication document between the client organization and a design agency, and usually provides a good insight into the level of environmental sustainability a company wants for the future product. But do companies take environmental parameters into consideration in their design briefs, and if so, how? And where is the focus placed?

To answer this question a content analysis of 35 industrial design briefs from 35 Belgium based companies was used as research methodology. Among those companies, 25 are categorized as small and medium-sized enterprises (SMEs), while the other 10 are classified as multinationals. Divers sectors and industries are covered, varying from the electric and electronic industry, lighting, furniture, medical equipment, building, engineering, technology and plastic industry.

All the described design assignments are performed by the design team of the Industrial Design Center Howest (IDC Howest) in Kortrijk, Belgium, a knowledge and research center specialized in Industrial Design Engineering. IDC Howest offers several design services for the industry, working in close collaboration with the master's program Industrial Design Engineering at Howest University. The level of innovation proposed in the design briefs varies from average to high. Projects with a low innovation level, such as product upgrades or incremental innovation design projects, are not accepted by IDC Howest due to a strict mission statement. The 35 design briefs are random selected among the total design assignments performed in the period between 2009 and 2011 by IDC Howest.

The IDC Howest standard design brief template contains 7 chapters, including project overview, objectives, quality requirements, policies on intellectual property, budget, design methodology and timing. There is no section devoted to the environmental impact of the product, environmental requirements can only be noted under the quality requirements section by answering a yes or no question.

In most cases, the client organization firstly contacts IDC Howest with a request for proposal or strategic brief. This document becomes a design brief after reviewing and discussing the problems and needs with both parties. Various meetings are preceded before the two parties sign the design brief. All projects studied in this case have one project owner from the company itself and one project leader from the IDC design team, each with specific tasks. Both are responsible for completing all the relevant sections of the design brief format.

The classification of the Life Cycle Design Strategies is utilized during the content analysis of the design briefs, as shown in Table 1.

Table 1: Life cycle design strategies

Lifecycle Design Strategies			
Product Level		Strategy	Substrategy
Product Concept Level	0	New Concept Development	Dematerialisation
			Shared use of the product
			Integrations of functions
			Functional optimisation of product
Product Component Level	1	Selection of low Impact materials	Cleaner materials
			Renewable materials
			Lower energy content materials
			Recycled materials
			Recyclable materials
	2	Reduction of materials usage	Reduction of weight
			Reduction in (transport) volume
Product Structure Level	3	Optimization of production techniques	Alternative production techniques
			Fewer production steps
			Lower/cleaner energy consumption
			Less production waste
			Fewer /cleaner production consumables
	4	Optimization of distribution system	Less / cleaner / reusable packaging
			Energy-efficient transport mode
			Energy-efficient logistics
	5	Reduction of Impact during use	Lower energy consumption
			Cleaner energy source
			Fewer consumables needed
			No waste of energy / consumables
Product System Level	6	Optimization of initial lifetime	Reliability and durability
			Easier maintenance and repair
			Modular product structure
			Classic Design
			Stronger product-user relation
	7	Optimazition of end-of-life system	Reuse of product
			Remanufacturing / Refurbishing
			Recycling of materials
			Safer incineration

The Lifecycle Design Strategies Wheel or LiDS Wheel, also called EcoDesign Strategy Wheel [19] presents eight EcoDesign strategies: new concept development (0), selection of low-impact (1), reduction of materials usage (2), optimization of production techniques (3), optimization of distribution system (4), reduction of impact during use (5), optimization of initial lifetime (6), and optimization of end-of-life system (7). Strategy 1 to 7 represent the product life cycle. Strategy 0 is either 'strategic', working on the product concept level, while strategy 1 and 2 relates to the product component level, strategy 4, 5 and 6 to the product structure level and strategy 6 and 7 tot the product system level. All life cycle design strategies are divided in multiple sub-strategies. Every design brief is systematically scored on each dimension of the Strategy Wheel. Also the way how strategies are handled, is indicated as being quantitatively or qualitatively. No distinction is made in the analysis between projects that are initiated with the intention of doing something sustainable vs. projects without a specific sustainability focus.

Limitations of the content analysis

It should be mentioned that the used methodology, design brief content analysis, has some limitations which are important to acknowledge when interpreting the results.

A design brief says nothing about the sustainability of the final product, as earlier research already showed. Petala et al. [11] concludes in the Unilever case study report on 'The role of new product development briefs in implementing sustainability' that the incorporation of sustainability in the new product development briefs not guarantee results. Several organizational issues could function either as success or failure factors for the entire process. The opposite is also possible, projects where environmental sustainability was not a fundamental concern in the design brief can turn out in environmental friendly products or services when new insights are obtained during the innovation process.

Secondly, the chosen methodology does not provide deep insights in push and pull mechanisms regarding sustainability, that can show up in meetings and discussions with the project team prior to the design brief. Also the influence of the project leader(s) or other design team members on the final outcome of the design brief remains unclear.

Results and findings

An overview of the results of the content analysis is shown in Fig. 4 and 5.

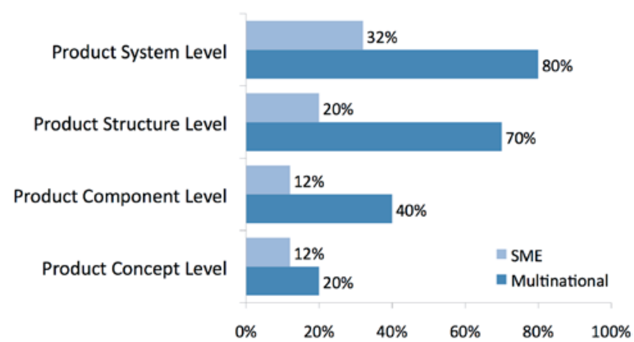

Fig. 4: Environmental profile of the design briefs on product level

Figure 4 gives an insight in the environmental profile of the design briefs on the different product levels. Figure 6 gives presents the most frequently used strategies in the design briefs. A distinction is made between SMEs and multinationals, demonstrated in the two bars.

The strategies 'optimization of initial lifetime' and 'reduction of impact during use' are most commonly found in the overall design briefs. While the most popular sub-strategy is 'reliability and durability' followed by 'modular product structure', 'lower energy consumption' and 'cleaner / recyclable materials'.

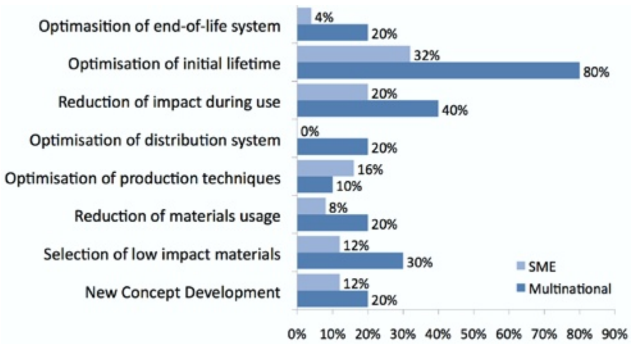

Fig. 5: Environmental profile of the design briefs on strategy level

This study shows that the uptake of environmental considerations into design briefs is still very limited in the analyzed briefs. In 14 SME design briefs there was no uptake at all. The findings indicates that multinationals more frequently integrate environmental considerations into the design brief comparing to SMEs. Quantitative environmental targets were absent in all the design briefs. This appear to be related to the innovation level. Defining quantitative environmental targets in the early stage of an innovation project appears to be very difficult for innovation projects with an average or high innovation level.

5 CONCLUSIONS

This study assumes a limited uptake of environmental sustainability in Belgian design briefs. Due to the limited number of research entities, and the fact that all participating companies where Belgian, no general conclusions could be made. The main conclusions on how to best 'green' the design brief can be summarized as follow: Firstly, using the front-loading strategy in the early stages of an innovation process can give a real boost to the integration of environmental sustainability in a design brief. It will brightening up sustainability opportunities (market demand, cost reduction, product differentiation, marketing) and requirements (legislation, retailer demands). Secondly, doing a sustainable design project would be far more successful when starting from discussing and identifying sustainability opportunities in every chapter of the design brief with the project team. More research is needed how to best bring environmental sustainability in every section of a design brief. Thirdly, pushing environmental sustainability upstream in the briefing process, starting with the request for proposal over the strategic brief to the design brief, will result in a higher success rate on integrating sustainability into the design brief.

Abstract

Taking measures for environmental conservation is one of the CSR-related activities that is becoming more significant as environmental awareness grows. Especially in the cosmetic industry, which benefits from natural substances, each firm is pursuing its unique environmental conservation programs under the umbrella of Green Action. Recently, it has become possible to see Green Action that is directly linked to the cosmetics, in other words, EcoDesign of cosmetics. In this context, through the analysis of several cases, this paper aims to examine how Green Action as a CSR is influencing cosmetic brand equity.

Keywords:

cosmetics, green action, EcoDesign, sustainability, brand equity

1 INTRODUCTION

In recent years, many companies around large ones are putting their efforts into Corporate Social Responsibility, and its concept has multiple aspects that vary as times change.
