Ann N. Dapice, PhD, is Director, Education and Research, of T. K. Wolf, Inc., a nonprofit Native American organization in Tulsa, Oklahoma, United States. With a PhD in Psychology, Sociology, and Philosophy from the University of Pennsylvania, she has served as professor and administrator at a number of universities, including the University of Pennsylvania, Widener University, Penn State University, and Goddard College, teaching Social Sciences and Native American Studies. Her cross-cultural research has been reported in professional journals, books, and academic presentations regionally, nationally, and internationally. Speaking engagements include topics related to addiction, stalking, and Native American issues. Dr. Dapice has served on the Elders Council for the American Indian Chamber of Commerce, is a Member of the Board of Directors of the Mental Health Association in Tulsa and the Tulsa Metropolitan Ministry/Domestic Violence Intervention Services Committee.

She consults with the University of Pennsylvania on Native American issues, where she is founder and Chair of the Association of Native Alumni.

Ted Goldberg, PhD, is Professor of Sociology in Stockholm, Sweden. He was awarded an undergraduate degree in Anthropology and Sociology from Uppsala University and a PhD in Sociology from the same university. Combining anthropological methodology with sociological theory, he has done extensive participant observation research on the drug scene in Stockholm. His main field of study is drug consumption and drug policy, and he has written numerous books and articles on these subjects. He has also written about modern Swedish society, the relevance of sociological theory for practical social work, migration, and alternative methods of teaching on the university level. For several decades, Dr. Goldberg has been one of the most outspoken critics of Swedish drug policy. He is currently teaching at the Department of Social Work at Stockholm University, and the Department of Caring Sciences and Sociology at the University of Gävle.

Dirk Hanson, MA, is a freelance science writer and novelist based in Ely, Minnesota, United States. Mr. Hanson has written extensively on technology, science, and medicine. He is the author of the books *The New Alchemists* and *The Incursion*, as well as a third, *Addiction: The Search for a Cure*. He maintains a blog, "Addiction Inbox," devoted to news and issues related to the science of substance abuse. He has also written for *California Magazine*, *Omni*, *CoEvolution Quarterly*, *Willamette Week*, *Whole Mind Newsletter*, and other magazines. He has worked as a business and technology reporter for the *Des Moines Register* and for numerous trade publications.

Mary F. Holley, MD, trained at Baylor College of Medicine in Houston, Texas. She is a licensed physician, formerly an obstetrician-gynecologist in northern Alabama, United States. She is founder and Director of Mothers Against Methamphetamine, a national nonprofit drug education organization. Dr. Holley is author of *Crystal Meth: They Call It Ice*, and has produced several educational videos for drug education and prevention. She serves on the Alabama Attorney General's Methamphetamine Task Force as Chairperson of the Education Committee. Her Web site can be seen at www.mamasite.net.

Olga Inozemtseva, PhD, obtained her PhD in the Behavioral Sciences (area of Neurosciences) at the Neuropsychology and Neurolinguistics Laboratory of the Institute of Neurosciences at the University of Guadalajara in Guadalajara, Jalisco, Mexico. Currently, Dr. Inozemtseva works in the same laboratory and gives courses concerning the structure and development of cognitive processes and executive functions. She directs theses and participates in tutoring committees at undergraduate, master's, and doctoral levels. She is the author of

several publications (articles, book chapters, articles for dissemination). She has participated in projects in the area of infant neuropsychology that focus on development of children with genetic and hormonal alterations. At present, her professional interests are leading to neuropsychology of drug addiction, particularly, the neuropsychological consequences of substance abuse among addicted patients in a phase of abstinence. Dr. Inozemtseva is a member of the National System of Researchers, CONACyT, México.

Sonia Johnson, MSc, MRCPsych, DM, Professor in Social and Community Psychiatry, has studied Social and Political Sciences and Medicine at Cambridge and Oxford Universities, and then did an MSc in Social Psychology at the London School of Economics. She has a Doctorate in Medicine from the University of Oxford. Dr. Johnson did her psychiatric training in South London and was a Clinical Lecturer in Community Psychiatry at the Institute of Psychiatry. Since 1997, she has been a Senior Lecturer and Reader in Social and Community Psychiatry at University College London, in London, England. Since 2003, her clinical work has been in the Camden and Islington Early Intervention Service for young people with psychosis. Since 2001, Dr. Johnson has been course director for the MSc in Psychiatric Research, and has experience as a PhD supervisor. Her research interests include the evaluation of innovative service models, such as crisis resolution teams, crisis houses, and assertive outreach teams; epidemiology and treatment outcomes in early psychosis; women's mental health needs; "dual diagnosis" of psychosis and substance misuse; the development of the European Service Mapping Schedule (ESMS); and staff morale.

Jorge Juárez, PhD, obtained his master's degree in Psychobiology and his PhD in Biomedical Sciences at the Universidad Nacional Autónoma de México. Currently, he is Researcher and Professor at the Institute of Neurosciences at the University of Guadalajara in Guadalajara, Jalisco, Mexico. He has published numerous scientific articles and several chapters in scientific books and coordinated the edition of books. Dr. Juárez has been reviewer of scientific articles in journals of recognized prestige. Since 1988, his main area of research has focused on the neurophysiologic substratum of motivational aspects of behavior, primarily in relation to addictions. Dr. Juárez has imparted courses at the master's and doctorate levels and has directed undergraduate, master's and doctoral theses. He has been Coordinator of the Doctoral Program, Research Coordinator, and Member of the Ethics Committee, and the Editorial Council of the Institute of Neurosciences at the University of Guadalajara. Since 1990, has he belonged to the National System of Researchers, CONACyT, México.

Paula K. Lundberg-Love, PhD, is a Professor of Psychology at the University of Texas Tyler (UTT) in Tyler, Texas, United States, and the Ben R. Fisch

Endowed Professor in Humanitarian Affairs for 2001–2004. Her undergraduate degree was in Chemistry, and she worked as a chemist at a pharmaceutical company for five years prior to earning her Doctorate in Physiological Psychology with an emphasis in Psychopharmacology. After a three-year postdoctoral Fellowship in Nutrition and Behavior in the Department of Preventive Medicine at Washington University School of Medicine in St. Louis, she assumed her academic position at UTT where she teaches classes in psychopharmacology, behavioral neuroscience, physiological psychology, sexual victimization, and family violence. Subsequent to her academic appointment, Dr. Lundberg-Love pursued postgraduate training and is a licensed professional counselor. She is a member of Tyler Counseling and Assessment Center, where she provides therapeutic services for victims of sexual assault, child sexual abuse, and domestic violence. She has conducted a long-term research study on women who were victims of childhood incestuous abuse, constructed a therapeutic program for their recovery, and documented its effectiveness upon their recovery. She is the author of nearly 100 publications and presentations and is co-editor of *Violence and Sexual Abuse at Home: Current Issues in Spousal Battering and Child Maltreatment*. As a result of her training in psychopharmacology and child maltreatment, her expertise has been sought as a consultant on various death penalty appellate cases in the state of Texas.

Mark K. Mathews, LADC, BCCR, is currently pursuing a master's degree in Holistic Health Studies. Mr. Mathews works as a bio-counselor at Health Recovery Center in Minneapolis, Minnesota, United States. He is also the president of Bio-Recovery, a nutritional supplement company specializing in formulas to address addictions and mental illnesses.

Joan Mathews-Larson, PhD, LADC, holds a Doctorate in Nutrition and is the founder and Executive Director of the pioneering Health Recovery Center in Minneapolis, Minnesota, United States, an orthomolecular (psycho-biological) model for treating addiction and emotional disorders. This unique focus combines therapy with physiological intervention to repair biochemical damage that often manifests as impaired mental functioning and behavioral problems. Her work has received national recognition because of the high recovery rates this model produces. The loss of her 17-year-old son to suicide directly after he completed a treatment program fueled Dr. Mathews-Larson's ongoing search for more effective solutions. Her clinic has now successfully treated many thousands of people over three decades. Her published research in the *International Journal of Biosocial and Medical Research* in 1987 and 1991 describes this work. Her approach is outlined in the best-selling book *Seven Weeks to Sobriety* in 1992; followed by *Depression Free, Naturally*, in 2001. Her books have been reprinted in Finnish, Japanese, Icelandic, and Russian. Articles about her work

have appeared in *Psychology Today, Let's Live, Alternative Medicine, Chicago Daily Herald, Harper's Bazaar, Prevention Magazine, Natural Health, Mpls, St. Paul Magazine, Minnesota Physician, Journal of Orthomolecular Medicine, San Francisco Chronicle, LA Times, New Orleans Times, Norway Times, Minneapolis Star Tribune,* and *Townsend Letter for Doctors*.

Scott E. McClure, PhD, is currently employed as a Senior Learning Skills Counselor with the University of California San Diego, Department of Psychiatry, Center for Criminality and Addiction Research, Training, and Application (CCARTA) in San Diego, California, United States. At CCARTA, he provides technology transfer of the most current evidence-based treatment procedures for substance use disorders to substance use treatment staff throughout the state of California. Dr. McClure has more than seven years of experience working with individuals who have co-occurring mental health and substance use issues across a broad scope of populations ranging from the severally mentally ill to university students. He has facilitated groups on post-traumatic stress disorder (seeking safety), adult attention deficit/hyperactivity disorder, dialectical behavior therapy, as well as implemented motivational interviewing and life skills groups while employed at the UCSD Co-occurring Disorder Outpatient Clinic. His clinical and research interests include criminality and addiction, trauma, ADHD, and multicultural issues.

Donald Omonge, BA, is pursuing his post-graduate degree (MA) in Disaster Management from the University of Nairobi in Nairobi, Kenya, and holds a Bachelor of Arts degree in sociology from Egerton University. He has six years of experience working with community-based organizations engaged in community development interventions, research, capacity building, and training. He is currently a training officer with SARAH (Substance Abuse Recovery And HIV/AIDS) Network, a Kenyan faith-based organization sponsored by the U.S. government for community-based HIV/AIDS and substance abuse prevention through behavior change interventions.

Emmanuel S. Onaivi, MSc, PhD, is Associate Professor in the Department of Biology at William Paterson University in Wayne, New Jersey, United States, and a Guest Scientist at U.S. National Institutes of Health. He received his MSc and PhD degrees from the University of Bradford, England. He conducted cannabinoid research as a Postdoctoral Fellow at MCV-VCU. He was an Instructor at LSU-Pennington Biomedical Research and a Visiting Research Scientist at Stanford University, before he was appointed to the faculty of Meharry Medical College, where his laboratory was the first to clone and sequence the mouse CB1 gene. At Vanderbilt University, his team reported racial and gender differences in the expression of CB1 cannabinoid receptors.

His current research is on cannabinoid genomics and proteomics on behavior and changes in anxiety and depression as a basis for addiction. Dr. Onaivi has published several papers, edited four books, including *The Biology of Marijuana from Gene to Behavior* (2002), supervised doctoral and postdoctoral fellows, and his student research was selected and presented on Capitol Hill in Washington, DC. He is a member of the Society for Neuroscience, IACM, and the newsletter editor for the International Drug Abuse Research Society. He received the William Paterson University Award for Excellence in Scholarship.

Meera Vaswani, PhD, earned her PhD degree from Delhi University, a leading university in India. She is a member of the National Drug Dependence Treatment Centre, Department of Psychiatry, All India Institute of Medical Sciences in New Delhi, Delhi, India, a prestigious and internationally recognized institute in India, where she was first a postdoctoral fellow, subsequently joined as a lecturer, and rose to be a professor. During this time, she was elected as Fellow of the Royal Society, London, and Member of the National Academy of Medical Sciences, India. She was selected for a United Nations fellowship, for which she worked in the University of Glasgow in the UK. She was one of the three scientists in the world selected for the Distinguished International Scientist Collaborative Award (DISCA) from the National Institute on Drug Abuse, National Institutes of Health, in 2007. Dr. Vaswani has completed several projects on addiction (alcohol and heroin addiction) and published many papers in both national and international journals. She has been a guest speaker in several national and international forums. She was the only delegate who was invited by Japan to represent India at the Asia Pacific Society of Biological Research in Alcoholism. Subsequently, she was elected to the Board of Directors for the Asia Pacific Society for Alcohol and Addiction Research (APSAAR).

Jace Waguspack, BS, received his BS in Psychology from Texas Christian University in May 2007. He is currently a master's level graduate student at the University of Texas Tyler in Tyler, Texas, United States. He is training in Clinical Psychology with an emphasis on Clinical Neuropsychology, and he intends to follow a PhD program in Neuropsychology upon attaining his master's degree. He hopes thereafter to become a licensed psychologist and assist in the assessment and rehabilitation of individuals that have received traumatic brain injury in a hospital setting. He has performed research in a neuroscience laboratory on the effects of neuro-immunological activation on learning in a mouse model. His current research interests include the study and use of neuropsychological assessment tools in populations with TBI and dementia.

Bethany L. Waits, BA, is a graduate student in Clinical Psychology at the University of Texas Tyler in Tyler, Texas, United States. She anticipates graduation in May 2010 and plans to pursue the licensed professional counselor designation upon completion of her degree. Ultimately, she would like to work as a therapist for a nonprofit community organization, such as a crisis center. In May 2007, she obtained her BA in Psychology from UT Tyler, graduating summa cum laude. Ms. Waits was accepted as a lifetime member of Psi Chi, the national honor society in psychology, and Alpha Chi, a national college honor society. While an undergraduate, she participated in a student panel addressing issues related to sexual assault on campus. Additionally, she has worked with several professors on various research projects.

Mary Theresa Webb, PhD, is founder and past Director of the Global Outreach for Addiction Leadership and Learning (GOAL) Project based in Aliquippa, Pennsylvania, United States. She was one of the founders of the International Substance Abuse and Addiction Coalition (ISAAC), based in the United Kingdom, and the OPORA Training Center in Moscow, Russia. (*Opora* is the Russian word for *support*. Moscow-based nongovernmental OPORA, which works with the Russian government to fight addiction, has trained more than 3,000 persons in addiction and Twelve-Step programs, and implemented 60 recovery groups in 31 cities in Russia.) As a global educator, she has personally and with others facilitated addiction trainings in the United States, Russia, Romania, Tajikistan, Bulgaria, Kenya, Tanzania, Honduras, and Egypt. Currently, Dr. Webb is the Project Director of the Kenya-based, USAIDS-funded Substance Abuse Rehabilitation and HIV/AIDS (SARAH) Network in Kenya. Dr. Webb holds a master's in Education from the University of Pittsburgh and a Doctor of Philosophy Degree in Family Systems/Addiction Intervention from the University of America. She is the author of *Tree of Renewed Life*, *Church Training Manual*, and coauthor of *Codependence in Family Systems*.

Kathryn M. Wells, MD, is Assistant Professor of Pediatrics and Pediatrician at the Kempe Center for the Prevention and Treatment of Child Abuse and Neglect at the University of Colorado Denver in Denver, Colorado, United States. She received her BA in Biology and Psychology with magna cum laude honors from Carroll College in Helena, Montana, and then attended medical school at Creighton University School of Medicine in Omaha, Nebraska. She received her MD in 1993. She received postgraduate training as a Pediatric Resident at Creighton University-Nebraska Universities Health Foundation Joint Pediatric Residency Program in Omaha. Dr. Wells has had fellowship training in Denver, Colorado, at the University of Colorado Health Sciences

Center, the Kempe Children's Center, and the Children's Hospital in the pediatric subspecialty field of Child Abuse and Neglect. She is often called on as an expert witness in child abuse and neglect cases as well as those involving substance abuse. She travels across the country as a medical expert on the effects of substance abuse on users and the children of users, especially methamphetamine. She is also actively involved in the Colorado Alliance for Drug Endangered Children and has made many presentations on the medical effects of methamphetamine use.

Cui-Wei Xie, MD, PhD, is a Professor in the Department of Psychiatry and Biobehavioral Sciences, David Geffen School of Medicine, and in the Semel Institute for Neuroscience and Human Behavior, at the University of California Los Angeles (UCLA), in Los Angeles, California, United States. She earned her doctoral degrees (MD, PhD) in 1984 from Peking University Health Science Center in Beijing, China. Her doctoral thesis work addressed opioid regulation of pain and cardiovascular function and received several awards from the National Ministry of Public Health in China. After receiving her degrees, Dr. Xie taught at Peking University and continued her research there as Associate Director of the Laboratory of Cardiopulmonary Endocrinology. She was named one of the 10 Outstanding Young Scientists by the Beijing Association of Science and Technology in 1986. Dr. Xie came to United States in 1987 as a visiting scholar at National Institutes of Health (NIH). She moved to Duke University two years later where she studied opioid regulation of hippocampal synaptic plasticity. Since joining UCLA faculty in 1995, Dr. Xie has continued her study on opioid receptor signaling and the cellular mechanisms underlying opioid desensitization and tolerance. She is the recipient of multiple research grants from NIH and has served on many review panels for the research grant programs of federal agencies and private foundations.

PART III: PRACTICES

Series Foreword

Tragically, most people across the globe have either struggled with a health- and relationship-damaging addiction or know someone who has. Addictions, broadly defined, have touched the lives of the majority of people in multiple cultures and locations. For centuries, numerous people have suffered with their addictions to alcohol and drugs as well as with other addictions, with often devastating outcomes. Sadly, important relationships, jobs and careers, and many lives have been lost due to the destructive power of addiction. These tragedies not only occur for those who suffer from addiction, but for their loved ones, coworkers, and community members, and for innocent victims who are perhaps in the wrong place at the wrong time when an addiction-related accident, crime, or violence occurs. The enormous cost of addiction in health care, traffic accidents, crime, violence, loss of workplace productivity, and broken families is too large to quantify. The global spread and success of organizations such as Alcoholics Anonymous (as well as related organizations such as Narcotics Anonymous, Sexoholics Anonymous, and Overeaters Anonymous) is a testament to the numerous people trying to recover from their addictions. Sadly, for every person seeking help for his addiction problem, there are likely to be many more people who never do. Clearly we need help to better understand, evaluate, treat, and cope with those who suffer from addictions.

In this remarkable four-volume set, *The Praeger International Collection on Addictions,* Angela Browne-Miller, PhD, DSW, MPH, has assembled an all-star and diverse team of leading experts from across the globe to provide a state-of-the-art understanding of the various facets of addiction. Each chapter

is written in a manner that is suitable for professionals working in the field as well as educated lay readers and those who either struggle with addictions or live or work with someone who does. What is especially remarkable about the four-volume set is its emphasis on addiction from around the globe, examining multicultural and international issues in addiction, as well as its coverage of so many multifaceted aspects of diverse addictions. For example, it certainly makes sense to cover fully addiction topics such as alcohol abuse and illegal drug use of, say, cocaine and heroin, yet chapters are also offered that examine addictions to caffeine, Internet pornography, work, television, intimate relationship abuse, and shopping. The chapters highlight biological, psychological, social, spiritual, and public health perspectives, with chapter authors who are psychologists, psychiatrists, other physicians, nurses, social workers, counselors, clergy, and other professionals. Dr. Browne-Miller is uniquely qualified to assemble this project as she is someone who has worked in the field of addiction for many years and has training in a unique blend of both the policy and the clinical sides of psychology, social work, education and public health.

The set is complete, state of the art, and highly informative and engaging. There is something for everyone interested in the field of addiction for professional or personal reasons. It is hoped that professionals and lay readers will greatly benefit from this important work and, in doing so, will find a way to improve the lives of those touched by addiction. It is my hope that both research and practice in the field of addiction will be greatly improved thanks to this set. The lives of those who either struggle with addiction or live with those who do will ultimately be improved thanks in part to this critical series. I am grateful to Dr. Browne-Miller and her assembled contributors for providing us all with such important and high-quality volumes that are now available to the public and professional communities. If only one life is saved or improved thanks to this set, it will be a great success in my view; yet I expect that many lives will ultimately be saved or greatly improved thanks to *The Praeger International Collection on Addictions*.

Praeger Series Editor, Abnormal Psychology

Preface

Angela Browne-Miller, PhD, DSW, MPH

Welcome to *The Praeger International Collection on Addictions,* addressing the insidious, pervasive, worldwide problem of human addiction. Addiction is clearly a global issue, touching every population, every nation, and every age group, people from all walks of life everywhere, directly or indirectly. Indeed, we are talking about an affliction of epic and epidemic proportions. We cannot look away. This is the health of the human species we are talking about.

The World Health Organization (WHO, 2008, p. 1) reports that "psychoactive substance use poses a significant threat to the health, social and economic fabric of families, communities and nations. The extent of worldwide psychoactive substance use is estimated at 2 billion alcohol users, 1.3 billion smokers and 185 million drug users" (p. 1). The WHO has estimated there to be at least 76.3 million persons with alcohol use disorders worldwide, and at least 15.3 million persons with drug use disorders worldwide. Alcohol use and abuse as well as the use and abuse of other psychoactive substances contributes to substantial individual and public health costs. Alcohol is but one substance playing a major role in this global addiction epidemic, but clearly there are many others, despite efforts to prevent new addictions and addicts, and to contain world drug markets (UN, 2008, p. 7).

For example, cocaine shares the stage with other abused drugs. Its prevalence is estimated to be up to 3 percent of the population in developing countries, with severe medical, psychological, social, and economic consequences including, but not limited to, the spread of infectious diseases (e.g., AIDS, hepatitis, and tuberculosis), plus crime, violence, and neonatal drug exposure.

Amphetamine-type stimulant (ATP) abuse is more widespread than cocaine abuse in at least 20 countries. Methamphetamine is presumed to lead in ATP addiction rates, with massive meth epidemics affecting several whole countries and entire regions of others. Social and public health costs of methamphetamine production and use via smoking, sniffing, inhaling, and injecting are staggering and growing in many regions. Additionally, there has been a global increase in the production, transportation, and use of opioids, especially heroin, with worldwide heroin production doubling or even tripling since the mid-1980s. Global estimates are that 13.5 million persons consume opioids, with 9.5 million of these being heroin users who face health risks including hepatitis, HIV, and death. And cocaine, meth, and heroin are just one piece of the picture.

The hotly debated drug cannabis—or the *Cannabis* family of drugs with the euphoric tetrahydrocannabinols, or THCs, including marijuana and hashish preparations—is said to be the most widely abused drug. Research is now suggesting the risk for acute health effects of long-term, chronic cannabis use, including potential impairment of cognitive development, learning, memory, recall, attention, and coordination. (Certainly the presence and extent of long-term effects of casual, of regular and of chronic use are as yet not entirely ascertained.) Both casual use of marijuana and medical use of forms of what is termed medical marijuana (e.g., dronabinol sold as Marinol, the cannabidiols, or CBDs) are subsets of all forms of cannabis use. There are legitimate therapeutic uses of this substance, and these uses make it all the more difficult to regulate marijuana drugs fairly and effectively.

We have here, and in the use of any psychoactive medication for therapeutic purposes, a gray area in which illicit and licit use overlap and can confuse many adult and youth consumers, researchers, and policy makers, among others. In the emergence (or reemergence in history, some will argue) of cannabis as medicine, we have a model for asking which, if any, abused substances may, and perhaps should, be repurposed for medicinal or treatment purposes, and how this is best done against the backdrop of the global addiction epidemic.

Regarding marijuana, we are confronted with the age-at-first-use issue, which suggests that early onset of regular cannabis use may affect not only the academic and social performance of children and teens, but also their future susceptibility to addictions. It was in the 1960s that the hotly debated label "gateway drug" was applied to marijuana, perhaps to scare off its use, and only in the decades since have we understood better what this might actually mean to us. It may not be that marijuana provides the training wheels for drug addiction, but rather that it may serve as an indicator of future use of the same or other drugs. Of course, today, with so many young people having access, and taking advantage of their access, to the whole range of psychoactive substances,

the question of which drug might be a gateway to which other drug dissolves into the fury of the countless addiction conundrums of our constantly changing times.

There is always a new, or rediscovery of an old, addiction on the horizon. There is also always a new (or rediscovered) psychoactive substance for exploratory, research, and perhaps even treatment purposes emerging (or re-emerging). Labeling all of these substances as addictive right out the gate may or may not serve science or even humanity itself. How can we be certain the approach we take will be a constructive one? With new legal (where licensed for development and experimentation) and illegal (where not being utilized under protection of law) so-called designer drugs emerging at a staggering rate, we must admit that we cannot know what is coming, nor whether the new compound will be addictive, or popular, or of medicinal value, or even accessible. We can only imagine what the brave new world of chemistry will continue to bring and whether any benefits can be made available without accompanying risks and detriments.

Moreover, the desire to explore and achieve various altered states of consciousness in religious, spiritual, ritual, and perhaps even treatment settings, is unfolding into debates about rights (Browne-Miller, 1989, pp. 258–260). When there is no demonstrated risk to self or others, we have to ask ourselves whether this right should be protected, especially in circumstances of traditional uses for religious purposes. Again, this dilemma arises against the backdrop of the global and runaway epidemic of substance addiction. How do we balance pressures from opposite directions (freedom protecting the right to use versus control to stop injury and costs of using), when these pressures are not balancing themselves?

Also against the backdrop of global addiction levels, is the massive level of addiction to legal drugs, many of which are heavily marketed to consumers. The legal drug tobacco is said to be the substance causing the most damage globally, with at least one-third of the global population smoking. While smoking rates may be dropping in some countries, the reverse is true globally. As just one of its effects, smoking accounts for some 90 percent of all lung cancer in men and 70 percent of all lung cancer in women. And yet tobacco use is overwhelmingly viewed as being "the single most avoidable cause of disease, disability and death" in the United States (CDC, 2008, p. 2).

And perhaps nothing here has touched so many lives as the regularly consumed, legal drug caffeine, perhaps because coffee drinking is considered so very normal and acceptable, even necessary, in everyday life. However, we must ask whether there is a level of caffeine use that is abuse—or perhaps self-abuse. Surely we do not want to throw caffeine use onto this list of substance abuses

and addictions. Still, a collection on addiction would not be complete without at least touching on this matter, and therefore we do address caffeine herein.

And then there are also the addictions to prescription drugs (such as Vicodin, Percocet, OxyContin, and Darvon), which we find increasing rapidly and already a worldwide phenomenon, with the most commonly abused prescription drugs being opiates. The U.S. National Institute of Mental Health characterizes prescription drug addiction as the second most common illegal use of drugs in the United States, second only to marijuana.

We must also note that unusual, virtually invisible psychoactive substances are working their way into our everyday lives. Household and workplace products contain many volatile substances, exposure to which can be not only damaging, but also intoxicating, and perhaps addicting. Although this domain of substance use and abuse is not specifically addressed herein, we must acknowledge the severe and perhaps largely unmeasured effects of this domain of even routine, legal substance use as well as unintentional and intentional abuse.

So as not to exclude nonsubstance addictions in this overview of addiction today, the fourth volume in this collection on addiction reminds us that work, television, shopping, food (with its particularly difficult-to-call-addiction nature), intimate partner relationship, gambling, Internet, and even pornography addictions make their marks in our lives, either indirectly or directly. These behavioral, nondrug addictions, which occur alone and co-occur with each other, also do co-occur with substance uses, abuses, and addictions. Every human being is in some way affected by the prevalence of behavioral addictions, either directly or indirectly. The study of behavioral addictions teaches us a great deal about addiction itself.

All this suggests the picture of an addiction-prone and largely chemically dependent human species. And this is just the tip of the iceberg. With this truly incomplete laundry list of human fallibilities—or better stated, perhaps, human *vulnerabilities*—this four-volume collection on addiction is truly that: a collection of perspectives, approaches, and findings. Each chapter is a snapshot of the work and thinking taking place in many fields of addiction. Contributors to this collection work with addiction on the various social, philosophical, psychological, spiritual, policy, political, economic, biological, and even cellular levels, all places where this thing we call "addiction" lives. Certainly this collection would have to comprise hundreds of volumes, rather than the four that it does, to address addiction in all its iterations.

Here we give voice to a diverse cross section of perspectives on addiction. This is in no way an exhaustive cross section (of either perspectives or addictions); rather, this collection suggests the diversity of perspectives, theories, practices, and types of addiction in the field—or better stated, *fields*—of addiction. The four volumes of this collection represent the voices of those who have

graciously and even bravely stepped forward from their numerous countries and arenas of work to contribute their ideas, research, and experiences. Certainly there are many others out there, many other aspects of addiction, and many other drugs and objects of addiction not addressed in these volumes.

This work is divided into four volumes, with the first three addressing addictions to substances and the fourth addressing behaviors that show characteristics of addiction. Volume 1, *Faces of Addiction, Then and Now,* offers a sampling of the depth and breadth of addiction today and in the past; volume 2, *Psychobiological Profiles,* surveys some of the interlinked psychological and biological aspects of addiction; volume 3, *Characteristics and Treatment Perspectives,* samples the range of addiction treatment perspectives and approaches; and volume 4, *Behavioral Addictions from Concept to Compulsion,* gives the reader a glimpse of behavioral addictions other than substance addictions.

Readers will observe that the content of these volumes is indeed diverse and in no way represents any one view or theory of addiction. There are many other voices out there who must also be heard, and only in the interest of time and space are we stopping here, at these volumes. The content of these volumes in no way expresses the opinion of this editor, nor of this publisher, regarding what is right, best proven, or even most en vogue in the addiction world; rather, this *International Collection on Addictions* seeks a display of, a sampling of, the diversity of effort to quell the detrimental effects of addiction on individuals, families, communities, societies, economies, and international relations; on ecologies; and in fact, on the human population of planet Earth.

Introduction to Volume 3: Characteristics and Treatment Perspectives

Angela Browne-Miller, PhD, DSW, MPH

This is volume 3 of *The Praeger International Collection on Addictions: Characteristics and Treatment Perspectives*. How addiction is treated has a great deal to do with how addiction is perceived, explained, and theorized. Addiction treatment philosophies range from spiritual to educational, social, psychological, medical, and to combinations of these. We might also include legal and correctional approaches although these are generally not considered treatment in themselves, and are too frequently anything but treatment. Both the designs and the outcomes of addiction treatment are measured and reported based on underlying philosophies and theories, implicit as well as explicit.

In this volume, we examine samples from the fascinating and diverse range of treatment as per theorized etiology, life course and other perspectives. The intention is not to favor one approach, philosophy, or theoretical stance over another, but rather to see at least some of the many characteristics of the field. Certainly there are viewpoints and approaches not addressed herein, and this is merely a time and space limitation, not one of interest or respect.

From the various vantage points presented herein, the very characteristics of addiction itself can appear different. The material in this volume builds on the psychobiological discussions in volume 2, where addictions were described in various ways, including as public health problems, as self-destructive behaviors, as adaptation gone awry, as frequently co-occurring with trauma and substance abuse, as related to or similar to allergies, as cognitive control conditions, and as neurobiological processes including the desensitization of sensory neurons.

"Part I: Paradigms" opens with a look at "The Social Construction of Drug Policy and Its Impact on Substance Abuse Treatment Philosophies in the

United States," contributed by Sean R. Hogan, PhD, MSW, at the Department of Social Work, California State University Fullerton, California, United States. The social construction of drug users and addicts as deviants and criminals is a relatively new (from a longer historical standpoint) conceptualization of this condition. Hogan calls for policies that can integrate the criminal justice system with the health professions (e.g., medical, psychological, social work, counseling) to begin shifting away from the present-day and quite dominant societal perception of drug users and addicts as criminals. Drug policy reformers call for far more than just this shift; however, this is at least a start. Hogan contends that reforming the current "prohibition-criminalization paradigm" and replacing it with a public health model will be a large job. However, we can work at this incrementally, beginning perhaps with the decriminalization—"depenalization"—of particular drug-related activities such as possession of a small amount of marijuana. This step can reduce law enforcement and prosecution costs, Hogan says, without raising the cost to society of marijuana use.

Next we hear from Lorraine T. Midanik, PhD, at the School of Social Welfare, University of California at Berkeley, Berkeley, California, United States, in chapter 2, "The Philosophy of Denial in Alcohol Studies: Implications for Research." Midanik discusses the machinations of denial in alcohol addiction, directing us to the distinction between denial and other "untruths." Denial is frequently misunderstood to be something that necessitates volition as per standard dictionary definitions. Denial and its definitions have a long history. Psychiatric definitions have referred to various processes that characterize denial, such as defense mechanisms. As early as 1911, T. D. Crothers wrote of "a progressive anesthesia of certain areas of the brain with unconsciousness of the real condition." And E. Morton Jellinek (who wrote the famous book, *Alcohol Addiction and Chronic Alcoholism*, in 1942) described the "rationalization of drinking behavior" and accompanying "well-known alcoholic 'alibis'." Midanik takes us on a journey through the social construction of denial—or at least of definitions of denial, and also of the politics of denial, reporting that, "we do live in a world where *denial* is an important mainstay in the alcohol field. It has provided a central ideology for the disease model." Midanik questions "the assumption that *denial* needs to be the central core of alcohol treatment."

In chapter 3, we have "The Spirituality of Recovery and the Twelve Steps of Alcoholics Anonymous," by Rev. Robert Davis Hughes, III, PhD, of the School of Theology, University of the South (Sewanee), in Sewanee, Tennessee, United States. The *Twelve Steps of Alcoholics Anonymous* was first written by "Bill W." (Wilson) in 1938 and was the next year published in what has come to be called "The Big Book." The Twelve Steps have become what Hughes describes as "the dominant gold standard in defining the spirituality of recovery." Hughes

notes that while the "recovery community" has accepted much of the new neuropsychological knowledge of addiction, it remains to be seen whether this community can expand to fully include "the broad range of other faiths and communities of spiritual practice, including new religions and persons of little or no faith, as the founders intended." This would "define a program of recovery that is 'spiritual but not religious'" and that would serve a broader population.

Consideration of denial and of spirituality in recovery from addiction takes us to the quite central if not always visible question of free will, in chapter 4, "Addictions and Free Will: A Structured Exploration of the Boundaries of Personal and Societal Responsibility," by Julian G. Martins, MA, MB, BS, of the Academy of Nutritional Medicine, Cambridge, England, and Basant K. Puri, MA, PhD, MB, BChir, MRCPsych, MMath, of the Medical Research Council (MRC) Clinical Sciences Centre (CSC), Hammersmith Hospital and Imperial College, London, England. When addiction is described as a "moral condition," the addicted person is said to be exercising "free choice" when choosing to behave in a certain way. Martins and Puri explain, "Although this position has the advantage of promoting a strong expectation of personal responsibility for behavior, it carries with it the risk of an excessive retributive response to addictive problems. . . . The potential advantage of addiction being seen as a chronic, relapsing brain disorder is that it is able to reduce the stigma associated with these problems, allow earlier access to more effective treatment programs, and avoid the overuse of ineffective and costly prison sentences. . . . In fact, not only is prison ineffective at tackling drug problems, it is also a high-risk environment for drug initiation." Martins and Puri note something taking place in some prison settings, "the neurosurgical ablation of the nucleus accumbens to treat addiction on subjects in penal settings in Russia and China where informed consent is doubtful." (Note that the nucleus accumbens is, in essence, a collection of neurons within the forebrain said to play a central role in the reward circuit, operating on dopamine and serotonin, promoting desire, and satiety and inhibition, respectively.)

Looking past, or perhaps deeper into, free will, we see the potential of religiosity to ward off addictions. Patrick McNamara, PhD, of the Boston Veterans Administration (VA) Healthcare System and the Boston University School of Medicine, Department of Neurology, Boston, Massachusetts, United States; and James Burns, PhD, of The Danielsen Institute at Boston University, Boston, Massachusetts, United States, share their perspectives on "Religiosity as Protective against Addictions in Adolescents" in chapter 5. McNamara and Burns underscore the "protective effects of religion against addictions in adolescents," discussing the potential mechanisms for this "protective effect," noting that among these "are the [very important] interactions between religious

beliefs/practices and the developing brain." McNamara and Burns suggest that, "religiosity and executive control processes such as impulse control and the planning and generation of implementation intentions mutually interact during development in such a way as to yield effective protection against addiction and risky behaviors in children and adolescents." While this chapter speaks largely from a prevention standpoint, per the "protective effort" described herein, we must ask, What might such an interaction between religiosity and the mind's own executive control processes play in addiction treatment itself? If this interaction works before an addiction is fully formed, can it also be important once the addiction is in place?

Part I of this volume is concluded in chapter 6 with an "Analysis of Intervention, Treatment, Policy, and Law That Contradict Ethical Criteria," contributed by Ann N. Dapice, PhD, of T. K. Wolf, Inc., a Native American–focused addiction treatment program in Tulsa, Oklahoma, United States. Dapice reviews the characteristics of truly moral decision making. Among these characteristics are: have no personal gain or interest; obtain as much information as possible about the problem; try to understand the consequences; react in the same manner to the same actions; and do not be sick or overly tired or stressed when making moral decisions. Dapice tells us that the tenets of moral decision making should inform and guide addiction intervention, treatment, law, and policy. But do they? Not entirely, as Dapice reminds us: "Nicotine [for example] remains in first place as a cause of preventable death . . . yet use of nicotine has often been condoned and encouraged through reward systems in mental health and drug rehabilitation facilities, other addiction settings, and prisons. Recently, U.S. federal funding has required that smoking not be allowed in federally funded mental health, addiction facilities, or prisons. Yet well-intentioned counselors can still be heard to say, 'We can't take their last drug away.'"

We then turn to Part II of this volume, "Models," which opens with consideration of "Family Issues in the Field of Addiction Treatment" in chapter 7, written by Giuseppe Carrà, MD, MSc, PhD, of the Department of Mental Health Sciences, Royal Free and University College Medical School, London, England; Massimo Clerici, MD, PhD, of the Department of Neurosciences and Biomedical Technologies, University of Milan-Bicocca, Milan, Italy; Hamid Ghodse, MD, PhD, DSc, of the International Centre for Drug Policy, St. George's Hospital Medical School, University of London, England; Flavio Poldrugo, MD, PhD, of the Office for Research and Innovative Projects on Alcohol, Other Addictions and Mental Health, Departments of Psychiatry and Addiction, University of Trieste, Italy; and, Nady el-Guebaly, MD, of the Department of Psychiatry, University of Calgary, Calgary, Canada. Carrà,

Clerici, Ghodse, Poldrugo, and el-Guebaly have graced this collection with their insights into the great complexity of family member roles in substance abuse treatment against the backdrop of essential cultural sensitivity. Among the findings are: confrontational approaches may or may not work within particular cultural contexts; families may split into rescuing and rejecting factions; and family systems approaches can be cost-effective when conducted with cultural sensitivity. The authors of this chapter note that "People with schizophrenia from families that express high levels of criticism, hostility and emotional over-involvement, according to the Expressed Emotion (EE) Index, have more frequent relapses than people with similar problems from families that tend to be less expressive."

In chapter 8, Mary Theresa Webb, PhD, of the Global Outreach for Addiction Leadership and Learning (GOAL) Project based in Aliquippa, Pennsylvania, United States, and of the International Substance Abuse and Addiction Coalition (ISAAC) based in the United Kingdom, also of the OPORA Training Center in Moscow, Russia; and, Ann Fabean, PhD, MA, of Greenburg, Pennsylvania, United States, retired from private practice, write on "Codependence from a Family Systems Perspective." Webb and Fabean note that, 30 years ago, the addiction field and the family systems field were just beginning to explore the effect of addiction on family systems. Delving into complex matters such as codependence, counterdependence, family emotional affect, and family roles can illuminate this aspect of co- and counter-addiction. Webb and Fabean emphasize, "Codependent family members frequently exhibit symptoms of the family disease for a longer period of time than the addict does. The addict can become abstinent and receive individual and group support and treatment and be *in recovery*. Family members who don't understand that their reactive patterns or maladaptive behaviors need to be healed are not *in recovery*. They need as much support and treatment—if not more in many cases—than the addict." Unfortunately, as the authors find, "in today's Western controlled-care climate, which allows only short outpatient treatment, family member treatment often is ignored. Even in Eastern and/or developing countries where therapeutic modalities of treatment exist, little is known or practiced for family recovery. In African countries, women who live with alcoholic or HIV-infected males need special culturally sensitive care and support. Many family members who live or have lived with active addicts and who still suffer from depression or posttraumatic stress deserve the same attention and care as the addict."

Next, in chapter 9, we study "Best Practices for Dual Diagnosis Treatment and Program Development: Co-occurring Mental Illness and Substance Disorders in Various Combinations," contributed by Kathleen Sciacca, MA,

of Sciacca Comprehensive Service Development for Mental Illness, Drug Addiction and Alcoholism, MIDAA, New York City, New York, United States. Sciacca directs our attention to dual diagnosis concerns and asks what the best practices are for addressing these issues. Detailing best practices, client readiness to change, and other factors, Sciacca presents the wisdom of her many years as a consultant to the design and implementation of dual diagnosis treatment and integrated services. Although the field of dual diagnosis has expanded markedly in recent decades, there remains a great need for expansion of the knowledge—and utilization of the knowledge—in this area. Given that some "40 to 60 percent of individuals presenting in mental health settings have a co-occurring substance abuse diagnosis, and 60 to 80 percent of individuals presenting in a substance abuse facility have a co-occurring mental health disorder . . . [and] at least 50 percent of the 1.5 to 2 million Americans with severe mental illness abuse illicit drugs or alcohol," it is not only humane to attend further to dual diagnosis issues, but it is also cost-effective to do so.

Then, in chapter 10, Ray B. Smith, PhD, private consultant based in Forestville, Maryland, United States, at the time of this writing with a CES research project in a field army hospital in Iraq, contributes "Cranial Electrotherapy Stimulation in the Treatment of Addictions." Here Smith reports on what evolved out of his earlier studies funded by a U.S. National Institute of Mental Health (NIMH) grant to work at the District of Columbia's (Washington, DC, United States) 600-bed Rehabilitation Center for Alcoholics. Smith concludes that cranial electrotherapy stimulation (CES, also known as "electrosleep") has been shown to, more effectively than pharmaceutical interventions, address "drug abstinence syndrome" in the treatment of addiction. CES is basically "a small electrical stimulation pulsed across the head for up to one hour a day for three weeks or less for FDA-accepted treatment claims of depression, anxiety, and insomnia. All these are symptoms of persons recovering from addictions, the drug abstinence syndrome." Smith points out that CES has been used outside the United States longer and more widely, and that perhaps the confusion of CES with electric shock therapy has dampened interest in the United States.

From here, Maria Dinis, PhD, DSW, at the Division of Social Work, California State University Sacramento, Sacramento, California, United States, shares "An Analysis of Service Providers' Treatment Model Choices for Cocaine-Using Clients: A Case Study," in chapter 11. Dinis inquires as to how treatment providers select their treatment approaches. She finds that educational background, professional and experiential training, work setting, personal belief system, age, and gender all affect the professional's selection of treatment to be applied. Dinis concludes that "It is, therefore, important to understand the relation between the background characteristics of treatment providers and

their treatment choices." Focusing on the choice of cocaine treatment models to exemplify this, Dinis finds additionally that providers' selection of treatment models is also complicated in light of their interaction with clients' beliefs about treatment models and other client characteristics that cause a model to work for one client and not for the next.

Van L. King, MD, Michael Kidorf, PhD, Kenneth B. Stoller, MD, Karin J. Neufeld, MD, MPH, and Jessica Peirce, PhD, all at Johns Hopkins University School of Medicine, Baltimore, Maryland, United States; and Robert K. Brooner, PhD, at the Johns Hopkins University Department of Psychiatry and Behavioral Sciences, also in Baltimore, Maryland, United States, contribute chapter 12, "Translating Efficacy to Effectiveness in Opioid Dependence Treatment." Here the focus is on opioid dependence in the forms of both heroin and the increasingly popular opioid of abuse, prescription opioid (oxycodone). The authors report that "Opioid dependence is a severe, persistent disorder often requiring long-term and at times intensive psychiatric treatment." The Motivated Stepped Care (MSC) treatment model is discussed, as it integrates medication, psychotherapy, and behavioral reinforcement into a comprehensive model of treatment. MSC is advantageous both clinically and as per its cost-effectiveness via its "matching the intensity of service to the severity of the problem in a dynamic fashion over time using behavioral reinforcement to motivate counseling adherence and treatment plan progress. In this way, only as much treatment as needed to improve and stabilize functioning is prescribed, and then intensity of care is reduced to minimize intrusiveness and cost." A "wide spectrum of pro-rehabilitation behavior change" is provided by this MSC treatment model.

Here, we pause to consider alternate aspects of rehabilitation and harm reduction, in chapter 13, "Shamanistic Harm-Reduction Practices," contributed by Michael Winkelman, MPH, PhD, at Arizona State University, in Tempe, Arizona, United States. Winkelman applies an evolutionary psychology approach to understanding similarities in drug and non-drug methods for altering consciousness, which is termed the "shamanic paradigm." Identifying the biological similarity between altered states of consciousness (ASCs) and drug-induced states suggests the potential for what may be called "shamanic practices" (based to some extent on traditional indigenous shamanic practices) for treating addiction. Winkelman contends that, "The shamanic approach supports the harm-reduction principles of alternatives to abstinence with natural and nonaddictive ways of meeting human needs to experience transcendent states of consciousness." Winkelman's approach is one of harm reduction, plus self-realization of goals and alternate futures, and then behaviors to reach these futures. Winkelman suggests that assisting the client to recognize the "spiritual dimension" can help the client to access the personal resources to make sig-

nificant behavior changes, including in drugging and drinking behaviors and addictions.

From here, we move into Part III of this volume, "Practices," turning first to chapter 14, "Therapeutic Approaches, Beliefs, and Perceptions of Providers When Treating Alcohol- or Drug-Using Clients: Selecting Best Practices," submitted by Maria Dinis, PhD, MSW, at Division of Social Work, California State University, Sacramento, California, United States; Joseph R. Merighi, PhD, MSW, at Boston University School of Social Work, Boston, Massachusetts, United States; and Kelly Anders, MAL, at the University of California Davis in Davis, California, United States. Dinis, Merighi and Anders warn that without programs to provide best practice approaches, these new models are virtually irrelevant. "The treatment-client community as a whole may not adequately benefit from the evidence-based knowledge professionals are currently developing or the gains made in substance abuse treatment strategies, including medications, until the treatment infrastructure is supported and the public demands quality of treatment care in the same way as they recognized that alcohol/drug abuse was associated with public health and safety problems." Again, we see how critical understanding of the public health perspective is to treating addiction. Funding must support public health approaches in programs that require "vital resources to maintain and utilize evidence-based practices in the treatment of addictions."

Chapter 15, "Brief Telephone-Based Interventions for Clients with Alcohol and Other Drug Abuse Problems," is written by Thomas Beers, PhD, of the California Screening, Brief Intervention, Referral and Treatment program (CASBIRT) in San Diego, California, United States; Melinda Hohman, PhD, of School of Social Work, San Diego State University, San Diego, California, United States; Katharine Slack, MSW, at CASBIRT and the California State University School of Social Work, Center for Alcohol and Drug Studies and Services in San Diego, California, United States; Daniela Sisneros, MSW, also at the Center for Alcohol and Drug Studies and Services in San Diego, California; and Susan I. Woodruff, PhD, at the San Diego State University School of Social Work, in San Diego, California. The authors explain that "Alcohol and other drug (AOD) abuse and dependency continue to be major problems . . . as they contribute to elevated health risks related to cardiovascular disease, stroke, pancreatitis, cirrhosis, and various types of cancer . . . [and associated problems such as] violence, family dysfunction, poverty, poor work performance, and criminal behavior." The authors suggest and report on the "CASBIRT Brief Treatment Program," which offers "short-term, harm-reduction treatment services for high-risk AOD abusers who typically would not be treated by community-based services." This innovative and cost-effective

treatment model utilizes motivational interviewing principles and cognitive behavioral approaches, with the advantage that this model minimizes barriers to program access with "no-cost services, bilingual counselors, flexible scheduling, and phone or in-person sessions." The findings of the authors' study of this treatment model indicate that telephone counseling can be "a viable treatment alternative to traditional face-to-face counseling" and that telephone service delivery is having "a number of positive effects and effects similar to in-person counseling," with "positive changes in AOD behavior" being suggested.

Ramadugu Shashikumar, MD, a consulting psychiatrist in Jallandhar, Punjab, India, shares his insights in chapter 16, "Screening and Brief Intervention for Alcoholics." "Screening is the procedure that identifies a disease or disorder in its early or presymptomatic stages and provides efficient identification of those users of alcohol who need a more comprehensive diagnostic evaluation and treatment planning." The author also notes that "in view of its easy availability, low cost, and greater sensitivity (which is an essential characteristic in screening tests and also a tool to monitor abstinence states), GGT [gamma glutamyl transferase] is an ideal screening biological marker."

Chapter 17, "Service Profiles: Provider Choices for Treatment of Alcohol- and Cocaine-Using Clients," is contributed by Maria Dinis, PhD, MSW, at California State University, Sacramento, Division of Social Work, and the Alcohol Research Group, Berkeley, California, United States; Lyndsay Ammon, MPH, at the University of California Berkeley, School of Public Health, and the Alcohol Research Group, Public Health Institute, Berkeley, California, United States; and Kelly Anders, MAL, at the University of California Davis, in Davis, California, United States. The authors conduct an important study regarding treatment provider choices to apply either one or a combination of services. "For instance, does pregnancy status play a role in treatment selection; and does the choice vary depending on the provider's own work setting and demographic characteristics? If so, what are the actual treatment choices being made? For example, professionals working in a hospital setting may tend to recommend only inpatient hospital treatment for their clients rather than referring them either to halfway houses, which cost a fraction (13%–17%) of inpatient care and about 50% of outpatient hospital-based treatment, or to no-cost self-help groups. . . . Conversely, those working in alcohol/drug treatment programs may recommend a broader range of services that they believe would result in better treatment outcomes for some clients, such as pregnant women."

Next, Jana Cook, MD, PhD, Scott E. McClure, PhD, Igor Koutsenok, MD, MS, and Scot Lord, CATC, FACT, all at the School of Medicine, Department of Psychiatry, Center for Criminality and Addiction Research, Training and Application (CCARTA) the University of California, San Diego (UCSD),

San Diego, United States, contribute chapter 18, "An Innovative Approach to Prison-Based Substance Use Treatment: The Implementation of Inmate Peer Mentor Programs." The authors note that, "The United States currently maintains the largest prison population in the world. Over the past 30 years there has been a continuous increase in the number of inmates in U.S. state and federal prisons. . . . The relationship between substance use and criminal incarceration is an undeniable factor in the nation's prison crisis." Other approaches to the criminalization of substance use—and to inmates' substance addictions—are essential and have emerged. The authors share the story of an important approach, that of the Therapeutic Community (TC). Cook, McClure, Koutsenok, and Lord explain: "In October 2006, the California Men's Colony (CMC) prison in San Luis Obispo, faced with staff recruitment and retention difficulties, decided to utilize long-term sentenced inmates as peer mentors to lead their prison-based TC program. Prior to this decision, several attempts to utilize contracted treatment providers from within the state as well as one out-of-state treatment provider had failed. This protracted struggle inspired the correctional counselor . . . to use the human resources available, inmates with long prison terms." There was a large pool of participants in need of treatment services and a valuable resource in the peer-mentor inmates with long-term sentences who had had previous experience in TC treatment. In fact, "Some of these participants had a history of active involvement in prison-based TC treatment that stretched back over 15 years, and their experience with the TC model was unquestionable." It became clear that peer mentors can "provide substance abuse treatment under close correctional and clinical supervision." In fact, the CMC Substance Abuse Treatment Program "Our House" became the first custody-based TC program within CDCR entirely run by peer mentors, independent from any outside treatment providers.

Chapter 19, "Advances in Corrections-Based Treatment: Building the Addiction Treatment Workforce," submitted by Igor Koutsenok, MD, MS, and Scott E. McClure, PhD, (who both are, as noted previously, at CCARTA and the University of California San Diego, California, United States). Koutsenok and McClure report that, "Cross-trainings are unique to correctional addictions treatment environments and have emerged to help foster productive relationships between treatment and correctional staff. Cross-trainings aim to help both staffs develop an enhanced understanding of their role in offender treatment." They go on to write that "trainings need to follow scientifically driven principles, be facilitated by well-trained and educated professional training staff, and be reinforced through clinical supervision, organizational acceptance, follow-up trainings, and implementation analysis. The ability to successfully improve the addiction treatment workforce is highly dependent on these fac-

tors." And the authors tell us how very important it is that we "bring science to front-line practice." We can learn valuable lessons regarding what makes treatment effective from this area of front line practice.

From here we shift gears to see another face of addiction treatment, in chapter 20, "Sacred Medicines for Harm Reduction and Substance Abuse Rehabilitation," by Michael Winkelman, MPH, PhD, who is, as noted earlier, of Arizona State University in Tempe, Arizona, United States. Winkelman reports that "the concept of sacred medicines refers to substances also known as psychedelics, hallucinogens, entheogens, and psychointegrators" and that "humans have used plants as sacred medicines for thousands of years for their vision-inducing properties, their ability to shift awareness and consciousness to a spiritual domain, and their ability to induce healing." Winkelman makes the case for including these substances in research and treatment, although they have been prohibited since at least the 1970s. Winkelman reports that "there has emerged significant evidence that these substances have important applications in the treatment of a variety of conditions, including addictions." Winkelman contends that given the "limited efficacy of current treatments" for drug addiction, the use of such "medicinal" substances for treatment of drug dependence is an "ethical responsibility of the medical field."

And last is chapter 21, "Entheogen-Enhanced Transpersonal Psychotherapy of Addictions: Focus on Clinical Applications of Ketamine for Treating Alcoholism." The authors are Eli Kolp, MD, in private practice, Tampa Bay, Florida, USA; Evgeny Krupitsky, MD, PhD, DMedSci, of the St. Petersburg State Pavlov Medical University, also of the Bekhterev Research Psychoneurological Institute, and also of the Health Care Committee of the Government of the Leningrad Region, Russia; Harris Friedman, PhD, Department of Psychology, University of Florida, Gainesville, Florida, United States; and M. Scott Young, PhD, at the University of South Florida, in Tampa, Florida, United States. Kolp, Krupitsky, Friedman, and Young present the results of studies researching the treatment of alcoholism, heroin addiction, and other problems such as treatment-resistant depression with ketamine. "Undeniably, alcoholism is an extremely destructive problem that resists most conventional treatment approaches. . . . Ketamine hydrochloride (ketamine) is a prescription medication widely used for general anesthesia. It was first synthesized in 1962 and later patented by Parke-Davis in 1966 as a human anesthetic. During the Vietnam War, ketamine was the most widely used battlefield anesthetic. The U.S. Food and Drug Administration (FDA) approved ketamine anesthesia for use with all ages (children, adults, and the elderly) in 1970. Since then, ketamine has been adopted by many hospitals and medical offices due to its rapid onset, proven safety, and short-duration of action." More than 7,000 publications describe its

"high effectiveness and safety" and "numerous clinical studies have detected no long-term psychological impairment following ketamine use."

This then is volume 3, *Characteristics and Treatment Perspectives,* of *The Praeger International Collection on Addictions*. This collection of essays reveals a shifting field, a brave new field of addiction treatment, expanding in several directions, building on an extensive knowledge base, years of research, and years of debates. The range of possibilities on the addiction treatment horizon is vast, exciting and perhaps unlimited. We look to the future of addiction treatment based on the work of the authors of this volume and their colleagues around the world.

Part I

PARADIGMS

This page intentionally left blank

Chapter 1

The Social Construction of Drug Policy and Its Impact on Substance Abuse Treatment Philosophies in the United States

Sean R. Hogan, PhD, MSW

> *Our grievous error was in allowing the narcotics addict to be pushed out of society and relegated to the criminal community.*
>
> —Rufus King (1953)

Historically, American society and its political representatives have interpreted illegal drug use from a moral perspective requiring some type of punitive response. From this perspective, drug use and addiction are seen as the self-inflicted consequence of characterologically weak, spiritually bankrupt, and socially deviant individuals whose behavior warrants stringent antidrug legislation and criminal justice intervention. This prohibition-criminalization paradigm (Rouse & Johnson, 1991) represents a consensus among the American people that illicit drug use is an immoral behavior and that drug users should be subject to arrest, prosecution, and incarceration. The rehabilitation and treatment of drug users and addicts are secondary goals to the elimination of an illegal drug-using presence in society (Jensen & Gerber, 1998).

Most of the discourse associated with the criminalization of addiction in U.S. society has focused on the negative social, legal, and economic consequences of illegal drug use. Outcomes, such as the creation of organized criminal networks and markets, the violence associated with drug manufacturing and trade, and the subsequent legal, health, and economic costs to U.S. society have become anathemas among advocates for drug policy reform (MacCoun & Reuter, 2001; Mosher & Atkins, 2007; Nadelmann, 1991). The role that criminalizing addiction has played in the subsequent substance abuse treatment philosophies

for drug addicts has not attracted as much attention. In this chapter, the early social and political foundations of America's response to drug use as a social problem are presented. Then, the implications of this response in the substance abuse treatment of persons who are addicted to drugs are examined. Last, some policy alternatives to America's current reaction toward illicit drug use are suggested. The intention of this chapter is to provide a clearer understanding as to why the United States embraces prohibitionist and punitive drug policy ideals and how these ideals directly affect the clinical treatment of drug addicts. In this chapter, all mentions of drug use refer to illicit drug use.

EARLY SOCIAL CONTEXTS

Interestingly, in the United States, drug policies are often constructed based on the characteristics of the people that are using the drugs rather than the harmful properties of the drugs themselves (Robinson & Scherlen, 2007). Prior to 1875, the United States had no antidrug policies or practices (Courtwright, 1982). The use of drugs was not considered particularly detrimental to society or its members. Individuals who became addicted to drugs were generally placed in the care of a physician and labeled as "unfortunate" (Booth, 1996). These individuals were regarded with compassion rather than with some type of social stigma or disapproval. Drugs and drug use had yet to fall subject to any serious moral distinction. As a result, substance use during the early history of the United States was not regulated or controlled. The true consequences of substance abuse had yet to be fully appreciated or comprehended by early Americans. While alcohol had been a part of U.S. society since the country's inception, drug use was just beginning to flourish during the nineteenth century (Courtwright, 1982).

The first drug to attain social prominence in the United States, other than alcohol, was morphine. Morphine sulfate, an opium alkaloid, had been discovered in 1804 by a German chemist named Friedrich Serturner (Lindesmith, 1957). The effectiveness of morphine as an analgesic and narcotic was quickly recognized by the medical and patent medicine establishments of the time. Without any antidrug regulation or legislation, patent medicines were readily and legally available to any individual. Patent medicines, or proprietary medicines as they were sometimes called, were popular elixirs sold by businesses and entrepreneurs as tonics or cure-alls (Courtwright, 1982). Opiate preparations, such as Mrs. Winslow's Soothing Syrup and McMunn's Elixir of Opium, as well as laudanum and paregoric, could be purchased at any local drug store or in any mail-order catalog (Lindesmith, 1957). These preparations were also very inexpensive. The combination of low price and high availability made

morphine and other opiate use during the last half of the nineteenth century fairly prevalent. Many early Americans were opiate consumers (Musto, 1999).

According to Courtwright (1982), by far, the greatest use of morphine in nineteenth-century America was by white, middle- and upper-class women. Women of this period used morphine as a panacea for many of their physical and emotional problems. Physicians prescribed morphine for everything from a toothache to menstrual cramps to melancholia (depression) (Aldrich, 1988). If a woman went to see a doctor in the late 1800s, chances are she would leave with a prescription for morphine. Another population that contributed to the high prevalence of morphine use during this period was Civil War veterans. Many soldiers, having incurred chronic or extensive injuries during the war, required prolonged morphine treatment. Following the end of the war, these soldiers were often maintained on morphine by their local physicians. The administration of morphine by physicians is regarded by some historians as the single greatest cause of opiate addiction in the United States during the nineteenth century (Courtwright, 1982; Durrant & Thakker, 2003).

So-called infant doping was another widespread practice of this period (Aldrich, 1988). Sedating children and babies with morphine mixtures was a common method for controlling loud, crying, and unruly children (Musto, 1999). Screaming babies were often given laudanum medicines as a calming agent (Aldrich, 1988). This practice led to early infant mortality studies in England, which resulted in that country's first opiate prohibition law, the Pharmacy Act of 1868. This law banned laudanum use unless it was prescribed by a physician (Berridge & Edwards, 1987). In the United States, the first legislation addressing the use of morphine and patent medicines came in 1906 with the passage of the Pure Food and Drug Act. This act was intended to curtail the use of adulterants in foods and, particularly, patent medicines, by requiring manufacturers to list a product's ingredients on its label. It did not, however, make patent medicines, morphine, or any other drug illegal.

One reason for the naïveté associated with substance abuse during this period was simply a lack of information and limited understanding on the parts of the medical establishment and U.S. society concerning the consequences of drug use and addiction. For example, early physicians thought morphine could be used as a cure for opium addiction. Ironically, heroin, developed commercially in 1898, was then thought to be a cure for morphine addiction. Cocaine, with its stimulating effects, was first thought to be a cure for alcoholism (Musto, 1999). With such a lack of knowledge surrounding drugs, insightful medical and policymaking decisions were virtually impossible. Fortunately, over time, the medical establishment's understanding of drug use and addiction would

become more advanced; however, America's social and political knowledge of this issue would progress much more slowly.

A significant shift in public perception and, consequently, the strategies designed to address substance use occurred when American society began to associate drug use with certain minority and ethnic groups (Courtwright, 1982; Musto, 1999). At the turn of the twentieth century there was a strong association between opium use and Chinese immigrants, and between cocaine use and African American males from the southern United States (Helmer, 1975; Musto, 1999). Racist and xenophobic sentiments, long a part of American history, contributed to an emerging social consciousness against drug users and subsequent campaigns to construct antidrug legislation. When drug use was associated with mainstream drug users and the dominant culture, it was not considered a serious social problem. However, once attention concerning substance use was directed toward less socially desirable members of society (e.g., immigrants and minorities), the American public's perception and reaction to drug use changed (Musto, 1999). Drug use and addiction were no longer seen as some type of personal misfortune. Instead, these phenomena were interpreted in more pejorative terms, as the self-indulgent and immoral behavior of a nonnativist lower class. This negative association of substance use with ethnic minorities was an important social factor in motivating a political response toward early antidrug legislation in the United States (Helmer, 1975; Lindesmith, 1957). It was in this context that the U.S. government passed its first comprehensive federal antidrug policy—the Harrison Narcotic Act of 1914.

THE HARRISON NARCOTIC ACT

The Harrison Narcotic Act, named after its author, Representative Francis Burton Harrison, was the final product of many years of legislative and political mediation among drug policy advocates, international drug control representatives, and powerful pharmaceutical and medical interests of the period (Musto, 1999). Adamant drug policy reformers and prohibitionists, such as Hamilton Wright, invested a great deal of personal energy in seeing the Harrison Act to fruition. Previous attempts and efforts to pass some type of comprehensive antinarcotic legislation, including an earlier and stricter version of the Harrison Act, the Foster Bill of 1910, had met with opposition and defeat (Musto, 1999). Too many interest groups simply wanted too many consolations and contingencies attached to an antinarcotic bill to pass such a measure. Finally, in June 1913, the chairman of the National Drug Trade Conference, a powerful drug lobby of the time, signed a draft of the proposed bill, which was then intro-

duced into the first session of the 63rd Congress by Representative Harrison (Musto, 1999). The bill would eventually pass and become the first landmark antidrug policy in U.S. history.

Within the Harrison Narcotic Act, there were two sections that would prove the most significant for controlling drug use in the United States. The first section stated that anyone engaged in the production or distribution of narcotics (i.e., opiates or cocaine; antimarijuana legislation would come later) must register with the federal government and keep records of all transactions with drugs. This section also mandated that all parties handling drugs, through either purchase or sales, must pay a tax. The second section of the act stated that unregistered persons could only purchase drugs by a prescription from a physician and that such a prescription must be for legitimate medical use (Belenko, 2000). The Harrison Narcotic Act was ostensibly a revenue measure that required persons who prescribed or distributed specified drugs to register and buy tax stamps. It also provided that possession of narcotics by any individual that had failed to register as a narcotics retailer or practicing physician was unlawful unless prescribed by a physician in good faith. The reason that this act was legislated within the context of a revenue measure, rather than a penal code, had to do with issues surrounding constitutionality and the powers of the federal government versus those of the state to enforce police powers on individuals (Pittman & Staudenmeier, 1994).

While the Harrison Narcotic Act was originally legislated as a means of raising revenues and regulating over-the-counter sales and medical prescriptions of opiates and cocaine (McWilliams, 1992), its enforcement by the U.S. Treasury Department's Narcotics Division quickly devolved into an exercise in drug prohibition and punishment. In their interpretation of the second section of the act, officials from the Narcotics Division deemed the prescription of drugs to drug addicts by physicians unlawful. As a result, agents from the U.S. Treasury Department began arresting physicians who supplied patients with opiates and cocaine for the purpose of treating an existing drug addiction (Musto, 1999). At this point in American history, this type of government intervention into the private lives of citizens was viewed as highly unconstitutional. This prompted litigation by arrestees of the Harrison Narcotic Act, challenging its propriety. Two crucial Supreme Court decisions in 1919 (*United States v. Doremus* and *Webb et al. v. United States*) upheld the constitutionality of the tax and denied maintenance supplies for addicts with no intention of ceasing drug use (Belenko, 2000). A 1922 case (*United States v. Behrman*) effectively ruled that physicians could not supply drugs to addicts for any reason (Dickson, 1968). According to Lindesmith (1965), "The Supreme Court decisions up to 1922 made it impossible for doctors to treat addicts in any way

acceptable to law enforcement officials" (p. 7). In 1925, the decisions of these cases were ultimately reversed (*Linder v. United States*); however, their effects on the medical establishment and its treatment of drug addicts were profound. In the two decades following passage of the Harrison Narcotic Act, "an estimated 25,000 physicians were arraigned on narcotics charges and 3,000 served prison sentences (Williams, 1938, as cited in Peyrot, 1984, p. 88).

While the Harrison Narcotic Act did not technically criminalize the use and possession of narcotics in the United States, its passage and subsequent legal interpretation would provide the foundation for the punitive antidrug policies that would follow. This was the first step in the history of U.S. drug policy toward defining drug use as a criminal act and, therefore, a social problem to be addressed by law enforcement and the criminal justice system. In less than a decade, the Harrison Narcotic Act transformed drug addicts in the United States from patients to criminals (Durrant & Thakker, 2003). By 1930, 35 percent of all convicts in America would be confined as a result of the criminalizing effect of the Harrison Narcotic Act (Booth, 1996). The interpretation of drug use and addiction as a public health issue, as exemplified by many of the European nations of the time, would not occur in the United States. The Harrison Narcotic Act would remain the basis of narcotics regulation in the United States for the next 50 years.

HARRY ANSLINGER AND THE FEDERAL BUREAU OF NARCOTICS

In 1930, the Narcotics Division of the U.S. Treasury Department was transformed into the Federal Bureau of Narcotics (FBN) and Harry J. Anslinger was named as commissioner (McWilliams, 1992). Anslinger was a staunch antidrug advocate. During his tenure as FBN commissioner (1930–1962), he was instrumental in promoting law enforcement and the criminalization of drug use (Musto, 1999). Some historians refer to Anslinger as America's first "drug czar" (McWilliams, 1992); noted sociologist Howard Becker (1963) characterized him as a "moral entrepreneur," (p. 147) and the FBN's work as a "moral enterprise" (p. 145). Anslinger's position as Commissioner of Narcotics allowed him great influence on America's early response to drug use and addiction. His prohibitionist and punitive ideals toward drug use coupled with his leadership of a public organization dedicated to federal narcotics enforcement helped institutionalize a criminal justice response to drug use in the United States.

During these formative years, Anslinger contributed significantly to the social construction of early U.S. drug policy. In order to maintain a high level

of antidrug sentiment among the public, Anslinger was constantly campaigning against the evils of drug use and abuse. Anslinger used youth as a device to elicit a negative public response to drug use; he aggressively propagandized drug use as a killer of innocent children. As an example of Anslinger's antidrug rhetoric, in 1937 he and a colleague wrote,

> The sprawled body of a young girl lay crushed on the sidewalk the other day after a plunge from the fifth story of a Chicago apartment house. Everyone called it suicide, but actually it was murder. The killer was a narcotic known to America as marijuana . . . a narcotic . . . as dangerous as a coiled rattlesnake. (Anslinger & Cooper, 1937, p. 150)

Anslinger also unscrupulously promoted marijuana use as the impetus for criminal and deviant behavior among minorities and the lower class, particularly Mexican immigrants in the American southwest (Bonnie & Whitebread, 1974). This discourse was instrumental in influencing public and political perceptions of drug use in the United States during this period. In essence, drug use and drug users were depicted as immoral and dangerous, reinforcing in the minds of Americans the need for increased antidrug legislation and law enforcement. These sentiments would also serve Anslinger well in his bureaucratic and professional goals of promoting the function of the FBN, its status as a government agency, and its value to a society becoming inundated with perceived drug problems (Dickson, 1968). If Anslinger could effectively construct a drug problem in the United States, he could perpetuate his and the FBN's political existence. These conditions would provide the social and political contexts for the passage of America's next significant antidrug policy—the Marijuana Tax Act of 1937.

The Marijuana Tax Act required every person who dealt with marijuana in any manner (i.e., imported, manufactured, sold, prescribed, etc.) to pay a special tax. Importers and manufacturers of marijuana were required to pay a $24-per-year tax; physicians, only $1 per year (Belenko, 2000). Furthermore, the Marijuana Tax Act required every person having contact with marijuana to register with federal authorities. Any individual that did not comply with the provisions of the act became subject to criminal penalties (Belenko, 2000).

The Marijuana Tax Act was intentionally kept separate from the Harrison Narcotic Act because of fears that it would be submitted to the same claims of unconstitutionality that plagued the Harrison Narcotic Act in its formative years. Anslinger and other federal antimarijuana advocates did not want to chance having the Marijuana Tax Act compromised by legal contestations. In an additional step to ensure the act's legitimacy, Anslinger and the U.S. Treasury's General Counsel Herman Oliphant strategized to model the Marijuana Tax

Act after an already Supreme Court–tested policy—the National Firearms Act of 1934 (Musto, 1999). The National Firearms Act stipulated that certain "firearms could only be transferred upon payment of a transfer tax. As peculiar as this tax may [have] seem[ed], it was held constitutional by the Supreme Court in March 1937" (Musto, 1999, p. 222). As a result, Anslinger and Oliphant decided to propose the Marijuana Tax Act as a transfer tax and revenue-collecting measure to the U.S. Congress. The act, which effectively criminalized marijuana use in the United States, passed through Congress with hardly a debate (McWilliams, 1992).

STRICTER PENALTIES

Despite the early attempts of antidrug legislators and law enforcement to eliminate drug use in the United States, it would continue to persist as a social problem. Following the Second World War, U.S. antidrug policymakers chose to address the country's drug problem by severely increasing the penalties levied for drug offenses (Brecher & the Editors of Consumer Reports, 1972). In 1951, the Boggs Act was passed, which imposed a mandatory minimum sentence of two to five years for a first conviction of narcotics possession (Booth, 1996). A second offense carried a mandatory 5 to 10 year penalty without chance of parole or reduced sentence. These measures were advocated by Commissioner Anslinger and endorsed by nearly every member of the U.S. Congress; however, some prominent professional organizations, namely the American Bar Association (ABA) and the American Medical Association (AMA), had reservations regarding the propriety of such punitive measures (McWilliams, 1992). The concerns of the ABA and AMA led the U.S. Senate, in 1955, to create a congressional subcommittee to review the efficacy of existing federal drug policies (i.e., Harrison Narcotics Act, Marijuana Tax Act, and Boggs Act). The subcommittee's investigation concluded that drug trafficking in the United States was a greater problem than first imagined and that heroin use was particularly problematic (Belenko, 2000). This perceived failure of the Harrison Narcotic Act, Marijuana Tax Act, and Boggs Act to effectively deal with drug use in U.S. society did not lead to a change in policy or philosophy. Instead, and much to the chagrin of the professional organizations, the U.S. Senate recommended tougher, more punitive antidrug measures.

In 1956, the U.S. government passed the Narcotic Control Act, imposing even stricter penalties on drug users, doubling the maximum sentencing guidelines mandated by the Boggs Act. Consequently, a first-time conviction for drug possession could result in a maximum sentence of 10 years; a second conviction could result in a prison term of 20 years. The Narcotic Control Act

also included a death penalty provision (at the discretion of the jury) for heroin sales to anyone under the age of 18 years by any individual over the age of 18 years (Musto, 1999). One goal of these punitive policy measures was to communicate to American society that the government was seriously addressing the drug problem and that "severe measures were at last being taken against addiction" (Brecher & the Editors of Consumer Reports, 1972, p. 56). These unprecedented levels of legal punishment for drug use effectively institutionalized drug use as a criminal justice problem in the United States. This social and political history of early drug policy construction represents the foundation of America's response to drug use as a social problem, a foundation predicated upon prohibitionist ideals and a need to punish individual drug users. The institutionalization of drug use as a criminal justice problem also reinforced the moral and legal interpretations of drug use in the minds of the American public. The construction of drug use as a moral and legal problem would ultimately have a direct effect on the clinical treatment of drug addicts in the United States.

SUBSTANCE ABUSE TREATMENT PHILOSOPHIES IN THE UNITED STATES

In the United States, abstinence-based treatment protocols dominate the substance abuse treatment system. In most drug treatment programs, total abstinence is the only measure of success; anything less is regarded as a treatment failure. A proportion of this treatment philosophy can be attributed to the disease model of addiction. In the disease model, addiction is seen as a chronic, progressive, and potentially fatal illness (Sheehan & Owen, 1999). The addicted person is incapable of controlling or moderating his or her drug use. This disease is incurable; however, it may be arrested if an addicted person "totally abstains from any addictive substance" (Miller & Hester, 1995, p. 83). The abstinence-only philosophy is also the basis of the Twelve-Step recovery model of Alcoholics Anonymous, which permeates virtually every substance abuse treatment program in the United States (Doweiko, 2006).

Despite the popularity of the disease model within the substance abuse treatment community, it plays a relatively minor role in the social and political responses to substance abuse in the United States. It is a philosophy supported by some health care providers, most substance abuse treatment professionals, and many recovering alcoholics and drug addicts; however, outside of these circles, it does not have much credibility. As emphasized earlier, most Americans believe drug use to be immoral and criminal. However, rather than refute the credibility of the disease and Twelve-Step models, these conflicting interpreta-

tions of substance abuse actually complement each other when determining a clinical course of treatment for drug addicts. When deciding which treatment protocol is most appropriate for drug addicts, moral and legal interpretations of substance abuse also prescribe abstinence as the only acceptable treatment outcome. The relative influence of these interpretations is not only evident in the abstinence-only treatment philosophy; it defines a zero-tolerance mentality existent within many substance abuse treatment programs in the United States. Wide acceptance of the disease model would presume a greater tolerance toward drug use among substance abusers, particularly those whose illness has reached an advanced stage requiring formal treatment. However, the reality is that most inpatient and residential treatment programs have zero tolerance for any substance use during a treatment episode, often resulting in the expulsion of the patient from treatment. While this treatment of patients may be necessary to preserve the integrity of an abstinence-based treatment environment, it does little to help the patient who continues to suffer from an incurable illness. From a medical perspective, the abandonment of a patient with a chronic illness for relapsing seems highly unethical. In the United States, physicians tend to avoid this ethical dilemma because few physicians actually treat drug addiction. This can be attributed to a number of factors, including the repercussions of the Harrison Narcotic Act, the early institutionalization of drug use as a criminal justice problem, the stigmatization and avoidance of drug addicts as a patient population, the inadequate training and education of physicians in addiction medicine, and the apathy of the American medical establishment to aggressively pursue ownership of substance abuse as a social problem.

The moral and legal interpretations of drug use and addiction have not only encouraged an abstinence-only, zero-tolerance treatment model, they have discouraged the federal legislation and clinical adoption of any harm-reduction interventions in the United States; the one notable exception has been methadone maintenance treatment. Harm reduction is a public health philosophy that recognizes and accepts that substance use is going to occur in society; however, rather than punish drug use, harm reduction attempts to reduce and minimize the harmful consequences associated with substance use (Erickson & Butters, 1998). The aversion to a public health model/harm-reduction approach to substance use in the United States is a direct result of the social construction of early drug policy and the institutionalization of drug use as a criminal justice problem. The goals and objectives of a prohibition-criminalization paradigm run counter to the goals and objectives of a harm-reduction approach (Erickson & Butters, 1998). Antidrug policies founded on law enforcement and punishment are designed to reduce the number of drug users in a society rather than

minimize the harm associated with substance use (MacCoun & Reuter, 2001). In the United States, the resistance to harm-reduction strategies is so strong that most political representatives risk severe remonstration at the mere suggestion of reducing criminal penalties for drug use or providing an alternative to punishment when dealing with drug offenders. As an example, in 1993 the Surgeon General of the United States, Joycelyn Elders, made a suggestion at a public meeting that the U.S. government should study the impact that legalizing drugs would have on U.S. society (Labaton, 1993). Dr. Elders, the country's highest ranking medical officer, did not advocate the legalization of drugs; she merely suggested studying the problem. The fallout from this statement was quite significant, eliciting public and political outrage, as well as repudiation from President Clinton denying any intentions to legalize drugs. Dr. Elders's controversial opinions on drug policy (and later, public sex education) led to her dismissal one year later.

As mentioned above, one substance abuse treatment intervention that appears to contradict the American resistance to harm reduction is methadone maintenance treatment (MMT). MMT is an opioid substitution therapy intended to help heroin addicts avoid opioid withdrawal symptoms, engage in substance abuse treatment longer, and lead healthier and more productive lives (Graff & Ball, 1979; Senay, 1985). Methadone was first developed in Germany during World War II as a substitute painkiller to morphine (Zweben & Payte, 1995). The development of MMT as a substance abuse treatment in the United States was pioneered by Drs. Dole and Nyswander during the 1960s. This occurred primarily as a result of the disapproval among members of the American Bar Association and American Medical Association of the highly punitive antidrug measures legislated in the 1950s, as mentioned previously (Musto, 1999). While the U.S. Senate was reviewing the efficacy of federal drug legislation, the ABA and AMA commissioned their own joint committee to study the issue of narcotics addiction. In 1958, this joint committee issued its report recommending that an outpatient facility prescribing narcotics for the maintenance of heroin addicts be established on a controlled experimental basis (Belenko, 2000). This recommendation paved the way for Dole to receive a grant from the Health Research Council of New York City to establish a research unit to investigate the feasibility of methadone maintenance treatment (Joseph & Appel, 1993).

MMT was enthusiastically received by the Nixon administration (1969–1974) during a period of intense concern regarding a perceived heroin epidemic and consequent rise in drug-related crime (Musto, 1999). Maintenance was seen as the most economical and successful way to treat thousands of heroin addicts, effectively reducing both drug use and associated crime. Heroin addicts

were actively recruited into methadone maintenance programs (Rosenbaum, Murphy, & Beck, 1987). In the United States during the 1970s and 1980s, methadone-treated patients numbered over 75,000 (Ball et al., 1987). By the 1990s, the United States had over 750 outpatient methadone maintenance programs treating approximately 115,000 patients on any given day (Parrino, 1993). Currently, it is estimated that approximately 160,000 persons receive MMT services in the United States (Firoz & Carlson, 2004). Contrary to the image these figures may portray, MMT in the United States is not a popular program. Medically, MMT is considered a pharmacological intervention; however, among most substance abuse treatment professionals, it is considered simply substituting one addictive substance for another. Politically, MMT is seen as a way to reduce drug-related crime and increase employment among drug addicts. Some authors (Erickson & Butters, 1998; MacCoun & Reuter, 2001) have stated that, in the United States, there is much more concern with the dangerous behavioral consequences and drug-related harm inflicted on non–drug users, than with the health and welfare of those actually afflicted with substance use disorders. From this perspective, a more critical interpretation of MMT is that it is utilized as a means to keep drug addicts and their unhealthy behaviors away from middle- and upper-class society, rather than a necessary treatment for heroin addiction. This interpretation, albeit cynical, appears more consistent with the social and political responses to drug use and addiction throughout American history and as an explanation for MMT as a harm-reduction exception in the American substance abuse treatment formulary.

POLICY ALTERNATIVES

Unlike the United States, most countries have not chosen to deal with drug use and addiction from a strictly prohibitionist perspective. Many societies acknowledge and accept the reality that drug use occurs and that attempts to fully eliminate drug use through punitive measures are unrealistic. These societies have attempted to balance a criminal justice response to drug use with harm-reduction strategies, such as maintenance treatment, needle exchange, safe injection sites, and the decriminalization of small amounts of prohibited substances (MacCoun & Reuter, 2001; Mosher and Atkins, 2007). In the United States, the prohibition-criminalization paradigm has resulted in over 500,000 drug-related imprisonments; this represents approximately 25 percent of the U.S. prison population. At a federal level, over half of all U.S. federal prisoners (approximately 55%) are incarcerated for drug law violations (Bureau of Justice Statistics, 2007). Despite a legacy of punitive criminal justice and vigorous law enforcement, drug use and addiction remain a social problem in

the United States. America's resistance to accepting a public health model of substance use has perpetuated the U.S. government's continued promotion of a "war on drugs" agenda, focusing the majority of resources on supply-side drug policies. Most drug policy advocates and scholars agree that current drug policies in the United States have a limited effect on curtailing drug use and addiction and that some type of reform is necessary.

The most extreme proposals for drug policy reform in the United States come from proponents of drug legalization. Drug legalization advocates feel that legalizing all drugs would counteract problems of drug-related crime, criminal justice and law enforcement costs and corruption, and the limiting of personal liberties (Jonas, 1991; Mosher & Atkins, 2007; Nadelmann, 1991). Some also see potential tax and health benefits associated with the legalization and government regulation of illegal substances (Nadelmann, 1991). While this discourse is academically stimulating, it is unrealistic that the United States, or any other country for that matter, will ever seriously consider legalizing all drugs. Drug legalization rhetoric may actually serve to reinforce a prohibition-criminalization paradigm in what is predominantly an ideologically conservative American public. Furthermore, American social policy tends to change incrementally, rather than in revolutionary-type movements (DiNitto, 2007). This implies that any movement away from the current status quo and toward drug policy reform will require relatively small policymaking initiatives and advancements.

According to Peyrot (1984), because the criminal justice response to drug use and addiction was the first response to become institutionalized in the United States, it virtually secured its position as the preferred approach to dealing with drug use and addiction in American history, to the extent of precluding any subsequent responses from replacing it. As a result, clinical approaches predicated on a medical interpretation of addiction as an illness or disease have only built on the preexisting moral and legal interpretations of this problem. Any attempts by the medical or substance abuse treatment professions to supplant the criminal justice system as the primary institution for dealing with drug use and addiction in the United States have not been successful. The limited acceptance of the public health and disease models of addiction also limits the alternatives available when contemplating drug policy reform. While many scholars and clinicians would like to see a revolutionary paradigm shift from prohibition-criminalization to public health and harm reduction, realistic policy alternatives must be considered. According to Peyrot's theory, successful drug policy modifications or changes must consider the role of the criminal justice system, as well as its inclusion in collaborative strategies across treatment and service systems.

One current collaborative intervention in the United States that achieves this goal is the drug court movement. Through a process known as "therapeutic jurisprudence" (Rosenthal, 2002, p. 154), drug courts effectively integrate the values of both the criminal justice system and the substance abuse treatment community. The first drug court opened in the United States in 1989, and currently there are more than 2,000 in operation serving more than 120,000 clients (Huddleston, 2007). Drug courts are designed to provide nonviolent drug offenders with an intensive court-based treatment alternative to incarceration (Nolan, 2002). Ideologically, the criminal justice system regards mandated substance abuse treatment as a reduced form of punishment while the substance abuse treatment community sees it as a positive step away from incarceration and into a therapeutic situation. Expansion of the current U.S. drug court system is a policy alternative that serves the interests of the criminal justice system and substance abuse treatment community, as well as drug users and addicts.

Expansion of substance abuse treatment services within the criminal justice system would also fit Peyrot's (1984) prescription. While some substance abuse treatment services already exist within the U.S. prison system, an expansion of services for nonviolent drug offenders both incarcerated and re-entering society would be a progressive step. Another policy issue that affects low-income drug offenders transitioning out of prison is their ineligibility for social welfare benefits. In 1996, as part of a national movement toward welfare reform, the U.S. government passed legislation denying public assistance (i.e., income maintenance benefits and food stamps) to any persons convicted of a drug felony (Personal Responsibility and Work Opportunity Reconciliation Act, 1996). This has had a particularly detrimental effect on low-income women transitioning back to their communities, as well as their children and families (Allard, 2002). A progressive policy alternative could have the public assistance eligibility status of nonviolent drug offenders reinstated upon completion of a substance abuse treatment program in prison. Another option that institutes the criminal justice system as the arbiter of substance abuse treatment services is to construct prison facilities exclusively for nonviolent substance abusers dedicated to rehabilitation rather than incarceration of drug users and addicts.

While these policy alternatives including the criminal justice system are far from optimal for most American drug policy reformers, they do represent options that may be politically salient to a bipartisan U.S. Congress. A more traditional harm-reduction policy that appears feasible in the United States is needle (or syringe) exchange. Currently, nearly every U.S. state has some type of needle exchange policy and program; however, the federal government has refused to pass any legislation or fund any programs supporting needle

exchange (Ip, 2007; MacCoun & Reuter, 2001). A consequence of this is that the U.S. government communicates to the American people that intravenous drug users and people with HIV/AIDS are not worthy of federal assistance, essentially perpetuating the stigmatization of these groups. Hopefully, unanimity at a state level will eventually have a positive influence on federal policymaking decisions.

Finally, if Americans want to take a significant first step toward reforming the current prohibition-criminalization paradigm and instituting a public health model of substance use they should at least consider examining the decriminalization (or depenalization; MacCoun & Reuter, 2001) of small amounts of marijuana. By decriminalizing small amounts of marijuana (e.g., half an ounce; 14 grams), drug users and addicts would not be subject to criminal justice penalties for the personal use of marijuana. This would not legalize marijuana use, nor relieve marijuana traffickers from arrest, prosecution, and incarceration. It would redefine personal marijuana use as an unhealthy behavior rather than a criminal act. In the United States, marijuana use accounts for 75 percent of all illegal drug use (Substance Abuse and Mental Health Services Administration, 2007). Decriminalizing small amounts of marijuana would lower criminal justice and law enforcement costs, as well as reduce perceptions among some Americans of the government's intrusiveness into personal liberties (MacCoun & Reuter, 2001). Furthermore, according to MacCoun and Reuter, depenalizing the possession of small amounts of marijuana would not increase marijuana use in U.S. society.

CONCLUSION

The statement by law historian Rufus King that opened this chapter was made in 1953 during a period of heightened punitive U.S. policymaking against drug users and addicts. His position implies that the prohibition-criminalization paradigm instituted in the United States was a mistake. Through antidrug policies, such as the Harrison Narcotic Act, Marijuana Tax Act, Boggs Act, and Narcotic Control Act, American policymakers effectively removed the care of drug users and addicts from the medical establishment and institutionalized drug use and addiction as criminal justice problems. This also served to construct drug users and addicts as criminals in the minds of the American people. If Americans are ever to change from moral and legal interpretations of drug use to a public health perspective, it must be preceded by a perceptual conversion among members of mainstream society to view drug users and addicts as useful and productive people rather than malcontents and deviants (Erickson & Butters, 1998). In the mean time, policy alternatives that integrate the

criminal justice system with helping professions (e.g., substance abuse treatment, medicine, and social welfare) may prove to be the most effective in transcending social and political proscriptions toward American drug users and addicts.

Chapter **2**

The Philosophy of Denial in Alcohol Studies: Implications for Research

Lorraine T. Midanik, PhD

In documentation and discussions of the development of the disease model of alcoholism, and most specifically Alcoholics Anonymous (AA), Al-Anon, and Adult Children of Alcoholics (ACA)/Codependency, very little has been written about how *denial* as a phenomenon came to be the central tenet of the disease ideology. Interestingly, *denial* was never originally mentioned in the Big Book of AA nor was it listed as a specific symptom or even part of a symptom in Jellinek's early work that became the scientific underpinning of the disease model (Jellinek, 1946, 1947, 1952). However, as argued by Kurtz (1979) denial was always an assumption underlying the identification and definition of alcoholism by AA.

> Denial, after all, had been earmarked by Alcoholics Anonymous to be the characteristic symptom and deep core of alcoholism. The clever use of language in service to denial has throughout history subverted true communication and so fostered alienation and the separations of mistrust. (p. 193)

Even though the relationship between denial and alcoholism is not explicit in early work in the alcoholism field, there is a strong connection between the two concepts. Yet, without it specifically being mentioned, this begs the question of why and how denial emerged in the alcohol field and also why it has retained its prominence and legitimacy over time.

Sometimes when two concepts are closely associated, such as alcoholism and denial, they begin to be viewed as universal truths. This phenomenon was discussed by Dwight Heath in his forward to Kai Pernanen's book titled *Alcohol*

in Human Violence (Pernanen, 1991). Heath points out that within specific social contexts, we tend to make linkages between words (in this case, alcohol and violence) that come to be known as common truths and over time are mistakenly taken to somehow represent reality. Pernanen's (1991) book focuses on multiple conceptualizations of the relationship between alcohol use and human violence, which serves to counteract partially the prevailing causative paradigm and to investigate more thoroughly the rather complex and intricate linkages between the two areas.

Alcoholism and denial—or more specifically the common notion that alcoholics or heavier drinkers often and predictably deny the extent of their use of alcohol, their subsequent alcohol-related problems, and their alcoholism per se—can be seen as another example of a somewhat universally accepted truth that, to some clinicians and researchers, does not necessarily require empirical verification. This assumption of denial based on a disease definition of alcoholism (the predominant model in the alcohol field) affects not only the ways in which studies of alcoholics or alcohol use are conducted but also the stance taken by researchers regarding self-report validity issues and the methods they select to demonstrate validity (Midanik, 1989).

There are two bumper stickers that have been prominent in the San Francisco Bay Area (in California, United States) for some time; both reflect not only the rebelliousness of the residents of this geographic area but also speak to the problem of unquestioned dominant paradigms. The first one, "Subvert the Dominant Paradigm," takes a social action perspective and implies a nonacceptance of the status quo by recommending that we overthrow it and replace it perhaps with one of our own. The second one merely says "I Survived the Dominant Paradigm," thus emphasizing the resiliency of some individuals to continue on with their lives despite nonacceptance of the predominant world view. Regardless of whether one subverts or survives the paradigm, it is first important to examine the assumptions behind each perspective, to question its dominance, and to explore alternative views that can only serve to understand better the phenomenon we choose to study. The predominant view in the alcohol field is the disease model, which includes this assumption of denial. In fact, the concept of denial has become so popular in the recent decade that it is not unusual to hear someone use the phrase "I'm in denial" as a way to apologize for not remembering some significant event or person.

The purpose of this chapter is to explore the concept of denial in more depth. It will be argued that denial, a very specific and extremely important cornerstone of the disease model, has permeated more than the clinical work for which it was originally intended. First, we will discuss the larger issue of truth telling and provide a context in which denial is one component. Second, we will

look historically at how denial as a defense mechanism has been defined over time. Then we will explore how this concept became part of the disease model of alcoholism and has been adopted by other Twelve-Step movements as well as the general field of alcohol studies, and how denial is infused in treatment, treatment evaluation, and prevention studies. We will discuss the political aspects of using denial in the alcohol field and assess how denial as an explanation for behavior has been a central force in the research world, particularly methodological work, in terms of how measurement issues are conceptualized and assessed by researchers. Finally, we will argue that belief in this philosophy of denial has compromised much methodological research in the alcohol field by researchers who have vested interests in the outcome, that is, that self-reports of alcohol use and alcohol problems are valid or not.

TRUTH TELLING, LYING, AND DECEPTION

Perhaps a good place to begin our assessment of what factors contribute to the importance of truth telling in research at different historical times is to consider how the alternatives, namely lying and deception, are viewed in our society and how they relate to denial. By taking a broader perspective, we can start to place denial and its effect on research and treatment in the context of larger philosophical issues around how lying is handled on a daily basis in our society.

It has been argued fervently that denial is a way of life that permeates individual lives by allowing traumatic events to be handled more effectively so that individuals can continue their lives in the least disruptive way. Political psychologists connect denial experienced by individuals as a result of early childhood and the interaction of children with their parents. During this time, avoidance of painful experiences serves a fundamental protective function that unfortunately may keep an individual in a fantasy world, unable, or unwilling, to face reality (Milburn & Conrad, 1996).

Beyond denial, there is the overall issue of lying and its pervasiveness in everyday life. Consider the following paragraphs from Sissela Bok's book entitled *Lying: Moral Choice in Public and Private Life* (Bok, 1978).

> Should physicians lie to dying patients so as to delay the fear and anxiety which the truth might bring them? Should professors exaggerate the excellence of their students on recommendations in order to give them a better chance in a tight job market? Should parents conceal from children the fact that they were adopted? Should social scientists send investigators masquerading as patients to physicians in order to learn about racial and sexual biases in diagnosis and treatment? Should government lawyers lie to Congressmen who might otherwise oppose a

> much-needed welfare bill? And should journalists lie to those from whom they seek information in order to expose corruption?
>
> We sense differences among such choices; but whether to lie, equivocate, be silent, or tell the truth in any given situation is often a hard decision. Hard because duplicity can take so many forms, be present to such different degrees, and have such different purposes and results. Hard also because we know how questions of truth and lying inevitably pervade all that is said or left unspoken within our families, our communities, our working relationships. Lines seem most difficult to draw, and a consistent policy out of reach. (pp. xv–xvi)

As children we are often told to be truthful; it is a value, an ethic, of our culture. We hear witnesses in courtrooms agreeing to "tell the whole truth and nothing but the truth." And, children are often told the story of George Washington who, despite possible negative consequences, confessed to chopping down a cherry tree (Saarni & Lewis, 1993). Yet, as noted in the preceding Bok quote, the line between telling the truth and lying is a difficult, if not impossible, one to draw. Despite this difficulty and the messages that we receive daily to the contrary, we somehow tend to operate under the assumption that the truth is both achievable and desirable in all situations.

Several books have been written about lying and deception from both a philosophical position (Fingarette, 1969, 1988) and a psychological perspective (Ekman, 1992; Ford, 1996; Lewis & Saarni, 1993). Despite the different perspectives represented by the authors writing in this area, they overwhelmingly agree that lying is pervasive in our society. Ford (1996) cites a U.S. poll from which 90 percent of the respondents claimed that they were deceitful. Their lies, in order of frequency, were about their true feelings, income, accomplishments, sex life, and age (Patterson & Kim, 1991). While Saarni and Lewis (1993) agree that it is commonplace in our society to lie, they ask the larger question of what contributes to this behavior within our culture. Factors, situational and individual, that foster lying and deception on an everyday basis are important to consider when assessing why these behaviors occur.

Regardless of whether deception is toward others or oneself, or whether there is or is not awareness of the deception, lying is very commonplace in our society. To demonstrate the pervasiveness of lying in our society, Ford (1996) compiled a list of 25 verbs, 21 nouns, and 5 adjectives that connote deceit. What is striking about this list is the multiple levels of deceit that are represented. Ford (1996) argues that the word "lying" is laden with emotion; thus, we need softer words, euphemisms, to describe different levels of the same phenomenon. Given the diverse terminology used to label deceit, how can one define the entire range of behaviors associated with telling lies?

It is simplistic to define lying as the opposite of truth. This assumes that proof, however defined, of the falsity of what is said or written constitutes a lie. Rather, Bok (1978) argues that it is the *intention to mislead* that differentiates a lie from an untruth. Establishing intent is often a very difficult if not impossible task, thus the demarcation between the two is perplexing and exceedingly complex. Lying is also a complicated subject to discuss because of the *gradations* involved. We tend to categorize the seriousness of lies based on the consequences or potential consequences of these actions. Thus, an individual who lies in court about committing a serious crime is judged much more harshly than someone who lies about his or her educational background on a job application. How we choose to define and clarify the gradations of lies has potentially important consequences on a societal level as well as on an individual level.

Bok (1978) also makes a distinction between different types of lying that include white lies and excuses. She contends that lying in ubiquitous; we lie when we overstate an individual's ability in a letter of recommendation, and we, as researchers, lie when we provide placebos in experiments. Yet while we defend some of these lies as harmless (hence, white lies), they are still intentional falsehoods despite the fact that we do not intend to hurt anyone in the process.

Perhaps equally important is the perception of individuals who think that someone is lying to them, and who can become resentful and disappointed because they feel manipulated. Moreover, they may perceive a shift of power to the perceived liar, which would be particularly problematic to deceived individuals who were originally in more powerful positions.

Saarni and Lewis (1993) provide a taxonomy of lying that is built on two dimensions: first, deception toward another person or toward oneself; and, second, whether the individual is aware or unaware of the deception. Based on these dimensions, Saarni and Lewis define three types of deception: (1) ordinary deception toward others committed with self-awareness; (2) deception toward others that requires some degree of self-deception; and (3) self-deception even in the absence of another, that is, the need for illusion.

The first type of deception, lying with self-awareness, most commonly occurs as a way to avoid retribution of others for behaving or not behaving in a particular way. The person committing the deception knows what is expected, knows what others expect, and chooses to lie as a way to avoid some type of punishment or anger. If this deception is disclosed, the recipients are offended for two reasons: failure to do what was expected as well as breach of trust. Saarni and Lewis (1993) also contend that these kinds of lies can be adaptive. For example, a person may well know that driving after drinking can increase

one's risk of a traffic accident. Yet when asked by a significant other if he or she had been driving after consuming alcohol, the response may be negative in order to avoid any arguments or reprisals.

The second type of deception involves deceiving others but being unaware or at least partially unaware of doing this (some self-deception). This is a more complicated type of deception given that the degree of self-deception is difficult to determine. Saarni and Lewis (1993) give an example of a man who tells his wife that he has not had an extramarital affair when in fact he has had an ongoing relationship with another woman. While he is very aware of his deception, he convinces himself that his failure to be honest with his wife is for her own good—it would hurt her.

The third type of deception, self-delusion, allows individuals to avoid bad or negative feelings about themselves and provides an alternative to the psychic costs of shame, humiliation, or embarrassment. Thus, losing one's job because of continued absences due to prolonged drinking bouts may be too difficult for an individual to acknowledge. It may be easier to create the illusion that the commute was too long, the supervisor was not fair, or the work was boring as better reasons that do not require that individuals lower their self-esteem. Interestingly, Saarni and Lewis (1993) speak to the advantages of self-delusion and argue that

> There is no question that self-deception—the creation of illusions, "looking at the world through rose-colored spectacles" has its advantages. Because of this, we cannot readily accept the idea that all forms of self-deception or other similar psychic phenomena like denial or forgetting are necessarily maladaptive. (p. 13)

Truth Telling and Research

The previous discussion is not intended to cover the entire field of philosophy of truth telling, lying, and deception but rather to address areas typically not discussed in these works. That is, the intent is to provide a brief background in this area so that methodological research aimed at determining who provides and who does not provide accurate information can be integrated within the larger context of truth telling across situations and environments in our society.

Connections previously made between lying and research have focused primarily on two distinct and important areas: research fraud and deceptive social research. In writing about research fraud, seminal books have been published that describe in detail the work of scientists, some of them quite famous, who created their data, consciously and overtly misinterpreted their data, or stole their data in order to become well-known in their respective fields (Broad &

Wade, 1982; Gould, 1981). These works contain fascinating accounts of the extent to which a few researchers will go to achieve fame at the possible expense of their reputations and academic positions. However, the focus is on researchers and what they chose to do or not do about their research and subsequent publications. The approach here is quite different. It is not on fraud committed by researchers per se, but rather on the research process itself and the difficulties of obtaining valid information directly from human subjects. Within this context, I ask the larger question of how the broader frameworks of lying and truth telling affect methodological research focused on the veracity of subjects' reports.

Like research fraud, much has been written about the conduct of social research projects that incorporate deceptive means to obtain data from participants. Deception in these instances ranges from lying or overtly misleading subjects about the actual purpose of the study to deluding mental health facilities about the condition of inpatients—for example, pseudo-patient studies (e.g., Rosenhan, 1973). While there are many cases of deceptive research, the classic examples in the United States that eventually led to the National Research Act of 1974, which requires national guidelines for the protection of human subjects, include the Tuskegee Syphilis Experiment (Jones, 1993) and the Obedience to Authority studies of Stanley Milgram (Milgram, 1974). In the former study, begun in 1932, the focus was on studying the natural history of syphilis in a population of very poor, rural, black males who had the disease. Throughout the 50-year-long study, the subjects were told that they were receiving treatment when they were, in fact, being given medical tests, some of which were quite painful (e.g., spinal taps), and when penicillin became the treatment of choice during the 1940s, this was withheld from the study population. The Obedience to Authority study also used deception in determining how far research subjects would go to obey orders by someone who appeared to have authority over them. Milgram found that with ample prodding, most research subjects would administer what they believed to be lethal shocks to unknown recipients if told to do so by someone who was perceived to be in authority. In both studies, the focus is on the lack of truth telling (or deception) of researchers in the recruitment of their subjects and in the conduct of their studies, particularly in terms of their safety and protection. Veracity of the subjects' reports or behaviors is clearly not the focus.

In the alcohol field, truth telling and research typically focuses on the validity of self-reports of respondents. Misreporting of alcohol consumption and alcohol problems is often viewed as lying—intentional misrepresentations of the truth because of denial. We assume that either individuals cannot admit, or refuse to admit, the problem or problems to themselves (denial) or that they

refuse to admit these problems to the researcher (denial or social desirability issues) or both.

Not only do we explain misreporting by these constructs, but there is also an implicit expectation that misreporting will occur given that denial is an integral component of the disease model. This self-fulfilling prophecy leads us to develop new and better ways to either help the individual overcome or break through denial, or find other, perhaps more clever, ways to get the truth, since it may not be readily available when conventional approaches are used. The results of the misreporting, termed "lies," is frustration and anger within certain research communities and ultimately a general mistrust and skepticism of all self-reported behavior.

The irony in this argument is that our expectations seem unrealistic in light of the world, specifically the research world in the social sciences in which we live and operate. If lying is so pervasive, why are we so surprised when we suspect under- or overreporting during the research process? Given the preceding discussion, it is somewhat difficult to believe that as researchers we are so astounded when we find that subjects' answers to questions do not either match our expectations or, more importantly, are not the same as responses obtained from other sources such as official records or collateral reports.

HISTORICAL LOOK AT DENIAL

To understand the definition of denial and how it differs from other untruths, it is first important to examine closely how it was formulated. This section will briefly review definitions of denial from a psychoanalytic perspective to provide a background for ways in which it has permeated the alcohol field.

Psychiatric definitions of denial refer to both the processes used by the individual who is denying and more specifically to what is or can be denied (internal or external states). Further, denial is placed under the larger umbrella of defense mechanisms, which are defined as "psychological strategies by which persons reduce or avoid negative states such as conflict, frustration, anxiety, and stress" (Holmes, 1984, p. 347). Beginning with Freud in 1894 (Slap, 1977), the concept of defense mechanisms began appearing in the literature as a basic defining principle of hysterical phenomena. By 1926, Freud argued for some categorization of defense mechanisms, which he believed may specifically be associated with certain forms of psychiatric illnesses (Laplanche & Pontalis, 1973). He further emphasized the importance of studying mechanisms of defense because they were the foundation on which psychoanalysis was built (S. Freud, 1914a, 1914b). Freud saw defense mechanisms as the key to interpreting conflict and hence central to the psychoanalytic understanding of neu-

rotic and psychotic patients. However, it was Anna Freud who defined denial in more depth and broadened its meaning to include its positive role particularly for children, whose options for handling problematic and potentially dangerous situations are more limited (A. Freud, 1946).

Specific defense mechanisms discussed by Freud and others include denial, repression, suppression, projection, displacement, regression, identification, compensation, reaction formation, sublimation, rationalization, and intellectualization. While a thorough discussion of these defense mechanisms goes beyond the scope of this chapter, it is important to recognize that defense mechanisms have three common characteristics. First, all of them are used to reduce or totally avoid negative emotional states such as anxiety or conflict. Second, when used, they distort reality, and third, individuals who use defense mechanisms are not consciously aware that they are using them (Holmes, 1984).

Definitions of denial vary somewhat by their specificity or lack of it. Originally termed scotomatization by Freud (Hinshelwood, 1989), denial is generally defined as one strategy to reduce or avoid negative states by not focusing on the threat-provoking aspects of a situation and by reinterpreting or reframing the situation so as to render it is less threatening. Other terms used for denial include redefinition and reappraisal (Holmes, 1984). There is some confusion over whether Freud originally intended denial to refer only to a defense against the claims of external reality, given that repression is a defense mechanism that applies to defending against internal issues such as instinctual demands or ideas (Eidelberg, 1968). However, it is generally agreed that denial includes selective attending to some aspect of reality in which "the ego refuses to become aware of an unpleasant or unwanted aspect of reality; in some instances the facts are accepted but their significance is denied" (Slap, 1977, p. 28).

If denial is being used as a defense mechanism because the patient is reinterpreting a threatening situation to a less threatening one, then it is assumed that one purpose of treatment would be to invoke reality into the patient's consciousness. From a psychoanalytic perspective this would involve locating the unresolved conflict and moving that conflict, or parts of that conflict that are unacknowledged, from the unconscious to the conscious in a safe environment—presumably treatment.

There are two major issues that arise when trying to translate and apply psychoanalytic definitions of denial to nonpsychoanalytic situations. The first issue is that denial as well as other mechanisms of defense are commonly used by most people since it is presumed that human beings strive to reduce negative or anxiety-provoking states (Holmes, 1984). Because use of defense mecha-

nisms is so ubiquitous in the general population, it is more difficult to differentiate pathology from normalcy. The question then becomes, at what point does denial become problematic? Given its pervasiveness, one would assume that problematic (or pathological) denial is a matter of degree but when and how this line gets drawn is unclear. Second, because psychoanalysts are writing from their clinical perspectives, they describe pathological denial as patients' refusal to look at significant and major aspects of their own lives. However, in less extreme cases (when denial is presumed to be used), it is important to keep in mind who is applying this label to whom. To the extent that denial is the label used to explain individuals whose realities differ from others, it is important to look at the vested interests of the individuals involved, the relative power between them, and the possible gain of specific individuals when the label of denial is applied (Brissett, 1988).

DENIAL IN THE ALCOHOL FIELD

The previous section provided a brief psychoanalytic history of denial and its application in the field of psychiatry. Because that section was not meant to describe the vast array of defense mechanisms and other intrapsychic phenomena included in psychiatric diagnosis and treatment, the attention to denial can be misleading. It is one of several concepts in the realm of psychiatric and psychological tradition. However, in the alcoholism literature, denial is a key component of identification, treatment, and recovery of the alcoholic (Brissett, 1988). The emersion of denial in the alcohol field will be traced in this section in terms of four interrelated and overlapping forces: AA, Al-Anon, the ACA/Codependency Movement, and the development of Employee Assistance Programs (EAPs).

Alcoholics Anonymous and Denial

While denial as a formal construct was not a part of the early alcohol literature until it was implicitly included in the formal development of AA, T. D. Crothers, in his treatise on the symptoms of inebriety, discussed it broadly as "egotism" as early as 1911:

> In many instances the most ingenious reasons are given to confirm and sustain his confidence in their reality, and no pressure or advice by friends can make any impression or indicate the real character of his mental condition. Persons with good judgment on all other matters will have the most delusional impression of their own conditions, and assert with great confidence that outside influences and undue anxiety and annoyance by friends are active causes of his present stage. This peculiar egotism is a species of general paralysis, particularly of the

> high brain centers. It literally means a progressive anesthesia of certain areas of the brain with unconsciousness of the real condition. (Crothers, 1911, p. 56)

Despite this claim of "progressive anesthesia" caused by excessive alcohol use, it is not until Jellinek's studies beginning in the mid 1940s that we begin to see some references to how deception may be part of the disease concept of alcoholism. Jellinek's *Grapevine Study* and subsequent research resulted in the delineation of four phases of alcohol addiction based on 43 symptoms (Jellinek, 1952). Within this categorization, Jellinek did not formally place denial as a separate symptom in his array of progressive symptoms. However, its existence is subsumed under symptom 9, "rationalization of drinking behavior" in the crucial phase, which Jellinek describes as follows:

> he produces the well-known alcoholic "alibis." He finds explanations which convince him that he did not lose control, but that he had a good reason to get intoxicated and that in the absence of such reasons he is able to handle alcohol as well as anybody else. These rationalizations are needed primarily for himself and only secondarily for his family and associates. The rationalizations make it possible for him to continue with his drinking, and this is of the greatest importance to him as he knows no alternative for handling his problems. (Jellinek, 1952, p. 680)

This concept of rationalization comes up again as the final symptom (43) in the chronic phase. It is commonly referred to as the breakdown of the rationalization system developed throughout the stages of alcoholism to justify one's behavior. This is an extremely important phase in Jellinek's nosology as it defines the process of "hitting bottom," the only point at which alcoholics can be able to receive the help they need. "Hitting bottom" is described as the point where

> the rationalizations become so frequently and so mercilessly tested against reality that the entire *rationalization system fails* (43) and the addict admits defeat. He now becomes spontaneously accessible to treatment. Nevertheless, his obsessive drinking continues as he does not see a way out. (Jellinek, 1952, p. 683, italics in the original)

Other researchers have differed with respect to where denial fits into the phases of addiction. Paredes (1974) argues that denial and "deceptive maneuvers" are more important in the early stages of alcoholism when the individual's family, work, and place in the community are still reasonably intact. While acknowledging that denial is involved throughout the course of alcoholism, Amodeo and Liftik (1990) see rejection of a diagnosis as its most common form and of particular importance in the middle stage of alcoholism. They outline three types of denial exemplified in the following statements:

> [T]here's nothing wrong with the way I drink . . . OK, so I drink. But I don't have a problem with it . . . If my drinking gets out of hand sometimes, it never leads to any big problem. (p. 132)

Curiously, as stated earlier, denial was never formally acknowledged as a key concept in the disease model. This may have been because the early founders of AA fervently worked to separate their fellowship from the influence of professionals in psychiatry or psychology. This was evident in the AA literature and in its descriptions of how alcoholism develops and the specific stages that one must pass through to "hit bottom" and hopefully move on to the recovery process.

In the third edition of *Alcoholics Anonymous: The Story of How Many Thousands of Men and Women Have Recovered from Alcoholism* (AA, 1976), the 44 personal stories are divided into three sections: (1) "Pioneers of A.A." (12 stories of men and women who entered AA in the late 1930s and 1940s); (2) "They Stopped in Time" (17 stories representing members who more recently joined AA); and (3) "They Lost Nearly All" (13 stories reflecting AA's changing demographics). In this edition, as in an earlier one published in 1955, changes were made to these stories to "represent the current membership of Alcoholics Anonymous more accurately, and thereby to reach more alcoholics" (AA, 1976, p. xii). Yet, while not explicitly discussed, denial as a concept is implied throughout the stories in this volume, which, of course, fits the sequencing of historical events recounted by the authors before the discovery that they were alcoholics. Examples of "implicit denial" include the following:

> I didn't think I was an alcoholic. I thought my problem was that I had been married to a drunk for twenty-seven years. And when my husband found A.A., I came to the second meeting with him. I thought it was wonderful, simply marvelous, for him. But not for me. Then I went to another meeting, and I still thought it was wonderful-for him, but not for me. (AA, 1976, p. 321)

> The only importance in all of this lies in the fact that at twenty-three I was just as sick as I was at thirty-three, when I came into A.A., but at that time I apparently had no place to go because I had no drinking problem. . . . I'm sure they could not have convinced me my sickness was within myself, nor could they have shown me the need for self-analysis that A.A. has shown me is vital if I am to survive. So I had no place to go. Or so it seemed to me. (AA, 1976, p. 546)

Al-Anon and Denial

Beyond the stages of the disease model and its clinical application, Al-Anon also is a formidable force that has integrated denial as both a necessary key element and sufficient condition for achieving membership in this group. In 1969,

Al-Anon Family Group Headquarters printed a pamphlet titled *Alcoholism: A Merry-Go-Round Named DENIAL* taken from a speech delivered by Reverend Joseph Kellermann at the Second Annual Workshop of the Connecticut Al-Anon Groups in Milford, Connecticut (Kellermann, 1969). In this pamphlet, Rev. Kellermann presents alcoholism as a tragic three-act play with four characters: the alcoholic, the enabler, the victim, and the provoker. The pivotal component of this play is denial manifested by the alcoholic in at least two forms. First, Kellermann contends that alcoholics are basically immature and dependent, yet "he may act in an independent way in order to *deny* this fact" (p. 2, italics in original). Second, alcoholics deny any responsibility for the results of their drinking behavior. Further, alcoholics hide the amount of drinking they do and repeatedly deny how important alcohol has become in their lives.

Beyond the many ways that alcoholics deny, Kellermann moves from the alcoholic to the enabler role to further elucidate the powerful effects of denial. An enabler is defined as a person who rescues alcoholics from their predicaments (a role that also includes the so-called helping professions). In the early literature (as in this pamphlet), the role of the enabler and the provoker (referring to the spouse) can be separate roles. Later literature combines these roles so that the spouse becomes the person who not only rescues the spouse but also harbors bitterness and resentment toward the alcoholic, which exacerbates an already troubled marriage. In his pamphlet, Kellermann makes the claim that the individual in the enabler role "denies the alcoholic the process of learning *by correcting his own mistakes*" (p. 5, italics in original). Thus, enablers are active participants in the denial process.

One of the most interesting parts of this pamphlet is Kellermann's misuse of the term "denial." Whereas defense mechanisms are clearly defined as occurring on a subconscious level beyond awareness, Kellermann argues explicitly that "The real problem is that the alcoholic is well aware of the truth which he so strongly denies" (p. 7). Thus, denial, as defined in this literature as well as in other alcohol literature, is a conscious process that is the central core of the disease process—"The key word in alcoholism is '*Denial*'" (p. 3, italics in original). This is also reflected in other Al-Anon literature. In a content analysis of Al-Anon stories published in two editions of *Al-Anon Faces Alcoholism* (Al-Anon, 1965, 1985), denial was directly referred to in a story that was included in the 1985 edition but not in the previous edition (Martin, 1992).

Adult Children of Alcoholics (ACA)/Codependency and Denial

In reviewing the linkages between the Twelve-Step movements and denial, there is clearly a progression from implicit to explicit use of the term. The lit-

erature in AA never quite uses the term "denial" but clearly describes such psychological processes as part of its disease symptomatology. Al-Anon takes this one step further and includes denial in some of its literature. As a self-help organization, Al-Anon does not seem opposed to using the concept of denial as an explanation of the behavior and psychological processes of a significant other who needs to be enlightened. The ACA/Codependency movement is at the other end of the continuum. Denial is an important and highlighted component of codependency. The term is readily used and acknowledged.

Cermak (1986) proposed *DSM-III* criteria defining "codependent" as a type of personality disorder. With one exception, Cermak's criteria for codependent personality disorder lacks any timeframe references; it also fails to specify how many times a specific behavior needed to occur before a diagnosis is justifiable. The first of his "E" criteria is the "excessive reliance on denial." To be diagnosed as codependent, three or more of the "E" criteria need to be met; thus, a person does not have to excessively rely on denial to be a codependent. Yet Cermak (1986), in his description of these specific criteria, argues that the similarity between the denial experienced by codependents of their codependency is exactly the same as the denial experienced by the person who is chemically dependent. He further maintains that

> Denial may be seen as an impaired strategy for achieving security. In the face of a threat, narrowing one's awareness can create the appearance of safety. . . . For active chemical and co-dependents, however, denial continues to give the false impression of security. It is rarely acknowledged and relinquished until the pain and emptiness of their ever narrower and more isolated life becomes too much to bear. (p. 22–23)

In a later book that focused on recovery for ACAs, Cermak (1988) devotes an entire chapter to denial titled "A Time to See: Pulling Down the Walls of Denial." Within this chapter, Cermak outlines the warning signs of denial by three levels: level I—denying your parents' alcoholism; level II—denying the effect of parental alcoholism; and level III—excessive use of willpower (while acknowledging parental alcoholism and its effects). What becomes quite clear in Cermak's descriptions of all three levels is that unless the ACAs/Codependents admit to some level of pathology (as defined by Cermak), they are experiencing some level of denial. It is not just any awareness that is the opposite of denial, but it is a well-specified awareness defined by the professionals in the field.

This literature, with its emphasis on becoming aware of the symptoms of codependency in order to begin the recovery process, has also been criticized by several researchers. Asher and Brissett (1988) contend that the spouses of alcoholics (primarily women) get labeled as codependents based on their

"retrospective reinterpretation of their lives with their alcoholic husbands, guided and legitimated by rehabilitation personnel" (p. 331). Taking a social constructionist approach, Asher and Brissett (1988) further argue that this labeling process has served to render these women's identities as deviant and thus medicalize their so-called condition. Thus, the enabler role, described and popularized by the Al-Anon movement, has further evolved and medicalized to the term "codependent" that now, like alcoholism, appears to be an objective medical condition with a legitimate diagnosis. Another perspective would be to view this behavior as one of several in a repertoire of coping behaviors for these women. However, this approach pathologizes these women by rendering them "sick."

Employee Assistance Programs (EAPs) and Denial

In his 1952 article in which he definitively outlines the four key phases of alcohol addition, Jellinek made a critical comment in his discussion of the 43rd and final symptom of alcoholism. As discussed earlier, he contends that the alcoholic must have a failure of her rationalization system during which she can no longer hide from reality and must admit defeat. This phenomenon of "hitting bottom" was interpreted as being the most crucial step in order to begin the recovery process. Yet in Jellinek's discussion of this symptom, he opens the door for other strategies.

> Formerly, it was thought that the addict must reach this stage of utter defeat in order to be treated successfully. Clinical experience has shown, however, that this "defeat" can be induced long before it would occur of itself and that even incipient alcoholism can be intercepted. As the latter can be easily recognized it is possible to tackle the problem from the preventive angle. (Jellinek, 1952, p. 683)

This recognition that the treatment process can begin without "hitting bottom" (or what is sometimes called "raising the bottom") became the rationale for different types of treatment approaches that included court-referral treatment programs and EAPs (Weisner & Room, 1984). The main goal of this approach was early case finding: the idea that some group or institution could actively seek out clients and, through strong persuasion (coercion) tactics, convince them to choose treatment as opposed to another alternative that was much less desirable (e.g., jail or unemployment). The foundation for this approach was the idea that the denial system of the alcoholic was permeable even at earlier stages. Programs found ways to codify their expertise in breaking through this denial and used as their primary strategy a technique called constructive confrontation that is also sometimes called intervention or confrontation.

The rationale for using such a strategy as constructive confrontation at an earlier stage of alcoholism lies in expanding the definition of an alcohol-related problem beyond the individual to a workplace issue (Trice & Roman, 1972). "The basic assumptions of constructive confrontation are that alcohol and drugs have no place in work organizations and that work organizations may legitimately expect unimpaired performances from their employees" (Trice & Roman, 1972, p. 174). Essentially, Trice and Sonnenstuhl (1988) argue that this process borrows from the anthropological literature on studies of drinking within different subcultures in which alcohol-related problems are rare. These studies point to the strength of these cultures to exert strong social controls over their members whenever drinking begins to interfere with role obligations. Thus, constructive confrontation can be defined as a management tool, or creation of a management culture, to maintain strong control over its employees by finding mechanisms to change their behavior (use of alcohol or drugs) if it affects their work performance.

Trice and Sonnenstuhl (1988) define constructive confrontation as a two-part process. The constructive aspect involves discussions that emphasize support and concern about the welfare of the employee, encourage the employee to conform to the workplace standards and policies so that group membership is not jeopardized, and provide concrete suggestions concerning how the employee can achieve a good performance record again. The confrontation part of the process reminds the employee of the work performance standards, informs the employee that if the standards are not met, some type of disciplinary action or sanction will be taken, and "establishes some social distance between the deviant employee and those group members who are meeting expectations" (p. 160).

While this approach has its roots in EAPs (and earlier occupational alcoholism programs) its ability to break through denial has also been utilized by more conventional treatment programs to recruit clients at an earlier stage of alcoholism. This is exemplified in Vernon Johnson's book (1973) titled *I'll Quit Tomorrow*. Johnson referred to the then new strategy to get alcoholics into treatment called "confrontation," which could purportedly break through an assumed denial system and allow the alcoholic to recover. The basic assumption behind this technique was that "even at his sickest, the chemically dependent person can accept reality *if it is presented to him in a receivable form*" (Johnson, 1973, p. 49, italics in original). This "receivable form" is an unexpected group meeting of the alleged alcoholic and his significant others during which time the individuals in the group present the alcoholic with the so-called reality of what his drinking and resultant behaviors have been and how they personally have been affected. It is also assumed that denial of reality is a major part of the

illness itself, necessitating therefore reality to be presented from a source other than the client. Johnson (1973) outlined seven principles for a successful intervention. Essentially, during this process significant others provide evidence that link behavior to drinking. The goal of this process is to move the individual from denial to acceptance of a new reality, the reality of the participants in the intervention. This reality dictates that drinking is the cause of that individual's problems and that, ultimately, treatment is the solution.

This strategy of intervention called confrontation or constructive confrontation was developed to allow treatment personnel to break through (or penetrate) the denial system of an alcoholic at an earlier stage, thereby allowing him to receive help for an alcohol problem before hitting bottom. This approach became the mainstay of occupational programs whose goals were to identify employees with alcohol problems based on job performance and to use the job as leverage to encourage (or coerce) those employees into alcoholism treatment early on in the process. The earliest forms of these occupational programs focusing on identifying employees with alcohol problems were called Occupational Alcoholism Programs (OAPs). OAPs first began in the 1940s, with 6 programs identified in 1945 and more than 4,000 in the United States by 1979. Googins and Godfrey (1987) list the basic rationale for OAPs, which includes an increased recognition that alcohol problems span a wide range of populations, including employed groups; that the costs of alcoholism to employers is high; that the workplace is appropriate for intervention; that treatment of alcohol problems can be effectively integrated into the work environment; and that alcoholism is a disease that is treatable based on the tenets of AA. The idea that alcoholics could be identified and referred to treatment early on in their disease progress was the basic philosophy behind OAPs. Without this emphasis and support for raising the bottom by creating a crisis through confrontation instead of waiting for alcoholics to hit bottom (as prescribed by the disease model), early case finding as a program strategy would not have been an effective tool and therefore sellable to management.

However, creating a crisis for an alcoholic in order to break through the denial system would not be possible if there was not a strong assumption that denial of an alcohol problem is a clear symptom of alcoholism in its early forms. Allen (1984) makes the strong claim that the one factor that "almost all problem drinkers have in common is that of denial" (p. 259). When faced with this denial during the assessment process, counselors are instructed to view this as a symptom of the disease of alcoholism. In other words, denial of one's excessive alcohol use and the problems it causes is to be expected. Counselors are also told that despite this denial, they will still be able to make accurate assessments if they have sufficient knowledge about substance abusers. Thus,

differences that may arise between the counselors' judgments of their employees' problems associated with alcohol and the perceptions of the employees of their own problems associated with alcohol are to be attributed to psychological processes—namely their denial system. What is perhaps one of the most interesting aspects of the use of denial in the case-finding process is the focus on individual attribution for alcohol-related problems and the assumed innocence of any structural, work-related environmental factors that might contribute to alcohol use.

> Denial of the drinking problem, or denial that drinking has any negative effects on job performance, which is often the critical barrier to improvement, can be gently dissolved by objective performance feedback that allows for a conclusion of self-attribution. (Chalmers, 1984, p. 305, italics in original)

Beyond the employees themselves, denial is also discussed as a problem of everyone around them including family members, friends, supervisors, and coworkers, leading them to ignore the problem. In relation to the workplace, the so-called cure for this form of denial is a training program to increase awareness (Scalon, 1991). Campbell and Graham (1988) actually expand the term to include "managerial denial" as a separate chapter in their EAP guide for managers. Within this framework, the managers become strongly implicated in the disease process itself and are thus included in the medicalization and labeling of codependency as a form of deviancy. Within this chapter, they also include a section titled "Breaking through Denial" (of the managers), which further suggests that managers, like their employees with alcohol problems, suffer from the same disease process and therefore need some intervention to break through their denial systems. However, unlike the employee with alcohol problems, constructive confrontation is not the answer for the manager. The treatment for the manager is education in the form of learning about the disease and learning how to document its individual effects in the workplace so that user denial can be broken.

EXPANDING DEFINITION OF DENIAL IN THE ALCOHOL FIELD

That specific forces and groups such as AA, Al-Anon, ACA/Codependency, and EAPs have embraced denial as one of their major defining constructs is not terribly surprising. What is perhaps more intriguing is how its definition has been massaged and expanded over time, going well beyond its original meaning. Hartocollis (1968), for example, is clearly ambivalent about the unconscious nature of denial. He asserts what might be termed "selective denial," meaning

that even though alcoholic patients may minimize the large amount of alcohol that they drink this "does not mean that these alcoholic patients are unaware of the extent to which they use alcohol—they may even boast of the amount of their drinking if with fellow drinkers" (p. 50). Wallace (1986) also questions the unconscious nature of denial, which he further terms "tactical denial." By calling denial a tactic and by defining it as a "common device" used by alcoholics to remain blind to the impact of alcohol on their work, health, reputation, and relationships, Wallace implies a conscious intent that differs considerably from the original definition. This is similar to Paredes (1974) alignment of denial with deceptive maneuvers used by alcoholics to conceal the extent of their drinking.

Haberman (1963) added a sociocultural dimension to the meaning of denial in his study of demographic differences between families who denied or admitted drinking problems. While there were few demographic differences between those who admitted or denied alcohol problems in their family, "Negro Baptists and parents with drinking sons more frequently denied problem drinking" (p. 141). Haberman (1963) concludes that class or cultural differences may account for whether or not alcohol problems are admitted. In a later article, Haberman (1970) used the term "denial" to simply mean saying "none" to an item on a questionnaire in a sample of New York City residents that asked respondents "would you say that you do *too little* or *too much*, or about the *right* amount of drinking alcoholic beverages?" (p. 710, italics in original).

While originally in the psychiatric literature denial was defined as one type of defense mechanism, denial in the alcoholism field has expanded far beyond its original meaning. "Denial includes a variety of ego defense mechanisms, such as rationalization, projection, and avoidance" (Amodeo & Liftik, 1990, p. 131). Anderson's (1981) treatise on denial also expands the definition to include simple denial, minimizing, blaming (projection), rationalizing, intellectualizing, diversion, and hostility. He argues that in order to protect self-esteem, alcoholics are more likely to choose defensiveness as opposed to coping, which he believes is a healthier way to handle threatening situations.

Another way in which denial has been conceptualized in the alcoholism field was presented by Paredes (1974), who noted that denial was part of a highly complex process that he likened to a dramatic performance (similar to *Alcoholism: A Merry-Go-Round Named DENIAL*). In order for alcoholics to maintain their drinking behavior and continue to refuse the label of "alcoholics," Paredes (1974) contends that they must continue to perform in fairly elaborate ways to maintain a status quo in their social and work relationships. Further, Paredes (1974) elaborates that "denial and the accompanying rationalizations and prevarications are part of a creative process requiring imaginativeness and

ingenuity" (p. 25). Thus, it is clear that Paredes also questions the unconscious nature of denial as it was originally intended by taking a somewhat interactional approach.

Finally, Tarter, Alterman, and Edwards (1984) conceptualize alcoholic denial by using a biopsychological approach. Within this framework, they argue that denial can be viewed as part of a cognitive-physiological theory that includes disturbed arousal regulation, cognitive impairment that hinders the ability to discriminate interoceptive cues and physiological states, and cognitive impairment that underestimates emotion-laden events. This unique framework removes denial from the psychiatric perspective and defines it as an interaction of the physical with psychological components and implications. With this approach, the authors argue that interventions aimed at improving cognitive awareness and modifying cognitive style are appropriate as well as interventions that enhance arousal ability, such as relaxation and biofeedback.

Denial Scales

Along with the expanded and somewhat dynamic definitions of denial have come a series of denial scales that purportedly measure this construct. One of the first attempts to quantify denial was by developed by Moore and Murphy (1961) in their study of 100 male veterans who were hospitalized as alcoholic inpatients. The degree of denial was rated at admission and discharge by reviewing treatment reports, notes by nurses and staff members, psychological test results, staff conference opinions, and social service contacts with families. Moore and Murphy utilized a 5-point scale based on the criteria ranging from "Patient saw no reason to decrease drinking while hospitalized" to "strongly wishes to remain abstinent" (pp. 599–600). Of interest and not surprisingly, this scale is disease model–based with no allowance for any rational choice to continue to drink. Differences among each level revolve around varying degrees of awareness by the patient that drinking is harmful and that he or she must stop drinking. It is presumed that once patients are fully aware of their drinking problems (no longer denying), the next step will be a commitment to abstinence. Because the framework is diseased based, it once again implies a linear progression of illness with denial as the single most crucial barrier to recovery.

Crawford (1982) also used a 5-point rating scale of acceptance/denial for alcohol patients obtained by staff. While the wording is slightly different, the assumptions behind each rating are fairly similar to Moore and Murphy (1961) and fit into the disease model perspective. In addition to the acceptance of alcoholism and a commitment to abstinence, Crawford (1982) also adds the dimension of active participation in sobriety. While this is not defined per se, it

also fits into an overall assumption of the disease model that sobriety can only be achieved through constant attendance at Twelve-Step meetings with active participation.

A third denial rating scale, the Denial Rating Scale (DRS) (Goldsmith & Green, 1988), was also developed on a clinic sample and it follows a similar way of assessing denial—namely the so-called awareness factor. However, the DRS differs slightly from the other scales in that it takes a broader approach in an effort to capture both the affective and intellectual understandings of each client concerning his or her alcoholism. In almost a self-actualization approach, the highest level, Level 8, can only be achieved if clients engage in a specific level of self-exploration that allows them to talk about what they are thinking and feeling. Like the other two scales, there is an assumption of linearity with "control" as a key factor. Level 8 can only be achieved if clients admit they cannot control their alcohol use, they are aware that alcohol is a problem in their lives, their problems go beyond alcohol and extend to other parts of their lives, they are willing to self-explore behavioral and affective levels, and they continue to have the self-image of an alcoholic.

While the interrater reliability scores were adequate, the authors attempted to establish construct validity in two ways: by assessing what factors were associated with the initial denial rating and by assessing the association between factors and changes in denial. That the authors assumed these analyses were tests of construct validity is quite puzzling. First, their results indicate that involuntary referrals had higher denial ratings than those who were voluntarily admitted to their program. This is clearly an interesting and expected finding, but it does not bring us any closer to a determination of whether this scale is measuring denial and, more importantly, of whether denial, as they have defined it, is as much the issue as is the fact that clients may conceptualize their alcohol issues differently than the predominant treatment modality at the clinic. Labeling these noncompliant patients as deniers allows the treatment personnel the luxury of not having to reassess their own belief systems concerning alcohol problems, alcoholism, and alcohol treatment. Second, factors that are correlated with change in denial as an indicator of construct validity are very unusual, given that presumably the treatment in the clinic is to break through denial. Given this, changes in the scale should indicate a positive outcome as opposed to a validating the construct of denial. Finally, in an effort to develop a valid and reliable scale on alcoholic defensiveness, Ward and Rothaus (1991) factor analyzed a 94-item scale and found two strong factors: denial and rationalization. What is particularly interesting about their scale is the assumptions behind the following 23 items, which comprise the denial factor. It is interesting to note that all of these items are from a disease model perspective. Thus, if

individuals in the authors' treatment program do not adhere to this model, they would score higher on this denial scale. Consider individuals who have other major problems going on in their lives (e.g. death of a loved one, loss of a home in a fire). Would it not be reasonable for them to answer "No" to items that stipulate that alcohol is one of the biggest problem and still not be in denial? If some individuals have a treatment goal that is not complete abstinence, does this mean that they are in denial? Further, if respondents to this scale have considerable resources, is it also reasonable to assume that continued drinking will lead them to the "gutter" as implied in one of the items?

POLITICAL INVESTMENT IN DENIAL

From the previous sections, it is clear that there are several sets of assumptions about denial that influence how it is has been applied in the alcohol field. First, denial is assumed to be present and a major factor when working with any or all alcoholics. Because denial is considered to be part of the disease of alcoholism, its presence legitimates the label and vice versa when excessive drinking or alcohol problems are suspected or reported. There is no room in this perspective for truth telling from the drinker himself. No stories of alcoholics are offered in the treatment literature that demonstrate early recognition of drinking problems or of excessive consumption by the alcoholic himself. One can only suppose that the label of alcoholic might, in some instances, not be appropriate based on how alcoholism is defined. Further, there is no room in the literature for alcoholics going beyond denial. That is, it is also assumed that alcoholics cannot overstate their drinking problems or their alcohol consumption. The presumption is that there is a continuum with denial on one end and truth telling on the other. Overreporting rarely if ever exists.

Second, the definition of denial in alcohol studies has been expanded well beyond its original meaning to include a wide variety of defense mechanisms as well as undesirable behavior (e.g., hostility) that somehow hampers the identification, treatment, or recovery from alcoholism. Thus, denial has taken on a much broader meaning and becomes the catchall word for any behavior that prevents the adoption of the tenets of the disease model system.

Third, as the denial scales indicate, measurement of denial is directly based on assumptions behind the disease model that attribute all problem areas to alcohol misuse. Individuals who disagree with these assumptions score high on these scales (are labeled "deniers"), but it is unclear whether the scale scores represent real denial, or having a different perspective on one's life than the researcher!

There are several political implications for denial as the primary defining principle of alcoholic behavior. First, because denial is purported to occur early in the disease process, it provides the rationale for earlier intervention. The earlier the intervention can be applied, the more clients can be amassed to assure a lucrative treatment industry. It fits well with an expanding treatment ideology in which

> denial legitimates treating drinkers involuntarily; it insulates and protects the industry from those outsiders who, being products of a cultural denial, are unable to see the magnitude and complexity of the alcohol problem, and it rationalizes and thereby mutes the criticism of the industry by these same misguided outsiders. (Brissett, 1988, p. 397)

It also allows the treatment system an out when treatment fails. Claims can be made that the alcoholic's denial system was too strong and could not be penetrated yet!

Another political issue raised by the use of denial as a main construct in the alcohol field is that there is a strong presumption that individuals around the drinker (e.g., family, counselors, etc.) are not only more knowledgeable about the alcohol problems but also have possession of the true reality, rendering the drinker's reality as false (Brissett, 1988). The assumption is most often that denial will contaminate self-reports. Moreover, the implications of whose reality is correct are enormous when one considers larger issues of social control versus individual control.

DENIAL IN ALCOHOL RESEARCH

The previous discussion has been directed at clinical treatment for alcoholics and research on alcoholic denial also conducted in clinical programs. Treatment evaluation studies in the alcohol field rely heavily on self-reports to assess baseline at treatment entry and then follow-up information usually immediately following the end of a treatment program and for at least one and sometimes several time periods following treatment. Because alcoholic self-reports are suspect by many in the research community, it behooves most alcohol treatment evaluators to provide some measure of self-report validity so that results from the study are not (or are less) suspect.

There is also a vested interest on the part of treatment evaluators and their funding agencies to show that self-reports are almost uniformly valid (albeit under certain conditions), as opposed to less valid, so that findings are taken seriously by the larger scientific community and by the leaders in the alco-

hol field as well. Thus, study after study and review after review report that alcoholics give valid self-reports despite the lack of a gold standard (Babor, Steinberg, Anton, & Del Boca, 2000). Less work is spent on delineating what demographic or social factors may predict less accurate reporting, on developing new ways to improve self-reports, or on why the validity question is being asked in the first place.

Just as importantly, there is little information on what evaluators sometimes call "unanticipated consequences" in validity studies in the alcohol field. That is, because denial is so prominent in alcohol research, little attention is paid to the possibility that overreports may occur, even though it is occasionally mentioned in the literature (Babor et al., 2000). In the early 1970s for my doctoral dissertation, I attempted to develop a model to predict early dropout from a comprehensive alcoholism treatment program and included a validity study for the 65 new entrants (Midanik, 1979). Each of the new entrants was asked in detail about his alcohol consumption during the past 24 hours and then a breath sample was obtained. The subjects did not know at the time of the interview that they would be asked to give a breath sample.

The results were quite surprising. Despite how self-reported blood alcohol concentrations (BACs) were calculated (including very liberal and very conservative estimates of elimination rates), a comparison of self-reported BAC and BAC as derived from breath tests showed that from 23 percent to 57 percent of this sample overreported their recent alcohol consumption (defined as + or – 0.05) (Midanik, 1982). Based on the literature at the time and currently, this finding was counterintuitive to the uniformly held belief that alcoholics deny and thus underreport their drinking.

Multiple explanations can account for these findings including how the questions were asked, the accuracy of the instrument used to validate the responses, assumptions that I made concerning the estimates of BACs from self-reports, and the context of the interview. Perhaps most importantly these findings occurred because the respondents, who were predominantly homeless, chronic alcoholics, were in desperate need of the food, shelter, and hopefully treatment that the program would provide. Thus, by overstating their alcohol consumption level, many probably felt that this ensured entrance into the program (Midanik, 1989).

This phenomenon is not brand new in the broader social science literature or in the alcohol field. Bradburn and Sudman (1980) have described in depth the role demands of the good respondent who assesses quickly the socially desirable behavior within a specific context. The hello-goodbye effect as described in the clinical psychology literature refers to how clients tend to overpresent their symptoms at entrance to treatment and underpresent their symptoms at

termination of treatment (Cave, 1999). Pernanen (1974) wrote from a personal communication from W. Schmidt, that there were instances where individuals reported alcohol consumption that was physiologically impossible without resulting in death for the respondent. Finally, Weisner and Room (1984) noted that the circumstances of treatment may strongly influence the way clients present themselves, particularly in reference to criminal justice clients (who are not drunk drivers) coming to the county alcohol treatment system. Thus, within different treatment contexts there are gains to be made by presenting oneself as being a heavier or a lighter drinker and as having few or multiple alcohol-related problems.

What is disturbing about these findings is that because they run counterintuitive to denial being the guiding force in the alcohol field, little additional research has been done in this area. If new entrants to an alcohol treatment program tend to overreport their recent alcohol consumption, there are important implications for treatment personnel who base treatment decisions on these self-reports. Further, overreports, particularly at baseline, can bias treatment evaluation studies by inflating success rates (presuming there was an opposite bias after treatment). Yet despite the implications of these findings, little interest has been shown by researchers in the alcohol field to explore this area.

BEYOND DENIAL

It is difficult, if not impossible, to imagine the alcohol field without the concept of denial as its major, but not only, legitimate explanation for why treatment was not as successful as hoped or for why our research findings do not fit with either conventional wisdom or with some outside criterion that purportedly is a more valid measure. In a world without the convenience of denial, AA stories would look very different. There would be an early recognition of a problem with alcohol and a full confession that the alcoholic made a rational choice to continue to drink despite this awareness. Treatment providers working with alcoholics might have to acknowledge that their insights may not have a universal allure and simply may not be applicable to everyone deemed to have alcohol problems. Al-Anon groups might have to consider other roles beyond the enabler to describe partners of alcoholics who choose to continue their behavior, admit to it, and thus, make their choices.

However, we do live in a world where denial is an important mainstay in the alcohol field. It has provided a central ideology for the disease model, and in doing so, it has become a kind of shorthand for those who are not quite at the recovery level. Lowney (1999) refers to this overall process as the religion of recovery with five core principles:

> (1) that one's own needs must come before the demands of society, (2) that families emotionally and spiritually wound children during the socialization process, (3) that those scars carry into adulthood, causing us to be stuck in debilitating behavioral patterns, (4) that to heal, we must let go of these private wounds by sharing them with others, and (5) that these patterns are symptomatic of the disease that ails us—codependency. Talking to others similarly hurt, who have "been there," can break the hold of the past that has had such power over the individual and permit the miracle of recovery to commence. (p. 89)

Lowney (1999) argues convincingly that the roots of this individualistic movement are in carnivals and revival meetings in which social problems were displayed as freaks in the sideshow, and the solution to these social problems involves public confession and public acceptance of a strong religious belief system. Recovery, thus, is good, and consequently denial, as the primary identified barrier to recovery (somewhere between steps 3 and 4 above), is considered to be bad.

The ultimate cost of this individualistic ideology is often not discussed. To do so means questioning the status quo and being considered an opponent of this very popular treatment modality that views denial as the enemy even though it has been argued that there may be a positive aspect to denial (Lazarus, 1983). However, this large investment in denial as the main defining feature of alcoholism has allowed clinicians and other people involved in treatment programs along with those who conduct research in the alcohol field to maintain a certain amount of power over clients. One purpose of this chapter was to question the assumption that denial needs to be the central core of alcohol treatment and to argue for more discussion on how denial has shaped research agendas. A reexamination of this assumption can only serve to further treatment and research in this field.

Chapter **3**

The Spirituality of Recovery and the Twelve Steps of Alcoholics Anonymous

Rev. Robert Davis Hughes, III, PhD

The *Twelve Steps of Alcoholics Anonymous*, first written by Bill W. (Wilson) in December 1938 and published in "The Big Book," *Alcoholics Anonymous* in 1939,[1] have become the dominant gold standard in defining the spirituality of recovery. Nowhere is this more apparent than in the fact that programs and treatment centers using other methods, especially secular ones, almost always have to define themselves as non-Twelve-Step approaches. Even these programs usually teach meditation or yoga as tools of recovery. The Twelve-Step community is overwhelmingly the largest single group of successfully recovering persons, and its definition of what it offers as "a program of spiritual recovery," that is "spiritual, but not religious," has not only defined the space in recovery circles but also set a tone for a whole generation's approach to questions of religion and spirituality, often in ways the founders never intended.

HISTORY

Bill W.'s own description of the historical sources of inspiration for his writing is most complete in the essays in *Alcoholics Anonymous Comes of Age: A Brief History of A.A.*, the publication of the addresses at the 20th Anniversary Convention of AA (Alcoholics Anonymous) in St. Louis in July 1955.[2] Culling from the various sources there, we can summarize as follows.

Ebby T. was a friend of Bill W.'s who first brought him a message of hope in November 1934. A friend of Ebby, never named, as far as I know, had been desperately seeking help for his own alcoholism, and visited Dr. Carl Jung

in Zurich in 1930. Jung, the most friendly of the patriarchs of psychiatry to religion and spirituality, had told this person that he was an alcoholic of the hopeless type, who could only be cured by a deep and life-changing spiritual experience akin to religious conversion.[3] In 1934, Bill W. had also received a diagnosis of "hopeless alcoholic" from Dr. William D. Silkworth, a New York psychiatrist working with alcoholics, who became one of the great friends of AA. He described alcoholism as an allergy leading to a compulsive obsession, the beginnings of the disease concept of alcoholism.

In August 1934, having been prepared by the friend who had seen Dr. Jung, Ebby got sober through contact with the Oxford Groups, an English evangelical movement founded by Frank Buchman. The major American exponent of these groups at the time was the Rev. Samuel Shoemaker, at that time Rector of Calvary Church, New York. He became both one of the great friends of AA and also the greatest evangelist of the Episcopal Church in that era. A word of caution is needed here. "Evangelical" at that time certainly meant a brand of protestant Christianity that emphasized a vital and personal experience of God in conversion and a subsequent life of moral earnestness. It did not, however, have associations with what has become known as the religious right in our own time. Indeed, it was usually aligned with progressive and reformist views on social issues. That was certainly true of Shoemaker. The Oxford Groups emphasized a well-established formula: admit you are licked; ask God for help; take stock and confess your defects to another person in confidence; make restitution for the harm you have done; practice sacrificial self-giving; and pray to whatever God you think is there for the power to do all that.[4]

Ebby visited Bill W. in November of 1934 and shared the story of his recovery. By this time Bill was looking for any answer, struggling with the God problem as a result of his scientific training; he decided to have a go, and visited the mission Calvary Church operated on 23rd Street, where Ebby had been lodged. There he responded to the altar call and gave his first testimony, to the initial embarrassment of Ebby! Hopeful at last, Bill returned home but got drunk again the following morning. He had, however, grasped a ray of hope, and he checked himself back into Towns Hospital under the care of Dr. Silkworth. Ebby visited him there and renewed the message of the Oxford Groups. Bill eventually cried out, "If there is a God, let him show Himself! I am ready to do anything, anything."[5] Immediately, he had a major ecstatic experience. Although he felt his life was changed, he still had his modernist doubts; these were quieted by Dr. Silkworth's medical view that such experiences were objectively possible; Bill also read the classic *Varieties of Religious Experience* by philosopher and psychologist William James (who laid out the archetypal description of the born-again experience in modernist, deistic terms), which was deeply

influenced by the Romantic movement.[6] In addition to James's account of the experience of a second birth, Bill W. was deeply influenced by James's description of "complete hopelessness and deflation at depth" as conditions for such an experience.[7] The result, then, is a blend unique to its own time: principles of Christian spirituality expressed in a classical evangelical form, embodied in the Oxford Groups and the ongoing counsel of Sam Shoemaker on the one side, but interpreted by the modernist, psychological approach of Bill W.'s own skepticism and the influence of Carl Jung, William James, and William Silkworth. The initial result was the "six steps" derived from the Oxford Groups but freed from any specific dogmatic content.[8]

The next major event was Bill W.'s trip to Akron and the conversation with the alcoholic Dr. Bob S. (Smith) and his acceptance of the program, which would, in years to come, lead to the treatment of over 5,000 alcoholics in St. Thomas Hospital in Akron by Dr. Bob and his nurse, Sister Ignatia. The beginning of AA is officially dated from this conversation in May 1935, and Dr. Bob's last drink on June 10. The personal piety of Dr. Bob and Sr. Ignatia, another of the great friends of AA, and the influence of the Akron Oxford Groups with which the first Akron group was affiliated, produced a more recognizable version of Christian orthodoxy that included the four Oxford principles: absolute honesty, absolute purity, absolute unselfishness, and absolute love.[9] Indeed, the Akron group remained affiliated with the Oxford Groups longer than the New York group, and the Akron tradition in AA to this day still maintains echoes of this connection.[10]

The situation was more complex in New York. As Bill describes it, there were three subgroups. First were the conservatives, who wanted to maintain the explicitly Christian and biblical focus. Second were the liberals, who wanted to keep the references to God and spirituality but to free the program from any commitment to religious dogma or doctrine. This was partly in response to the observation (still true, I believe) that the purely religious approach produced few cases of significant, long-term sobriety. The third group, the radicals, were a handful of atheists and agnostics who wanted no reference to God at all. They argued for a purely psychological approach, allowing the alcoholic, once lured in, to take the God bit or leave it alone. The groups had agreed that a book, later published as *Alcoholics Anonymous* in 1939, was necessary to tell their story and broaden the audience for recovery. As Bill was drafting the steps, which ended up being expanded from 6 to 12, in December of 1938, the conflict among these groups over the God content reached a pitch, with the radical side being led by Henry, an avowed atheist. As the publication date approached, anxious conversations ensued, until finally a compromise was reached. In step 2, God was described as "a Power greater than ourselves," the language about kneeling

was removed from step 7, and the references to God in steps 3 and 11 were expanded with the now famous phrase "as we understood Him" (Anonymous, 58–60).

While this looks like the triumph of the liberal position, it actually reflects the original Oxford formula as reported by Ebby. Indeed, approval of the book quickly came not only from Sam Shoemaker (who by this time was wrestling with the problems of cult of personality in the Oxford Groups, which would eventually lead to his breaking with them); acclaim also came from the greatest preacher of the time, Henry Emerson Fosdick, in a favorable book review; and a favorable opinion from the Church Committee on Publications of the Roman Catholic Archdiocese of New York was also welcome.[11] This latter stream became embodied in the person of Fr. Ed Dowling, S.J., of St. Louis, in 1940. This was after the publication of "The Big Book" but substantially before the definitive commentary on the steps and traditions, *Twelve Steps and Twelve Traditions*, first published in 1953. Fr. Ed became another of the great friends of AA, and the influence of Sam Shoemaker continued as well. Further work needs to be done on this later text, but the commentary in the 1953 book reflects a good deal of classical spiritual wisdom and even an air of Ignatian influence that can probably be traced to Fr. Dowling. The purpose of toning down the God language in the steps was not to decrease the expectation of real conversion and vital spiritual experience, or even what was seen as the normal return of most members to a practice of a particular religion, but rather the desire to widen "our gateway so that all who suffer might pass through, regardless of their belief or *lack of belief*."[12] Confirmations of the approach came from successful recoveries of practicing Hindus in India and approval of the steps by Thai Buddhists (with a suggestion that "God" be translated "good," but acknowledging that the phrase "as we understood Him" makes the steps acceptable).[13]

Thus the concept was born of a program that was to embody classical principles of Christian conversion compatible with both a Protestant/Evangelical and also a Catholic/Ignatian reading (and, as subsequent events have shown, an Orthodox/Patristic reading) on the one hand, and a modernist, psychological reading open to persons of no faith at all on the other. This tension remains in the movement, usually damped down by the maxim "spiritual but not religious." Within AA itself it is now scarcely controversial and causes few arguments. But as the program is presented to outsiders, some religious conservatives see only a New Age cult, while militant atheists see religion coming in the back door. My own sense is that a postmodern reading is most helpful: the Twelve Steps (and the equally important Traditions) are deliberately written (perhaps as a gift of God) to allow for alternative readings. As a result, we should perhaps not speak

so much of Twelve-Step spirituality as Twelve-Step spiritualities. That not only allows the doubting newcomer to enter, but also allows the earnest recovering seeker to find more defined religious paths of spirituality that are one way of living compatibly with the program.[14]

ANALYSIS OF THE TWELVE STEPS

The definitive original statement of the Twelve Steps is chapter 5 of "The Big Book," *Alcoholics Anonymous* and the definitive commentary is *Twelve Steps and Twelve Traditions* for AA.[15] Other groups, such as Al-Anon and Narcotics Anonymous, which also use the Twelve Steps, have produced their own versions and commentaries, definitive for their reading and practice of the steps. Nothing substitutes for reading the original sources, especially for the person seeking recovery. What follows is an introduction to the spiritual rhythm of the steps, and for simplicity's sake, based on AA only. First, some preliminary points.

Step 1 begins with "We," and implicitly the other 11 do as well. The "We" is the some one hundred people who had found recovery at the time "The Big Book" was first published. It now encompasses a recovery community of several million worldwide. But the point is crucial—this is not a "self-help" program but a program of a therapeutic community. One current expression of this is the combination of therapeutic community treatment (as, for example, in the De Hoop model) with Minnesota model Twelve-Step treatment, a combination currently having great success in Egypt.[16] This "We" reminds the newcomer that the group is an essential component of recovery, a new community of those who are succeeding in recovery following this path. It is not a program of spiritual or moral discipline to be undertaken alone. Even in extreme circumstances in which a person must be solitary for a time, it is a program taken in the company of the worldwide "We." This is an important corrective both for the isolation that is often the result of the disease and for Western solipsism (extreme individualism). It also reminds the newcomers that a social context for their new life of sobriety already exists.

Second, the steps are in the past tense and are suggestions. That means some people have already walked this road to recovery successfully. It also means that admitting, for example, that we are now powerless with unmanageable lives does not mean we need to stay that way forever. The suggestion rubric means, as so often is said in meetings, "take what works for you, and leave the rest, at least for now." It allows each person to find his own path on this broad road. The resultant community is thus more like a postmodern family than a military unit, and indeed the organizational principles in the traditions reinforce that.

A remarkable characteristic of AA fellowship is that of universal support. No one is liked by everyone; no one really in recovery, however, would wish another member would not succeed but go back out. It is the only organization I know of in which everyone really roots for everyone else. Restored fellowship and right relationships begin with the group but eventually extend to the family, the workplace, and the larger social environment as long as people in these locales accept the requirements of the new life of the recovering person, and ideally enter recovery themselves for treatment of codependency issues. In AA, Al-Anon, and other Twelve-Step groups, the concept of sponsorship is a primary focus of this fellowship. The sponsor is a person chosen by the recovering person, usually with more sobriety time than she has, who serves as a kind of *anamcara* (Irish for "soul-friend"),[17] who listens to the story of newly recovering persons and guides them in their practice of the steps while introducing them into the fellowship of the recovery program.

Third is the statement "we claim spiritual progress rather than spiritual perfection."[18] In its immediate context this is designed to reduce the fear expressed as "What an order! I can't go through with it." At the same time, it has deep resonances with a tradition of spiritual growth that found its Christian expression in Gregory of Nyssa's definition of perfection itself as an endless journey of progress, Luther's *simul justus et peccator* (at the same time justified and sinner), and John Wesley's idea of Christian perfection, which was, as we now know, deeply influenced by a reading of Gregory. The one type of spirituality this challenges is the kind that expects moral perfection as an immediate gift following conversion. That approach to recovery from addiction often produces dramatic but short stretches of dryness (abstinence from drinking or drugging). It is my experience that mature pastors, even in denominations that lean in that direction, have come to recognize this problem and the need for the more extensive "discipling" the steps provide. Perhaps the most essential point is this: deep recovery requires spiritual growth, but also spiritual growth for the truly addicted requires recovery, including abandoning the idea that drug-induced states of euphoria are genuine spiritual experiences. Addiction is increasingly seen as a kind of blanket over any other psychological issues preventing therapeutic healing or further developmental growth; it is primary and must be dealt with before other issues can be addressed and normal developmental growth resumed. Even more so for the spiritual growth, the deeper tides of the spiritual life cannot be enjoyed by an addicted person until the primary spiritual issues of addictive disease are addressed.[19]

Turning to the steps themselves, they fall into three groups that express a natural spiritual rhythm certainly familiar in classical Christian expressions

but also held in common with many other traditions: conversion (steps 1–3), cleansing (steps 4–9), and building a new life (steps 10–12).

The first three steps express a process of conversion. Like all good theories of conversion, this must address conversion *from* and conversion *to:* an honest appraisal of the unsatisfactory life one wishes to leave, the realistic hope for a new and different life, and a commitment of trust to undertake that new life. So, step 1 requires from the addict an honest admission of powerlessness over the drug and the resultant disease, and of the havoc of unmanageability in one's life that results. This step is the keystone of recovery, and also the one that has been most controversial. Because the program was originally defined by Bill W.'s apprehension of James's definition of "deflation in depth," the original sweeping application of powerlessness to the lives of the privileged with overweening egos resulted, and conversion was seen largely as repentance. Critics noted that this approach was not suitable for persons whose lives had not allowed them to develop such well-formed egos. Some proposals, usually by well-intended "civilians" (what recovering people call others without the disease) with the interests of the oppressed and the abused at heart, actually compromised the notion of powerlessness to the point of endangering recovery.[20] My own sense is that accepting healing and liberation as legitimate modes of conversion helps more, by allowing the oppressed to develop the selves they have been denied while still acknowledging the powerlessness over the primary obsession of the disease as simply empirically true. Indeed, all conversions involve some of all three modes (repentance, healing, liberation), but different circumstances suggest different balances. The virtue to be learned in this first honest look at one's circumstances is humility, not as humiliation (though the life affected by the disease often brings some of that) but simply as an honest and truthful acceptance of the reality of who one is and the nature of the life one is currently leading.[21] It does, in at least one limited area of life, require acceptance of defeat, and a kind of surrender, but the surrender is not to hopelessness, nor certainly to any oppression and abuse, but to what comes next.

What comes next is "We came to believe that a Power greater than ourselves could restore us to sanity." Step 2. Having admitted the hopelessness of our situation in step 1, "we" now come to hope in something or someone else. Having been defeated by a power greater than we are, we look for one on our side, as it were. Here the tension inherent in the original history is obvious—the Oxford Group side clearly meant to point here to the Christian concept of God, while the more radical New York group wanted no such reference. "Higher Power," as we have seen, became the compromise. The experience of most people in Twelve-Step recovery is that any old sense of a Higher Power will do for a start,

even the group itself, but that this usually evolves into a more specific direction later, though not always. What is essential is the connection between humility and hope in these first two steps. Only true humility leads to the possibility of a realistic hope.

Having come to this belief, or at least having agreed to make the experiment of this belief, "We made a decision to turn our will and our lives over to the care of God *as we understood Him*." In many groups today that final masculine is optional. This is the initial birth of faith out of the dialectic between humility and hope, faith as a trusting commitment in the form a turning over of our will and lives to whatever of God we understand. The experience of many is that this is enough, that whatever Higher Power there is, is happy to work with the feeblest and least understood efforts to turn around in a new direction, and it is "turn around" that is the classic definition and root meaning of "conversion." Many who find the concept of surrender difficult are helped when they see that the step does not require them to surrender will and life to a God who becomes their authoritarian dictator but rather to the *care* (from Latin *caritas*, Greek *agapé*, love) of such a Higher Power, who will take care of them, not possess them or dictate to them.

These first three steps are dominated by what the text later calls three pertinent ideas:

(a) That we were alcoholic and could not manage our own lives.
(b) That probably no human power could have relieved our alcoholism.
(c) That God could and would if He were sought.[22]

The task for soul-friends, sponsors, pastors, therapeutic counselors, or even treatment during these stages is not to try to turn the person around (that is the job of the Higher Power), but rather to *make space* for the person to turn around when he is ready. This will include consistent feedback about the reality he actually faces; help in breaking through the denial about that, which is the first symptom of the disease; assistance in breaking away from communities and relationships that reinforce the denial; and offering the first glimpses of the possibility of a hopeful new life. Recovery groups themselves are often the most helpful wardens of such space.

If we have been stuck in the mud and covered with slime, the first thing we want after being rescued is a good shower. That is the essence of the cleansing in steps 4 to 9, which fall naturally into three groups. In step 4 we make an *examination of conscience*, a fearless and searching moral inventory of ourselves, looking especially for deep character flaws associated with the disease and the actions flowing from them, as well as any deeply held sources of guilt and, equally important, virtues and other assets we may not be fully utilizing.

One of the true strokes of genius, even in the description of this step, is the recognition of resentment as the "number one offender," most likely to get us drunk again. This is not appropriate anger, but anger that is stored and cherished to the point of idolatry. While dealing with resentment, we also note that we are taking our own inventory, not anyone else's. We are responsible only for cleaning up the mess on our side of the street.[23] Or, as it is put in *Twelve Steps and Twelve Traditions*, "It is a spiritual axiom that every time we are disturbed, no matter what the cause, there is something wrong with us."[24] The emphasis is clear: the one thing in a situation, however unacceptable, over which I am surely not powerless, is my own attitudes and behavior. The growing ability of recovering persons to take adult responsibility for their own emotional lives and actions is one of the great gifts of the program.

Having completed this inventory, step 5 asks us to admit "to God, to ourselves, and to another human being the exact nature of our wrongs." Any who have done this will acknowledge both the additional honesty and increased objectivity that is called forth by actually saying these things out loud to another human being; there is also as a rule a deeper sense of being forgiven if someone pronounces it. For those who practice a religion that includes rites of oral *confession*, the label that classical spiritual traditions put on this act, that is recommended; but it should be recalled that this admission came directly from the Oxford Groups, where the tradition was more evangelical: any trustworthy person will do.[25] It is most helpful to recall in steps 4 and 5 that we are looking for "the exact nature of our wrongs," the flaws and defects that are the wellspring of our disease and insanity, much more than a laundry list of everything we have ever done that is wrong or stupid.

At this stage, counselors, therapists, sponsors, and pastors make room for the struggle of the inventory, and support the recovering person through the difficulties while preparing themselves, and any community they influence, to welcome back a newly cleansed and forgiven fellow sufferer. Those authorized by faith communities or called in some other way will also be prepared to hear a 5th step, where the principle art combines a firm commitment to encourage rigorous honesty, completed by a clear ability to assure the penitent of forgiveness and a welcome back to the human race. A deep sense of one's own ongoing defects helps. This is the point at which standard Minnesota Model treatment usually ends, and the newly recovering person is sent back into his old environment with an after-care plan or is encouraged, where appropriate, to undergo extended treatment or a halfway house first.

Having identified and admitted the nature of our wrongs, we turn to what the tradition calls *amendment of life*, in steps 6 and 7. Here we rely on our Higher Power to remove the defects of character we have uncovered in the

previous steps, especially at first those most likely to get us drunk. Again, with great insight, the founders made this process into two steps—first working on the willingness to have these defects removed and facing our own attachment to them. The notion of willingness, as opposed to willfulness, becomes very pertinent here.[26] Indeed, most recovering persons find they need to practice these two steps over and over, as the removal of one set of defects and attachments uncovers another. Then, in step 7, we ask God to remove the defects. This is the first point in the program in which we have actually asked God for something. It is also critical to understand this is not a program of moral self-improvement. Though recovering persons will have plenty of work of their own to do, here we ask God to do it, to remove "every single defect of character which stands in the way of my usefulness to you and my fellows."[27] This is part of what is called the 7th step prayer. The importance of these steps is underlined by the failures many alcoholics have experienced when faced with moralistic demands that have been put upon them, demands they have failed to meet over and over until either despair or rebellious rage become the options. The deep surrender of these steps becomes not a defeat but a kind of relaxing into the care to which we committed ourselves in step 3. The task of counselors, sponsors, and pastors at this point, often different from those who have guided someone through the first five steps, is to reinforce both courage in facing the detachment and deep relaxation in letting go.

In most classic spiritual traditions, the final step of cleansing is *restitution*. Part of taking responsibility for having made a mess is the willingness to clean it up as far as is possible and prudent. Step 8 asks us to "make a list of all persons we had harmed, and become willing to make amends to them all." Rigorous honesty, thoroughness, and willingness continue to be significant. No limits are placed on this list, though it is useful to distinguish people we have actually harmed from those who simply observed and were embarrassed by our jackass behavior. We strive to become willing to make amends to all we have truly harmed, without qualification. Counselors, sponsors, and pastors at this point can encourage thoroughness and accuracy and can help to develop the willingness. The key to the latter emerges most clearly in situations in which the recovering person feels deeply wronged by the other person. Again, the emphasis must be on our own side of the street without seeking to control the action or reaction on the other. Neither here, nor anywhere else in the program, however, should forgiveness be identified with permission to continue abusive behavior. Amends does not include willingness to be further victimized.

That latter notion is one of the prudential elements that a good sponsor, counselor, or pastor can underline in supporting someone in doing step 9 amends, "wherever possible, except when to do so would injure them or oth-

ers." This needed prudence has four elements: (1) Am I focused only on my self and my own actions? (2) Is the timing right? The temptation to try to make amends all at once or prematurely needs to be resisted. Each one requires careful thought and prayer. (3) Is the means chosen for the amends (direct conversation, letter, a quiet restitution) appropriate? (4) Can we be sure that the proposed amends will not harm the other person or anyone else? Once these are worked through, those in support roles can assist the recovering person in finding the courage to make the hard ones and can help them process the results afterwards.

Step 9 concludes the process of conversion and housekeeping, and it is at this point that recovering people are led to expect the beginnings of the deep consolations and benefits of sobriety expressed in what are called "the promises."[28] Here, a significant corner is turned. Up to this point, the focus has been on not using and staying clean and dry. Counselors and the group can support this, but the ultimate responsibility is with the recovering person. One frequently hears in meetings, "We don't promise to keep you sober, but we do promise to ruin your drinking," since no one who has come to understand the disease ever has really good experiences of further use of alcohol or other drugs. As the promises begin to come true, however, something deeper emerges—the new life of sobriety itself. The real turning point toward wellness is when the recovering person turns away from the fears, guilt, and shame of the life left behind and falls deeply in love with the new life of sobriety. Of great significance is giving up any resentment or regret that further successful use of alcohol or drugs is not possible. This is a deep shift from negative to positive regard for the new life, often embedded in the saying "You have to go to meetings until you want to; then you don't have to go anymore, but you will because you want to." No matter how long we are sober, the support of the group helps us maintain and deepen our new lives of sobriety. On a personal note, I have often observed persons succeed in getting clean and dry using other methods than the Twelve Steps, even for extended periods of time. I have never seen anyone turn this corner I have just described except by practicing Twelve-Step recovery, the turn from "I must not drink or use anymore," to "I love being sober." This is the first truly deep spiritual result of the program, and it makes all the others possible.

The remaining steps are designed to support and maintain this new life, though doing so is also necessary for ongoing sobriety. Step 10 continues, in a very Ignatian manner that may, at least in later works, reflect the influence of Fr. Dowling, the process of self-examination on a daily basis, and it contains the important wisdom, "when we were wrong, promptly admitted it." Many have learned that when we delay such admissions, we pay the price in indigestion and other distress. Step 11 encourages daily prayer and meditation "to improve

our conscious contact with God as we understood Him." Those who are able to do so are encouraged to return to, or newly undertake, the disciplines of a particular faith community, and the deeper blessings offered there now become truly available for the first time.[29] In any case, books of daily meditations are provided by various agencies, including AA itself.[30] Much of the spiritual wisdom of the program is condensed in these little books and in *Twelve Steps and Twelve Traditions*.

Step twelve has three parts. "Having had a spiritual awakening as the result of these steps," raises the issues of "spiritual awakening." The definitive discussion of this is Appendix II in "The Big Book."[31] The point most emphasized there is that the concept includes both the sudden, dramatic, Damascus Road types of experience and also the slower, more gradual experiences that are only noticed in retrospect. My own sense is that the best focus is on turning that corner from not drinking or using to being in love with sobriety. The other thing to note is that in focus here is a spiritual experience *as a result of these steps;* one of the hard things that must often be learned is that previous "spiritual experiences," especially under the influence of any mind-altering substances, may well be bogus. Even Bill W. had to learn this the hard way in his experiments with LSD.[32] Here, as in the previous step, the sponsor, counselor, or pastor may find it best to refer the recovering person to a spiritual director versed in the wisdom of at least one great tradition, unless they themselves are so qualified. Discernment can be a key gift at this point.

The second part of step 12 is the best known: "tried to carry this message to alcoholics." This is the "pass it on" step, and the one that led Bill W. to call Dr. Bob in Akron in May of 1935. There is much wisdom in the program about this, most important being avoiding so-called two-stepping: the practice of jumping from a first attempt at step 1 to an annoying and naive effort at carrying the message. Many organizations succumb to the temptation of harnessing the enthusiasm of the new recruit in proselytizing efforts. AA actually forbids this, and postpones carrying the message until the other steps have been worked and a spiritual awakening has occurred. At that point, however, continuing sobriety may depend on willingness to share the message. Care must also be taken for prudential concerns, including gender and sexuality issues, always going in pairs, not getting hooked into expectations for results. "We carry the message, not the alcoholic." Sponsorship itself is seen as one effective way of fulfilling this part of the step.

The third part is "to practice these principles in all our affairs." The tools and wisdom gained in AA or similar programs are for all of life, not merely a cordoned-off sobriety. Here ongoing participation in the group is especially helpful in combating the structures of mental mismanagement arising from

the denial inherent in the disease, the notorious "stinking thinking," which can often result in a dry drunk.

The 12 traditions largely govern the common life of the groups, but tradition 12, and its "backwash" into tradition 11 remind the recovering person that "Anonymity is the spiritual foundation of all our Traditions, ever reminding us to place principles before personalities." This probably grows out of the negative experience of personality conflicts in the Oxford Groups around the time AA was forming, but it also becomes a real protection against false pride in recovery. The traditions also embody the "third legacy" of AA: service, to the suffering alcoholic or addict, the group, the larger organization, and the world.[33] Our recovery is not for own sake alone, but so that we might be of use.

THE SERENITY PRAYER

The so-called Serenity Prayer is used at most meetings and has also assumed an important role in recovery spirituality. No one is quite sure where it came from, though the appearance on a Christmas card of Reinhold Niebuhr's appears definitive.[34] Its primary use is as a tool to discern powerlessness (the things I cannot change) from areas of responsibility (the things I can). Many recovering people have found that repeating it at times of great concern is of immense help and often brings actual serenity.

POSTMODERN CHALLENGES

The Romantic, deistic psychology of William James and Carl Jung was the means at hand in the late 1930s for reading the spiritual wisdom of the Christian tradition in a manner that opened the gateway to recovery of persons of religious faith other than Christian and to persons of little or no faith of any kind. This psychology is no longer widely accepted, at least in its original form, by the medical, scientific, and therapeutic communities, while the Romantic, universalistic deism of James and Jung is under serious critique by postmodern scholars of spirituality and religion, both those who practice a traditional religion and those who do not.[35]

Perhaps the biggest challenge is to recognize the need to move beyond the definition of conversion Bill W. picked up from James as being "deflation in depth"; to recognize that while deflation may still be an appropriate approach to the powerlessness of the disease for persons of relative privilege and strong ego, approaches of liberation and healing are more appropriate for the young, disempowered, oppressed, abused, and even postmodern persons not afflicted with an overweening autonomous ego. At the same time, alternative readings

shaped around the needs of those persons must not compromise the actual powerlessness and unmanageability that does result from the obsession inherent in the disease itself, which is no respecter of persons. Alternative *versions* (as opposed to alternative *readings*) that compromise on step 1 do not as often lead to successful, long-term recovery, in my experience.

The recovery community has largely absorbed the new neuropsychological knowledge of addiction and brain chemistry as a better explanation for the obsession of the disease than the original metaphor of "allergy" (not the later scientific analyses of allergic reactions as these relate to addictions). Newer methods of motivational interviewing show promise in closing the gap between the hard-core abstinence advocates and the proponents of harm reduction. The challenge on the spiritual side, then, is whether the recovery community can also let go of the modernist psychologism of Romantic deism present at the birth of AA and still maintain a community of authentic recovery *spiritualities;* these would be based on a family of acceptable readings of the steps that keep in common the core of what is needed for recovery but that align with the concrete spiritual practices of faith communities that include the original Christian womb of AA and also the broad range of other faiths and communities of spiritual practice, including new religions and persons of little or no faith, as the founders intended.

In large, urban areas with many groups, this may mean some meetings devoted to reading and practicing the steps in alignment with particular faith communities. In the Chicago area, for example, once there was a meeting for atheists and agnostics, there could also be one that read the steps as Christian, as long as both groups kept the traditions. For example, the Christian group *allows* the use of Christian language for "Higher Power" but does not require it; the only requirement for membership is still a desire to stop drinking. One could imagine groups aligned with other faith communities also, as long as they kept the traditions. My own sense is that these groups should be seen as supplementary meetings, with attendance at more inclusive meetings also recommended. The challenge in the inclusive meetings is greatest—how to move beyond the modernist expression of inclusivism as the spiritual generic to a postmodern family of spiritualities of concrete practice, each with an authentic reading and practice of the steps. That would give a whole new meaning to the dictum that the steps define a program of recovery that is "spiritual but not religious."

Chapter **4**

Addictions and Free Will: A Structured Exploration of the Boundaries of Personal and Societal Responsibility

Julian G. Martins, MA, MB, BS, and
Basant K. Puri, MA, PhD, MB, BChir, MRCPsych, MMath

In the 1960s . . . two Supreme Court holdings . . . set forth a legal distinction between status (having the disease of addiction) and behavior (the acts performed by the addicted person). I suggest that these judicial decisions remain relevant, that the "disease model" of addiction does not excuse all harmful addiction-induced behavior, and that the addict's acceptance of his or her disease and entering into therapy is just the bright line that the law seeks in order to establish responsibility.

—Cohen (2007)

Whether addiction is best understood as a brain disease or a moral condition . . . is often centered on the question of whether and to what degree we can justly hold addicted individuals responsible for their actions . . . [however,] it may be wise for societies to err on the side of holding addicted individuals responsible for their behavior . . . [but] it should be with the view to rehabilitation of the addicted person and protection of society rather than moral opprobrium.

—Hyman (2007)

Our penal system is highly counter-productive from a consequentialist perspective, especially in the USA, and yet it remains in place because retributivist principles have a powerful moral and political appeal . . . It is possible, however, that neuroscience will change these moral intuitions by undermining the intuitive, libertarian conceptions of free will on which retributivism depends.

—Greene and Cohen (2004)

The preceding quotations from recent work considering the boundaries of personal responsibility in addiction summarize the approach to be adopted in this brief overview of the subject. Notably, we are establishing a model of responsibility in addiction that seeks to both foster the development of personal responsibility and to also take into account recent findings from neuroscience. These seemingly juxtaposed positions—responsibility versus neuroscience—affect the roles of therapeutic, societal, and legal responses to addiction in either helping or hindering the development of the very personal responsibility we seek to foster.

It is beyond the scope of this chapter to provide a detailed analysis of the philosophical underpinnings of the nature of free will, but it may be helpful to provide a brief overview of the central concepts. Three principal models have been advanced to conceptualize free will: determinism, libertarianism, and compatibilism. In the deterministic model, free will is essentially an illusion, and human choices are a result of predetermined genetic, environmental, neurocognitive, and random influences over which the individual has no ultimate control. In the libertarian model, human choices are held to be entirely the responsibility of the individual concerned, independent of any outside influence. In the compatibilist model, which tries to reconcile these two opposites, acknowledgement is made of the fact that certain mental deficiencies—for example, in legal insanity and infancy or, in neuroscientific terms, lack of cognitive or affective control—might undermine the capacity for free choice. With respect to the logical response to individuals who transgress societal norms, in the deterministic model punishment makes no sense at all, whereas in the libertarian model, retributive punishment is easily justified on the grounds that the individual has willfully and freely chosen to act in a criminal fashion. Currently, the law tends to favor the libertarian perspective with mitigation being allowed only under extreme circumstances—for example, insanity, duress, and certain cases of extreme provocation. With advances in neuroscience, however—for example, the substantial impairments in cognitive control (the ability of an individual to suppress impulsive acts and rationally appraise alternative choices)—that are emerging from research in addiction, the boundaries of the legal response to such problems are likely to be shifted more to the compatibilist perspective, in which case retributive responses become harder to justify. Greene and Cohen (2004) argue for what they describe as a forward-looking consequentialist approach to these problems in which holding people personally responsible for their actions is useful only in so far as it serves to promote the individual's ability to regain self-control through appropriate access to treatment, and to provide the justification necessary for the protection of society through temporary containment. They argue that holding people

responsible simply to justify a retributive response is not scientifically tenable, as in reality there will always be certain factors that can be identified from a person's background that render this response suspect:

> Intuitively, we want to punish those people who truly deserve it, but whenever the causes of someone's bad behavior are made sufficiently vivid, we no longer see that person as truly deserving of punishment. This insight is expressed by the old French proverb: "to know all is to forgive all." (Greene & Cohen, 2004, p. 1783)

Against the background of these philosophical considerations, models of responsibility in addiction will be summarized together with their respective advantages and disadvantages. The overall shortcomings of these models will then be discussed, with particular reference to how societal responses that purport to tackle problems of an addictive nature might actually increase the overall burden of such problems through unforeseen systemic mechanisms. Finally, an alternative model of responsibility in addiction, as a further development of the aforementioned forward-looking consequentialist model, will be advanced, together with a discussion of possible new research methodologies that might be employed to lend scientific weight to the establishment of alternative approaches to the problem of addiction and related behavioral disorders.

MODELS OF RESPONSIBILITY IN ADDICTION

Addiction as a Disease

Modern definitions of addiction focus on the disorder as compulsive use despite ongoing negative consequences (American Psychiatric Association, 2000), rather than necessitating the presence of tolerance and withdrawal syndromes, as important drugs of abuse such as cocaine have little or no associated physical dependency syndromes. Despite the fact that this view of addiction is defined in somewhat tautological medical terms, researchers have amassed considerable evidence to support a disease model (Leshner, 1997; McLellan, Lewis, O'Brien, & Kleber, 2000) ranging from known risk factors, to a typical relapsing course, to associated genetic risk factors (Goldman, Oroszi, & Ducci, 2005; Hurd, 2006). Recent advances in cognitive neuroscience have begun to reveal the mechanisms that underpin the characteristics of addiction, notably how repeated episodes of drug taking consolidate behavior into compulsive use, how the risk of relapse from a drug-free state can persist for years, and how drug-related cues come to control behavior. Common to most if not all drugs of abuse is the release of dopamine from pathways in the brain that,

rather than stimulating pleasure directly as was once thought, serve to govern how the brain interprets signals of reward positively or negatively (incentive salience), which then shape how the brain remembers what was most rewarding (stimulus-reward learning) and how the brain then selects which rewarding goals to pursue (stimulus-action learning). There is increasing evidence that drugs of abuse lead to long-term neurological changes in synaptic plasticity, neural structure, gene expression, and protein synthesis that consolidate these patterns of behavior (see Hyman, 2005; Hyman, Malenka, & Nestler, 2006 for detailed reviews). Being an abnormally potent and consistent stimulus for dopamine release, as opposed to natural rewards such as food, shelter, finding a mate, and leisure activities, drugs of abuse usurp these natural rewards in a manner eloquently described by Hyman (2007, p. 10):

> Addictive drugs always signal "better than expected." Neural circuits "overlearn" on an excessive and grossly distorted dopamine signal . . . Cues that predict drug availability such as persons, places, or certain bodily sensations gain profound incentive salience and the ability to motivate drug seeking. Because of the excessive dopamine signal in the prefrontal cortex . . . drugs become overvalued compared with all other goals. Rational goals such as self-care, working, parenting, and obeying the law are devalued. In addition, normal aspects of cognitive control weaken; even if the addicted person wants to "cut down." prepotent cue-initiated drug-seeking responses are extremely difficult to suppress. If the person is successful in delaying drug seeking (or is, for external reasons unable to seek drugs), intense craving may result . . . Because the changes in synaptic weight and synaptic structure that underlie memory are among the longest-lived alterations in biology, the ability of drug-related cues to cause relapses may persist for many years, even a lifetime.

In addition to drug-induced changes resulting in reduced cognitive control, preexisting deficits in prefrontal lobe cortex function resulting either from injury (Damasio, 2007) or from developmental origins, particularly in the area of poor regulation of mood (Charland, 2007), both increase the risk for initiation, maintenance, and relapse of drug-taking, lending further weight to the disease model of addiction.

The modern definition of addiction as compulsive use despite negative consequences has led to the inclusion of certain categories of non-drug-related compulsive behavior under the umbrella of the "behavioral addictions" such as gambling (Potenza, 2006) and compulsive sexual activity (Bancroft & Vukadinovic, 2004; Goodman, 2008; Grant, Brewer, & Potenza, 2006; Mick & Hollander, 2006). This remains controversial, however, particularly in the situation of behaviors that attract strong moral opprobrium, such as sex offending that may be associated with compulsive sexual activity in a propor-

tion of cases, as concern is often expressed from statutory agencies that such a formulation may result in diminution of the offender taking full responsibility for his or her actions. This concern has, on occasion, required offenders to sign agreements prior to entry into therapeutic programs to the effect that sex offending is not an illness, it is a choice. Whilst in the majority of cases this is undoubtedly the case, and the goal of encouraging the taking of full personal responsibility is essential for long-term recovery, such categorical stances might be counterproductive in that they could inhibit an offender's ability to feel free to disclose behavior that he or she perceived to be significantly underpinned by compulsive elements. On the other hand, in other circumstances, particularly when the perceived risk to the public is high, statutory agencies abandon the choice model and call upon the medical model to justify other interventions.

This dualism in approach is strongly illustrated by the fact that, in the United States, a diagnosis of mental illness under the category of *DSM-IV* paraphilia was used as the initial justification for enacting civil commitment laws to detain violent sex offenders indefinitely following the end of their sentences, which, following a U.S. Supreme Court judgment *Kansas v. Hendricks* (1997), have been extended to include those without evidence of mental disorder (La Fond, 2000, 2008). In the United Kingdom, the prevailing view is that sex addiction plays no part in sex offending, although recently there has been some acknowledgement that medical components may play a role in sex offending in terms of the possible benefits of selective serotonin reuptake inhibitor (SSRI) antidepressants and of hormone treatment. More specifically, there has been increasing recognition that conventional cognitive behavioral group therapy programs do not sufficiently address the needs of a subgroup of offenders who exhibit what is described as obsession with sex or deviant sexual interest. As a result, a new therapeutic program, the Healthy Sexual Functioning Program, comparing specialized psychological intervention with SSRIs in a randomized controlled trial methodology is currently underway in the United Kingdom. This program seeks to address the compulsive elements that may underpin sex offending in a proportion of cases (*HSF-SSRI Trial*, n.d.).

The potential advantage of addiction being seen as chronic, relapsing brain disorder is that it is able to reduce the stigma associated with these problems, allow earlier access to more effective treatment programs, and avoid the overuse of ineffective and costly prison sentences (Carter & Hall, 2007). In fact, not only is prison ineffective at tackling drug problems, it is also a high-risk environment for drug initiation. A recent UK study showed that even in the absence of psychological vulnerability, a prison sentence substantially increases the risk of acquiring a new drug habit on leaving prison that did not exist before simply

because of factors such as boredom and the ubiquitous availability of drugs in penal establishments (Boys et al., 2002).

Contrasting with this there have been some unwelcome disadvantages of the disease model of addiction, notably the rapid detoxification regimen that offered hopes of a long-term cure for heroin addiction only to be associated with a substantially increased risk of death from overdose following drug resumption (Hall, 2000). Other examples include: the neurosurgical ablation of the nucleus accumbens to treat addiction on subjects in penal settings in Russia and China where informed consent is doubtful (Hall, 2006), calls for compulsory immunization (Hall, Carter, & Morley, 2004); genetic testing (Sherman, 2006) to target those vulnerable to drug use; and, the more widespread use of coercion and civil commitment for these problems (Hall et al., 2004). Finally, from the point of view of taking responsibility for behavior, the disease model could undermine the development of this responsibility and inadvertently worsen the prognosis for change. These issues will be further discussed later.

Addiction as a Moral Condition or Free Choice

Other authors argue that addiction is a moral condition in that addicts are making a free choice to behave in the way that they are because self-control can be achieved in certain contexts, for example, under the threat of coercion (Satel, 1999), or in the instance of returning Vietnam veterans who in the vast majority of cases were able to simply (apparently) discontinue their heroin addiction indefinitely (Robins, Davis, & Goodwin, 1974; Robins & Slobodyan, 2003), with some doing so through a process of maturing out (Winick, 1962). They also cite that addiction involves a complex series of voluntary acts to achieve the goal of drug taking and cannot be simply regarded as impulsive. An extreme example of this position has been put forward by Foddy and Savulescu (2007), who claim that addictive desires are merely pleasure-orientated desires not qualitatively different from any other preference except in strength, their tendency to tap into direct biological sources of pleasure, and the tendency for them to be socially unacceptable. These authors do not argue that addictive choices are moral ones per se, simply that they are chosen freely because they are a source of pleasure among many other alternatives. To justify this position they argue that there is a long history of the medicalization of behaviors deemed socially unacceptable, for example the so-called disease of drapetomania described by Cartwright (1851) to characterize the behavior of slaves that ran away from their masters. They also provide justification in terms of the fact that not enough is known about the neurobiology of normal desire in that the neuroadaptive changes described in addiction may actually be similar for

any normal preference if that were to be studied in as much detail as addictive preferences have.

Although this position has the advantage of promoting a strong expectation of personal responsibility for behavior, it carries with it the risk of an excessive retributive response to addictive problems. Also, the arguments put forward in favor of this perspective have scientific flaws in that it is well known that the circumstances in which an addiction is acquired strongly influence the specific cues that trigger relapse; therefore, the data on the low incidence of relapse in returning Vietnam veterans is not valid as indicative of self-control in these subjects in that back in the United States the veterans were simply not exposed to the kinds of cues that might have triggered a relapse. In addition, it is becoming increasingly recognized that semiautomatized complex behavioral sequences can be enacted following exposure to drug-related cues through the mechanism of stimulus-action learning described previously. Finally, data from life-course perspective studies of drug and alcohol use, to be described later in this chapter, reveal a picture of a chronic relapsing condition with very significant morbidity and mortality (Hser, 2007) and with an increased risk of relapse in untreated natural recovery groups (Moos & Moos, 2007), which makes it hard to equate addiction with a purely free choice model.

Addiction as a Social Ill

Levy (2007) argues that in addition to considering factors that relate to the individual addict's capacity for self-control or otherwise, due weight needs to be given to the myriad of influences from the social environment that either ameliorate or exacerbate addictive problems. For example, there is a consistent relationship between the relative price of alcohol as determined by taxation level and the extent of alcohol-related harm in any given society (see Chaloupka, Grossman, & Saffer, 2002 for a review of studies). As a possible mediator of this relationship, Levy (2007) gives the example of studies that have examined the ability of normal subjects to exercise self-control in the context of a continuing demand for restraint. Essentially, the longer subjects have to exercise self-control in one task, the less likely they will be able to persist in a subsequent independent task involving the need to exert self-control. This phenomenon has been termed *ego depletion* (Baumeister 2002; Baumeister, Bratslavsky, Muraven, & Tice, 1998) and illustrates that self-control is a limited resource on exposure to the continuing need for self-restraint. The advantages of this approach are that it clearly points to various social policy objectives that could be implemented to reduce the overall burden of addictive problems in a given society by reducing the availability of harmful substances and opportunities

to enact addictive behaviors, but again the disadvantage is that it could serve to deflect from the development of individual responsibility of the addicted person for their recovery.

Addiction as a Variable Lack of Rational Capacity

Morse (2007) argues for a position between the extremes of the brain disease and free choice models by promoting the concept of variable lack of rational capacity in addiction. This concept is similar to that of diminished cognitive control as described by Hyman (2007). Morse, however, sees this lack of rational capacity as a more fluid concept that might wax and wane depending on a variety of factors such as the extent of neurocognitive brain maladaptation as a result of the drug taking itself, the individual's affective state, the presence or absence of social support, or other factors. He recognizes that during periods of active drug taking, an addict's rational capacity might be severely impaired, but during periods of abstinence, the addict should be held responsible for future episodes of nonresponsible behavior; a phenomenon known as *diachronous responsibility* in philosophy. Other authors have enlarged on this concept, stating that just because there is strong evidence for a brain disease element in addiction this does not obviate the addict from all responsibility. Cohen (2007) cites other disease states where this is the case. For example, epilepsy is undoubtedly a brain disease that requires sufferers to nevertheless curtail certain behaviors such as driving if this would pose a risk to themselves or others. Similarly, he cites the case of HIV-infected individuals who may have to refrain from certain forms of sexual activity in order to prevent them from harming others. Cochrane (2007) adopts a similar interactional perspective, arguing that trying to claim that addiction is either a brain disease or a moral free choice is a false dichotomy because both perspectives are useful to achieve worthwhile goals; the neurobiological in terms of greater understanding of the addict's predicament and opportunities for the development of new effective therapies, the moral in so far as it can help to motivate addicts to muster sufficient rational capacity to take responsibility for their actions.

What is increasingly clear, however, is that good rational capacity or self-efficacy, the self-belief that an addict has the capacity within herself to take responsibility and maintain abstinence, is consistently one of the best predictors of long-term abstinence in numerous studies. For example, in the well known study Project MATCH (matching alcoholism treatments to client heterogeneity) comparing Motivational Enhancement Therapy (MET), Cognitive Behavioral Therapy (CBT), and Twelve-Step Facilitation (TSF), readiness to

change and self-efficacy were the strongest predictors of long-term drinking outcome (Project MATCH Study Group, 1998).

Consideration of the many studies that have been published by Project MATCH provides some valuable insights as to how self-efficacy might be promoted in differing groups of people with addictive problems. The self-efficacy study was originally designed to test the hypothesis that it would be possible to allocate subjects presenting with alcohol-related problems into one of the three previously described treatment conditions on the basis of their characteristics at recruitment. For example, it was predicted that subjects with high initial anger would respond best to MET, subjects with psychiatric symptoms to CBT, and subjects with strong network support for drinking to TSF, an intervention that encouraged participants to attend Alcoholics Anonymous (AA). Overall results did not support the matching hypothesis in that broadly speaking the outcome was similar in all of the three groups studied. However, more fine-grained statistical analyses revealed that the subjects with the most anger at presentation did respond preferentially to MET (Project MATCH Study Group, 1998), that subjects with the highest levels of network support for drinking did respond better to TSF (Project MATCH study group, 1998), and, crucially, that subjects with low initial self-efficacy (i.e., those one would expect to fare the worst) responded best if they received CBT (Witkiewitz, van der Maas, Hufford, & Marlatt, 2007) and if the therapist was able to establish a strong therapeutic alliance with the client (Ilgen, Tiet, Finney, & Moos, 2006). Self-efficacy was also found to both mediate the relationship between AA attendance and positive drinking outcome as well as AA attendance itself having positive effects on the development of self-efficacy (Bogenschutz, Tonigan, & Miller, 2006; Connors, Tonigan, Miller, & MATCH Research Group, 2001).

However, a note of caution is necessary concerning the Twelve-Step approach, as there is evidence that, because of the strong emphasis on spiritual beliefs in AA, atheist or agnostic alcoholics are far less likely to initiate or sustain contact with AA than those with preexisting religious beliefs (Tonigan, Miller, & Schermer, 2002). In addition, the first three steps "we admitted we were powerless over alcohol—that our lives had become unmanageable," "came to believe that a Power greater than ourselves could restore us to sanity," and "made a decision to turn our will and our lives over to the care of God as we understood Him" together with AA's understanding of alcoholism as a disease (Alcoholics Anonymous, 1953) could have the tendency to undermine the sense of personal responsibility for one's actions in the long-term despite increases in self-efficacy in the short-term. There is some evidence that this

might be the case, as self-efficacy and not AA attendance substantially reduced the risk of relapse in a 16-year follow-up study of alcoholics (Moos & Moos, 2007). Alternative self-help organizations not using the Twelve-Step approach have more recently emerged, namely SMART Recovery (http://www.smartrecovery.org/) and Rational Recovery (http://www.rational.org/), that are based on secular and scientific principles. Drawing on research evidence of the use of MET, CBT, and Rational Emotive Behavior Therapy, SMART Recovery (Self Management and Recovery Training) views addictive behavior as a dysfunctional choice rather than a disease, although it acknowledges that certain people for genetic and neurobiological reasons may have a predisposition to addiction. It divides the process of recovery into four phases—building motivation, coping with urges, problem-solving, and lifestyle balance—and aims to provide participants with the cognitive tools to deal with these challenges as well as support through facilitated meetings. Rational Recovery places even greater emphasis on self-efficacy and is based on a cognitive technique of challenging the so-called addictive voice (internal distorted thinking that supports intoxication). It does not view addiction as a disease but as a voluntary choice, and it discourages the adoption of the forever recovering alcoholic persona that can be a consequence of prolonged AA attendance. As yet, these two secular approaches have not been studied in as nearly as much detail as AA participation, and it remains to be seen as to whether they, in combination with professional interventions, offer the opportunity for greater development of self-efficacy in the long-term than Twelve-Step approaches.

PROBLEMS WITH THESE MODELS

The aforementioned models of responsibility in addiction have certain weaknesses. With the exception of the variable rational capacity model, they tend to view addiction in exclusive rather than inclusive terms; in other words, addiction is either completely a brain disease or a completely free choice, whereas the consensus view that is emerging is that the risk for developing an addiction is multifactorial. In addition, these models tend to underemphasize the developmental and life-course perspective on addictive problems; they tend to focus on relapse prevention and negative outcomes rather than on what promotes a good life and long-term positive outcomes. Finally, they also tend to underacknowledge the reciprocal relationship between societal responses, social policy, and legal perspectives on the likelihood of positive versus negative outcomes in addictive behaviors. These problems will be briefly reviewed in the following sections, followed by a description of an alternative comprehensive model of responsibility in addiction.

The Developmental and Life-Course Perspective on Addiction

One of the first studies to examine the developmental antecedents of drug use was the classic study by Shedler and Block (1990), who followed up a cohort of subjects from preschool to 18 years to examine what factors predicted subsequent drug use. They found that the subjects fell into one of three groups: the experimenters who had the best psychological adjustment at 18, the abstainers who tended to be anxious and lacking in social skills, and the frequent drug user group who showed a distinct behavioral profile of interpersonal alienation, poor impulse control, and emotional distress. Membership of these groups was predicted by the quality of parenting received in early childhood, and therefore these authors argued that drug use was a symptom, not a cause, of an underlying developmental problem of self-regulation stemming from suboptimal parenting experiences. Since this original study, the notion that experimenters were better adjusted than abstainers has been refuted (Milich et al., 2000; Tucker, Ellickson, Collins, & Klein, 2006), but numerous other studies have confirmed the association between adverse early life experience including abuse, social disadvantage, poor parenting, parental substance misuse, and delinquent peer affiliation with subsequent problems with behavioral self-regulation and substance misuse (Castro, Brook, Brook, & Rubenstone, 2006; Doherty, Green, Reisinger, & Ensminger, 2008; Fergusson, Horwood, Boden, & Jenkin, 2007; Fothergill & Ensminger, 2006; Kliewer & Murrelle, 2007; Marcenko, Kemp, & Larson, 2000; McCauley et al, 1997; Roche, Ahmed, & Blum, 2008; Wong et al., 2006). In addition, these problems appear to be additive, with no one single factor exerting a predominant influence (Melchior, Moffitt, Milne, Poulton, & Caspi, 2007). In short, there is robust data to indicate that adverse early life experience predicts the initiation of substance abuse in later life. With respect to models of responsibility, therefore, there is a need to broaden the concept of responsibility from the individual to parents, society, and policy makers, as these factors increase the likelihood of addiction in young people via the mechanisms of poor parenting, socioeconomic disadvantage, and inadequate educational opportunities.

In contrast to these factors responsible for initiation of drug use, a separate set of factors connected broadly to the concept of individual responsibility and self-efficacy appear to operate regarding maintenance of cessation of drug use once it has started. Data from life-course perspective studies of substance misuse provide valuable insights in this regard. Using a sophisticated longitudinal statistical methodology called growth mixture modeling in a 33-year follow-up study of heroin usage, three groups of addicts were identified within the sample: early quitters, stable high-level users, and late decelerated users (Hser,

Huang, Chou, & Anglin, 2007). The early quitter group had a later onset of drug use than the other two groups, lending support to the notion that early intervention is important to prevent long-term severity of addiction as has been identified by other workers (Anthony & Petronis, 1995). In a separate analysis of this same cohort, self-efficacy and reduced psychological distress were predictive of long-term stable recovery from heroin addiction, whereas childhood factors of disadvantage and family problems were not predictive of ongoing use (Hser, 2007).

These data indicate that a developmental and life-course perspective is essential when planning therapeutic, social, and legal responses to the problem of addiction, as different influences operate at multiple potential branch points in the trajectories of change throughout the lifetime of someone suffering from an addiction. It is imperative that such research methodologies are adopted more comprehensively if progress is to be made in tailoring interventions that are appropriate at each stage in the developmental progression of addiction.

Relapse Prevention and Negative Outcomes versus the Good Life and Positive Outcomes

The model outlined earlier examining the influence of the social environment as it relates to ego depletion has quite profound implications for the approach to addictive behaviors and indeed offending behavior in general as it may serve to explain why relapse-prevention strategies might ultimately be self-defeating, as the ability to exercise self-restraint over prolonged periods in the absence of altering the fundamental desire is problematic. Indeed, a recent study examining eight-year recidivism in sex offending following a well-designed randomized controlled trial of a relapse-prevention program found no beneficial effect (Marques, Wiederanders, Day, Nelson, & van Ommeren, 2005). In contrast, new approaches to the treatment of sex offending, collectively known as the good lives model are showing great promise (Ward, Mann, & Gannon, 2007). These approaches seek to reformulate this troublesome behavior as a dysfunctional way of meeting basic human needs or goods. The approach is based on working with offenders to establish a set of positive, pleasurable, prosocial life goals that build motivation for change in ever-increasing positive feedback loops as new goods such as jobs, appropriate relationships, and hobbies are acquired. This serves to devalue and reduce the intensity of the desire previously attached to deviant sexual behavior, thus placing less stress on the limited resource of self-control. A sole emphasis on relapse prevention, often accompanied by the use of extensive avoidant coping strategies and resulting social exclusion leads to profound deficits in social goods, and this does nothing to devalue the devi-

ant desire, thus increasing the risk that self-control will eventually break down (for a criticism of the Marques study see Marshall & Marshall, 2007). A similar good lives social inclusion approach to the management of sex offending is known as circles of support and accountability (COSA), whereby offenders, often at substantially high risk of reoffending, are offered regular support and mentorship by a group of especially trained community volunteers who both work with the offender to identify appropriate positive goods that can be achieved and serve to challenge any distorted thinking that might lead to relapse. Results of evaluations so far have been highly impressive, showing a 70 percent reduction in recidivism compared to a matched comparison group with communities stating that they felt safer knowing that a COSA group was functioning in their area (Wilson, Picheca, & Prinzo, 2005). These findings have been replicated using the same approach in the United Kingdom (Quaker Peace & Social Witness, 2003).

Similar models have been put forward in general criminology and in studies of the prolonged lifetime use of heroin where the concept of the loss of social capital (Sampson & Laub, 1992, 1993) as a result of imprisonment contributes significantly and progressively to the difficulty in establishing abstinence. This model also offers an explanation as to why early intervention and cessation of drug use before too much social capital has been lost is associated with long-term recovery (Hser, 2007). In addition, as mentioned before, life-course studies show that positive alcohol- and drug-free long-term recovery is promoted by self-efficacy and approach-focused, as opposed to avoidant, coping strategies (Hser, 2007; Moos & Moos, 2007).

Generally speaking, it is easier for all human beings to motivate themselves toward a positive goal, doing something, rather than an avoidance goal, not doing something. In relation to the data on ego deletion, this has important implications with respect to treatment intervention studies, and social and legal policy in relation to addictive behaviors, to ensure that the balance is weighted in favor of the realistic opportunity to achieve positive goals rather than on excessive demands for the addict to comply with negative, risk-informed, avoidance behaviors and punitive control that are likely to be counterproductive in the long term.

The Reciprocal Influence of the Social and Legal Context

As well as being mindful of developmental, life-course, and negative versus positively focused interventions, the profound influence of societal reactions, social policy, and legal frameworks with respect to the individual expression of addictive behavior has to date been grossly underestimated. Very often, and

particularly in relation to behaviors that cause society the most anxiety and opprobrium, excessive focus is attached to the punitive management and containment of those identified as exhibiting the behavior, with little regard as to how this approach might deter those at an early stage of these behaviors from seeking appropriate help to prevent further harm.

There is concrete evidence to suggest that this is occurring with respect to the emotive issue of child sex offending in the United States. In the summer of 1996 in Vermont, the Stop It Now! organization, a charity that seeks to prevent child abuse by offering confidential telephone support to those worried that a child might be being abused and to potential abusers who are contemplating committing an offense, launched its pilot site. Initially almost 60 percent of the calls were from sexual abusers or those at risk of abuse. When news of Megan's Law (open access community notification on the whereabouts of known sex offenders in the United States) emerged in the Vermont press, the number of phone calls from these groups fell to zero. This indicates that a social policy purportedly designed to protect children from the threat of strangers was now inhibiting others from disclosing about abuse in the home, which in any case accounts for 80–96 percent of all cases of child abuse. In addition, abusers themselves were going underground, further increasing the risk to children (Fitch, 2006). The Stop It Now! organization described the problem thus:

> The specter of notification, the accompanying shame, the potential vigilante response from the community, the inability to restore life to some level of normalcy post-release, the potential for the humiliation of other family members besides the abuser him/herself are all deterrents [from voluntary disclosure by victims and abusers] in a very real way. (Deborah Dobovan Rice of Stop It Now!, written communication, quoted in Fitch 2006, p. 37)

This data would suggest that there may be a reciprocal relationship between the perceived level of vilification and punitive control of known sex offenders and the willingness of both victims to disclose an offense (particularly in the largest category of intrafamilial abuse) and people worried about their sexual behavior from coming forward for help that might prevent abuse from occurring. Although the situation in the United Kingdom does not entail widespread community notification as in the United States, being placed on the sex offenders register is often reported in the press at the time of sentencing and is associated with significant social stigma. There is also continuing pressure from various quarters for the introduction of U.S.-style notification, and it is therefore likely that similar fears of disclosure by victims and potential abusers are operating in the United Kingdom too. As an illustration of the scientific irrationality of these policies, a hypothetical model is presented below based

on UK Home Office data on the frequency of child sex offending in England and Wales, the numbers of registered child sex offenders in England and Wales, and the 16 percent prevalence of the concurrent level of abuse of children in the United Kingdom under the age of 16 (Cawson, 2000). The number of predicted offenses committed by registered offenders has been multiplied by a factor of three, as on average it has been found that there are three victims for each index offense (Beech, Fisher, & Beckett, 1998). Even despite this loading, the model clearly suggests that if the overall burden of child sexual abuse is to be reduced, then policy needs to switch significantly toward more investment in preventative intervention (see Table 4.1 and Figure 4.1) alongside a more positively orientated good lives and COSA model of support and supervision of known offenders that is less likely to deter victims and potential abusers from voluntary disclosure. Moreover, a recent report by the National Society for the Prevention of Cruelty to Children (NSPCC) in the United Kingdom highlights the need for primary prevention:

> The NSPCC recommends that treatment services must be available for individuals who come forward because they are worried about their own thoughts, feelings and behaviors. This would ensure that there is a primary prevention element in the provision of services. (NSPCC, 2006, p. 21)

A similar model could be hypothesized with respect to the reluctance of heroin users to present early for treatment because of fears of prosecution. Given the importance of early intervention for reducing the risk of developing a severe, life-course persistent trajectory of drug use, new social and legal policy needs to be subject to this kind of analysis as to its likely effect on the overall burden of addiction prior to implementation.

6PR: An Alternative Model of Responsibility in Addiction

In order to encompass the multiple perspectives necessary to ensure a reasoned, balanced, scientific, and humane response to the problem of addiction, this chapter will conclude with a proposed list of factors and key questions against which any new therapy, social policy, or legal framework should be tested prior to implementation. The factors to be discussed have been given the acronym 6PR, which stands for: personal, public, positive, pragmatic, preventative, and panoramic responsibilities.

1. Personal responsibility
    a. To what extent and by what mechanisms does the proposed intervention promote the development of self-efficacy so as to foster the ability of the addict to manage his own behavior successfully over the life-course?

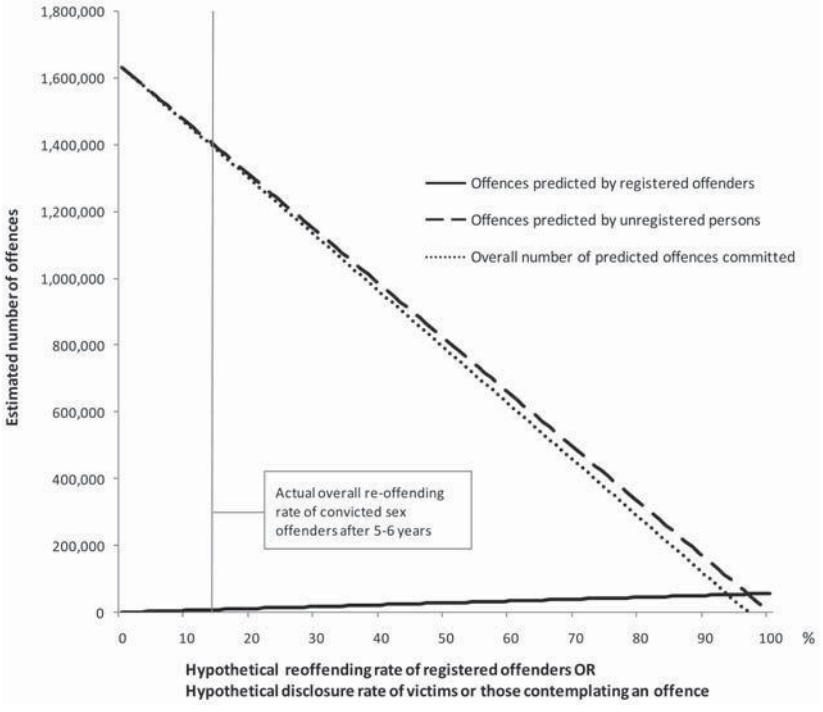

FIGURE 4.1: Hypothetical model of child sex offending assuming a reciprocal relationship between the perceived level of punitive control of registered offenders and spontaneous disclosure by victims or those contemplating an offense.

b. Are there any adverse effects from other influences that are likely to counteract the intended results of the intervention or diminish the addict's capacity for self-efficacy?

2. Public responsibility

   a. Will the proposed social policy or legal intervention exacerbate the problem in question?
   b. Will the proposed social policy or legal intervention reduce the overall burden of the problem in question?

3. Positive responsibility

   a. Is the proposed intervention based on a good lives model?
   b. Is the proposed intervention based on increasing the likelihood of a positive outcome and not just the avoidance of a negative one?

Table 4.1
Figures for Child Sex Offending in England and Wales for 2006–2007 on Which the Graphical Representation of the Hypothetic Model in Figure 4.1 is Based

Figures for 2006–2007	
Total population in England and Wales[a]	53,728,800
Child population < 16 years in England and Wales[a]	10,236,100
Percentage of population under 16	19.05%
Total number of sex offenses committed in England and Wales[b]	57,542
Number of child sex offenses committed in England and Wales[b]	35,024
Conviction rate for child sex offenses	0.000652
Predicted number of offenses from conviction rate	6,673
Concurrent sexual abuse in UK children < 16 years[c]	16%
Estimated actual number of offenses	1,637,776
Estimated number of offenses committed by unregistered persons	1,631,103
Estimated percentage of offenses committed by unregistered persons	99.59%
Number of sex offenders register in England and Wales	29,973
Estimated number of child sex offenders on register[d]	18,244
Average number of victims per index offense[e]	3
Actual overall reoffending rate of convicted sex offenders[f]	13.7%

[a]Data from http://www.statistics.gov.uk.
[b]Data from Table 2.04, http://www.homeoffice.gov.uk/rds/crimew0607.html.
[c]Cawson (2000).
[d]Data on the age of the victim is not recorded on the register, so this figure is estimated from the ratio of the number of child sex offenses to the total number of sex offenses committed.
[e]The numbers of predicted offenses by registered offenders has been multiplied by a factor of three (Beech et al., 1998).
[f]Hanson and Morton-Bourgon (2005) report an overall recidivism rate of 13.7 percent from 82 studies following up 29,450 offenders over an average of five to six years.

4. Pragmatic responsibility
    a. Is the proposed intervention likely to produce the maximum benefit for the maximum number of people?
    b. Does the proposed intervention avoid excessive retributive elements that may exacerbate the overall problem?
5. Preventative responsibility
    a. Does the proposed intervention increase or decrease the likelihood that those with addictive behaviors will present at the earliest opportunity for help?

   b. Does the proposed intervention increase or decrease the likelihood that victims of addictive behavior will be able to disclose?

6. Panoramic responsibility
   a. Has the proposed intervention been examined for its potential impact in all relevant areas to ensure there are no adverse unforeseen consequences?
   b. Is the scientific method used to evaluate the intervention sufficiently wide ranging to model all the relevant variables?

In order to answer these questions scientifically, it may be necessary to integrate and further develop methodologies to accommodate the multiple influences at work. For example, the promising techniques of growth mixture modeling in the life-course analysis of addictive behavior may need to be integrated with new techniques in social network analysis (Butts, 2008; Hall & Valente, 2007) in order to simultaneously model individual developmental trajectories against societal influences so as to begin to answer the difficult and emotive questions that addictive behavior raises as rigorously as possible. Armed with this new information, and alongside advances in the cognitive neuroscience of addictive problems, there are grounds for optimism in tackling one of mankind's most troublesome and baffling afflictions.

Chapter **5**

Religiosity as Protective against Addictions in Adolescents

Patrick McNamara, PhD, and James Burns, PhD

There is now substantial evidence supporting the claim that religiousness can protect against a variety of addictions in adolescents (see Smith, 2003, for review). We believe that the evidence is strong enough to justify a search as to how religion confers its protective effects on adolescents. What does religion do for adolescents that allows them to avoid addiction? In what follows, we first review key findings in the literature demonstrating protective effects of religion against addictions in adolescents. We then summarize potential mechanisms for this protective effect. Among these potential mechanisms are the interactions between religious beliefs/practices and the developing brain. Because these latter interactions have been neglected in the literature, we focus on these protective interactions in an effort to identify potential mediating pathways for religion's effects on adolescent risk for addiction.

DEFINITIONS OF RELIGIOSITY

Studies of adolescent substance use have used various definitions of *religiosity* (Wallace & Williams, 1997). In most studies of the impact of religiosity on health-related outcomes, including substance use and addictions more generally, religiosity was measured with only a single question or a single subscale indexing frequency of attendance at religious services. Recent theoretical work, however, suggests that the broader construct of religiousness is multidimensional, including facets of belief, private religious practices, participation in ritual services, and coping (Fetzer Institute, 1999; George, Larson, Koenig, & McCullough, 2000; McNamara, 2002). For purposes of this chapter, we will define religiosity as composed of two major factors: perceived importance of a

belief in God (faith) and religious *practices* associated with faith-related institutions (rituals, prayer, worship, etc.).

RELIGIOSITY CONFERS A PROTECTIVE EFFECT AGAINST ADDICTION IN ADOLESCENTS

Recent reviews of the literature on potential protective effects of religiosity against addiction in both adults and adolescents have demonstrated that greater religiosity, as measured by participation in religious services or by strength of religious convictions, is associated with lower risk of use of addictive substances (Blyth & Leffert, 1995; Booth & Martin, 1998; Galanter, 2006; Gorsusch, 1995; Koenig, McCullough, & Larson, 2001). Findings from the National Study of Youth and Religion (Smith & Faris, 2002) support a strong inverse relationship between religiosity and addictions in adolescence. After controlling for a host of potential confounders, the survey of a national sample of 2,478 teens found that religious high school seniors were less likely to smoke, drink, or use illicit substances than their less religious counterparts. Brown, Schulenberg, Backman, O'Malley, and Johnston (2001), also examined a nationally representative sample of high school classes who graduated between 1976 and 1997 (N = 188,000). The researchers, who were interested in whether the correlates of tobacco use changed across time, surveyed a random sample of 15,000 and 19,000 high school seniors from approximately 135 high schools each year. The investigators found a highly consistent association between lower cigarette use and greater religious involvement across the 22-year study period. There is little doubt therefore that an inverse relation exists between religious involvement and engagement in risky behaviors associated with addiction.

Religious involvement of course is complex and means many different things to as many different people. What aspects of religious involvement are most effective for protecting against addiction? One of the strongest predictors of protective effects of religion in adolescence is the variable frequency of attendance at religious services (Adlaf & Smart, 1985; Amey, Albrecht, & Miller, 1996; Foshee & Hollinger, 1996; Hadaway, Elifson, & Petersen, 1984; Wallace & Williams, 1997). Attendance at ritual services either yields a direct protective benefit or it may do so indirectly, perhaps through reinforcing religious beliefs or through extending the social networks of participants, encouraging prosocial attitudes leading to engagement in prosocial behaviors such as those motivated by learned altruism. There is some evidence that both of these factors may be operative. For example, strength of belief in religious tenets is strongly and inversely related with substance abuse (Bahr, Maughan, Marcos,

& Li, 1998; Barnes, Farrell, & Banerjee, 1994; Brown & Gary, 1991; Jessor, Chase, & Donovan, 1980; Jessor & Jessor, 1977; Resnick et al., 1997). Jessor and colleagues (Jessor et al., 1980; Jessor & Jessor, 1977) have found that a scale on the perceived importance of religion was inversely related to measures of problem drinking in regional and national samples of high school students. It is not clear, however, that this effect of perceived importance was independent of attendance at religious services. Nevertheless, these studies clearly show that both belief and attendance are critical to the positive effect of religiosity.

MECHANISM OF THE PROTECTIVE EFFECT

In his recent systematic review of the literature on religion's protective effects on adolescents, Smith (2003) identified several key factors that could potentially mediate religion's constructive effects: moral directives, spiritual experiences, role models, community and leadership skills, coping skills, cultural and social capital, network closure, and extracommunity links. He summarized these factors as clustering into three major domains of functioning: learned competencies; moral order, and social/organizational ties. In this chapter we focus on the first of these three domains of functioning: namely, learned competencies.

LEARNED COMPETENCIES IN PROTECTION AGAINST RISK: THE KEY ROLE OF IMPULSIVITY AND POOR DECISION-MAKING/PLANNING IN ENHANCING RISK

Two of the most robust proximate predictors of adolescent risk behaviors are impulsivity and poor decision-making and planning (Boyer, 2006; Hawkins et al., 2000). Impulsivity and poor decision-making reflect the failure to learn or to acquire the crucial set of skills that allows one to stop, think, and plan for the most optimal outcomes under conditions of stress. Stanford and colleagues (Stanford, Greve, Boudreaus, & Mathias, 1996) demonstrated, with a reasonably large sample of adolescents and young adults ($N = 1{,}100$), that highly impulsive individuals were more likely than less impulsive individuals to engage in a number of risk-taking behaviors (e.g., peer aggression, drunk driving, and drug use). Several investigators (Beyth-Marom, Austin, Fischhoff, Palmgren, & Jacobs, 1993; Furby & Beyth-Marom, 1992; Steinberg, 2006) have pointed out that adolescents and adults are equally aware or knowledgeable concerning the potential for adverse consequences in risky situations, but adolescents tend to impulsively discount the costs of risky situations and fail to plan or to take steps to avoid risky situations. Adolescent impulsivity and decreased ability to

be playful may be further related to a decreased recognition of being addicted as well as a challenge to recovery for the stages of change necessary for sufficient movement away from addictive surroundings and behaviors. This is known to require a contemplative state that precedes action (Prochaska, DiClemente, & Norcross, 1992).

Studies of the relation between risk taking and cost versus benefit analyses in adolescents suggest that young people who score high on traits such as impulsivity, novelty seeking, and reward dependence tend to discount long-term costs and unduly augment short-term benefits and thus are more likely to engage in risky behavior (e.g., Fromme, Stroot, & Kaplan, 1993; Goldberg & Fischhoff, 2000; Horvath & Zuckerman, 1993; Lavery, Siegel, Cousins, & Rubovits, 1993; McBride, Weatherby, Inciardi, & Gillespie, 1999; Singer, Dai, Weeks, & Malave, 1998; Thorton, Gibbons, & Gerrard, 2002). We suggest that the effects of these traits on risk of substance abuse or for addiction more generally may be moderated by religiosity levels and cognitive functions that regulate impulsivity levels. There is a large independent literature on the cognitive functions implicated in control of impulsivity and poor decision-making when individuals are under stress. Those cognitive functions (or learned competencies) are typically called the executive cognitive functions (ECFs).

EXECUTIVE COGNITIVE FUNCTIONS VERSUS IMPULSIVITY IN ADOLESCENCE

Executive Cognitive Functions (ECFs) refer to such functions as planning, initiation, impulse control, cognitive inhibition, attention, monitoring, and adjustment of nonroutine and goal-directed behaviors. ECFs allow for inhibition of impulses, delay of gratification of wishes, and thus accurate appraisal of long-term future rewards versus immediate short-term and more salient rewards. When ECF development is delayed, self-control and self-regulation are also delayed and can be significantly derailed. Thus, risky behaviors are more likely. A substantial body of research supports our conjecture. For example, early self-regulatory abilities as measured by ECF tasks significantly predict later cognitive and social competencies (Metcalfe & Mischel, 1999; Mischel, 1983; Mischel & Ayduk, 2004; Mischel, Shoda, & Peake, 1988; Mischel, Shoda, & Rodriguez, 1989; Sethi, Mischel, Aber, Shoda, & Rodriguez, 2000).

We can get some idea of normative development of ECFs in typically developing children via administration of neuropsychologic tests that tap various executive processes such as the Stroop task, the go/no-go or stop signal tasks, verbal fluency measures, and card sort tasks. The standard Stroop task requires respondents to name the ink color of either 100 patches of the colors red, blue,

and green or 100 color names printed in a discrepant ink color. The subject has to inhibit the impulse to read the name rather that to report the color, and thus the outcome measure is the difference in the time required to complete the two tasks (color words minus color patches). In the Stop-signal task, respondents are told to stop responding with button presses to a visual stimulus (letter X or O) when hearing a tone (stop signal). The outcome measure is the minimum delay between the onset of stimulus and tone necessary to stop the response, the so called stop-signal reaction time (SSRT). In verbal-fluency tasks, respondents are asked to produce all the words they can think of in a given category like animals (semantic fluency) or as many words as they can starting with a certain letter (phonetic fluency). All tasks are timed. Levin et al. (1991) found an increased ability to inhibit responses with increasing age on the go/no-go test in a normal sample. Impulsive errors (commissions) declined steadily up to adolescence and then plateaued. Williams, Ponesse, Schachar, Logan, and Tannock (1999) reported similar findings for this task. Using a matching to sample type task, Welsh, Pennington, & Grassier (1991) also found that impulsive responding matured by age 10. Brocki and Bohlin (2004) assessed a variety of ECFs in children and adolescents and then conducted dimensional analyses on performance scores. The dimension interpreted as speed/arousal seemed to be the first one to reach maturity, with the most active period of development occurring around the age of eight. The withholding dimension of inhibition revealed maturity around age 10, along with the first developmental spurt on the fluency factor. The second developmental spurt on working memory/fluency continued into adolescence.

In short, for most typically developing children, inhibitory ECFs as measured by stop signal and Stroop-like tasks develop up to the time of puberty and then level off, while working memory and verbal fluency skills continue to mature into the adolescent period.

These neuropsychologic results are consistent with a host of recent neuroimaging studies of the developing brain (reviewed in Blakemore, den Ouden, Choudhury, & Frith, 2007, and Paus et al., 2001). Both gray and white matter volumes increase in most brain regions until puberty. After puberty, gray matter volumes do not change significantly, while white matter volumes continue to increase. Giedd et al. (1999) observed a linear increase in gray matter volume in the parietal and frontal regions between four years of age and the approximate age of onset for puberty. In girls, the asymptote for these anatomical developments was at 10.2 years in the parietal cortex and 11.0 years in the frontal cortex. For boys, the asymptotic ages were 11.8 years and 12.1 years for the two respective areas.

These neuroanatomical and neuropsychologic data suggest that trajectories involving acquisition of new inhibitory ECF capacities begin to decline with

the onset of puberty. Thus, the child must cope with pubertal changes and hormonal surges with whatever inhibitory ECFs he or she has developed up until pubertal onset. Any additional resources that can enhance ECF capacities, therefore, would presumably help the child deal with pubertal changes. We suggest that one such resource is religion. This supposition predicts that children who utilize religious practices to self-regulate impulsivity levels after puberty will be better able to regulate impulsivity levels than children who do not utilize religious practices.

To show how religion can be used as a resource to self-regulate impulsivity levels, it will be necessary to go into greater detail on the neurobiology of addiction and of impulsivity more generally.

BRAIN BASES OF ADDICTION: FRONTAL LOBES, DOPAMINE, AND IMPULSIVITY

The prefrontal cortex (PFC) constitutes approximately one-third of the human cortex and is the last part of the human brain to become fully myelinated in ontogeny, with maturation occurring in late childhood/early adolescence (Huttenlocher & Dabholkar, 1997). The PFC receives projections from the mediodorsal nucleus and gives rise to the primary motor cortex, as well as premotor, supplementary motor, and the dorsal and orbital sectors of the prefrontal (proper) lobes. All of these PFC areas send inhibitory efferents onto their sites of termination in other areas of the brain and spinal cord, thus suggesting a supervisory or regulative role for the PFC.

Impairment in prefrontal cortical function in humans is functionally implicated in virtually every major neuropsychiatric disorder, including depression (Starkstein & Robinson, 1991), schizophrenia (Lewis, Cruz, Eggan, & Erickson, 2004), obsessive-compulsive disorder (Tek & Ulug, 2001), bipolar disorder (Haznedar et al., 2005), Parkinson's disease (Starkstein & Merello, 2002), Huntington's disease (Troster & Woods, 2003), the disinhibitory impulsivity syndromes (Berlin, Rolls, & Iversen, 2005), addictions (Winstanley, Theobald, Dalley, Cardinal, & Robbins, 2006), and several others besides, such as memory retrieval dysfunction and the dementias (Cummings & Mega, 2003). The frontal lobes mediate what are believed to be distinctively human mental capacities, such as language generativity (Miller & Cummings, 1999), autobiographical memory retrieval (Wheeler, Stuss, & Tulving, 1997), theory of mind (Baron-Cohen, 2004) empathy (Adolphs, Baron-Cohen, & Tranel, 2002), working memory (Goldman-Rakic, 1987), executive functions (Goldberg & Bougakov, 2005), impulse control (Berlin et al., 2005), volition (Passingham, 1995) and possibly even the sense of self (Northoff & Bermpohl, 2004).

NEUROCHEMISTRY OF FRONTAL LOBES

The frontal lobes are densely innervated by dopaminergic (DA) fibers originating in the ventral tegmental area (VTA) and the substantia nigra (SN). The nigrostriatal system indirectly influences the frontal lobes through the basal ganglia. The mesocortical system originates in the VTA and terminates in the ventral striatum, amygdala, nucleus accumbens, and the frontal lobes. This latter mesocortical system is crucially important for understanding human behavior as its stimulation appears to be intrinsically rewarding. All drugs/substances of addiction, for example, appear to derive their addicting properties by their abilities to potently stimulate this frontal dopaminergic system. Dopamine neurons of the VTA and SN have long been associated with the reward and pleasure systems of the brain. Virtually all of the known addictions (including cocaine, heroin, amphetamines, alcohol, food, and sex) exert their addictive actions, in part, by prolonging the influence of dopamine on target neurons (Wise, 2005). VTA DA neuron responses appear to be necessary to facilitate formation of associations between stimuli that predict reward and behavioral responses that obtain reward (Schultz et al., 1995). The orbital frontal cortex integrates the most complex level of associations of reinforcement with both stimuli and responses (Rolls, 2004). In summary, stimulation of dopaminergic terminals in the mesolimbic-frontal systems constitutes the substrate for a most potent reward/reinforcing system and thus the substrate for addiction. PFC inhibitory efferents that terminate onto orbitofrontal, limbic, VTA DA and brainstem arousal centers constitute the substrate for control of impulsivity levels. To the extent that religion can engage PFC inhibitory circuits, it can function to control impulsivity levels.

RELIGION AND THE FRONTAL LOBES

Religiosity has traditionally been linked to the temporal lobes (e.g., Bear & Fedio, 1977; d'Aquili & Newberg, 1993; Persinger, 1987; Ramachandran, Hirstein, Armel, Tecoma, & Iragui, 1997). But most of the evidence for a role of the temporal lobes in religious experience was based on observations of the behaviors of a small subset of temporal lobe epileptics who exhibited the interictal behavioral syndrome (Bear & Fedio, 1977; Dewhurst & Beard, 1970;. The so-called syndrome included hyperreligiosity as one of its signs. D'Aquili and Newberg (1993) very sensibly assume that all the major association areas of the cortex generate some aspect of the total religious experience. In their models, the temporal lobes attach meaning and significance to events, while posterior parietal sites participate in construction of both the sense of self and the accom-

panying sense of the dissolution of the self during mystical states. With respect to the frontal lobes, d'Aquili and Newberg (1993) reviewed a number of studies that apparently established a link between sustained attention associated with the practice of meditation and electroencephalography (EEG) theta waves above the prefrontal cortex. The EEG data therefore suggests that sustained meditation results in activation of prefrontal networks. Newberg, Alavi, Baime, Mozley, and d'Aquili (1997) later confirmed these EEG data using single photon emission computed tomography (SPECT) imaging techniques. Regional cerebral blood flow changes were studied in six highly experienced meditators while they meditated. Results demonstrated significantly increased blood flow to the inferior frontal and dorsolateral prefrontal cortical regions while the subjects engaged in intense meditation. More recently and using functional magnetic resonance imaging (fMRI) techniques, Azari et al. (2001) later reported greater dorsolateral frontal, dorsomedial frontal, and medial parietal cortex activation during religious recitation in self-described religious subjects.

In summary, it appears that religious practices do indeed engage prefrontal neural networks and therefore can potentially help regulate impulsivity levels. We now need to suggest how this is accomplished at the cognitive level.

THE INTERACTION OF RELIGIOUS AND PFC ECFS: IMPLEMENTATION INTENTIONS

We postulate that one key way in which religiousness protects against addiction and other risky behaviors throughout childhood is via practice in formulating *implementation intentions* or the ability to translate a motivated intention ("I will not engage in premarital or unprotected sex") into an implementation plan ("I will seek a partner in my religious community who agrees with me about premarital sex" or "If my boyfriend pressures me for sex, then I will insist on condom use and I will present to him a condom"). All religions emphasize development of moral character, of putting into practice a suite of moral behaviors and inhibiting sinful or sanctioned behaviors. A host of religious practices are recommended as aids in this character formation process. These religious and spiritual practices are recommended as aids against temptation and tools to help implement good behaviors. We contend that religious practices also help the individual form implementation intentions.

RELIGIOUSNESS AND IMPLEMENTATION INTENTIONS

Spiritual practices can enhance the ability to generate effective implementation intentions. Spiritual and religious practices focus the individual's attention

on moral character, right action, follow-through, actions not words, trustworthiness, steadfastness, and so on. Religious practices such as prayer, religiously orientated meditation, devotional worship, attendance at liturgical or ritual celebrations, study of scripture, engaging in charitable practices, and so on are action sequences designed to realize an overall goal of moral character formation (Batson, Schoenrade, & Ventis, 1993; McNamara, 2002). Religious practices like prayer and meditation, for example, are seen as tools to facilitate generation of what we now call implementation intentions in service to that goal. In fact, it is difficult, if not impossible, to fully engage simultaneously in prayer and an addictive behavior(s).

All religious traditions appear to utilize petitionary prayers and rituals directed at supernatural agents to solicit help, strength, and guidance. Similarly, the sacred texts and scriptures are generally read for guidance on how to behave in order to implement the intention to become a good member of the religious group. Likewise, within theistic traditions, participation in ritual services are understood to be occasions to obtain particular powers/graces (e.g., through communion with God) to become a better participant (e.g., Christian). In an exhaustive review of characteristics and functions of rituals, Boyer and Liénard (2006) have pointed out that goal demotion is characteristic of many and perhaps all religious rituals. Performance of the ritual is focused on correct performance or implementation of each step in the ritual itself rather than on its putative overriding purpose. In summary, among all its other effects, religion appears to train and assist people in creating effective implementation intentions in order to enhance adherence to behavioral and ritual standards of the group and to enhance moral character formation.

PROTECTIVE EFFECTS OF IMPLEMENTATION INTENTIONS

It has been demonstrated repeatedly that forming an implementation intention enhances many health protective behaviors including smoking cessation efforts, cancer checks, exercise regimens, dietary changes, and even safe driving practices (Armitage, 2004, 2006; Cohen & Gollwitzer, 2007; Milne, Orbell, & Sheeran, 2002; Orbell, Hodgkins, & Sheeran, 1997; Orbell & Sheeran, 2000; Prestwich, Lawton, & Conner, 2003; Sheeran & Orbell, 1999, 2000; Sheeran & Silverman, 2003; Verplanken & Faes, 1999). These implementation intentions apparently heighten the accessibility of anticipated situational cues that are often used by individuals to halt an impulsive choice, reconnect to an original superordinate goal and go with a longer-term behavioral plan (Gollwitzer, 1990, 1993, 1996, 1999; Gollwitzer & Schaal, 1998; Heckhausen,

1991; Heckhausen & Gollwitzer, 1987; Sheeran, 2002; Sheeran, Milne, Webb, & Gollwitzer, 2005). More specifically, implementation intentions require people to specify the situations in which they will perform an intended target behavior and the strategies that they will use in order to ensure that their goals/intentions are realized (e.g., superordinate goal: "I want to avoid sexually transmitted diseases while remaining sexually active"; implementation intention: "If I am pressured to have unprotected sex with my boyfriend, then I will stop everything and initiate a conversation on use of condoms"). Again, when examining successful relapse prevention techniques, the ability to remain goal oriented and intentional underlie the ability to be abstinent and or to maintain it after relapse (Prochaska & DiClemente, 1986).

Implementation intentions trigger action initiation in an automatic fashion when the specified situation cues are met (e.g., Brandstätter, Lengfelder, & Gollwitzer, 2001; Gollwitzer & Brandstätter, 1997; Orbell & Sheeran, 2000; Webb & Sheeran, 2004). The more situational cues people specify in their implementation intention (i.e., the more "if" statements that people generate in their implementation intentions), and the greater the number of strategies for performing the behavior that people generate (i.e., the more "then" statements that people generate in their implementation intentions), the more likely they will be to successfully achieve their goals. Based on the foregoing literature review we believe it is reasonable to suppose that religiosity and executive control processes such as impulse control and the planning and generation of implementation intentions mutually interact during development in such a way as to yield effective protection against addiction and risky behaviors in children and adolescents.

Chapter **6**

Analysis of Intervention, Treatment, Policy, and Law That Contradict Ethical Criteria

Ann N. Dapice, PhD

Intervention in addiction through prevention, treatment, policy, and law requires responses guided by scientific knowledge. A considerable body of research demonstrates the physiology of addiction—whether the addiction is a substance such as food, nicotine, alcohol, or cocaine, or a behavior such as gambling, internet pornography, or stalking. Research also demonstrates the role of genetics, pre- and postnatal environment—or both. Studies show the wide variety and numbers of addictions that exist worldwide (Saah, 2005). Growing evidence indicates that what we call addiction is the result of once adaptive behaviors that no longer serve humans well (Dapice, 2006; Dapice, Inkanish, Martin, & Brauchi, 2002; Popkin, 2007). It is imperative that we analyze responses to addiction in order to determine to what extent they are knowledge-based and ethical.

When an illness causes people to act in ways that result in danger to themselves and others, what are adequate responses? If we cannot, or do not, stop addictive behaviors that are a danger to people and society, whose responsibility and obligation is it to protect all who are endangered? Our jails are full of the addicted and the mentally ill—who are often also addicted—and our statistics from treatment and intervention remain unsatisfactory. Progress on brain imaging and genetics now provides us with much new information, but older science has too often been ignored in addiction treatment, policies, and laws.

Until recently, the medical model has generally not blamed individuals who suffer from disease. It has been expected that individuals who have an illness

will attempt to obtain treatment. Whether treatments are successful or not, those with a disease will not be held responsible for the success or failure of treatments. For example, if individuals are diagnosed with cancers not related to known behaviors, and they undergo treatment for the cancers, relapses of the cancer will be seen to be either the result of ineffective treatment or a sign of the fact that no effective treatments are yet available. This is especially true in that cancer treatment is mainly carried out by physicians and nurses—not left to cancer victims to treat by themselves. In cancer and other diseases, patients are normally given a prognosis for treatment and a likely success rate for cure related to the kind of treatment. While the American Medical Association declared addiction to be a disease in 1956, treatment has most often not followed a disease model (Interlandi, 2008). In addition to the science of addiction, the science of moral development, values, and personality types provides information that is critical in understanding how we react to the problem of addiction.

HUMAN BEHAVIOR THAT AFFECTS RESPONSES TO ADDICTION

Studies of moral development over several decades (Kohlberg, 1984) have indicated that most people do not develop past lower stages of moral reasoning. Of six stages, stage 1 individuals focus on avoiding punishment and deferring to power. Stage 2 individuals seek to satisfy themselves and occasionally others. Stage 3 individuals behave for approval of others. Stage 4 individuals are oriented to authority and fixed rules. Stage 5 individuals define right action after examination. Stage 6 individuals use ethical principles such as the Golden Rule to decide ethical conduct. The addicted, their families, counselors, researchers, and policy and law makers can all be seen to be at one of six stages. Kohlberg and others in cross-cultural studies observed most people to be at stage 3—behavior for the approval of others (the peer pressure stage), with fewer individuals at lower stages and fewer still at higher stages.

Applied to addiction, a person at stage 1 will be dissuaded from activities of addiction out of avoidance of punishment and deference to power. Family members, counselors, researchers, and policy/law makers could all reason at this, the punishment stage. At stage 2 people will act just to satisfy themselves. An interesting thing happens, however, because at whatever stage the addicted individual can reason, acting on the addiction and maintaining the addiction moves the individual to the behaviors of stage 2, satisfying self—in spite of possible punishment (stage 1), in spite of lack of approval from others (stage 3), in

spite of laws (stage 4)—and even if the individual can reason at the a higher stages of 5 or 6, stages which generally correlate with altruistic behavior.

Kohlberg's work was based on conscious reasoning in reply to a situational dilemma. Dapice (1997) studied more than 6,000 individuals using the Values Unfolding Instrument (VUI), which was developed to allow access to less conscious values. Results from analyzing responses to the VUI showed that initial values stated by individuals unfolded to deeper values only six percent of the time and quite different values and themes developed in the unfolding process. Nearly all values first listed showed concern for others (e.g., love, compassion, fairness, etc.—ideal values) but unfolded to values that are concerned with self (real values). Factors such as gender, race, occupation, and religion made no difference in the results. When there was a conflict in values between self and altruism, people's behavior matched their unfolded self values (e.g., feeling good, success, status, feeling loved and appreciated). The large majority (93 percent) is self-oriented at the less conscious level but consciously believe themselves to be otherwise. They may act in ways that help others, but only if doing so accomplishes values important to them—feeling good, success, being liked and loved, and so forth. It is important to note, however, that seven percent not only unfolded more altruistic values but their anonymously documented behaviors paralleled their anonymously written results by their increased altruistic behaviors.

Such self values can play out in a number of ways in addiction. The most common unfolded values theme in the values research is feeling good. This could be called the dopamine or pleasure pathway value. These values themes also have negative versions, so in factor analysis the feeling good theme correlates with not having to struggle or have difficulty. Security versus fear could be called the fight/flight cortisol theme. Two other themes are: harmony and calm versus anxiety and stress, and excitement and stimulation versus boredom (Dapice, 1997, pp. 25–26). These have correlations to the functions of a number of neurotransmitters in the brain and body.

The Myers-Briggs Type Inventory (MBTI) includes four different continuums (Myers, 1980): Extroverts (E) focus on the outer world, people, and things; introverts (I) prefer an inner world of ideas and impressions. Sensing (S) types focus on the present and concrete information, while intuitive (N) types prefer the future, patterns, and possibilities. Thinking (T) types base decisions on logic and objective analysis of causation; feeling (F) types focus on values, the subjective, and person-considered concerns. Judging (J) types want a planned and organized life with decisions made; perceiving (P) types (like a flexible and spontaneous approach to life, preferring to leave their options

open. These four preferences yield 16 different types, for example, an ESFP would be extroverted, sensing, feeling, and perceiving (Myers, 1980).

One-size-fits-all addiction treatment ignores differences not only in diagnoses, or situations where there are multiple diagnoses, but also differences in Myers-Briggs psychological types (Myers, 1980). Whether client or counselor, differences in psychological type need to be assessed. Testing psychological type in an outpatient setting is easily and readily done. An individual's type does not provide an excuse, but it does give understanding of the different counseling needs to be met. Here are just a few of the clinical observations related to type.

Clinical experience shows that extroverts often enjoy attending Twelve-Step and other support groups, while introverts feel exposed and exploited or will feel like extroverts talk even when they have nothing important to say. Extroverted counselors will want to practice as their peers do (Kohlberg stage 3) so that they will be liked and appreciated by others. Introverts are more likely to counsel in a way that makes sense to them.

Sensing types will have difficulty with change, whether client or counselor. The saying, "If it ain't broke, don't fix it" is true here. For sensing types, things rarely are seen to be broken—even if everyone else can see that they are. Since sensing types are the majority of the population in the United States (Keirsey & Bates, 1978), this becomes a real challenge for counselors where a need for change is indicated. Intuiting types, however, relish change, and often will change from one modality to another—even when it is not required. This can be confusing to a vulnerable client.

Thinking types will be uncomfortable in talking about feelings, yet some treatment programs will insist that using a thinking preference is only denial. In fact, it is the failure to deal with both mental and emotional issues that cause problems. Feeling types will generally be more comfortable in talking about and labeling their feelings but, as noted before, may not be able to understand the consequences of their actions. They will often say, "I didn't intend for that to happen."

Judging types, client or counselor, will often respond using arbitrary power and control—as in "my way or the highway!" A counselor's or client's preference for gray areas (perceiving type) will be seen as lack of clarity to a judging type where things are only seen in terms of black and white. Meanwhile, a perceiving type will not respect a client or a professional who uses status or position to determine how treatment should occur. To a perceiving type, respect is always earned, never automatically given.

Clinical observation over a number of years testing clients for the 16 different psychological types indicated that no one type is more likely to be suc-

cessful in treatment than another. However, if counselors and clients do not understand the differences in type, there may be early failures—if for no other reason than that they will not understand, and thus, trust, each other.

Moral development, values research, and Myers-Briggs types involve motivations and behaviors that affect all in addiction—the addicted, the families, counselors, and policy and law makers. People with different Myers-Briggs types often have perceptions of reality that make it difficult for them to understand each other. Applying ethical principles in response to the addicted will be difficult for those at lower levels of moral and values development—where satisfying self is the main focus, consciously or otherwise.

ETHICAL THEORIES TO GUIDE INTERVENTION, POLICY, AND LAW

In *psychological egoism*, all actions are seen to be selfishly motivated and, unlike the Dapice research mentioned previously, there are no exceptions (Feinberg, 1987). People are perceived as only doing things for others when it satisfies them. *Ethical egoism* states that not only do people act in their own self interests but that they *should* act according to their own interests. The good that makes up people's interests may be defined as happiness or pleasure, or it may be of a more enlightened nature. Ethical egoism is considered to be the business ethic. Because the helping professions are expected to work at higher level of moral reasoning and action, a conflict can occur when employed by a for-profit organization. In *utilitarian theory*, a choice will be made that results in the greatest total good for everyone, regardless of the impact on the decision-maker (Hospers, 1982). It is the ethic of science. Scientific study can involve action that may result in good for many but not for all. For example, while using control groups, sick people may die when they are not being treated. *Deontological theory* is the professional ethic. The Golden Rule is the most common example of deontology and has been found as a stated ideal across cultures. A frequent misinterpretation of the Golden Rule is that immature people often understand and act on "Do unto others as they've done unto you" (Kohlberg stage 1–revenge) or "Do unto others so they'll do for you" (Kohlberg stage 2). Egocentric individuals may make decisions based on their own preferences. An example of this in addiction treatment it would be: "It worked for me so everyone should do what I did." In addiction, the goal should be what will best help the addicted client, not the preference of the professional, or a one-size-fits-all treatment. The needs of clients, not professionals, should be reflected in the professional codes of ethical conduct.

More recent ethical theories include:

1. *Rawls's distributive justice* (Rawls, 1971), which says that rights to liberty should be compatible with the liberty of others, and equities should be arranged to the advantage of all.
2. *Frankena's theology of obligation* (Albert, Denise, & Peterfreund, 1988), which says that results *must be good,* not just that we want or *intend* to do good. We should: (a) not do harm, (b) prevent harm, (c) remove harm, and (d) do and promote good.
3. *Firth's ideal observer* (Firth, 1970) states that there are five characteristics of moral decision-making. We should: (a) not have personal gain or interest (disinterestedness), (b) obtain as much information as possible about a client's problem and situation (omniscience), (c) try to understand consequences of decisions as if they are happening to us (omniprecipience), (d) react in the same manner to the same actions (consistency), and (e) not be sick, overly tired, or stressed when making moral decisions (normality).

Each of these theories shows that practicing in a professionally ethical way is not as simple as following a set of rules set out by one's profession. However, most of us were taught the universalizing Golden Rule as a standard. All major religions, as well as philosophy, have taught this standard. These modern ethical guidelines help us do the Golden Rule better. As we learn more about the science of any problem, we are challenged to develop better responses through treatment, policies, and laws in order to meet our ethical obligations.

SCIENTIFIC RESEARCH TO GUIDE RESPONSES TO THE PROBLEM OF ADDICTION

Tobacco and food are in competition for first place as fatal forms of substance abuse (Tanner, 2004). Obese individuals have the same processes occurring in their brains as do users of cocaine (Brookhaven National Laboratory, 2004). Obesity is a primary factor in cardiovascular disease and type 2 diabetes. Nicotine remains in first place as a cause of what is called "preventable death" —known ethically as "preventing harm" —yet use of nicotine has often been condoned and encouraged through reward systems in mental health and drug rehabilitation facilities, other addiction settings, and prisons. Recently, U.S. federal funding has required that smoking not be allowed in federally funded mental health, addiction facilities, or prisons. Yet well-intentioned counselors can still be heard to say, "We can't take their last drug away." This is a major concern since nicotine use is the leading cause of relapse to alcohol and other drugs (Mathews-Larson, 1991). New studies show the relationship of smoking to increased incidence of type 2 diabetes (Willi, Bodenmann, Ghali, Faris, & Cornuz, 2007, pp. 2654–2664), increased antisocial behavior on the

part of children whose mothers smoked during pregnancy (Button, Maughan, & McGuffin, 2005), and its harmful impact on users and those around them (Fields, 2008; Yam, 2007).

Since the 1980s we have had scientific knowledge about genetically shaped EEG brain waves, showing that reduced amplitude correlates with alcohol dependence. The chromosomal region that affects the P300 electrical brain wave has been identified and correlated with alcohol craving and predisposition to relapse. These EEG abnormalities occur in alcoholics and their children who have not yet used alcohol (Begleiter & Porjesz, 1988; Propping, Kruger, & Mark, 1981; Tabakoff & Hoffman, 1988; Volavka, Pollock, Gabrielli, & Mednick, 1985). Studies have shown that relapse to alcohol, cocaine, and opioid dependence can be predicted by brain waves and that these are better predictors of relapse than other variables (Bauer, 2001).

A growing body of knowledge shows the relationship of stress, cortisol, and the predisposition to self medication. A special issue on stress and drug use by the National Institute of Drug Abuse (2002) summarized the results of stress in laboratory experiments, severe prenatal stress, stress early in life, and posttraumatic stress disorder (PTSD). In 1999, Koob observed that heavy drinking not only depletes the brain's supplies of neurotransmitters necessary for feelings of wellbeing and pleasure (dopamine, serotonin, GABA, and opioid peptides), but also promotes the release of cortisol. Release of cortisol causes tension and depression, in turn causing the individual to drink more, leading to an ongoing vicious cycle. Imaging now allows the observation of damage from child abuse, neglect, sexual abuse, and verbal abuse to the cerebellar vermis in the brain. The damaged brain attempts to suppress electrical irritability physiologically, and the individual attempts to alleviate the irritability through abuse of alcohol and drugs (Anderson et al., 1999; Teicher, 2002).

Meanwhile, it has been shown that hypoglycemia affects up to 95 percent of alcoholics, causing them to become irritable, angry, depressed, hostile, and crave carbohydrates in the form of food or alcohol. Consumption of carbohydrates in various forms can relieve symptoms temporarily until surges of insulin cause the cycle to continue. In the alcoholic community this phenomena has been known as dry drunk and can be observed in individuals who have never used alcohol. A related statistic is that one in four deaths among sober alcoholics is due to suicide. There is little improvement in the suicide rate of alcoholics after sobriety. Addiction treatment requires more than just removing the substance or behavior (Bell & Martin, 2002; Mathews-Larson, 1991).

The need for effective addiction treatment that promotes physical healing and repairs physiological damage is not new and has been studied for decades. Bill Wilson, the cofounder of Alcoholics Anonymous (AA), first established

the link between alcoholism and hypoglycemia and the need for biochemical treatment using niacin and B vitamins to regulate blood sugar. His own experience suffering depression long after sobriety caused him to research the need for these vitamins in treating alcoholism. However, he was advised by his board not to incorporate this information into AA practice (Mathews-Larson, 1991). In spite of changing attitudes that begin to see addiction as a legitimate illness, as opposed to a moral failing, there is resistance from some in the addiction community who are wedded to Twelve-Step programs (Interlandi, 2008, p. 38).

Success rates from Twelve-Step and all but a few rehabilitation programs range between three and eight percent after four years (Mathews-Larson, 1991; National Institute on Alcohol Abuse and Alcoholism, 1996; Polick, Aarmor, & Bracker, 1980). A person diagnosed with cancer, given that prognosis, would likely dictate a last will and testament and make a desperate attempt to find research or treatment that is more successful. In cancer treatment, as in other medical treatment, it is ethically and legally required that such information, the prognosis, be given to victims of disease. It is important that addiction counselors and agencies do the same. When children have a serious disease such as cancer, the parents are legally forced to have them treated based on scientific research if they do not choose to do so on their own. It is curious that we do hold similar rules for underage addicted children who likewise have court ordered treatment—but it is not usually treatment that is based on scientific research.

According to the largest survey of Americans' drinking ever conducted (Dawson, 1996) only about one in four alcohol-dependent individuals enters treatment, including AA. According to AA, 1 in 10 of those who come to AA continues as long as a year. In the largest trial of psychotherapy so far (National Institute on Alcohol Abuse and Alcoholism, 1996), few alcoholics abstained for even as long as a year following treatment: 9 percent for outpatient treatment, and 35 percent for those who first had inpatient treatment. Another study (Krystal, Cramer, Krol, Kirk, & Rosenheck, 2001) examining the benefits of Naltrexone for 627 randomly assigned veterans with chronic, severe alcohol dependence found no significant difference in outcomes between the Naltrexone groups and the placebo group. Even though Naltrexone is approved by the FDA for treatment of alcoholism, the researchers concluded that their research does not support such treatment. After hearing the low treatment success rates at a conference, one individual said, "Well, it worked for me—I'm one of the few! It's not my problem if it doesn't work for everyone else."

Addicts are often told that they have to bottom out first—advice that can be a death sentence. In a personal communication (September 19, 2003), Harold

Stecker , a psychologist who has worked for decades with the mentally ill and addicted, stated that given the reality that alcoholism is active in 10 percent of the population, the numbers that actually enter treatment, the numbers that relapse, and the death rates, 19 out of 20 bottom out through death. Whatever the intent of advice about bottoming out, the reality is that most destroy their lives, often the lives of others, and the longer alcoholism continues without treatment, the greater the damage is to the brain, making treatment even more difficult. Such advice does harm and not good. It would be the same as telling cancer patients to wait for surgery, chemotherapy, and radiation treatment until they had pain sufficient to motivate them to endure treatment. Since pain is generally a late symptom in all cancers, this would ensure death. It is important to begin providing clients with the prognosis of addiction, as well as the success rates for treatment in facilities.

Successful treatment and intervention require responses that are appropriate to the disease. One would not send a cancer patient to a Twelve-Step program for treatment of the cancer without an ensuing lawsuit. A cancer victim might attend a cancer support group, but that would not be the only treatment provided. As Thomas McLellan of the University of Pennsylvania has said, "The specialist doesn't discharge you to a church basement. If he did, we would call it malpractice" (Interlandi, 2008, p. 42).

Research informs us that at a minimum, successful treatment requires: (1) balancing the affected EEG brain waves and neurotransmitters (Bauer, 2001; Begleiter & Porjesz, 1988; Koob, 1999; Propping, Kruger, & Mark, 1981; Tabakoff & Hoffman, 1988; Volavka et al.,1985), (2) addressing brain damage from substance abuse and cortisol toxicity, (Amen, 2005; Anderson, et al., 1999; National Institute of Drug Abuse, 2002; Teicher, 2002), (3) educating about conditions of hypoglycemia, and (4) supplying missing biochemicals such as L-Glutamine, B vitamins, and other substances needed by the brain (Amen, 2005; Bell & Martin, 2002; Mathews-Larson, 1991).

An example of research-directed treatment is FDA accepted cranial electrotherapy stimulation (CES). Studied in double- and triple-blind experiments for decades (Klawansky, Yeung, Berkey, & Shah, 1995), it works well for anxiety (Overcash & Siebenthall, 1989), depression (Marshall & Izard, 1974; Passini, Watson, & Herder, 1976), and PTSD, as well as cognitive damage from substance abuse (Smith, 2007, p. 45; Smith & O'Neill, 1975). Since it does not have to cross the blood-brain barrier it has no serious or lasting side effects. Electro-medicine stimulates and balances neurotransmitters while normalizing brain waves (Heffernan, 1997)—including the P300 craving wave (Braverman, Smith, Blum, & Smayda, 1990). By the 1980s, 80 percent of clients using CES treatment were still sober after seven years. CES has been studied and found

effective in a variety of addictions including alcohol, cocaine, benzodiazepines, heroin, marijuana, methadone, and nicotine (Jarzembski, 1985; Patterson, 1986). It is an inexpensive, self-administered microcurrent delivered by a 9-volt battery.

Addiction nutrition is also important whether the addiction is to food, a drug, or behavior. L-Glutamine is used sublingually to quickly regulate blood sugar and related cravings for carbohydrates, tobacco, and alcohol (Mathews-Larson, 1991). Carl Anderson, researcher at Harvard University Medical School, reported in a personal communication (September 10, 2004) that L-Glutamine is missing in the brains of smokers but not in the brains of those who can take or leave tobacco products. The kinds of foods we eat are critical to brain health. It is important to know the kinds of foods we should not eat in excess and how to supplement with nutrients what we do not normally receive in our diets (Amen, 2005; Mathews-Larson, 1991).

When treatment is not effective, it is important to test for levels of cortisol and to perform other laboratory blood work. A brain scan may be necessary to determine if there are other conditions in the brain not identified. Brain scans can demonstrate numerous physiological and anatomical conditions that otherwise will remain unknown and prevent effective treatment. While scans are expensive, the cost does not begin to compare with that of the addiction when not successfully treated. Treatment requires knowledge specific to the individual. Psychiatrist Daniel Amen states that studying brain scans and behavior has revealed that there is no typical person with alcoholism or drug addiction (Amen, 2005, pp. 51, 233). Except for brain imaging and recent progress in genetics, much research indicating the physiology of addiction and necessary interventions has been available for decades, yet finding addiction facilities that respond to these needs is often a challenge.

In addiction treatment there is a history of ignoring the mental and physical aspects of addiction while focusing on emotional and spiritual aspects. Much of this understanding is due to false dichotomies of Western thought that mental, emotional, physical, and spiritual aspects are somehow separate from each other. Brain imaging and physiological research show that the mental, emotional, physical, and spiritual are all processed through the brain. Neurotransmitters do not only exist in the brain but throughout the body. Humans are mental-emotional-physical-spiritual beings and these are all connected (Dapice, 2006, p. 251). Each is an aspect of the whole person. When people are ill, their reasoning, emotions, and spirits are all necessarily affected, and often they lose status and support from society as well. Becoming stuck in one aspect allows the areas ignored to become sicker.

Each aspect needs to be addressed: (1) mental—substance damage to the brain, examination of consequences, accurate information about addiction;

(2) emotional—stress, anxiety, depression, PTSD, anger, irritability, and grief; (3) physical—substance and cortisol damage to organs, EEG and neurotransmitter normalization, nutrition specific to addiction; (4) spiritual—practices individualized to the client's belief system that give meaning but are not compulsive or destructive and that move the person from despair to hope. In effective treatment of addiction, each aspect will improve with treatment that responds to the disease. The goal is the balancing of the mental, emotional, physical, and spiritual aspects for health (Dapice, 2006, pp. 256–259).

It is clear that treatments provided for even a narrower range of addictions such as alcohol, methamphetamines, and opiates have not generally responded to the science of addiction—some of which is decades old. It is also true that scientific findings often change as we develop better tools and understanding. Available knowledge is ongoing, and professionals are expected to continually update their knowledge and skills. Having not responded well to existing knowledge about specific addictions in the past, how do we take action regarding a much larger array of addictions such as food, gambling, shopping, and pornography?

Example after example of current response to addiction shows that professional omniscience—or updated knowledge—is missing. There is a reluctance to change even in the face of evidence that present actions are not working. Prevention of harm is often missing when there is evidence that child abuse, violence, traumatic events—as well as inherited and old once adaptive brains—are making people sick. Good intentions are too often not examined for results. Given the earlier discussed research on moral development, less conscious values, and personality types, none of this is a surprise. Since large numbers (the majority) of the population are at lower stages of moral and values development and focused on themselves, since large numbers (the majority) of the population are sensing and do not want change, since large numbers (the majority) of the population are extroverted (Keirsey & Bates, 1978) and want to do what their peers do even if it is not based on scientific knowledge, the surprise would be that responses to addiction are going well. That does not change the reality of addiction that we are faced with, however.

ETHICAL OBLIGATIONS OF ORGANIZATIONS, COMMUNITIES, AND GOVERNMENTS

Beyond addicted clients and counselors, ethical analyses are important in evaluating what organizations, agencies, communities, and governments are accomplishing when it comes to addiction and all who suffer as a result of the addiction. Are we accomplishing good and how is it measured? Agencies too often count how many they have served but do not evaluate the impact of the

service. In the human sciences we know far more about the prevention of harm and removing it than is actually acted on. How do we promote good? These are all policy questions that can be measured and should be part of all moneys and grants given to service providers—private or public. Most often they are not.

What are the results of treatment over time? It is often difficult to find statistics on a treatment facility's long-term success rates. Professionals casually talk about best practices at addiction conferences but too often do not demonstrate how and why they are best, the scientific rationale behind the practices, and what they have accomplished in long-term results. Accrediting bodies for licensed counselors have not only the ability but the obligation to ascertain that not only is new research being presented to those who work in the addiction field but that there is evaluation of what attendees learn through pre- and posttesting. It is a moral imperative that all education, whether courses and programs on addiction in universities or continuing education programs, be updated with the latest research—and how to implement the knowledge. Unfortunately, there has often been a schism between researchers in universities and counselors in the field, but this does not meet the needs of the addicted—only the needs of the researchers and counselors.

Those who make policies and laws need to reckon with the reality of stage 2 behavior of the addicted. In addiction, the effect of the drug on the pleasure pathway hijacks the addicted brain and moves the person to behaviors of stage 2, in spite of possible punishment (stage 1), in spite of lack of approval from others (stage 3), in spite of laws (stage 4)— even if the individual can reason at a higher stage 5 or 6, as some well known authors and statesmen have shown. One-size-fits-all laws ignore not only the levels of moral development but also personality types. In a more individualized approach, if the desire is to punish an extrovert, solitary confinement will be used, and if the desire is to punish an introvert, a lot of group activities will be used. The opposites will serve as rewards. Because we ignore research, we put useless dollars into programs, rewards, and punishments that cannot, by their nature, work.

CONCLUSION

If only for financial reasons, we cannot continue the treatments, policies, and laws of the present that are not working. Variously attributed to Einstein and Benjamin Franklin—as well as AA's "Big Book," it is said that "Insanity is doing the same thing over and over again and expecting different results." The human and financial costs worldwide are staggering. Brain processes once protective can now be destructive in a world with excesses of food, nicotine, alcohol, and illegal drugs—and excesses of opportunity for gambling, electronic pornography, and stalking.

Damage done to brains through stress and abuse and addiction is now visible for all to see through brain imaging. We must use our old and often broken brains to do the creative work they are still capable of in order to find brakes to use in a time of destructive excesses. Addiction endangers us all and must be stopped for the good of the addicted and the good of all. Finding brakes for our old and broken brains is an ethical imperative.

Family Issues in the Field of Addiction Treatment

Giuseppe Carrà, MD, MSc, PhD, Massimo Clerici, MD, PhD, Hamid Ghodse, MD, PhD, DSc, Flavio Poldrugo, MD, PhD, and Nady el-Guebaly, MD

SUBSTANCE USE DISORDERS AND FAMILY INTERVENTIONS

Substance use and aspects of family life and relationships have long been connected to the initiation, exacerbation, and relapse of the spectrum of substance use disorders. In the literature, drug misuse is seen as both a "problem *of* the family" and a "problem *for* the family" (Bancroft, Carty, Cunningham-Burley, & Backett-Milburn, 2002, p. 15). Examples include the way in which poor parent-adolescent relationships consistently predict adolescent drug use across cultures and time or how negative communications and poor coping strategies within a marriage may initiate and perpetuate drug use while close relationships with healthy families-of-origin may buffer the abuser from relapse (Rowe & Liddle, 2003). The evidence that points to traumatic family experiences, such as childhood neglect, homelessness, abuse, loss, and bereavement, increasing the likelihood that a person will go on to have drug problems (Kumpfer & Bluth, 2004), can be seen as a problem *of* the family. As 60 to 80 percent of people who misuse drugs live or are in regular contact with their family (Stanton & Heath, 2005), drug misuse can also be said to be a problem *for* the family. The impact on family members may differ depending on the roles

and responsibilities within the family (Lewis & Williams, 1994). The impact may be psychological (e.g., depression and anxiety), physical (raised blood pressure and ulcers) (Velleman et al., 1993), social (feelings of isolation and work, family and social difficulties) (Hudson, Kirby, Firely, Festinger, & Marlowe, 2002), and financial.

Involvement of family members and carers in the assessment and treatment process may also facilitate a successful outcome for the user (Clerici et al, 1988). Furthermore, it is crucial to address the needs of carers and other family members, such as stigmatization and feelings of exclusion (Best, Campbell, & O'Grady, 2006).

In contrast, a number of reviews of family-based interventions over the last 30 years concluded that while several strategies were identified as promising, the relative dearth of empirical studies precluded the demonstration of efficacy or effectiveness of some modalities (Copello, Velleman, & Templeton, 2005; NICE, 2007; O'Farrell & Fals-Stewart, 2003). Within the last 10 years, more rigorous investigation of the impact of these interventions have been published, spurred by the availability of several manualized couple/family-based approaches. Three preponderant theoretical perspectives for family strategies in addiction have emerged (Fals-Stewart, O'Farrell, & Birchler, 2004). Table 7.1 compares the various tenets involved:

a. The family disease approaches whereby addiction is conceptualized as a family illness suffered not only by the addicted individual but by family members viewed as codependent. Each member must address his respective disease process individually. This tenet, while popular, has limited empirical evidence.
b. The family system approaches, whereby general systems theory is applied to the family interactions becoming organized around the addiction and maintaining a dynamic balance between the addiction and family functioning. Related strategies have included:
    - Unilateral engagement techniques educating the family about intervening as a group to confront or motivate their affected relative to become aware of his problem and need for remedial help. In this early phase, the concerned family member is not involved.
    - Inclusive systems techniques, preferred by many family therapists, aiming at modifying family dynamics and interactions that dominate the family's need for their relative's addiction
c. The behavioral approaches whereby it is assumed that family interactions reinforce the addictive behavior and therapy aims at breaking this reinforcement and fostering behaviors conducive to abstinence.

Table 7.1
Marriage and Family Therapy of Alcoholism

Model	Family disease (e.g., Twelve-Step, Al-Anon)	Family systems: (a) Unilateral (b) Systems engagement (e.g., CRAFT, PTC, Johnson Intervention)		Behavioral marital (BCT)
Theory	Addiction is a family illness of codependence	Family can either reinforce or discourage drinking	Addiction has "functional benefit" for family system	Relationship conflict may trigger or perpetuate addiction
Target group	Concerned significant other (CSO)	CSO	Family seen with addict	Addict with spouse
Goals	Personal well-being of family members	Influencing addict to enter treatment	Relationships change underlying addiction	Abstinence and stable relationships
Interventions	Detachment and focus on personal growth	Reinforce nondrinking communication and treatment invitation	Changes in roles, communication, and problem-solving	Abstinence contracts, increasing positives, and communication skills
Main evidence	Rychtarik and McGillicuddy (1998) manualized controlled study (CSO waiting list)	Miller, Meyers, and Tonigan (1999): manualized CRAFT; Johnson, Barber and Gilbertson (1998): promising PTC	Steinglass, Bennett, Wolin, and Reiss (1987): review of strategies	Fals-Stewart et al. (2004): more abstinence, less problems, more cost-effective

CRAFT: Community reinforcement and family training; PTC: Pressure to change.

However, despite methodological weaknesses in this area, a number of conclusions can be advanced that support wider use of family-focused interventions in routine practice. A slightly different conceptualization framework reviewed three types of interventions: those aimed at involving the family in engaging the substance misuser in treatment; those focused on jointly involving family members and substance-misusing relatives in the treatment of the latter; and those focused on affected family members in their own right (Copello et al., 2005). There is evidence that working with family members affected by substance misuse can trigger treatment entry for the substance misusers (Garrett et al., 1998). Furthermore, family involvement in treatment is effective

in a number of formats such as community reinforcement and family training (CRAFT) a manualized treatment program that includes training in domestic violence precautions, motivational strategies, positive reinforcement training for carers and their significant other, and communication training. (Meyers, Miller, Hill, & Tonigan, 1999) as well as network methods (Copello et al, 2002; Galanter, 1993). Finally, family interventions that see the family members as their main target have been shown to enhance coping mechanisms and improve attitudes (Copello, Templeton, Krishnan, Orford, & Velleman, 2000). Particularly, the five-step intervention seeks to help families and carers in their own right, independent of relatives who misuse drugs. It focuses on three key areas: stress experienced by relatives, their coping responses, and the social support available to them. Step 1 consists of listening and reassuring the carer, step 2 involves providing relevant information, step 3 counseling about coping, step 4 counseling about social support, and step 5 discussion of the need for other sources of specialist help. This intervention consists of up to five sessions. Though it has been shown to be feasible, and beneficial, for specialist drug and alcohol services to deliver a brief intervention to family members (Templeton, Zohhadi, & Velleman, 2007), organizational issues mean that routine delivery of such an intervention may not yet be possible, until full recognition is given to the view that addiction problems are best dealt with in a more holistic way that takes into account the family context within which most people live.

Among *adolescent populations*, cost-effective family systems approaches are now shown to significantly reduce drug use, achieve better retention rates, reduce comorbid externalizing problems, and improve school performance as well as overall family function. A major comparison of the available strategies has been the National Institute of Drug Abuse (NIDA) Cannabis Youth Treatment Study (CYT), a multisite randomized clinical trial of five state-of-the-art approaches. The family approaches included multidimensional family therapy (MDFT), a developmentally and ecologically oriented approach to reducing adolescent drug use and related problems by intervening in the multiple systems that maintain these symptoms. MDFT reduced adolescents' substance use by 27 percent from intake to discharge in the CYT study, and 65 percent had no past month use at the three-month follow-up (Liddle, 2002).

The second approach, the family support network (FSN), combined individual cognitive behavior therapy (CBT) and motivational enhancement therapy sessions for the adolescent with parent psychoeducational groups, home visits, and case management services. FSN reduced past month use by 44 percent between intake and the end of treatment and similar to MDFT had 64 percent no past month use at the three-month follow-up (Dennis et al., 2002).

A third approach, multisystemic therapy (MST), a social ecological approach to altering the multiple risk factors that create and maintain adolescent substance abuse and delinquency, was compared in a four-year outcome trial with community services as usual. The percentage of urines free of marijuana among adults receiving MST (55 percent) was higher than the comparison group (28 percent) (Henggeler, Clingempeel, Brondino, & Pickrel, 2002).

The main tested behavioral approach in this age group is functional family therapy, which aims at altering family maladaptive patterns that reinforce the adolescent's problems and establishing more effective problem-solving approaches (Waldron, Slesnick, Brody, Turner, & Peterson, 2001). This approach, particularly combined with CBT, demonstrated significant reductions in drug use between intake to treatment and a seven-month follow-up assessment.

In the adult groups, the preponderance of evidence has been provided by a series of studies involving behavioral couples therapy (BCT). Suited to a predominantly nuclear family structure in North America, BCT has gained prominence for enlisting the family's help after the alcohol or drug-dependent person has sought treatment. In recognition of the destructive cycle between substance abuse and relationship dissatisfaction, instability, and irritability, the main objectives of BCT are to eliminate abusive drinking and drug abuse and to engage the couple/family's support for the patient's effort to change as well as restructuring to that effect the couple/family's interactions patterns. BCT involves the spouse or partner expressing active support for the person who misuses drugs in reducing drug use, including via the use of behavioral contracts. Couples are helped to improve their relationship through more effective communication skills and are encouraged to increase positive behavioral exchanges through acknowledgement of pleasing behaviors and engagement in shared recreational activities The number of sessions administered have ranged between 15 to 20 sessions for individual couples over five to six months or brief group sessions for three to four couples together over 9 to 12 weeks. BCT has been fully manualized (Fals-Stewart et al., 2004). BCT is only suitable for couples who are committed to their relationships (partners for at least one year and, if briefly separated, attempting to reconcile). They must be able to acquire new information and skills and must both share a primary goal of abstinence. Aggression is an exclusion criterion and so are addicted couples, which are more enabling of each other. This in reality has had the unfortunate result of eliminating more female patients in a relation with a using male. Couples-based interventions were consistently associated with abstinence both at end of treatment and at 6- and 12-month follow-up for people with primary stimu-

lant or heroin dependence (Fals-Stewart, Birchler, & O'Farrell, 1996; Kelley & Fals-Stewart, 2002; Winters, Fals-Stewart, O'Farrell, Birchler, & Kelley, 2002). Most of the published outcome studies have focused on individual marital therapy. A pilot group BCT therapy program, based on the experience with 38 couples so far seen, 3 or 4 couples at a time, compared to 33 couples who refused the approach, demonstrated sizable improvement at the six-month follow-up (el-Guebaly, Richard, Currie, & Hudson, 2004).

CULTURE AND FAMILY THERAPY

One of the most significant limitations of this treatment literature, however, lies in the fact that most studies have been conducted in specialist research centers in the Western world, using approaches that may be difficult to apply in most settings. Family interventions within other cultural contexts must account, among other factors, for significantly different structures, power division, religions, and attitude toward drugs and the role of self-help. Families in multicultural societies for more than one generation will also develop their unique blended perspectives. Within the constraint of this update, a few examples of the impact of culture are presented.

Families are the conveyors of traditional cultural norms, rules, and values and will accordingly shape attitudes toward substance use. For instance, smoking among Pakistani and Bangladeshi men is an accepted tradition, contributing to group cohesion and identity. Consequently, young boys grow to become smokers. Contrastingly, smoking among women is not acceptable and carries a cultural taboo and stigma. When transplanted into multicultural societies, like in the United Kingdom, offspring of these families criticize their fathers for smoking (Bush, White, Kai, Rankin, & Bhopal, 2003).

Each family has its own culture and its own dynamic, and, when substance abuse occurs, the response of different family members is not necessarily uniform. For example, the family may split into rejecting and rescuing factions, leading to family conflict. Wider cultural factors undoubtedly also affect the family's response to substance abuse. In traditional societies, accustomed to folk methods of confronting difficulties and problem-solving, a professional therapist may meet considerable resistance, which can be alleviated if the position of an older person in supervising treatment is recognized and acknowledged. To understand the experience of a family from a very different culture requires a mind that can be open to new constructions of the pattern of family life, both internally and externally and in terms of custom and expectation. For example, respected kinship and authority structures in Asian and African extended families are strikingly different to those in Western families, and, in countries where

the family is the nucleus of society, it often plays a significant role in bringing the abuser to treatment. Certainly, substance abusers themselves perceive family support as most important for remaining in treatment (Oyefeso, Jones, & Ghodse, 1996). A review of research studies testing the effectiveness of culturally adapted family-based interventions reported an increase in treatment retention by 40 percent compared to generic family interventions (Kumpfer, Alvarado, Smith, & Bellamy, 2002). This is of particular importance as the use of services by ethnic minorities tends to be low.

Family attitudes toward drinking and the drinker may also be harnessed toward prevention and recovery. It has been recognized that in some family-centered European cultures (like the Italian, Greek, Portuguese, and Spanish), exerting familial informal social control with regard to drinking is successful in preventing alcohol abuse. Families act as the primary groups for alcohol-related problem intervention. The Italian experience in extended family recovery started 30 years ago. The number of Clubs of Treated Alcoholics (CAT), a program originally established in Croatia (Room, 1998), is four times greater than groups of Alcoholics Anonymous. The CAT considers addiction as a family and community style, thus involving family and community members early into treatment. Changes in alcoholics' social functioning should be visible within the community in order for it to change (Patussi, Tumino, & Poldrugo, 1996). Modalities of treatment mainly involve extended family and community reinforcement training, but other components like BCT are also present (Poldrugo, 2003).

EXPRESSED EMOTIONS AS ATTITUDINAL INDICATOR

Recently, emotional attitudes toward the patient of key relatives have been associated with maladaptive coping mechanisms. These attitudes are also shaped by culture. People with schizophrenia from families that express high levels of criticism, hostility, and emotional overinvolvement, according to the Expressed Emotion (EE) Index, have more frequent relapses than do people with similar problems from families that tend to be less expressive. Little is known about EE as predictor of relapse for substance-related disorders. Alcoholic patients with high EE spouses, when compared with their counterparts with low EE spouses, were more likely to relapse, had a shorter time to relapse, and drank on a greater percentage of days in the 12 months after starting behavioral marital therapy (O'Farrell, Hooley, Fals-Stewart, & Cutter, 1998).

In a pilot trial in Milan (Carrà & Clerici, 2004), frequencies of high EE were investigated by the Camberwell Family Interview in relatives of people with heroin dependence in outpatient and residential treatment and were compared

with those of relatives of schizophrenic patients in standard outpatient care. Thirty patients affected by *DSM-IV* opioid dependence were recruited before entering an outpatient program, and 47 key relatives were identified; 12 other patients were recruited before entering a residential program, and 24 of their key relatives were identified. A random comparison sample of 30 patients with schizophrenia were recruited along with 45 of their key relatives. Relatives with higher EE appeared to be positively correlated to the severity of the opiate condition. Indeed, the relatives scores of the residential group were similar to those of schizophrenia. The EE score did not, however, predict the potential for relapses in a 24-month follow-up. A trial is currently being conducted about the effectiveness of manualized psychoeducation treatment in improving knowledge about addiction and lowering the EE profile as well. Following nine 90-minute weekly sessions, the EE profile was lowered in 18 among 35 retested relatives (34.6 percent; $p = 0.002$) at six-month follow-up. The family's knowledge about addiction increased as well. The Italian cultural approach to psychoeducation seems to favor an open discussion about presented topics and belief systems. On the other hand, a confrontational approach is not often accepted and may result in further emotional suffering.

CONCLUSIONS

This update summarizes the growing empirical evidence supporting the effectiveness of couple- and family-based therapies in the management of substance-related disorders. It also highlights the importance of cultural sensitivity and adaptation to enhance accessibility and retention of families and to improve the outcome of these interventions.

Research and guidelines in cultural adaptation are sparse because of the complexities presented by the diversities of culture, yet cultural competence is an important therapeutic ingredient. A pilot study using an EE index is presented for its promising comparative cultural potential. More related studies are encouraged. So far, the most sound recommendations appear to be those drafted by NICE (2007), emphasizing the need to offer guided self-help, to facilitate contact with support groups, to provide information and education about drug misuse, and to explore and promote effective coping behaviors.

Chapter **8**

Codependence from a Family Systems Perspective

Mary Theresa Webb, PhD, and Ann Fabean, PhD

BACKGROUND

Thirty years ago, the chemical dependence/addiction field and the family systems field were beginning to explore how alcoholism and other chemical dependencies affect families. While those working in the addiction field noted certain behaviors of addicts and family members that were characteristic of the disease and started treating the whole family in family weeks, marriage and family counselors lacked assessment tools to determine the extent to which alcoholism and other addictions led to dysfunctional family patterns. Addiction professionals were the first to recognize that the dysfunctional patterns they observed in addicts' families contributed to the perpetuation of their denial systems and enabled addictions to continue. They labeled the co-addict, spouse, or parent of the addict *codependent*.

Dr. Timen Cermak, a psychiatrist, attempted to define a codependent personality disorder with appropriate diagnostic criteria (Cermak, 1986) so that treatment could be reimbursed by insurance He identified codependence as a personality disorder most resembling narcissism and echoism with intergenerational enmeshment of personal boundaries. He further classified two levels of codependence, primary and secondary. Although his theory had not been accepted as a mental health disorder when their studies began, other diagnoses, such as mixed personality disorder or dependent personality disorder, come closest. Yet neither Cermak nor other mental health professionals have put the term in a broader family systems model.

In the 1970s and 1980s, some addiction professionals began to recognize traits in the family system that provided insights into the concept of family codependence. Virginia Satir (1967), Don Wegscheider (1979), and Sharon Wegscheider-Cruse classified and named the chemically dependent family roles and functions. They explored the intergenerational aspects of alcoholic families. Since then, others such as , John Bradshaw (1988), and Melody Beattie (1989) have expanded on their work. Pia Mellody, with Andrea and Keith Miller, in their book, *Facing Codependence* (Mellody, Miller, & Miller, 1989), traced the roots of codependence in family processes.

Reactions from other mental health professionals followed. Some criticized the broad use of the term *codependent* in the addictions field. They claimed the term was oversimplified, overused, and was founded in an antiquated disturbed personality hypothesis (Horney, 1950).

Yet it was Karen Horney who named some of the characteristics that lead to codependence in her book, *The Neurotic Personality of Our Time* (Horney, 1937). She examined childhood histories of a number of neurotic persons and concluded that "the common denominator in all of them is an environment showing the following characteristics in various combinations: a lack of warmth and affection, actions or attitudes on the part of parents that arouse hostility" (Horney, 1937, p. 68). She discussed what professionals today call a *double bind*. This term means that children conditioned by their parents to feel guilty for expressing hostile feelings, particularly anger or for being oppositional when caught, also felt inadequate when they did rebel and broke a rule, no matter how unfair or incongruous the family rule might be.

Carter and McGoldrick (1989) in their book, *The Changing Family Life Cycle*, identified stressors that create disruptions of the family life cycle and produce dysfunctional symptoms. These stressors include family patterns, myths, secrets, and legacies handed down through multiple generations, as well as the unpredictable stressors of untimely death and chronic illness.

Meanwhile, respected family therapists such as Salvadore Minuchin recognized the impact a family has on an individual. "Family structure is the invisible set of functional demands that organizes the ways in which family members interact" (Minuchin, 1974, p. 51). In other words, he expressed how family members use their learned behavior in relating to and interacting with others outside the family environment, starting with conditioning in childhood.

Murray Bowen (1978), another renowned family therapist, focused his theories on determining a healthy family ego mass. In order to function in a healthy state, a family has to protect the whole system while, at the same time, respecting the autonomy of the individual within the system. This does not usually

happen in a system affected by chemical dependence (Zerwich & Michaels, 1989). Zerwich and Michaels concluded that low self-esteem is at the core of an addicted family's ego mass.

Froma Walsh (1982), in compiling her research on well-functioning family systems, reaffirmed Bowen's theories of a family needing a healthy ego mass. In an addicted family, the ego mass is skewed or unbalanced. The family roles identified by Satir (1967) and Wegscheider (1979) become necessary in order to rebalance the system.

Today, both addiction professionals and family therapists note that blaming, scapegoating, rigidity, emotional repression, shaming, poor self-esteem, excessive control, problems of intimacy, and blurring of generational boundaries form some of the pathology surrounding an addicted family. In an attempt to tighten up the concept of codependence to assist addictionologists, social workers, marriage and family counselors, psychologists, and psychiatrists, and to diagnose and treat individuals and family members affected by one person's addiction, we choose to define the term *codependence* as follows:

> Intergenerational patterns of living and problem-solving that are formed within a family system where there are or have been various dysfunctional patterns that include chemical abuse or dependence. The system then supports dependence and counterdependence in interpersonal relationships with a loss of individual autonomy and a distortion of reality.

We designed the Codependence Assessment Guide identifying eight constructs to treat affected persons holistically with subjective but quantifiable Likert Scales for therapists for treatment planning. Our model bridges the gap between the chemical dependence model that is based on the biological, psychosocial, and spiritual disease model of addiction and the family systems model or theory. We have refined and enlarged on our theory in the practice of therapy and in international training sessions. We have asked clients or trainees to prepare individual family genograms, diagrams of the intergenerational physical and mental illnesses, relationships, and patterns, in order to heal from codependence family patterns. Our tool was first presented in 1989 to the staff at the Staunton Clinic of Sewickley Valley Hospital, Pennsylvania. Since then we have taught it around the world and used it to help clients in therapy heal. We are indebted to the Beavers-Timberlawn Family Evaluation Scale (BT) for providing a methodology from which to work (Fredman & Sherman, 1987, pp. 33–35). In this chapter we present the eight constructs that follow with questioning strategies, expanding Fredman and Sherman's

measuring tools to include such items as chemical usage and attitudes that foster inappropriate use of chemicals. In addition, we included constructs of intimacy, triangulation, validation (which builds self-esteem), counterdependence, manipulation and control, shame, playfulness, and belief systems. We realize that normal families may exhibit some of these behaviors, therefore we designed our measuring tool and tested its validity to find just what range normal would be. We have revised this guide for laypersons to read and study to gain insight into their own nuclear and intergenerational family systems. (The full assessment guide for clinicians with the measuring scale will be available for download electronically on Amazon.com.)

CODEPENDENCE CONSTRUCTS: STRUCTURE OF THE FAMILY

Between Generations

Questioning Strategies

1. Can you explore or write about the traditions, patterns, or myths and how they got started in your family?.
2. What is/was your relationship with your grandparents?
3. To whom do/did you go in your family for guidance?
4. How do/did you see your grandparents or parents interacting or interfering in the life of your family?

Rationale

Interference and control by one or more senior family members who have set unhealthy patterns and traditions that must be followed leads to enmeshment or disengagement.

These reoccurring patterns, myths, and traditions are expected to be handed down from one generation to another. An example might be introducing alcohol as a rite of passage to those entering adolescence or upon graduating from high school. Some of these traditions or customs are abusive, such as wife inheritance, another tradition found in African tribal areas and today one of the leading factors in the spread of HIV/AIDS. In pathological systems, particularly alcoholic families, family members develop an identity that is that is not separate from that of the family and have malfunctioning hierarchical boundaries (Minuchin, 1974). In healthy systems, individuals learn about boundaries, and these boundaries are flexible. Boundaries are defined and explained in Pia Mellody's book, *Facing Codependence*, 1989).

Intimacy

Questioning Strategies

1. Are/were you relaxed with your family when you are/were together?
2. Can/could you share your feelings as well as thoughts with someone in your family or someone close to you?
3. Do/did you feel comfortable in close relationships?
4. Do/did all members of your family have a chance to express freely their thoughts, feelings, and wishes and have them accepted by others?
5. Did you have special times by yourself when you were growing up? Can you describe any of those times? Do you like being alone today?
6. Do/did good feelings about yourself depend on how others in your family system respond(ed) toward you?
7. Do you have any sexual problems? Can you explain what they are?

Rationale

If one is not able to share private thoughts, feelings, and wants because of the fear of being hurt or being abused this person lacks intimacy.

Erikson defined six progressive stages of growth from infancy to adulthood (Harder, 2002). These developmental stages are important to an individual's well-being and can make a difference where health or dysfunction are concerned. Erik Erikson's study of these stages showed the importance of each stage leading to the next. In the sixth stage, the stage that Erikson describes as intimacy versus isolation, a child grows into mature adulthood with a sense of well-being about himself both inside and outside around others. Intimacy in close relationships means that individuals can safely share private thoughts, feelings, and wants without the danger of being hurt. They can accept each other's weaknesses as well as appreciate and encourage another's strengths. Because emotional, physical, and sexual abuse occur in families where there is substance abuse, children who grow up in these families find themselves either dependent and intertwined or isolated.

Power and Control

Questioning Strategies

1. Does/did one person in the family attempt to make all decisions for other family members, to answer for anyone else, to tell anyone else what to do, or to accept the blame for someone else's behavior?
2. When something goes/went wrong, is/was someone else always to blame?

3. Are/were you responsible for another's behavior?
4. What is/was the worst thing that can/could happen if you don't/didn't fix the problems in your family?

Rationale

Next comes the issue of power and control in families and couple relationships and the issue of who exerts that power or control and how. Power can exhibit itself through an authoritarian parent or grandparent or through the seeming helplessness or dependency created by one family member's manipulation or abuse of one or more other family members. Sometimes power and control are manifested in destructive ways. In a codependent family, the chemically dependent person exerts the power, while the codependent spouse exerts the control. Controlling or being controlled is at the very core of codependency. In healthy families, the parents share power. Consensus and self-autonomy are fostered and encouraged.

Parental Coalition

Questioning Strategies

1. Who do/did you see as the dominant person or persons in your family system?
2. Can you describe how decisions are/were made in your family?
3. Do/did your mother and father argue very much? Do/did you ever feel that you have/had to side with one parent or another?
4. Do/did your parents ever talk about going on a date together?
5. Do/did you think your mother and father treat/treated you and each other fairly?

Rationale

In codependent families, parents cannot make shared decisions. One partner in the marriage is dependent and passive and the other dominates and acts as caretaker for the chemically dependent spouse. Cermak (1986) refers to this as the Narcissus/Echo pattern. Battles for power and control often ensue between parents. One child or another, at various times, gets caught in that power struggle, or all children are equally ignored in the ongoing conflict. In healthy family parents share decision making.

Triangulation

Questioning Strategies

1. Who do/did you think absorbs/absorbed the pain in your family?

2. Who in your family speaks/spoke for an issue between your parents?
3. Do/did you feel trapped in your family? If you do/did, explain how and when this happens/happened and what this is/was like.
4. Do/did you feel that you have/had to fix it or protect one of your parents from the other?

Rationale

Triangles are characteristics in families where there is unresolved conflict. Murray Bowen (1978) examined the phenomenon of triangulation in some depth. Triangles are prevalent in codependent families.

Either a child gets drawn up into in a conflicted parental relationship or an abused chemical or another form of addiction becomes the third party in the triangle.

CHEMICAL SUBSTANCES

Use of Chemical Substances

Questioning Strategies

1. Do/did you discuss chemical dependence or addiction in your family? Does/did anyone try to avoid talking about this issue? Or is/was there discomfort when the subject is/was brought up?
2. What is your favorite drink?
3. Did any of your grandparents have problems with alcohol or any other drug? When that person was abusing, who got more involved?
4. In what ways is your drinking or drug use different or like that of your grandparents?
5. Have you ever felt you needed to, or has anyone ever told you to, cut down on your drinking/drugging? Have you ever felt bad or guilty about your drinking and or drugging?
6. Do you need the drink or drug to steady your nerves or to relax?
7. Can you stop drinking/drugging after just one?

Rationale

Chemical abuse is indicated when someone is using a mindaltering chemical—alcohol, nicotine, marijuana, cocaine, or a prescribed drug—and that chemical is causing physical, emotional, or relational problems. Chemical dependency is indicated when the chemical being abused is causing that person to experience blackouts (with alcoholics), withdrawal symptoms, or inability to stop using the chemical. Appropriate use is defined as using prescription

medications under a physician's guidelines for appropriate use, or, in the case of alcohol, for special religious or family celebration functions. One or two ounces of alcohol a day may not cause problems for adult social use, but that depends on an individual's metabolism, weight, sex, and age, as well as other factors. For example, women can become alcoholic sooner than men because of a lack of a stomach enzyme called alcohol dehydrogenase, used by the body to digest alcohol (Frezza, Padova, Pozzato, Terpin, Bardona and Lieber, 1990).

Enabling

Questioning Strategies

1. Are/were you concerned about anyone in your family drinking or drugging too much?
2. Does/did anyone in your family act crazy, silly, or mean when drinking or drugging?
3. What rules do/did you have in your family around the use of alcoholic beverages or other mind-altering drugs?
4. Do/did you ever have any fights about one another's drinking or drug use?
5. Who drives/drove home after a party where there has/had been alcohol consumed?

Rationale

There is an interesting phenomenon that occurs in families where chemical abuse or dependence exists. The drinking or drug use is never talked about with the abuser directly. It is the family secret! Often a spouse or a child is expected to make sure there is an adequate supply in the house. An enabling spouse, parent, or sibling will deny there is any problem, or will use with the addict to keep him company. When chemical usage begins to be a problem, family members may talk among themselves. An enabler thinks that the right thing to do is protect and take care of another. Centuries of religious training and cultural conditioning reinforce doing to and for others before taking care of oneself. To be able to endure the suffering caused by someone else's behavior while under the influence of mind-altering chemicals is equated with Christian martyrdom (Cermak, 1986). Yet taking care of one's own self increases one's ability to be able to be concerned for others Family members of addicts need to stop enabling and care enough to come together with a professional to plan an intervention to express their how they feel about the drugging or drinking behavior with love when he or she is under the influence.

COMMUNICATION

Directness in Communication

Questioning Strategies

1. Does/did someone communicate aggressively both verbally and nonverbally (e.g., finger pointing or attacking or labeling another as "bad")?
2. Can/could you talk about things that matter to you in your family?
3. When there are/were discussions with family members do/did you feel comfortable in expressing your feelings openly and directly?
4. How do/did you go about planning for a family outing?
5. If something bothers/bothered you, whom do/did you tell?
6. How do/did you solve problems when they arise/arose in daily life, or are/were they ignored?

Rationale

In healthy families, each person has a sense of autonomy and importance in the family system. Communication is clear, direct, honest, and specific, and each person has a chance to express her opinions. Differences of opinion on issues are discussed and respected. In a codependent family, communication is indirect, often going through a third party. There are many "you" statements with judgmental overtones (I'm right and you're wrong). Differing opinions are not accepted. Cognitive distortions and irrational ideas abound. Sometimes family members interrupt or finish each others' sentences. Clear messages are not received or are misinterpreted. Communication contains judgmental or global statements—for example, the use of *should*, *ought*, *never*, or *always*, or personalizations, mind reading, and overgeneralizations.

Validation

Questioning Strategies

1. Do/did you or any of your family members talk of suicide or self-destructive behavior? If so, these individuals need/needed professional help.
2. Do/did your family members support one another? How?
3. Do/did your family members show more approval or disapproval of each other?
4. Can you name some ways your parents affirm/affirmed you as a person?

Rationale

In healthy family systems, nurturing and bonding give each member a positive sense of self-worth. In a codependent family system, messages conveyed are negative and critical. They are internalized and lead to a sense of inadequacy and wrongness about oneself. Codependent family systems are constantly invalidating each family member's perception of another's behaviors Adults raised in families where there is no validation look for validation by being people pleasers or controllers. They become depressed or exhibit psychosomatic illnesses to get attention.

Family members deny there are problems and need to put on a good public face ("I'm fine" or "We're all fine"). When together one or more family members will appear despondent or hopeless (e.g., eyes downcast, face sagging, or body slouched and hands limp). When discussing a family crisis, someone might respond: "It's not so bad" or, in the case of reoccurring bad dreams, "maybe I'm making it up," Someone else might say that the situation is hopeless or that life is not worth living.

Counterdependence

Questioning Strategies

1. Does/did the level of intensity in your family escalate?
2. Do/did sentences get cut off by interruptions?
3. Does/did one person try to counter or explain what another person says/said or does/did?
4. Are/were you comfortable talking with other family members?
5. Does/did someone always win and someone else always lose in your family discussions?
6. Do/did your discussions often end with your feeling frustrated or angry?
7. When you communicate. communicated with other persons in your family, do/did you feel that you have/had been heard? Describe how you know/knew that you've/you've been heard.
8. Do/did you have to explain or defend your thoughts or your feelings to others?

Rationale

Reacting to each other rather than listening to one another stifles effective communication. Such is often the case in codependent families. Communication about even the most routine matters often ends in shouting matches. One unhealthy way to relieve the tension between parents in these families is for

one person in the marriage to use chemical substances, food, or sex to relieve the tension. With constant interruptions, threats, and intimidations, messages are often cut off before they have a chance to be heard. This leads to internalized feelings of frustration and resentment. Children from these families may grow up into adulthood with posttraumatic stress syndrome.

FAMILY EMOTIONAL AFFECT

Range of Feelings Expressed

Questioning Strategies

1. Do/did you believe you or other family members use the various defense mechanisms in place of emotions?
2. Do/did you or family members have difficulty understanding what is meant when asked questions about feelings or when the answer is/was "I'm fine" or "we're fine"?
3. Can you discuss what feelings you are in touch with—now and in the past?
4. Is/was it safe to discuss feelings in your family?
5. Which feelings are/were okay to express and which feelings are/were not okay to express?

Rationale

In family systems where there is chemical dependence certain feelings are repressed, especially negative feelings, as well as feelings that might make an individual vulnerable, such as feeling hurt, sad, or scared Emotional affect is flat or frozen. Elaborate defense mechanisms are used to survive, such as projective identification, denial and avoidance, psychosomatic or exaggerated illness, fantasizing, intellectualizing, rationalizing, and minimizing.

Mood and Tone

Questioning Strategies

1. Can/could you or your family members smile and laugh comfortably, or does/did the laughter camouflage uneasiness?
2. Does/did one family member ridicule another or put the other person down either by her tone or via style of communicating?
3. Is/was there affection displayed by family members?
4. Is/was anger and hurt expressed in your family, and if so, how, and by whom? How are/were these emotions displayed?

Rationale

In healthy family systems, there is a fair exchange of mood and tone from affection and warmth to anger and hurt. In codependent systems, the playfulness often has an overtone of hostility, anger, and rage. There is a need to shame and demean. This toxic shame permeates the family system and is carried over from one generation to another. It is dehumanizing.

Manipulation and Control

Questioning Strategies

1. Do/did you usually do what is/was expected of you by family members whether you want/wanted to or not? How do/did you feel about it? Give an example.
2. Do/did you ever feel conned?

Rationale

As with power and control, the need to manipulate comes out of a sense of inadequacy and weak ego strength (Cermak, 1986). Since there is little trust in codependent family systems, empowering others is usually not an option. Manipulation is done either subtly or covertly with either blurred boundaries or disengagement. Underneath the layers of manipulation and control there is suppressed anger, hurt, and fear from living in a toxic shame-based family system.

Climate

Questioning Strategies

1. Do/did your family members seem relaxed with one another or do/did they seem uptight (e.g., do/did they sit on the edge of their chairs?)?
2. Does/did anyone have any nervous habits? Is/was there a certain rigidity of appearance?
3. Does/did anyone in your family have stress-related illnesses?
4. What happens/happened when there is/was a crisis in your family or in your relationships?
5. What ways do/did you find to relieve your stress when a crisis occurs?

Rationale

In normal families, times of anxiety and stress are unavoidable At other times, family members are relaxed and at ease with one another. In codepen-

dent families, stress and anxiety are constantly present. There is one crisis after another, and family members are under a state of constant tension and stress. Chemical and food abuse, compulsive exercising, smoking, and other compulsive, obsessive behaviors relieve the stress. Health problems such as cardiovascular diseases, back problems, intestinal disorders, ulcers, and other stress-related illnesses result.

Conflict Resolution

Questioning Strategies

1. When you have/had disagreements with others, how do/did you feel and how do/did you manage your feelings?
2. Do/did you avoid conflict in your relationships when they occur/occurred? Or do/did you discuss the issues around the conflict with the person whose views conflict/conflicted with yours?

Rationale

Having conflict and resolving it is normal in interpersonal relations. Real forgiveness can only occur when the conflicting parties hash out their differences and find some resolution. Conflict occurs whenever self-autonomy clashes with group expectations and goals or whenever one person's interests, wishes, and/or expectations clash with another's and there is an underlying "I win; you lose" competitive atmosphere. Anger, anxiety, resentment, blaming, and guilt continue until there has been some attempt to listen to each other, clarify the issues, and participate in a decision-making process.

In chemically abusive or codependent family systems, there is much unresolved intergenerational conflict. Conflict management styles range from blaming to intellectualizing, generalizing, or avoiding and pretending that everything is fine and there is no conflict. The intensity of these problems gets worse with each succeeding generation until all the family members find healing.

Trust

Questioning Strategies

1. Whom did you trust in your childhood family?
2. Whom do you trust now?

Rationale

As a result of unresolved conflict, power struggles, and inconsistent discipline and nurturing, dysfunctional and codependent family members learn either

not to trust or to trust blindly. Mistrust is rooted deeply in these families and is difficult to change. It is difficult even in the context of a counseling relationship.

ROLES

Family roles

Questioning Strategies

1. Can you identify yourself and family members in one of these roles either through the use of mobiles, role play, or reading any of the following authors' books?
2. What does being yourself mean to you? Is/was it okay to be yourself in your family?
3. Do/did you have a set role in your family?
4. Are you okay with who you believe you are now?

Rationale

Although Sharon Wegscheider-Cruse first defined and identified the roles of family members in the chemically dependent family as dependent, enabler, hero, scapegoat, lost child, and mascot, Don Wegscheider modified these and relabeled them victim, protector, caretaker, problem child, and family pet. Each role has set behaviors, feelings, and perceptions.

These roles were created to identify some of the typical behaviors family members may exhibit in codependent families as well as how the roles keep the family system in balance. Sometimes adults from codependent families rigidly define themselves by the role with which they identify, the role becoming a pathological label. In recent years family and marriage specialists have cautioned against assuming these roles are rigid and unchangeable since they can also be found in normal families. In normal families members move from one of these identified roles to another role more easily than in codependent families.

Blaming

Questioning Strategies

1. What function do/did you have in your family?
2. Do/did you ever think you cause/caused it when something goes/went wrong in your family?

Rationale

Blaming and attacking are common defense mechanisms for the chemically dependent or other addicted person. These defense mechanisms go along with the denial that surrounds the codependent family system. The blaming occurs because of repressed feelings of pain, hurt, and rejection that cannot be safely verbalized. When problems occur for the addicted person, others are blamed. This is really emotional abuse. Those accused can stay victimized in adult life. They survive by placating, protecting, or distracting. The one who placates is the family reconciler who tries to keep anger in check. The protector is the caretaker. The distracter uses diversionary tactics, such as humor, to relieve tension. Blaming and attacking by one family member of another can be observed through verbal use of "you" statements and aggressive body language such as finger pointing.

FAMILY RULES

Function

Questioning Strategies

1. What were some of the rules in your family when you were growing up?
2. Did you have any say in formulating these rules?
3. Were these rules clear?
4. How are rules made in your family now and what purpose do they serve?

Rationale

In healthy families, rules are flexible and set according to need. Children's concerns are expressed and heard, and both parents cooperate in leadership in the family. The rules parents set have a purpose of meeting the shared goals of their leadership. Rules in a dysfunctional family are inconsistent and frequently reflect parents' unfulfilled ego needs. In chemically affected families, not only are rules inconsistent but they are also usually rigid and closed, implicit but not explained ("My way is the only way"). There is no opportunity for other family members to express individual concerns. For the addict, "my way" varies according to "my" mood or the affect of "my" use of chemicals on "my" moods.

Honesty

Questioning Strategies

1. Do/did you always know why your parents tell/told you to do certain things?
2. Do/did you think the rules in your family are/were fair?

Rationale

The rules formulated in a healthy family are clear and concise, and they have a function, even though children in these families—particularly adolescents—may sometimes think the rules are not fair, whereas in codependent families rules are manipulative. These manipulative rules serve the addict's or the co-addict's neurotic needs at the moment.

Discipline

Questioning Strategies

1. How are/were you disciplined?
2. Who is/was the disciplinarian?
3. Do/did you always know why you are/were being disciplined?

Rationale

Every child needs clear boundaries for what is acceptable and unacceptable behavior. When the rules are clear and have a set function, children know an infraction of those rules means there will be consequences. In healthy families, those consequences are known to the child and are appropriate to that child's age level. The child might even have a say in setting those consequences. In codependent families, discipline is meted out inconsistently and frequently applied with anger. When one or both of the parents is abusing chemicals, and depending on the extent of the abuse, discipline is more likely to be physically or sexually abusive. It is chaotic and often violent.

Shame

Questioning Strategies

1. Can you describe what you like/liked or dislike/disliked about yourself or another member of the family?
2. Do/did family members put down one another? In what way?
3. Do/did you feel that you are/were abused or violated in any way? How?
4. Do/did anyone in your family have rage attacks?

Rationale

When children do something wrong, they feel a sense of shame. We experience shame when we violate our own or someone else's boundaries. Human beings learn by experience that they are not perfect and that they often fall short of their own and other's expectations. This is called healthy shame. This

kind of shame leads to a healthy conscience and a quality of humility. Shame in a nonnurturing, codependent family system is unhealthy or toxic. Such families are emotionally abusive and often sexually and physically abusive. Once a person's boundaries have been violated sexually, emotionally, physically, or spiritually (Mellody, et al., 1991) the child grows up feeling bad and rotten about herself.

PLAYFULNESS

Use of Humor

Questioning Strategies

1. Does/has anyone in your family ever teased you?
2. How does/did this make your feel?
3. When someone in your family tells/told jokes, do/did they make you laugh?
4. Can you tell a funny story about yourself right now?

Rationale

The ability to laugh with each other and oneself is important to personal and family health. The attitude of playfulness generated in family dynamics makes it fun to be together and with one another. Joking and teasing in healthy families is at no one else's expense. There are families where dry humor and sarcasm are frequently used to relieve tension. These are only attempts at humor and are not true humor. The more intense the climate in the family, the less humor there is. In family gatherings, there is frequent intense, serious talk. It is only with the use of alcohol or other mind-altering drug use or addiction that any lightening of intensity can take place, and then it may have tragic consequences and embarrassing repercussions to the family. The intensity is relieved at the expense of everyone's health.

Family Interaction

Questioning Strategies

1. Do/did your family's free time activities foster collaboration or one-upmanship?
2. How do/did you feel about family holidays and why?
3. What kind of games do/did you play when you get/got together?

4. Describe what happens/happened where and when your family gets/got together with relatives?
5. What do/did you do to have fun in your family?

Rationale

When healthy families play together, they collaborate to see that everyone has a good time and no one feels hurt or left out. Parents who encourage their children to play games competitively need to be careful that the competitive spirit is not carried over into family sibling rivalry and jealousy. This also applies to couples and how they spend their recreational time.

BELIEF SYSTEMS

Family Beliefs

Questioning Strategies

1. Are/were all of the members in your family loyal to a set of rules that are/were controlling and demanding of perfection?
2. Can/could anyone in your family ever do anything "good enough"?
3. Can/could you ever do anything "good enough" in the eyes of your family?
4. Do/did individuals in your family have boundaries?
5. Is/was it okay to discuss differences in beliefs and values?
6. Is/was it okay to have differences in beliefs and values accepted by the family?

Rationale

In the developmental process of an individual in a family system, internalization and externalization work together to formulate a belief system. If the external stimuli are negative and shame-bound, then the internalized process is one of negativity and shame. This permeates an individual's values and belief of self. Therefore, it is important for individuals and families to explore messages handed down through the generations that have affected values and beliefs.

Moral Standards

Questioning Strategies

1. What are/were your family's moral standards, and do you agree with them?

2. Are/were these interrelated with the family's denominational religious beliefs?
3. How are/were these morals enforced?
4. Does/did the family attend a church, synagogue, or other place of worship? Do/did they attend together or separately?
5. Is/was dialogue, questioning, or challenging of these beliefs or moral standards permitted?
6. How does/did your family respond to anyone who challenged, questioned, or disagreed?

Ratonale

For many, the adage that the family that prays together stays together is very significant. For such families, religion can be a stabilizing factor and can provide a positive moral code by which to live. (Note that moral codes can exist without religion, that religion is one, and a primary, source of moral code.) In functional, healthy families, a moral code can present certain morals and standards that require accountability while, at the same time, can permit dialogue about each individual's perspective on and perceptions of this moral code. Individuals are permitted to question and challenge and still be part of the system. In codependent family systems, religion or any moral code can be used to negate self-autonomy and insist on perpetuation of rigid, negative, and judgmental morality.

CONCLUSION: CHALLENGES

Codependent family members frequently exhibit symptoms of the family disease for a longer period of time than the addict does. The addict can become abstinent and receive individual and group support and treatment and be *in recovery*. Family members who do not understand that their reactive patterns or maladaptive behaviors need to be healed are not *in recovery*. They need as much support and treatment—if not more, in many cases—than the addict does. Attending Codependents Anonymous, Emotions Anonymous, Al-Anon, or ACOA Twelve-Step support groups as well as counseling can help codependent family members release their destructive family patterns, traditions, and behaviors so that they can function in healthier ways.

In the 1970s, 28-day treatment programs for addicts included an extra week for family members. However, in today's Western controlled-care climate, which allows only short outpatient treatment, family member treatment often is ignored. Even in Eastern or developing countries where therapeutic modalities of treatment exist, little is known or practiced for family recovery. In

African countries, women who live with alcoholic or HIV-infected males need special culturally sensitive care and support. Many family members who live or have lived with active addicts and who still suffer from depression or posttraumatic stress deserve the same attention and care as the addict.

Chapter **9**

Best Practices for Dual Diagnosis Treatment and Program Development: Co-occurring Mental Illness and Substance Disorders in Various Combinations

Kathleen Sciacca, MA

The literature suggests that between 40 and 60 percent of individuals presenting in mental health settings have a co-occurring substance abuse diagnosis, and 60 to 80 percent of individuals presenting in a substance abuse facility have a co-occurring mental health disorder (Mueser, Drake, Turner, & McGovern, 2006). An earlier review by the U.S. Alcohol, Drug Abuse and Mental Health Administration (ADAMHA) cited that at least 50 percent of the 1.5 to 2 million Americans with severe mental illness abuse illicit drugs or alcohol as compared to 15 percent of the general population (Ridgely, Osher& Talbott, 1987). This does not account for people with co-occurring disorders who are not seen in either system.

Receiving simultaneous treatment, in one setting—integrated treatment—has been shown to improve substance use outcomes, including abstinence or harm reduction from substance abuse. Clients who receive integrated treatment experience improvements in independent living, symptom management, competitive employment, and non-substance-using social contacts; these clients also expressed improved quality of life (Drake, McHugo, Xie, Packard, & Helmsletter, 2006). Unfortunately, research shows that 50 percent of people with co-occurring severe mental illness and substance disorders receive no care; 45 percent receive poor care; and only 5 percent receive evidence-based care (Drake et al. 2006).

This chapter will detail a treatment approach that has been integrated into a variety of program models across services and systems of care. This consensus-based best practice model incorporates evidence-based interventions for the

treatment of people who have varying profiles of co-occurring mental health and substance disorders. The discussion will be based in part on the author's experience as a consultant with the design and implementation of the model over the past 24 years across the United States and internationally.

There is a wide range of diagnosed co-occurring disorders that include mental illness and substance disorders. The following clinical profiles may be useful in identifying the target population within a given agency, service, or system. They are broad categories that are found across systems.

DIFFERENTIATING CATEGORIES OF PEOPLE WITH CO-OCCURRING MENTAL ILLNESS AND SUBSTANCE DISORDERS

There are two recognizable broad categories and one subcategory of people with co-occurring mental illness and substance disorders (Sciacca, 1991). These include:

1. **MICAA** (Mental Illness Chemical Abuse and Addiction): This clinical profile includes people who have a severe, persistent mental illness (SPMI) (Axis I), chemical abuse, or addiction. These clients are usually found in the mental health system. This acronym was introduced by the New York State Commission on the Quality of Care in 1987 (Sundram, Platt, & Cashen, 1986)
2. **CAMI** (Chemical Abusing Mentally Ill): This clinical profile includes people who have chemical dependency or abuse with co-occurring personality disorders (Axis II) and other emotional problems. Their mental health symptoms do not include SPMI. These clients are usually found in the substance abuse system.

A subcategory of CAMI is substance-induced acute symptoms, which may include psychotic symptoms such as delusions and hallucinations. These clients cross over from drug and alcohol services to mental health services, utilize both systems, and may be confused with the MICAA population. They do not have SPMI; rather, their acute symptoms are evoked by substance-induced chemical imbalances, making it difficult to differentiate these clients from people with active acute symptoms resulting from SPMI. The important difference is: When CAMI clients' acute symptoms go into remission, no negative or residual symptoms remain. Instead, they resume their usual behavior, attitudes, and activities.

The essential difference between MICAA and CAMI clinical profiles is that the MICAA client has a diagnosed severe persistent mental illness on Axis I (also termed major mental illness) that would be present without the use of

alcohol or drugs—for example, schizophrenia or bipolar disorder. The major mental illness is free-standing from substance disorders yet co-occurring with them. MICAA profiles include a broad range of co-occurring disorders that meet diagnostic criteria. Examples: schizophrenia and crack abuse; bipolar disorder and alcohol dependence; major depression and polysubstance abuse. Most MICAA clients require medication for the treatment of their mental illness.

The CAMI client does not have a severe persistent mental illness on Axis I. Mental health symptoms may be within the realm of personality disorders, Axis II—for example, antisocial personality disorder, borderline personality disorder, or acute symptoms that are substance-induced or mental health symptoms resulting from traumatic experiences. It is reported that the prevalence of personality disorders is at least 50 percent in substance-abusing populations (Nace, 1990). According to Nace (1990, p. 186), the most severe levels of substance abuse are associated with character pathology rather than serious mental illness.

Each of these systems of mental health and substance abuse has a responsibility for its particular population. The mental health system and specific programs need to include a screening tool to detect substance abuse in clients who are known to have a mental illness. In the best practice model presented here, the modified CAGE (cut down, annoyed, guilty, and eye-opener) questionnaire (Mayfield, McLeod, & Hall, 1974, Sciacca, 1990–2008) is implemented for that purpose. The substance abuse system and specific programs need to employ a screening tool that screens for mental health symptoms among clients who are known to have substance disorders. In the model presented here, the Mental Illness Screening Form (MISF) (Sciacca, 1990–2008) is used.

Where there may not be any clinical information, such as among people who are homeless, screening for both mental illness and substance disorders is necessary. There are a number of screening tools and evaluative tools that are used to screen for mental illness and substance disorders for this purpose. The screening tools noted here are recommended for use at the point of client intake into services.

Clients who present with active acute mental health symptoms or substance-induced acute symptoms could benefit from drug and alcohol testing to determine if a particular episode is substance related. For example, a MICAA client who presents with acute symptoms may have evoked her symptoms through substance use or withdrawal. Either condition may exacerbate mental health symptoms. Empirical evidence strongly supports the adverse effects of substance abuse on the course of severe mental illnesses. The consequences of substance abuse for clients include symptom exacerbation, increased hospital-

ization, medication noncompliance, disruptive behaviors, and decreased social functioning (Mueser, Bellack, & Blanchard, 1992).

The CAMI client who presents with acute symptoms may have substance-induced symptoms due to chemical imbalances. Examples include: cocaine-induced psychotic disorder with delusions; cocaine-induced psychotic disorder with hallucinations; cocaine-induced mood disorder, and so forth. In either case, the knowledge that drugs or alcohol are involved in any particular acute episode will assist in ascertaining the possibility of interaction effects and also serve to provide some assurance that co-occurring disorders are not overlooked. This information is valuable for both provider and client, particularly if there are repetitions that warrant further evaluation or if there are indications of the need for dual diagnosis treatment.

ADDITIONAL SYMPTOMS FOUND IN MICAA AND CAMI

People who have MICAA or CAMI profiles have a high incidence of traumatic experiences, including sexual abuse. It has been reported that one in three women and one in seven men is the victim of sexual assault before age 18. Clinical studies report 30–90 percent of women and 30–45 percent of men in substance abuse treatment have a history of sexual abuse. Victims of sexual assault and rape are much more likely to use alcohol and other drugs to cope with the trauma of their victimization (Kilpatrick, Edwards & Seymour, 1992). Traumatic experiences may result in various symptoms including substance abuse and mental health symptoms. The resulting mental health symptoms should be included in evaluations and pronounced within the client's overall diagnostic profile. In some cases, a narrative of the client's traumatic experience accompanies the client's diagnostic profile as a aside story, but the resulting symptoms are not included in the diagnostic profile. For example, resulting depression, dissociation, anxiety, panic disorder, and posttraumatic stress disorder (PTSD) are not included.

Addressing symptoms resulting from trauma and trauma issues is important when designing integrated programs. In a five-year study conducted by the U.S. Substance Abuse and Mental Health Services Administration (SAMHSA), the findings showed that when each of these three areas—mental health, substance abuse, and trauma issues—were addressed with women using an integrated model, those who received counseling addressing all three areas showed greater improvement than those who did not. In addition, women who participated in treatment decisions regarding their own care had better outcomes (Morrissey, Jackson, et al., 2005; Morrissey, Ellis, A. R., et al., 2005; Sciacca & Dobbins, 2001).

MICAA and CAMI Clients in Treatment

MICAA and CAMI clients can be treated together in treatment groups, and when group leaders are comfortable with both populations their differences may enrich the group process. The model of group treatment for co-occurring disorders outlined in this chapter is appropriate for the inclusion of MICAA *and* CAMI clients, as well as for treating these populations separately. The distinction in treatment for clients who differ in these profiles is based on the degree of structure, treatment intensity, and pace of the treatment.

MICAA clients do well with less intense, less frequent treatment groups, ancillary services, and programming, at a pace that corresponds to their participation. CAMI clients, on the other hand, do better with more frequent (though not more intense or confrontational) treatment groups, ancillary services, and programming, at a pace that matches their participation. It has been demonstrated that people with co-occurring disorders have improved outcomes when they receive simultaneous treatment for *all* of their symptoms (SAMHSA, 2002).

THE BEGINNING OF TREATMENT FOR CO-OCCURRING DISORDERS

The first treatment groups designed specifically for people who have co-occurring disorders began in 1984, in the New York State Psychiatric Care System (Sciacca, 1987a, 1991, 1996). Many clients attending a psychiatric day treatment program had severe, persistent mental illness and co-occurring substance abuse and dependence. They had been falling out of the system prior to that time, and they continued to do so as new interventions got under way.

Today we find these clients in large numbers in alternative systems, particularly among the homeless and in the criminal justice system. Early surveys reported that 10 to 20 percent of homeless persons were dually diagnosed with severe mental illness and alcohol or drug problems (Tessler & Dennis, 1989). In the criminal justice system, 16 percent of jail and prison inmates were estimated to have severe mental health and substance-abuse disorders. Among detainees with mental disorders, 72 percent also had a co-occurring substance-abuse disorder. (National Alliance for the Mentally Ill, 2003).

In the mental health and substance-abuse systems, MICAA clients were essentially unwanted, believed to be untreatable and costly to the systems, and presented clinical challenges not considered to be within the domain of mental health *or* substance abuse practitioners. CAMI clients may have received treatment for their addictive disorders alone or, with the added complexities

of differential diagnosis in the CAMI population, mental health symptoms may have been interpreted as substance related (which some of them may have been) rather than preexisting conditions or free-standing symptoms (the alternative possibility) or may not have been addressed at all. During this time, the concept of dual disorders emerged and grew in popularity. Treatment systems, however, including mental health and substance abuse, were unresponsive. The New York State Commission on the Quality of Care later corroborated this claim (Sundram et al., 1986).

It continues to be held that there are systems barriers in both systems and that clients are perceived as 'misfits' at every level—at the system policy level, at the program design level, at the clinical practice level, and at the clinician competency and training level—in terms of regulations, information systems, funding mechanisms and clinical credentialing and certification" (Minkoff & Kline, 2004, p. 66).

Through early attempts to provide group treatment interventions for MICAA clients, they initially responded angrily to any suggestion that they might have substance-abuse or dependency issues. Some found this suggestion to be derogatory and interpreted that staff were calling them drug addicts, which implied stigma and very negative connotations for them, or they protested that their simple pleasure of drinking alcohol would now be taken away from them. Conversely, CAMI clients in the substance-abuse system found suggestions that they may have mental health symptoms to be derogatory and implying the stigma of being called crazy and all that implied. It became clear that developing interventions required that practitioners: (a) accept clients where they were and (b) accept symptoms and conditions, and each client's level of readiness to address these or to engage in a process of change. Interventions were "nonconfrontational, and included a phase model of intervention identifying clients' movement along a continuum of change delineated by group-treatment phases.

Pronouncing that clients were at different phases and stages of readiness to address substance abuse was in direct contrast to the traditionally held readiness criteria for acceptance into substance-abuse treatment services. Potential clients were expected to acknowledge their substance disorders, be ready and motivated to accept treatment, and comply with abstinence. MICAA clients did not present themselves in that light; therefore, there was no alternative but to provide combined mental health and substance abuse interventions within the mental health system—integrated treatment.

From the beginning, in 1984, it was necessary to begin at the client's readiness and motivation and to view progress or change incrementally. This was later corroborated through consensus in the SAMHSA-Center for Mental Health

Services (CMHS). The "Standards of Care, Practice Guidelines, Workforce Competencies and Training Curricula" (Sciacca, 1998a) report (SAMHSA-CMHS, 1998) which recommended phase and stage models of intervention for working with people who have co-occurring disorders. The report articulated some of the following recommendations:

- For each disorder, assessment should include a definition of the stage of change or level of motivation.
- When mental illness and a substance-use disorder coexist, each disorder should be considered as primary, and integrated dual primary treatment should be provided; the treatment for each disorder should be matched to the diagnosis and the stage of change (SAMHSA-CMHS, 1998).
- Within each subtype of the treatment population, consumers are in different phases of treatment and at different stages of change with regard to their illnesses. Thus a comprehensive array of interventions that are phase and stage specific is required.

As the dual diagnosis group treatment model evolved in 1984, three phases of group participation emerged (Sciacca, 1991; Sciacca & Thompson, 1996). In phase 1, for example, clients are less prepared to self-disclose or discuss their personal situations; in phase 2, they begin to talk about themselves and may include some early discussion of their own behavior. Two readiness scales were designed to measure clients' starting points and progress along a continuum of incremental change (Sciacca, 1990–2008) for their substance abuse and mental health symptoms (see Tables 9.1 and 9.2).

Very frequently, clients were at different levels of readiness to address different symptoms. Treatment usually began with clients who were physically addicted to drugs or alcohol, who actively used substances, and who had active mental health symptoms. It proceeded from denial through recovery (Sciacca, 1987, 1991), and through stages of change—precontemplation through maintenance (Prochaska & DiClemente, 1984). Clear strategies and treatment content were correlated to each readiness level (Sciacca, 1987, 1991; Sciacca & Thompson, 1996), and stage matched tasks were identified for the stages of change (DiClemente 2007; Prochaska & Norcross, 2001).

As the field of dual diagnosis forged ahead, in 1986 the New York State Office of Mental Health initiated the MICAA Training Site for Program and Staff Development New York. State-wide, this program remained viable until 1992. Providers of all disciplines, from a variety of systems, participated in training events and program-development initiatives. This included the substance-abuse system where CAMI clients were regularly encountered. Interventions and dual diagnosis programs were designed with the same elements: noncon-

Table 9.1
Sciacca Comprehensive Service Development Readiness Scale for Substance Abuse

Assessment of Client's Readiness to Address Symptoms or Engage in Treatment for Substance Abuse:

1. Client is denying the scope or existence of his substance-abusing behavior and is unwilling to seek treatment or information.
2. Client is denying the scope or existence of his substance-abusing behavior but is willing to learn more about alcohol/drugs, substance abuse, and other topics.
3. Client is agreeing that he has a substance-abuse problem but believes that he can manage it without additional treatment or information.
4. Client is agreeing that he has a substance abuse problem, is willing to seek information, but has not demonstrated working on the substance-abuse problem itself.
5. Client is aware of the problems that substance abuse has caused, is willing to seek information, and is engaged in some form of treatment to work on these problems.

Please write the number indicating the level of treatment readiness alongside each of the substances client uses.

frontation, and phase- and stage-specific interventions correlating to each client's readiness to engage in treatment (Sciacca, 1996). This work has since been replicated in numerous states and cities—for example: Tennessee (Sciacca, 1998b), Washington, DC (Sciacca, 1999), Michigan (Sciacca, 1997a), Georgia ("GA Seeks Statewide Implementation," 2003).

The challenge was to engage clients in discussion about a variety of related topics, including symptoms, without requiring them to acknowledge substance abuse, mental illness, or other behavioral problems. As this objective became clear, an impersonal approach, one that did not require clients to agree or admit to having either mental health or substance-abuse symptoms was necessary. One strategy that facilitated this process was the inclusion of educational materials from a variety of media on a variety of topics that clients discussed and critiqued. Materials such a fact sheets, videos, and outside speakers were

included in groups. The focus was on discussing the opinions of clients on a broad range of topics rather than clients' self-disclosure or didactic education.

Fact sheets providing information about mental illness, substances, addictive processes, interaction effects, HIV, family issues, stress-related issues, and other topics could be read aloud by participants and discussed from various points of view, without implying that the participants were users, and without requiring self-disclosure. As this work proceeded, the group treatment approach that began in 1984 evolved into the following comprehensive model, which adapted to clients' responses and needs (Sciacca, 1987, 1991; Sciacca & Thompson, 1996). This process was further evolved with the development of the pregroup interview (Sciacca, 1990–2008).

DUAL DIAGNOSIS BEST PRACTICES GROUP TREATMENT MODEL

Interactions with clients in dual diagnosis groups resulted in further adaptations to meet their treatment needs and to engage them in explorations to assist them to clarify their situations (Sciacca, 1987, 1996, 2007). The objectives of this approach included the following:

1. Assist clients in recognizing and accepting that they have symptoms of mental illness and substance disorders and dispel any associated shame, self-blame, guilt, and stigma;
2. Help clients learn and understand the real properties of mental illness, substance abuse, and dependence, and the interactions between co-occurring disorders;
3. Facilitate explorations of the benefits and disadvantages of behavior change, leading to accepting or rejecting treatment;
4. Help clients reach an understanding of their unique situations and make decisions regarding change;
5. Provide a client-centered, empathic listener, who elicits and attends to clients' points of view, beliefs, experiences, feelings, disappointments, aspirations, and goals; and
6. Offer a support group where clients can give and receive support in a safe, respectful environment and where they can embark on a process of change with established alliances.

ENGAGEMENT IN DUAL DIAGNOSIS GROUPS

Once clients are identified as potentially having dual/multiple disorders through screening, the group leader is made aware of their candidacy for the dual diagnosis group.

The leader will include them on a client disposition form (Sciacca, 1984) and refer to that list to set up pregroup interviews as openings occur in the group.

The client will be advised by her primary counselor, or by other staff, that there is a group or program that may be beneficial to her and that the leader would like to meet to discuss this. The client's potential to have this meeting will determine how formal (scheduled date and time to meet with the leader) or informal (meet with client in the waiting area or community room) the setting of the interview will be. This interview may take place in a variety of settings across systems. The interview usually does not exceed one-half hour.

The group treatment process begins with the pregroup interview (Sciacca, 1987a, 1991, 1990–2008), conducted by the group leader prior to the client's participation.

The pregroup interview (Sciacca, 1987, 1991, 1990–2008) may begin with an open-ended question, such as, "What are your thoughts about participating in group discussions?" This provides an opportunity for clients to discuss their understanding of groups; if pertinent, their previous experiences in groups; or whether or not they believe they have any need for such an intervention. This is an opportunity for the group leader to listen to and understand clients' perspectives. The leader can now follow up with client-centered interviewing (Rogers, 1946). Here is an example of how the client may respond: "I don't really like groups." The leader may reflect: "So you have attended groups before and did not find them very useful to you."

The client-centered approach entails following the client's thoughts for a while and conveying, through empathic, reflective listening, that the listener understands the client's perspective and feelings. The experience of having a good listener, one who is interested in the client's perspective and who conveys respect and understanding, can help build valuable rapport. "If the client feels that he is actually communicating his present attitudes, superficial, confused, or conflicted as they may be, and that his communication is understood rather than evaluated in any way, then he is freed to communicate more deeply" (Rogers, 1946, p. 6). Client-centered reflective listening sets the tone for collaboration between client and leader. In dual diagnosis treatment the client-centered "following" approach is complemented by directive strategies employed by the leader. Interventions are strategically correlated to the client's readiness level, the treatment phase (Sciacca, 1991), and are stage-matched to the client's stage of change (DiClemente, 2007; Prochaska & Norcross, 2001) in an effort to facilitate an exploration that may lead to a process of incremental progress along a continuum to acceptance, problem recognition, action, and recovery.

One objective of the pregroup interview is to establish a purpose for each client's participation. This may include a client who is mandated to treatment by the criminal justice system, a client who is in a mental health program and denies any use of substances, or a client who is in a substance-abuse program and denies any mental health symptoms. A purpose for the client's participation may include an expressed interest in learning or in providing support to other group members. The client may not acknowledge his symptoms of co-occurring disorders. Clients' perceptions of their situations are acceptable to the group leader. However, a group leader should not readily accept clients into groups who have not identified any purpose or reason for attending. These clients may proceed to behave accordingly, by tuning out or by reiterating their disdain, during group sessions. The client is given every opportunity to identify topics of interest other than mental health and substance disorders that may be more relevant, more useful, or more comfortable to discuss. An open question may also yield some ideas: "What would you like to get out of participating in

group discussion?" In addition to the client's interests, the leader also facilitates an exploration of possible contributions the client may make to the group and its members. Mandated clients are making a choice to attend treatment versus other alternatives, and the leader wants to acknowledge that choice.

THE FIRST ELEMENT OF THE INTERVIEW—SUPPORT

Clients are asked whether or not they can be supportive of others who may be working on change, even though they do not perceive themselves as having problems. (During actual groups, leaders and group members define the concept of support through interactions and discussions.) This is followed by an overview of other group members' readiness. For example, the leader may say: "In our group, we have people like you, who do not believe that they have any problems, (symptoms, etc.); we have some people who are exploring this possibility; we have others who are trying to change; and we have some who have successfully changed." This sets the tone for the various readiness levels clients will encounter in groups; the leader may have to repeat this premise in group when the topic arises.

If MICAA and CAMI clients attend group together, the leader informs clients of this and asks clients of each profile if they have any thoughts or concerns about this. For example, a CAMI client might be asked, "In our group, we have participants who have a serious mental illness, and some who take medication. Do you have any thoughts about that?" The reverse would be asked of the MICAA client: "In our group we have participants who have serious substance disorders who do not have a serious mental illness. Do you have any thoughts about that?" The leader would use language that is pertinent and comfortable to describe each profile to each client. The point is that clients should not simply find themselves among others who have symptoms that they do not identify with or feel uncertain as to why they are in group with others whom they experience as different. This works both ways, where MICAA clients may not identify with CAMI clients. This area of discussion reaches more broadly than the group alone. Here, the leader is opening dialogue and setting the tone for important changes that are necessary when we include dual diagnosis programming in general. The initiation for every client is that we are all supportive of one another, regardless of the differences we may have. Clients are reminded: This is a *support* group. We are all here to help one another, regardless of our differences. This may not exclude the need to address clients' perceptions of their differences from one another or their concerns. In general, disrespectful behavior originates from stigma and judgmental attitudes. This is the antithesis of the content and process of the dual diagnosis group model and the approach

of the leader. As participants learn the real properties of each of these disorders and they experience the respect of the leader, they grow to be empathic toward one another.

THE SECOND ELEMENT OF THE INTERVIEW—EDUCATION

The leader discusses the educational component. Here the leader fans out the educational topics beyond mental health and substance disorders. Dual diagnosis groups include a broad range of topics. The leader might discuss the inclusion of a number of topic areas: coping with stress; understanding relationships; mental health issues; how one goes about attaining goals; various substances and their effects; and understanding how people change. The client may express interest in learning more about a particular substance, giving the reason that a roommate is a user, or a parent or child has been addicted. This is acceptable as an identified interest in learning and a purpose for attending.

THE THIRD ELEMENT OF THE INTERVIEW—OUTSIDE SPEAKERS

The leader asks about the client's interest in the inclusion of outside speakers who address various topics in groups. The leader addresses any forms of consent that may be necessary to include outsiders.

THE FOURTH ELEMENT OF THE INTERVIEW—RECEPTIVITY TO LEARNING

The leader discusses the client's receptivity to learning, even with the awareness that she may not believe there is a problem or a reason for change. "Even though you do not think you have problems in any of these areas would you be open to learning from the materials presented and from others who attend the group?"

THE INTERVIEW IS SUMMARIZED

The leader summarizes the interview by highlighting the client's reasons for attendance. These reasons may include: willingness to help others or other contributions the client may make, interest in learning about a specific topic, or other previously identified reasons for group attendance.

MEASURING CLIENTS' READINESS TO CHANGE

In 1992, with the advent of the publication of *Motivational Interviewing* (Miller & Rollnick, 1991) the correlations across a number of the motivational interviewing concepts and practices and dual diagnosis best practices were surprisingly apparent (Sciacca, 1997b). Among them was the description and utilization of the stages of change (Prochaska & DiClemente, 1984). The stages of change provided a second way to conceptualize clients' readiness and motivation and an incremental process of change and became included in the dual diagnosis best practice model.

At the end of this interview, it is important when possible, to measure the client's readiness to address specific symptoms or to embark on changing particular behaviors. In some cases this may require more strategic discussion, as outlined in the preadmission interview (Sciacca, 1987b). Readiness to address mental health and substance-abuse symptoms are measured with the Sciacca Readiness Scale (Sciacca, 1990–2008) (see Tables 9.1 and 9.2). Later, as treatment goals are formulated, the stages of change (Prochaska & DiClemente, 1984) are included and applied.

Clients are frequently at different levels of readiness to address different symptoms or behaviors. For example, a client may think alcohol is problematic but find marijuana useful. Readiness is defined on a 1-to-5 scale (Sciacca, 1990–2008, with 1 as "least ready" and 5 as "participating in an action plan." In this example, we have a 1 for marijuana and a 4 for alcohol on the Substance Abuse Readiness Scale, Table 9.1. This would correspond to the stages of change with the precontemplation stage and the preparation stage, respectively.

Stating a willingness or desire to change does not yield a measure of action, but it may be indicative of the preparation stage. At the preparation stage, a collaborative change plan would be developed. When the client follows through on various elements of the plan, he is in the action stage. It is important to measure readiness early in the process and to employ interventions that facilitate change processes that are stage-matched.

Goal planning optimally includes a goal stated in behavior change terms. Here is an example for substance abuse: client will abstain from alcohol. Here is an example for mental health: client will spend less time in isolation and participate in more activities. Each goal includes the client's stage of change and readiness scale measure (Sciacca, 1990–2008) followed by stage-matched facilitations. One wants to avoid mismatching stages and processes. "Action oriented therapies may be quite effective with individuals who are in the preparation or action stages. These same programs may be ineffective or detrimental, however, with individuals in pre-contemplation or contemplation stages"

(Prochaska & Norcross 2001, p. 447). In the transtheoretical stage of change model, behavior change is conceptualized as unfolding over time and involves a progression through six stages. Both the stages of change and the Sciacca Readiness Scale are nonlinear, and clients may return to earlier stages or readiness levels.

APPLYING THE STAGES OF CHANGE

The perspective that has become common among addictive behavior researchers and clinicians subdivides the process of change into specific stages that attempt to capture critical tasks that need to be accomplished to modify these behaviors (DiClemente, 2007). Five stages of change are formally recognized in the stages of change literature, and the tasks for advancing through each of them are articulated (DiClemente, 2007; Prochaska, DiClemente, & Norcross, 1992).

- *Precontemplation* is the stage where the client has no intention to change behavior in the foreseeable future. Clients in this stage are unaware or underaware of their problems. Tasks: creation of concern and interest in change. Example: Facilitate awareness of the need for change and concern about the current pattern of behavior; envision the possibility of change. Increase client's awareness of risks and consequences of current behavior.
- *Contemplation* is the stage in which clients are aware that a problem exits, may be seriously thinking about overrcoming it, but have not yet made a commitment to take action. *Ambivalent* is a term frequently used to define the client's experience in this stage. The client may identify both positives and negatives, but there is no intention to change at this time. Clients can remain stuck in either the precontemplation or the contemplation stage. Tasks: decisional considerations and decision-making. Example: Facilitate analysis of the pros and cons and the costs and benefits of change, decision-making. Aim to tip decision balance in favor of change. Elicit reasons for change, risks of not changing, and help strengthen client's confidence and self-efficacy.
- *Preparation* is a stage where the clients are intending to take action. The negatives outweigh the positives, they have reached the decision to make a change. They may report some small changes, such as reduction in the behavior, but they have not yet reached the criteria for effective action such as abstinence. The client lacks a plan for change. Tasks: increase commitment and create a collaborative change plan. Assist client to find a change strategy that is acceptable, accessible and effective. Administer a functional analysis. Facilitate confidence building.
- *Action* is the stage that involves the most overt behavioral changes and requires commitment of time and energy. The client is participating in a plan

of action. This may include actions that the client has identified, changing a social network ,or that the provider has suggested, additional treatment, self-help and so forth. Tasks: initial modification of the behavior. Help facilitate the implementation of strategies for change, revising the plan as needed, sustaining commitment in the face of difficulties. Affirm client's commitment for change. Help client identify steps and skills for change. Help client identify additional resources that may be helpful. Include coping strategies for high-risk situations. Note: Preparation for maintenance entails assessment of triggers, as well as in preparation for action. A functional analysis may be administered. Alternative responses in high-risk situations and coping skills are recommended in both the action stage and the maintenance stage.

- *Maintenance* is the stage in which clients work to prevent relapse. The behavior or symptom is now in remission. Tasks: sustaining the new behavior and creating a stable new pattern. Example: assist client to sustain change over time and across situations. Accentuate positive benefits since changing behavior. Develop strategies to prevent relapse. Provide referrals and resources. Develop an overall plan of maintenance services and supports.

  The mechanisms needed to accomplish these tasks are called processes of change.

Two additional considerations are postulated.

- *Relapse*—Slipping back to previous behavior and re-entering the cycle of change.
  - Assure client that relapses are normal and can be overcome.
  - Help reframe slips into learning experiences, revise the maintenance plan and help client to renew determination and confidence in order to resume change efforts.
- *Termination*—Leaving the cycle of change.
  - Low temptation, high self-efficacy, new behavior is normative, multiple changes to sustain change.

The vast majority of addicted people are not in the action stage. Aggregating across studies and populations (Abrams, Follick, & Biener, 1988; Gottleib, Galavotti, McCuan, & McAllister, 1990), 10–15 percent of smokers are prepared for action, approximately 30–40 percent are in the contemplation stage, and 50–60 percent are in the precontemplation stage. If these data hold for other populations, then action-oriented programs may underserve, misserve or not serve the majority of their target population (Prochaska et al., 1992).

When addressing co-occurring disorders, it is likely that a client in substance-abuse treatment is in the precontemplation or the contemplation stage to address his mental health symptoms. The reverse is true for clients in mental health programs. Many of these clients do not generally see substance abuse

as a problem. In effect, dual diagnosis treatment requires that interventions are matched with the earliest stages in order to effectuate the possibility for behavior change.

This process of goal planning, stages of change, readiness measures, and incremental change includes continual updates and outcomes that are tracked on the client behavior change update form (Sciacca, 2000). If the client agrees to attend the group, she will participate in the following group process.

PHASES OF DUAL DIAGNOSIS GROUP TREATMENT

Three phases of group treatment have been identified (Sciacca, 1991; Sciacca, 1990–2008); each phase has goals and objectives.

Phase one: This phase includes exposure to information as the initial focus; there is no need for clients to self-disclose if they are not ready to do so. Clients are free to express their opinions about the topics presented through literature, videos, and speaker's ideas. The objectives include:

1. Developing a trusting atmosphere that is nonconfrontational and respectful of one another, including other members' symptoms and opinions;
2. Providing clients with information that provides the real properties of substance disorders, mental illness, and interaction effects;
3. Dispelling judgments, morality, and stigma;
4. Exposing clients to information regarding the risks and consequences of ingesting various substances, and interactions with mental health symptoms and medication; and
5. Addressing and discussing related topics such as relationships, social networks, stressors, family involvement, goals, aspirations, values, and processes of behavior change.

If clients gain a cognitive and experiential understanding of their situations through this process, it will eventually lead to acceptance of symptoms. This process is intended to facilitate a shift, from the client's exclusive or primary focus on the positive experiences with substance use, or the lack of awareness of any impact at all of substance disorders or mental illness (precontemplation stage), to the identification of positive *and* negative experiences resulting from substance use, including interaction effects, and recognition of risks and consequences of not addressing mental health symptoms (contemplation stage.)

Phase two: Client self-disclosure, and an exploration of positives and negatives, may eventually lead to problem recognition. When trust has developed—and shame, self-blame, and guilt are alleviated—clients begin to self-disclose. This may be minimal at first; the objective is to continue to explore and expand on this recognition.

In this phase, more attention is focused on each individual, and the format of the group may change. For example, leaders will begin groups by checking in with each member and discussing their pursuits and current issues. This is followed by a group theme, explored by everyone. Topics may continue to evolve around adverse effects of substance abuse, unchecked mental health symptoms, and interaction effects. Leaders will facilitate an exploration of each client's experiences in these areas. Strategies such as the pros and cons and the decision balance can be utilized among other themes that generate discussion around decision-making. Teaching the stages of change and facilitating group members' identification of their stages for a particular goal facilitates the recognition of change as a process, normalizes change—including ambivalence or feeling stuck—and further reduces shame, blame, and negativity.

Themes that relate to clients' values and strengths, including previous successes, afford discussion around confidence issues. The group ends with a summary, where the leader may affirm each member, review what occurred in the session, and provide an opportunity for each member's input and closure.

In phase two, group leaders who are also clinicians administer a co-occurring clinical assessment in individual sessions (Sciacca, 1990–2008); clients' responses inform a refined treatment plan. The objectives in phase two include the following:

1. To facilitate each client's identification of risks and consequences while the leader employs a nonjudgmental, client-centered, empathic approach;
2. To facilitate bringing risks and consequences into clear focus for each client;
3. To elicit the recognition and discussion of additional risks, consequences, and benefits of change;
4. To facilitate the client's resolution of ambivalence and to foster problem recognition (pros and cons, decision balance);
5. To assist clients in attaining the necessary confidence and hope that change is possible; and
6. To help clients learn about and understand how people change.

This open process empowers each client to explore and reach decisions about the effects of substance abuse on his mental health and well-being, and the effects of mental health symptoms on substance abuse symptoms. In effect, this understanding may help the client move toward behavior change.

Phase three: The client identifies a problem and begins planning for and executing behavior change (preparation and action stages). Here, the client may address only one of a number of symptoms, a particular substance used, and so forth. This is acceptable to the leader and to the group process.

The leader will listen for and reinforce and further develop discussions about change. In particular, commitment talk (e.g., "I will do this") leads to planning for change and correlates to outcome (Amrhein, Miller, Yahne, Palmer, & Fulcher, 2003).

A change plan is collaborative and will include the client, the leader, and possibly the group members. Moving into the action stage will include confidence building, and actions will be planned and prioritized according to their potential for success. The leader may check in and follow the client's behavior change pursuits during initial group go around and will continue to provide direction and support.

The change plan may include services outside the primary program, such as self-help programs, additional therapy, detoxification, or medication. The overall plan is followed by the group leader, who helps the client make necessary adjustments, including revising elements of the change plan that do not work for the client.

As clients experience success in one area of change, they frequently identify additional problematic behaviors and embark on other changes. Strategies and interventions now include appropriate increments of change that assist clients with symptom management, symptom remission, stability, acquiring coping skills, and relapse prevention. Facilitating bringing all symptoms into remission is the overall goal.

SUMMARY OF DUAL DIAGNOSIS GROUP PROCESS

1. Clients are critics, not students of the information presented or discussed.
2. Videos, fact sheets, and speakers are examples of educational materials used. One topic, alcohol, may be presented with different forms of media. Unless this is a time-limited group, this is not one-time learning.
3. Education and information are not purely didactic. There is a balance between information (cognition) and personal experience regarding all topics. Clients give their opinions based on their own experiences or the experiences of others whom they know.
4. Clients may validate or invalidate the information. There is no right or wrong answer.
5. Providers do not present themselves as experts. They employ an exploratory approach, and are open to learning with *and from* the clients and the information discussed.
6. Clients are not pressured to self-disclose. A client who recognizes adverse effects, and who decides to work on substance abuse/mental health symptoms, does so as a willing participant (intentional change), rather than one who might be bribed or coerced.

THE BENEFITS OF INTEGRATED DUAL DIAGNOSIS SERVICES, PHASES OF TREATMENT, STAGES OF CHANGE, AND CLIENT-CENTERED INTERVENTIONS

The following are some of the benefits of integrating dual diagnosis treatment, the stages of change, and client-centered interventions into agencies and services for people who have co-occurring disorders:

- Empathic, accepting, client-centered interventions improve the engagement potential for many dually diagnosed clients who have been disengaged from treatment because of rejection or lack of competent care.
- Client-centered interventions facilitate gaining knowledge and understanding of the client's true self including his understanding of symptoms and behaviors, readiness to engage in behavior change, goals, aspirations, and disappointments and broaden the interventions beyond medication and symptom-focused approaches.
- Group treatment has evolved as an effective model to treat dual disorders; the inclusion of the stages of change and related strategies and materials in dual diagnosis groups or in groups that exclusively adhere to stages of change topics is highly effective, adding important learning experiences within the psychoeducational component of treatment and enhancing the recovery process of dually diagnosed clients.
- Providers who treat co-occurring disorders learn a comprehensive set of strategies and skills that enhance their professional competence and have the potential to greatly improve the outcome of their clients.
- Clients who receive simultaneous treatment for mental health and substance disorders in one setting are able to participate in the program or system they are familiar and most comfortable with. They have the opportunity to address all of their symptoms and the resulting interaction effects and thereby learn whether or not co-occurring disorders are an obstacle to their recovery from substance disorders, mental illness, or both.

CLIENT-CENTERED INTERVENTIONS—ESSENTIAL AND EFFECTIVE

Employing a client-centered approach (Rogers, 1946) is essential and extremely beneficial to both the client and practitioner. From the onset, clients are listened to, understood, and communicated with beyond their clinical symptoms, to the real self. Rapport building may ensue and alliances may be formed. This is in direct contrast to previous experiences of clients being unwanted or being treated as misfits or being confronted about having symptoms that they may not agree with. The client-centered, reflective listening

approach begins with an engaging versus disengaging process, one in which the client feels understood and recognizes that she is an important part of the process.

The practitioner's approach in employing client-centered, dual diagnosis and stages of change concepts is transitioned to one who facilitates explorations leading to the client's movement along a continuum of incremental change and decision-making instead of one whose former approach was to feel pressured to make people change and usher them into action whether or not change was precipitated by external pressure, threat, or bribery. In any of the latter cases, change would likely last only as long as the external pressures did.

Participating with providers who are accepting and respectful, who are empathic and inclusive, and who allow the clients' process of change to unfold is both essential and invaluable to clients who have co-occurring disorders.

The benefits to clients who receive these interventions include genuine alliances and caring; a listener who wants to understand their perspectives and facilitate a respectful exploration of their ideas and feelings as they relate to their present issues and goals; and insight and understanding into the behavior change process. Most important is the recognition of the stages of change as a normal process of change.

Client-centered, reflective listening creates the necessary experience of safety and the opportunity for deepening the exploration and, thereby, the ability to potentially address the real and often underlying issues around behavior change. This can lead to resolving the deeper causes of being stuck. For example, a client may present a problem initially stated as "My wife wants to go back to school. She has enough to do, and I don't think she needs to, so we argue." Reflective listening may lead to the client's revelation of some deeper issues such as these later statements. "She might go back to school and decide she doesn't want anything anymore. She doesn't want any family." Now the client has moved from a cognitive presentation of a problem—disagreement as to whether or not his wife needs more education—to an underlying emotional issue, fear of abandonment.

Movement from cognitive presentations of problems to underlying emotional issues is frequently very rapid (anywhere from within 10 minutes to within one session and so on) even when reflective listening alone is employed.

Other important ways that client-centered, reflective listening is essential to this process includes the many kinds of thought processes a leader or practitioner may relate to during the course of engagement or treatment. For example, a client with transient psychotic delusions may talk about his wife and children being upstairs at the day center while he is attending the dual diagnosis treatment group downstairs. The client doesn't have a wife or children. The

practitioner can reflect the essence of the client's statement without engaging in invalidating the details. For example: "It seems that you have been thinking about your family a lot lately." This response can validate the client's statement. It may also lead to discussion about the client's actual family.

A client who has recently been diagnosed with a late-onset severe persistent mental illness transitions from a high-pressure lifestyle to participating in a day treatment program. He states to the therapist, "I am really enjoying just lying around the day center without anything at all to do." Here a therapist may get concerned that the client is lapsing into lethargy. Reflective listening can provide the following validation: "You seem to be appreciating some relief from the high-pressured lifestyle you have been living." Rather than opposing the use of day center as a way for the client sink into lethargy, this response opens the door to explore many other ways the client may relieve that stress yet still be able to function.

A client tells her therapist that she goes out with a man on weekends (one whom it seems may be engaging in some illegal drug use); they go dancing, and she states that she is really having a good time. Here again a practitioner may feel pulled into the precautions of the situation, but reflective listening can simply validate the underlying need. "You really need to have something fun and exciting going on in your life. It makes a real difference for you." This opens the possibility to explore alternatives for fun and excitement.

There are many examples of reflective listening interventions that convey respect, understanding, validate the client's needs, thoughts, and feelings, and facilitate the client's exploration. The practitioner remains connected to the client throughout providing thoughtful reflections. Reflective listening is never judgmental, and the practitioner always strives to convey to the client that he or she is understood. At the same time the practitioner also employs directive strategies such as pros and cons, decision balances that facilitate explorations and insights that may lead to problem recognition and the decision to change one's behavior.

READINESS TO CHANGE, PHASES OF TREATMENT, AND STAGES OF CHANGE

Designing services around a client's readiness to address symptoms is revolutionary for programs, providers, and clients. Service systems and individual programs that show progress only when a client reaches the action stage, particularly with clients who have co-occurring disorders, are likely to show failing results in the areas of program outcome, provider outcome, and client outcome.

When clients' progress is measured incrementally, programs, providers, and clients show real success and outcome is reversed. Matching interventions to client readiness provides the opportunity for improved outcomes. Providers and clients are working together at the client's level of readiness and stage of change, and the process of change is facilitated. The relationship between client and provider is greatly enhanced.

Rather than a client being viewed in negative terms, such as uncooperative or resistant, the client's stance or behavior is defined by his readiness or stage of change.

If a client is understood to be in the precontemplation stage and the provider is trying to get him to go into action to change behavior, the resulting responses and attitudes the client conveys will be understood by the nature that he is in precontemplation and not that he is uncooperative or opposing the provider. It is the stage of change that defines the client's relationship to the change process.

Where such clients formerly found themselves participating in programs that required participation in action plans and abstinence or symptom management, which inevitably set them up for failure, within the incremental change model the same clients can explore their perceived benefits and lack of concerns and move beyond the negative struggle.

In addition to the action-ready model, many providers have been taught through expediency that symptom activation or remission alone also equals successful outcome or failure. This medical model of symptom management is primarily symptom focused and impersonal. The focus can be placed on medication compliance or whether a client's particular symptom is active or in remission on a particular day. The client-centered approach to medication is not used; instead, clients are expected to comply with given regimens.

Here is another very important juncture where collaborative, client-centered interventions can give voice and participation to the client's pros and cons as to what is good about the medication what is not good about it and learn what the options are from a good listener. A client who participates in the process of medication adjustments is far more likely to reach a medication regimen that is least detrimental and most effective.

In all areas of treatment, the client who is in a relationship with providers who accept her readiness level, employ client-centered collaborative interventions, listen carefully and make a genuine effort to employ strategies to assist the client to move through the process of change, reaps the benefits of feeling connected to another human being who is genuinely concerned. The client's true self is involved; thereby a meaningful, inclusive, and empowering experience is possible.

NEW SKILLS AND APPROACHES, BENEFITS TO PRACTITIONERS

Practitioners who receive education and training to prepare for treating co-occurring disorders expand both their knowledge and their skills as they learn new approaches in assisting people to change. They are prepared to accept clients as they present for services and to employ interventions that are accepting, engaging, pertinent, and effective. Their task has changed from beingresponsible for making people change to being a facilitator of a thorough exploration of each client's situation, thereby affording them the opportunity to recognize problems and to reach the decision to change or not to change. This dramatically reduces the incidence of burnout. Instead, progress is charted realistically and incrementally along each client's process through the stages and phases beginning from denial to recovery and from precontemplation to maintenance.

Learning dual diagnosis treatment, the stages of change, and client-centered interventions results in knowledge, skill, and wisdom for each practitioner who subscribes to it, regardless of her clinical orientation or system of care. The acceptance of clients regardless of their clinical profile is essential.

Discarding negative interpretations of client behavior while promoting awareness of the difficulties and hardships that all symptoms impose on clients evokes empathy and opens the path to alliances and engagement. This allows the process of the examination of areas, such as the pros and cons, to go forward and facilitates an exploration that may result in the decision to change one's behavior.

THE BROADER IMPACT OF INTEGRATED TREATMENT FOR CO-OCCURRING DISORDERS

Programs and systems also benefit from the inclusion of these approaches. A departure from the premise that all clients are in the action stage, and systemic recognition of each client's level of readiness and stage of change (including the fact that the client may be at different stages of readiness to change different behaviors), changes a program from one that is failing to bring clients into action to a program that is charting successful outcome along a number of incremental and more realistic criteria. This benefits both programs and systems in their accountability and outcome.

Where the action-focused model leads to interpretations of client, provider, program, and systems failure, programs that utilize incremental strategies and measurements of change demonstrate success in each of these areas. From this perspective, the effectiveness and popularity of concepts such as readiness to

change and stages of change serve to revolutionize the way we view behavior change and how we document progress within our programs and for our clients, as well as providing strategies and interventions that correlate to client readiness and strategies and that are directive in facilitating movement through the process of change. The impact on all programs and systems that reach this realization is immense. Providers who learn this distinction are convinced that outcome measures that are exclusively focused on the action outcome are unrealistic, result in client opposition rather than movement, and staff burnout rather than gratification.

The field of dual diagnosis has grown tremendously since its beginning in 1984, yet there are far too few services available for far too many people who suffer with co-occurring disorders. Education, training, and integrated program development need to be approached more aggressively and simultaneously with systems change, staff development, and program implementation. The sequential model that frequently entails years of work with small groups of key providers who address systems changes before staff development, program development, and client care can ensue is unnecessary and wasteful (Sciacca, 2007). A simultaneous approach to systems issues, staff development, and integrated services implementation is far more effective and advantageous (Sciacca, 2007). The main objective is to prepare administrators, management, and staff to bring effective services to the clients who need this essential professional help. The integrated dual diagnosis approach discussed in this chapter does exactly that. Existing programs have the ability to design integrated program tracks along with clinical tools and program underpinnings and educate and train staff to provide effective interventions. In effect, each agency or service-delivery system has the responsibility to provide integrated care for the dually diagnosed clients it regularly encounters. Many of the clients are already in attendance; it is a matter of engaging these clients in meaningful discussions about their perceptions of their own situations and to provide information that may be valuable to assist them to review their ideas and experiences in the light of some new information.

It is our responsibility as providers in behavioral health care, social services, and primary health care to accelerate this process and to bring effective services to those who so sorely need them.

Chapter **10**

Cranial Electrotherapy Stimulation in the Treatment of Addictions

Ray B. Smith, PhD

Cranial electrotherapy stimulation (CES) first caught this author's attention when it was found that it reversed symptoms of the drug abstinence syndrome better than any then current or present day medication and that it reversed back to normal what had until that time (1972) been thought of as permanent brain damage in addicted persons.

CES is the U.S. Food and Drug Administration's (FDA) name for what in most countries of the world is called electrosleep. It refers to a small electrical stimulation pulsed across the head for up to one hour a day for three weeks or less for FDA-accepted treatment claims of depression, anxiety, and insomnia. All these are symptoms of persons recovering from addictions, the drug abstinence syndrome.

While they vary, the stimulus parameters most encountered in the research literature are 100 pulses per second, biphasic, at 1.0 mAmp on a 20 percent duty cycle. The energy source is usually one nine volt battery. The electrode placement also varies, but most often electrodes are placed just behind the ears on the mastoid process or just below.

Because the vast majority of studies in the CES literature—more than 120 to date—have been either single or double blind, the treatment stimulation has been given below sensation threshold and the patient has felt no electrical stimulation during the treatment.

This author began early studies of CES in addicted persons when he was assigned by a U.S. National Institute of Mental Health (NIMH) grant to work as a research scientist in the District of Columbia's (Washington, DC) 600-bed

Rehabilitation Center for Alcoholics. Some two years later, Ray Gilmer, president of NeuroSystems, Inc., in Garland, Texas, arrived with a large, 15-pound device that promised to alleviate stress. At that time, the FDA did not have control over medical devices, so the safety and effectiveness of CES were not known. Nonetheless, there had been no problems found with its use in Europe and the then-Eastern Bloc nations since its development in 1953, and because we were to use it at subsensation stimulus thresholds, the hospital director determined that we should research it.

Perhaps fortunately, this author, who thought it was no less than the return of the Argon box, was not asked, but told to do the research. Subsequently 76 patients who had completed detoxification and had entered the rehabilitation program, many of whom were on daily doses of Lithium, Librium, Sinequan or other psychoactive medication, were entered into a research program in which one-half of them would receive stimulation while one-half received sham stimulation.

Since double-blinding devices had not become available at that time, the research was conducted in a single-blind manner, with not only the patient but the psychometrist and the statistician also blind. Only the nurse who gave the treatment knew who was getting treatment, and she was instructed to talk to the patient as little as possible. The instructions were simple. She would attach a moistened felt electrode pad on each side of the forehead just above the eyes and an electrode on each mastoid process with Velcro straps. After telling the patient to raise his hand when he felt something, she would slowly turn the current knob up until the patient raised his hand, then turn it back down until the patient lowered his hand, signifying that he no longer felt anything. At that point she would check her sheet of paper to see if the patient was to get actual treatment, in which case she would leave the current set at that level and go to the next patient. If the patient was to receive sham treatment, she would turn the stimulation off, down to but not including the final click of the on/off knob. The control knobs remained out of the line of vision of the patients.

This being a new treatment in the center, we didn't know what to measure but decided to use what the pharmaceutical companies were using to test their new psychoactive drugs, the Profile of Mood States (POMS), which presented the patient with 44 words or short phrases describing emotions, such as unhappy, confused, energetic, panicky, and so forth. The patient could mark the box labeled 0 for not at all, up to 4 for extremely, depending on his level of agreement with the word or phrase. From these items, five negative mood factors were statistically derived: tension/anxiety, depression/dejection, anger/hostility, fatigue/inertia, and confusion/bewilderment. A positive factor, describing a positive energy state but considered nonclinical, was also derived.

The score for the positive energy state was subtracted from the sum of the five negative factors to produce a total mood disturbance score.

Since we did not know how long the treatment would take to be effective, if at all, we had the patients complete the POMS every day following treatment. The center had different treatment and rehabilitation programs every hour, and it took the patients some 10 minutes to get to the next activity, so we decided to treat the patients with CES for 45 minutes each day, which would give the nurse 5 minutes to get the electrodes on and off the patients and still allow them to get to the next class. Because staff were not that readily available on weekends, the treatment was given Monday through Friday each week, for three weeks.

After the three weeks were over we found that the anxiety level in patients who received actual treatment was reduced 46 percent, while the depression was reduced 70 percent. And while we had not planned to study insomnia as such, it was later found that the prn Seconal medication requested each night by the patients who received actual treatment was reduced 64 percent during that three-week period, while remaining the same by the controls. The patients who were on sham treatment had actually gotten somewhat worse on all the dependent measures during the three-week period. Those results were significantly better that those obtained by even the most widely prescribed psychoactive medications today (Kirsch & Sapirstein, 1998).

The confusion/bewilderment (C/B) score was of interest to the present author who, as a physiological psychologist had an interest in the brain damage of addicted persons. He was intent on trying to find what exactly caused it and how to prevent it, because it was well known at that time that there was no cure. He was therefore quite surprised to discover that the C/B score, which correlated strongly with brain dysfunction scores on other tests, had also improved by 54 percent. The results were so surprising to our research team that we selected another 76 patients and repeated the study, which replicated almost exactly the results of the first, so we published the results (Smith & O'Neill, 1975).

We were curious how long the improvement would last, so we routinely had all patients who had been in the two studies complete the POMS every Friday morning following the studies. This went on for about six weeks when patient attrition—they were in a 90-day treatment program—forced us to discontinue the evaluation. What was found, however, was that patients who had received actual CES treatment continued to improve over the six weeks following treatment, while the scores of the sham-treated patients continued to deteriorate.

In the process we had yet another serendipitous finding: Patients who had received actual CES treatment stayed in treatment until their time was up,

while patients who had received sham treatment had a 50 percent greater likelihood of leaving the program early against medical advice (AMA).

At the center, psychologists often administered the Wechsler Adult Intelligence Scale (WAIS) to selected patients, and all patients entering the center were given the Army Beta intelligence test, a nonverbal test that could be given in a group setting.

Earlier the author had found a strong correlation between the C/B score on the POMS and the three so-called organic brain syndrome (OBS) scales on the WAIS. He also found the C/B score strongly correlated with the formboard test on the Army Beta, the one subtest among five that was significantly reduced in most alcoholic patients who arrived for treatment at our center.

Those subtest score reductions were thought to reflect the permanent brain damage that our patients were then thought to have. It seemed unlikely that if the C/B score on the POMS was so highly correlated with the OBS scale(s) on psychological tests that the C/B score should have been improving because of CES treatment. In subsequent research with CES it was decided to use those other mental tests also.

In 1977 we published a study in which the identical single-blind treatment protocol was used, but with the Army Beta test as the measure of choice. We found that the formboard subtest of the Army Beta test of those patients receiving actual CES treatment, but not the sham-treated controls, came back within normal limits when compared with the other four non-OBS scales. The improvement on that subscale was 86 percent (Smith & Day, 1977). Later, we were to test more than 300 patients in confirming this result (Smith, 1982). Later still, Schmidt, Capo, Frazier, and Boren (1984), in a double-blind study, repeated those findings, this time using the full WAIS as the dependent measure. For the first time, Schmidt and his group were studying patients with one or more addictions other than just alcohol alone. They found results in other addictions similar to those we had found in alcoholic patients.

Later still, in another double-blind study, Schmidt and his group replicated our finding that patients receiving actual CES treatment, compared with sham-treated patients, had reduced AMA attrition rates by 50 percent or more, and also reduced recidivism rates (patients returning for additional treatment) by 50 percent or more, while very effectively reducing their anxiety (Schmidt, Capo, & Boyd, 1986).

Other researchers would publish results of their treatment of alcoholic persons with CES, while others would research cocaine patients, marijuana users, smokers, and methadone users, among others. All found significant reductions in the stress involved in the drug abstinence syndrome, and those who checked for it also found reductions in AMA attrition rates and recidivism rates.

It is perhaps of interest that while many studies were of the relatively more expensive double-blind design, the results from those were almost exactly matched by the less expensive and time-consuming single-blind studies. Also, in the few studies that controlled for placebo effect, no such effect has ever been found from CES treatment in published studies to date.

MECHANISM OF ACTION

Earlier peer reviewers had difficulty with CES studies, because it was so new that few had heard about it. Some reviewed CES studies under the impression that they were studies using electroshock treatment. Others assumed that the small electrical current provided in CES stimulation could not effectively enter the brain, while yet others decided that even if by chance it could find its way past the cranium, the amount of stimulus was too small to have an effect on neurons in the brain.

Researchers over the years have found that the electric current from CES stimulation goes through every part of the brain. One of these researchers was a doctoral candidate studying the possibility of combining CES and biofeedback simultaneously, measuring the electroencephalograph (EEG) in the process (Shroeder, 1999). A second, a doctoral candidate using low resolution brain electromagnetic tomography (LORETA) imaging, found that CES induced changes in every one of 2,394 gray matter voxels measured (Kennerly, 2006). A study at the University of Wisconsin found that CES stimulated the emptying of presynaptic vesicles in the rabbit brain, then generated an increased number of vesicles in the presynaptic neuron as stimulation continued. These returned to a normal level following cessation of stimulation. These changes were measured by implanted devices placed in numerous areas of the brain, covering the majority of the cortex (Siegesmund, Sances, & Larson, 1967).

To learn the mechanism in which changes had been wrought in depression and anxiety scores, researchers began to measure neurotransmitter levels prior to and following CES treatment. Pozos, Strack, White, and Richardson (1971), at the University of Tennessee Medical School, deliberately Parkinsonized canine subjects by chemically altering their adrenergic/cholinergic balance. He then discovered that either L-dopa or CES could similarly bring the subjects back to a normal, non-Parkinsonian state in a few hours, while subjects put on normal rations of food and water required several days to return to a normal state. CES, he inferred from his results, acts as a rebalancing force in organisms whose normal neurotransmitter system is out of balance.

Gold and his cohorts later researched a similar system with patients withdrawing from methadone use. They theorized that heroin use had interrupted

the dopamine system as those neurons fired into the *locus cerelus*, and in the absence of methadone or heroin, the increased fire into the *locus cerelus* caused the withdrawal symptoms. In a double-blind study they gave either the dopamine blocker, Aldomet (alpha methly dopa), or CES to withdrawing patients. The physicians monitoring the patients' withdrawal could not determine which were on Aldomet and which were on CES until after the study, when the Aldomet patients suffered a rebound depression. They theorized that this was due to a chemical rebound reaction in the Aldomet patients, while CES was bringing the dopamine system back into a normal balance in those patients (Gold, Pottash, Sternback, Barbaban, & Annitto, 1982). Dougherty and Dafny (1989; Dougherty, Dong, Faillace, & Dafny, 1990), at the University of Texas, found similar results when withdrawing rats from morphine. Shealy et al. (1989) found altered serotonin and norepinephinre levels in the brain consequent to CES stimulation, as did Closson (1985), who also measured adrenocorticotropic hormone production.

Over the years, researchers began to organize the myriad studies of CES in meta-analyses. Harvard University researchers completed perhaps the first such study, combining CES studies of several different treatment populations. Bianco (1994) was the first to meta-analyze studies of CES in polysubstance abusers, in which he found a highly significant response to CES in those aggregated studies. Most recently, Smith (2007) has published a meta-analysis of 15 studies of the drug abstinence syndrome involving 535 research subjects, as well as 7 studies of cognitive dysfunction involving 558 polysubstance abuse subjects. He found an average improvement of 60 percent in the abstinence syndrome patients, which involved many substances of abuse, and 61 percent in the studies of cognitive dysfunction.

SAFETY

There was some reluctance among the first patients in our center to be treated with CES, since many of their relatives had earlier been treated with electroshock therapy in psychiatric institutions. From the first, and for several years afterward, we had to begin treatment by letting the patients hold the electrodes in their hands and then gradually turn up the current level themselves. When they felt the initial tingle we explained that this was all they would feel on their head during CES treatment, and if they were to be treated in a research project they would only feel the tingle for a second until the current was turned back down.

After completing research with more than a thousand patients and treating many thousands more, this author had encountered no significant negative side

effects from CES treatment. In our first research project, we found that three percent of the treated patients complained of headache. On further evaluation of the data, we found that a similar three percent of the sham-treated patients also complained of a headache. Looking into this still further, we found that all headaches occurred during those hours when the other patients were out in basketball practice. Nevertheless, some patients may have a slight headache if they turn their CES device up to a high stimulus intensity. Any such headache will go away when they turn the current down.

Earlier we also found that some patients who had been missing REM sleep for whatever reasons had the most vivid, intense dreams they had ever had, following their first few CES treatments. That sometimes alarmed patients who may have had relatives or friends who were schizophrenic or who had other mental problems. Once the clinician assured them that they were just making up for lost REM sleep and that this is normal, they were very pleased and sometimes were saddened when the intense dreams ceased, which they invariably did after a night or two.

The FDA was concerned about the safety of CES early on, so it gave a grant to the National Research Council's Division of Medical Sciences (National Research Council, 1976) to assess the possible safety problems from the use of CES. After researching it in some depth, the council reported back to the FDA that there could be no possibility or harm to a patient from this level of electrical stimulation.

Of more than 100 studies involving more than 4,000 patients that this chapter's author meta-analyzed, not one study reported a significant negative side effect from the treatment. Of course, for the most part the treatment was subsensation threshold. On the other hand, this author has had much clinical experience with teenage cocaine addicts whose habit was to turn their CES units up as high as they would go during treatment, then request new batteries the next day because the feeling the second day was less intense. This is contrasted with the many heroin addicts who did not wish to feel any of the electrical stimulation, so kept theirs turned down very low during treatment. In neither case were negative side effects seen.

We did have a couple of questions when CES first began to be used in addiction treatment. Would it cause seizures in patients known to have withdrawal seizures? Was CES itself addicting?

To avoid any possibility of triggering seizures in our patients, our clinical policy was to not treat patients with CES until they had been discharged from the detoxification unit and entered the main rehabilitation program. After a few years of this, we were told by the staff at Charity Hospital in Louisiana that they had always used CES specifically during detoxification in order to prevent

seizures and that this worked quite successfully. CES has also been used in other patients, such as closed head injured patients who were known seizure patients, without triggering seizures of any kind (Smith, Tiberi, & Marshall, 1994).

To discover whether or not CES might itself be habit forming or even addicting, 111 patients in a polysubstance abuse clinic in Santa Barbara, California, were given personalized units to take home with them upon discharge from the hospital. After one year they were called back in to the clinic and asked about their use of their CES device over the course of the year. Most of them reported using it only a few times for a few days when under unusual stress. None had used it during the past 30 days. They were obviously not addicted to CES, but they didn't want to give the units back either.

HOW TO USE CES

CES devices began in the United States as very large units that were considered for hospital or clinic use only. In the early 1980s they were miniaturized to about the size of a pack of cigarettes that could be worn in a shirt pocket. Much of the impetus for this was so that patients could have their own unit at home following treatment. We decided on this after a patient got on a Greyhound bus one day (our center was 40 miles from town) and arrived at our center, asking for the CES nurse. She was surprised to see him because he was a former patient who had been discharged several months before. He asked her if he could be put on the CES device for an hour. She complied with his request, but after 30 minutes he got up, removed the electrodes and said, "Thanks, nurse. That did it."

"Did what?" the nurse asked.

"I was on a dry drunk and that stopped it," he told her.

It was in this manner that we discovered that CES could successfully treat any recurring urge to use an addicting substance. Subsequently, we put a unit in each of our halfway houses so the men could get to them when they were experiencing the urge to use again. Finally, when the units were downsized even more, patients were often given their own device when leaving treatment, because by then we had also discovered that treatment with CES invariably reduced recidivism for additional treatment.

CES devices are prescription devices that can be ordered for a patient by any licensed health service provider, including most addiction treatment personnel such as physicians, nurses, psychotherapists, and even licensed massage therapists if they work with addicted persons. The CES device is usually used for 30

minutes to one hour on a daily basis for 10 to 15 days or until the symptoms being treated subside. Patients who are to leave with a CES device, or receive one on an outpatient basis, should be taught to use it daily for 30 minutes to one hour for two to three weeks until they feel it has had its maximum effect, then to use it again any time they feel they need it for stress reduction or to help with their sleep. They should also be told to wear it anytime they feel a withdrawal symptom arising, or a dry drunk, as some describe it, coming on.

ADDITIONAL READING

Kirsch self-publishes a very helpful book, the 2nd edition of which includes abstracts of 126 human and 29 animal studies. They are grouped under the condition studied, dependent measure used, and CES device used in the study. The book can best be found on the web (Kirsch, 2004). Earlier, Smith (1985) published possibly the largest review to date of all the CES studies in the U.S. literature up to that time, which included some studies that were not in his 2007 meta-analysis, with an explanation of why they were not included.

Kirsch's book tends to be updated as more studies come on stream, so it is usually more up-to-date than any other CES reference source.

SUMMARY

CES is a very potent addiction treatment device that can reduce or eliminate many of the symptoms of the drug abstinence syndrome more dramatically than any prescription pharmaceutical has been shown to do. Patients are more likely to complete a treatment program when CES is used, and they are less likely to come back for additional treatment following their discharge. No significant negative side effects have ever been found from its more than 45 years treatment history in the United States in which tens of thousands of patients suffering from almost every type of addiction have been treated.

Chapter **11**

An Analysis of Service Providers' Treatment Model Choices for Cocaine-Using Clients: A Case Study

Maria Dinis, PhD, MSW

There are various models of alcohol and drug treatment to which service providers subscribe. These treatment models (e.g., moral/prevention, medical/disease, psychological, sociocultural, and integrative/biopsychosocial models) have been widely described in the literature and are often referred to as treatment philosophies or orientations (Institute of Medicine, 1990; Miller & Hester, 1989, 2003; Miller & Kurtz, 1994; Peterson, Nisenholz, & Robinson, 2003). In the Institute of Medicine (1990) report, the committee explained that "a model for treatment consists of a certain perspective on or orientation toward the etiology of alcohol problems that in turn specifies the preferred methods of intervention and suggests expected outcomes" (p. 51).

How do service providers select treatment models or approaches to treat their clients? In general, professionals may select treatment approaches based on factors such as their educational background, professional and experiential training, work setting, personal belief systems, age, and gender. For example, a social worker employed as a probation officer may or may not select the same treatment approach as a social worker working in a hospital setting. It is, therefore, important to understand the relation between the background characteristics of treatment providers and their treatment choices.

Scott (1982) described how organizational missions and goals, in addition to professional training and socialization, influence professionals' work structure and decision-making processes. Lipsky (1980), however, argued that organizations cannot control decision-making behavior because street-level bureaucrats (e.g., police officers, teachers, social workers, nurses, doctors, and

lawyers) implement public policies based on decisions they make, routines they establish, and devices they invent to cope with uncertainties and work pressures. Additionally, professionals' clinical decisions are influenced by personal beliefs that ascribe causal explanations to alcohol and drug problems (Lipsky, 1980; Morgenstern & McCrady, 1992; Rosenberg & Davis, 1994) and inform the selection of treatment approaches for different populations (Nunes-Dinis, 1996).

Previous studies have examined the influences on professionals' treatment model choices for people with alcohol problems (Nunes-Dinis, 1996). More specifically, professionals from diverse community agencies—for example, alcohol and drug, criminal justice, health care, social welfare, mental health, and religious—were interviewed about their treatment choices for people with alcohol problems. Study findings revealed a complex relationship between providers' beliefs and model choice for heavy alcohol users. Overall, respondents selected models that corresponded with their personal belief system, except when treatment was provided to pregnant women. That is, the medical model was considered the optimal treatment approach for pregnant women, and pregnancy status emerged as a better predictor of service model choice than the providers' professional training or work setting (Nunes-Dinis, 1996).

Although pregnancy status was an important factor across professional groups in their treatment model choice for heavy alcohol-using clients, it is unclear how other drug use would influence professionals' treatment choices in similar situations. Cocaine-using clients, for example, may benefit from the use of different treatment approaches by professionals because the stigmatization associated with drug versus alcohol use may vary (Chavkin, 1990; Murphy & Rosenbaum, 1999). In addition, the difference in physiological consequences of alcohol versus cocaine use on fetal development may also influence treatment choice. Studies have indicated that alcohol contains a teratogen agent that causes congenital malformations such as fetal alcohol syndrome, whereas cocaine exposure alone has not been shown to exhibit teratogenic consequences (Batshaw & Conlon, 1997; Berenson, Wilkinson, & Lopez, 1996; Chasnoff, 1988; Gómez, 1997; Inciardi, Surratt, & Saum, 1997; Levitt, 1998).

In chapter 14 in this volume Dinis, Merighi, and Anders provide a literature review describing models or therapeutic approaches, beliefs, and perceptions of providers when treating alcohol or drug-using clients. The focus of this case study is to describe professionals' treatment model choice for women (pregnant and nonpregnant) and men who misuse cocaine. Predictors of treatment model choice included professionals' beliefs about the causes of drug addiction, educational background, and work setting. The following questions were examined to test what demographic variables constitute the best predictors of

treatment model choice: (1) What demographic factors can be used to predict providers' selection of medical, sociocultural, or integrative treatment models for the treatment of cocaine misuse?; (2) Are there differences in treatment model choice for cocaine-using women (pregnant and nonpregnant) and men?; and (3) Do providers with similar personal beliefs, educational backgrounds, or work settings choose identical treatment models regardless of the gender and pregnancy status of their clients?

METHODS

Sample

This is a secondary data analysis of a provider study originally conducted during 1995 in a northern California county, the site of the Alcohol Research Group's Community Epidemiology Laboratory (CEL). The CEL county was selected based on a broad cross-section of population characteristics, including: ethnicity, rural and urban mix, socioeconomic status, and a variety of health and social services agencies. The overall methods and study design has been described in other reports (Room & Weisner, 1988; Weisner & Schmidt, 1995).

A two-stage probability sample approach of health and human service providers was representative of service organizations and staff in the county. This sample of agencies was stratified by the following service sectors: substance abuse treatment, criminal justice, mental health, health care, welfare, and religious organizations. This cross-sectional survey of providers included workers in health and human service organizations and solo practitioners in mental health treatment and health care systems. A listing of organizations and individuals in the county was developed by using telephone directory listings, snowballing of agencies' listings, and follow-up phone screening interviews with a provider from each organization. From a listing of 2,390 eligible organizations, 117 stratified agencies were selected randomly. A simple random sample of practitioners (i.e., physicians and psychotherapists) was drawn from a separate listing. Permission was obtained to interview providers in the 117 organizations, and a list was developed of all direct service professionals working at least half time. Individual providers were sampled proportionate to organization size. Line service providers were the units of analysis. Of the total 610 solo and agency providers, 73 percent were interviewed (N = 457). The response rate includes the nonresponse at both the organizational and individual levels of sampling.

Forty-two percent of the providers responding were male (n = 191) and 58 percent were female (n = 265). About two-thirds were married or living

with a partner. More than half of the providers were under 44 years of age. Approximately half of the sample completed graduate education at the master's or doctoral level, 22 percent were college graduates, and 28 percent had some college training.

Weights (ranging from 0.04–2.29) were calculated to adjust for nonresponse bias and for design effects due to stratification at the first stage of sampling and varying selection intervals at the second stage. Those weights were representative of the actual proportion of different kinds of providers working in the stratified service sectors.

Procedures

Trained interviewers who were not affiliated with any of the agencies administered a one-hour structured in-person survey usually in the workplace, but arrangements were made to interview providers in other locations when necessary. Informed consent was obtained and participation was completely voluntary.

Measurement

Our analysis focused on the kinds of treatment models providers would recommend for white women (pregnant and nonpregnant) and men who were using cocaine. Providers' drug addiction beliefs and sociodemographic characteristics were taken into account. Responding to case situations described in the survey, service providers recommended services options that were then classified into models using the criteria from the Institute of Medicine (1990) report. These models were categorized into program components and service types: medical, sociocultural, and integrative. Medical models are physician-driven and often employ medications such as antidepressants or beta-blockers. Sociocultural models operate in social settings like halfway houses and in self-help groups (e.g., Cocaine Anonymous). Integrative models are other models identified such as biopsychosocial, dual-diagnosis, or compulsory approach (some kind of legal sanction—anything from a fine to incarceration). The treatment models were classified according to the number of times providers selected them. Only three models (medical, sociocultural, and integrative) were used as outcomes (dependent) throughout the logistic regression analysis because providers primarily selected those models across the three groups: women (pregnant and nonpregnant) and men who were using cocaine.[1]

The independent variables associated with treatment model choice were the etiological beliefs of drug addiction, personal demographics, professional degree, and work settings. The etiological beliefs were: if service providers had

to choose, would they say that drug addiction was mostly a genetic problem—something a person is born with, or social, psychological, or multiple problems. The personal demographics of the service providers included: gender (male or female); age (under 35 years old, 35–44 years old, or 45-plus); and level of education (non-postgraduate [some college training and college graduates] and postgraduate [master's or doctoral level graduate education]). Professional degree was categorized as no advanced degree, criminal/social science/liberal arts/education, science/medical, counseling/therapy, social work, theology/divinity, and business/management/law. The work settings were alcohol/drug, criminal justice, mental health, health care, welfare, and religious.

Data Analysis

Chi-square tests were used to assess significant differences between model choice of service providers based on their etiological beliefs of drug addiction, type of professional degree, work settings, and sociodemographic characteristics. Weighted data were used.

Logistic regression analyses were used to predict providers' model choice using their etiological beliefs of drug addiction, type of professional degree, work settings, and sociodemographic characteristics of providers as independent variables. These independent variables were coded as 1 and 0; for example, gender was coded 1 for male and 0 for female. Other independent variables were coded with this same pattern: education (non-postgraduate vs. postgraduate); and etiology (genetic vs. all other beliefs, social vs. all other beliefs, and multiple vs. all other beliefs). The comparison group for all others for genetic belief included social, psychological, and multiple; for social belief, they consisted of genetic, psychological, and multiple; and for multiple beliefs, they contained genetic, social, and psychological beliefs. For independent variables with more than two attributes, the comparison group selected was: the category of counseling/therapy for the variable professional degree, alcohol/drug for settings, and 45-plus for age. The data analyses used SPSS (SPSS, 2006).

RESULTS

Table 11.1 compares demographic characteristics of respondents and their selection of models to treat three treatment groups. Women providers were more likely than men to select the sociocultural model for women clients misusing cocaine, and the same trend nearly approached significance ($p < .06$) for men misusing cocaine. Overall, age was not a significant predictor of provider's treatment model choices. Providers, ages of 35 to 44, were more likely to

choose the integrative model for women who were not pregnant. Education was important in model choice. Individuals with some college training and college graduates (non-postgraduate) selected the medical model for pregnant women, and nearly approached significance for men ($p < .08$), while those with master's or doctoral-level (postgraduate) education were less likely to select sociocultural and integrative models for pregnant women. Providers with postgraduate degrees also selected the sociocultural model for men misusing cocaine.

Table 11.2 examines the relationship between type of professional degree and providers' selection of treatment models. Regardless of the professional degree, the medical model was chosen for pregnant women. For other groups, the medical model was also recommended but not consistently chosen. For instance, those with professional degrees in counseling or therapy and science or medicine were less likely to select the medical model for nonpregnant women or men. Among those who chose the medical model, a larger proportion had professional degrees in business/management/law, criminal/social science/liberal arts/education, and theology/divinity.

A higher proportion of providers adopted the medical model for pregnant women than for any other group and adopted the sociocultural model for nonpregnant women and men cocaine misusers. More providers selecting the medical model for all three client groups had professional degrees ranging from business to criminal justice to theology, even though a significant proportion had no advanced degree. Although not statistically significant, providers with scientific or medical, counseling or therapy, and social work educational backgrounds also selected integrative models for the three groups.

Table 11.3 shows the proportion of providers across work settings and their model choices. For all work settings, the medical model was by far the most frequently selected for pregnant women. Although the medical model was indi-

cated for nonpregnant women and men cocaine misusers, a similar number of providers selected the sociocultural and integrative models—30 and 32 percent, respectively. In fact, in alcohol/drug and health care work settings, the sociocultural and integrative models were chosen more frequently than the medical model. The range of providers selecting the medical model for pregnant women was between 47 and 78 percent, whereas for the other two groups it was between 18 and 44 percent.

Clients' pregnancy status rather than a particular gender group influenced model choice of providers in various work settings. A higher proportion of providers selected the medical model, as compared to all other models, for pregnant women across the professional settings.

More providers selecting the medical model across the three groups worked in the criminal justice setting, followed by welfare, mental health, and religious settings. Providers adhering to the sociocultural model for nonpregnant women and men were primarily from alcohol/drug treatment settings, followed by health care and criminal justice settings.

Logistic regression analyses were conducted to determine significant predictors of model choice (medical vs. all others, sociocultural vs. all others, and integrative vs. all others), using etiology, profession, work setting, and demographics as independent variables (Table 11.4). Although not shown, providers reported that drug addiction is mostly a social problem (52%), followed by

psychological (27%), genetic (12%), and multicausal (9%). Women providers were almost twice as likely to adopt the medical model for pregnant women and men cocaine users. When compared with counseling and therapy, those in the profession of theology were nearly 11 times more likely to select the medical model for nonpregnant women and over 6.5 times as likely to select the medical model for men.

Providers who believed drug addiction was a social problem were about half as likely to support a medical model for pregnant women but were twice as likely to select the sociocultural model for nonpregnant women and the integrative model for pregnant women. Women providers were nearly twice to six times more likely than men to select the sociocultural model for all three groups. Non-postgraduates were less than half as likely to select the sociocultural model for all groups. Providers in the clergy profession were 13 percent less likely to adopt the sociocultural model for nonpregnant women. It is important to take caution when interpreting results from the pregnant sociocultural category because there was inadequate statistical power due to small sample size in this category.

Providers who believed that drug addiction has multiple causes (i.e., those who alluded to more than one etiological cause of addiction) were nearly three to four times as likely to adopt an integrative model for all three groups and about a third less likely to select the sociocultural model for men. Women providers were half as likely to endorse the integrative model for pregnant women only. Providers, ages 35 to 44, were more than twice as likely to choose the integrative model for nonpregnant women and men.

DISCUSSION

In this study, the gender of providers was important in predicting their selection of treatment models. Individuals with postgraduate degrees in any field of study were more likely to choose the sociocultural and integrative models for pregnant women. Regardless of the work setting of the providers, the medical model was selected more for the pregnant women but less frequently for the other two groups.

The relationship between beliefs about etiology of drug addiction is imperfect in predicting model choice. The only significant match across all three groups was between providers who believed in multiple causes and their selection of the integrative model. This may have occurred because integrative models facilitate the combination of biological, psychological, and social factors in assessment and treatment of alcohol and drug problems (Brower, Blow, & Beresford, 1989; Institute of Medicine, 1990; Johnson, 2004; Peterson et al.,

2003). In this approach, there is recognition that problems are determined by multiple factors, involve different causes, and that one or a combination of the factors may determine individual outcomes. It may be speculated that providers may feel more comfortable with a combination of solutions offered by integrative models than by any one of them by itself. There were other congruent beliefs between social etiology and multiple etiologies and the selection of corresponding models for men and nonpregnant women. Providers who believed in a social or multiple etiologies for men and pregnant women were less likely to select medical or sociocultural models respectively. Although those beliefs are not necessarily congruent with the corresponding model, providers may be showing support for their selection of the integrative model for men and pregnant women. In the literature, however, providers are inconsistent in their beliefs about addiction and agree with conflicting perspectives ranging from the disease concept to psychoanalytic interpretations to moralistic attitudes (Kahle & White, 1991; Taxman & Bouffard, 2003; Taxman, Simpson, & Piquero, 2002; Wechsler & Rohman, 1982). This may explain why providers believe in various causes of drug addiction and do not necessarily adopt corresponding models of treatment for any of the groups.

Providers across work settings were not always consistent in the models they selected for the three groups. Work settings of providers were not an important predictor of model choice, but possessing a theology degree was significant. In the bivariate analysis, providers from various professional backgrounds selected the medical model. In the multivariate analysis, only providers from a theology professional background adopted the medical model for nonpregnant women and men misusing cocaine. With only 32 theologians in the sample, this finding probably represented a random result, given that we did many tests and the bivariate difference shown in Table 11.2 is not very dramatic.

Work settings were not related to beliefs about etiology and model choice. In the bivariate analysis (not shown), 47 percent of providers in the alcohol/drug settings believed that drug addiction is a social problem, but they selected the medical model for pregnant women. In fact, between 48 and 59 percent of providers in all work settings believed that drug addiction was a social problem, yet they selected the medical model for pregnant women. While only approximately 18 percent of providers believed that drug addiction was a multicausal problem, over one-third of the providers in alcohol/drug and health care settings selected the integrative model for nonpregnant women and men.

From the bivariate analysis, beliefs, professional degree, and work settings were important until we controlled for gender and education. In the multivariate analysis, gender and education significantly influenced model choice. Women providers selected the medical model for pregnant women and men, the socio-

cultural model for all three groups, and were less likely to select the integrative model for pregnant women. The extent of education seems to be more important than the type of professional education. Those with at least some college training and college graduates were less likely to select the sociocultural model for all three groups. That group may lack familiarity with the sociocultural model or perceive the use of professionals in medical and integrative models more effective for their clients than peer-run or self-help approaches (i.e., sociocultural). Also, respondents having either some college or only bachelor's-level training are perhaps in job positions that require following agency dictates rather than their own beliefs. For example, in some work settings such as criminal justice, they may have protocols that require first referring medically before suggesting other options. It is interesting to note, however, that as the level of providers' education increased to master's or doctoral-level training, the less likely they are to adopt the more professional-based medical model, but those with some college or bachelor's-level training do select the medical model.

It is unclear what variations in suggesting treatment for pregnant women may be attributed to pregnancy status or gender differences. It is not known if the perception of pregnancy as a medical condition influences providers to choose the medical model foremost. Further, it is unclear whether medical conditions of any type automatically determine a medical selection or if providers perceive a difference in treatment between men and women. Perhaps providers might also first choose a medical model for men with diabetes, for instance, before considering drug treatment issues. Providers may not recommend models of treatment based on the need of treatment but instead may first address medical conditions like pregnancy. In the bivariate analysis, similar proportions of providers selected across the three major treatment models for nonpregnant women and men.

In general, in this sample, providers selected the medical model to treat pregnant women while they chose similar proportions across all of the three models for the other two client groups. These findings suggest that providers primarily may not be selecting treatment approaches based on factors such as personal belief systems, educational or professional training, work setting, or demographic characteristics. Even though currently the medical condition of pregnancy dominates treatment choice for pregnant women, there are other cocaine-misusing clients where factors interplay in their selection of treatment options. Further research is needed to examine why providers have personal belief systems that are incongruent with their corresponding model choice. Perhaps providers select models that are incongruent with their beliefs because the current treatment approaches available restrict them. That is, providers may have particular beliefs and not a treatment model that corresponds to

their belief. For example, providers may believe that drug addiction is primarily caused by genetic factors and yet not necessarily equate that they would principally only want to treat the condition medically. Having a belief in a genetic predisposition for drug misuse does not automatically imply that providers will necessarily select a medical treatment option. Similarly, providers who believe in social or multiple causes of addiction may recognize the limitations of the corresponding models to ameliorate large-scale environmental social problems and other personal conditions (e.g., poverty, racism, class distinctions, and mental health issues) contributing to drug misuse. These findings indicate the complexity involved that providers must encounter when selecting treatment models for their clients because the interaction between beliefs, treatment models available, and what may work for a client at one time but not another are all factors that may be involved in the decision-making process of providers.

Acknowledgments

Preparation of this chapter was supported by a National Institute on Alcohol Abuse and Alcoholism (NIAAA) (R01-AA005595–11) award to the Alcohol Research Group in Berkeley, California and the California State University, Sacramento, Research and Creative Activity Award Program. The author wishes to acknowledge Constance Weisner, Lee Kaskutas, Lois Lowe, Joe Merighi, and Kelly Anders for helpful comments and Tammy Tam for statistical consultation.

NOTE

1. Fewer than eight percent of the providers adopted prevention or psychological models for the three groups, which resulted in a small sample size with cells less than five cases to include in the logistic regression analysis. Thus, percentages do not total 100 in the tables because providers also selected prevention and psychological models.

Chapter **12**

Translating Efficacy to Effectiveness in Opioid Dependence Treatment

Van L. King, MD, Michael Kidorf, PhD, Kenneth B. Stoller, MD, Karin J. Neufeld, MD, MPH, Jessica Peirce, PhD, and Robert K. Brooner, PhD

Opioid dependence is a severe, persistent disorder often requiring long-term and at times intensive psychiatric treatment. Though opioid dependence in the United States has primarily involved heroin use, opioid users are increasingly turning to prescription opioid (e.g., oxycodone) misuse in recent years. To date, most approaches to opioid dependence treatment utilize single or sometimes two treatment approaches, often with only modest improvements in the patient's quality of life. In this review, we describe the development and implementation of Motivated Stepped Care (MSC), a community-based, adaptive, combination treatment model for chronic opioid dependence created through translational research that utilizes insights gained from medication development and behavioral experimental findings. MSC fully integrates medication therapy, behavioral reinforcement (also called contingency management) procedures, and counseling psychotherapy into an intervention that addresses numerous aspects of drug use disorders and results in improved outcomes. In particular, we demonstrate how MSC addresses poor treatment adherence, a problem in all medical interventions and a particularly acute problem with this treatment population. By focusing not only on the underlying neurochemistry of addiction with medications but also on altering the behaviors of patients through targeted behavioral reinforcement, we demonstrate how MSC increases the amount of treatment that is provided, thereby significantly improving treatment outcome.

First we outline the development of several efficacious interventions for the treatment of opiate dependence by discussing the development of medication

interventions, which include opioid medications (medications that act similarly to morphine and heroin) and opioid-blocking medications (medications that block the euphoric and pain-relieving effects of opioids). In this chapter, we use the word *efficacy* (efficacious) to describe treatment benefits to patients enrolled in research studies with well-defined subjects and controlled treatment conditions. *Effectiveness* refers to patient improvement demonstrated in nonresearch treatment settings that typically treat a less selected, real world patient population and so measure the utility of a treatment to appropriately trained community-based health care providers.

Much of the success of current treatment for chronic opioid dependence relies on medications developed in a translational manner by responding to naturalistic experiments using existing compounds. We use the term *translational* to describe the process that investigators use to develop novel research and clinical paradigms based on observations made by researchers in other areas of scientific inquiry. It not only refers to knowledge from basic scientific discoveries inspiring treatment applications (such as a new antibiotic developed on the basis of new information about a specific bacteria) but also to translating the results of efficacy studies into effective, everyday clinical practice (Woolf, 2008). For example, inspired by early morphine maintenance treatments (see later in this chapter), methadone maintenance was conceptualized in the 1960s as an adjunct to psychosocial treatment for opioid dependence. Because of its usefulness, other opioid and opioid-blocking medications (i.e., L-alpha-acetylmethadol, buprenorphine, and naltrexone) were developed in an attempt to improve on or offer alternatives to methadone maintenance treatment. The concept that chemical compounds could be targeted to affect a patient's desire to use opioid drugs was a key insight that translated into several extensive lines of investigation and subsequent medication treatments.

Next we discuss the translational development of behavioral interventions derived from learning theory (primarily operant conditioning) that have been used successfully in specialized behavioral treatments for drug dependence. Based on the idea that drug dependence is a highly specific, goal-oriented pattern of behaviors motivated by the expected positive consequences of drug use (Bigelow, Brooner, & Silverman, 1998; McHugh & Slavney, 1998), drug use behavior is understood as a consequence of the individual's decision to use drugs, and the result of weighing the positive and negative consequences of the behavior rather than a result of uncontrollable urges. This perspective recognizes the strength of drugs as powerful motivators in the lives of patients and can be used to help shape behaviors that compete with and ultimately supplant drug-dependent behavior. Contingency management treatment approaches are

an excellent example of how these more basic insights have been translated and adapted to create an array of behavioral treatments for substance dependence.

Medication and behavioral interventions are only partially effective, however. The next section underscores the importance of psychotherapy in combination treatments for substance use disorder. Unfortunately, even though most treatment experts agree that psychotherapy is an important ingredient in a comprehensive substance abuse treatment (APA, 2006), the effectiveness of psychotherapy is significantly limited by poor attendance. In fact, virtually all medical treatments are significantly limited by poor adherence, but this problem is especially problematic in substance use disorder treatment. Even relatively effective treatments such as methadone maintenance fall far short of a definitive treatment intervention, with many patients continuing to use illicit drugs on a regular basis and discontinuing treatment prematurely. One of the greatest challenges that accounts for these unsatisfactory results is poor patient adherence to the prescribed plan of care. How to improve patient adherence to maximize the effectiveness of psychotherapy and other treatment approaches is an ongoing challenge.

Finally, we describe how these complementary treatment approaches are incorporated into the MSC model. Utilizing research from disparate sources, we show how medication interventions and behavioral research findings dramatically improve treatment adherence rates in an opioid-dependent population. Targeted reinforcement of patient behavior is a key component in this model of care, creating a synergy that significantly improves treatment effectiveness. By focusing not only on offering care, but also on altering the behaviors of patients to ensure that the care is received, treatment outcomes are significantly improved. This unique model of care is the next advance in translating efficacious research findings into effective community-based treatment models.

MEDICATION TREATMENT TRANSLATIONS

Opiates (drugs derived from naturally occurring compounds that activate opiate receptors in the body) have been used for centuries as important medicinal compounds as well as for their euphorogenic, and therefore behaviorally reinforcing, properties. That is, many individuals like the subjective effects of these medications and will work to obtain and use them. Opioid drugs include all naturally occurring as well as synthetic drugs that activate opiate receptors. Chronic daily administration of opioids leads to tolerance (increasing doses of the drug must be taken to obtain the same effects) and physical dependence (routine use of the drug is required to prevent the onset of characteristic physi-

cal withdrawal symptoms). Even though opioid abusers initially use the drug for its euphorogenic effects, as tolerance develops, they increasingly use opioids to relieve the withdrawal symptoms consequent to the physical dependence (severe muscle aches, diarrhea, abdominal pain, vomiting, insomnia, malaise, goose flesh, and other symptoms) and get little pleasure from the drug use. Many seek treatment at this time, unable to tolerate the severe flulike symptoms of opioid withdrawal (so called cold turkey due to the presence of goose flesh and chills that accompany the syndrome) without medical intervention.

Treatment of opioid withdrawal symptoms has been approached in a variety of ways over the years, but the most difficult problems arise in those who develop the clinical syndrome of opioid dependence disorder (also called opioid addiction). This syndrome is characterized by a maladaptive pattern of drug use causing significant clinical impairment or distress (APA, 2006). Individuals typically exhibit physical tolerance and withdrawal symptoms if they stop opioid use, social problems such as failing to meet role obligations as a parent or head of household, and other symptoms consistent with a loss of control over drug use. These individuals frequently relapse to daily opioid use even after periods of detoxification and abstinence and in the face of serious social and legal sanctions. The strong psychological and behavioral aspects of opioid dependence are at least as important in the persistence of the drug use problems as the physical withdrawal symptoms. In this section we examine agonist, partial agonist, and antagonist medications that are used in the treatment of opioid dependence (Center for Substance Abuse Treatment, 2005; Stoller & Bigelow, 2006).

Opiate Receptor Agonists and Partial Agonists

Agonist medications activate the cellular receptors specific to the medication, causing a specific action as a result of the activation. Partial agonists can only activate the receptor to a degree that is less than maximal, so they have less powerful effects. Prior to the advent of agonist treatment, treatment for opiate dependence was hospital or residentially based and abstinence oriented, with patients expected to stop all drug use and follow the plans of the treatment providers after leaving the institution. Unfortunately, these approaches were often not effective, and physicians found themselves in the uncomfortable position of rationing or denying opiate prescriptions for opiate-dependent patients without acute medical needs for opiates but who either could not or would not discontinue opiate use. Rather than accept this at times adversarial role, and because they recognized the chronic and relapsing nature of opioid dependence, some physicians resorted to ongoing prescription of morphine (so-called mor-

phine maintenance) as a treatment for opiate dependence so that these patients would not resort to illegal means to acquire opiates. This approach was found to benefit some patients who could be maintained on relatively stable doses of morphine for extended periods of time. Subsequently, shortly before and around the year 1920, specialized morphine maintenance clinics were established in New York City, Shreveport, Louisiana, and other cities around the United States to improve access to maintenance treatment. These clinics were a rational response to a problem with no good solutions at the time.

However, in 1919, the Supreme Court upheld the U.S. Treasury Department's restrictive interpretation of the Harrison Narcotic Act, so all of these efforts were closed in the early 1920s. Opioid dependence came to be viewed as a criminal activity, and organized efforts to treat it with maintenance opiates were criminalized. Treatment for opioid dependence advanced little during the ensuing years, but in the early 1960s, mounting opinion from medical groups and the federal government favored trials of opioid maintenance treatment to address an escalating national problem with heroin abuse. Vincent Dole, MD, a researcher in metabolism at the Rockefeller University, received a grant in 1962 to investigate the feasibility of opioid maintenance treatment. He recruited Marie Nyswander, MD, a psychiatrist and author specializing in addictions treatment, to collaborate with him to develop an opioid agonist treatment for heroin dependence that would complement psychotherapy and other rehabilitative treatment.

Using observations from the early morphine maintenance projects, they took a more rigorous and scientific approach, recruiting volunteer opioid-dependent subjects for inpatient studies to determine which opioid agonist medication would be most suitable for this purpose. Of the several medications in the trials, methadone had the most desirable chemical properties. It was well absorbed orally and had a long action in the body such that once-daily dosing was adequate to treat opiate withdrawal symptoms. Sufficient doses of methadone (typically in the range of 50–150 mg daily) allowed the patient substantial control over opioid cravings and withdrawal symptoms and blunted the effects of illicit opioids by reducing the capacity to experience desired opioid drug effects (APA, 2006). Simply put, if patients don't receive the euphoric effects of opioid use, they reduce their use dramatically. The results were extremely positive. Patients maintained on individualized maintenance doses of methadone were much more likely to remain in programs of rehabilitation, acquiring employment and eventually ceasing all heroin use. These results were in stark contrast to the poor results obtained from detoxification and psychotherapy treatments available at the time (Dole, Nyswander, & Kreek, 1966). Their program of methadone maintenance treatment was introduced in New York City in 1965.

Methadone maintenance is now the most researched treatment for chronic opioid dependence, with overall better results than treatments not utilizing opioid agonist or partial agonist medications (Mattick, Breen, Kimber, & Davoli, 2003). However, there are shortcomings to methadone maintenance treatment such as daily dosing and restriction to certified narcotic treatment programs, so other medications with different profiles of activity have been developed over the years as treatment options to complement the effectiveness of methadone maintenance treatment. The first of these opioid agonist medications was LAAM (L-alpha-acetyl-methadol), another synthetic opioid that, like methadone, was developed in Germany during World War II. It was introduced in the United States in 1993 as a longer-acting agent that was taken only every two to three days. This quality of the medication reduced some of the burden of methadone treatment when patients would otherwise be required to report to the treatment clinic every day. Buprenorphine, a partial opioid agonist, also has a longer action in the body than methadone and a safer risk profile in overdose. It was approved in 2000 as a Schedule 3 compound that could be prescribed by certified physicians for office-based treatment of opioid dependence, potentially expanding the capacity of opioid dependence treatment providers into entirely new treatment venues not restricted to certified clinics. Investigators and clinicians recognized the importance of the opioid agonist activity for the acceptability and the utility of agonist and partial agonist treatments. They provide rapid symptomatic relief of opioid craving and physical withdrawal symptoms that is often of primary concern to patients entering treatment, thus making these compounds mainstays for chronic opioid dependence treatment.

Opiate Receptor Antagonists

A completely different approach to medication treatment involves blocking the opiate receptor with an antagonist compound such that individuals are unable to experience opiate agonist effects. Ideally, an antagonist would cause no drug effects itself but would simply prevent the effects of opioids that were taken after the antagonist. The compound cyclazocine was originally investigated as an opioid antagonist for possible use in substance abuse treatment, but it had unpleasant adverse effects that significantly limited its utility (Resnick, Schuyten-Resnick, & Washton, 1979). However, investigators recognized that two subsets of patients could be identified based on their response to cyclazocine. One group refused to take the medication and responded better to agonist treatment. These patients appeared to use opiates as a form of self-medication to relieve symptoms of emotional problems and chronic stress. The group that was more likely to respond positively to cyclazocine did not have the same lev-

els of emotional problems, and opiate use was largely linked to environmental and conditioning factors. The assumption was that more patients in this latter group would agree to take an antagonist if it were better tolerated. These facts, combined with a growing heroin abuse problem, led to a federal government mandate in 1971 to synthesize and develop opioid antagonist compounds that might be more acceptable for use in substance abuse treatment (Julius, 1976). Naltrexone was chosen for this initiative, and the federal government funded the entire medication development effort through the point of approval by the Food and Drug Administration. For the most part, naltrexone was a success: good oral bioavailability, affordable, with few side effects, and very effective in preventing opioid-induced euphoria and physical dependence.

However, naltrexone suffers from one of the same major problems as cyclazocine: patient nonadherence. Most patients will not continue taking the medication though it will reliably prevent development of opioid physical dependence (Fals-Stewart & O'Farrell, 2003). It is much less effective in substance abuse treatment compared to agonist medication. Similar to cyclazocine, naltrexone tends to be more helpful for patients who are less psychologically impaired and more highly socially rehabilitated with other compelling motivation to take the medication and remain abstinent from opioid use (e.g., professionals at risk for losing their professional licensure). In this case, application of basic science knowledge was translated into a rational and efficacious treatment, but with limited effectiveness. The motivation of the patient to take the opioid agonist (e.g., heroin) may overpower the motivation to take the antagonist unless there are significant supports in place to ensure that the patient continues to ingest the antagonist medication (for a contemporary perspective see Sullivan, Comer, & Nunes, 2006).

Unfortunately, the poor effectiveness of naltrexone as a treatment for opioid dependence is not an exception among substance abuse treatments. In addition, though there are many fewer problems with adherence to opioid agonists compared to adherence to antagonists, simply taking the medication usually does not eliminate heroin use. All of these medications are only partially effective in treating chronic opioid dependence and have little, if any, effect on nonopioid abused substances. This is because individual patient characteristics, environment, and social settings contribute greatly to continued drug use. Many patients exhibit co-occurring substance use disorders (e.g., alcohol, cocaine) and other psychiatric and medical disorders that also influence continued drug use. Without a supportive context for the medication treatment, the drug dependence will successfully compete with more prosocial behaviors and the patient will benefit only partially, remaining at risk for many serious problems of continued substance abuse: crime, communicable diseases, social isolation, and demoralization.

BEHAVIORAL TREATMENT TRANSLATIONS

Behavioral approaches to substance abuse treatment are based on a large body of basic experimental research on operant conditioning in animals and humans. *Operant* refers to behaviors of an organism that change (or operate on) the surrounding environment, and operant conditioning is based on the understanding that the consequences of a behavior predict whether the behavior will occur under the same conditions at a future time (Stitzer, Petry, & Silverman, 2006). According to this perspective, substance use disorders are learned behaviors supported by the often powerful and biologically reinforcing effects of drugs of abuse. Many of these behavioral insights were first identified in animal research studies, where a variety of animal species demonstrate that they self-administer many of the same drugs that humans abuse. Human and animal studies also show that manipulating the consequences of behavior can increase or decrease drug self-administration. Therefore, behavioral reinforcers (consequences of a behavior that *increase* the likelihood of that behavior in the future) and punishments (consequences of a behavior that *decrease* the likelihood of that behavior in the future) are logical means to effect behavior change in treatments for substance abuse.

Translating these basic behavioral insights, *contingency management* procedures use behavioral reinforcement to promote a desirable behavior change (e.g., submitting drug-negative urine samples) by use of motivational interventions. These interventions use positive reinforcers (e.g., monetary vouchers), negative reinforcers (e.g., removal of medication time restrictions such that patients can receive methadone dosing at more desirable times), or punishments (e.g., methadone dose taper) in varied and creative ways to motivate drug abstinence or other important treatment goals. Many research studies have demonstrated the utility of contingency management approaches (Stitzer et al., 2006).

Behavioral reinforcers can be conceptualized on a continuum from high specificity to the type of treatment offered (e.g., methadone take home doses in methadone maintenance treatment) to very low specificity to the type of treatment offered (e.g., availability of recreational activities with a family member contingent on following the treatment plan). For example, many studies have shown that patients will reduce drug use if provision of negative urine samples is tied to availability of methadone. These reinforcers include methadone take-home doses such that patients do not have to attend the clinic daily for medication ingestion (Brooner, Kidorf, King, & Stoller, 1998; Calsyn & Saxon, 1999; Chuatape, Silverman, & Stitzer, 1999; Kidorf & Stitzer, 1996), availability of continued methadone treatment services (Calsyn & Saxon, 1987; Kidorf & Stitzer, 1993), and availability of higher daily methadone doses (Stitzer, Bickel, Bigelow, & Liebson, 1986). Use of the inherent reinforcing effects of agonist

medications is a very therapeutic and useful aspect of methadone or buprenorphine treatment that can easily be integrated into the plan of care.

Other behavioral reinforcers that are less specific to the type of treatment can also be effective. Some strategies allow individuals to work and earn money based on negative drug testing. This can occur in the setting of an employee health program, where patients must resolve drug or alcohol use problems to stay employed (Lawental, McLellan, Grissom, Brill, & O'Brien, 1996), but has also been used in specialized programs where access to work on a daily basis is allowed based on drug testing several times per week (Silverman et al., 2002). However, this latter method requires close collaboration with an employer or provision of workplace opportunities, which is unusual in treatment settings. Strategies that use cash or monetary vouchers as reinforcers for drug abstinence are more flexible and less clinic specific because the vouchers can be exchanged for a wide variety of goods and services, and higher reinforcer value is more likely to improve the response to the intervention (Preston, Umbricht, & Epstein, 2000; Silverman, Chutuape, Bigelow, & Stitzer, 1999). However, some criticize the monetary voucher reinforcement approach because of concern that the voucher reinforcement is temporary and that patients will resume drug use after the voucher motivation is removed (Ledgerwood & Petry, 2006; Piotrowski et al., 1999). The cost of the voucher reinforcement procedure is also cited as an impediment to this type of contingency management, though low cost incentives (e.g., approximately $100–$200 per patient over a 12-week period) have been shown to decrease drug use and improve treatment adherence (Peirce et al., 2006; Petry, Martin, & Simcic, 2005). Even so, these drawbacks currently limit the implementation of this approach in the community setting.

Even though highly structured behavioral treatments can be effective in reducing substance use, they are not commonly used as stand-alone treatments in community-based treatment programs because the effects of the treatments don't tend to continue once the behavioral treatment is discontinued. Like medication treatments, they are only partially effective because other psychological, social, and environment factors play key roles in the patient's overall progress. Other, complementary approaches are needed to develop a comprehensive substance abuse treatment model that addresses all areas of rehabilitation.

PSYCHOTHERAPY AND THE PROBLEM OF POOR TREATMENT ADHERENCE

Psychotherapy Treatments for Substance Abuse

Group and individual psychotherapies form the core of most substance abuse treatment interventions. Cognitive-behavioral therapies, motivational

enhancement therapy (MET), psychodynamic and interpersonal therapies, family-couples therapies, group therapies, and Twelve-Steporiented approaches have demonstrated benefits in the treatment of substance use disorder (APA, 2006). Whether these therapies are delivered in individual or group formats, patients learn how to reduce and eventually stop abusing substances by changing maladaptive behaviors, gaining necessary insights, and receiving important emotional support. These therapies also offer the opportunity for therapists to aid the patient in achieving other important goals such as medical care, legal referral, or treatment for other psychiatric problems. All have in common the interpersonal nature of the treatment and the focus on rational behavior change to promote rehabilitation, and they address the social and environmental aspects of the patient in a manner that is different from and complementary to medication or behavioral treatments. Though several studies have examined the differential efficacy of these various treatments (e.g., Project MATCH, 1997), no specific psychotherapy has been shown to be more efficacious overall than any other approach. On the other hand, most treatment experts agree that psychotherapy of some type is an essential component in a comprehensive plan of rehabilitation.

But these treatments are plagued with poor adherence. Careful reading of many studies of psychotherapy for substance abuse reveals fair to poor adherence to scheduled psychosocial counseling sessions, with substantial rates of treatment attrition (Crits-Christoph & Siqueland, 1996). This at least in part explains the lack of positive findings or poor treatment response reported in the studies. For example, adherence to scheduled counseling sessions can be abysmally low in standard methadone maintenance clinics, often falling below 50 percent attendance for minimal levels of counseling service (Ball & Ross, 1991). Two studies on the use of specialized psychotherapies in methadone maintenance patients also highlight the poor rates of attendance to these types of treatment (Rounsaville, Glazer, Wilber, Weissman, & Kleber, 1983; Woody, McLellan, Luborsky, & O'Brien, 1995) as well as substantial rates of attrition (e.g., 46%–62% in the Rounsaville et al., 1983 study). The National Institute on Drug Abuse Collaborative Cocaine Treatment Study (Crits-Christoph, Siqueland, Blaine, Frank, Luborsky, & Onken, et al., 1999) also reported poor attendance to scheduled counseling sessions (<50%) as well as significant treatment attrition (approximately 70% did not complete the six-month treatment episode). Many studies do not report adherence data, so one cannot be certain if the poor outcomes were due to a lack of treatment delivery due to nonadherence rather than a lack of treatment efficacy.

Comparing Treatments for Substance Abuse versus Other Chronic Medical Conditions

Poor adherence is a common and pervasive problem in the treatment of all chronic medical conditions. A recent World Health Organization report identified this treatment parameter as one of the largest problems affecting treatment effectiveness (Sabate, 2003). A reasonable conclusion from this report is that the best way to improve outcome is to ensure that the prescribed amount and intensity of treatment is actually delivered to patients.

Patient adherence to medication treatment regimens is an excellent example of this phenomenon. Adherence problems are common with most prescribed medications including antihypertensives (Burnier, Santschi, Favrat, & Brunner, 2003), antidepressants (Delgado, 2000; Thompson, Peveler, Stephenson, & McKendrick, 2000), asthma medications (Rand & Wise, 1994), diabetes management regimens (Rubin, 2005), as well as medications to aid in substance abuse treatment such as disulfiram (Liebson, Tommasello, & Bigelow, 1978) and naltrexone (Fals-Stewart & O'Farrell, 2003; Volpicelli et al., 1997). Rates of adherence to medication regimens range from 30 percent to 80 percent depending on the medication and the complexity of the medication regimens, with adherence tending to decrease rapidly over time.

Figure 12.1 shows the rates of adherence to scheduled treatment for chronic medical problems in developed and developing countries, and compares them to substance abuse counseling attendance in 12 communities in the United States (Kerr, McGlynn, Adams, Keesey, & Asch, 2004; Sabate, 2003). Even though developed countries are more likely to have efficacious treatments and the patients to have more resources to access these treatments, substance abuse counseling adherence falls between the adherence rates for treatment of chronic medical problems in developing versus developed countries. This fact significantly limits the effectiveness of even the most promising treatment. Furthermore, if one component of a multiple intervention treatment is poorly attended (such as psychotherapy) or not regularly ingested (such as medication) the entire treatment plan is jeopardized. A simple calculation tells us if a group of hypothetical patients is only 50 percent adherent to counseling and only 50 percent adherent to additional medication treatments (generous adherence given the results of many studies), very few patients will receive the most common type of prescribed combined treatment. Essentially, though a two-component treatment intervention is planned, the majority of patients will receive either one or no treatment intervention.

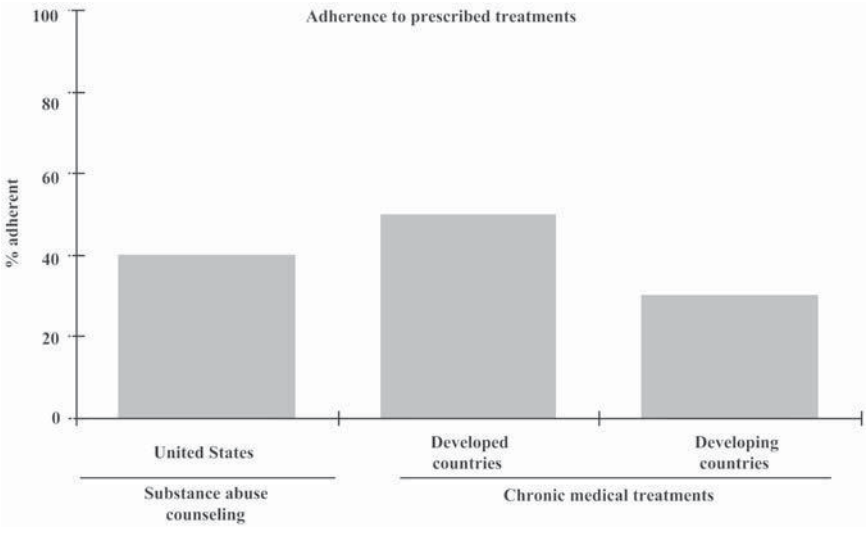

FIGURE 12.1. Adherence to Prescribed Treatments. Rates of adherence to scheduled treatment for chronic medical conditions in developed and developing countries compared to adherence to substance abuse counseling attendance in 12 communities in the United States.

Another perspective is even more concerning. In certain instances, poor adherence to treatment can be detrimental to the patient (Moos, 2005). Perhaps the easiest example to cite involves antiretroviral therapy for HIV infection. Poor adherence can result in development of resistant strains of the virus, shortening the patient's lifespan by reducing availability of effective antiviral agents. In another example, if patients miss antidepressant medication doses they can develop uncomfortable medication discontinuation effects that can be mistaken for worsening depression. Patients may then be treated with higher-than-required doses or needlessly switched to other, potentially more hazardous agents. In psychotherapy treatments, lack of effectiveness may result simply from poor attendance, yet an otherwise efficacious treatment may be abandoned. From a psychological perspective, patients may become demoralized because of the mistaken belief that they are not able to benefit from treatment. From a societal perspective, only low intensity treatments may be offered because higher intensity treatments are no more effective than low intensity treatments. Unfortunately, the primary difficulty may be poor adherence to the prescribed treatment, and few treatments work well if not taken as prescribed.

Therefore, specific efforts to enhance adherence are needed to avoid these types of poor outcomes. We next show how contingency management can help avoid this pitfall in the example of psychotherapy treatments.

Using Contingency Management to Enhance Treatment Adherence

Given the evidence that psychotherapies can be very effective in reducing substance abuse symptoms, organizing systems of care to increase patient attendance to these therapies could be an important strategy to improve treatment effectiveness. Table 12.1 lists several studies that demonstrate how clinic-based behavioral reinforcement positively affects counseling attendance in methadone maintenance treatment. A wide variety of contingencies can be used to reinforce targeted behaviors (in this instance, counseling adherence). These incentives range from methadone take-home doses (Iguchi et al., 1996; Kidorf, Stitzer, Brooner, & Goldberg, 1994), to chances at winning a prize in a lottery drawing (Petry et al., 2005), to vouchers redeemable for goods and services (Jones, Haug, Silverman, Stitzer, & Svikis, 2001), to cash (Svikis, Lee, Haug, & Stitzer, 1997), and to an integrated set of behavioral reinforcers (Brooner et al., 2004). Some of these studies demonstrate dramatic improvements in counseling attendance and are associated with overall improvement in treatment outcome, demonstrating the benefits of integrating contingency management approaches with other forms of treatment.

Community-based behavioral reinforcement can also be very effective in motivating treatment attendance. Perhaps one of the most common types is the drug court model where offenders are mandated to attend treatment services to avoid incarceration. Individuals in these programs can respond as well or better than patients who are not legally mandated to treatment (Kelly, Finney, & Moos, 2005; Lawental et al., 1996; Miller, 1975). Clearly, this approach relies on the threat of punishment to motivate the patient, but a broader approach would utilize positive reinforcement as well. In the community reinforcement approach (CRA; Azrin et al., 1994; Higgins et al., 1993; Hunt & Azrin, 1973; Smith, Meyers, & Delaney, 1998), family members or other individuals in the community who are important to the patient provide contingent reinforcement (e.g., room and board, access to employment, shared recreational activities, etc.) for important treatment goals. The reinforcers used in CRA are limited only by the extent of the patient's integration into his community and the ability of the treatment staff to engage these individuals in the treatment process. Strongly positive findings highlight the concept that relevant environmental and prosocial motivators can be excellent reinforcers of substance abuse treatment and

Table 12.1
Effect of Behavioral Contingencies on Counseling Attendance

Study	Reinforcer	Counseling attendance	
		With reinforcer	Without reinforcer
Kidorf et al., 1994	Methadone take-home dose	75%	7%
Iguchi et al., 1996	Methadone take-home dose	60%	< 1%
Svikis et al., 1997	$10 cash incentive	46%	31%

eventual drug abstinence. This approach also taps an important treatment resource often missing in opioid dependence treatment and treatment research: family and community supports for substance abuse treatment and drug abstinence (Kidorf et al., 2005).

Agonist therapy, psychotherapy, and contingency management are all efficacious therapeutic interventions. However, each approach by itself is only partially effective, with many patients continuing to suffer with significant symptoms, and often with rapid return of substance abuse symptoms if the interventions are discontinued. The next step in the evolution of treatment translation utilizes each of the aforementioned approaches in an integrated model of care, expanding on previous research models. In this translation, contingency management is used to reinforce additional aspects of treatment other than just attendance and drug abstinence, including more permanent and personally meaningful behavioral change (e.g., developing friendships with drug-free individuals and acquiring employment). This long-term perspective is a key ingredient in the successful treatment of chronic disorders such as severe opioid dependence.

TRANSLATING EFFICACY TO EFFECTIVENESS: MOTIVATED STEPPED CARE (MSC)

The MSC model combines and thoroughly integrates medication, psychotherapy, and behavioral reinforcement (contingency management) into a

comprehensive treatment service delivery system for severe opioid dependent patients. Using an adaptive, stepped care approach (Murphy, Lynch, Oslin, McKay, & TenHave, 2007; Sobell & Sobell, 2000), MSC addresses the long-term requirements of chronic substance dependent patients in an efficient and cost-effective manner by matching the intensity of the service to the severity of the problem in a dynamic fashion over time using behavioral reinforcement to motivate counseling adherence and treatment plan progress. In this way, only as much treatment as is needed to improve and stabilize functioning is prescribed, and then intensity of care is reduced to minimize intrusiveness and cost. Figure 12.2 is a schematic diagram of the most current MSC model. All patients begin at Step 2, receiving 0.5 to 1.5 hours of weekly drug abuse counseling combined with weekly urine monitoring and individualized methadone maintenance dosing. For those patients who respond well to this step of care for several months (no drug use, steady progress on the treatment plan), a reduction to Step 1 care is appropriate (0.5 hours of counseling monthly and twice monthly urine testing), though patients can attend more counseling if desired.

For patients who do not respond well to Step 2 (i.e., continued drug use, treatment nonadherence), advancement to Step 3 is required. Step 3 patients receive an additional two hours per week of intensified group-based counseling treatment in an effort to curb ongoing drug use and make progress in the plan of rehabilitation. If patients do not respond to Step 3 care within two to four weeks, they are advanced to an intensive outpatient level of care, Step 4. Here patients attend up to nine hours of counseling per week including individual counseling, stress management therapy group, relapse control therapy group, cognitive-behavioral therapy group, coping skills therapy group, and a community support therapy group.

Behavioral reinforcement is active at all steps of care but becomes increasingly important at higher steps, and access to methadone medication treatment is one of the most powerful behavioral reinforcers available in the clinic. For example, not only are patients expected to attend the clinic on all scheduled days for medication, all scheduled counseling must be attended to avoid advancement to higher steps of care. If patients do not attend scheduled counseling sessions, they are subject to increasingly later restrictions on available methadone medication dosing times (however, they can be medicated earlier if they attend a scheduled session). For example, a patient who has an unexcused absence from counseling one day will have his earliest methadone medication dosing time advanced from 12 p. m. to 4 p. m. This time restriction for dosing is then reversed after one week of adherence, but would advance by one hour for each day of missed counseling. Take-home metha-

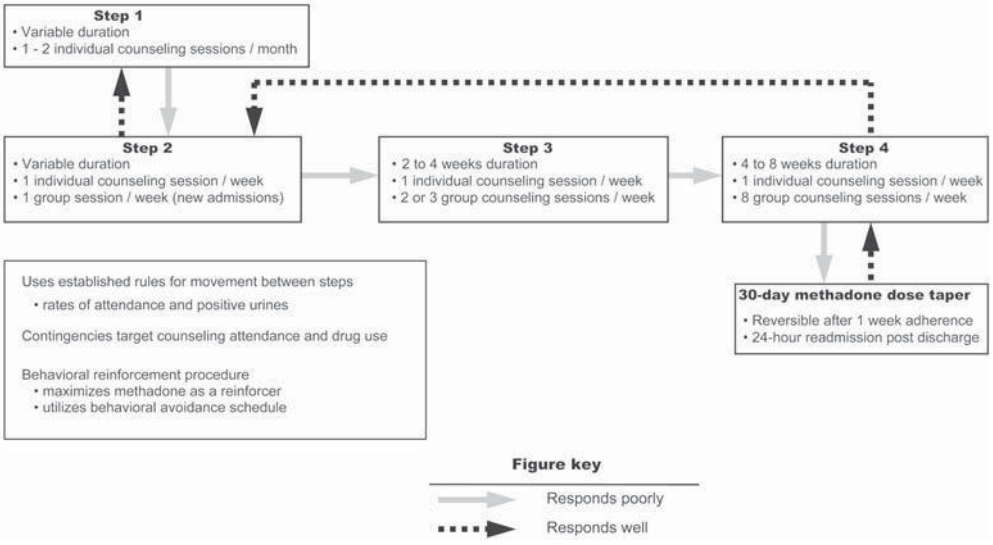

FIGURE 12.2. Motivated Stepped Care. Patients begin at Step 2 and move to Step 3 for two to four weeks after missing any counseling sessions and/or submitting drug-positive urine specimens for two consecutive weeks. They return to Step 2 after attending all scheduled counseling and testing negative for drug use for two consecutive weeks. Patients in Step 2 that attend all scheduled counseling and submit drug-negative urine specimens for six-months may reduce their intensity of care to Step 1. Patients who do not adhere to the schedule of treatment in Step 3 are advanced to Step 4 and must attend all scheduled counseling and provide negative urine specimens for four consecutive weeks within an eight-week period to return to Step 2. If they do not accomplish this goal, they begin a 30-day methadone dose taper in preparation for discharge from the clinic. However, the taper can be stopped by attending all counseling sessions for one week and providing a drug-negative urine specimen. Step 4 patients who complete a methadone dose taper are discharged but are guaranteed rapid readmission, restarting Step 4 with the goal of adherence to the updated treatment plan.

done doses are removed for nonadherence but are returned when adequate adherence to the treatment plan is accomplished. Ultimately, if patients do not adhere to the plan of care, they are subject to a methadone taper in preparation for discharge and referral to alternate treatment. However, this taper can be reversed after one week of adherence to the entire treatment plan, and patients begin Step 4 again with the aim of four weeks of consecutive adherence. Once this is accomplished, the patient is transferred to Step 2 with continuing care aimed at solidifying gains accomplished during the Step 4 episode.

Behavioral Contingencies Motivate Counseling Attendance and Reduced Drug Use

Brooner et al. (2004) reported on a trial of MSC versus a noncontingent, standard methadone maintenance treatment control. The MSC condition was basically conducted as described in the preceding section (we made some minor changes in groups and step movement over the years), while, as seen in Figure 12.3,

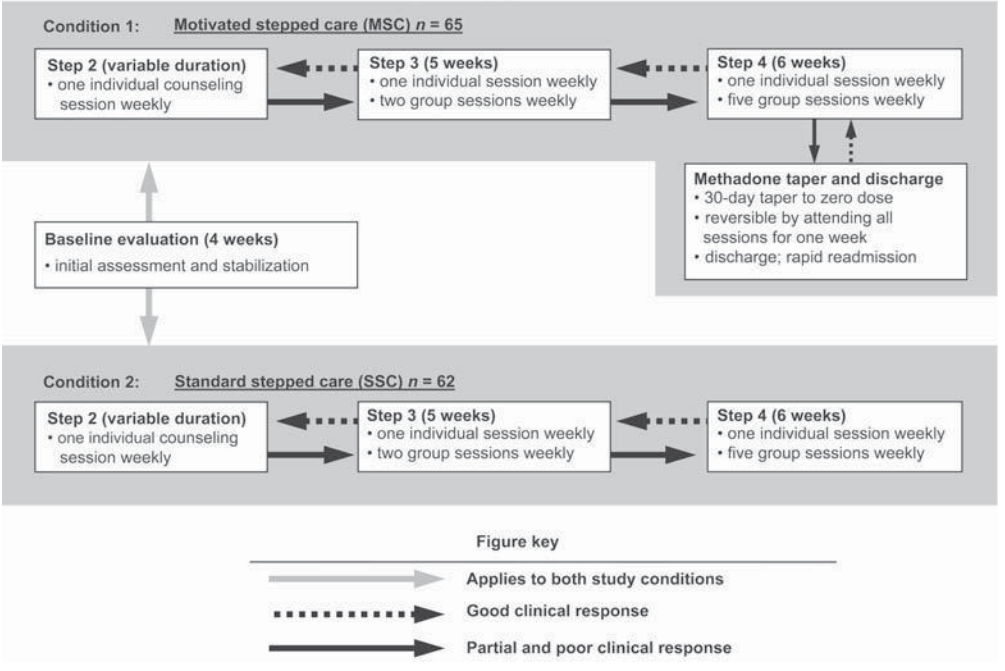

FIGURE 12.3. Randomized Treatment Conditions. MSC and SSC subjects begin randomized treatment in Step 2 following the baseline evaluation (Brooner et al., 2004). All subjects move to Step 3 after submitting drug-positive urine specimens or missing counseling sessions in any two out of three weeks. They return to Step 2 after attending all counseling and testing negative for drug use in weeks four and five. Subjects in Step 3 that miss counseling sessions or submit drug-positive urine samples in weeks four or five move to Step 4. They return to Step 3 after attending all counseling and testing negative for drug use in weeks five and six. Subjects in the MSC condition that demonstrate a partial and poor response to Step 4 (i.e., are nonadherent to counseling and submit drug-positive urine specimens in week five and six) begin a 30-day methadone dose taper in preparation for discharge. However, the taper is reversible and subjects move back to Step 3 after producing two consecutive weeks of counseling attendance and drug-negative urine specimens. Step 4 patients who complete a methadone dose taper are discharged but are guaranteed rapid readmission. Subjects in the SSC condition stay in Step 4 until they satisfy criteria to reduce intensity to Step 3, or until they satisfy the 90-day therapeutic rescue procedure that transfers them to the MSC condition.

patients in the standard stepped care (SSC) condition were encouraged to attend the same counseling sessions, but no contingencies were placed on the methadone medication treatment if they did not adhere to the treatment plan. During the first 90 days of the study, the MSC group attended significantly more counseling sessions (MSC 83% versus SSC 44%, $p < .001$). Figure 12.4 illustrates how behavioral reinforcement in the MSC model shifted the counseling attendance rates dramatically over the study period, with many more patients attending more than 50 percent of scheduled counseling in the MSC versus SSC condition. Not surprisingly, there were nonsignificant differences in overall drug use (including opioids, cocaine, alcohol, and benzodiazepines) over the first 90 days because there was limited time for the MSC patients to be exposed to the higher intensities of care (MSC 49% drug-positive urine specimens versus SSC 54%, $p = ns$).

At the end of the first 90 days of the study, patients assigned to the SSC condition that were doing poorly in treatment were therapeutically transferred to the routine MSC condition. In this subset of patients, significant changes in counseling attendance *and* urine drug tests were seen over the subsequent 90 day study period (see Figures 12.5 and 12.6). In these figures, the first 90 days of treatment (SSC) is compared to the second 90-day period (MSC).

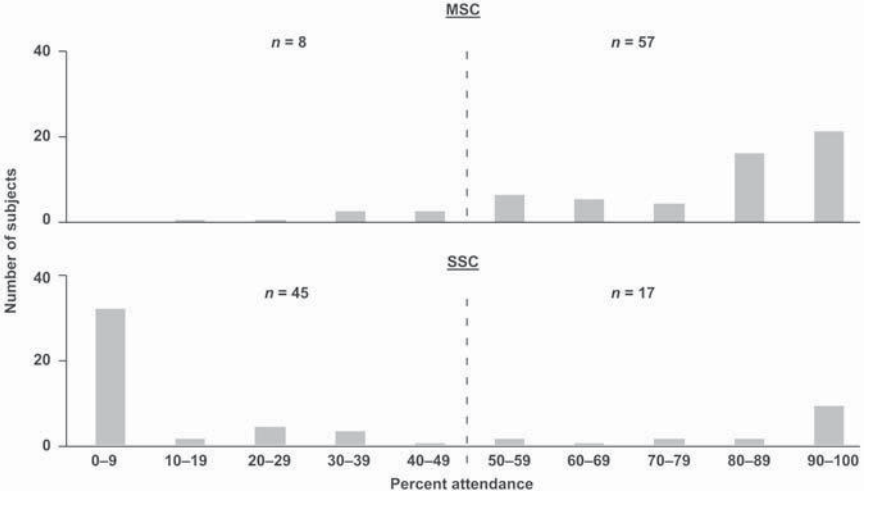

FIGURE 12.4. Group Comparisons of Counseling Attendance. Behavioral reinforcement in the MSC condition shifted the counseling attendance rates dramatically over the 90-day study period, with many more patients attending more than 50 percent of scheduled counseling in the MSC versus SSC condition.

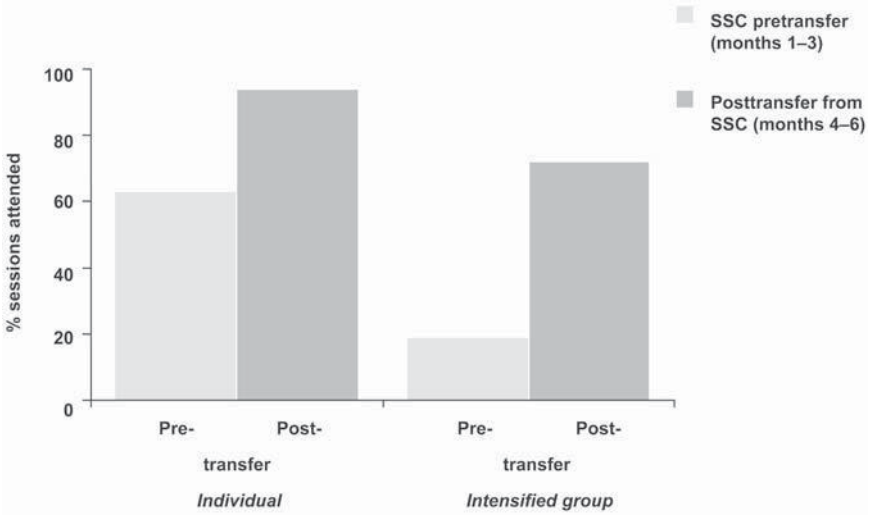

FIGURE 12.5. Within-Subject Crossover Comparison Counseling Attendance. At the end of the first 90 days of the study, patients assigned to the SSC condition that were doing poorly in treatment were therapeutically transferred to the routine MSC condition. In these figures, the first 90 days of treatment (SSC) is compared to the second 90-day period (MSC). Significant changes in rates of counseling attendance were seen over the subsequent 90-day study period (Individual sessions: pretransfer = 63%, SD = .35 vs. posttransfer = 94%, SD = .16; $t(35) = 5.48$, $p < .001$. Intensified group sessions: pretransfer = 19%, SD = .25 vs. posttransfer = 72%, SD = .27, $t(33) = 8.19$, $p < .001$.).

Marked increases in counseling attendance were correlated with significant reductions in drug use after behavioral reinforcement was added to the SSC condition. Another important finding in this study was that six-month retention was good in the MSC condition (70%) and comparable to the SSC condition and to six-month retention in other community programs even though this treatment was significantly more demanding than standard methadone maintenance treatment.

In a separate study, Brooner et al. (2007) used a four group design to compare MSC with and without voucher reinforcement for drug abstinence with a control, noncontingent counseling condition, also with and without voucher reinforcement for drug abstinence. Again, the findings were remarkably positive in this six-month study. Use of MSC plus voucher reinforcement demon-

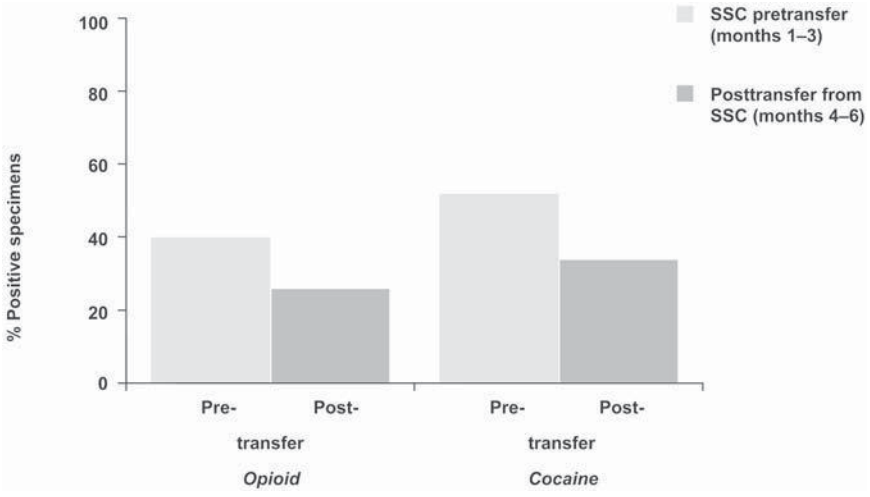

FIGURE 12.6. Within-Subject Crossover Comparison Urinalysis Results. At the end of the first 90 days of the study, patients assigned to the SSC condition that were doing poorly in treatment were therapeutically transferred to the routine, MSC condition. In these figures, the first 90 days of treatment (SSC) is compared to the second 90-day period (MSC). Significant changes in rates of drug use were seen over the subsequent 90-day study period (Opioid use: pretransfer = 40%, *SD* = .35 vs. posttransfer = 26%, *SD* = .29; $t(35) = 3.65$, $p = .001$. Cocaine use: pretransfer = 52%, *SD* = .36 vs. posttransfer = 40%, *SD* = .34; $t(35) = 2.54$, $p = .016$).

strated the best drug use outcomes (60% drug-negative urine specimens), the MSC-only and voucher-only conditions were next best (49% and 50% drug-negative urine specimens, respectively), and the noncontingent condition was significantly worse than all the contingent conditions (29% drug-negative urine specimens). Counseling attendance was excellent in the contingent counseling conditions. This study also showed that voucher-based positive reinforcement was associated with improved six-month retention versus the nonvoucher experimental conditions (74% versus 59%, respectively). Similar to the previous study of MSC (Brooner et al., 2004), MSC demonstrated powerful treatment effects.

MSC Initiates and Reinforces a Wide Spectrum of Prorehabilitation Behavior Change

Behavioral reinforcement with methadone in MSC is associated with improved outcomes across several important substance abuse treatment

goals: employment, social support, as well as the primary goals of adherence to scheduled counseling and accompanying reductions in substance use. Table 12.2 shows results from several studies utilizing the MSC treatment model. The first two studies in Table 12.2 were discussed earlier in this chapter. Given these results, it is no surprise that patients with persistent marijuana use problems also benefited from behavioral reinforcement (Kidorf, Neufeld, King, Clark, & Brooner, 2007). In this study, MSC acted as an avoidance schedule for patients with lower frequency marijuana use (i.e., they stopped to avoid

Table 12.2 (continued)

Article	Targeted behaviors	Findings
Kidorf et al., 2004 "Combining Stepped-Care Approaches with Behavioral Reinforcement to Motivate Employment in Opioid-Dependent Outpatients"	Employment acquisition	93% of able-bodied patients in methadone maintenance clinic currently working 15+ hrs/wk. Work associated with improved substance abuse treatment outcomes
Kidorf et al., 1997 "Motivating Methadone Patients to Include Drug-Free Significant Others in Treatment: A Behavioral Intervention"	Acquire drug-free significant other (community support person) to attend conjoint weekly therapy group and participate in weekly social activity	85% of 75 patients obtained significant other (SO) and patients who identified SO attended 77% of scheduled sessions
Kidorf et al., 2005 "Involving Significant Others in the Care of Opioid-Dependent Patients Receiving Methadone"	Acquire drug-free significant other (community support person) to attend conjoint weekly therapy group and participate in weekly social activity	93% of 59 patients obtained SO and 78% achieved at least 4 weeks drug abstinence during the intervention

more intensified counseling treatment) and as a platform for delivering higher intensity treatment for patients who were dependent on marijuana. Examining a different population, the strong behavioral reinforcement element of MSC may have been responsible for the comparable and very positive outcomes when comparing patients with a history of attention deficit hyperactivity disorder (ADHD) versus no history of these behavioral problems (King, Brooner, Kidorf, & Mirsky, 1999). Rates of intensified treatment as well as treatment retention were comparable between the ADHD and non-ADHD groups. The fifth study, examining methadone medical maintenance, demonstrated how the MSC approach serves as an excellent platform to expand the range of treatment intensity for highly stable patients who desire long-term substance abuse treatment (King et al., 2006). This expanded service delivery system matched appropriate levels of substance abuse monitoring and treatment with the needs

of highly stable patients who occasionally experienced increases in substance use disorder symptoms. Finally, MSC behavioral reinforcement motivated unemployed patients to seek and begin employment (Kidorf, Hollander, King, & Brooner, 1998; Kidorf, Neufeld, & Brooner, 2004) and socially alienated and isolated individuals to form initial community supports for drug abstinence (Kidorf, Brooner, & King, 1997; Kidorf et al., 2005). Targeting specific behaviors with behavioral reinforcement in an integrated care model initiates important behavioral changes and, with the help of the community support intervention, begins to integrate the patient into the larger society that then provides additional reinforcement for drug abstinence. This may be most apparent when key community reinforcers that are provided by family and other social supports (e.g., employers and spiritual organizations) move the patient's rehabilitation out of the clinic and into his emerging life as a healthier and more productive person. It is apparent from this range of studies that the MSC model can motivate chronic opioid dependent patients to attain many important short-term and long-term treatment goals.

RESEARCH IMPLICATIONS AND OTHER POTENTIAL APPLICATIONS

These findings have important research implications, especially for studies involving clinical populations. Given the importance of adherence behavior in successful treatment outcomes, this variable should be assessed not only as a primary overall outcome measure, but also for any discrete elements of the treatment (e.g., medication versus psychotherapy adherence). In this way, adherence to separate treatment elements can be evaluated, and considerations for types of motivational interventions can be made for elements that exhibit poor adherence. For maximum treatment effectiveness, service delivery systems that maximize adherence to the plan of care are essential. As in the case of naltrexone treatment for opioid dependence, this step in the process of treatment innovation can be just as important as the original findings of efficacy.

This general model of care, including the use of behavioral reinforcement that is available in the clinic or in the community, could be transposed to many different clinical situations with appropriate modifications. The parallel is perhaps most apparent for other chronic disorders that have significant behavioral aspects that influence the onset or course of the illness. For many patients, these disorders are primarily caused and exacerbated by lifestyle behaviors. For example, behavioral reinforcement could be used in a structured treatment program to motivate desirable eating and exercise behaviors in patients with diabetes or hypertension. Starting with simple behavioral prescriptions that

are reinforced and supported by family involvement, many patients would not only take medication more regularly but also improve their own health maintenance. Clearly, this approach would demand more time and effort on the part of care providers, but tackling disorders that are caused by continuing detrimental lifestyle choices with medications and brief, occasional, office–based individual counseling are unlikely to fully treat these problems because these approaches are only partially effective. Integrating contingency management into our routine treatments could have dramatic positive effects, helping to optimize the effectiveness of our present and future medical treatments. To do this, we need to shift our focus from just the primary treatments to include and emphasize new delivery systems that specifically address patient behaviors with the goal of increasing treatment adherence. Translating efficacious research-based treatments into more effective, community-based clinical services could have an enormous impact on long-term patient health.

CONCLUSION

Scientific understanding of the molecular and genetic basis of neurological and psychiatric disorders is progressing at a rapid pace, and along with these new understandings comes the promise of powerful new therapies. However, one important and overarching aspect of therapeutics has lagged behind in our scientific advancements: patient behavior as the means by which these scientific advancements can be translated into meaningful changes in the lives of patients. Patient behavior can support and enhance the new molecular and genetic-based therapies, or it can drastically limit their effectiveness. These advancements are on our doorstep but will ultimately disappoint when patients continue to be poorly adherent to prescribed treatment regimens. One can easily appreciate how the promises of new genetic discoveries and medication therapies will be substantially reduced by treatment nonadherence. As simple a task as taking a medication once daily is frequently not accomplished by patients.

Though adherence problems are common in all areas of medical treatment, they are even more pernicious in psychiatric settings, where patients are more likely to have behavioral disorders that either interfere with the treatment process or are themselves the focus of treatment. Therefore, the best opportunity to transform efficacious treatments into more effective treatments is to improve adherence. The extensive literature on behavioral reinforcement clearly demonstrates how this principle can be used to greatly enhance treatment outcomes, yet these approaches are rarely used in routine treatment settings. To get the most out of powerful and sophisticated new treatments, we must use service delivery systems of equal power to ensure that the treatment is received. Without significant improvements in this aspect of care, we will develop mounting num-

bers of treatments found to be efficacious in well-controlled studies, but with continued problems of limited effectiveness in real-world settings.

In this chapter we examined how translational insights were used in the development of medication and behavioral therapies for opioid dependence. However, these approaches by themselves are only partially effective. Psychotherapy is another important treatment approach but is plagued with the problem of poor adherence. Using all three treatment strategies in an integrated fashion is most effective. However, successful implementation depends on all treatment components working synergistically, because if patients do not adequately adhere to one component, then the entire treatment model is jeopardized. The final strategy for effective treatment integration expands the use of behavioral reinforcement by directly addressing adherence behavior in the overall treatment plan.

The MSC model of treatment for severe opioid dependent patients was developed specifically using these key understandings. MSC combines and translates efficacious interventions into a more effective, integrated model of care that recognizes and addresses the very common problems associated with poor treatment adherence. Contingent access to methadone motivates the patient to attend counseling sessions. It can also motivate other prorecovery target behaviors such as job seeking and involving community supports in treatment, thus allowing systematic exposure to other elements of treatment that might not otherwise occur without the behavioral reinforcement intervention. As expected, patients demonstrate remarkably improved outcomes when adherence is improved. The key translational insights of opioid agonist therapy and behavioral reinforcement enable the treatment providers to engage the patient more completely in the rehabilitation process and obtain treatment outcomes that exceed any of the results of the individual treatments used alone. MSC is the next developmental advance in the translational application of efficacious interventions for substance use disorder, and it also serves as a potential model for approaching other chronic medical disorders that have significant behavioral components.

Chapter **13**

Shamanistic Harm-Reduction Practices[1]

Michael Winkelman, MPH, PhD

Drug use and addiction are obviously driven by biological dynamics associated with the alteration of consciousness, but conventional addiction treatment approaches have, in general, not directly engaged this modification of consciousness as a normal and intrinsic part of human nature and healing processes. Nonetheless, a number of investigators have noted relationships among substance dependence, altered states of consciousness (ASC), ritual, and spirituality (e.g., Heggenhougen, 1997; Jilek, 1994; McPeake, Kennedy, & Gordon, 1991; Metzner, 1994; Miller, 1998; Rioux, 1996; Smith, 2000; Winkelman, 2001a, 2003). Siegal (1990) and Winkelman (2000) provide models that illustrate how addictions reflect an innate drive to seek ASC. McPeake et al. (1991) suggest that addictions be viewed in the context of a universal human desire to enter ASC, and they propose that natural modifications of consciousness be used to reduce recidivism. Mandell (1980) conceptualized this common basis for addiction and ASC in a psychobiological model of "transcendent states" in which both endogenous and exogenous mechanisms of altering consciousness share a common biological substrate in the serotonergic system. Commonalities in addictive and spiritual ASC reflect an underlying biologically based integrative mode of consciousness (Winkelman, 2000). Metzner (1994), however, notes that addictions constitute a contracted state of consciousness, in contrast to the expansive states of consciousness of mysticism.

The biological basis for ASC and our addictive tendencies is manifested as a universal of human societies—shamanistic healers who lead community ritual practices for achieving spiritual experiences, ASC, and healing. These

practices originated in the shaman, who leads dramatic all-night rituals involving drumming, singing, clapping, dancing, myth-telling, and visionary experiences. Shamanism involved the most central communal activity found worldwide in hunter-gatherer and other technologically simple societies. While shamanic practices changed as a function of sociocultural evolution, the same biological potentials underlying shamanism remain in more complex societies, reflecting the persistence of ASC-based healing practices. Features of the original forms of shamanism persisted across sociocultural evolution (e.g., the development of agriculture, political integration) in communal use of ASC in healing rituals (Winkelman, 1992, 2000). The innate psychology involved in communal ritual healing processes evolved to meet psychobiological needs for personal and social integration and provided experiences of unity and transcendence. While shamanistic practices evolved to meet humans' psychobiological needs (Winkelman & Baker, 2008), such practices are virtually absent from the mainstream spiritual practices of contemporary urban societies, where instead epidemics of drug addiction rage.

Shamanistic practices are extensions of a genetically based primate ritual system that evolved for the coordination of the individual with society and the production of psychological integration. Shamanism's roots are found in primate social bonding rituals that were elaborated across human evolution to enhance group unification, psychosocial bonding, and therapeutic responses (Winkelman, 2004a, 2008). Shamanic processes engage some of our innate cognitive modules, integrating these specialized systems to overcome a fragmented consciousness and contributing to the evolution of modern symbolic cognition (Winkelman, 2002). These ancient spiritual practices constitute natural healing processes, an evolved psychology providing mechanisms for integration of consciousness and emotional well-being. A shamanic approach to harm reduction recognizes that humans' innate drive to alter consciousness underlies both addictive behaviors and ritual practices for inducing spiritual transcendence. Shamanic harm-reduction approaches provide ritual methods for inducing safe ASC experiences, using them to integrate the psyche in healing processes.

ALTERED STATES OF CONSCIOUSNESS THERAPY

McPeake et al. (1991) suggested that relapse prevention and recovery could be enhanced by teaching recovering individuals to experience nonsubstance-induced ASC that can help instill a positive sense of self and provide alternatives to the drug-induced state. Shamanic ASC can meet this drive to alter consciousness in constructive ways, providing a prevention strategy, adjuncts

to primary treatment modalities, and specialized alternative approaches for addressing recidivism. Shamanic practices provide far more powerful tools for altering consciousness than found at typical Alcoholics Anonymous meetings—where consumption of tobacco and coffee serve as mechanisms for altering consciousness. Shamanism provides more direct techniques for the alteration of consciousness and production of spiritual experiences, which are considered fundamental to recovery in Alcoholics Anonymous, where step 11 recommends meditation and step 12 refers to the needed change in consciousness as a "spiritual awakening."

These conventional approaches, however, have failed to consider the role of ASC in human nature or drug dependence. This in part reflects cultural perceptions and biases regarding ASC, a puritanical attitude that rejects ASC in general. "Despite the rich literature on ASCs in psychology and spiritual writing, and despite the fact that AA clearly points its members toward an ASC, reviewing the published literature on rehabilitation treatment or surveying current rehabilitation treatment programming reveals a paucity of writing or treatment programming that clearly integrates ASCs with recovery" (McPeake et al., 1991, p. 78). McPeake et al. propose an ASC therapy (ASCT) approach to substance abuse as a natural complement to AA's Twelve-Step recovery program. ASC can enhance recovery by inducing "positive mental attitudes, goal directedness, certain types of cognition or self-talk, certain types of imagery, as well as consciousness of a power greater than self" (McPeake et al., 1991, p. 78). An ASCT approach can meet innate human needs to alter consciousness and, furthermore, provide tools for personal exploration and transpersonal growth. Such an approach can help address substance abusers' genetic or other predispositions to seek altered states, giving them safe and controllable experiences of ASC and providing insight that can promote growth beyond their developmentally fixated stage of drug dependence. Shamanic rituals can provide a direct mechanism for inducing the transformation of consciousness and spiritual awakening considered essential to recovery in AA programs.

An ASCT program should provide both patient and staff education, as well as a variety of opportunities for nondrug-induced alterations of consciousness. These would include: physical activities, including extensive exercise, which could induce the opiate-mediated, so-called runners high; activities in nature, which can provide opportunities for natural high experiences; relaxation training based on progressive relaxation; yogic techniques and the use of vivid imagery; cognitive therapies in art and other forms of aesthetic experience; and meditation and prayer, including Eastern meditative techniques, mantras, biofeedback, dance, music, and other natural methods of inducing ASC (see McPeake et al., 1991). While there is still a lack of double-blind clinical studies

evaluating such effects, McPeake et al. point to the abundant anecdotal information indicating the efficacy of these approaches. Where such programs have been provided, the clients strongly endorse these ASC treatment principals; therapists already utilize many of these modalities as supportive aspects of therapy; and the ASCT approach helps many people recontextualize the spiritual and religious aspect of the Twelve-Step program in ways that are easier to understand and incorporate into their lives.

This chapter elaborates on these ASCT bases for a harm-reduction approach involving the potentials of shamanism by: (1) providing a brief description of shamanic practices, ASC, and healing principles; (2) characterizing the common psychobiology of shamanic and drug ASC; and (3) summarizing clinical studies of shamanistic practices—drumming circles and Transcendental Meditation—used as adjunctive therapies for addiction. Shamanism provides harm-reduction approaches in: (1) precluding addictive impulses with natural methods for altering consciousness that can address the basic psychobiological needs that drive the dynamics of addiction and (2) approaches for reducing recidivism through powerful therapeutic tools for accessing deep levels of the unconscious to discover the dynamics of one's addiction. Chapter 20 in this volume addresses another shamanic technique, the use of sacred plants that induce dramatic transformations of consciousness and personal experiences that produce changes in identity necessary for ending one's career as an addict.

SHAMANISM IN CROSS-CULTURAL PERSPECTIVE

The term *shaman* is used in a variety of ways; it reflects something empirical, a cross-culturally valid concept representing similar religious practitioner found in premodern foraging and simple horticultural and pastoral societies worldwide (Winkelman, 1992, 2000). Eliade (1964) championed a cross-cultural concept of the shaman as someone who entered ecstasy to interact with the spirits on behalf of the community. Eliade characterized the shamanic performance as an unparalleled activity in the lives of the members of the community. The shamanic ritual is typically a nocturnal event for the entire local community; they congregate around a fire with the shaman, who dances while drumming, rattling, or clapping, exhorting the spirits through ancient songs and chants. The shaman would exhort evil spirits to cease their afflictions or exorcise them with assistance from their spirit allies. The shaman may describe these encounters or act out his struggles with the spirits, the behaviors of the animal powers he has summoned, or his journey through the spirit realms.

While shamans were generally male, females might also practice prior to or following their reproductive years. Key to becoming a shaman was a spe-

cial relationship with the spirit world that resulted from the shaman's ability to enter into special ecstatic ASC. These ASC might occur spontaneously, or be produced by fasting and isolation; the effects of drumming, singing, chanting, and dancing; or ingestion of emetics, tobacco, and other psychoactive substances. Shamans spend hours dancing, drumming, and chanting to deliberately induce ASC that provide entry into the spirit world and contact with supernatural powers. While in ASC, they are able to diagnose the causes of disease, determine the reasons why the hunters have not found game, to find friends and enemies, and to divine the future.

A central characteristic of the shaman's ASC is a soul journey or magical flight, a spirit world encounter in which one experiences his soul or spirit traveling to spirit worlds. These shamanistic soul journeys or out-of-body experiences are based in several innate capacities, including body-representation, imagery, and self and other representation processes (Hunt, 1995; Winkelman, 2000). The body-referenced aspect of soul flight (e.g., the out-of-body experience) is a cultural universal that derives from biologically based self-representation structures that reflect an innate system of self-conceptual structures. Humans know the world through their bodies and the action of their bodies on the world; the body becomes by extension the metaphoric system for all human knowledge. Thus out-of-body experiences constitute a symbolic evolution superseding the limitations of body-fixated egocentric perspectives and knowledge.

A significant feature of the soul journey is a disembodied sense of self, seeing one's body from the perspective of the other. Hunt analyzes these experiences in terms of the innate capacity to see one's own self from the perspective of others, which provides the capacity to inform one's own behavior with the perspectives of others. Hunt discusses these experiences as involving presentational symbolism, an imagistic modality that is different from our representational (word) symbolism. These experiences reflect symbolic structures of the nonverbal mind and provide connections with self, emotions, and repressed memories. These shamanic encounters with spirits engage an alternate understanding of the self and social others, manifested in identities linked to animals and animal spirits. These capacities reflect innate structures of humans' evolved psychology, combining the innate system for animal representation with the innate features of the human cognitive architecture used in individual and group identity psychodynamics. These animal-based representations provide tools for individuation and social identity by modeling individual qualities and shared social characteristics.

The spirits involved in the shaman's activities are typically acquired during a vision quest that is part of the shaman's training and development. During

this quest, an initiate is expected to encounter a spirit ally who will teach him a particular power that he will develop during his life. Older shamans may supervise and guide the initiates during their vision quests, but typically the shaman encounters the spirit powers alone in the wilderness. These initiatory experiences typically involve the initiate's experience of his personal death, followed by a subsequent rebirth. This often occurs in conjunction with visions in which the shaman experiences being torn apart by animals and then put back together by the animals and spirit beings. The spirits reassemble the shaman into a stronger and more knowledgeable person with powers to enter the invisible worlds. Because of the shaman's personal experience of death and knowledge of the ways to control spirits, that the shaman is called on to find lost souls and to guide the souls of the deceased to their afterlife destination.

Although the view of the world takes different forms in different cultures, shamans' cosmologies share a view of the world as consisting of at least three principal realms or levels. Humans occupy the middle world, while spirits and other supernatural beings are found in both this world and in the upper and lower worlds. These different realms are connected by a horizontal axis mundi, a world axis, often depicted as a tree or hollow mountain that connected the levels. The beings found in these different realms have different powers, which they use to keep the universe functioning and in balance. The animal and plant spirits that the shaman acquires provide him with numerous powers and abilities, including the potential to transform into animals (his spirit allies). Shamans can learn many things from these beings, such as how to travel along the paths that connect the worlds and how to acquire and use the powers of the spirit beings. This knowledge allows them to journey throughout the universe in quest of the knowledge they need to help their communities. These shamanic views of the interconnectedness of nature reflect contemporary cognitive science theories of meaning (see Hubbard, 2002).

Biological Bases of Shamanic Universals

Winkelman (2000, 2002, 2004a) illustrates how central features associated with shamanic practices around the world involve underlying biological systems in:

- Community bonding rituals that extend mammalian attachment processes, eliciting the opioid-attachment mechanisms that united groups and helped assure well-being through enhanced access to resources and support;
- Singing, chanting, dancing, and drumming, manifestations of ancient mammalian, primate, and hominid emotional communication and social integration systems;

ASC, particularly a soul flight, which reflects a higher level of integration of consciousness produced by the separation of self-reference from the body;
Spirits, particularly animal powers, that provided systems of individuation and self-expression that facilitate psychological development and social identity formation;
Divination and prophecy that integrated diverse forms of unconscious information into symbolic visionary experiences (see Winkelman & Peek, 2004); and
Healing rituals that managed a variety of endogenous healing processes, including effects on serotonergic and opioid neurotransmitter systems (also see Winkelman & Baker, 2008).

The worldwide distribution of shamanism derives from human nature and aspects of humans' evolved psychology, particularly the activation of biological processes such as those involved in ASC, as well as innate modules involved in our capacities for inferring the thoughts and desires of others and reasoning about the qualities of the natural world and animal species (Winkelman, 2000, 2002, 2004a; Winkelman & Baker, 2008). Many universal features of shamanism are directly related to utilization of some of these basic evolved features of the innate modules of the human brain. For example, what is called the natural history module, a component of our mental hardware that enables us to understand animal species and their differences, is exploited by shamanism. Shamans take this innate capacity for understanding animals and extends it to produce more complex representations of the self and others. This is manifested in terms of understanding one's own potentials as animal powers and allies, and in totemism, in which animal species provide systems of representation for social groups (e.g., bear clan). Shamans' roles in managing aspects of self and social identity through animal concepts are exemplified in the special relationships shamans have with animal powers and the transformation of identity provided by animal familiars. Shamanic ritual activities engage these innate cognitive processes related to unconscious aspects of self and identity to facilitate social and psychological integration. Shamanic rituals and concepts provided adaptive strategies and technologies for integrating a variety of capacities—biological, social, and cognitive—that contributed to human evolution, adaptation and survival.

THE PSYCHOBIOLOGY OF SHAMANIC ASC

Understanding how shamanistic activities can provide a harm-reduction strategy requires recognition of the fundamental similarities in altered states produced by a variety of processes, ritual and pharmacological. Shamanic ASC

are typically predisposed by fasting, sexual abstinence, and isolation and are induced through singing, chanting, drumming, and dancing. This leads to a phase of collapse and apparent unconsciousness during the shaman's experiential engagement with the spirit world. These ASC central to shamanic training and practice are induced by a variety of procedures that have the same basic overall physiological dynamics—activation of the autonomic nervous system (sympathetic excitation) until exhaustion and collapse (parasympathetic dominance) induces the body's relaxation response (Winkelman, 2000).

ASC also stimulate coherent theta brain waves (three to six cycles per second) that induce synchronization of the brain. These brain wave patterns are produced by discharge activity in the limbic system (the emotional or paleomammalian brain) that activates serotonin linkages with lower brain structures (Mandell, 1980). These discharges generate powerful synchronous brain waves that propagate upward into the frontal cortex, where they replace the normal fast and desynchronized brain wave activity with the coherent slow wave discharges in the alpha and theta range (Mandell, 1980; see Winkelman, 2000, for review). Overall effects of shamanic ASC integrate brain information from the emotional and behavioral brains into the frontal areas of the brain.

The common physiological mechanisms that Mandell (1980) proposes underlie diverse ASC (drug and nondrug) are exemplified in the effects of meditation (Walton & Levitsky, 1994) and psychointegrators (hallucinogens) (Winkelman, 2007a). This high voltage slow wave electroencephalograph (EEG) activity (alpha, theta, and delta, especially three to six cycles per second) is produced by hypersynchronous discharges across the hippocampal-septal-reticular-raphe circuit linking our emotional limbic brain with the so-called reptilian behavioral brain. These lower brain discharge activities spread to the frontal lobes, producing pleasurable sensations and feelings of well-being. These patterns contribute to healing by reducing stress hormone levels and increasing serotonin levels, which play central roles in integration of emotional and motivational processes and the synthesis of information across the functional levels of the brain. ASC integrate information from the lower emotional and behavioral preverbal brain structures into the language-mediated activities of the frontal cortex. Consequently ASC are often experienced as providing enlightenment, a sense of unity, and feelings of connection and personal integration.

Physiological changes associated with ASC facilitate healing and psychological and physiological well-being through: physiological relaxation; facilitating self-regulation of physiological processes; reducing tension, anxiety, and phobic reactions; manipulating psychosomatic effects; accessing unconscious information in visual symbolism and analogical representations; inducing inter-

hemispheric fusion and synchronization; and facilitating cognitive-emotional integration and social bonding and affiliation (Winkelman, 2000).

Social Opioid Mechanisms in Shamanic Practice

While most of the psychobiological research on shamanic ASC has focused on their interactions with the serotonergic system, there is also ample evidence that these practices constructively engage the endogenous opioid mechanisms as well. Shamanistic rituals involve practices that enhance social integration, strengthen group identity, and promote interpersonal and social bonding at physiological and psychosocial levels. A literature review (Frecska & Kulcsar, 1989) indicates that community activities elicit the opioid-attachment mechanisms, with ritual eliciting our innate drives for affiliation and evoking opioid release. Ceremonial opioid release is based in emotionally charged cultural symbols that are cross-conditioned with endocrine systems during early socialization, linking the body's physiological responses with cultural symbol systems. This association of physiology and symbols provides a basis for ritual elicitation of the opioid system through shamanic rituals. Opiate receptor locations and functions in the brain illuminate the adaptive functions of ritual ASC. The opiate receptors are most highly concentrated in the limbic system and mid-brain structures primarily responsible for attachment, motivational and affective behaviors, and our reward centers. It is in this region of the brain that we find the most intensive foci of ASC theta wave activity and the densest concentrations of opioid receptors in the brain. Winkelman (1997, 2000) reviews the physiological aspects of many different shamanic ASC practices, illustrating that they have inherent therapeutic effects related to elicitation of our endogenous opioids. Physical mechanisms for opioid elicitation in shamanistic healing include: extensive drumming, dancing, and clapping; repetitive physical activity; temperature extremes (e.g., sweat lodges); stressors such as fasting, flagellation, and self-inflicted wounds; and nighttime activities when endogenous opioids are naturally highest (see Prince, 1982 and Winkelman 1997, 2000, for reviews).

SOUL LOSS AND SPIRITUALITY IN SHAMANISTIC THERAPEUTIC INTERVENTIONS

Shamanic cultures consider a number of spiritual causes of illness. One cause involves soul loss, which often occurs when an individual experiences a great fright or commits a transgression that causes the soul to leave the body. Diseases may also be caused by a foreign object that has intruded into the body.

Such objects often take the form of magical darts, which may be sent into the body by a malevolent individual (such as a sorcerer) desiring to harm or kill the person. In the ecstatic state, the shaman can see into the body of a sick person, find the disease-causing object, and then remove it.

A major paradigm of shamanic healing is soul recovery, involving reintegration of aspects of the self. Soul loss reflects dissociation from the self, as well as a lack of individual connection with broader social identity. Shamanic conceptualizations of soul loss involve a view similar to AA concepts of addiction as resulting from a lack of spirituality. Spirituality can be seen as reflecting collective dimensions of the individual connectedness with the social group. Soul loss reflects this lack of individual connection with broader social and cultural identity. Since fundamental aspects of shamanic practice are concerned with establishing a connectedness with animal spirits and personal souls and allies, such practices can provide a means for addressing the collective soul loss and lack of spirituality. Spiritual perceptions have a psychobiological basis, reflecting basic structures of the brain and consciousness (Winkelman, 2004b). The spiritual experiences induced by shamanic practices make it a potentially important resource in addressing both psychological integration and incorporation of the spiritual aspects of the self, providing a new sense of identity.

Shamanic rituals heal through recovery of lost aspects of one's soul and by obtaining allies and powers. Power animals and guardian spirits are conceptualized as metaphors that represent different kinds of healing energies (Rioux, 1996), providing an expansion of the Twelve-Step concept of a Higher Power and its healing effects. A number of therapists have illustrated how to introduce shamanic techniques into work with addict populations that are treatment resistant and high recidivist (e.g., see Eshowsky, 1993, 1998, 1999; Rioux, 1996; Winkelman, 2004c). Shamanic practices provide tools for assessing the spiritual dimensions of healing and direct mechanisms for experiencing spiritual contact. Shamanistic practices provide access to the deep structure of the unconscious, where engagement with the spirit world involves access to aspects of the self. These visionary experiences involve the brain's primary processing capacities, symbolic structures of the nonverbal mind and representations of self, emotions, and others (Winkelman, 2000). These experiences provide information from the deep unconscious that helps to meet therapeutic needs for self-awareness, emotional insight, and psychological integration, thereby enhancing therapeutic processes (Rioux, 1996).

The role of spirituality in recovery from substance abuse may reflect a protective factor provided by religious involvement and spiritual engagement (Miller, 1998). Spiritual practices may have role in the healing of addiction by providing a sense of meaning to life often found lacking among substance abus-

ers. Shamanism is the original form of spirituality, providing a direct spiritual awakening, a means for transcendence of personal consciousness, and consequently a mechanism for overcoming addiction.

Rioux (1996) illustrates that shamanic techniques can play a role in a holistic addiction counseling approach that integrates spiritual perspectives into a biopsychosocial approach to healing. Shamanism has exceptional techniques for engaging one in a focus on inner realities to produce self wholeness. Shamanic relations with animal spirits and personal allies can strengthen identity and character formation. Shamanic ASC can help clients achieve wholeness, transforming consciousness by providing a link between inner and outer realities, and enabling inner world perspectives to operate on the outer world to produce harmony and wholeness. Important aspects of the shamanic ASC include the focusing of intention on one's purpose and spending time in relaxed conditions that provide restful healing. ASC practices also free one from ego-bound emotions and provide a balance of conflicting internal energies. Work through dreaming and shamanic journeying can help achieve the sense of wholeness, countering the sense of self-loss at the basis of addictive dynamics. Spiritual relations and experiences can enhance self-esteem by providing connectedness beyond the egoistic self.

Drumming as a Shamanistic Harm-Reduction Strategy

A universal feature of shamanism is percussion, particularly drumming. Researchers (e.g., Blackett & Payne, 2005; Eshowsky, 1993, 1998, 1999; Winkelman, 2003, 2004c) report beneficial effects on addictions from various drumming activities. Winkelman reviews how drumming facilitates management of addictive tendencies through physiological, psychophysiological, psychological, and social effects. Blackett and Payne note therapeutic effects of drumming that have far-reaching implications for a harm-reduction approach. These effects include: reduction of stress; fostering of emotional processing; enhanced immune system responses; enhanced social cohesion; enhanced communication; transcendental spiritual experiences and other beneficial alterations of consciousness; and facilitation of concentration, memory, and other cognitive processes.

Drumming has many effects indicated by clinical studies (see Friedman, 2000, for reviews). Drumming induces the signature brainwaves of ASC, eliciting synchronous responses in the theta and alpha range (see Winkelman, 2000, for reviews). These slow wave discharges synchronize the frontal areas of the brain with ascending waves that integrate nonverbal information from lower brain structures. Enhanced connection with the lower brain integrates its infor-

mation into the frontal cortex, addressing psychodynamic needs of addicts for self-awareness and insight. Effects of drumming on the limbic (emotional) brain often enhance awareness of preconscious material, particularly repressed emotions. Drumming can contribute to an integration of the self and an enhanced sense of connectedness with others, reducing the self-centeredness, isolation, and alienation characteristic of addicts. Among physiological effects of drumming is an increased hypnotic susceptibility, which contributes to relaxation, as well as pleasurable experiences. Other physiological changes associated with ASC-induced healing in general include: facilitating self-regulation through psychosomatic effects that reduce tension, anxiety, and phobic reactions; providing access to unconscious and preconscious material through visual imagery and dreamlike mentation; increasing cognitive integration through inducing interhemispheric fusion and synchronization of the frontal cortex; and integrating information across the brain's neuraxis, contributing to integration of behavioral, emotional, and cognitive dynamics (Winkelman, 2003).

Drumming groups also address dynamics of addiction and support recovery through enhancing social support networks that are particularly relevant for addicts whose social isolation and lack of support are significant in the relapse. Drumming groups enhance a natural sense of connection among participants and emotional bonds important for personal transformation of the addict. Drumming circles also can produce psychobiological effects, as community rituals can evoke physiological responses in the opioid attachment mechanisms (see Frecska & Kulcsar, 1989). Reports from people in rehabilitation programs using drumming suggest drumming induces relaxation responses. The positive effects of group drumming experiences on recovery attested to by people in substance abuse rehabilitation programs provide a compelling rationale for its utilization (see Winkelman, 2003, 2004c). Drumming can provide harm-reduction and therapeutic responses through: induction of relaxation; release of emotional trauma; reintegration of self; and addressing the addict's self-centeredness, isolation, and alienation by creating a sense of connectedness with self and others.

Physiological and Psychosocial Effects of Drumming

Drumming produces physiological, psychological, and social stimulations that enhance recovery processes. Drumming enhances hypnotic susceptibility, increases relaxation, and induces shamanic experiences (Maurer, Kumar, Woodside, & Pekala, 1997). Drumming and other rhythmic auditory stimulation impose a driving pattern on the brain, particularly in the theta and alpha ranges (see Winkelman, 1997, for review). The enhanced theta and alpha wave

entrainment produced by drumming typifies general physiological effects of ASC, (Mandell, 1980; Winkelman, 1997, 2000), including meditation (Walton & Levitsky, 1994). Drumming induces an enhanced awareness of preconscious dynamics, a release of emotional trauma, and reintegration of self. Drumming provides a secular approach to accessing Higher Power yet can apply spiritual perspectives to the psychological and emotional dynamics of addiction. Drumming circles have important roles as complementary addiction therapy, particularly for repeated relapse and where other counseling modalities have failed.

A variety of benefits have been noted from community drumming practices:

Relaxation
Stress-reduction
Enhancement of your brain's pleasure centers
Reestablishment of balance in opioid and serotonergic systems
Alteration of consciousness and meditation
Experiences of transcendence
Greater awareness of your unconscious powers
Connection with your emotions
Reduction of self-centeredness, alienation, and isolation
Emotional insight
Personal and psychological integration
Enhanced self-esteem
Reinforcement and empowerment for personal change
Healing and release of emotional trauma
Forgiveness and release of guilt
Tapping your visionary potential
Obtainment of spiritual guidance
Production of spiritual awareness, experiences, and contact
Increased self-awareness and understanding
Connection with others
Community healing and bonding
Reprogramming the self with spiritual assistance
Making spiritual amends
Spiritual awakening and self-assessment
Spiritual transcendence

TRANSCENDENTAL MEDITATION AS ADDICTION TREATMENT AND HARM REDUCTION

The effectiveness of shamanistic ASC in harm reduction is illustrated in clinical assessments of Transcendental Meditation (TM) (see Gelderloos,

Walton, Orme-Johnson, & Alexander, 1991; O'Connell & Alexander, 1994). A meta-analysis (Alexander, Robinson, & Rainforth, 1994) of 19 studies utilizing TM for the treatment of drug addiction reported an effect size of between .5 (medium) and .8 (large). TM had substantially larger effect sizes than: relaxation, peer pressure resistance, DUI intervention, and combined drug prevention programs. Comparisons with controls illustrate that TM treatment effects are not due to nonspecific aspects (e.g., attention, expectancy, social support, motivation). Alexander et al. (1994) suggest TM's effectiveness in addressing substance abuse derives from effects on physiological through social levels, intervening in a range of causal and contributory factors.

Effects of meditation on addiction have physiological foundations that address anxiety, tension, and stress and imbalances in neurotransmitter systems produced by drugs (Alexander, et. al., 1994). TM reduces stress and physiological arousal, increases serotonin levels, reestablishing psychophysiological equilibrium and changing autonomic responses to stressful stimuli. Walton and Levitsky's (1994) neuroendocrine model of the mechanisms of meditation addresses its effects at the physiological level involving depletion of serotonin by chronic substance abuse. The ability of TM to reduce stress and enhance serotonin functioning addresses the physiological level of addictive behavior and the cycle of addiction—the depletion of serotonin by chronic substance abuse and the interference that it produces in homeostasis and stress responses. Meditation provides a natural process for producing relief from stress, producing physically relaxed states reflected in low levels of autonomic arousal and enhanced EEG coherence. Major areas of the brain at which meditation can intervene in the cycle of drug dependence include the "components of the central nervous system responsible for maintaining homeostasis . . . the hypothalamus, the hippocampus, the locus coeruleus and the raphe nuclei. These areas . . . interface with the endocrine system principally through the hypothalamic-pituitary-adrenocortical (HPA) axis, the sympatico-adrenomedullary axis, and the parasympathetic nervous system" (Walton & Levitsky, 1994, p. 95). Effects of TM in reducing addictive behaviors results from actions on the *locus coeruleus* (LC), producing an increased availability of serotonin that exercises an inhibitory action on the LC similar to sedatives. The effects of meditation in increasing serotonin levels has the consequence of reducing cortisol levels and the release of corticotropin-releasing factor. This results in a reduction of stimulation of anger and fear centers of the limbic brain and their effects on the hypothalamic pituitary adrenal (HPA) axis that contributes to chronic stress. "[B]ecause of serotonin's roles at multiple sites involved in successful interaction with the environment, its decreased availability may be one of the most important neurochemical components in the production of tendencies toward

addiction" (Walton & Levitsky, 1994, p. 110). TM-induced increases in serotonin availability mirror Mandell's (1980) model of serotonergic mechanisms for ASC (transcendent states) in general and suggests their generic role in providing biological mechanisms through which ASC are able to interrupt drug dependence. The overall physiological dynamics of meditation ASC are the same as those associated with other ASC (Mandell, 1980; Winkelman, 2000), suggesting that the effectiveness of meditation in drug rehabilitation would also be obtained from other kinds of naturally induced ASC.

TM addresses psychological factors contributing to addictive tendencies, including low self-esteem, negative affect, impulsiveness and rebelliousness, external locus of control, inadequate coping skills, and distorted and overlearned or stereotypic cognitive response patterns (Alexander, et al., 1994, p. 16). Alexander et al. suggest Vedic psychology provides perspectives from which to appreciate how meditation can provide relief for addicts and substance abusers. These include: producing restful alertness, enhanced mental functioning, pleasant affective experiences, and a sense of intimacy with all of life. Meditation is "a natural way to achieve the experiences substance users are looking for: relief from distress, increased self esteem, enhancement of well-being and self-efficacy, and a sense of personal power and meaning in life" (Gelderloos et al., 1991, p. 317). Meditation counters negative emotions associated with addiction (depression, anxiety, anger), helping to resolve the emotional and interpersonal difficulties that trigger relapse. Meditative practices enhance awareness of deeper levels of the mind and the unconscious, promoting self-actualization, which has an important role in producing spiritual experiences.

CONCLUSIONS

Development of shamanic approaches to harm reduction is strongly justified—even demanded—in light of the consequences of widespread drug addiction and recidivism and limited success rates of current treatment modalities. Shamanistic practices can be applied to recurrent problems encountered in substance abuse rehabilitation to facilitate recovery, reduce recidivism and the harm experienced by addicts, and can be employed proactively to reduce the drive to experience ASC through the harmful avenues of drug addiction.

Alexander et al.'s (1994) review of the roles of TM in addressing addictions suggests that shamanistic approaches in general can address addiction at multiple levels: the physiological aspects of addiction; the cognitive, emotional and psychodynamic aspects; the spiritual dimension associated with core values and a dependence on a Higher Power; and the social environment, particularly the proximal social relations affecting substance abuse. Research shows that TM

provides an effective antidote to the addict's poor coping abilities and problems with interpersonal stressors and mental anxiety. Alexander et al. (1994) expand on the perspective that addictive behaviors derive from spiritual problems, suggesting that so-called loss of soul contributes to addictive behaviors. This concept of soul may be viewed as a subtle aspect of one's existence and personal substance involving connectedness with others. Alexander et al. suggest that spiritual wellbeing derives from healthy functioning at all levels of the individuals—"body, mind, spirit, social interaction and environment" (Alexander et al., 1994, p. 18). The shamanic healing practices are renowned for such effects across the multiple dimension of being.

Winkelman (2001a, 2001b, 2003, 2004c; also see Winkelman and Roberts 2007) outlines a variety of ways in which the shamanic paradigm and ASC can be applied to substance abuse rehabilitation. Drumming circles and other shamanic ASC activities can address multiple needs of addicted populations through:

The physiological effects that induce natural ASC characterized by enhanced theta wave entrainment, a natural method for altering consciousness that addresses the psychobiological needs for pleasure, balance, and integration that drive addictive behaviors;

Inducing the relaxation response and restoring balance in the neurotransmitter systems disturbed by drug abuse;

Meeting psychodynamic needs for self-awareness, insight, emotional healing, and psychological integration;

The support group that can meet social needs for an intimate community for affiliation, interpersonal support, and connectedness with others and interpersonal support;

The psychological and emotional effects of the shamanic journey that meets psychodynamic needs for spiritual contact and personal relationships with a power beyond ourselves; and

opportunities for emotional insight, self-awareness, psychological integration, and therapeutic processes acquired through accessing deep levels of the unconscious.

An evolutionary perspective on substance abuse suggests an understanding in which humans evolved addictive potentials for adaptive reasons that may be explained by the dopamine hypothesis, which postulates their role in producing feelings of well-being. Since ASC reflect underlying psychobiological structures and innate needs, when societies fail to provide legitimate procedures for accessing these conditions, they are sought through other means. Because contemporary Indo-European societies lack mainstream legitimate institution-

alized procedures for accessing ASC, they tend to be sought and utilized in deleterious and self-destructive patterns—alcoholism, tobacco abuse, and illicit substance dependence

The shamanic approach supports the harm-reduction principles of alternatives to abstinence with natural and nonaddictive ways of meeting human needs to experience transcendent states of consciousness. It engages the client's desires for transformations of consciousness and constructive avenues of change with powerful tools that access deep levels of the self and unconscious. Shamanic procedures have the potential to help the client access deep levels of personal history that have contributed to addictive behaviors. They also provide visionary experiences that reveal the problematic aspects of substance abuse and help envision new goals and alternate futures instead of waiting until drug problems lead to hitting the bottom.

Chapter **14**

Therapeutic Approaches, Beliefs, and Perceptions of Providers When Treating Alcohol- or Drug-Using Clients: Selecting Best Practices

Maria Dinis, PhD, MSW, Joseph R. Merighi, PhD, MSW, and Kelly Anders, MAL

How do providers select therapeutic approaches when they treat clients with alcohol or drug problems? When clinicians make treatment decisions, they may utilize empirically validated interventions or models, have knowledge of specific treatment outcomes, or incorporate their own belief systems to inform their treatment choice. At the same time, they may be limited to services available in their geographic region or by requirements imposed by insurers or funders. The interplay of treatment approaches, outcomes, provider beliefs, availability of services, and funding is central to a provider's selection of a best practice approach when treating people with substance abuse problems.

PRINCIPLES OF ADDICTION TREATMENT

The 13 principles of effective addiction treatment set forth by the National Institute on Drug Abuse (1999) specify a road map for providers to use when working with chemically addicted persons. These principles are: (1) having providers match treatment settings, interventions, and services to the needs of their clients because there is not one single treatment that is suitable for everyone; (2) having treatment available when individuals are ready to receive it; (3) having treatment address the range of needs of an individual beyond his drug use; (4) having the treatment and service plan assessed and modified as the individual's needs change; (5) having individuals remain in treatment for an appropriate amount of time (usually up to three months) to achieve treatment effectiveness; (6) having individual or group counseling to assist

with motivation concerns, develop skills and problem-solving techniques to resist using drugs, and use other behavioral therapies to improve functioning with personal, family, and community relationships; (7) having individuals use medications to reduce craving or treat mental health disorders in combination with other counseling and behavioral therapies; (8) having individuals with co-occurring substance and mental health disorders assessed and treated for both conditions; (9) having medical detoxification as only the first stage to address acute physical symptoms such as withdrawal prior to clients participating in a longer term addiction treatment program; (10) having involuntary treatment coerced by the family, employer, or criminal justice system, which can be effective because sanctions can increase the rates of entering and staying in treatment as well as drug treatment intervention success; (11) having individuals monitored during drug treatment (e.g., urinalysis) to detect their current drug use so that treatment plans can be adjusted accordingly and clients can be provided with important feedback; (12) having individuals assessed in treatment programs for many types of infectious diseases (e.g., HIV/AIDS, hepatitis B and C, and tuberculosis) and provide counseling to assist clients with behavior modification of high-risk behaviors and assist those already infected to manage their own illness; and (13) having multiple treatments available for persons who relapse, and participating in self-help programs during and after treatment to maintain abstinence and rebuild personal functioning.

Whether providers take account of the aforementioned principles—which are considered the gold standard of effective addiction treatment as set forth by the National Institute on Drug Abuse (1999)—when they make their selection of treatment approaches and services for chemically addicted clients is not easy to discern. Providers selecting best practices to treat alcohol or drug-using clients may depend on a combination of factors related to treatment approaches, belief systems, and availability of services. In other words, the selection of best practices is likely to encompass the cumulative knowledge providers have of treatment models and outcomes; their beliefs of what treatment approach works best; and the availability of services in the client's geographic region.

MODELS OF ALCOHOL/DRUG TREATMENT

Alcohol or drug treatment models to which service providers subscribe or to which they refer clients (e.g., moral/prevention, medical/disease, psychological, sociocultural, and integrative/biopsychosocial) are widely described in the literature and are often referred to as a treatment philosophy or orientation (Institute of Medicine, 1990; Miller & Hester, 1989, 2003; Peterson, Nisenholz, & Robinson, 2003). These models embrace a range of services (e.g.,

medical, counseling, psychiatric, or social services) and methods (e.g., pharmacotherapy, psychotherapy, or self-help groups) to achieve the overall treatment goal of harm reduction or abstinence from alcohol or drug use. Treatment models contain a perspective or orientation toward the etiology of alcohol or drug problems, and thus specify the method of intervention (Institute of Medicine, 1990). While the term *treatment approach* is used to refer to a kind of model, treatment approaches also encompass treatment systems that may utilize various models. With respect to definitions, treatment systems are also called treatment settings because they describe the living arrangement or institutional milieu in which treatment takes place (e.g., inpatient, outpatient, hospital, prison, residential facility, day treatment center, and halfway house) (Institute of Medicine, 1990; Musto, 2002; White, 1998). The term *medical* refers to approaches that are physician driven and "pertaining to medicine or to the treatment of diseases" (Saunders, 1988, p. 992). In contrast, the term *disease* is taken to mean a lack of individual-level ability to control drinking, which eventually causes physical, emotional, or social harm (Alexander, 1987; Jellinek, 1960).

Given that alcohol and drug use may be seen as a crime, illness, way of life, or deviant behavior (Siegler & Osmond, 1968), professionals across disciplines and in different work settings may have differing views on alcohol misuse and treatment. Their views may also be applied differently depending on the population that is misusing alcohol. For example, pregnant women who misuse alcohol and drugs have been offered drug treatment and, in some cases, have been prosecuted criminally (i.e., charged with child neglect and/or losing custody of their children) (Chavkin, 1990). However, these sanctions have not applied to fathers. Part of this confusion may be related to the disagreement among obstetricians and their staff about the use of alcohol or drugs during pregnancy. Some providers believe that pregnant women should abstain from alcohol during pregnancy while others promote moderate drinking; others screen pregnant women, not as a way to prevent future alcohol/drug-related problems, but to establish the need for substance abuse treatment (Kennedy, Finkelstein, Hutchins, & Mahoney, 2004; Morse, Greshan, & Hutchins, 1997; Roche & Richard, 1991).

Because service providers maintain different attitudes about optimal choices for substance use treatment, professionals across disciplines may also subscribe to different models when addressing these problems. Professionals such as physicians, ministers, psychotherapists, and police officers may use diverse definitions and criteria for alcohol addiction. The guidelines physicians use to determine whether alcoholism is a disease are not necessarily the same guidelines that ministers use to determine if alcoholism is a sin, or psychotherapists

use to define it as a neurotic problem. Within different disciplines or professions, there are different theories that define alcohol addiction. There is no obvious way to compare these theories, however, because they are different across and within disciplinary lines.

While models are not theories, they can be used to classify theories (Nunes-Dinis, 1996; Siegler & Osmond, 1968; Siegler, Osmond, & Newell, 1968). In general, models are constructed from the theoretical dimensions (i.e., diagnosis, etiology, prognosis, treatment, etc.) of various professional disciplines (Institute of Medicine, 1990; Siegler & Osmond, 1968), and they can be used to inform the treatment of substance use problems. Although earlier writers focused exclusively on alcohol, the current conceptualization of overlapping alcohol and drug problems has resulted in the use of these models for alcohol and drugs interchangeably (Hubbard, 1990).

Treatment models can be classified under five major categories or perspectives: moral/prevention, medical/disease, psychological, sociocultural, and integrative/biopsychosocial (Miller & Hester, 2003; Nunes-Dinis, 1996; Peterson et al., 2003). Although there are contemporary prevention models premised on moral, ethical, and value-based ideologies of health to prevent alcohol problems, the broad public health model emphasizes the interaction of factors (e.g., individual, environment, and agent-based) and encompasses primary (prevention), secondary (early detection), and tertiary (treatment) intervention and preventive approaches (Bukoski, 1991; Institute of Medicine, 1989; Johnson, 2004; Leukefeld & Bukoski, 1991; Miller & Hester, 2003; Wallack, 1984).

The terms *medical* or *disease model* are used synonymously in the literature (Miller & Hester, 2003; Miller & Kurtz, 1994; Peterson et al., 2003). The medical model, which is physician driven, is perhaps the dominant model among providers to treat those with alcohol and drug problems (Brower, Blow, & Beresford, 1989; Keller, 1990; Leonelli, 1993; Miller & Hester, 2003). In accord with this model, medical treatments (e.g., detoxification as the standard first stage regimen) and pharmacotherapy (e.g., disulfiram for alcohol users, naltrexone for drug users, and tricyclic antidepressants for alcohol and/or drug users) are often used to reduce craving, change behavior, and diminish anxiety and depression (McNeece & DiNitto, 2005; Torrens, Fonseca, Mateu, & Farre, 2005).

Psychological models, and especially psychotherapeutic methods, are nonpharmacological approaches utilized in alcohol and drug treatment. These treatment approaches, which are under the auspices of mental health professionals, focus on individual or family change and consist of long-term psychotherapy (individual, group, or combination) (Institute of Medicine, 1990; Kissin, 1977; Lindstrom, 1992; Miller & Hester, 2003). Psychological models may include

such approaches as motivational, social learning (behavioral model), stages of changes (transtheoretical model), family therapy, and brief interventions (DiClemente, 2003; Johnson, 2004; McNeece & DiNitto, 2005; Miller & Hester, 2003; Peterson et al., 2003; Prochaska & DiClemente, 1992).

In the sociocultural models, the treatment foci are on both the person and the social and physical environments, employing a variety of techniques such as environmental and social restructuring (e.g., changing the person's drinking behavior by creating new social relationships), changing the social environment by providing alternative living arrangements (such as a halfway house), or involvement with self-help groups (like Alcoholic Anonymous [AA] or other mutual self-help groups) (Institute of Medicine, 1990; Lindstrom, 1992; McNeece & DiNitto, 2005; Miller & Hester, 2003; Peterson et al., 2003).

Finally, integrative/biopsychosocial models strive to address alcohol/drug problems on various levels, that is, physiological, psychological, or sociological. An example is dual diagnosis, which integrates the self-medication and medical (disease) models to treat both depression and chemical dependency (Brower et al., 1989). The Minnesota model also has been seen by proponents as integrating alcohol/drug problems at these various levels (Anderson, 1981; Johnson, 2004; Laundergan, 1982; Peterson et al., 2003; Spicer, 1994). Curiously, this approach is regarded as limiting because it includes everything in the diagnosis and treatment at all levels, which then may be excessive (Oakley & Ksir, 1999; Peterson et al., 2003).

Summary of Model Elements

A summary of key model elements, including strengths and weaknesses of each, is included (Table 14.1). In examining the relative advantages and disadvantages of a given approach toward substance abuse treatment, the evolutionary and profession-driven manner in which treatment models have arisen is highlighted. One model's weakness will be addressed strongly in a second model, but in so doing the latter model suffers by taking a less thorough tact on a key treatment component of the former. For instance, a strength of the psychological models lies in their focus on the resolution of individual personality conflicts, a dimension addressed inadequately by sociocultural models, which instead stress social and physical environments (at the expense of handling individual psychological issues thoroughly). Similarly, a major weakness of the psychological models is their tendency to blame the victim; this consideration becomes a strength with the moral and sociocultural models, in which users are held responsible for solutions (but are not blamed for having the problem in the first place). In addition, sociocultural models have a tendency to blame

Table 14.1
Summary of Model Elements

Model	Strength	Weakness	Treatment goal	Type of staff
Moral/prevention	User is responsible	Punitive	Increase willpower, promote moderate drinking	Clergy, law enforcement, public health workers
Medical/disease	Blame the disease not the person	Focus on the biological	Abstinence, methadone, maintenance, and medications	Physicians, nurses, counselors
Psychological	Resolving personality conflicts	Blaming the victim	Improve psychological health and self-control through learning new behaviors	Mental health professionals (psychologists and therapists)
Sociocultural	Focus on individual, family, social, and physical environment	Blaming others and not taking responsibility for solutions	Improve individual and social functioning by changing coping responses of users and environments	Recovery persons, counselors, social workers
Integrative/biopsychosocial	Addresses biological, psychological, and social factors of the client	Lack of resources	Assist users with personality restructuring and change social conditions	Physicians, nurses, psychotherapists, social workers, counselors, recovery persons

others for the problems, while psychological models address problems by striving to resolve some personality-related issues. Finally, although both sociocultural and integrative models recognize the contribution of social and physical environments in developing and sustaining alcohol/drug problems, political and economic constraints generally result in a situation in which accountability for solution-finding still sits at the individual level. In fact, a lack of resources (a good example being the lack of treatment slots for pregnant women with children) is a key weakness of integrative models; and under these circumstances, holding alcohol/drug users responsible for solutions seems quite untenable. In effect, these treatment models at best can be used to treat only some individuals and families, even though their elasticity ranges from simply treating the individual to addressing the social and physical environments as well. It is also

possible that, should a combination of models be used simultaneously in treatment programs, the strengths and weaknesses of the models could be in fundamental conflict with or cancel each other out so much that very little would be left to utilize, and mixed treatment messages could potentially be puzzling for both clients and providers. For example, holding users responsible in the moral model is in fundamental conflict with the disease model's focus on causes outside an individual's control (Nunes-Dinis, 1996).

WHAT MODELS DO SERVICE PROVIDERS CHOOSE?

Models of alcohol and drug addiction, and their treatment, have been constructed from theoretical dimensions of various professional disciplines, but in practice the use of a given treatment does not necessarily follow a provider's professional orientation. The relationship between treatment model application and provider discipline is an understudied area. Generally, studies instead present professionals' views on the disease concept and opinions about their primary treatment goal; few have considered the providers' choice of alcohol and drug treatment models or approaches. However, there are many studies that examine staff or provider beliefs about addiction treatment and their subsequent selection of treatment models and approaches.

Staff or Provider Beliefs about Addiction Treatment

While there are significant limitations with regard to previous studies' validity (Nunes-Dinis, 1996), scholars generally agree that beliefs congruent with the medical/disease model or with assumptions that hold alcoholics as responsible for their disease are common among a variety of medical and mental health professions (Kahle & White, 1991; Mackinem & Higgins, 2007; Miller & Frances, 1986; Ogborne, Rush, & Ekdahl, 1986; Palm, 2006; Schwartz & Taylor, 1989; Weisner, 1981).

In terms of providers' views toward the goal of treatment, almost without exception, the medical and mental health professionals support complete abstinence (Kahle & White, 1991; Lee, 1983; Miller & Frances, 1986; Schwartz & Taylor, 1989). Endorsement is not quite as universal among alcohol treatment agencies (outpatient, inpatient or mixed, halfway houses, and prevention/education), although abstinence as a treatment goal was endorsed by over three-quarters of the respondents in another study (Rosenberg & Davis, 1994). Turning to differences based on whether an agency offers services only for alcoholism or offers more general social services, Weisner (1981) found that providers in alcohol-specific agencies endorse abstinence, while those in non-

alcohol-specific agencies were more likely to recognize and treat the underlying disorders (psychological and sociological) that providers in those agencies believed cause the alcohol problem. However, changes in the nature of alcohol treatment service delivery in both public and private sectors (with many agencies now delivering combined alcohol and drug treatment services) may affect contemporary providers' views of treatment goals. In addition, there has been a decrease in public sector programs, which may further modify the treatment goals across agencies.

Previous studies, using a variety of sample frames, have found some differences in choice of treatment approach according to providers' particular profession (Cutler & Storm, 1973; Knox, 1973; Lee, 1983; Miller & Frances, 1986; Morgenstern & McCrady, 1992; Rosenberg & Davis, 1994; Weisner, 1981). For instance, Lee (1983) found that psychologists were more likely than psychiatrists and paraprofessionals to support the behavioral model, while psychiatrists (also Miller & Frances, 1986) and paraprofessionals supported the disease model; doctoral-level experts were more likely to choose both behavioral and disease models (as advocated by AA) (Morgenstern & McCrady, 1992); and AA was the preferred approach among staff at alcohol treatment programs (Rosenberg & Davis, 1994). Humphreys, Noke, and Moos (1996) noted that staff members in recovery did not necessarily endorse the disease and psychosocial (learned behavior) models but an eclectic approach to treat substance abuse problems.

These studies carry with them a number of limitations. Some do not identify the treatment model or do not control for variables that may explain model choice; others have low response rates or are otherwise difficult to generalize; and most fail to explain why some modalities are used more often than others. However, without controlling for professional training or background, beliefs, as well as other variables such as number of years in practice or type of work setting, it is difficult to ascertain the reasons for, or the meaning of, these findings. For example, psychologists may support the behavioral model and controlled drinking more than psychiatrists do because they work more with outpatient rather than residential or hospital clients. Alcohol counselors may support the disease model and abstinence because most are themselves recovering persons in AA and strongly endorse the AA approach. Non-alcohol-specific agencies may adhere to a variety of models but give preference to the psychological, reflecting their professional background training in a way that is not as evident in alcohol-specific agencies (which may not have resources to train their staff on other models).

Further, Knox's (1973) findings in the Veterans Administration (VA) regarding the dominance of AA in that system are important, but it is difficult

to generalize from social workers working in the VA to others in a different work setting. Knox's (1973) study neither explains the effect of working for VA nor does it compare the results with social workers working in other settings. It is probable that the alternatives available to social workers working with alcoholics in the VA are quite different than the options other social workers have when working in a different setting (e.g., probation, jail, mental health agencies, clinics, or community organizations).

More recently, Willengring et al. (2004) reporting on the beliefs about evidence-based practices among providers (physicians, social workers, psychiatric staff, nurses, and addiction counselors) in the VA program, noted that 93 percent of the respondents in that system routinely recommend integrated treatment of psychiatric disorders and cognitive behavioral relapse prevention whereas over half (55%) do not recommend verbal confrontation. A third of these VA providers also did not recommend disulfiram to treat alcohol dependence, nor did they know whether to recommend a methadone dose of equal to or greater than 60 mg/day. It is relevant to note that more than 85 percent of the programs were outpatient and continuing care, with 64 percent of the patients receiving self-help groups, less than 30 percent participating in psychotherapy, and 73 percent receiving urine toxicology screening. The main barriers perceived by the VA providers to implement evidence-based practices in addiction treatment were lack of administrative support (50%), insufficient staff time (49%), and lack of skills or knowledge (38%).

As a final example from previous studies, the finding that self-help groups are used more frequently among psychiatrists (Miller & Frances, 1986) may reflect psychiatrists' belief that such groups are very effective, or it may simply be a pragmatic approach to serving a poor population who cannot afford other types of treatment. Of note in that study is the finding that about three-quarters of the staff respondents indicated that life events and practical experiences were the major reasons they became interested in alcohol and drug dependency, demonstrating potential confounders that make it difficult to explain modality or concept choice among providers in these studies.

More recent studies have also examined counselor treatment philosophies. Thombs and Osborn (2001) found that client-directed counselors who thought the causes of addiction were unique to each individual client were more likely to be white and have more advanced professional certification and educational degrees compared to counselors who endorsed a mix of psychological and disease factors involved in causing addiction. The study conducted by Moyers and Miller (1993) on the philosophical perspectives of alcoholism counselors found that therapists in recovery were more likely to support the disease model of addiction and those with higher educational levels adhered

to a belief of multiple causes for addiction. Taxman, Simpson, and Piquero (2002) examined the relationship between perspectives on the causes of drug abuse and endorsing a particular treatment technique. They found that the social learning perspective was supported the most, followed by social control and labeling perspectives; however, their interventions were not necessarily consistent with these approaches. Instead, the counselors endorsed sociological theories of social control, social learning, and strain for treatment interventions. Then, Taxman and Bouffard (2003) conducted another study on the perceptions of the causes and interventions by counselors on services delivered to offenders in drug court programs. Although counselors support a number of different causes of substance abuse (disease model, cognitive behavioral deficits, psychopathic personality traits and antisocial values, and social learning and social control issues), they tend to attribute the cause of substance abuse within the individual personality or their experiences compared to societal-level influences or even moral failings. While the counselors support a number of different causes of substance abuse, they do not endorse a single treatment approach. Instead, they adhered to the use of eclectic models (cognitive-behavioral strategies, education and aftercare, environmental safety [psychological and physical] and self-exploration, and self-help or peer support therapeutic community) that they believe were effective to treat clients. These results show that counselors do not have a preference for the types of components they believe are effective, and the knowledge and beliefs they have are not necessarily translated into their choices for treatments. Throughout the literature, we have often found that a provider's beliefs and subsequent choice of treatment model are often inconsistent—they believe in one perspective of causation for addiction and yet select other type of approach to treat the addiction (Kahle & White, 1991; Knox, 1969, 1971, 1973; Taxman & Bouffard, 2003; Taxman et al., 2002; Wechsler & Rohman, 1982). Consequently, mixed messages are likely to be delivered to clients between the belief systems providers hold and their subsequent selection of eclectic evidence-based treatment approaches, which may affect long-term success of different treatment interventions. The lack of knowledge about selecting every evidence-based practice approach may translate into delivering very little, especially in short treatment sessions with limited focus and brief discussions on topics. This may result in treatment programs lacking clearly defined goals and objectives and the need to focus on skill development for counselors (Taxman & Bouffard, 2003).

There is a need to understand provider's treatment philosophies to gauge how they adopt and use evidence-based practices to deliver services. A series of studies has shown providers select treatment approaches differently across settings, job categories, and levels of education (Ball et al., 2006; Forman, Bovasso,

& Woody, 2001). Forman et al. (2001) surveyed staff members (i.e., counselors, physicians, nurses, social workers, case managers, and assistants) on their beliefs about addiction treatment. The 18-item survey was on beliefs about addiction treatment modalities. The staff was from the Delaware Valley Clinical Trial Network with treatment settings in Pennsylvania, New Jersey, and Delaware. These treatment settings had been in operation at least 10 years within the network. The following were the types of treatment settings and their distribution in the study: hospital-based inpatient detoxification and rehabilitation programs (10%); non-hospital-based detoxification and rehabilitation centers (16%); outpatient and intensive outpatient drug-free clinics (40%); methadone maintenance clinics (10%); and freestanding recovery houses (24%). The primary demographic characteristics of the staff were: education level (master's level [30%], bachelor's level [17%], and MD/PhD level [11%]); major job category (42% were counselors/therapists); and experience (28% of the staff had 11 or more years of work experience in the addiction field). Gender of the staff was not reported.

Although only 57 percent of the 317 staff completed the survey, more than 75 percent of the respondents endorsed items such as innovation (new approaches should be used more . . .), Twelve-Step/traditional treatment (addiction is really a disease, Twelve-Step programs and recovery houses should be used more . . .), and spirituality (spirituality should be emphasized more . . .) (Forman et al., 2001). There were differences of opinion found between staff members for various policies: (1) the policy to discharge noncompliant patients (36% in favor versus 40% in disagreement); (2) the use of medications (38% supported increased use versus 12%, and 46% who were specifically unsure about the role of naltrexone); (3) more staff (40%) opposed than supported (33%) using methadone maintenance; and (4) over half of the staff (52%) supported the increased use of psychiatric medications, while 20 percent did not. Nearly half of the staff (46%) believed that confrontational techniques should be used more often with clients, which is a strategy not recommended by the research community. This support was found among those with the least formal education. Those working in methadone maintenance clinics (89%) supported this approach as compared to only 20 percent of the staff working in drug-free clinics. Regardless of treatment setting, registered nurses and case managers were the most likely to disagree with increasing the use of methadone maintenance, and they were also the staff most involved with operating these clinics; physicians, in comparison, were in favor of increasing the use of methadone maintenance (Forman et al., 2001).

In another study, Ball et al. (2006) surveyed 66 clinicians from 11 community treatment programs who were mainly white (77%), female (65%),

highly educated (52% had a master's degree, and another 18% had a bachelor's degree); half of them had certification/licensure in drug/alcohol and 21 percent in social work, and they had an average of 7.1 years of counseling experience. In the clinician and supervisor survey, the clinicians rated the following theoretical orientations or techniques from *most* to *least* used in their practice: (1) relapse prevention/cognitive-behavioral; (2) Twelve-Step/disease concept; (3) Rogerian/client-centered; (4) reality therapy; (5) motivational interviewing; (6) psychodynamic/interpersonal; and (7) gestalt/experiential. But when they rated a client they had seen in the last six months, clinicians scored highest using the motivational enhancement therapy/motivational interviewing (MET/MI) approach. Clinician beliefs differed across gender and education. Female clinicians were less likely than males to view effective counseling as advice, guidance, suggestions, and reaching resistant clients. More males than females adhered to a cognitive-behavioral/relapse prevention approach. Those with a master's degree were more likely than others with lower levels of education to select a psychodynamic orientation and were less likely to adhere to the Twelve-Step/disease concept. As it might be expected, clinicians who self-identified to be in recovery themselves, compared to all others, reported a stronger allegiance to the Twelve-Step/disease concept and endorsed the importance of the abstinence goal. The counselors with a master's level of education selected more psychodynamic approaches in treating their clients, and recovering counselors incorporated more of the Twelve-Step principles.

In another study, Knudsen, Ducharme, Roman, and Link (2005) also found that counselors without a master's degree and those who adhered to a Twelve-Step treatment philosophy were less likely to accept and perceive the effectiveness of the buprenorphine medication to treat opiate addiction. A similar finding was noted by McGovern, Fox, Xie, and Drake (2004) that clinicians who endorsed a Twelve-Step model were less likely to adopt addiction medications. Similarly, Thomas, Wallack, Lee, McCarty, and Swift (2003) found that only 15 percent of physicians and 5 percent of nonphysicians report prescribing or recommending naltrexone medication often to treat alcoholism even though they scored high in the importance medications plays on the role of treating alcohol abuse. Those clinicians who recommend naltrexone believed the medication is effective while others do not. The barriers to adopt naltrexone that clinicians reported were: high cost, lack of knowledge about the medication, and insufficient evidence on its effectiveness. Clinicians who endorsed a Twelve-Step model were less likely to adopt addiction medications.

Additionally, disseminating empirically supported therapies through manual-guided approaches that emphasize best practice guidelines for treatment programs to utilize is regarded as being crucial to address the changes in health

care policy because of the need to improve standardized treatment procedures, cost-effectiveness, and outcome (Ball et al., 2006; Morgenstern, Morgan, McCrady, Keller, & Carroll, 2001). Distributing manual-guided therapies to providers is an important step to bridge the gap in the technology transfer process between researchers and practitioners; however, the infiltration of treatment manuals into standard clinical practice remains sparse because clinicians feel that structured manuals restrict their ability to respond to the individual needs of their clients (Ball et al., 2006). The gap between research and practice is considered wider in the addiction field than others because of the differences between the training, professional identification, and treatment philosophy or orientation of the researchers and practitioners. This gap may influence the success of one approach over another to transfer the technology and knowledge between researchers and practitioners. Matching types of training to types of clinicians may be a necessary procedure to ensure the success of a particular evidence-based intervention to use with alcohol/drug clients (Ball et al., 2006; Morgenstern et al., 2001).

Finally, Forman et al. (2002) surveyed 10 community-based addiction treatment organizations from the National Drug Abuse Clinical Trials Network, whose staff participated in an educational session about research practices and human subject protections. Pre- and postsession surveys were completed by 119 respondents: 13 clinical supervisors, 52 counselors, 15 case managers, 18 administrators, and 21 others, that is, psychiatry ($n = 1$), nursing ($n = 4$), social work ($n = 7$), clerical ($n = 6$), and other unidentified categories ($n = 3$). Prior to the educational session, 44 percent of the participants believed that clients could participate in clinical trials without understanding what would happen during the course of the study, 30 percent agreed that clients should be required to stay in a study even if they were doing poorly, and 55 percent believed clinicians had a right to transfer clients that were doing poorly in a clinical trial. After the educational session, 76 percent of the staff believed that clients participating in clinical trials had to be completely informed but almost one-quarter of them did not believe the right of informed consent would be protected in clinical trials. More than half (52%) of the staff believed that patients doing poorly could transfer out of a study. Seventy percent of the staff believed they had a right to transfer clients out of clinical trials. Even after the educational session, one-fourth of the staff believed that paying clients to participate in clinical trials could undermine their recovery, and only 29 percent of the staff agreed that clients' chances for recovery were improved by participating in a clinical trial. This study suggests that providers do not adequately recognize human subject protections built into clinical trials, the importance of informed consent, or even the relevance of their clients participating in a

clinical trial to improve their recovery—another gap that may widen and place a strain between researchers and practitioners. Similarly, Knudsen, Ducharme, Roman, and Link (2007), using data from the National Institute on Drug Abuse's Clinical Trials Network, reported a higher counselor turnover intention when they perceived that their job demands had increased due to research being conducted in community-based treatment organizations. This relationship was significantly lower if the treatment counselors perceived the research activities to result in improvements for clients and the organization.

PUBLIC TREATMENT AVAILABILITY

Regardless of how providers select treatment models/approaches or even the interplay of their belief systems and subsequent choices for treatment options, the availability of public treatment programs has been affected by a recognition of alcohol/drug abuse being considered a public health and safety problem as well as the changes in the management of health care during the 1990s (McLellan, Carise, & Kleber, 2003). By 2001, 55 percent of all clients referred to substance abuse treatment were from the criminal justice system, while the welfare system referred an additional 10 percent, and mental health and health clinics referred between 10 and 15 percent more individuals (*Drug Abuse Services Information System*, 2001). Referrals for clients who were coerced from these systems required professionals with extensive experience and a variety of medical and social service options generally not available in many of the treatment centers (Belenko, 1998; McLellan et al., 2003; Woolis, 1998). In the case of the managed health care system, by 2002, less than 10 percent of all treatment programs were residential or inpatient hospital, 12 percent were methadone maintenance programs, and 78 percent were abstinence-oriented outpatient programs (*National Survey of Substance Abuse Treatment Services*, 2001).

McLellan et al. (2003) interviewed the directors and staff from a representative sample of 175 alcohol/drug treatment programs. They found that less than half of the programs had a full-time physician or nurse on staff, and social workers or psychologists were rare in the treatment programs. Abstinence-oriented group counseling was the most common approach used by the staff to treat persons with alcohol/drug problems. Admission intake procedures ranged from two to four hours to collect data and fulfill the reporting requirements of managed care organizations and those of city, state, and federal agencies; these paperwork procedures were neither useful for clinical decision-making nor for program planning. Very few programs had a clinical information system to conduct or monitor care.

In recent years, there has been a development of effective medications and various forms of individual therapies that require trained clinical personnel and information management systems currently not available in most public treatment programs (McLellan et al., 2003; McLellan, O'Brien, Lewis, & Kleber, 2000; O'Brien, 1996). However, the pay is too low to attract high-level professional staff, staff turnover is high, closure and administrative reorganization of treatment programs is common, there is a lack of insurance or Medicaid reimbursement, and the technical infrastructure of programs is not funded adequately in order to operate clinics. Financial and technical investment is necessary to improve the regulating, monitoring, and credentialing of the public treatment system as well as provide incentives to raise the quality of those programs and attract excellent personnel (Appel, Ellison, Jansky, & Oldak, 2004; McLellan et al., 2003; Powell, 2006).

CONCLUSION

In sum, having treatment models or best-practices approaches for providers to select or treatment services for them to refer clients is only relevant if the programs exist in the first place. As McLellan et al. (2003) reported, 15 percent of the public facilities either closed or had stopped providing substance abuse treatment, and another 29 percent had been reorganized under a different administrative structure (i.e., mental health or another agency). This implies that what national treatment experts may consider state-of-the-art treatment will be scarce for the majority of public clients and only accessible to people who can afford to pay privately. The treatment-client community as a whole may not adequately benefit from the evidence-based knowledge professionals are currently developing or the gains made in substance abuse treatment strategies, including medications, until the treatment infrastructure is supported and the public demands quality of treatment care in the same way that it recognized that alcohol/drug abuse was associated with public health and safety problems. Funding public treatment programs sufficiently is a necessary step to address current infrastructure weaknesses and support our own acknowledgment that public health and safety problems are important concerns in society that need our attention and vital resources to maintain and utilize evidence-based practices in the treatment of addictions.

Chapter **15**

Brief Telephone-Based Interventions for Clients with Alcohol and Other Drug Abuse Problems

Thomas Beers, PhD, Melinda Hohman, PhD, Katharine Slack, MSW, Daniela Sisneros, MSW, and Susan I. Woodruff, PhD

Alcohol and other drug (AOD) abuse and dependency continue to be major problems in the United States as they contribute to elevated health risks related to cardiovascular disease, stroke, pancreatitis, cirrhosis, and various types of cancer (Li, Hewitt, & Grant, 2007). Other problems associated with AOD abuse and dependency include violence, family dysfunction, poverty, poor work performance, and criminal behavior (Compton, Thomas, Stinson, & Grant, 2007).

AOD abuse and dependency are often combined together when studying problems, issues, and rates but are usually defined as distinct categories for intervention or treatment purposes. The *Diagnostic and Statistical Manual-IV-TR* defines AOD abuse as "maladaptive patterns of substance use [or alcohol use] leading to clinically significant impairment or distress . . . it is manifested by one or more of the following symptoms: (1) recurrent use [or drinking] resulting in failure to fulfill major role obligations at work, school, or home; (2) Recurrent use [or drinking] in situations in which it is physically hazardous; (3) Recurrent substance- [or alcohol] related legal problems; or (4) Continued substance [or alcohol use] despite persistent or recurrent social or inter-personal problems or exacerbated by the effects of alcohol" (American Psychiatric Association [APA], 2000, pp. 198-199, 214). AOD dependence is similar to abuse except that that the definition adds tolerance, withdrawal effects, and drinking (or using drugs) in larger amounts or over a longer time than was intended (APA, 2000). There are some who question these as distinct categories and propose that alcohol use disorders fall more along a continuum,

where the various criteria could fall in different places than those proposed by the *DSM-IV-TR* (Helzer, Bucholz, & Gossop, 2007; Saha, Stinson, & Grant, 2007). Also, quantifying the amount ingested at one sitting may be relevant for diagnosis. For instance, alcohol abuse has been defined as a pattern of drinking that brings the blood alcohol level (BAL) to .08 or above, which is typically five drinks for men and four for women (Li et al., 2007; Saha et al., 2007).

In 2001–2002, the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC) (N = 43,093) found that 65 percent of those surveyed over the age of 18 drank alcohol; alcohol abuse (meeting *DSM-IV* diagnostic criteria) over the past year was 6.93 percent of males and 2.55 percent of females, and drug abuse was 2.0 percent in males and .8 percent in females. Lifetime rates of AOD abuse were even higher, with 24.6 percent of males and 11.5 percent of females abusing alcohol and 10.6 percent of males and 5.2 percent of females abusing drugs (Compton et al., 2007; Grant et al., 2004).

In the NSEARC study, only 8.1 percent of the sample who were AOD abusers had ever obtained any kind of treatment. When they did seek treatment, it was more likely to be from a private physician or some other health care provider (Compton et al., 2007). Because of this and other prior research, it was felt that screening patients in emergency departments and primary care clinics while they wait for care may be a way to identify those who are high-risk drinkers or drug users in what may be a teachable moment and to provide a brief intervention to reduce AOD use and concomitant problems (Gentilello et al., 1988; Solberg, Maciosek, & Edwards, 2008). These formal screenings and intervention projects, or SBIRT (Screening, brief intervention, and referral to treatment), were funded in 2003 in 6 states by the Substance Abuse and Mental Health Administration (SAMSHA), with current contracts with 10 states and 12 university-based sites. As of August 2007, over 536,000 screenings had been performed (SBIRT, 2008).

SCREENING AND BRIEF INTERVENTIONS

SBIRT is defined as,"a comprehensive, integrated, public health approach to the delivery of early intervention and treatment services for persons with substance use disorders and those at risk" (Babor, McRee, Kassebaum, Grimaldi, & Bray, 2007, p. 7). The brief screening and intervention follows four steps. First, health educators, physicians, or other health professionals raise the issue of alcohol and drug use and ask permission from patients to discuss these topics with them. Next, patients are screened using the Alcohol, Smoking, and Substance Involvement Screening Test or ASSIST (WHO ASSIST Working Group, 2002) and the results of their scores are fed back to the patient. Third,

using motivational techniques (Miller & Rollnick, 2002), patients are asked what they make of those scores, how ready they are to change their AOD use, and to explore the benefits and concerns of this use. Finally, patients are asked to negotiate a goal or determine their next step regarding reduction of AOD use. If the screening has found them to be in a no- or low-risk category, patients are encouraged to maintain this level. Those who are at risk in their use are given a brief intervention on site and advised to cut down. Those who are at high risk (AOD abusers) are given a referral for free, outpatient counseling, which is described later in this chapter. Those who are at severe risk (AOD dependent) are referred for traditional outpatient or residential AOD counseling (Academic ED SBIRT Research Collaborative, 2007; Babor et al., 2007). The whole procedure takes about 5–15 minutes (Bertholet, Daeppen, Wietlisbach, Fleming, & Burnand, 2005).

CASBIRT

The California Screening, Brief Intervention, and Referral to Treatment (CASBIRT) program is one of several national SBIRT demonstration projects funded by the Substance Abuse and Mental Health Services Agency (SAMHSA). CASBIRT was established in 2002 and funded until 2006. It was refunded in June 2007, and is currently administered by the California Department of Alcohol and Drug Programs (DADP), managed by the county of San Diego Alcohol and Drug Services Department, and implemented by San Diego State University School of Social Work's Center for Alcohol and Other Drug Studies and Services. As of March 2008, over 20,000 screenings have been attempted in 12 hospital/clinic sites. Screenings were completed for approximately 65 percent of the patients (15,000), with most incomplete screenings due to the patient being too ill or injured to be fully interviewed. The current screening sites include emergency, trauma, burn departments, and a primary clinic. The screenings and brief interventions are provided by 15 health educators and three supervisors, all of whom are bilingual in Spanish. Health educators use the ASSIST to quickly determine the level of AOD use and risk category (i.e., no/low risk, at risk, high risk, or severe risk). Approximately 600 patients (4%) fell into the high-risk category and were referred to the Brief Treatment Program.

THE CASBIRT BRIEF TREATMENT PROGRAM

One of the core elements of CASBIRT is the brief treatment (BT) program. This program provides assessment and psychoeducational services to nonde-

pendent substance users who have been identified as being at *high risk* for future substance use problems during the screening process. Using a harm-reduction model, the goal of BT is to provide cognitive-behavioral skills and strategies to assist these clients in reducing the risk in their use of substances. This program was developed as there are few programs in the community that provide services for those who fall into the abuse category of AOD use. The program starts when the health educators (HEs) screen individuals as being at high risk for subsequent substance use problems. Those individuals categorized as high risk according to the ASSIST measure are encouraged by the HE to begin the BT program. The full BT program consists of three initial assessment/motivational sessions followed by psychoeducational sessions that cover up to six additional topics. The topics covered in BT are based on those used in previous research studies evaluating short-term cognitive-behavioral approaches, and include: (1) functional analysis; (2) dealing with urges to use; (3) refusal skills; (4) alternate pleasurable activities and support systems; (5) problem-solving and relapse prevention; and (6) termination and discharge assessment (Barry, 1999; Carroll, 1998; Monti, Abrams, & Cooney, 1989; Sampl & Kadden, 2001).

In the first session of BT, the HE meets face to face with the client and conducts a structured interview using the ASSIST to identify the client's risk level for future substance use problems. For those clients scoring in the high-risk level, the HE conducts an immediate Brief Intervention session. This consists of the HE providing feedback on the client's risk level, giving advice regarding the physician's recommended levels of drug and alcohol use, and asking for a commitment to reduce substance use to these levels. In addition the HE assesses the client's motivation to change and offers a referral for the client to speak with a counselor about continuing in the BT Program.

If the client accepts the referral, the HE arranges an in-person or telephone follow-up appointment with a counselor. At this first session, the counselor describes the BT Program, assesses the client's concerns and motivation to change, and explores the client's interest in setting up an orientation/intake appointment to continue in the program. This appointment and all subsequent sessions of BT may be conducted in-person or by phone depending on clients' preferences or needs.

At the orientation/intake appointment, the counselor discusses the client's concerns, describes the BT program, reviews the program consent form, and answers any questions the client may have. All BT counselors have specific training in the principles and techniques of motivational interviewing (MI) (Miller & Rollnick, 2002) and use this approach in all interactions with clients. At this point the counselor asks the client if he is ready to sign the consent that constitutes the intake to the BT program. If the session is conducted over

the phone, the counselor requests the client's permission to address the legal requirements of the program and record a verbal consent (the counselor will send the client a copy of the *Informed Consent*, *Audio Consent*, and a packet of session handouts). After the consent is completed, the client and counselor begin the assessment process with a brief review of the client's current pattern and history of substance use. Finally the counselor and client set initial goals for participation in the program using the *Personal Goal Worksheet* (Miller & Rollnick, 2002).

The third session of BT is the extended evaluation. During this session the counselor and client review the impact that substance use has had on major areas of the client's life. To obtain and record this information the counselor conducts a structured interview using the Addiction Severity Index Lite (ASI-L) (McLellan, Luborsky, O'Brien, & Woody, 1980) with the client. The counselor and client assess high-risk situations for substance misuse by completing the *Challenging Situations Tool*. At the completion of the assessment the counselor provides feedback to the client as to her diagnosis according to *DSM IV-TR* (APA, 2000), reviews and updates the *Personal Goal Worksheet*, and discusses the next steps in the process.

Subsequent involvement in the BT program depends on the client's diagnosis. Counselors give feedback to clients who meet *DSM IV-TR* criteria for substance dependence that the physician's advice is for them to abstain. Since the BT program is designed to be used with nondependent substance users, the counselor offers to refer the client to more intensive community services to assist him in achieving abstinence. Dependent clients who decline referrals to more intensive treatment and are not in need of medically managed care (e.g. detoxification, methadone maintenance) may continue in the BT program as long as the BT clinical director and counseling staff determine them to be appropriate for and profiting from services. Those dependent clients who are in need of medically managed services will be told that the BT program is not able to accommodate their needs, will be discharged from BT, and will be given referrals for the appropriate level of care.

Clients who meet *DSM IV-TR* criteria for co-occurring psychiatric disorders are encouraged to seek treatment for these conditions and will be given referrals for psychological/psychiatric treatment. Clients with co-occurring disorders may continue in BT if the BT clinical director and counseling staff determine that their psychiatric condition is stable and will not interfere with participation in the BT program. Those clients whose psychiatric conditions are judged by BT clinical director and counseling staff to be likely to interfere with the program will be discharged from BT and given referrals for community resources for treatment of both psychiatric and substance use disorders.

Counselors give clients who meet diagnostic criteria for substance abuse feedback on their diagnosis and start them on the aforementioned topics covered in BT. It is important to make clear that counselors will continue to assess clients' appropriateness for participation in BT throughout the program. Whenever the clinical director and counseling staff determine that a client is no longer appropriate for BT services, the counselor will discharge the client from BT and refer her to those community agencies that can best address the client's needs.

As previously mentioned, there are six additional topics covered in BT that constitute the cognitive-behavioral portion of the program. These topics consist of the functional analysis of the client's use of substances and four skill training topics along with a final treatment review/termination session. Each topic is designed to be covered in a single 45–60-minute session but may be continued to additional sessions if circumstances require. The counselors follow a manualized format for each session, which, while not a script, does present a recommended sequence of issues to be covered for each topic. The content and format of these sessions were drawn from previous work on brief interventions with substance use disordered patients (Carroll, 1998; Monti et al., 1989; Sampl & Kadden, 2001). The counselors incorporate the principles of MI in their work with clients and utilize MI techniques and interventions throughout the BT program.

In the functional analysis session, the counselor describes the importance of understanding the role that substances play in the client's life. The counselor and client then use the Functional Analysis Worksheet (Jaffe, Brown, Korner, & Witte, 1988) to analyze a recent episode of the client's use of substances. In this process, they review the areas of: triggers for use, thoughts and expectations regarding use, patterns of use, and positive and negative consequences of use. The counselor points out how future sessions will focus on acquiring skills to address each of the areas in the functional analysis process and assigns homework for the client to complete between sessions. The homework for this topic consists of the client completing an additional functional analysis worksheet for another incident of substance use.

The next four skill training topics cover the areas of: coping with urges and impulses to use, learning refusal skills, acquiring alternate pleasurable activities/improving support systems, and learning problem-solving (D'Zurrilla & Goldfried, 1971) and relapse prevention techniques. During each session the counselor reviews the client's goals for use, his current usage of substances, and the level of motivation to reach his goals. For each topic the counselor first presents information regarding the importance of the skill in helping the client to reduce his risks in the use of substances. Next the counselor and client

practice the skill in the session and discuss any challenging situations the client anticipates for the next week. Finally the counselor assigns homework for the client to complete between sessions.

The final topic of BT is the termination/discharge assessment session. During this meeting, the counselor and client establish the client's current level of substance use, review her goals for reducing risks and assess what progress she has made while going through the program. The counselor and client then discuss next steps for the client to take in achieving/maintaining any gains she has made and what referrals may be helpful. Finally the counselor asks the client for feedback on what she found helpful in the BT program and any suggestions she might have for improvement.

BRIEF TELEPHONE-BASED COUNSELING

Offering counseling services by telephone is a promising new option for treatment. Despite the brief history of this approach, recent research has shown promising results for telephone counseling. Telephone therapy has evolved from primarily being used to provide crisis intervention or hotline services, to being paired with traditional face-to-face counseling, to today being offered as a stand-alone treatment (Reese, Conoley, & Brossart, 2006). Telephone services are now widely utilized in providing a number of health services and health behavior interventions (McBride & Rimer, 1999). The CASBIRT BT program offers sessions via phone to enable maximum patient access to brief intervention services. Telephone counseling services reach many patients who otherwise would be unable to attend an in-person office appointment.

Reese, Conoley, and Brossart (2002) found that over 82 percent of clients reported improvement on their presenting problem based on participation in telephone counseling. They also reported strong levels of satisfaction with telephone therapy. A later study by the same authors (2006) noted that more than half (58%) of the participants who had received both telephone and traditional face-to-face therapy preferred telephone counseling; 96 percent would be willing to receive counseling services by phone again, compared to 63.1 percent who would be willing to seek face-to-face counseling.

Research highlights several advantages of telephone counseling services. Clients report convenience, accessibility, control, and lack of inhibition as appealing aspects of telephone counseling (Reese et al., 2006). Clients appreciate the convenience of receiving counseling at home by phone, as well as being able to receive services the day they initiate contact with a providing agency; services are easily accessible. Clients have a part in controlling the process of the session, and some clients feel that receiving counseling services by phone

provides more privacy, and as a result they feel less inhibited in talking about sensitive issues.

As indicated previously, the CASBIRT BT program primarily utilizes MI and cognitive-behavioral therapy, offering services by telephone or in person. Much of the research on telephone counseling has incorporated MI or motivational enhancement techniques (Mermelstein, Hedeker, & Wong, 2003; Tedeschi, Zhu, Anderson, Cummins, & Ribner, 2005). One study examined both the use of MI and service delivery by telephone. Study results suggest that an adaptation of MI administered through telephone sessions may significantly reduce drinking for alcohol abuse or dependent male primary care patients (Brown, Saunders, Bobula, Mundt, & Koch, 2007).

Expressing empathy is one of four main principles of MI (Miller & Rollnick, 2002). MI is empathic in that the counselor listens to the client's feelings without judgment, criticism, or blame. The delivery of counseling services by telephone, as previously stated, may enhance empathy and rapport-building within the client-counselor relationship due to an absence of potential visual biases (Reese et al., 2002). The absence of visual biases in telephone services may also improve the potential for collaboration to occur, another major component of MI.

CASBIRT counselors' experiences with telephone counseling mirror much of the research to date. Phone services appear to reach those who otherwise would not be reached by traditional face-to-face counseling. Additionally, as the research suggests, many clients initially question the benefits of telephone counseling. Once clients have completed a session or two by phone, however, they appear to appreciate the convenience, privacy, and anonymity of telephone counseling. The majority of our clients (90%), when given the choice of meeting in person or by telephone, choose the latter.

It is also important to note that Reese et al. (2002) found no difference in the amount of therapeutic bonding or social influence, the most consistent predictor of therapeutic outcomes, in telephone counseling sessions versus face-to-face services. CASBIRT counselors also commented that the level of anonymity offered by phone sessions appeared to, in some cases, decrease the impact of differences such as age, gender, culture, or ethnicity on the rapport built in the client-counselor relationship. The therapists have also found that clients, whether in person or by telephone, tend to expect that the counseling will be traditional, confrontational, and abstinence-oriented in approach, and are often surprised to experience the MI approach with harm-reduction goals.

A challenge of telephone counseling is actually born of one of the advantages—lack of inhibition. As a result of clients feeling more privacy, and in turn less inhibition, a counselor may actually need to be more conscientious about

defining the boundaries of the therapeutic relationship. There are virtually no outside controls or cues to inform the counselor-client relationship. There is no office with a receptionist that the client visits once a week for an appointment—a client could be anywhere, doing anything, when a counselor calls for an appointment. The unique circumstances of delivering counseling services by telephone may call for stricter monitoring of transference and counter-transference issues because of the mode of service delivery. Further research could explore whether these aspects of telephone counseling would in fact create any major challenges to service delivery.

Telephone counseling also requires adjustment on the part of the therapist. Few clinicians receive any training on conducting counseling services by telephone. The telephone offers an entirely different therapeutic medium, and adjustments have been made in the training and practice of CASBIRT clinicians. For this project, the therapist training includes role-playing the various sessions sitting back-to-back with a "client" to practice the intervention and adapt it to this type of setting. Many of the visual cues that guide the clinician in building rapport and trust with a client are lost when counseling is done via the telephone. For instance, when a client is silent, the therapist may have difficulty interpreting what it means (sad? crying? upset? asleep?) and use more probing questions than would normally occur. Additionally, when conducting a telephone session, CASBIRT therapists tend to ask permission more often when transitioning from one topic to the next or probing a client's thoughts.

Many clients are accustomed to the face-to-face counseling model and are therefore reluctant to try telephone counseling. Reese et al. (2006) found that before receiving telephone counseling, fewer than half (44.3%) of the study's participants thought it would be helpful. CASBIRT counselors observe this in their clients as well. As previously mentioned, many clients initially question the benefits of telephone counseling but are quick to adjust to and often prefer this as a service delivery method.

CULTURAL NEEDS AND IMPLICATIONS

There is no one best or most effective way to counsel minority groups; however, certain considerations should be taken into account. According to Torres-Rivera, Wilbur, Phan, Maddux, and Roberts-Wilbur (2004), cultural aspects specific to minority groups are often overlooked by conventional Euro-American substance abuse counseling approaches, which suppose problems are a result of individual intrapsychic disorganization or dysfunction. Instead, a culturally specific counseling approach that allows for substance abuse problems to be explained from a multidimensional perspective should be applied

when working with minority groups. This section will mainly focus on working effectively with Latinos in a clinical setting, as they are the largest minority group served by CASBIRT in San Diego County.

Counselors engaging in a therapeutic relationship with Latinos should have knowledge about interpersonal etiquette specific to Latino cultural value orientations. When engaging with Latinos, it is appropriate to address them in a kind and respectful manner. Individual differences exist among Latinos; however, according to Santiago-Rivera, Arredondo, and Gallardo-Cooper (2002), the following value orientations are most common in Latino interpersonal relationships and should be applied when engaging with Latinos: *personalismo, respeto, dignidad, simpatía, confianza* and *cariño*. Showing *personalismo* is a demonstration to the client that he is more important than time or what is occurring at the moment. *Respeto* is one of the most important value orientations in the Latino culture and has several meanings. It is demonstrated by being compassionate towards the client's situation. *Respeto* also mean respecting authorities, family, and tradition. Counselors should also be aware that Latinos believe in *dignidad,* meaning that everyone is worthy and should be respected. *Simpatía* refers to someone who is considered a pleasant person. Latinos are attracted to individuals who are relaxed, friendly, and entertaining. *Confianza* refers to trust and closeness in a relationship. At first most Latinos are reserved; however, once trust has been established Latinos are known to form close bonds with those around them. Latinos also need the restrictions of confidentiality to be explained to them. Some Latinos may hold back on sharing information in fear that they might be reported to immigration authorities. Lastly, counselors working with Latinos should consider being *cariñosos,* as it is greatly admired in the Latino culture. *Cariño* in the Latino culture is expressed through verbal and nonverbal endearment messages, such as, greeting a Latino with a hug (Santiago-Rivera et al., 2002).

Most important when counseling Latinos is matching client and counselor characteristics to help ease and bring cohesion to the therapeutic relationship. Matching can be based on language, race, or culture, but language matching is critical because language barriers are often the reason why Latinos do not seek counseling or health services (Santiago-Rivera et al., 2002). Not conducting a counseling session in Spanish when necessary could result in an inconsistent assessment of the Latino client's feelings. Counselors should also determine the need for a translator by conducting an acculturation level assessment of the client. Counselors working with specific Latinos should be bilingual, with a strong grasp of the Spanish language, since many Latinos communicate with proverbs, metaphors, regionalism, and sayings particular to their culture

(Santiago-Rivera et al., 2002). All of the CASBIRT health educators are bilingual in Spanish and several of the BT staff are bilingual.

Several other counseling considerations to have when working with Latinos include assessing their spirituality and religious influence. Because of the strong belief in fatalism in the Latino culture, it is has been suggested by Sue and Sue (2008) that counselors not change this belief but rather comprehend it. Assessing for acculturation levels is also recommended when working with Latinos, since many Latinos hold on to their traditional beliefs while others assimilate to the main culture. Counselors working with Latinos should specifically assess for cultural and societal contributions to the problem. External factors such as poverty, lack of shelter, unemployment, English language deficiency, racism, lack of familiarity, interactions with bureaucracies, and fear of deportation can be great stressors that are contributing to the problem (Sue & Sue, 2008).

Brief telephone counseling has been shown to be promising when working with minority groups such as Latinos. According to Williams and Douds (2002), phone therapy allows for client control and anonymity, in addition to resolving geographic obstacles. Having to come into an office for substance abuse counseling can be shameful, whereas counseling over the telephone gives clients power to end the conversation if they feel or become uncomfortable. Another advantage of telephone counseling is that clients are able remain anonymous and control for the negative consequences of their self-disclosure (Williams & Douds, 2002). This is true for Latinos and other ethnic groups residing in the U.S. illegally, who may avoid services available to them for fear of possible deportation. Telephone counseling also resolves geographical obstacles to services for clients who lack mobility or who live far from where the counseling services are being offered.

Significant efforts have been made to improve culturally sensitive counseling, yet most counseling values and practices continue to be tailored to serve a portion of the population. Bilingual CASBIRT counselors have found that telephone counseling does not take away from their ability to apply their knowledge about the interpersonal etiquette specific to Latinos and that it even has additional value with certain Latino groups. Counselors have also observed an increase in the rate at which *confianza* develops between counselor and client. They note that the level of anonymity offered by phone sessions, in some cases, decreases the impact of differences such as age, gender, culture, or ethnicity on the rapport or *confianza* built in the client-counselor relationship. Overall, the CASBIRT experience has been promising when applying telephone counseling to Latinos; however, further research is still needed to fully explore the impact of telephone counseling on the counseling relationship.

INITIAL FINDINGS

CASBIRT data indicate that about 4 percent (n = 600) of the patients screened to date fell into the high-risk category and were encouraged by the HE to accept a call from a BT counselor. Half (n = 300) of these individuals agreed to have the BT counselor call them to set up an initial counseling appointment conducted either face-to-face or over the phone. BT counselors were able to contact 34 percent (approximately 100) of the 300 potential clients; the remaining 66 percent could not be conducted because of an incorrect/disconnected or nonworking phone number, or they did not return the BT counselor phone messages.

Fifty-two patients received at least one BT session. Two-thirds of these patients were male. The average age was 41, with a range from 20 to 65 years. About 40 percent of these patients were Hispanic/Latino; 16 percent of the patients had sessions delivered in Spanish. The mean number of sessions (i.e., dose) delivered was 2.76 sessions (SD = 2.8). Ninety percent of sessions were conducted over the telephone.

Analysis of 23 patients with pre-BT and post-BT effectiveness measures showed that daily alcohol consumption decreased significantly over time (t = 2.11, p <.05), and that confidence in reducing alcohol/drug use increased significantly over time (t = –2.005, p < .05). Linear regression analysis showed that a higher dose of sessions tended to be related to positive changes in confidence, accounting for about 10 percent of the variance; changes in daily consumption, however, was not related to dose. Other measures of effectiveness (e.g., frequency of alcohol consumption, importance of changing one's alcohol/drug use) showed changes in the desired direction but did not reach statistical significance due in part to the small sample size.

SUMMARY AND CONCLUSIONS

SBIRT programs were developed to provide a continuum of care for individuals varying in their levels of alcohol and drug use severity. Opportunistic screenings, brief on-the-spot interventions, and referrals to more intensive treatment are conducted in nontraditional settings, such as emergency departments while patients wait for care (SBIRT, 2008; Solberg et al., 2008). The brief treatment element is offered to those patients whose screening results indicate they are at high risk for AOD.

The CASBIRT BT program was developed to offer short-term, harm-reduction treatment services for high-risk AOD abusers who typically would not be treated by community-based services. BT counselors utilize MI principles and

cognitive-behavioral approaches to assist clients in reducing their use of substances. To minimize barriers to access, the program offers no-cost services, bilingual counselors, flexible scheduling, and phone or in-person sessions.

Telephone-based counseling was implemented as an alternative way to engage reluctant clients and to provide a resource for those who have other psychosocial issues, such as lack of transportation or difficult work hours. This too has proven to be a challenge as we have described. However, once clients get past their initial concerns about telephone-based counseling, they engage with the counselor and are willing to participate. Interestingly, Latino clients have responded well to the telephone-based services. BT counselors have had to amend their counseling styles by paying attention to cues such as silence and probing more often to determine clients' thoughts and feelings.

Despite the efforts to overcome the obstacles to access, treatment counselors have encountered both logistic and motivational problems engaging clients in brief treatment services. As mentioned in the "Initial Findings" section of this chapter, counselors were unable to contact a large percentage of referred clients who did not have a permanent address or access to a phone. This may be an unavoidable consequence of the relatively low socioeconomic status of a great deal of the clients targeted by the program. Many other clients that counselors did contact felt that their problems were not that bad and that they could modify their AOD use without treatment. To some extent this reluctance to participate in services may reflect the reality that many abuse-level clients have not yet thought much about these issues, are in an early stage of readiness of change (precontemplation), and are not prepared to initiate reductions in use. In this case the counselors focused on raising the clients' concerns about their use, reinforcing the clients' independent efforts to change, and leaving the door open for utilizing BT services in the future. Other reasons for clients' reluctance to participate in services may be related to their concerns about common societal attitudes regarding problematic AOD use. Among these is the cultural understanding of alcoholism/addiction as a disease, widespread confusion over the issues of abuse versus dependency, and commonly held beliefs that treatment is limited to abstinence-oriented goals for those who are dependent. As a result, abusers may not see themselves as needing help to achieve harm-reduction goals. From a public health perspective, this may mean public education programs need to teach that treatment is not just for alcoholics/addicts with the goal of abstaining from AOD use and attending self-help programs. Treatment needs to be more broadly conceptualized as including getting help to cut down to lower-risk drinking or use patterns.

Our preliminary experience indicates that telephone counseling is a viable treatment alternative to traditional face-to-face counseling. Research reveals

telephone service delivery as having a number of positive effects and results similar to in-person counseling (Brown et al., 2007; McBride & Rimer, 1999; Reese et al., 2002), and our limited data suggest positive changes in AOD behavior as a result of the BT. Because the approach is relatively new, there is much left to be discovered about telephone-delivered services. Future research could continue to explore the advantages and challenges of telephone counseling and formally evaluate the effects of the approach.

Chapter **16**

Screening and Brief Intervention for Alcoholics

Ramadugu Shashikumar, MD

SCREENING

Screening is the procedure that identifies a disease or disorder in its early or presymptomatic stages and provides efficient identification of those users of alcohol who need a more comprehensive diagnostic evaluation and treatment planning. By screening for hazardous and harmful drinkers among regular alcohol consumers we can identify high-risk alcohol users. (Pal, Jena, and Yadav, 2004). Hazardous drinking is a pattern of alcohol consumption that increases the risk of harmful consequences for the user or others; such drinkers are of public health significance despite the absence of any current disorder in the individual user. *Harmful use* refers to alcohol consumption that results in physical, mental health, and social health consequences (Babor, Campbel, Room, & Saunders, 1994; World Health Organization [WHO], 1993).

Social environmental influences, ignorance of knowledge of drinking limits, and the risk associated with alcohol consumption are known to contribute to problem drinking (hazardous and harmful). We should be concerned about these people on two counts. First, that although not all problem drinkers become dependent, the pathway to dependence is through problem drinking. Second, many of them are amenable to change and betterment. So screening these people offers an opportunity to take preventive measures (Babor, Higgins-Biddle, Saunders, & Monteiro, 2001).

Screening is also important because many people who are at risk have or who are already experiencing alcohol-related problems do not seek treatment (Grant, 1997; Sobell & Sobell, 1993).

Alcohol use disorder represents more of a spectrum of illnesses, and that morbidity and mortality needs to be assessed on a continuum rather than as a dichotomous entity. There is high prevalence of harmful and dangerous drinking among otherwise asymptomatic patients in primary care settings, and a considerable burden of the disease is borne by them (Odd, 2003).

QUESTIONNAIRES

Screening can be done by using self-reporting questionnaires and measurement of biomarkers for alcohol. The former are easier to apply in a large population and several such are available. These are rapid, inexpensive, and often appealing for application in general populations. Some of the commonly used scales are the CAGE questionnaire, Michigan Alcoholism Screening Test (MAST), Alcohol Use Disorders Identification Test (AUDIT), AUDIT Consumption Studies (AUDIT-C), and Lubeck Alcohol Dependence and Abuse Screening Test (LAST) (Pal et al., 2004).

CAGE

CAGE, a mnemonic based on the first letter of a key word from each of the four items it measures is a rapid Screening-instrument. A score of two out of four indicates problem drinking (Ewing, 1984). See Questionnaire 1 in the Appendix.

MAST

MAST is a 25-item test (see Questionnaire 2 in the Appendix). It was originally developed for screening general population (Selzer, 1971). However, both CAGE and MAST have drawbacks in that they depend heavily on possibly unreliable self-reporting, they detect lifetime use rather than current use, they focus on dependent or nondependent use of alcohol, and they do not give quantity and frequency data (Schuckit & Irwin, 1988).

LAST

LAST was developed in a general hospital sample by combining CAGE and MAST; the questionnaire consists of seven dichotomous items (two from CAGE and five from MAST) and is scored without weightings, with a cut-off score of 2 (see Questionnaire 3 in the Appendix). However, it is more suitable in a hospital setting rather than in general population (Rumpf, Hapke, Dawedeit, Meyer, & John, 1998; Rumpf, Hapke, Meyer, & John, 2002).

AUDIT-C

The AUDIT-C includes the first three items of the original AUDIT instrument (see Questionnaire 4 in the Appendix). (Bush, Kivlahan, McDonell, Fihn, & Bradley, 1998). It is faster but is not more sensitive than AUDIT in detecting at-risk drinking (Rumpf et al., 2002).

AUDIT

AUDIT was developed by WHO as a simple method of screening for excessive drinking and to assist in brief assessment (see Questionnaire 5 in the Appendix). The AUDIT differs from other self-report screening tests in that it was based on data collected from a large multinational sample and used an explicit conceptual statistical rationale for item selection. It emphasizes identification of hazardous drinking rather than long-term dependence and adverse drinking consequences (Babor et al., 2001). Studies have shown that it is more culturally appropriate than CAGE or MAST and that it reflects the extent of alcohol involvement along a broad continuum of severity (Fleming, Barry, & MacDonald, 1991; Hays, Merz, & Nicholas, 1995; Sinclair, Mcree, & Babor, 1992). Advantages of using AUDIT are that it has been validated for use in primary health care patients. It is the only screening test that identifies hazardous and harmful alcohol use, as well as dependence. Other advantages include it being rapid, brief, and flexible. AUDIT has high internal consistency and high test-retest reliability (r = 0.86). These qualities have been established in several language versions and across several nations. There are three domains of AUDIT, namely, hazardous use of alcohol brought out by the first three questions, dependence symptoms brought out by the fourth to sixth questions, and harmful use of alcohol brought out by the last four questions (Babor, 2001) (Babor et al., 2001).

BOX 1

Domains and Item Content of the AUDIT

Domains	Question Number	Item Content
Hazardous alcohol use	1	Frequency of drinking
	2	Typical quantity
	3	Frequency of heavy drinking
Dependence symptoms	4	Impaired control over drinking
	5	Increased salience of drinking

Harmful alcohol use	6	Morning drinking
	7	Guilt after drinking
	8	Blackouts
	9	Alcohol-related injuries
	10	Others concerned about drinking

Source: Babor, T. F., Higgins-Biddle, J. C., Saunders,J. B., & Monteiro, M. G. (2001). WHO, Department of Mental Health and Substance Abuse. AUDIT—The Alcohol Use Disorders Identification Test: Guidelines for use in primary care. WHO/MSD/MSB/01.6a. Geneva, Switzerland.

Total scores of 8 or more are recommended as indicators of hazardous and harmful alcohol use, as well as possible dependence. A cut-off score of 10 will provide greater specificity at the cost of sensitivity. The purpose of AUDIT is to give primary emphasis to screening, not case-finding. The validity status revealed that 100 percent of alcoholics had a score of 10 or higher and only 0.5 percent of nondrinkers had a score of 8 or more. Overall the Cronbach's alpha was 0.80, suggesting a high internal consistency (Duane & John, 2002).

Having identified problem drinkers, what do you do with them? General practitioners in primary health care have generally been reluctant to screen for problem drinkers and, when any are identified, these practitioners are more reluctant to do something about it. Reasons generally put forth are that it would require too much time, that they have inadequate training to deal with such things, that they fear antagonizing patients over a sensitive personal issue, or that alcohol is altogether not a matter that needs to be addressed in primary health care (Babor et al., 2001) and that alcoholics do not respond to primary care interventions (Aira, Kauhanen, Larivaara, & Rautio, 2003; Heather, 1996; Rush, Powell, Crowe, & Ellis, 1995). Another reason could be that alcohol screening and interventions are laborious and time-consuming activities that have a small yield (Aalto & Seppä, 2004).

BIOMARKERS

Screening questionnaires, especially self-reporting types, when used in a population study often need to be complimented by use of a biological marker for identification of problem drinkers. This would facilitate early detection and intervention. Alcohol biomarkers include tests that tell us about the acute/chronic alcohol consumption (state/trait markers). They help improve knowledge of drinking patterns in both individuals and populations and are valuable

tools for the objective evaluation of intervention programs (Montalto & Bean, 2003).

There are several substances that can be evaluated in an alcoholic individual to ascertain an alcohol drinker's pattern of drinking and his/her abstinent status. Such a substance should be amenable to be tested in a large number of people. The test should be easily available, be cost-effective, and most importantly be useful as a tool in the assessment of the brief intervention program. More research is needed to determine the value of markers along with or without questionnaires to help us arrive at clearer clinical algorithms and have well-defined outcome variables. Several biomarkers have been available and have been used in different kinds of contexts and settings. One of the most traditional biological markers was alanine transaminase, aspartate transaminase, and mean corpuscular volume (MCV). The former two are susceptible to change by several other substances like drugs and diseases of the liver, and the latter is much influenced by age (Gotz, Klaus, Jorg, Daniela, & Karl, 1999; Karen, 2004) and its sensitivity is too low (24%) to allow use in a general population (Reynaud et al., 2000). Over the years, therefore, in a yearning for a biological marker that has both high specificity and sensitivity, several substances have been evaluated. Some of these are fatty acid ethyl esters (FAEE), sialic acid (SA), serum, activity of "N-acetyl β hexosaminidase" (HEX), Leptin, sialysation of apolipoprotein J (SIJ), carbohydrate deficit transferrin (CDT), and gamma glutamyl transferase (GGT).

FAEE

FAEE level in human hair is influenced by quantity and frequency of alcohol intake. The cut-off mark to distinguish heavy drinking/alcoholism from social/moderate drinking is 0.4 ng/mg of hair (Wurst et al., 2004). Though FAEE has high sensitivity and specificity (100% and 90%, respectively) (Karen, 2004), use is restricted by its limited availability and has not been much researched yet (Minna, Maya, Nissen, Anetie, & Swolainen, 2007). FAEE is also measured in serum. FAEE is a nonoxidative esterification product of alcohol and ethanol. It is detectable even after 24 hours of alcohol consumption and even with as little ethanol as 100 mg/L, which by other tests for alcohol would have tested negative. Thus it may evolve as both a short- and long-term marker of ethanol ingestion. (Michael, 1997).

HEX

HEXN-acetyl β hexosaminidase is a lysosomal enzyme. HEX has a sensitivity of 94 percent and specificity of 91 percent, which makes it more effective than CDT (Stowe, Stowel, Barrett, & Robinson, 1997). However, its

normalization on abstinence takes place faster than GGT, making it difficult to ascertain long-term alcohol abuse (Markowski, Ferens-Sieczowska, Zwierz, & Wojtulewska, 2003).

Leptin

Leptin is a cytokine-type peptide recently implicated as a putative state marker of alcohol use (Wurst et al., 2003). Leptin levels are increased by even a moderate level of alcohol intake (15–30 g/day) (Roth et al., 2003). However, another study has shown that there is only a minor influence on leptin levels of acute alcohol intoxication in alcohol-detoxified patients (Wurst et al., 2003).

Sialic Acid

Sialic acid, because of its clear potential as a highly specific marker for alcohol use, is being directly measured in plasma rather than as part of a complex protein chain. Sialic acids are the acetyl derivatives of muraminic acids that occur as nonreducing terminal residues of glycoproteins/gylcolipids in biological fluids and membranes. It has similar sensitivity and specificity to CDT for measuring alcohol consumption. It takes longer than GGT or CDT to decrease in abstinent patients. It is not affected by nonalcoholic liver damage. However, its widespread availability is still restricted. It is likely to be a useful test in the future (Karen, 2004; Romppanen et al., 2002).

SIJ

Plasma sialic acid index of apolipoprotein J is another substance that can be used to detect alcohol levels. Apolipoprotein J is a glycoprotein found in lipoproteins that are responsible for transporting fats in the blood. Sialic acid content of these proteins is reduced after alcohol intake. Sialic acid content is four times more in apolipoprotein J than in transferrin, it is therefore easier to measure changes in it caused by heavy alcohol intake. It has a sensitivity of 90 to 92 percent. It is valid when alcohol intake exceeds 60 g/day and is markedly diminished in chronic alcoholics (Ghosh, Hale, & Lakshman, 2001).

CDT

Carbohydrate deficit transferrin is a collective term referring to isoforms of transferrin from which sialic acid residues have been removed. Alcohol intake knocks off that sialic acid, and the concentration of CDT increases (Das, Nayak, & Vasudevan, 2003). Some of the advantages of using CDT as an alco-

hol state marker are its high specificity, the fact that it is not affected by liver disease, and its low incidence of false positives (Stibler, 1991).

However, its main disadvantages are lack of wide availability, high cost (TIP 45 SAMHSA, 2006), and the fact that some people with high levels of transferring may have elevated CDT even without alcohol intake (Karen, 2004). Some primary care studies using CDT have shown low sensitivity (Salaspuro, 1999) and may even have false negatives (Karen, 2004). It may therefore not be suitable for screening for subjects with alcohol abuse in the general population (Golka & Wiese, 2004).

GGT

Gamma glutamyl transferase is a biliary canalicular enzyme that is induced by alcohol and serum levels rise in response to acute hepatocellular damage (Rosalki, 1984). Because during abstinence in a case of a heavy drinker GGT levels fall gradually and return to normal levels only after six to eight weeks, it provides a useful confirmation that alcohol was the cause of the cellular damage (Das et al., 2003). It is a useful screening substance even though it is also elevated easily due to nonalcoholic liver damage (Gotz, Klaus, Jorg, Daniela, & Karl, 1999). GGT is a measure of cumulative alcohol use (Golka & Wiese, 2004). It is more influenced by drinking intensity than frequency (Anton, Stout, Roberts, & Allen, 1998). It has also been found that those with high GGT levels have more vulnerability to alcohol, a characteristic that appears to be stable with time (Daeppen, Schoenfeld-Smith, Smith, & Schuckit, 1999).

Sensitivity of GGT in different studies ranges from 40 to 70 percent (Mihas & Tavassoli, 1992; Reynaud et al., 2000; TIP 45 SAMHSA, 2006) and specificity is from 40 to 80 percent ([Reynaud et al., 2000; TIP 45 SAMHSA, 2006], that is, the ability to not misidentify or confirm alcohol use to other disorder). It does correlate with alcohol intake but requires more than 60 g/day intake. GGT is helpful as a motivational enhancer in patients with a high degree of denial to show them both evidence of drinking and liver damage. Reducing levels with abstinence provides motivation in remaining abstinent.

Most biological markers are influenced by duration of abstinence, age, and alcohol consumption (Das et al., 2003; Gotz, Klaus, Jorg, Daniela, & Karl, 1999). GGT has the advantage of being more sensitive in those who are recently abstinent (≤ 4 days). Age has no effect on CDT and GGT but on MCV with increasing values with age (Gotz, Klaus, Jorg, Daniela, & Karl, 1999).

Thus we see that none of the biological markers are clearly optimal to play a role as an alcohol intake marker in the general population. However, in view

of its easy availability, low cost, and greater sensitivity (which is an essential characteristic in screening tests and also a tool to monitor abstinence states), GGT is an ideal screening biological marker (Hoaskema & de Bock, 1993). When it is combined with CDT, its usefulness in identifying problem drinkers is enhanced greatly.

BRIEF INTERVENTION

But what are the interventions that are available and known to be effective in primary health care, and how can they be delivered? Three different kinds of intervention are generally available for implementation among the alcoholic population. They are alcohol education, simple advice, and brief counseling.

BOX 2

What Interventions to Be Given

Risk Level	Intervention	AUDIT Score
Zone I	Alcohol education	0–7
Zone II	Simple advice	8–15
Zone III	Simple advice plus brief counseling and continued monitoring	16–19
Zone IV	Referral to specialist for diagnostic evaluation and treatment	20–40

Source: Babor, T. F., Higgins-Biddle, J. C., Saunders, J. B., Monteiro, M. G.(2001). WHO, Department of Mental Health and Substance Abuse. AUDIT—The Alcohol Use Disorders Identification Test: Guidelines for use in primary care. WHO/MSD/MSB/01.6a. Geneva, Switzerland.

Alcohol education is appropriate for those procuring a score below 8 on AUDIT. Though no intervention as such is required, it contributes to the general awareness of alcohol risk in the community (Saunders, Kypri, Walters, Laforge, & Larimer, 2004).

Simple advice is for those who score between 8 and 15 on AUDIT. Such individuals require advice to avoid drinking to intoxication. It entails giving them the feedback that their drinking patterns are risky for their health and social outcomes in future. They are provided information on specific risks of continued drinking above recommended guidelines. Then the most important part of simple advice is for the patient to establish a goal to change drinking behavior and give advice on drinking limits (Saunders et al., 2004).

However, some in this group are to be given advice to stop drinking rather than on low-risk drinking. These are those with a prior history of alcohol/drug dependence, prior or current mental illness, women who are pregnant, and those whose medical conditions require complete abstinence of alcohol (Saunders et al., 2004).

Brief counseling is appropriate for those who score 16–19 on AUDIT. It differs from simple advice in that it is a systematic, focused process that relies on rapid assessment, quick engagement of the patient, and immediate implementation of change strategies. Its goal is to provide tools to the patient to change basic attitudes and handle a variety of underlying problems. It involves giving information booklets. The patient goes through stages of precontemplation, contemplation, preparation, action, and maintenance. An important component of brief intervention at all stages is giving encouragement (Saunders et al., 2004). Brief intervention for alcoholics encompasses both simple advice and counseling. Those scoring above 20 on AUDIT should ideally be referred to a specialist treatment center.

Who provides this brief intervention? Several studies have shown that when this is implemented in a clinic at all levels of primary health care system or even by a nurse, it is effective (Aalto et al., 2001; Drummond, Thom, Brown, Edwards, & Mullan, 1990; Israel et al., 1996; Kaariainen, Pekka, Pauli, & Seppa, 2001; Latt & Saunders, 2002; McIntosh, Leigh, Baldwin, & Marmulak, 1991; Ylva, Anders, & Aberg, 1998).

Even when it is applied as a 5–60-minute motivational counseling and alcohol education over one to four scheduled sessions to problem drinkers, it would still help a large number of excessive drinkers to cut down consumption to safer levels (Grant, 1997). Controlled studies at primary health care settings have shown up to 20 percent reduction in alcohol consumption by problem drinkers (Latt & Saunders, 2002; Sobell & Sobell, 1993), whereas some have found up to 50 percent having significant reduction in drinking (Aalto et al., 2001). Odd Nilssen, in a nine-year old follow-up study of the effect of brief intervention in at-risk alcohol drinkers, found that after one year there was a 50 percent reduction in alcohol intake in the intervention groups and a 20 percent increase in the control group. The impact of brief intervention appears to be long-lasting. At nine years follow-up, at-risk drinkers disclosed GGT values close to that of the background population (Odd, 2003). Grossberg, Brown, and Fleming also reported reduction in high-risk drinking behaviors and consequences in a four-year study (Grossberg, Brown, & Fleming, 2004).

Saunders et al. reported that using AUDIT for screening and providing very brief advice by a general practitioner (GP) when appropriate found 30 percent reduction in hazardous drinking (Saunders, Aasland, Babor, de la Fuente, &

Grant, 1993). Fleming et al.'s 48-month study found direct evidence that brief physician advice is associated with sustained reductions in alcohol use, health care interventions, motor vehicle accidents , and associated costs (McIntosh et al., 1991).

Aalto et al. found that when a GP discussed the amount of alcohol consumed and harm caused by alcohol with patients, even when such discussions lasted for less than four minutes, this was not only acceptable but also useful (Aalto & Seppä, 2004). Similar findings are suggested by Kaariainen et al. (2001).

As a policy matter also, brief interventions are very useful, even if approximately 1 percent of patients who have required counseling make lasting changes. A brief intervention is cost-effective, and if approximately 10 percent change, much resources of health care will be saved (Andréason, Hjalmarsson, & Rehnman, 2000). A meta-analytical review of studies comprising brief interventions with either controlled or extended treatment conditions found little difference between brief and extended treatment conditions. This review also suggested that because evidence regarding brief interventions comes from different types of investigations with different samples, generalization should be restricted to the populations, treatment characteristics, and contents represented in those studies (Moyer, Finney, Swearingen, Carolyn, & Vergun, 2002).

Bein, Miller, and Tonigan. also reported in a meta-analytical review of 32 controlled studies that brief intervention is as effective as more intensive treatments (Bein et al., 1993). Several other studies have also found that those receiving brief intervention did better than those not receiving it at 6 and 12 month periods, while some have found that it might serve as an initial treatment for severely dependent patients seeking extended treatment (Bein et al., 1993; Moyer et al., 2002).

While some studies have showed that since the public health impact is enormous, further research is required on specific issues, because cases of harmful use of alcohol can be effectively attended by well-designed intervention strategies, which are feasible even as employee assistance programs (Kahan, Wilson, & Becker, 1995; Wilk, Jensen, & Havighurst, 1997).

Despite all this evidence, it is generally seen that brief intervention is not widely implemented and attempts to integrate it in regular practice have not been successful, probably because of lack of interest in prevention methods themselves or ineffective marketing strategies Andréason et al., 2000). Whitlock, Polen, Green, Orleans, and Klein also suggested that future research should focus on implementation strategies to facilitate adoption of means of identifying and providing intervention for problem drinkers in routine health care (Whitlock, Polen, Green, Orleans, & Klein, 2004). Roche et al. proposed

that perhaps we have the right vehicle but the wrong driver and that until closer scrutiny is made of this key prevention area it will continue to fail to achieve optimum results (Roche & Freeman, 2004).

CONCLUSION

To conclude, we may say that brief intervention, when provided after appropriate screening procedures, is very effective. This is true even whether it is provided by the primary physician, the health worker, or the nurse. It would go a long way in reducing the burden of ill health on the individual and the society at large at a very minimal cost to the health care system.

APPENDIX

1. CAGE Questionnaire

The CAGE consists of the following four items:

1. Have you ever felt you ought to cut down on your drinking?
2. Have people annoyed you by criticizing your drinking?
3. Have you ever felt bad or guilty about your drinking?
4. Have you ever had a drink first thing in the morning to steady your nerves or get rid of a hangover?

Source: Ewing, J. A. (1984). Detecting Alcoholism: The CAGE Questionnaire. The *Journal of the American Medical Association,* 252, 1905–1907.

2. Questionnaire: Michigan Alcohol Screening Test (MAST)

Sr No		Yes	No
1.	Do you feel you are a normal drinker? (By normal we mean you drink less than or as much as most other people.)		
2.	Have you ever wakened the morning after drinking the night before and found that you could not remember a part of the evening?		
3.	Does your wife, husband, a parent, or other near relative ever worry or complain about your drinking?		
4.	Can you stop drinking without a struggle after one or two drinks?		
5.	Do you ever feel guilty about your drinking?		
6.	Do friends or relative think you are a normal drinker?		
7.	Are you able to stop drinking when you want to?		
8.	Have you ever attended a meeting of Alcoholics Anonymous?		
9.	Have you ever gotten into physical fights when drinking?		
10.	Has drinking ever created a problem between you and your wife, husband, a parent, or other near relative?		

11. Has your wife, husband, a parent, or other near relative ever gone to anyone for help about your drinking?
12. Have you ever lost friends or a partner because of your drinking?
13. Have you ever gotten into trouble at work because of your drinking?
14. Have you ever lost a job because of drinking?
15. Have you ever neglected your obligations, your family, or your work for two or more days in a row because you were drinking?
16 Do you drink before noon fairly often?
17. Have you ever been told you have liver trouble? Cirrhosis?
18. After heavy drinking have you ever had delirium tremens (DTs) or severe shaking, or heard voices or seen things that weren't really there?
19. Have you ever gone to anyone for help about your drinking?
20. Have you ever been in a hospital because of your drinking?
21. Have you ever been a patient in a psychiatric hospital or on a psychiatric ward of a general hospital where drinking was part of the problem that resulted in hospitalization?
22. Have you ever been seen at a psychiatric or mental health clinic or gone to any doctor, social worker, or clergyman for help with any emotional problem, where drinking was part of the problem?
23. Have you ever been arrested for drunken driving, driving while intoxicated, or driving under the influence of alcoholic beverages?
24. Have you ever been arrested, even for a few hours, because of other drunken behavior?

Source: Selzer, M. L. (1971). The Michigan Alcoholism Screening Test: The quest for a new diagnostic instrument. *American Journal of Psychiatry,* 127, 1653–1658.

3. LAST Questionnaire

1. Are you able to stop drinking when you want to?
2. Have you ever felt you ought to cut down on your drinking?
3. Have people annoyed you by criticizing your drinking?
4. Does any near relative or close friend worry or complain about your drinking?

Source: Hans-Jurgen Rumpf, Ulfert Hapke, Andreas Hill, and Ulrich John. Development of a Screening Questionnaire for the General Hospital and General Practices. *Alcoholism: Clinical and Experimental Research*. 1997: 21; 894–898. Blackwell Publishing.

4. Questionnaire: AUDIT-C

1. How often do you have a drink containing alcohol?

Never	Monthly or less	2–4 times a month	2–3 times a week	4 or more times a week

2. How may drinks containing alcohol do you have on a typical day when you are drinking?

1 or 2	3 or 4	5 or 6	7 or 9	10 or more

3. How often do you have 6 or more drinks on one occasion?

Never	Monthly or less	2–4 times a month	2–3 times a week	4 or more times a week

Source: Babor, T. F., Higgins-Biddle, J. C., Saunders, J. B., Monteiro, M. G.(2001). WHO, Department of Mental Health and Substance Abuse. AUDIT—The Alcohol Use Disorders Identification Test: Guidelines for use in primary care. WHO/MSD/MSB/01.6a. Geneva, Switzerland.

5. Questionnaire: AUDIT (Alcohol Use Disorders Identification Test Screening Instrument)

Please circle the answer that is correct for you

1. How often do you have a drink containing alcohol?

Never	Monthly or less	2–4 times a month	2–3 times a week	4 or more times a week

2. How may drinks containing alcohol do you have on a typical day when you are drinking?

1 or 2	3 or 4	5 or 6	7 or 9	10 or more

3. How often do you have 6 or more drinks on one occasion?

Never	Less than monthly	Monthly	Weekly	Daily or almost daily

4. How often during the last year have you found it difficult to get the thought of alcohol out of your mind?

Never	Less than monthly	Monthly	Weekly	Daily or almost daily

5. How often during the last year have you found that you were not able to stop drinking once you had started?

Never	Less than monthly	Monthly	Weekly	Daily or almost daily

6. How often during the last year have you been unable to remember what happened the night before because you had been drinking?

Never	Less than monthly	Monthly	Weekly	Daily or almost daily

7. How often during the last year have you needed a first drink in morning to get yourself going after a heavy drinking session ?

Never	Less than monthly	Monthly	Weekly	Daily or almost daily

8. How often during the last year have you had a feeling of guilt or remorse after drinking?

Never	Less than monthly	Monthly	Weekly	Daily or almost daily

9. Have you or someone else been injured as a result of your drinking?

No	Yes, but not in the last year	Yes, during the last year

10. Has a relative or friend, or a doctor or other health worker been concerned about your drinking or suggested you cut down?

No	Yes, but not in the last year	Yes, during the last year

Chapter **17**

Service Profiles: Provider Choices for Treatment of Alcohol- and Cocaine-Using Clients

Maria Dinis, PhD, MSW, Lyndsay Ammon, MPH,
and Kelly Anders, MAL

A variety of treatment services, including medical, psychological, peer-based, and social services, are available to providers treating alcohol and drug users. These are being offered either alone or in combination with another service. Examples of these services include the following: physician-supervised, hospital-based programs, including pharmacological approaches; nonmedical residential programs such as halfway houses; mental health programs, including individual or group psychotherapy facilitated by counselors, psychologists, social workers, or religious-based clerics; Twelve-Step programs such as Alcoholics Anonymous or Narcotics Anonymous; and the criminal justice or penal system (Gerstein & Harwood, 1990; Institute of Medicine, 1990; Musto, 2002; White, 1998).

This chapter explores whether provider treatment recommendations are related to a disciplinary perspective that varies by provider's work setting and demographic characteristics. Work settings, for example, include alcohol and drug, criminal justice, mental health, hospital and medical, social welfare, and religious. Demographic characteristics of the providers are gender, age, and education level. Specifically, this chapter investigates providers' decisions regarding their treatment choices because these choices may reflect how a client type (e.g., men, pregnant women, and nonpregnant women) is matched to a particular treatment, especially considering complicating factors (such as pregnancy) that may restrict options, and the interplay between the provider work setting and demographics influencing the selection of one treatment method over another.

Earlier work concluded that the "medical" or "disease" model, terms used interchangeably in the literature, is probably the most dominant approach

among specialized treatment providers for treating people with alcohol and drug problems (Brower, Blow, & Beresford, 1989; Institute of Medicine, 1990; Keller, 1990; Leonelli, 1993). The dominant treatment approach of nonspecialized treatment providers is not known for certain. Preliminary research suggests a complex relationship between provider beliefs and model choice for heavy alcohol users (Nunes-Dinis, 1996). When a probability sample of professionals from diverse community agencies (e.g., alcohol and drug, criminal justice, health care, social welfare, mental health, and religious) were asked to select treatment models, respondents tended to answer according to their personal beliefs (e.g., alcohol is a genetic, social, or multiple-cause problem). The only exception was treatment for pregnant women, for whom the medical model was generally considered the optimal treatment approach. Pregnancy status emerged as a better predictor of service model choice than provider professional training or work setting (Nunes-Dinis, 1996).

Both academic researchers and public policymakers seek to better understand what influences professionals' treatment choices for their clients. Currently the variability of the decisions they make in the selection of treatment services is not clearly understood (Fischhoff, 1992; Mitchell, Dyer, & Peay, 2006). For example, factors influencing the delivery of methadone maintenance are reported to vary according to the physician's professional orientation, geographical location, and experience as well as the patient's characteristics such as pregnancy, employment status, appearance, and social support (Mitchell et al., 2006). In addition, the medical specialty of physicians, their practice setting, and their age, gender, race, and social class are known to influence their clinical decision making in the delivery of medical care (Clark, Potter, & McKinlay, 1991; McKinlay, Potter, & Feldman, 1996). The gender, education, and age of providers have also been studied with therapists in relation to client utilization of health services (Crane, Wood, Law, & Schaalje, 2004); to predict the therapeutic alliance between client and therapist in alcohol treatment (Connors et al., 2000); to estimate variations in outcomes attributed to therapists in managed care (Wampold & Brown, 2005); to understand physicians' clinical decision-making processes (Clark et al., 1991), and to give alcohol-related treatment advice to patients by primary care providers (Burman et al., 2004). Understanding the variability in the decisions made by treatment providers may inform policymakers and administrators who are planning and funding alcohol and drug treatment programs (Simpson, 2002; Trentacoste, Holtgrave, Collins, & Abdul-Quader, 2004); enhance the knowledge of ramifications for treatment retention and outcome (Bell, 2000; Mitchell et al., 2006; Strang & Sheridan, 2001); emphasize the need for training treatment providers (Mitchell et al., 2006; Simpson,

2002); and promote technology transfer between researchers and practitioners (Forman, Bovasso, & Woody, 2001; Simpson, 2002).

Several researchers have pointed out the importance of understanding the variation in the decision making of providers choosing either one or a combination of services and why they use particular services with specific populations (Clark et al., 1991; Fischhoff, 1992; McKinlay et al., 1996; Mitchell et al., 2006; Simpson, 2002; Strang & Sheridan, 2001). For instance, does pregnancy status play a role in treatment selection; and does the choice vary depending on provider's own work setting and demographic characteristics? If so, what are the actual treatment choices being made? For example, professionals working in a hospital setting may tend to recommend only inpatient hospital treatment for their clients rather than referring them either to halfway houses, which cost a fraction (13%–17%) of inpatient care and about 50 percent of outpatient hospital-based treatment, or to no-cost self-help groups (Borkman, Kaskutas, Room, Bryan, & Barrows, 1998; Kaskutas, Witbrodt, & French, 2004). Conversely, those working in alcohol/drug treatment programs may recommend a broader range of services that they believe would result in better treatment outcomes for some clients, such as pregnant women (Hankin, McCaul, & Heussner, 2000; Howell & Chasnoff, 1999; Weisdorf, Parran, Graham, & Snyder, 1999).

To further study the question of provider treatment choice, we used Delany et al. (Delany, Broome, Flynn, & Fletcher, 2001) concept of treatment service delivery profiles derived from the Drug Abuse Treatment Outcome Study. This line of research considered the range and type of services offered (i.e., minimal versus comprehensive and inpatient versus outpatient). Our approach is further guided by earlier work that has examined organizational factors such as the academic training of treatment staff, and the types and amount of treatment services (medical, psychological, family, legal, educational, vocational, and financial services) offered to clients who use alcohol or drugs (D'Aunno & Vaughn, 1995; Etheridge, Craddock, Dunteman, & Hubbard, 1995; Etheridge, Hubbard, Anderson, Craddock, & Flynn, 1997; Friedmann, Alexander, & D'Aunno, 1999). This chapter addresses the services that providers would recommend for clients, asking respondents not to be constrained by the services offered in their own work settings. We first determined the dominant treatment recommendations and then used those to develop service profiles for treating alcohol- and cocaine-using men and for pregnant and nonpregnant women. Next, we tested whether provider work setting and demographics are related to their service profile treatment choices and whether some providers are more likely than others to select a single service rather than a combination of services.

METHOD

Sample and Procedure

This is a secondary data analysis of a provider study conducted during 1995 in a Northern California County, the site of the Alcohol Research Group's Community Epidemiology Laboratory (CEL). The CEL county was selected based on a broad cross-section of population characteristics including ethnicity, rural and urban mix, and socioeconomic status. The overall methods and study design have been described in other reports (Room & Weisner, 1988; Weisner, Matzger, Tam, & Schmidt, 2002; Weisner & Schmidt, 1995).

In the provider study, a two-stage probability sample of health and human service providers was drawn in order to be representative of service organizations and staff in the county. This sample of agencies was stratified by the following service sectors: substance abuse treatment, criminal justice, mental health, health care, welfare, and religious organizations. A listing of organizations and individuals in the county was developed by using telephone directory listings, snowballing of agencies' listings, and follow-up phone screening interviews with a provider from each organization. From a listing of 2,390 eligible organizations, 117 stratified agencies by service sectors were randomly selected. A simple random sample of physicians and psychotherapists was drawn from a separate listing. Permission was obtained to interview providers in the 117 organizations and a list was developed of all direct service professionals working at least half time. Individual providers were sampled proportionate to the size of the organization. Service providers were the units of analysis.

Of the total 610 solo and agency providers, 73 percent were interviewed (N = 457). The response rate was calculated by multiplying the number of eligible participating agencies (66/75) by the number of eligible respondents (457/549) who completed the interview (see Nunes-Dinis, 1996). Fifty-eight percent of the providers responding were female (n = 265). About two-thirds were married or living with a partner. More than half of the providers were under 45 years of age. Approximately half of the sample completed graduate education at the master's or doctoral level, 17 percent were college graduates, and 33 percent had less than a college degree.

Weights (ranging from .04 to 2.29) were calculated to adjust for nonresponse bias and for design effects due to stratification at the first stage of sampling and varying selection intervals at the second stage. Those weights were representative of the actual proportion of different kinds of providers working in the stratified service sectors (Gassman & Weisner, 2005; Nunes-Dinis, 1996).

Measures

Six hypothetical vignettes were presented to service providers in order to obtain their treatment recommendation for each distinct group: (1) a heavy-drinking pregnant woman, (2) a cocaine-using pregnant woman, (3) a heavy-drinking nonpregnant woman, (4) a cocaine-using nonpregnant woman, (5) a heavy-drinking man, and (6) a cocaine-using man. Each vignette instructed the provider to assume the client was white, single, 30 years of age, and had no money constraints (see Table 17.1 for example of a vignette). A heavy drinker was defined as someone who drinks five or more drinks in one sitting at least once a week, and a cocaine-using person was defined as someone who uses cocaine regularly. For each scenario, providers were given a list of nine possible treatment services: (1) hospital-based alcohol and drug program; (2) Twelve-Step program (Alcoholics Anonymous or Cocaine Anonymous); (3) one-on-

Table 17.1
Example of an Alcohol Vignette

These next questions ask for your treatment recommendation for people with different kinds of problems. First, please think about a pregnant woman who is a heavy drinker—by that I mean she drinks five or more drinks at a sitting at least once a week. Assume she's white, 30 years old, and single. If money were no object, what kind of service would you recommend to help her stop drinking? You'll find the possible answers to this on page 13 (of your booklet).

CODE ALL MENTIONED, WITHOUT PROBING FOR ANY OTHERS.

[ ] Would not recommend any service

(1) Medications like Antabuse or antidepressants to help her stop drinking

(2) Treatment in a hospital-based alcohol program under the direct supervision of a physician

(3) Prevention programs such as health education or community intervention

(4) Some kind of legal sanction—anything from a fine to incarceration

(SPECIFY: _____)

(5) Alcoholics Anonymous or a Twelve-Step program

(6) A stay in a halfway house or some other nonmedical residential program

(7) One-on-one or group psychotherapy

(8) Counseling by a minister, priest, or clergyman

Some other kind of service:

(9) (SPECIFY: _____)

(10) (SPECIFY: _____)

one or group psychotherapy; (4) counseling by a minister, priest, or clergyman; (5) nonmedical residential program (halfway house); (6) medications, such as Antabuse, antidepressants, or beta-blockers; (7) legal sanctions, such as anything from a fine to incarceration; (8) prevention or educational health or community intervention programs; or (9) specify any other kind of service. Providers were asked which treatment service, either only or in combination with other services, they would recommend to treat clients in each vignette.

Initial data analyses of service providers' treatment recommendations were performed by type of substance used (alcohol or cocaine), gender, and pregnancy status (pregnant or nonpregnant). These analyses showed similar service recommendation patterns by substance type and gender but not by pregnancy status. Based on these findings, analyses were then conducted by collapsing alcohol and cocaine users into one substance use variable and creating a dichotomous client grouping variable comprising (1) pregnant women and (2) men and nonpregnant women.

Dependent Variable (Service Profiles)

The most frequently reported services for pregnant women versus men and nonpregnant women were analyzed via reliability tests. Initially, an alpha value of .50 or higher was used to determine what services would be included in the categorization of each service profile. To maximize the total number of providers in each service profile, we included every service they selected. We categorized the four major services selected by providers (i.e., hospital-based alcohol and drug program, Twelve-Step program, psychotherapy, and halfway house) for the two client groups as either (1) recommended alone or (2) recommended alone or in combination with any other services. There were two types of dependent variables used as outcomes throughout the analysis for all client groups—the first included only one service, and the second included the service alone *or* in combination with any other services.

Independent Variables (Demographic Characteristics)

The demographic variables in this study include gender, education (less than a college degree, college degree, or postgraduate degree), age (less than 45 years or 45 years and over) and work setting (alcohol/drug, criminal justice, mental health, health care, welfare, and religious).

Data Analysis

Pearson's chi-square test of association was conducted on all categorical data. We report *p*-values. The chi-square test was conducted *within* each service

profile (and not across service profiles) to meet the mutually exclusive conditions required of categorical variables. The percentages shown in the tables are greater than 100 because providers could select multiple responses (or more than one service profile).

Logistic regression analyses were conducted to discern the best predictors for each provider service profile choice. The service profiles selected by providers were coded to distinguish whether the service was recommended: (1) alone or in combination with any other services versus not at all and (2) as one service profile only versus not at all. The independent variables were coded as 1 and 0. For example, gender was coded 1 for male and 0 for female. The independent variable age was coded using this same pattern (45+ vs. <45). For the independent variables with more than two categories, the comparison group "alcohol/drug" was selected for work setting variable and "less than a college degree" for the education variable. Alcohol/drug was selected as the comparison group because providers in this setting work directly in delivering alcohol and drug treatment services and are regarded as professionals with substance misuse treatment expertise. Providers in other work settings, however, may or may not provide direct alcohol/drug treatment services to their clients other than serving as referral sources. The data analyses were conducted with SPSS Version 6.0 (SPSS, 1996).

RESULTS

Service Profile Recommendations

Table 17.2A shows the top four service recommendations for treating alcohol- and cocaine-using pregnant women, and men and nonpregnant women by provider work setting, gender, age, and education. These four service profiles include: hospital-based alcohol and drug program, Twelve-Step program, one-on-one or group psychotherapy, and nonmedical residential program (halfway house), either alone or in combination with other services.

The majority of providers selected hospital-based treatment for pregnant women (88%) and about one-third recommended a Twelve-Step program. This relationship differed for treating the men and nonpregnant women, with over 60 percent of the providers selecting Twelve-Step programs and over half recommending hospital-based services. A similar proportion of providers (22%–30%) chose psychotherapy or halfway house services to treat both client groups.

Differences in characteristics of providers were found when they chose Twelve-Step for either pregnant women or men and nonpregnant women. Nearly half of the providers in the alcohol and drug setting recommended

Analyses are conducted on weighted data. Percentages do not equal 100 because providers may have selected more than one service profile. Chi-square tests of significance were conducted within each service profile. ns = not significant.

Twelve-Step for pregnant women while less than one-fifth in the criminal justice setting selected this profile ($p < .05$). In addition, proportionately more female compared to male providers recommended Twelve-Step to a pregnant woman ($p < .05$). There were no differences in provider age and education in recommending Twelve-Step programs to pregnant women.

However, providers in a hospital or medical setting were most likely to recommend Twelve-Step programs for men and nonpregnant women, while those in a religious setting were least likely to select Twelve-Step for this population ($p < .001$). Furthermore, female and younger providers were more likely to choose Twelve-Step to treat men and nonpregnant women ($p < .05$). The only remaining significant differences in recommended service profiles were found with more female providers selecting hospital-based and halfway house services ($p < .05$).

One-Service Profile Recommendations

Table 17.2B presents comparisons of providers who selected only one service to treat alcohol- and cocaine-using pregnant women, men, and nonpregnant women. Nearly half of the service providers recommended only hospital-based treatment for pregnant women. Of those providers, over half in the criminal justice, mental health care, and social welfare settings chose only hospital-based treatment, while approximately one-third did so in the alcohol/drug, hospital/medical, or religious settings ($p < .01$). There were no other significant differences in selecting hospital-based treatment for pregnant women. Few providers recommended any other one-service profile for pregnant women.

There were few reports of providers selecting only one type of service to treat men and nonpregnant women. Less than one-fifth of the providers recommended hospital-based or Twelve-Step treatments alone for men and nonpregnant women.

Service Profile Alternatives

In an effort to further understand how providers select services for their clients, we next considered which of the dominant service profiles providers selected if they did not recommend one of the four major profiles. For example, what service did a provider choose who had not selected the Twelve-step profile for men and nonpregnant women? Table 17.3 presents the service profile alternatives to hospital-based, Twelve-step, psychotherapy, and halfway house treatments alone or in combination with any other services chosen by providers for treating alcohol- and cocaine-using pregnant women, men, and nonpregnant women. Few providers did not select the hospital-based service profile

for pregnant women (n = 53). Among those few, at least one-quarter recommended psychotherapy, Twelve-step, or a halfway house treatments. Although 301 providers did not select Twelve-step programs for pregnant women, 88 percent reported they would choose hospital-based treatment. A similar trend was found for those providers who would not recommend sending a pregnant woman to psychotherapy or a halfway house.

Approximately 70 percent of the providers did not select psychotherapy, while 68 percent did not choose a halfway house for men and nonpregnant women. Over half of those providers thus recommended Twelve-step and hospital-based treatment.

Service Profile Predictors

Logistic regression analyses were conducted to determine multivariate predictors of service profile choice (Tables 17.4A and 17.4B). Of the 202 providers who recommended only the hospital-based program for pregnant women compared to those in the alcohol and drug setting, providers in the criminal justice (odds ratio [OR] = 3.12, $p < .01$) and mental health (OR = 1.90, $p < .05$) settings were more likely to select this service. Additionally, male compared to female providers had 0.60 times the odds of recommending only the hospital-based service. Compared to those with less than a college degree, providers with a college degree were more likely to choose hospital-based services alone, and postgraduates were more likely to select both hospital-based and psychotherapy services. Providers who work in the criminal justice (OR = 0.29, $p < .01$), mental health (OR = 0.52, $p < .05$) and social welfare settings (OR = .41, $p < .05$) compared to those in an alcohol and drug setting were less likely to recommend Twelve-step alone or in conjunction with other services. A similar trend was seen for recommending halfway houses for pregnant women.

For men and nonpregnant women, providers in criminal justice, mental health, social welfare, and religious settings were more likely to select hospital-based treatment alone compared to providers in an alcohol and drug setting (OR = 7.68, $p < .001$; OR = 5.30, $p < .01$; OR = 6.36, $p < .001$; OR = 5.27, $p < .01$; respectively). No other significant differences arose for recommending only hospital-based treatment. Twelve-step alone was more likely to have been recommended by providers in the criminal justice system (OR = 3.03, $p < .05$) and the hospital/medical field (OR = 2.55, $p < .05$) compared to those in the alcohol and drug setting. Psychotherapy services were twice as likely to be selected by postgraduates compared to those with less than a college degree. Finally, providers in the alcohol and drug setting were more likely to choose

DISCUSSION

We found that providers selected four dominant services to treat alcohol- and cocaine-using women (pregnant and nonpregnant) and men: hospital-based, Twelve-step, psychotherapy, and halfway house treatment. For pregnant women, providers selected primarily hospital-based treatment followed by Twelve-step programs, whereas for men and nonpregnant women this service profile preference was reversed. In contrast, selection of psychotherapy and halfway house services did not appear to be associated with the client group.

Service Profile Selection: Are There Differences across Provider Work Setting?

There is evidence that providers in alcohol and drug treatment settings have a different decision-making framework than other providers when selecting service profiles for pregnant and nonpregnant clients. For example, criminal justice and mental health providers were two to eight times more likely than those working in alcohol and drug programs to select hospital-based treatment as the only service profile for all client groups. There may be several reasons for this outcome. For instance, prior referral agreements may be in place; providers may perceive that hospital-based treatment represents a best practice or more effective treatment modality; or providers may assume that a hospital environment provides a more intensive level of patient care. The recommendation of hospital-based treatment for pregnant women may also be related to a variety of health concerns and legal issues. These issues may include the availability of prenatal care in the hospital setting, a decreased likelihood of legal intervention for the pregnant mother, and potential liability issues for the providers who fear medical complications coupled with potential negative birth outcomes (Finkelstein, 1993, 1994; Weisdorf et al., 1999).

Although 70 percent of the providers did not recommend Twelve-step at all for pregnant women, criminal justice and hospital/medical providers in non-alcohol/drug treatment settings were more likely than those working in the alcohol/drug treatment sector to select Twelve-step-only services for men and nonpregnant women. These providers may not think that formal treatment contributes greatly to the resolution of client alcohol or drug problems. These results are consistent with arguments made by Weisner et al. (Weisner, McCarty, & Schmidt 1999) regarding the disconnection between expectations of referral sources, like the criminal justice system and the workplace, versus those of treatment programs. Providers who are only in the treatment system may have a better appreciation for the limits of hospital-based treatment,

especially pertaining to provision of wraparound services that would address client's criminal behavior or absenteeism—the very issues that are paramount to criminal justice providers. Treatment providers also recognize the need for ongoing social support following a hospital-based treatment episode and thus tend to also recommend Twelve-step programs for all client groups.

In addition, several groups of providers were less likely than alcohol/drug treatment staff to recommend Twelve-step for men and nonpregnant women (religious setting) or for pregnant women (criminal justice, mental health, and social welfare). This may reflect a perception of Twelve-Step as giving too much authority, control, and responsibility to the client. This is consistent with our companion finding that criminal justice and hospital/medical providers are more likely (than treatment providers) to recommend Twelve-Step-only for nonpregnant clients. Since Twelve-Step services are free, these providers may be considering the following as relevant when pregnancy is not an issue: financial barriers to receive health services (Friedmann et al., 1999), insurance problems (Friedmann, D'Aunno, Jin, & Alexander, 2000; Greenfield et al., 2004), and growing evidence that client participation in self-help groups increases their abstinence rates from drugs and alcohol (Bond, Kaskutas, & Weisner, 2003; Humphreys et al., 2004; Humphreys & Moos, 2001).

One final revealing finding in terms of work setting difference between treatment system workers and those in other settings is the apparent reluctance of nontreatment staff to recommend halfway house services for all client groups. This may be a result of philosophical and professional differences. The providers working in the alcohol/drug setting, especially staff in halfway houses, are often individuals in recovery themselves who may be influenced by the principle of Twelve-Step programs that recovering alcohol/drug users are the best persons to help those with alcohol/drug addiction issues (Borkman et al., 1998). The medicalization and professionalization of substance abuse treatment does not favor the selection of peer-based halfway house treatment because medical intervention and licensing requirements transfer authority "from experiential knowledge to clinical training" (Borkman et al., 1998, p. 12). Providers may have selected halfway house services less often because they viewed these services as suitable only for some of their clients. For example, halfway house programs tend to serve low-income and minority populations (Borkman et al., 1998), so providers may select these programs less often for their middle-class clients with insurance. In addition, providers may be concerned that alcohol clients with a higher education level than peers or the staff may not view their authority or experiential knowledge with legitimacy (Borkman et al., 1998).

While outside of the alcohol/drug setting there was this lack of popularity of halfway house treatment, 12 percent of those within the treatment sector

selected halfway house as the only service profile for men and nonpregnant women. About one-quarter of the providers in our sample recommended halfway house services for pregnant women, a finding similar to Grella's (1999) study that found a higher proportion of pregnant women in women-only residential drug treatment programs and that service providers were more likely to refer pregnant than pregnant women to residential drug treatment. The preference for residential treatment of some sort was also reported in Howell and Chasnoff (1999). Taken together, these studies indicate a perceived need to remove pregnant substance-using women from their social and physical environment. More research is needed to further judge the apparent reluctance to recommend halfway houses.

Do Provider Demographics Predict Service Profile Choice?

We found that the demographic characteristics of providers were important in predicting their selection of service profiles. In the bivariate analysis, there were small but significant demographic differences of 10 percent more female than male providers selecting hospital-based, Twelve-Step, and halfway house services. In the multivariate analysis, male providers were less likely to recommend only the hospital-based service to treat pregnant women. The influence of provider gender has been studied and found to be the most important variable in relation to medical ethical decision making (Wertz, 1994). Wertz reported that female geneticists were less authoritative, more perceptive, and more compliant with patient requests than male geneticists. Provider gender has also been examined in regard to client satisfaction with community mental health services (Vetter, 2003) and how male and female service providers prioritize ethical dilemmas differently when selecting vocational rehabilitation services for persons with disabilities (Baker, 1996). As client demographic characteristics have often been used to understand and explain the potential reasons for their alcohol and drug treatment outcomes (Craddock, Rounds-Bryant, Flynn, & Hubbard, 1997; Simpson, 2003, 2004; Simpson, Joe, & Brown, 1997), provider gender also seems to influence the selection of alcohol and drug treatment services.

Similarly, provider age and level of education were significant in predicting their selection of service profiles. Providers 45 years of age or older were less likely to select halfway house services, and individuals with higher education were more likely to recommend hospital-based and psychotherapy services. Older providers and those with college degrees may be in higher-level management positions that require following agency dictates. For example, in some work settings such as the criminal justice, protocols may require providers to

refer clients medically before suggesting other service options. Ogborne et al. (Ogborne, Braun, & Schmidt 1998, 2001) have argued that research is needed on the characteristics of service providers (e.g., education) so that such information is available for the increased demands associated with establishing standards of care and accountability, having baseline data on treatment providers to monitor changes, and planning agency certification and professional development opportunities. Our research findings suggest that provider characteristics have intrinsic value as well, in that they predict service recommendations.

Limitations

The study limitations include: (1) limited generalizability; (2) a hypothetical whites-only client group; (3) categorization of the service profiles; and (4) age of the data set. This study is difficult to generalize because it examines a single U.S. county. However, the alcohol and drug problems and treatment policy of this county are similar to others throughout the United States; it has been used for the CEL studies and the U.S. site for the World Health Organization's Study of Community Response to Alcohol (Greenfield & Weisner, 1995; Weisner, Delucchi, Matzger, & Schmidt, 2003; Weisner & Schmidt, 1995). Issues of generalization have been previously addressed by testing measures and conducting comparisons with other national databases such as the National Alcohol Survey, the National Drug and Alcohol Treatment Utilization Survey/ Uniform Facility Data Survey, and the National Household Survey on Drug Abuse (see Greenfield & Weisner, 1995; Weisner et al., 2003).

The hypothetical treatment groups in this study were composed solely of white clients, which limits the generalizability of this hypothetical client. In future studies, hypothetical vignettes should include ethnically diverse clients in order to examine the potential effect of ethnicity on provider profile selection. This study was limited to vignettes about one racial group because the sample size (i.e., 457 providers across 10 strata was too small to incorporate additional vignettes).

Although the services recommended by providers were grouped according to the number of times they selected that service, this categorization may constitute a faulty classification scheme of the service profiles that may raise construct validity issues. Treatment in a hospital-based alcohol and drug program or some other nonmedical residential program also includes components of other services such as individual or group psychotherapy. The implications of incorrectly classifying profiles are serious because providers may recommend one type of service and consider it to be inclusive of all treatment components. For example, providers may not have selected psychotherapy as frequently as

other services because they consider that service already included in either hospital-based or nonmedical residential treatment programs.

Finally, the provider study data were collected more than 10 years ago. Since then, there have been changes in the treatment system and in the development and testing of new therapeutic approaches that may influence how providers would now recommend services. For instance, the current dominant setting for alcohol and drug treatment (more than 85%) is outpatient (McLellan, McKay, Forman, Cacciola, & Kemp, 2005; Substance Abuse and Mental Health Services Administration, 2002; Weisner et al., 2000). Furthermore, the number of uninsured individuals continues to climb (Fong, 2003; Wu, Kouzis, & Schlenger, 2003), and for the privately insured, alcohol and drug treatment under managed care reforms has become less intensive with the use of more group, episodic, and brief therapies (Oggins, 2003). Treatment therapies (Twelve-Step facilitation, cognitive-behavioral, and motivational enhancement), including medications such as naltrexone and acamprosate, have also been tested in clinical trials showing similar reductions in alcohol use from baseline to follow-up (Fiellin, Reid, & O'Connor, 2000). This may give providers treatment options to choose depending on what is locally available. Another therapeutic approach, the strengths perspective, which therapists utilize to empower clients in learning how to identify and build on their internal and external capacities to manage social problems, is used and has been recommended by social workers since the late 1990s to treat clients in addiction treatment (Saleebey, 1992, 2002; van Wormer & Davis, 2003). These changes may have an effect on provider selection of treatment services.

Implications

In general, providers in this study primarily selected four service profiles to treat all client groups. Clearly, one service was not considered adequate or custom-built for providers to treat clients. For those few providers recommending only one service, in consideration of the complex nature of many client alcohol and drug problems, we may need to develop training opportunities in treatment facilities and professional schools that emphasize the advantages of providing multiple services. Even though some providers may only offer referrals to clients for treatment services, their knowledge of viable and multiple treatment options is an important educational training goal in augmenting the service delivery alternatives recommended for clients. Further research is needed to examine why some providers select services within and outside of their own work setting. This will enhance our understanding of professionals' use and development of coordination of services across disciplines, including issues of

turf battles. Additionally, it is important to examine the role that client type or provider demographic characteristics plays in the selection of alcohol and drug treatment services. Such considerations may lead to the provision of appropriate gender-specific treatment services and to the development of curriculum opportunities and career planning advisement in professional schools as well as in treatment training programs.

A combination of survey and qualitative (e.g., in-depth interviews) research is needed to uncover provider motivations and intentions in treatment decision making, and to elucidate the processes by which past professional and personal experiences play a role in the variety of services selected to effectively treat alcohol/drug-using clients. To better understand the reasons why providers selected specific services for different client groups, future research should illuminate some of the questions currently inside the black box of treatment.

Acknowledgments

The authors wish to acknowledge Lee Kaskutas for support and mentorship on this project, and Connie Weisner, Lois Lowe, Enoch Haga, and Joseph Merighi for helpful comments on earlier drafts of this chapter. Preparation of this chapter was supported by National Institute on Alcohol Abuse and Alcoholism (NIAAA) (R01-AA005595-11) and California State University, Sacramento, Research and Creative Activity Award Program. Chapter presented at the Kettil Bruun Society, Social and Epidemiological Research on Alcohol: 31st Annual Symposium, May 30–June 3, 2005, Riverside, California.

Chapter **18**

An Innovative Approach to Prison-Based Substance Use Treatment: The Implementation of Inmate Peer Mentor Programs

Jana Cook, MD, PhD, Scott E. McClure, PhD,
Igor Koutsenok, MD, MS, and Scot Lord, CATC, FACT

SUBSTANCE USE AND INCARCERATION

The United States currently maintains the largest prison population in the world. Over the past 30 years there has been a continuous increase in the number of inmates in U.S. state and federal prisons. The 2006 Bureau of Justice Statistics figures illustrate that nearly 1.6 million inmates occupy our nation's federal and state prisons. California leads the nation's population totals with 175,512 inmates, rivaled only by Texas, which hosts 172,116 inmates. During 2006, the prison population grew at an alarming rate of 2.8 percent from 2005, making it the fastest rate of growth in the past five years.

The relationship between substance use and criminal incarceration is an undeniable factor in the nation's prison crisis. The 2003 Arrestee Drug Abuse Monitoring Program (ADAM) report identified that nearly 74 percent of all male and female offenders tested positive for either drugs or alcohol. Due to the high prevalence of substance use disorders among criminal offenders, rigorous efforts to develop effective treatment interventions have occurred. Significant advances in addiction treatment methods and research have lead to substantial progress in the identification and implementation of evidenced-based addiction treatment practices, which are essential for the continued growth and improvement of prison-based addiction treatment (Friedmann, Taxman, & Henderson, 2007).

PRISON-BASED THERAPEUTIC COMMUNITY TREATMENT

The therapeutic community (TC) is identified as a highly effective evidence-based treatment model for incarcerated individuals with substance use disorders (Pearson & Lipton, 1999; Welsh, 2007). The TC is defined as a long-term, highly structured, hierarchical, intensive behavioral modification treatment model. TCs are drug-free, mostly residential treatment environments that foster increased levels of personal and social responsibilities, primarily through peer influence. The TC model utilizes a variety of group processes to help individuals learn and assimilate prosocial norms, values, skills, and behaviors. The TC comprises a mix of professional staff and peers, with the primary agent of change being the norms and rules of the community. The treatment process is focused on overlapping areas of personal development that include: behavioral modification; emotional/psychological development; intellectual and spiritual growth; vocational/educational growth; life coping skills; and biomedical management if needed.

Meta-analytic reviews have identified the TC as an effective model to reduce recidivism rates for incarcerated individuals with substance use histories (Aos, Miller, & Drake, 2006; Lipton, Pearson, Cleland, & Yee, 2002). The addition of postrelease continuing care has been shown to further reduce recidivism rates compared to untreated control groups and in-prison-treatment-only groups with no continuation of care (Knight, Simpson, & Hiller, 1999; Martin, Butzin, Saum, & Inciardi, 1999; Wexler, Melnick, Lowe, & Peters, 1999). While the majority of the literature highlights the necessity of aftercare following in-prison TC treatment for successful reductions in recidivism and reduced relapse potential (Inciardi, Martin, & Butzin, 2004; Knight et al. 1999; Martin et al., 1999; Messina, Burdon, Hagopian, & Prendergast, 2004; Wexler et al., 1999), there is evidence that prison-based TC treatment can effectively reduce recidivism rates independent of continuation of care postrelease (Prendergast, Hall, Wexler, Melnick, & Cao, 2004). Most recently, Welsh (2007) examined the two-year postrelease treatment outcomes across five Texas prison-based TC programs and identified that TC treatment significantly reduced rearrest and reincarceration rates compared to treatment control groups that consisted of a mix of psychoeducation, peer-led ancillary support groups, and drug and alcohol education programs. Most importantly, these results were maintained without continuation of care postrelease and may lend support to the fundamental TC principle that the power of the community is the agent of change.

CHALLENGES WITH PRISON-BASED TC TREATMENT PROGRAMS

Clearly the TC is an effective treatment model for incarcerated individuals with substance use disorders; what is less clear are the discrepancies in treatment effectiveness found across treatment programs. One potential explanation for differences in treatment outcomes may be an inconsistency of treatment programming, which often leads to a modification of the evidence-based model. The rapid increase of TC implementation in corrections-based treatment has lead to deviations from the original model to meet the specific needs of the institutions providing treatment. These needs are affected by the diversity of the population being treated, mixing the general inmate population with the treatment population, limited resources for treatment implementation resulting in efforts to reduce treatment costs, and institutional demands such as overcrowding and limited availability of qualified staff for both corrections and treatment. Unfortunately, these modifications usually result in less intensive programming schedules, curriculum-driven treatment, and staff that is not adequately trained to deliver services as demanded by the evidence-based model. These modifications to the original evidence-based model can place limitations on the ability to effectively utilize essential TC components, which ultimately eliminate the core principle of the community as the agent of change, the critical component that drives the TC model (Saum et al., 2007).

Modifications to the evidence-based model hinder the ability of researchers to identify the effective components of TC treatment. Simultaneously, modifications that have not been adequately tested to demonstrate effective treatment may result in reduced quality of treatment. Other dilemmas for effective TC treatment implementation include obstacles such as frequent staff turnover, often influenced by salaries that are not adequate for the cost of living in some regions, as well as burnout due to individuals working with a demanding population and a lack of adequate training and experience. Farabee et al. (1999) identified the recruitment and training of treatment staff as one of the major common barriers to developing effective correctional treatment. This theory has persisted for nearly a decade and was recently revisited in the February 2007 Inspector General's Report (Cate, 2007), which identified the implementation of treatment as a current failure of our system rather than a lack of effective treatment models.

The University of California Los Angeles (UCLA) noted in its evaluation report of in-prison treatment programs that providers in rural areas have difficulties locating and hiring staff with previous training and experience in the

therapeutic community treatment model (Prendergast, 2002). Limited staffing pools and high turnover rates among the substance abuse treatment counselors have led to problems in maintaining quality and continuity in treatment services. The importance of variables related to effective treatment counselors seems to be underestimated and is insufficiently represented in the literature (Wormith et al., 2007).

In a typical TC, clients and staff make up the community, creating a social environment in which peers and staff represent role models of successful personal change and serve as guides to the recovery process. In order to stimulate an effective treatment process, it is crucial to address the treatment delivery system. One solution to the maintenance and retention of qualified staff in areas with limited applicant pools of qualified treatment staff is to hire and train individuals who were successful participants in prison TC treatment. Unfortunately, the limited acceptability of hiring individuals in recovery and ex-felons makes the situation even more difficult. Although the original TC model supports the use of recovering addicts as staff (DeLeon, 2000), it is very difficult and often impossible to hire ex-offenders, primarily because of the internal policies of many correctional institutions.

DEVELOPMENT OF A PEER MENTOR–FACILITATED TC

An alternative and promising strategy for effective treatment delivery in a difficult-to-staff correctional environment is to recruit and train inmates with long prison sentences as peer counselors and mentors. This strategy would eliminate staff turnover issues and allow the TC to operate as a 24-hour continuous treatment environment as the original model intended. Furthermore, well-trained recovering inmates are likely to be more capable of establishing credibility and demonstrating understanding compared to hired treatment staff with little or no background in substance use treatment. In addition, long-sentenced inmates are active participants in both the TC and prison in general, which bring back a model of treatment more like the original TCs that were entirely peer driven (DeLeon, 2000).

The successful implementation of inmates as peer mentors has already taken place at the Amity prison-based TC project, established in 1990 at Richard J. Donovan (RJD) state prison in San Diego. Specially trained and supervised lifer mentors ensured 24-hour support of the TC culture and environment beyond the working hours of treatment staff (Prendergast et al., 2004), thus enhancing the power of community.

In October 2006, the California Men's Colony (CMC) prison in San Luis Obispo, faced with staff recruitment and retention difficulties, decided to uti-

lize long-term sentenced inmates as peer mentors to lead their prison-based TC program. Prior to this decision, several attempts to utilize contracted treatment providers from within the state as well as one out-of-state treatment provider had failed. This protracted struggle inspired the correctional counselor III (George Freitas) to use the human resources available, inmates with long prison terms. Mr. Freitas recognized that there was a large pool of participants in need of treatment services as well as a valuable resource of peer-mentor inmates with long-term sentences who had previous experience in TC treatment. Some of these participants had a history of active involvement in prison-based TC treatment that stretched back over 15 years, and their experience with the TC model was unquestionable. Mr. Freitas approached the California Department of Corrections and Rehabilitation (CDCR) with a proposal to begin the implementation of a new type of program, a program in which peer mentors would provide substance abuse treatment under close correctional and clinical supervision. CDCR accepted the proposal, and the CMC Substance Abuse Treatment Program "Our House" became the first custody-based TC program within CDCR entirely run by peer mentors, independent from any outside treatment providers.

TRAINING THE PEER-MENTOR FACILITATORS

Upon program approval, the Office of Substance Abuse Programs (OSAP) requested that the mentors receive the most comprehensive and highest level training possible. The University of California San Diego (UCSD) Center for Criminality and Addiction Research, Training, and Application (CCARTA) has long held the responsibility of training all California state in-prison treatment staff in substance abuse treatment and was therefore recruited to train the peer mentors. UCSD provides a Work Force Development (WFD) training series that features 155 hours of comprehensive substance abuse treatment curriculum, including a 30-hour cross training in which treatment and custody professionals strive to improve their working relations through team-building and problem-solving exercises. The training is fully compatible with the instruction given to outside providers and is designed to fulfill the educational requirements of the nationally accredited Forensic Addictions Correctional Treatment (FACT) certification program.

UCSD CCARTA delivered the full curriculum directly to the peer mentors on-site at CMC over the course of five months, which began in February 2007, and finished in June 2007. In addition to UCSD training materials, the peer mentors were provided with publications from the Substance Abuse and Mental Health Services Administration's (SAMHSA) Treatment

Improvement Protocol (TIP) and Technical Assistance Publication (TAP) series of books. The inmates were noticeably well-studied and enthusiastic to learn new material. Following each training session, the trainees completed a written test to ensure they met the highest standards of competency. The cross training proved to be a particular highlight of the series as correctional officers and peer mentors participated together in the 30-hour training. This provided a unique experience in which correctional officers and inmate peer-mentor trainees worked cooperatively to learn how to support one another in the common goal of collaboratively producing positive treatment outcomes.

Following completion of the Work Force Development training, the Orange County Department of Education (OCDE) joined the CMC Our House TC program to help supervise and manage program logistics such as providing materials needed to run the community, curriculum arrangement, and liaison services between custody and peer mentors. OCDE staff is composed of qualified professionals in the delivery of alternative education for youth and adults who have an established working relationship with CDCR. Their staff also attended CCARTA WFD trainings to enhance their understanding of substance use treatment in correctional settings but did not stand in as replacement counselors in an effort to allow the community to remain peer driven. In other words, the OCDE plays an important role in supporting the community's structural and educational needs but does not provide clinicians or counselors.

THE OUR HOUSE TC TREATMENT PROGRAM

The Our House treatment program is an inmate peer-mentor-facilitated multiphase treatment continuum grounded in the TC treatment approach. It adheres to the TC model by holding daily process groups, diverse subject matter curriculum groups, community celebrations and ceremonies, and community meetings designed to recognize and address positive and negative behaviors displayed by participants.

The curriculum includes information on the development of employment skills (i.e., job search resources, resume writing, interviewing skills); life skills (i.e., decision making, effective communication, building healthy relationships); and education on relapse prevention strategies, appropriate parenting techniques, introduction to computer literacy and information technology, as well as functional financial strategies such as budgeting and credit restoration.

It is important to mention that the phase progression process (or lack of such) for each participant is based entirely on behavioral indicators as identified by the community. This process is more in line with the original TC model, rather than phase transition based on time enrolled in the program, which is

unfortunately the common determinant for phase progression in most of the California prison-based TCs. Overall, the program is designed to facilitate comprehensive behavioral modification toward prosocial norms, a core function of any TC program.

The first phase of the Our House TC program is orientation. It is facilitated by two of the most seasoned TC peer mentors, each with more than 15 years of experience in the model. During the orientation phase, participants learn the basic principles of a TC, how it operates, and how they can benefit from being a part of it. Participants are also instructed in what behaviors are deemed appropriate and inappropriate within the community as well as the range of reinforcements for prosocial behaviors and the consequences of negative actions. During this phase, participants are informed of the community expectation of sharing personal experiences as a method to enhance personal growth.

Following completion of the orientation phase, participants progress to the second phase of treatment, called "breaking barriers." During this phase, peer mentors guide participants toward an increased understanding of the group process, their personal process, emotional maturity, and coping strategies for counterproductive emotional states with the aid of the Our House program breaking barriers group. For some participants, this is their first exposure to the group process, so the peer mentor's role is to safely guide them toward an understanding of this process as well as train them in enhanced communication skills and healthy boundaries.

The third treatment phase, alternatives to violence, requires an increased expectation for TC participants to demonstrate critical analysis of their behavior and increased motivation for change. During this phase, peer mentors progressively challenge participants' behaviors to create a safe and supportive environment within a culturally diverse group. This is particularly important because prison settings in California actively participate in racial segregation and inmate participants often have difficulty with emotional expression. A blend of nondirective and interactive forums guided by the alternatives to violence and life skills curriculum, process groups that utilize a "here and now" focus for the exploration of emotions and related behaviors, are used to achieve these goals.

The final in-prison treatment phase, prerelease, is focused on preparation for parole. It addresses such subjects as continuing education, employment skills, and financial literacy. In order to minimize postrelease-related stress, peer mentors address the following issues with the participants: (1) Is the participant ready for transition? (2) Is the participant prepared to get a job and maintain it? (3) Does the participant have a safe support system (including continued care) in place? Each participant develops a personal postrelease plan, which is discussed and scrutinized within the community. The maturity and

supportive structure of the community during this phase offers participants a safe environment to talk about the pressing issues and anxieties associated with the transition to parole.

During the prerelease phase, participants are given the option to attend the Truck Driving Academy (TDA). The TDA is a widely accepted and successful truck driving program equipped with state-of-the-art simulators, software, and projectors. The TDA offers quality instruction and curriculum and provides participants with the opportunity to pass a written truck driving exam. This truck driving course is currently the only one of its kind in California, and completion provides each graduate with a new employable skill upon parole.

CONCLUSION

In times of organizational change within prison-based substance abuse treatment programs, the ability to provide cost-effective, professional, and evidence-based treatment is essential. The recent development and implementation of the peer-mentor-facilitated Our House TC program may present a solution to some of the barriers that limit the success of prison-based addiction treatment.

The concept of the mentor has ancient origins as described in the classic Greek epic poem Homer's *Odyssey* when Odysseus left his young son in the care of a companion named Mentor. Today, peer mentors remain a valid and irreplaceable component of addiction treatment. Mentoring is the process by which an older (or more experienced) person counsels and guides a younger (or less experienced) person in the needed skill set. The mentor serves as a protector, coach, and counselor.

Through critical self-examination and strategic planning, the peer-mentor-facilitated Our House TC treatment pilot project will continue to evolve. Since its establishment in October 2006, the program has demonstrated an exceptional ability to influence participation in postrelease continuing care. From September 2007 to February 2008, the Our House TC treatment program reported mean postrelease aftercare rates of 81 percent, a rate far higher than all other prison-based TC programs in the state (G Freitas, personal communication, July 28, 2008). If this trend continues, it may demonstrate an effective model for increased post-release aftercare, a variable shown time and again to be instrumental for reduced recidivism.

Chapter **19**

Advances in Corrections-Based Treatment: Building the Addiction Treatment Workforce

Igor Koutsenok, MD, MS, and Scott E. McClure, PhD

BIASES AND PRECONCEPTIONS AS BARRIERS TO EFFECTIVE TREATMENT IN CORRECTIONAL SETTINGS

The relationship between substance use and criminal incarceration is an undeniable factor in the nation's prison crisis. The 2003 Arrestee Drug Abuse Monitoring Program (ADAM) report identified that nearly 74 percent of all male and female offenders tested positive for either drugs or alcohol. Because of the high prevalence of substance use disorders among criminal offenders, rigorous efforts to develop effective treatment interventions have occurred. Over the past 20 years there has been substantial growth in addiction treatment research for criminal offenders (Friedmann, Taxman, & Henderson, 2007). In the past decade efforts to implement research into practical application has made tremendous progress and has identified the utilization of evidence-based practices as an essential factor for the improved quality of treatment in correctional settings (Friedmann et al., 2007).

Advances in neuroscience, brain imaging, molecular neurobiology, and the behavioral sciences have significantly enhanced our understanding of addictive behaviors and their treatment (Koutsenok, Deitch, Marsolais, & Franc, 2004). Regardless of these advances, there remains an unfortunate gap between the scientific research and its implementation in correctional treatment settings. One barrier to the implementation of evidence-based principles in correctional treatment programs is that many addiction treatment counselors trained to

work in correctional environments come with preconceived biases of what works in treatment. These biases are most often based on personal experience, previous training experiences, varied expectations, professional orientation, personal beliefs about addiction, and an overall lack of knowledge about addiction and treatment, especially for offender populations. In addition, many addiction treatment counselors are in recovery themselves and have been heavily influenced by the treatment models that made their recovery successful. Unfortunately, these biases are rarely evidence-based or scientifically driven, often resulting in a resistance to utilize scientifically proven treatment strategies under the premise that their way is the only way (Leshner, 1997). This attitude can have a detrimental influence over treatment delivery, especially if it remains with individuals as they advance into leadership positions and permeate their views throughout treatment staff.

In addition to treatment biases shared by addiction treatment professionals, there are also many common counterproductive beliefs held by custody staff, such as: "nobody gets better," "they don't deserve treatment anyway," and that treatment professionals are an additional threat to prison safety as they may participate in illegal activities with inmates or are obstacles in the way of correctional staff maintaining order. These biases can serve as major obstacles for treatment as they increase tensions between corrections and treatment staff, and they are an unfortunate side effect of the misperceptions of job duties and functions of both correctional and treatment staff.

Biased attitudes in addiction treatment can arrest the development of effective treatment implementation. This is especially problematic in correctional treatment programs where offender treatment needs are escalated because of stressors unique to the prison environment. These stressors include so-called prison yard politics, lockdowns, prison guard interactions, lack of social and familial support, and often increased incidents of violence compared to civilian environments. The consequences for not implementing treatment principles proven to work in correctional settings include programmatic failure, increased recidivism rates, and stressful work environments for staff who are trained in evidence-based principles during professional trainings but are not supported by leadership when they make attempts to implement these principles. As a result, many treatment professionals adopt a business as usual attitude, which is unacceptable in our current system, where recidivism is the norm. By far, the largest consequence is a failure to effectively change the addictive behaviors of offenders. This failure contributes to the revolving door of offender recidivism, leaving society to pay the consequence for those who resist the implementation of scientifically proven addiction treatment principles.

DEVELOPING THE MODERN DAY ADDICTION TREATMENT COUNSELOR

The need for well-trained addiction treatment counselors was recognized as early as the 1960s when most physicians, psychologists, psychiatrists, and social workers did not want to be involved with substance use treatment (Mustaine, West, & Wyrick, 2003). In the early 1970s the Comprehensive Alcohol Abuse and Alcohol Prevention, Treatment, and Rehabilitation Act was passed by Congress, which resulted in large sums of money to be utilized for the treatment of alcohol use disordered patients as well as for the training of treatment staff to implement proper care for this population (Banken & McGovern, 1992). Congress additionally established the National Institute of Drug Abuse (NIDA) and the National Institute for Alcohol Abuse and Alcoholism (NIAAA), which marked the beginning of specialized trainings for the counseling skills needed to treat individuals with substance use disorders (Banken & McGovern, 1992).

The fast-growing and immediate need for substance use treatment counselors and the lack of counselors available limited the field's ability to require formal academic graduate level training of substance use counselors. As a result, the addiction treatment field has relied more heavily on counselors' education and experience, which is primarily gained through workshops, training seminars, or college courses as well as two to three years of experience working in the field under the guidance of experienced counselors (Mustaine et al., 2003). In an attempt to develop a minimum standard for the training and education for addiction treatment counselors, addiction treatment certifications were developed. The immediate need for addiction treatment counselors and lack of participation in addiction treatment practices from other professional groups has lead to certification training requirements that remain controversial in regard to the minimal training standards deemed acceptable for certification when compared to the higher academic qualifications needed for other counseling professions (Mustaine et al., 2003).

Regardless of the growing body of evidence that suggests a significant increase in quality of treatment outcomes with increased training and education, the educational requirements for addiction counselor certifying bodies are significantly less than those required by other counseling professions (Mustaine et al., 2003). Though there are some college- and graduate-level addiction treatment specialists in the workforce, the majority of the workforce is composed of adults from various cultural and vocational backgrounds, without college education, and often with personal histories of substance use rehabilitation.

Kerwin, Walker-Smith, and Kirby (2006) performed a comparative analysis of state requirements for the training of substance abuse and mental health counselors and identified that 45 percent of states do not require a college degree to qualify as a substance abuse counselor, whereas 98 percent of states require at least a master's degree to qualify as a mental health counselor. Only one-half of the states require a credential to be qualified as substance abuse counselors compared to 86 percent of states that require a credential to be qualified as a mental health counselor.

The current obstacle of balancing the need for treatment versus the lack of qualified applicants, due to low salaries and often undesirable work locations, hinders the substance use treatment field's ability to hire individuals with the required background and training for optimal treatment outcomes. This is especially true in correctional treatment programs, often located in undesirable areas to live or in areas where the cost of living far exceeds the pay of treatment staff. Unfortunately, these barriers remain despite the growing demands faced by modern-day addiction treatment counselors, who are expected to understand the co-occurring complexities of mental health issues, family dynamics, as well as the gender and cultural differences of the individuals they treat.

Ideally, all addiction treatment professionals working in correctional environments would meet the education and training standards utilized by medical and other professional treatment models. In reality, the need for qualified treatment counselors in correctional settings far exceeds the availability of graduate-trained professionals. This has resulted in the addiction treatment field making its best efforts to develop qualified individuals at the pace of placement need.

Today's addiction treatment counselors are required to understand and utilize the latest evidence-based treatment procedures (motivational interviewing, therapeutic community, cognitive-behavioral therapy, and risk-needs assessment), case management skills, as well as the ability to recognize mental and physical health issues and learning disabilities. Most of these requirements were traditionally performed by master's-and doctorate-level clinicians with much more education and training. These increased expectations and demands have led the addiction treatment field to look to the scientific communities of university's and other professionals to aid in the dissemination of the latest evidenced-based practices and theories needed for the treatment of addiction disorders in correctional settings. The immediate and vast need to disseminate evidence-based addiction treatment for offenders has opened the door to the new and evolving field of professional training for addiction treatment professionals.

TECHNOLOGY TRANSFER AND BARRIERS TO SUCCESSFUL KNOWLEDGE DISSEMINATION

The promotion and adoption of evidence-based practices and state-of-the-art addictions research is essential for the improvement of frontline addiction treatment (Addis, 2002). Current approaches to disseminate advances in scientific research, such as conference presentations and journal articles, are geared mostly toward academia and not frontline addiction treatment staff. Even though evidence-based principles are often translated into manuals or practice guidelines, this process does not guarantee the actual implementation or behavioral change by providers in correctional settings. Likewise, addiction treatment agency leaders may be quick to adopt new practices without taking into account the fact that frontline addiction counselors may lack the education and training needed to successfully implement these practices. In addition, because many corrections-based addiction treatment counselors have not been educated in traditional graduate degree programs, their attitudes about research are often skeptical, leading to a lack of research-practice partnerships and little awareness of the benefits of evidence-based approaches.

The successful dissemination of evidenced-based knowledge into correctional addiction treatment programs depends largely on the knowledge, skills, and attitudes of the organizations and individuals being trained. Though training is an essential tool for technology transfer, it is only one aspect of the overall knowledge dissemination process. Technology transfer involves creating a mechanism by which change is accepted and reinforced at all organizational levels (Addiction Technology Transfer Center Network [ATTC], 2004). In essence, successful technology transfer in corrections-based addiction treatment needs to be designed to develop a sustainable model and mechanism for workforce development specific to the needs of this unique environment. For clients in treatment, change may be slow, difficult, occur in stages, and produce natural resistance. In a similar way, any attempt to change practices among practitioners and treatment programs may be met with discomfort, doubt, and hesitancy.

Successful knowledge dissemination, whether through professional training or other means, is best performed when the disseminating body takes into consideration an organization's stages of change (Prochaska & DiClemente, 1982) and addresses each of them with appropriate strategies. The use of incremental and gradual interventions along with contingency planning and ongoing monitoring of new treatment principles and implementation are essential for effective knowledge dissemination. Effective knowledge dissemination will address the following goals: (1) Establish systems to measure performance and

ensure *accountability;* (2) build, enhance, and maintain newly acquired treatment infrastructure and *capacity;* and (3) enable all trainees and providers to deliver *effective* treatment services.

The common barriers for successful training and knowledge dissemination often overlap. It is essential that trainers are prepared to manage an expected level of resistance to change with trainees just as knowledge dissemination experts are prepared for organizational resistance to change. Several barriers for successful training that often overlap with barriers for technology transfer have been identified (Addiction Technology Transfer Center Network [ATTC], 2004; Bartholomew et al., 2007; Farabee et al., 1999; Koutsenok et al., 2004):

- Staff and funding limitations that dictate the type and frequency of training treatment professionals can attend.
- Lack of time for trainings including client overload, too much paperwork, and other duties to meet organizational demands.
- New material conflicts with agency philosophy.
- Maintenance of preconceived beliefs about substance use treatment regardless of scientific evidence.
- Leadership is not supportive of changes.
- Access to training and education is limited for providers in rural settings.
- High turnover rates for substance use disorder treatment staff.
- Conflicting goals between corrections and treatment.
- Correctional officers are frequently transferred to different yards, limiting the ability for corrections and treatment staff to establish relationships.

Barriers to change, whether on the individual trainee or organizational level, are to be expected, and strategies to address these barriers will expedite the change process. To minimize resistance, trainers should skillfully and directly address it. This can be achieved through discussion of the pros and cons of change, listening to the fears and concerns of individuals, actively listening to resistors, providing incentives and rewards, and celebrating small victories (ATTC, 2004). In addition, it is important to involve as many people as possible in the knowledge transfer process, including frontline providers, supervisors, directors, correctional staff, and, when appropriate, offender clients who are leaders in their communities. This will ensure that everyone affected by the change process is involved and will provide a safe platform for cross-agency discussions about the implementation of change that is mediated by knowledge transfer experts. Though many barriers exist between science and the implementation of evidence-based practices in correctional settings, there is no barrier too great to account for the insufficient training of scientifically validated treatment strategies (Koutsenok et al., 2004).

TRAINING ADULT LEARNERS

Adults are a unique group of learners who have often acquired a significant amount of life experience, knowledge, and skills that can both help and hinder their ability to learn. In order to maximize training effectiveness for adult learners, trainers must use educational concepts that are personally relevant to them and their work environment (Koutsenok et al., 2004). Adult learners perceive themselves as responsible, self-directing, and independent persons who demand that the trainer accept them as such. Resistance to learning often solidifies under conditions that do not maintain the concept of self-direction and instances when training content is not relevant to practice. The best approach to training adults is to view training as a planned and sequential process designed to provide meaning to the learner. This process is best when it activates previous knowledge, elicits self-awareness, and allows adult learners to utilize the skills, knowledge, and attitudes needed to perform particular tasks relevant to the learner (Koutsenok et al., 2004.; Stuart, Tondora, & Hoge, 2004).

In order to foster the most effective training environment for adult learners, trainers must maintain a balance between making directive decisions for trainees while, whenever possible, encouraging trainees to be responsible for suggestions regarding training content and design. This increases feelings of ownership and fosters personal engagement with the training. In addition, adult learners have been found to identify believability, acceptability, and usefulness of information as requirements for successful training implementation (Stuart et al., 2004). The most effective trainings for adults are designed with the following points in mind:

- A climate of mutual respect must exist between trainer and trainees.
- An open, friendly, and casual atmosphere that facilitates the exchange of differing viewpoints and ideas should be fostered.
- Trainees should be aided in identifying their own skill and growth needs, as well as in analyzing the specific training elements needed by their agency.
- Adults learn best from that which is relevant and useful to them. "Here and now" challenges should be the focus of training. Whenever possible, training ideas should be applied to current work situations. The emphasis should always be on illustrating new concepts as they relate to the life and work experiences drawn from the trainees (Kolb, 1984).

EFFECTIVE TRAINING TECHNIQUES FOR ADDICTION COUNSELORS IN CORRECTIONAL SETTINGS

Professional trainers for corrections-based addiction treatment are most effective if open-minded, culturally sensitive, and well-educated in the specific

needs of the individuals who work in correctional settings. The typical training participants from corrections-based addiction treatment programs include correctional professionals, addiction treatment counselors, and medical and educational staff. Individuals who provide frontline addiction treatment in correctional settings are faced with many dynamics and demands unique to the prison environment. Treatment participants are usually coerced into treatment, frequently do not believe they need treatment, are forced to deal with inmate politics, have to cope with inmate racial tensions, and often share both an addiction to substance use and criminal behavior. In addition to unique inmate dynamics, corrections-based addiction treatment counselors come from several cultures and backgrounds, may or may not be in recovery, may have served time in jail or prison, or may have no history of legal involvement or substance use. Corrections-based treatment programs are made up of a diverse mixture of treatment staff and inmates who often have different worldviews, philosophies, and life experiences. Thus, it is essential that professional trainers are aware and sensitive to the unique needs of the individuals with whom they train.

Without a doubt, the implementation of efficient and effective training is needed for addiction treatment counselors working in correctional environments. The 2007 SAMHSA action plan for behavioral health administration reported significant concern by stakeholders regarding the nature of training and education currently offered to the workforce. Currently, there is a need for more evidence-based training research in the addiction treatment field (Bartholomew, Joe, Rowan-Szal, & Simpson, 2007). Because there is a lack of research on evidence-based training practices for addiction treatment counselors, we must look to the scientific literature regarding effective teaching and skill development strategies utilized by the medical and behavioral health fields.

First and possibly most important—the solitary use of didactic lecture, the method of instruction by which an individual delivers knowledge through lecture to individuals who do not yet possess this knowledge (Stuart et al., 2004)—has been shown to increase knowledge but yields no scientific evidence of building skills among trainees (Korte, 2006; Stuart et al., 2004). Thus, the traditional teaching technique that involves an active teacher and passive participants is not an effective method of training for adult learners. Typical errors trainers make in addition to the sole use of didactic lecture include:

- Not thoroughly understanding the material they train.
- Not staying with the training objective.
- Not relating the subject content to the audience.
- Being underprepared.
- Poor time management.
- Not involving the audience.

- Underestimating the audience.
- Providing false information.

SKILLS FOR EFFECTIVE TRAINING DELIVERY

Effective trainers have not only successfully learned to avoid the typical training errors but have also developed enhanced skills in communication and public speaking. Effective trainers are adept at creating audience participation. They use several means to encourage audience discussion, including: the strategic use of disagreement to stimulate discussion, pulling multiple audience-delivered ideas together, positive affirmations and compliments to validate participation, as well as interactive role plays.

Prior to training delivery, it is essential that trainers are well-prepared. When possible, it is best for trainers to have direct communication with the organization in need of their services. This allows the trainer to identify and research the specific needs of the organization in order to thoroughly prepare for the training session. It is recommended that trainers develop an abstract of the training needs, take time to study relevant research or other relevant materials, anticipate and prepare for problems that may occur during training, and take time to practice the material to be delivered.

In addition to being well-prepared, trainers must remain open-minded and fluid in their approach. The specific needs of the training may shift or be changed spontaneously before or during the training session. Trainers who are well-educated and experienced in the training topic and have solid technique will make this transition feel natural to the audience without interrupting the flow of the training.

Prior to training delivery, it is important to arrive 30–45 minutes early in order to properly set up the room, organize training materials, and resolve any problems associated with the facility or training equipment. When trainees begin to arrive, trainers are to maintain a positive attitude, greet the audience, pass out outlines and materials, and then highlight three to five major points that will be covered during the training. This ensures the audience knows who the trainer is, why he is there, and what they can expect to learn from the training.

While presenting the training material, trainers should be sensitive to the attention span of the trainees, taking frequent breaks if needed. A good rule of thumb for adult attention span is to add 15 minutes to the age of the adult. For example, a 40-year-old adult is likely to have an attention span of 55 minutes. Though attention spans will vary, it is advised to take short breaks every 1.5 to 2 hours, encourage participant involvement, and have energizing activities throughout the training if presenting in a didactic mode.

Slide presentations are to be aimed at providing both direction and structure for the information presented. They are best if the information is accompanied by illustrations, pictures, short videos, and humor when appropriate. A good slide presentation will both provide needed information and stimulate the senses of the trainee. Slide presentations should be concise, orderly, have visual stimulus, and use the least amount of words possible to deliver the point. They should avoid language above the 10th-grade reading level, and if new vocabulary or jargon is used, these terms should be explained by the trainer upon first use.

During the presentation delivery, trainers are most effective if they make good eye contact, involve the audience, monitor their delivery time, continuously connect and summarize the delivered information, and end with major points of discussion. It is very important for trainers to maintain control of the group discussion and not allow for participants to highjack the training with comments or discussions that move away from the goals of the training. The successful use of humor and positive reinforcement for appropriate audience participation can ease this process. Most importantly, the trainers and the trainees should have fun while training. Enthusiastic and compassionate trainers will absorb the audience in the material and allow the training to be a fun learning experience.

EFFECTIVE TRAINING MODALITIES IDENTIFIED THROUGH RESEARCH

Training success is measured by its impact on organizational change and the utilization of new skills by individuals within the organization. Even if trainings are delivered by the most charismatic and interesting trainers in the world, if no behavioral change occurs after the training, it was ineffective. In addition to effective training delivery, it is important for trainers to utilize the modalities and techniques of training as identified through scientific research. This will increase the likelihood that the training will have a lasting impact on individual and organization change. Training modalities that have been identified as effective include: interactive training sessions; sequenced, longitudinal learning; outreach; auditing of practice with feedback; reminders; and the utilization of opinion leaders (Bartholomew et al., 2007; Davis et al., 1999; Korte, 2006; Stuart et al., 2004).

Interactive training is a form of active learning that identifies learners at the center of the educational process, involves problem-solving and solutions related to the learner, is self-directed and facilitator-guided, and utilizes a two-way cooperative engagement between the facilitator and learner (Stuart et al.,

2004). Interactive learning is often achieved through the use of small task-oriented groups, large problem-solving groups, role-play activities, and interactive exchanges between facilitators and trainees. Bartholomew et al. (2007) found that engagement in training materials and comfort with the applicability of the material while training was predictive of later use of training materials in practice.

Sequenced, longitudinal learning (academic detailing) is marked by face-to-face interactions with the intent of changing a trainee's behavior and his clinical practices. Academic detailing techniques include: conducting individual interviews to investigate baseline knowledge and motivations for current practice behavior patterns; defining clear educational and behavioral objectives; using concise, graphic educational materials; highlighting and repeating essential messages; referencing unbiased scientific literature while presenting both sides of controversial issues; engaging active trainee involvement in the academic detailing process; and providing positive reinforcement of improved practices in follow-up visits.

Outreach visits are performed by specialized learning facilitators who meet with trainees at their place of occupation to examine trainees while working and provide information for enhanced performance of treatment techniques.

Auditing of practice with feedback is any summary of counselor performance over a given period of time (Mazmanian & Davis, 2002). It may or may not include recommendations for improvements and differs from outreach visits in that audits may be achieved through examination of inmate treatment records, databases, inmate interviews, or direct observation.

Reminders are any interventions that prompt trainees to utilize the skills acquired from trainings (Stuart et al., 2004). Reminders can include stickers, posters, follow-up reports of techniques used, visits from trainers, and any other mechanism that prompts the use of newly acquired skills.

The training of *opinion leaders* involves focused training on organizationally identified influential peers that will in turn have influence on training other staff through formal or informal education (Stuart et al., 2004). Often, organizations need influential staff members to enhance readiness for change when new treatment modalities are identified. Accurate identification and training of opinion leaders can speed the process of knowledge dissemination and reduce resistance to change from coworkers.

To date, the aforementioned training techniques have been identified to be effective through scientific investigation and should serve as the golden standard for effective knowledge dissemination. Other training techniques such as didactic lecture, single-session presentations and workshops, as well as providing handouts, audiovisual materials (e.g., videos), or electronic publications

have been identified as having limited impact on changing trainee behavior (Stuart et al., 2004) but are still helpful if used in combination with the previously listed evidence-based approaches and should not be discarded entirely.

Though many techniques have been identified as effective when used alone, combining multiple techniques has been shown to significantly increase training effectiveness. The positive effects of combining training interventions was demonstrated by Davis, Thomson, Oxman, and Haynes (1995) when they found that including two or more interventions resulted in a 64 percent increase in positive provider behavior change and that adding an additional intervention resulted in a 79 percent positive behavior change. Thus, training has the most impact on behavioral change when mixtures of several techniques are combined. Combining multiple techniques allows the learner to take on new information through multiple channels, helps decrease boredom, and increases the odds of affecting individuals with different learning styles (Koutsenok et al., 2004; Stuart et al., 2004).

CROSS-TRAINING IN CORRECTIONS-BASED ADDICTION TREATMENT

Cross-training is a unique and essential training for addiction treatment staff who work in correctional settings. It unites addiction treatment staff and corrections staff for several days to provide a safe, mediated environment for both staffs to work together to develop an increased understanding of their job roles in the correctional environment. Unfortunately, both treatment staff and corrections staff alike share many misconceptions about each other and their job duties. For example, treatment staff often jokingly refers to corrections staff as "knuckle draggers," while corrections staff refer to treatment staff as "hug a thugs." Though seemingly humorous, such names paint a picture of the misconceptions of the job duties of both staffs.

It is important to have cross-trainings early in a new treatment program's development and as frequently as possible to help train new staff. Cross-training serves a vital role in improving relationships between treatment and custody staff. This relationship is essential for effective treatment delivery as both treatment and corrections staff have constant direct contact with offenders in treatment and share the overarching goal of reducing offender recidivism. During a cross-training, both staffs participate in educational and team-building activities. These activities provide factual information about job roles, safety awareness, and allow individuals to interact in a less restrictive manner, which helps them understand each other's similarities and differences beyond their job descriptions.

While training, it is not unusual to be met with marked resistance from both corrections and treatment staffs. Comments commonly made by one or both staffs include, "You don't understand our jobs," "They aren't children, kids, or clients; we call them inmates," or "Treatment or rehabilitation means going soft." These beliefs are usually superficially based and often resolved before the end of training. Effective trainers will allow for open discussion, even if heated, and will monitor the mood and appropriateness of the discussants. In doing this, trainers will provide factual evidence to clarify myth and opinion, validate individual emotions and experiences, help both staffs better understand each other's job roles, and work to help both corrections and treatment staff understand their shared goal of reduced recidivism.

MULTIPLE DOMAINS OF LEARNING

The successful implementation of several learning techniques can be demonstrated through the utilization of multiple domains of learning while providing professional training. Learning theory has identified three independent domains of learning that can be experienced simultaneously: cognitive, affective, and psychomotor. The *cognitive* domain is the mind-based domain, which is focused on acquisition of information, intellectual ability, and the thinking process. Training strategies to stimulate this domain often include didactic lecture, manuals and handouts, and one-on-one interactions. The *affective* domain is the feeling domain and is focused on the internalization and increased connection to emotions, attitudes, values, beliefs, and personalized interests. Training strategies that stimulate the affective domain include Socratic questioning, case vignettes, role-playing, gaming, and group discussions. The *psychomotor* domain is a skill-based domain that focuses on motor activities. Training strategies to stimulate the motor domain are focused on imitation, practice, and habit development. Techniques may include demonstration and practice of new techniques while training.

Effective trainings will include activities to elicit each of the learning domains, and many activities may elicit several domains simultaneously. For example, imagine a role-play activity that addresses conflict resolution through communication and body language. Participants are asked to pair up and role play an offender client and counselor involved in conflict with one another. Each trainee must first understand the didactic lecture and handouts provided prior to the activity, which reflects cognitive learning. Each participant will also utilize her own personal emotional experiences, which will likely change throughout the role-play activity during conflict escalation and resolution. In addition, each trainee will be asked to provide the role-play demonstration to a larger group

in order to have his skills evaluated and critiqued. This single training activity elicits the cognitive, emotional, and psychomotor learning domains, is interactive, evaluative, and a good method of multidimensional learning acquisition.

MAINTENANCE OF SKILLS LEARNED POSTTRAINING: IMPLEMENTING CLINICAL SUPERVISION

The success of knowledge dissemination is dependent on the implementation and maintenance of the newly trained skills in the workplace. Though several training techniques, as discussed earlier, have been shown to increase skill comprehension and utilization in the field, more efforts are needed to ensure quality implementation and longevity of change with frontline treatment providers working in correctional settings. As mentioned in the technology transfer section of this chapter, organizational acceptance of evidenced-based practices is instrumental for long-term program change and growth. If acceptance is achieved, the implementation of a clinical supervisor well-versed in evidence-based practices for addiction treatment in correctional settings will substantially increase the speed of change as well as the quality of services delivered.

Addiction treatment professionals who receive quality clinical supervision have been shown to demonstrate increased job performance, cope better with stress, and are less prone to work burnout (Roche, Todd, & O'Conner, 2007). Because of this, clinical supervision may be an essential component for improved treatment outcomes in correctional settings. Clinical supervision can protect against treatment staff burnout, which often leads to increased staff turnover. Staff turnover often places undue demands on the remaining staff as it temporarily increases caseloads and responsibilities, which often include training new treatment staff. Adding licensed clinical supervisors, such as psychologists, social workers, or other clinically trained professionals can provide a source of support and guidance needed for treatment staff to help cope with work-related issues, protect against burnout, and enhance clinical skills. In addition, like inmates, corrections-based addictions counselors have to cope with unique stressors such as highly resistant clients, violence, and philosophical differences between corrections staff and treatment staff. The presence of a clinical supervisor who is well-versed in addiction treatment, corrections policy, and addiction counselor needs may serve as the necessary support needed to reduce staff stress and improve treatment outcome.

In order to accurately implement clinical supervision, it is essential to make the distinction between line-management supervision and clinical supervision (Roche et al., 2007). Although line-management supervision does share some

overlap with clinical supervision, such as professional development delivery and professional practice appraisal, it is primarily focused on organizational quality control and performance appraisals that are utilized for promotions, dismissal, and career development. Thus, because of its hierarchical nature, line-management can be a barrier for some individuals to obtain the objective support they need for skill enhancement and other job-related issues. In contrast, the effective implementation of clinical supervision minimizes power differential issues by not exercising authority over supervisees but providing a safe environment with minimal disclosure over issues discussed in supervision, with exception to mandated topics dictated by law or organizational policy.

An additional method to enhance the maintenance of skills learned in trainings is to increase the number of hours required for workforce development. Currently, the education and experiential requirements needed to be an addiction treatment counselor remain controversial, as most all clinical and health-related fields have substantially higher standards for professional certification (Mustaine et al., 2003). Though the exceptional demand for addiction treatment professionals renders it unreasonable to expect all treatment staff to be licensed clinicians with extensive training in substance use disorders, increasing the amount and quality of trainings along with the implementation of clinical supervision is a reasonable solution to enhance the current workforce. An increase in overall training hours is necessary to enhance the skills learned in trainings. Increased training hours would allow for follow-up visits by trainers to assess for new skill implementation, improvement needs, and organizational barriers to change. In addition, increased training-based education incentives, such as higher pay and promotions for treatment staff who choose to increase their formal education and treatment experience, can help develop new leaders for the future of addiction treatment with an enhanced understanding and acceptance of evidence-based practices and principles.

The implementation of clinical supervisors, increased training hours aimed at skill development and program skill utilization assessment, as well as increased incentives for individuals who make efforts to increase their formal education and training experiences in the addiction treatment field can assure that knowledge dissemination of evidence-based practices is successful.

CONCLUSION

Over the past 20 years, substantial change and growth has occurred in corrections-based addiction treatment. In the past decade significant advances in evidence-based treatment for offenders have been made. These advances have given scientific evidence to the most effective treatment modalities to be used

with offender populations and will likely become the norm for offender addiction treatment as government funding bodies increase the standards of program effectiveness based on outcome measurement.

The addiction treatment field originated as a community-driven model and did not adhere to the path of development of the medical model. The medical model is based on a top-down hierarchy in which individuals are required to obtain the appropriate training, education, and experience prior to providing treatment services. The overall lack of participation by psychology, psychiatry, and other behavioral health professionals in the treatment of individuals with addiction along with the vast need and rapid growth of the addiction treatment field has led it to be developed from the bottom up.

With time, formalized trainings emerged as the specific needs for addiction counselors were identified, eventually leading to the presently controversial certification process. Though controversial because of minimal education and training standards, certification is a necessary step to ensure the quality of training that addiction treatment counselors receive. Ideally all addiction treatment counselors would receive formal education and training, similar to that of other medical and behavioral health professionals, but at this time it is unrealistic if we are to meet the needs and demands of the addiction workforce. Thus, as in other professional models, the implementation of effective training aimed precisely at the unique demands and requirements of addiction treatment counselors is a viable option for the development of the field.

When utilizing a professional training and certification model for workforce development, it is essential that the quality of training and trainers is at its highest capacity. Though there is a lack of scientific research specifically aimed at training in addiction treatment, there is literature about the training modalities found to be most effective with adult learners. Training modalities that have been identified as effective include: interactive training sessions; sequenced, longitudinal learning; outreach; auditing of practice with feedback; reminders; and the utilization of opinion leaders (Bartholomew et al., 2007; Davis et al., 1999; Korte, 2006; Stuart et al., 2004). In addition to effective training modalities, trainer style is also a key component for successful knowledge dissemination. Trainers who are open-minded, authentic, honest, and allow adult learners to actively participate in the training process are most effective.

Cross-trainings are unique to correctional addictions treatment environments and have emerged to help foster productive relationships between treatment and correctional staff. Cross-trainings aim to help both staffs develop an enhanced understanding of their role in offender treatment. Trainers facilitate the cross-training process, allowing individuals to discuss their perceptions and misperceptions of job responsibilities. Trainers serve as mediators to ensure a safe learning environment. They present fact-based information, challenge

biased opinions and myths, and facilitate group-oriented activities that influence interaction and team building between corrections and treatment staff. Cross-trainings are an essential component in corrections-based addiction treatment in that they help develop the camaraderie and understanding needed by both staffs to cooperate toward the common goal of reducing offender recidivism.

Fortunately, with specialized trainings aimed at disseminating the latest evidence-based research for addictions treatment, the addiction treatment field can grow to meet the capacity of needs in the field. With this being said, the success of knowledge dissemination is dependent on its utilization in the field after individuals are trained. For this to occur, trainings need to follow scientifically driven principles, be facilitated by well-trained and educated professional training staff, and be reinforced through clinical supervision, organizational acceptance, follow-up trainings, and implementation analysis. The ability to successfully improve the addiction treatment workforce is highly dependent on these factors. Hence, the future success of corrections-based addiction treatment is highly dependent on organizational, leadership, and treatment counselor attitudes, as well as the economic availability to maintain qualified treatment staff, implement clinical supervision, develop well-rounded leadership, and increase the amount of trainings and evaluations necessary to bring science to frontline practice.

Chapter **20**

Sacred Medicines for Harm Reduction and Substance Abuse Rehabilitation

Michael Winkelman, MPH, PhD

The concept of sacred medicines refers to substances also known as psychedelics, hallucinogens, entheogens, and psychointegrators (see Rätsch, 2005; Schultes & Hofmann, 1992; also see Winkelman 1996, 2007a, for overview).[1] Humans have used plants as sacred medicines for thousands of years for their vision-inducing properties, their ability to shift awareness and consciousness to a spiritual domain, and their ability to induce healing. While these substances have been largely excluded from human research and treatment since their broad prohibition in the 1970s, there has emerged significant evidence that these substances have important applications in the treatment of a variety of conditions, including addictions (see Winkelman & Roberts, 2007a for assessment and 2007b, vol. 2, for review articles).

It might seem unconscionable to treat addicts with drugs that are generally classified by the federal government as Schedule I substances, which is to say that they are considered to have a high abuse potential and no established therapeutic effectiveness. Nonetheless, many forms of evidence suggest that this classification is political rather than scientific (Feeney, 2007), and that these substances constitute both safe and effective treatments for many. First, the psychedelics have a much greater safety profile than the major addictive drugs, legal and illegal (see Frecska, 2007). Second, they produce little if any physical dependence (McKim, 1991). Third, they directly interact with the serotonin neurotransmitter system, with afterglow effects that appear to reflect their enhancement of neurotransmitter systems imbalanced by the use of addictive drugs. Finally, there is a variety of forms of evidence for the efficacy of the

sacred medicines such as peyote, ibogaine, and ayahuasca, as well as similar chemical substances such as LSD, in the treatment of substance abuse.

A review of the use of these sacred substances as harm-reduction approaches and drug abuse and treatment strategies, combined with general considerations of their mechanisms of efficacy, illustrate why there is a moral imperative to apply them in substance abuse rehabilitation. Halpern (2007) points out that given the limited efficacy of current treatments for drug addiction, the use of psychedelic substances for treatment of drug dependence is an ethical responsibility of the medical field. These treatment approaches are more ethical than maintenance/treatment programs that employ drugs of high abuse or substitutes (e.g., methadone treatment, or supervised application of heroin)[2] because of their abuse and overdose potential.

SACRED MEDICINES AS PSYCHOINTEGRATORS

Since the 1960s, the principal effects of the major sacred plants (as well as similar synthetic substances such as LSD) have been recognized as being derived from their effects on the serotonergic neurotransmitter system (Aghajanian, 1994; Vollenweider, 1998).[3] While activation of other neurotransmitter systems is also established, it is the effect on serotonin neurotransmission that underlie the well-known phenomenological, physical, emotional and cognitive dynamics of these substances (see Winkelman, 1996, 2001, 2007b, for general overviews). While specific knowledge of these mechanisms is primarily based on studies of LSD, generalization to the broader group of substances is substantiated by the cross-tolerance among most of these substances. While there are additional mechanisms of action, and specific differences in effects among these plant substances, they share similar effects in their neurochemical mechanisms involving serotonin. The common effects on serotonergic neurotransmission and the roles of serotonin in the brain have guided my reconceptualization of these substances as *psychointegrators*.

The Concept of the Psychointegrator

In a series of publications (Winkelman, 1996, 2001, 2007b), I have provided a synthesis of laboratory, clinical, and ethnographic findings on the sacred medicines that illustrates why the term *psychointegrator* is a more appropriate characterization of the similar effects of these diverse substances. The concept of psychointegrators replace less accurate terms (such as *hallucinogens* and *psychomimetics*) with a referent that reflects their effects on the brain and experience. The root "psyche"—referring to the soul—also reflects the concep-

tualization of the basic effects of these sacred medicines as seen from the perspective of the many cultures that have employed these substances in religious activities.

This concept of psychointegration reflects similar effects revealed by neurophysiologic, clinical, and cross-cultural studies, reflecting their action within the serotonin system, which has multiple roles reflected in its characterization as a neuromodulator that regulates the balance among many neurotransmitter systems. Psychointegrative effects are epitomized by the functions of serotonin in modulating the activities of dozens of bodily and brain processes and neurotransmitter systems and by psychointegrators' systemic effects on the serotonergic neurotransmitter system that enhances the integration of information across levels of the brain. This enhanced integrative function is epitomized by the systemic effects at the level of the raphe and reticular formation, where there is an enhancement of excitatory effects, and at the level of the limbic brain, where emotions and memories are formed.

The effects of psychointegrators are reflected in synchronized alpha and theta brain wave hyperactivity across the neuraxis, the nerve bundle linking the structural levels of the brain from the brain stem to the frontal cortex. In the process of inducing synchronous discharges across this nerve bundle, psychointegrators elicit processes central to awareness and fundamental aspects of self, emotions, and attachments. These processes of psychointegration are manifested physiologically in the typical coherent theta wave discharges that produce a synchronization of brain waves across the neuraxis and lobes of the brain. Psychointegration is also manifested in psychological experiences, particularly those related to emotional healing and the sense of interconnectedness (e.g., cosmic consciousness and other transpersonal experiences). Psychointegrators' effects on neural, sensory, emotional, and cognitive processes enhance consciousness through integrating normally unconscious emotional and self information into the frontal cortex and consciousness. This integration of the unconscious into consciousness underlies the general potentials of psychointegrators as a harm-reduction approach.

SACRED MEDICINES USED IN THE TREATMENT OF ADDICTIONS

One of the areas in which there is a substantial and growing body of literature regarding the efficacy of the psychointegrators in the treatment of illness is in the field of addictions. While we still lack the highly esteemed but sporadically applied double-blind clinical trials, there is evidence regarding the effectiveness of psychointegrators in the treatment of additions. As Alper

and Lotsof (2007) point out, we find validation of the effectiveness of these substances in the treatment of addictions from triangulation and synthesis of many forms of evidence—animal studies, laboratory data, medical case studies, personal case accounts, and case series. Treatment practices involving ritual and clinical use of the sacred plants peyote, ibogaine, and ayahuasca, as well as synthetic analogues such as LSD, are reviewed to illustrate their potential as part of harm-reduction and substance abuse rehabilitation strategies.

The Native American Church: Peyote as Addiction Treatment

One of the widely used psychointegrators in the treatment of addictions is peyote (*Lophophora williamsii*), employed as a sacrament within the Native American Church (NAC, the Peyote Religion or Peyote Way). NAC members consume peyote in an all-night meeting during which all the community may participate in the singing, prayers, chanting, and drumming. The amount of peyote ingested may be quite small, often less than the minimal dose required for notable visual psychoactive effects. The pharmacological effects are not the only mechanism of treatment. The effectiveness of the NAC as a health care delivery system is also dependent on a variety of supportive psychotherapeutic modalities: a master guide, marathon group sessions, ego reduction techniques, social networks, self-actualization, and psychotropic drugs (Calabrese, 1997, 2007; Wiedman, 1990). Many addictions professionals consider the NAC the only effective treatment of alcoholism among Native Americans, and the U.S. Indian Health Service provides reimbursement for the treatment of Native American alcoholics by so-called road men, the peyote ritual leaders (Calabrese, 2007). The Peyote Religion rejects the use of alcohol, making it a natural support group for recovering alcoholics.

Peyote contains mescaline, with stimulant properties similar to ephedrine and amphetamines; while different from indole alkaloids typical of the psychointegrators, its transformation in the body produces similar visionary effects. It is also accepted that part of the effects of mescaline are mediated through the serotonergic system (McKim, 1991). Alternate models of the physiological effects of peyote in healing addictions are characterized by Jilek (1994) as involving altered states of consciousness (ASC) that he points out can be induced through nondrug means (e.g., drums, chanting, prolonged sleeplessness; also see Winkelman, 2000). The overnight nature of the activity also contributes to the typical visionary experiences predicting one's future ruin as an addict. This awareness contributes to a sense of hitting bottom and a heightened consciousness of the need to change one's lifestyle.

The physiological effects of peyote in addressing the dynamics of addiction should not, however, be completely discounted. In addition to the general ASC-inducing effects, peyote also produces an afterglow (e.g., see Halpern, 1996, for review) that has been noted as conducive to therapeutic interventions. This after-effect lasts up to six weeks and includes not only enhanced affect but an increased openness to communication regarding one's problems, making them more accessible to therapeutic intervention.

The NAC also addresses addiction through social psychological mechanisms, forming a sense of community that promotes a new identity and a social support group that does not use nor tolerate alcohol use. The NAC brings hope to Native American communities, instilling a moral code of devotion to family and obligation to the community and producing feelings of spirituality and unity (Aberle, 1966). Peyotism provides Native Americans with religious healing, transcendence, release from guilt, and guidance and a sense of purpose (Aberle, 1966). A significant aspect of the effects of peyote is inducing a sense of control in meeting challenges and initiating change. Heggenhougen (1997) suggests therapeutic effects involve managing cultural alienation experienced by young Native Americans, providing a context for a ritual death-and-rebirth, and constructing a positive identity with one's culture. Jilek (1994) conveys the peyotists' perspective that the peyote ritual combats alcoholism through reducing physical and mental stress and enhancing mental and physical strength through contact with the supernatural.

Calabrese (1997, 2007) describes the Peyote Way as a cultural psychiatry involving meaning-manipulative therapies that engage social and intrapsychic processes. Calabrese uses the term desematicizing agent to refer to how the effects of peyote facilitate a reinterpretation of self. De Rios, Grob, and Baker (2002) similarly characterize the effects of peyote as a nonspecific facilitator that contributes to the development of a new sense of identity through grounding and connection with a community that gives a sense of belonging. Calabrese (1997) assesses the effects in terms of a "social manipulation of consciousness states and symbols to support socially-valued patterns of ritual experience, self awareness and emotional control . . . [rendering] adults more suggestible and thus more open to education and mental health interventions" (pp. 238–239). In this sense, peyote rituals heal by shaping consciousness in ways that facilitate symbolic healing processes. Calabrese (2007) also notes that unlike many traditional etiologies that attribute personal misfortune to supernatural causes (e.g., witches, taboo violations), the Peyote Way instead places the causal factors in a lack of personal responsibility for one's own behavior.

The practices of the NAC have many effects on social, psychological, and emotional well-being. Specific pharmacological actions of peyote in the treat-

ment of addictions may be best characterized in terms of the general effects of inducing ASC and the associated transcendental spiritual experiences. Aberle (1966) points to the ability of peyote to induce a sense of connection with the spiritual world that was lost by many Native American individuals and groups in their forcible assimilation to American culture. The significance of spiritual experiences for rehabilitation of the addicted self has been noted in many therapeutic traditions and may be particularly relevant for Native American groups deprived of their own spiritual traditions.

While further research on specific physiological mechanisms of peyote and its diverse compounds is definitely needed, evidence exists regarding its relative safety and effectiveness. While there are limited toxicology studies that constitute Phase I of the Food and Drug Administrations's ideal evaluation process, there is no evidence of physical harm found in long-term peyote users (see Halpern, Sherwood, Hudson, Yurgelun-Todd, & Pope, 2005). The Phase II evaluations that are used to provide evidence of proof of concept—specific effectiveness of an agent for a health condition—can be derived from case studies of Peyote Church members (also see Halpern, 1996). Evidence of Phase III—approved therapeutic use—is found in the practice of the Indian Health Services, a branch of the U.S. federal government, which approves reimbursement for road men who use of peyote for treatment of alcoholism among Native Americans (see Calabrese, 2007).

Ibogaine Use in Withdrawal Cessation

Ibogaine is an indolealkylamine extract from an alkaloid found in the root of iboga (*Tabernanthe iboga*); it is characterized as both a stimulant and hallucinogen. Dosage and other factors (additives, diet, activity) determine whether iboga induces dreamy visions, and possibly stupor and unconsciousness, or acts as a powerful stimulant (De Rios, 1984). The traditional uses of iboga in west central Africa were primarily ritual, but it was also employed for relief of fatigue, to enhance hunting skills, and for divinatory purposes. Iboga was also imbibed in large quantities to produce stupor by the Bwiti secret societies of Gabon and Congo and in all-night village or intervillage initiation ceremonies (Fernandez, 1972). The Bwiti cult combined Christian and traditional symbols in a revitalization movement that addressed community dislocation caused by colonialism. Communicating with and affirming relationships with the ancestors reintegrated individuals into traditional kinship ties and systems of social control that helped reestablish social stability and well-being (De Rios, 1984). Iboga was interpreted as provoking experiences of contact with the ancestors and a sense of the relationship of the individual to group spirit.

Ibogaine also has a history of informal treatment of addiction in addict communities, functioning largely within the context of both addict and medical subcultures in the public sector rather than in conventional medical settings (but see Alper & Lotsof, 2007; Alper, Lotsof, Frenken, Luciano, & Bastiaans, 1999; Alper, Lotsof, & Kaplan, 2008; Mash et al., 1998; Mash et al., 2001). Iboga is used as treatment for narcotic addiction, particularly the amphetamines, opiates, and cocaine, with a reputation for terminating withdrawal. Informal research on iboga began within the United States in the 1960s and, while placed on Schedule I in 1967, has remained unscheduled in many other countries where various forms of research have continued (Alper & Lotsof, 2007). Ibogaine became an important element in heroin self-help groups in the Netherlands, where it became a central feature of the harm-reduction movement there. The U.S. National Institute of Drug Abuse (NIDA) funded Phase I studies of toxicity in the early 1990s (Mash et al., 1998) but in spite of promising results failed to continue funding the study for Phase II evaluations. It has nonetheless remained available in alternative nonmedical treatment settings around the world and through more conventional medical approaches in countries where permitted by law. This persistent use is based not only on the widespread success encountered among the addict and medical subcultures involved (see Alper, Lotsof, & Kaplan, 2008) but also because of the findings of a wide range of studies that illustrate that ibogaine ought to be considered as having passed the equivalent of Phase I and II evaluations.

Although the FDA withheld funding for the planned and approved Phase I and II protocols, the continuing use of ibogaine for addiction treatment in the United States and around the world constitutes a vast uncontrolled experiment. This has provided many forms of information—including case reports, preclinical toxicological evaluations, and initial Phase I trials of safety pharmacokinetics—which constitute a substantial body of evidence constituting preclinical proof of the concept and the equivalence of Phase I and II trials (see Alper, 2001; Alper & Lotsof, 2007; Alper et al., 1999; Mash, et. al., 1998).

The typical use of ibogaine in addict communities and medical subcultures is without the ritual and ceremonial aspects associated with the indigenous traditions, but there are also other models, including spiritual ones (see Lotsof & Wachtel, 2003). Ibogaine is typically used with the patient located in a dark room and with a bed for reclining during the majority of the session. Administration (see Alper & Lotsof, 2007, for details) is with large doses that provoke visions incorporating repressed memories. While often characterized as a hallucinogen, the effects may be better conceptualized as oneiric, referring to the dreamlike experiences evoked in the internal mental space experienced with eyes closed. The visual effects are characterized as high density images

generally of autobiographical nature and central to life narrative, although archetypal and cartoonlike imagery is also reported. Notable effects reported by addicts include the loss of craving and the lack of withdrawal symptoms and an aversion to the drug, generally eliminating the addict's desire to further use drugs. The patient's experience under ibogaine typically includes visions that provide psychological insight into his drug use, particularly understandings that help overcome psychological blocks (Alper & Lotsof, 2007). Iboga's ability to induce a cosmic consciousness experience may also underlie iboga's effectiveness in treatment of drug addiction (Sanchez-Ramos & Mash, 1996). Iboga's effectiveness in facilitating psychotherapy is attributed to its ability to evoke repressed memories, clarify thoughts, promote introspection, and facilitate manipulation and reenactment of images and scenes (Sanchez-Ramos & Mash, 1996).

Human and animal research (see Alper & Lotsof, 2007, for review) suggests that ibogaine has physiological efficacy in reducing withdrawal cravings and addictions. In reviewing nonmedical clinical studies in the United States and the Netherlands, Alper and Lotsof (2007) point to the "attenuation of opioid withdrawal symptoms within several hours of ingestion, and lasting resolution of the acute opioid withdrawal syndrome within 12 to 18 hours" (p. 49). These limited studies also suggest a short-term effect in reducing cocaine addictions that lasts several weeks to months. Physiological effects (rather than placebo effects) are illustrated in animal studies that show ibogaine may reduce the reinforcing effects of opiates and decrease the experience of withdrawal (see Alper & Lotsof, 2007, for review and original sources).

Alper and Lotsof (2007) review research indicating that the mechanisms of action of ibogaine are different from other substances used to address the neurobiology of addiction, being neither opiate agonists nor opiate antagonists, nor related to the agonism and antagonism of serotonin receptors. Alper and Lotsof (2007) suggest "that ibogaine treatment results in the 'resetting' or 'normalization' of neuroadaptations thought to underlie the development of dependence" (p. 44). They point to evidence indicating that ibogaine has a selective effect on the "learning encoding of drug salience" (p. 54), a selective interference with learning related to prior drug exposures. Other mechanisms of ibogaine action include effects on the inferior olive of the brain stem and the Purkinje cells, where it induces prolonged tremors induced by the release of glutamate. Studies in animals suggest that effects on these centers controlling behavioral routines could produce cessation of addiction by destroying or exhausting these cells, eliminating previous behavioral patterns. In humans, this brain stem excitation is hypothesized to ascend into the brain circuitry underlying REM sleep (dreams) and the thalamus and *locus coeruleus*. These

natural mechanisms involved in forgetting may produce similar destruction of previous behavior patterns reinforcing addiction.

Ayahuasca in Addictions Treatment

Ayahuasca typically refers to a combination of two plants, *Banisteriopsis caapi* and *Psychotria viridis*. The *Banisteriopsis* vine (also called ayahuasca) contains several monoamine oxidase (MAO) inhibitors that render the N,N-Dimethyltryptamine (DMT) of *Psychotria* orally active (see McKenna, 2007, for sources of primary research). Scientific characterizations of the active ingredient from ayahuasca brews implicate the DMT from the *Psychotria*, but the *Banisteriopsis* is generally considered to be the source of the more important psychoactive ingredients among many cultures that use it ritually.

In tribal contexts, ayahuasca was used for a wide range of purposes (e.g., see Schultes & Winkelman, 1996, for review). Primary contemporary uses include: contacting spirits of the dead; telepathy, clairvoyance, diagnosis, prophecy, and healing; and adult transition rites and collective ceremonies. Contemporary rural Amazonian basin groups take ayahuasca in collective adult rituals to strengthen group cohesion and identity and to facilitate psychosocial and conceptual adaptation to rapid cultural change (Andritzky, 1989). Ayahuasca traditions have also diffused to urban areas, where broad segments of the population employ them for healing psychosomatic and ethnomedical conditions, particularly those associated with anxiety and stress (De Rios, 1984). Among these urban traditions are the Brazilian ayahuasca churches (see Labate & Araujo 2002) that have incorporated ayahuasca as a sacrament in syncretistic Christian religions.

The Takiwasi Program

Mabit, Giove, and Vega (1996; also see Mabit, 2007) review the Takiwasi program that incorporates ayahuasca in ritual treatments for rehabilitation of cocaine addicts in the Peruvian Amazon. The program integrates traditional ayahuasca rituals and physical, psychological, and spiritual activities into treatments that address a range of factors contributory to addiction. The program claims widespread evidence of clinical success, although formal clinical studies are lacking. The success is attributed not to the ayahuasca alone, but to the ritual setting and interactions with therapists. The traditional medicines and rituals are combined within the Takiwasi program with modern transpersonal psychology and social techniques to guide the personal transformation of addicts, using the ayahuasca ritual to produce profound ASC that change their outlook on life and their spiritual strength and faith.

The Takiwasi program takes the ritual approach to treatment seriously, incorporating traditional medicine approaches at organic, psychological, and spiritual levels. These three levels of treatment are synchronized with the induction of ASC to enhance access to unconscious levels of the individual. This shamanic approach takes the addict's desire to engage in an alteration of consciousness and initiates him into a kind of vision quest to accesses deep levels of meaning and a sacred dimension of experience that produces personal reorganization.

The Takiwasi treatment program begins with a focus on the organic level of the body, providing a physical detoxification to eliminate toxins acquired through drug use. The consequences of withdrawal and dependency are also addressed. Treatments at the psychological level address the emotional dynamics that contributed to drug addiction. Ayahuasca induces ASC that bypass rational functions to provide access to deep levels of the personal unconsciousness, particularly repressed memories. The patient is empowered through the ayahuasca to become his own healer, discovering the cause of his problems in his visions and taking personal responsibility for the healing processes that he must engage in. The verbalization of these realizations with their therapists allows patients to reflect on their personal conditions and receive feedback regarding their self-perceptions, attitudes, and emotions. These ayahuasca-induced experiences also provide access to spiritual and transpersonal levels that take the patient beyond himself, instilling a value orientation that provides new meaning to life. This spiritual restructuring is an essential aspect of the healing process. It requires a deflation of the ego that produces reconciliation with self, others, nature, and the universe at large.

The first phase of the Takiwasi program begins with a 10-day isolation, followed with up to two months of detoxification to deal with the long-term consequences of cocaine paste addiction and withdrawal symptoms. This includes the use of purgatives, rituals, chants, massages, and tobacco smoke to address tension and anxiety and balance the patient's energy level. Meditation, music therapy, saunas, and relaxing teas are the focus after the isolation period. Following a two-month isolation from family, visits from family members are allowed. This third month also begins a period of retreats into the isolation of the jungle to take additional plants specific for the personality of the individual and his therapeutic needs. A folk healer administers the plants and a carefully controlled diet and observes the patient for energetic disturbances. This experience, similar to an initiation, helps reinforce the will to heal and overcome addiction. The treatment program continues up to seven or more months, using ayahuasca and other ASC-inducing techniques (e.g., meditation, holotropic breath work) to reveal unconscious material for therapeutic

work. Dream material is also the focus of therapeutic processes, integrating the unconscious dynamics into a fuller understanding of self. This enhanced self-knowledge contributes to an increasing sense of serenity and a focus on transcendent concerns that reflect a spiritual deepening in patients lives.

The efficacy of ayahuasca ritual treatments are considered the consequence of many factors—the physiological properties of the ayahuasca, their interaction with the patients' psychological conditions, the environment, and the social relations with therapists and other participants in the treatment center. The therapists consider a central aspect of the treatment effects to be produced through the tobacco smoke blown on the patient and the songs sung throughout the sessions. The physiological action of ayahuasca has been characterized as a disinhibitor that promotes the manifestation of the most basic perceptual capacities of the organism. This is manifested in the visions and other experiences loosely characterized as hallucinations but reflecting symbolically important information for the person. The patient's psychological condition, particularly attitudes of openness, trust, and surrender accompanied by commitment to the process, evoke the healing power of ayahuasca. Inappropriate diet, drug use, and sex before or after sessions are considered to undermine the therapeutic process or even cause deleterious effects.

Effects of Uniao do Vegetal on Drug Use

Studies (e.g., Callaway, Airaksinen, McKenna, Brito, & Grob, 1994; Callaway, McKenna, et al., 1999; McKenna, Callaway, & Grob, 1998) of the adherents to the ayahuasca church Uniao do Vegetal (UDV) revealed that people with a history of alcoholism underwent profound life changes leading to sobriety shortly after joining the church. The effects were seen as having derived from the changes in their worldview and having developed from a generous attitude towards others. There was also an effect on social relations, restoring stability to personal and familial relationships. Case study approaches (e.g., Guimaraes dos Santos, Carvalho de Moraes, & Holland, 2006) have also implicated ayahuasca in recovery mechanisms. Case-control studies showed that long-term regular religious ayahuasca users were healthier than ayahuasca nonusers in terms of drug abuse and psychiatric symptomatology (Da Silveira et al., 2005; Doering-Silveira, Grob, et al., 2005; Grob et al., 1996) and were similar on neuropsychological assessments, suggesting no negative effects from ayahuasca use. There is evidence that participation in the UDV ayahuasca churches reduces the risk of adolescent alcohol use, as well as anxiety, depression, and psychiatric symptomatology (Doering-Silveira, Grob, et al., 2005; Doering-Silveira, Lopez, et al., 2005).

Although ayahuasca treatment programs for drug addicts have shown considerable promise (see Guimaraes dos Santos et al., 2006; Mabit et al., 1996; Mabit, 2007), formal assessments are still lacking. There is however, justification for further applications. The equivalence of basic Phase I studies have been carried out (for reviews see Grob et al., 1996; McKenna, 2007), and there is a limited amount of Phase II evidence (see Doering-Silveira, Grob, et al., 2005; Doering-Silveira, Lopez, et al., 2005; Mabit, 2007; McKenna, 2007).

Lysergic Acid Diethylamide (LSD) in the Treatment of Alcoholism

While LSD is considered to be a synthetic chemical, it has its natural analogues in the ergot alkaloids found in a number of plants (Rätsch, 2005). The use of LSD in the treatment of alcoholism is the most widely investigated clinical application of the psychointegrators to addictions treatment (see Abuzzahab & Anderson, 1971; Halpern, 1996, 2007; Mangini, 1998, for reviews). The early (e.g., 1950s and 1960s) applications of LSD to the treatment of alcoholism suggested the potential to curtail use and reduce recidivism (Halpern, 1996). These applications began with the hypothesis that the delirium tremors that often led alcoholics to change their behavior might be induced by LSD. This hypothesis was rejected but lead to other insights about LSD's potential efficacy as a treatment for addictions. LSD sessions could produce a vivid awareness of one's personal problems, presenting graphic images of the immediate and long-term deleterious effects of the alcohol. The recovering alcoholics often credited these realizations as providing the motivation to change their behavior. Furthermore, some studies indicated that those who received the greatest effects in achieving sobriety were those who experienced a profound spiritual or transcendent experience from LSD. Such spiritual motivation for their recovery was often attested to by the former alcoholics, echoing the main theme of Alcoholics Anonymous: alcoholism is a disease characterized by a deep spiritual craving that can be overcome only by a spiritual awakening.

The limited methodological designs (i.e., lacking double-blinds and placebo controls) and limited follow-up, however, left the findings in a poorly defensible position. This has led many people to dismiss them. Halpern (1996, 2007), however, has shown that there are some valuable findings and applications to be culled from this early research.

Abuzzahab and Anderson (1971) performed a meta-analysis of 31 early (1953–1969) studies using LSD with alcoholics, illustrating the potential of LSD in addictions treatment. Single-dose studies showed an improvement of greater than 50 percent in treatment over control groups. However, these and

other reviews indicate that the improvement differences decline across time. Studies employing LSD with narcotics addicts are far fewer than those assessing effects with alcoholics; Halpern nonetheless finds that the studies provide encouraging results. These studies indicate that a more effective treatment of alcoholism derives from a psychedelic model (using large doses to produce spiritual experiences), rather than a psycholytic model (using small repeated doses to facilitate insight) (see Passie, 2007). Large psychedelic doses that produce life-transforming cosmic experiences appear to be a critical factor in changing one's self-concept and lifestyle in ways that contribute to a resolution of alcoholism.

The limited research done with LSD in the treatment of addictions prior to general prohibition of such studies lead Halpern to conclude that doses of LSD (as well as indolealkylamines such as DMT, ibogaine, and psilocybin, and phenethylamines such as mescaline and MDMA [3,4-methylenedioxymethamphetamine, commonly known as Ecstasy]) have finite effects in diminishing the use of addictive substances. There is the essence of Phase I assessment, however (see Farber, Hanslick, Kirby, McWilliams, & Olney, 1998) and limited Phase II treatment evidence (also see Grof, 1979, 1992; Halpern, 2007). Halpern's assessment of the literature suggests that the antiaddictive effects of a single dose may last only one to two months. They nonetheless appear to provide a time-limited afterglow where the addict experiences a reduction in craving for drugs and an increased openness to communication about personal problems that can contribute to their therapeutic resolution.

Yensen and Dryer (2007) place the therapeutic effects of LSD in the context of the relationship between addiction and peak experience and the reactions of hopelessness and despair to emotional (and physical) pain that leads to addiction as a substitute solution. Peak experiences provide a fundamental shift in consciousness that lead one from anger, despair, and false gratification to a shift in consciousness that provides a profound motivation for positive change. They attribute the therapeutic outcomes less to the drug effect alone than to its ability to contribute to the complex reliving of memories in a safe and supportive context in which a healing relationship facilitates psychotherapeutic transformation.

MECHANISMS OF EFFICACY AND HARM REDUCTION FROM PSYCHOINTEGRATORS

The effects of psychointegrators in reducing addictive behaviors and associated harm are best understood in terms of biopsychosocial interactions, where their physiological effects are molded by ritual, set, and setting. The various

psychointegrators nonetheless also have physiological effects that can directly reduce addictive tendencies, independent of ritual, set, and setting, as illustrated in animal studies (for example see Alper and Lotosf's [2007] review of ibogaine research). Nonetheless, prominent effects of the psychointegrators are derived from their ability to function as nonspecific facilitators of the dynamics derived from set and setting—the social factors, the ritual, social setting, and personal expectations regarding treatment.

Physiological Effects

The psychointegrators produce a wide range of physiological effects as a function of dosage and other factors (see Winkelman, 1996, 2001, 2007a, for reviews). Halpern (1996) suggests that the general physiological aspects of therapeutic efficacy may involve an afterglow effect involving serotonergic mechanisms. The noted reduction of craving provides the addict with additional resources for gaining a sense of self-control that contributes to the development of an abstinent lifestyle.

Serotonin Enhancement

A principal physiological aspect of the efficacy of psychointegrators in the treatment of addiction likely comes from their effects on the serotonergic neurotransmitter systems. The research on LSD provides ample evidence with regard to these effects on serotonin. Serotonin is depleted by long-term drug use, and low serotonin levels predispose depression, a contributory factor in drug use (Walton & Levitsky, 1994, p. 110). The effects of the LSD-like psychointegrators on serotonin are presumably responsible for the widely noted mood-enhancing effects, as well as the reported reduction of anxiety, depression, aggression, and compulsions. Serotonin's role as a neuromodulator, with direct effects on other neurotransmitter systems, enables serotonin-enhancement effects to cascade into other neurotransmitter systems affected by addictions. In the case of ibogaine, both case studies with humans and laboratory research with animals illustrate the reduction of craving that follows from such treatments, although these are not likely serotonergic mechanisms (see Alper & Lotsof, 2007, for review).

Psychointegration and Systemic Brain Function

Psychointegration (Winkelman, 1996, 2001) characterizes the physiological effects of these substances, reflected in highly synchronized and coherent brain wave patterns that propagate from the brain stem through the emotional

(limbic) brain and into the frontal cortex (Mandell, 1980). These brain wave patterns integrate information from physiological, behavioral, and emotional levels of the brain into the frontal cortex. These synchronized theta waves also produce a relaxation response and physiological integration of behavioral, emotional, and cognitive processes (see Winkelman, 2000, for review).

Altered States of Consciousness and Unity Experiences

A wide variety of means of inducing ASC, including drug and nondrug procedures, have basic similarities (Mandell, 1980; Winkelman, 1992, 2000). This high voltage slow wave electroencephalograph activity (alpha, theta, and delta, especially 3–6 cycles per second) provokes slow wave hypersynchronous discharges across the hippocampal-septal-reticular-raphe circuit, which spread to the frontal lobes, producing pleasurable sensations and feelings of well-being (Mandell, 1980). General physiological aspects of ASC—parasympathetic dominance, interhemispheric synchronization, and limbic-frontal integration—are collectively an inherent aspect of human consciousness, the integrative mode of consciousness (Winkelman, 2000). These manifestations of consciousness have inherent therapeutic effects related to addiction; these involve stress reduction and activation of aspects of the brain related to mental and emotional integration. They also produce spiritual experiences, particularly with large doses, that produce life-changes that help in ending addictive behaviors. This paradigm of LSD use known as the psychedelic paradigm suggests that the changes in worldview and perceptions produced by these dramatic experiences are key to the treatment effects. While psycholytic therapy with small doses may have a role in addictions treatment, the general consensus is that the best results come from the large psychedelic doses that produce profound effects (see Passie, 2007). These psychointegrator-induced changes in worldview include a sense of connection with nature and others, providing a sense of wholeness and connection often lacking in the addict.

Access to Repressed Memories

A basic technique of psychotherapy involves enhanced access to repressed memories. Increased access to memories and repressed trauma elicited by psychointegrators reflects their physiological actions on the limbic brain and associated structures that mediate memory processes and emotions. The well-recognized effects of psychointegrators in promoting the emergence of repressed material into consciousness contributes to therapeutic effects through enhancing awareness of the nature of the consequence of one's addictive behavior. Integration of these deeper levels of human identity, reflecting the

reptilian and paleomammalian brains' automated and emotional processes, is important for resolving addictions. Psychointegrators stimulate the brain stem and limbic structures of the brain and their behavioral, emotional, and social processes, producing ascending nerve impulses. These and other physiological effects enhance information availability, producing limbic-frontal integration and interhemispheric fusion, which contribute to the insight necessary to change behavior. Interhemispheric fusion is the enhanced communication between the two hemispheres of the frontal brain through the corpus collosum. Psychointegrators enhance the rate of transfer of information, increasing the integration of cognition from the nondominant, nonverbal hemisphere and the dominant, language-based information processes, producing insight and cognitive-emotional integration (Mandell, 1985).

Psychophysiological Effects

Effects of psychointegrators also reflect psychophysiological enhancement of ritual and contextual effects on the experiences. De Rios et al. (2002, p. 239) suggest that these substances are efficacious because the changes that they are capable of producing in overall psychosocial functioning enables them to exert effects as nonspecific facilitators of set and setting (also see Bravo & Grob, 1989).

Internal Focus of Attention

Large dosages of psychointegrators produce a withdrawal from the external world and a focus on the internal environment. Contextual factors may reinforce the internal focus of attention on memories, personal relationships, behavioral conflicts, traumas, and other subconscious and unconscious material. This introspection facilitates awareness of the personal psychodynamics underlying addiction.

Suggestibility

A recognized effect of psychointegrators is cathartic expression and increased suggestibility. Ritual healing processes capitalize on this suggestibility to facilitate the induction of cultural scripts or dramas for a resocialization and social incorporation of the addict. The extreme suggestibility helps the individual overcome his current reality, escaping his sense of a traumatized self, and instead experiencing a sense of emotional relief and connectedness, unity, and community with others.

Emotional Enhancement

A recognized effect of psychointegrators is the enhancement of emotional experiences, particularly manifestations of emotional conflicts and issues central to personal identity and relationships with others. Other effects include the enhanced sense of emotional harmony, joy, euphoria, and sense of connection and integration with others.

Behavioral Dishabituation

Psychointegrators increase arousal and information flow but interfere with habitual behavioral patterns. This often leads to reversal of habituation and typical response patterns. This reversal of habituation often leads to the development of new behavioral patterns.

Ego Suspension

Another psychophysiological effect involves the suspension of ego structures, which allows the addict to view his own behavior and criticisms and feedback in a less defensive way. This allows new perspectives on the psychodynamic material released by the psychointegrators. There is also a tendency to maintain an increased openness to others and a willingness to communicate with others.

Psychological Integration

The psychointegrators provide a physiologically based set of changes that enhance the ability of ritual to produce an integrated sense of self, personally, socially, and cosmologically (an enhanced sense of connection with one's worldview about the cosmos). A notable aspect of this psychological integration is the enhancement of the sense of one's soul and personal spiritual contact. Many consider these spiritual dynamics to be at the foundations of addiction rehabilitation.

Psychosocial Effects

The engagement with psychointegrators may be a very solitary process typical of the shamanic vision quest, but these substances also produce a variety of social effects that are notable in their ability to counteract some of the central dynamics of addictions.

Redemption as Social Reintegration

De Rios et al. (2002) characterize the effects as producing an alleviation of addiction by providing redemption. Redemption, whether secular or religious, involves restoring a person's relationship with god and community by freeing him from an undesirable state (e.g., sin, addiction). The community and spiritual connection provided by redemption are pillars of the major alcoholism treatment approaches, embodied in Alcoholics Anonymous.

Prosocial Effects

Some of the most important effects of the psychointegrators include the setting. Significant applications to the treatment of addictions may be achieved by enhancing the context effects, in particular the dynamics of intensive, small-group interactions. These settings generally develop high degrees of relaxed intimacy; the widely recognized prosocial effects of MDMA has led to the coining of the term "empathogen." Psychointegrators can be seen as having important applications in treatment of addiction in terms of reducing, preventing, and interpersonally managing aggressive behavior.

CONCLUSIONS: POLICY DIRECTIONS IN THERAPEUTIC DEVELOPMENT

Federal prohibitions on psychointegrators and similar medicines are considered by many to lack constitutional grounds, since there is no article in the constitution or amendments to the constitution that allows the federal government to regulate what we put into our bodies (Boire, 2007). Remember, it took the 18th Amendment to the U.S. Constitution to restrict the use of alcohol by the federal government. After Timothy Leary won his U.S. Supreme Court case regarding the illegality of federal laws concerning marijuana, the Nixon administration made an end-run on the constitution and regulated such substances through the channels of administrative law. This processes of placing them in Schedule I—substances considered to be without evidence of medical efficacy and with a high potential risk for abuse—has, however, been achieved through political actions rather than on the basis of scientific evaluations (Boire, 2007).

So how can we proceed? Winkelman and Roberts (2007a) have provided an overview of the multiple levels of society at which we need to act to change the current political climate that regulates these substances. Political pressure on federal regulatory agencies remains a central approach for opening up experimental use of these substances. This pressure involves many forms of

action, including general education, education of the media, activities in public health and policy organizations, private funding of research, and perhaps even corporate developments. What remains key is applying the cumulative scientific, clinical, ethnographic, and cross-cultural evidence regarding the immense potentials of these substances to public education to facilitate professional, media, and popular pressure to effect administrative changes in federal regulation.

With *Psychedelic Medicine* (Winkelman & Roberts, 2007b), we have laid a groundwork for this public health and harm-reduction endeavor. Education, public policy development, and collective political action, rather than just more science, is necessary for changing opportunities for the use of psychointegrators in treatment of some of the most ravaging social diseases of our times such as the addictions to alcohol, tobacco, methamphetamines, and opiates and their synthetic derivatives. The acknowledged success rates of the conventional addictions treatment industry are not much different from the spontaneous remission rate. In contrast, the case study and other evidence effectiveness of the psychointegrators—particularly peyote, ibogaine, ayahuasca, and LSD—is substantial for those who are willing to consider the evidence. In general, we must say that the Phase II evidence is limited, as it lacks double-blind controls; nonetheless, the principles of Phase II assessment are strongly suggested by other forms of validation such as animal research, medical case studies, personal accounts, and case series.

Physicians have a moral imperative to seek the applications of these more effective venues of treatment for these devastating psychosocial diseases. Because of the great cost of a Phase III studies, and the imitations on patenting natural substances, we won't see these developments without changes in the government funding or industry approaches to make these substantial investments. Even where there are approved drugs that also have a demonstrated effectiveness in addictions treatment, such as ketamine, the drug industry is disinterested in further clinical trials. Ketamine is already classified as a Schedule III drug, with approved uses. Phase I, Phase II, and Phase III clinical trials in the ketamine psychedelic psychotherapeutic treatment of alcoholism and opioid dependence have been carried out, and currently there is research that constitutes the beginning of Phase IV (see Krupitsky et al., 2002; Krupitsky & Kolp, 2007). But the drug company that owns ketamine is not interested in the further development of a treatment that requires only one or two lifetime doses, as such a treatment has negligible potential revenues.

Psychotherapists have a limited range of therapeutic options for the use of psychointegrators. Boire (2007) provides guidelines for adapting to the legal constraints on the psychotherapeutic use of these substance created by the

current administrative and professional regulations. Boire outlines a medical necessity defense, a justification for using a substance as an alternative when lawful medical treatments have been found to be ineffective. Individual users may also be able to make such claims directly. Boire contends that one can base a valid defense on the assertion that although the treatment is prohibited by Schedule I classification, its use reduces the patient's severe suffering without causing disproportionate harm to others (patient, other people, or to the state's interest). Such a valid defense surely could be mounted for cluster headaches (see Sewell & Halpern, 2007). The general failure of the addictions treatment industry might justify similar conclusions about the applications of psychointegrators to the treatment of addictions.

Fenney (2007) expands our understanding of the possible permissible uses of these substances. The constitutional and legislative provisions relating to protection of religious freedoms and the federal government's special protections of the religious rights of the Native American nations has resulted in a variety of legal precedents affecting the rights to use peyote and other psychoactive sacraments. The federal rulings regarding Native Americans' rights to use peyote have established rights for members of federally recognized tribes. Feeney contends that our legal system cannot logically—or perhaps even legally—deny the same rights to other ethnic groups in society. The inconsistencies in rulings lead Feeney to conclude that the use of peyote, or by extension any psychoactive sacrament, cannot be restricted to specific groups, Native American or otherwise, as long as they are sincere believers. In addition, other venues for increasing opportunities for the use of these sacred medicines may be found in the development of religious-based uses such as the Uniao do Vegetal and Santo Daime churches, which use ayahuasca as a sacrament (Groisman & De Rios, 2007; Labate & Araujo, 2002).

NOTES

1. This chapter includes sections of material based on information previously published in Winkelman (1996, 2001, 2007a&b) and Winkelman and Roberts (2007a).
2. For instance, regarding such risks of the standard treatments, see Lintzeris et al. (2006) regarding the practice of intrafemoral heroin administration.
3. Other principal sources consulted for characterization of serotonin and psychointegrator neurophysiology and mechanisms include Aghajanian (1994), Glennon (1990), Kruk and Pycock (1991), Mandell (1980, 1985), McKim (1991), Miller and Gold (1993), Ribeiro (1991), and Vollenweider (1998). It is generally accepted that the primary effects of the psychedelic medicines is through their action on the 5-HT1A and 5-HT2A serotonergic neurons; there is also binding with the

5-HT5 and 5-HT7 receptors (Vollenweider, 1998). Serotonin 5-HT1A receptors in the raphe system, which mediate responses of the serotonergic neurons with respect to their own transmitters, show a strong sensitivity to LSD-like substances (Aghajanian 1994, p. 140), inhibiting their firing in the raphe area and depressing neuronal firing in lower areas of the brain. LSD affinity for 5-HT2A and 5-HT2c receptors facilitates the functioning of the locus coeruleus, which receives numerous somatosensory and visceral inputs and projects diffusely to most of the brain (Miller & Gold, 1993). LSD effects the hippocampus by blocking or suppressing the typical depressant functions of serotonin, permitting the release of responses similar to dreaming and contributing to production of the typical visual experiences by disinhibiting postsynaptic neurons in the limbic and visual areas. Indoleamine and phenethylamines cause greater activation of 5-HT2 serotonin receptors relative to other serotonin receptors (Aghajanian, 1994). Primary effects of LSD-like psychointegrators involve their action on the 5-HT2 serotonergic neurons. Large concentrations of serotonin 5-HT2 receptors are in the limbic system in the hypothalamus and basal ganglia; these sensory processing functions are antagonized by LSD (Kruk & Pycock, 1991). LSD-like psychointegrators also affect the cerebral cortex and the locus coeruleus 5-HT2 receptors (Aghajanian, 1994).

Chapter **21**

Entheogen-Enhanced Transpersonal Psychotherapy of Addictions: Focus on Clinical Applications of Ketamine for Treating Alcoholism[1]

Eli Kolp, MD, Evgeny Krupitsky, MD, PhD, DMedSci, Harris Friedman, PhD, and M. Scott Young, PhD

Undeniably, alcoholism is an extremely destructive problem that resists most conventional treatment approaches (Miller et al., 1995; Nathan, 1986). In the United States, alcohol is the most abused drug, with an estimated 17.6 million adults suffering alcohol-related problems, while 115 million use alcohol regularly (National Institute on Alcohol Abuse and Alcoholism [NIAAA], 2004). The use of alcohol is related to numerous maladies, including accidents, cancer, cardiovascular disease, fetal alcohol syndrome, liver disease, and suicide. NIAAA estimated that approximately 200,000 deaths per year in the United States are attributed to alcohol-related problems, incurring an estimated annual economic cost of approximately $185 billion. Similarly, the cost of other addictions, both economically and to human lives, is steep.

Ketamine hydrochloride (ketamine) is a prescription medication widely used for general anesthesia. It was first synthesized in 1962 and later patented by Parke-Davis in 1966 as a human anesthetic. During the Vietnam War, ketamine was the most widely used battlefield anesthetic. The U.S. Food and Drug Administration (FDA) approved ketamine anesthesia for use with all ages (children, adults, and the elderly) in 1970. Since then, ketamine has been adopted by many hospitals and medical offices because of its rapid onset, proven safety, and short duration of action. There are more than 7,000 publications that describe its high effectiveness and safety (e.g., Bauman, Kish, Baumann, & Politis, 1999; Dachs & Innes, 1997; Ersek, 2004; Reich & Silvay, 1989; Ross & Fochtman, 1995; Shapiro, Wyte, & Harris, 1972). It is also noteworthy that numerous clinical studies have detected no long-term psychological impairment following

ketamine use (Siegal, 1978). Furthermore, according to several studies, ketamine even prevents brain damage in some high-risk circumstances, such as from low blood sugar, low oxygen levels, epileptic seizure, head trauma, heart attack, and stroke (Hirota & Lambert, 1996; Rothman, Thurston, Hauhart, Clark, & Solomon, 1987; Shapira, Lam, Eng, Laohaprasit, & Michel, 1994; Weiss, Goldberg, & Choi, 1986), suggesting that it is more than merely safe but actually may be protective in many adverse circumstances.

But ketamine also has some unusual properties. As a rapid-acting, nonbarbiturate and nonnarcotic agent, ketamine has been called a dissociative anesthetic since it appears to create a sense of disconnection between so-called mind and body. This is quite unlike the properties of conventional anesthetics, which basically extinguish consciousness. The dissociative property of ketamine creates what can be described as an emergence phenomena, which is a nonordinary consciousness state that can be viewed as psychedelic or transpersonal. In this state, inner awareness and perception of the outer world are dramatically altered, which is characteristic of psychedelic substances. Also, ketamine induces experiences that can be called transpersonal, such as the following: identity loss or ego dissolution; mythological, archetypal, or mystical interconnectedness/unity; out-of-body or nonphysical being; rebirth, dying, or even reliving past incarnations (Khorramzadeh & Lofty, 1976; Krupitsky & Grinenko, 1997; Krystal et al., 1994; Lilly, 1988; Moore & Alltounian, 1978; Weil & Rosen, 1983). Substances that produce such transpersonal states are often called entheogens for the frequent religious and spiritual significance of these experiences.

Although ketamine can be classified with other psychopharmacological compounds called psychedelics because of its mind-altering effects, it is the only psychedelic that is legal for physicians to prescribe for therapeutic purposes in the United States, because it has been so extensively researched for safety as an anesthetic. Ketamine is not banned under any of the provisions of the U.S. Controlled Substances Act, so it is readily available for use as an anesthetic—and it can also be legally administered off-label in the United States by licensed physicians for treating various medical concerns. Some of its possible off-label uses have been studied, such as for treating severe intractable pain, such as ischemic limb and neuropathic pain disorder, as well as refractory cancer pain (Carr et al., 2004), and for treating mood disorder (Zarate et al., 2006). In this context, it should be noted that there has been a recent renewal of interest in psychedelic therapy for treating a wide variety of psychological and psychiatric problems, including alcoholism and various forms of substance abuse (Friedman, 2006). Many have argued that transpersonal or spiritual experience is a crucial factor in recovery from addiction to various substances

(e.g., Amodia, Cano, & Eliason, 2005; Corrington, 1989; Grof, 1980; Halpern, 1996; Krupitsky & Grinenko, 1997; Kurland, Savage, Pahnke, Grof, & Olson, 1971; Robinson, Brower, & Kurtz, 2003; Whitfield, 1984). This is also the core teaching of many self-help movements, such as Alcoholics Anonymous (AA). AA's cofounder, Bill Wilson, recovered from alcoholism after a spontaneous spiritual experience in 1934; after that, he never again doubted God's existence, nor took another drink (Alcoholics Anonymous World Services, 1984, pp. 120–121). It is well-known that, subsequently, AA and various Twelve-Step programs adopted a spiritual orientation (Corrington, 1989; Whitfield, 1984). It is lesser known, however, that Wilson in 1956 took a psychedelic drug (LSD) under supervision by a psychiatrist at the Los Angeles Veterans Administration Hospital. He had a profound experience, similar to his previous spiritual experience, and felt that this second spiritual experience eliminated "many barriers erected by the self, or ego" and thought he "might have found something that could make a big difference to the lives of many who still suffered" from alcoholism (Alcoholics Anonymous World Services, 1984, pp. 368, 371). A therapy enhancing the likelihood of spiritual experience, therefore, could have great utility for treating alcoholism and other substance use disorders. Consequently, this opens an avenue to how using psychedelics such as ketamine may be therapeutic for treating such concerns.

MECHANISMS FOR UNDERSTANDING POSSIBLE THERAPEUTIC APPLICATIONS OF KETAMINE

Most contemporary U.S. researchers exploring the therapeutic application of ketamine seem to assume it operates through a biochemical mechanism, similar to the way actions of other medications are generally construed. Even other psychedelics are primarily seen as a psychotomimetic agent affecting neurotransmitters, most often the serotonin system. Interestingly, ketamine is not primarily based on serotonergic actions; rather, its biochemical mechanism appears primarily based on glutamatergic N-methyl-D-aspartate (NMDA) antagonism. In this way, ketamine is often seen as a more appropriate model for psychosis than are serotonergic psychedelics, such as lysergic acid diethylamide (LSD), N,N-Dimethyltryptamine (DMT), and psilocybin (Krystal et al., 1994).

In addition to biochemical perspectives, psychedelics are sometimes seen as operating through neurobiological, rather than neurochemical, mechanisms. For example, visual effects of ayahuasca could be related to alterations in cortical oscillations in visual pathways, a top-down, as opposed to bottom-up, mechanism (Frecska, White, & Luna, 2003, 2004). In this regard, ketamine

seems to affect different cortical regions, based on positron emission tomography data, than do other psychedelic drugs like psilocybin (Vollenweider, 1992–1993). The neurobiological mechanisms involving ketamine and most other psychedelics are complex and not yet fully understood, but they provide a plausible alternative to neurochemical explanations that seem to prevail (Friedman, 2006).

In addition to these possible neurochemical and neurobiological mechanisms, effects of ketamine may be explained psychologically. Ketamine often induces psychodynamic experiences, such as a life-review similar to what is sometimes described in near-death experiences (NDEs) when one's past history is vividly seen unfolding (Kolp et al., in-press). These experiences may reveal patterns that are sometimes portrayed in richly symbolic forms of visionary experiences. Such revelations can bring into awareness previously unconscious maladaptive themes that, when made conscious, allow possibilities for life decisions to change these patterns, including changing ingrained destructive addictions such as alcoholism and other forms of substance use disorders.

Ketamine may also produce other effects that are extraordinary by conventional standards, namely transpersonal phenomena (e.g., experiences of death/rebirth, ego dissolution, and unity with humanity, nature, and the supernatural). These transpersonal emergence phenomena have been well-documented in multiple studies and appear in general not to result in ensuing psychological problems (White, Way, & Trevor, 1982), though they can be disturbing for some. Many have speculated that psychedelic drugs, including ketamine, might be useful primarily because of transpersonal, rather than neurochemical or neurobiological, effects (Friedman, 2006). Previous psychedelic psychotherapy studies (e.g., Grinspoon & Bakalar, 1979; Grof, 1980; Jansen, 1997, 2001; Khorramzadeh & Lofty, 1973, 1976; Krupitsky et al., 2002; Krupitsky et al., 1997; Krupitsky et al., 1992; Kurland et al., 1971; Leary, Metzner, & Alpert, 1964; Roquet, 1974; Strassman, 1995) suggested that transpersonal experiences may be beneficial through contributing to catharsis, stabilizing positive changes, enhancing growth and self-awareness, catalyzing insights, increasing creativity, broadening spirituality, and harmonizing relationships with people and the world.

Grof (1980) developed the most comprehensive transpersonal theory of psychedelic psychotherapy, presenting not only theory but also supporting data that psychedelics can facilitate experiences of symbolic death/rebirth, which allows clients to work through unconscious trauma. Grof applied psychedelic psychotherapy successfully with over 750 clients by discouraging analyzing psychological problems and, instead, encouraging transcending them through emphasizing their growth potential.

One specific transpersonal mechanism that may inure uniquely to ketamine, as compared to other psychedelic substances (in addition to ketamine being available legally by off-label prescription), is that it reliably replicates NDEs (Grinspoon & Bakalar, 1979; Lilly, 1988). Ketamine-induced NDEs produce all of the common features associated with natural NDEs, including a sense of being truly dead, of consciousness being separated from the body or out-of-body, that what is being experienced is absolutely real and that it cannot be adequately described in usual language, and of transcendence of space/time (Jansen, 1997, 2001). It is noteworthy that ketamine-induced psychedelic experience differs significantly from that caused by serotonergic hallucinogens. Most (approximately 70%) NDEs result in feelings of peacefulness, while some (approximately 30%) result in fear. Memories are often reorganized in a life-review, and transcendent states with visions, such as of important figures in one's life like parents and teachers (who may be dead or alive at the time), as well as of archetypal images including angels and gods/goddesses, may be experienced. Frequently, the experience of a sense of God is reported as luminescent white light (Jansen, 1997, 2001). Similar to natural NDEs, these ketamine experiences are often transformative, changing worldviews and deepening spiritual understandings (Ring, 1984). Thus, NDEs provide a plausible transpersonal mechanism to understand the possible efficacy of clinical applications of ketamine. Specifically, we speculate that ketamine-induced NDEs provide opportunity for intense life-review that can facilitate powerful experiential shifts in attitudes toward alcohol and substance use, motivating clients to change therapeutically.

HISTORY OF KETAMINE USE IN PSYCHOTHERAPY

Lilly (1988) first began to explore the psychotherapeutic use of ketamine during the 1960s. He administered ketamine, often using sensory isolation tanks to enhance its effects. Lilly documented relationships between dosage levels and the qualities of ketamine experiences. He noted clear dose relations such that intramuscular injections of ketamine at 25 mg did not cause visual images, whereas at above 30 mg it produced such images when the subject's eyes were closed. At above 75 mg, visual images increased and feelings of detachment of the mind from the body began. At above 150 mg, feelings of complete dissociation of the mind from the body were common, as were intense visual experiences, whereas doses above 300 mg produced unconsciousness.

Khorramzadeh and Lofty (1973) were the first to study ketamine in the practice of psychiatry by administering ketamine to 100 clients with psychiatric and/or psychosomatic diagnoses, including anxiety, conversion reaction,

depression, hypochondriasis, hysteria, neurosis, obsessive-compulsive phobias, tension headaches, and ulcerative colitis. They reported that 91 of these patients did well after six months, while 88 did well after a year. Complications from ketamine were minimal, leading them to conclude that the mind-expanding potential of ketamine related to abreactive (cathartic) healing. Later, Khorramzadeh and Lofty (1976) studied the relationship of client personality to types of emergence phenomena induced by ketamine. Using a well-known personality inventory (Eysenck Personality Inventory) with 606 clients who took ketamine as anesthesia during surgery, Khorramzadeh and Lofty reported a variety of meaningful patterns.

Fontana (1974) employed ketamine adjunctive to psychotherapy for depression to facilitate "a deep regression to prenatal level, experienced as disintegration and death, followed by a progression experienced as a rebirth" and observed that ketamine "allows the therapist not only to witness the dream but also to introduce himself into it and to correct, in situ, the primitive experience through the bi-personal relationship" (p. 39). He emphasized the advantages of ketamine as making it possible "to reach such levels of regressions as had never been observed before" (p. 39).

Roquet (1974) used ketamine in group psychotherapy, combining psychoanalytic techniques with indigenous Mexican healing ceremonies, and created an approach to psychotherapy he called psychosynthesis (not the psychosynthesis developed by Robertos Assagioli, 1965). Roquet primarily treated neurotic clients, although he also treated personality disorders and some psychotic clients. His therapeutic regimen also incorporated additional psychedelic substances, such as LSD, peyote, psilocybin, and *Datura ceratocaulum*.

Grof (1980), who developed a comprehensive psychedelic psychotherapy, primarily employed LSD, but he also acknowledged ketamine as holding great potential because of its "affinity for positive dynamic systems" and reported that the effects of ketamine were so powerful that "it catapults the patient beyond the point of impasse from the previous LSD session, and can make it possible for him or her to reach the better level of integration" (Grof, 1980, p. 214).

As mentioned previously, most contemporary ketamine research in the United States stems from a biochemical approach in which the ketamine psychedelic state is often seen as a model for psychosis. Many of these recent studies have been conducted by John Krystal and have concentrated on the perceptual and cognitive effects of ketamine (Krystal et al., 1994). However, his research team has also completed one clinical study of ketamine, showing it to be very effective for treatment-resistant major depression (Berman et al., 2000). In addition, other recent work suggests ketamine may be highly effective for treatment-resistant major depression (Zarate et al., 2006).

KRUPITSKY'S CLINICAL RESEARCH WITH KETAMINE

One of us, Krupitsky (who formerly worked with Krystal), has conducted the most extensive and rigorous clinical research on ketamine to date. He began administering ketamine in 1985 as part of psychotherapy and has treated without complications more than 1,000 clients. His early exploration used ketamine as part of an aversive conditioning treatment of alcohol dependence, but his later work gradually shifted to an existential and transpersonal model focused on ketamine treatment of alcohol and, to a lesser extent, heroin dependence.

Among his noteworthy findings, Krupitsky has shown that ketamine-enhanced psychotherapy is dose-related, being more effective with a relatively high dose (2.0 mg/kg to 2.5 mg/kg), which is seen as psychedelic, than with a relatively low (or subpsychedelic) dose (0.2 mg/kg) (Krupitsky et al., 2002). Quantitative assessment of the ketamine-induced effects within the high-dose group using the Hallucinogen Rating Scale (HRS; Strassman, Qualls, Uhlenhuth, & Kellner, 1994) were comparable to those using a tryptamine hallucinogen (DMT) described as fully psychedelic by experienced users of psychedelic (Strassman, 1996). In that regard, Krupitsky argued that the salutary effects of ketamine are likely related to its psychedelic properties. It should be noted, however, that subpsychedelic doses do induce some psychedelic effects but not a fully psychedelic experience. High-dose subjects in this study had psychedelic peak experiences, while low-dose subjects experienced something less potent, sometimes called ketamine-facilitated guided imagery (Leuner, 1977). Consequently, Krupitsky argued that the salutary effects of ketamine are likely psychedelic in nature.

Other studies by Krupitsky (e.g., Krupitsky et al., 2002; Krupitsky & Grinenko, 1997; Krupitsky et al., 1992) have shown that clients treated with ketamine reported better ability to attribute meaning and purpose in their lives, as well as changes in values that reflected an increased understanding of positive alternatives to alcoholism and substance abuse. This is congruent with Frankl's (1978) existential approach, which considers alcohol and substance use disorders to be related to loss of meaning in life—and these findings suggest that ketamine psychotherapy might address existential voids rooted in human existence. These same studies by Krupitsky also indicated that ketamine treatment affected Minnesota Multiphasic Personality Inventory personality profiles in beneficial ways, showing that clients became more confident, emotionally open, and optimistic about their futures and, conversely, less anxious, depressed, and neurotic. Other psychological measures used in these studies demonstrated positive transformations of nonverbal, unconscious aspects of self-concept and attitudes toward other people and increases in levels of spiritual development.

All of these psychological changes were judged to favor sober, nonabusing lifestyles.

Krupitsky has also used electroencephalography data in studying ketamine (Krupitsky & Grinenko, 1997), demonstrating that ketamine increases delta and theta activity in the cortex, evidencing limbic system activation as well as limbic-cortex interaction. This can be considered indirect evidence of strengthening of interactions between conscious and subconscious levels of mind. Krupitsky also provided rich data from biochemical studies showing that pharmacological action of ketamine affects opioidergic and monoaminergic neurotransmitter metabolism, neurochemical systems involved in pathogenesis of alcoholism (Krupitsky et al., 1990). So, though Krupitsky favors a transpersonal understanding of the clinical effectiveness of ketamine, he is also open to concomitant biochemical processes as well.

Krupitsky's studies (Krupitsky & Grinenko, 1997; Krupitsky et al., 1992) demonstrated that ketamine psychotherapy increases abstinence rates in clients with alcoholism. Of many subjects who received ketamine, 69.8 percent were judged abstinent for one year, while only 24 percent in a control group remained abstinent during a one-year follow-up. Krupitsky et al.'s (2002) research with heroin addicts similarly showed the one-year abstinence rate in a group receiving ketamine was five times higher (25%) than of a control group, while corresponding relapse rates were also lower. This study also showed that ketamine reduced cravings for heroin and produced no significant negative reactions. This study, a double-blind clinical trial, clearly supported the efficacy of ketamine in psychotherapy for addictions due to its scientific rigor. Last, it should be noted that many of Krupitsky's clients in these studies became more spiritual through transpersonal experiences obtained with ketamine.

THERAPEUTIC APPLICATIONS OF KETAMINE

The present body of research clearly documents that ketamine can be effective for the treatment of addiction. Although most studies to date have concentrated on alcoholism and, to some degree, opioid dependency, research results may be extrapolated to treatment of other addictions and depression, as well as possibly in the treatment of neurotic, psychosomatic, and personality disorders.

The techniques of ketamine psychedelic psychotherapy have now evolved as a procedure with the specific goal of inducing ego-dissolving transpersonal experiences. This method generally includes one to three sessions using ketamine with a conducive set, or expectations, and setting, or clinical environment. We consider it important to emphasize that ketamine alone is not a

healing agent, as in a biochemical model of medicine, but rather is adjunctive to a psychotherapeutic process involved in treating underlying biopsychosociospiritual problems.

Ketamine psychotherapy as used by Krupitsky and, to a lesser degree, by another one of us (Kolp) in his practice, involves three stages: preparing, administering, and integrating. In the preparation, preliminary psychotherapy is conducted with clients, who are informed that psychedelic sessions may allow important insights concerning personal problems, systems of values, notions of self and world, and life-meaning to become conscious. Patients are encouraged to view all of these possible insights as leading to potentially positive changes important for healing problems and embracing sobriety. At least 5 and up to 10 hours of psychotherapy may be provided before the initial ketamine session to establish psychospiritual goals for a possible transpersonal experience. This information is not simply explained to the client; rather, it is discussed at length in an individualized fashion. The therapist closely attends to issues such as personal motives for seeking treatment, goals for sobriety, and thoughts concerning causes and consequences of the problem being treated. The client and therapist form an individualized psychotherapeutic myth, which creates a set favoring confidence and mutual trust. In our view, this is the most important psychotherapeutic factor responsible for success during the second stage.

The second stage involves the induction of a transpersonal experience through administration of ketamine. Breakfast is omitted prior to a morning ketamine administration, and clients refrain from food and drink for eight hours prior to administration. Clients are instructed that they will have some unusual experiences and are encouraged to surrender to them.

Clients are asked to assume a comfortable supine position using eyeshades to reduce external visual stimulation. Ketamine is then injected intramuscularly in psychedelic doses of 2.0 mg/kg to 2.5 mg/kg. The intramuscular route provides a more gradual onset and psychedelic experiences last longer. With intravenous psychedelic doses (i.e., from 0.7 mg/kg to 1.0 mg/kg), effects last only 15 to 20 minutes, while with intramuscular injection from 45 minutes to an hour is typical.

Administration of ketamine is accompanied by specially chosen music, generally classical or New Age, and clients typically have ego-dissolving transpersonal experiences. Afterwards, there is a recovery period, which usually takes one to two hours, and clients begin to feel the return of ordinary reality. At this point, clients usually describe their experiences, and discussion begins with the psychotherapist. After the session, there is a rest period in which clients are asked to write detailed self-reports of the transpersonal aspects of the ketamine experience.

The third stage involves integration of transpersonal experiences. It is generally conducted in group psychotherapy because we (Kolp and Krupitsky) have clinically judged group therapy to be more powerful therapeutically than individual sessions for this treatment. Typically three to five hours of group psychotherapy are provided to facilitate integration of the experiences into clients' everyday lives. Clients discuss and interpret personal significances of the symbolic content in their ketamine-induced experiences. This discussion is aimed toward helping clients forge a relation between their psychedelic experiences and their problems, both intra- and interpersonal. The therapist assists clients with integrating the spiritual transformations that can result from direct transpersonal experience, often by helping clients generate fresh insights and new, often unexpected, attitudes, meanings, and values about self and the world.

Two additional points need to be addressed. First, it is noted that some clients do not fully benefit from just one ketamine session. Such so-called treatment-resistant clients may require one or two additional ketamine sessions. In addition, data from Krupitsky et al. (2007) most recent study provide evidence that three ketamine sessions may work better than one in providing a higher abstinence rate in heroin addicts, suggesting that increasing sessions may increase treatment efficacy. Second, despite the power of this type of psychotherapy, it may not have long-lasting effects without appropriate support structures, which is why we stated earlier that ketamine alone is not adequate as a treatment—it must be provided in a therapeutic context. Many clients may experience what has been called psychedelic afterglow after receiving psychedelic psychotherapy (Grinspoon & Bakalar, 1979). Such afterglow includes positive changes induced by the psychedelic experience that usually last only up to a few weeks, providing only a transient psychotherapeutic benefit that, though often pronounced for several weeks after treatment, may start declining rapidly (Halpern, 1996).

POTENTIAL FOR KETAMINE MISUSE

Ketamine is part of the group of chemicals including phencyclidine (i.e., Sernyl, PCP). These chemicals are called arylcyclohexylamines and are classified as hallucinogens or psychedelics. Ketamine, although legal for medical administration, is a controlled substance requiring prescription and is listed on Schedule III (Controlled Substances Act of 1970). Medical evidence regarding possibilities of it being abused or leading to dependence suggests that its abuse potential is similar to that of phencyclidine and other hallucinogens (Siegal, 1978). Although phencyclidine and the other hallucinogens do not meet criteria for causing drug dependence, since they do not lead to tolerance or with-

drawal symptoms, individuals with a history of heavy psychedelic drug use have reported cravings. In addition, ketamine may affect cognition (thinking), mood (feelings), and perception (imagery) in ways that may motivate some people to repeatedly use. Therefore, ketamine should only be used under direct supervision by a licensed physician.

FUTURE DIRECTIONS FOR TREATMENT AND RESEARCH

Research supports that ketamine used as part of psychotherapy may be highly effective in the treatment of both alcoholism and opioid dependency (Krupitsky et al., 2002; Krupitsky & Grinenko, 1997; Krupitsky et al., 1992). It is also possible that ketamine psychotherapy may be equally effective for treating similar dependencies, such as to depressants including benzodiazepines and barbiturates. In addition, preliminary results (Krupitsky & Grinenko, 1997) have suggested that ketamine psychotherapy may be effective for treating dependency on ephedrine, a stimulant, as well as other psychostimulants, such as amphetamines, caffeine, cocaine, and nicotine. More broadly, ketamine may find use in many areas of psychiatry, in line with studies demonstrating significant improvements with various psychiatric disorders and psychosomatic illnesses (Khorramzadeh & Lofty, 1973; Zarate et al., 2006).

This opens the possibilities for many productive research efforts. More rigorous research could explore the effectiveness and efficacy of ketamine for treating a variety of psychological problems in which preliminary data appear promising. More basic research of both a biological and psychological nature could also occur, such as to further explore the connection between clients' personality profiles and types of ketamine transpersonal experiences, as well as relationships between both of these phenomena and clients' subsequent response to ketamine treatment. Another potential research area would be to explore similarities between ketamine-induced transpersonal experiences and NDEs, following up on Jansen's (1997, 2001) work in this area. Last, the very materialistic assumptions engrained in modern science are strained by some of the powerful phenomenological reports generated by ketamine experiences; in this sense, ketamine may offer a particularly valuable tool for exploration of fundamental epistemic and ontic mysteries (Friedman, 2006).

CONCLUSION

Ketamine is an anesthetic that can legally be administered in the United States off-label by a licensed physician for psychiatric treatment as an adjunct

to psychotherapy. In this way, it differs from other psychedelics that are illegal to use in the United States, except in closely controlled research contexts. In subanesthetic doses, ketamine is a psychedelic that reliably induces transpersonal experiences. In addition, ketamine has advantages over other psychedelics due to its rapid onset, safety, and short duration of action.

A body of careful scientific research documents that ketamine psychotherapy is effective in the treatment of alcoholism and opioid dependency, as well as to some extent on abused stimulants (e.g., ephedrine). Additional data show that ketamine may be successfully used for treating various psychiatric illnesses (e.g., depression, obsessive-compulsive disorder, posttraumatic stress disorder, and phobias), some personality disorders (e.g., avoidant and histrionic personality disorder), and also some psychosomatic illnesses (e.g., tension headaches and ulcerative colitis). These studies demonstrate impressive benefits for many clients who showed improvements after receiving ketamine, including becoming more responsible, emotionally mature and open, self-confident and self-sufficient, and having increased ego strength and less anxiety and depression. In addition to these many benefits, clients often experienced both existential and spiritual growth. These transformations may reinforce positive attitudes toward sobriety and healthy lifestyles that supported stable recovery from alcohol and substance use disorders. Continued scientific research on ketamine in well-controlled studies is indicated now because of its demonstrated therapeutic effectiveness, biological safety, and pragmatic availability as one of the few legally available psychedelics and the only one that has shown clinical value.

NOTE

1. This chapter is based on earlier works by the first two authors (Kolp & Krupitsky, 2007) and all of the authors (Kolp, Friedman, Young, & Krupitsky, 2006).

About the Editor and Contributors

EDITOR

Angela Browne-Miller, PhD, DSW, MPH, is the Set Editor of the *Praeger International Collection on Addictions* (2009), Director of Metaxis Institute for Personal, Social, and Systems Change, based in northern California, United States; Director of Browne and Associates Violence, Substance Abuse, and Trauma Treatment and Prevention Program, also in northern California; has been a keynote speaker at conferences around the world on addiction, violence, and behavior change; and is the author of numerous books, including *To Have and to Hurt: Seeing, Changing or Escaping Patterns of Abuse in Relationships* (2007) and *Rewiring Your Brain to Change Your Behavior* (2009). Dr. Browne-Miller earned two doctorates and two master's degrees at the University of California, Berkeley, where she lectured in three departments for 14 years, and has served as a National Institute of Mental Health Postdoctoral Fellow, a U.S. Department of Public Health Fellow, the public relations director for Californians for Drug Free Youth, the Research Education and Treatment Director for the Cokenders Alcohol and Drug Program, a member of the board of directors of the Employee Assistance Society of North America, an advisor to addiction treatment programs in the United States and several other countries, and project director on three California Department of Health violence prevention projects.

CONTRIBUTORS

Lyndsay Ammon, MPH, is a doctoral candidate in epidemiology at University of California Berkeley's (UCB) School of Public Health in Berkeley, California, United States. Ms. Ammon received an MPH from Boston University's School of Public Health. Currently, she is a research associate at the Alcohol Research Group (ARG) in Emeryville, California and a predoctoral research fellow in ARG's and UCB's joint National Institute of Alcohol Abuse and Alcoholism's Training Program. She has conducted research on the relationship between formal and informal drug and alcohol services and alcohol-related outcomes. In addition, she has published in the area of substance use in relation to sexual risk behavior. In her dissertation, Ms. Ammon is evaluating whether prenatal multivitamin use modifies the relationship between prenatal exposure to alcohol and perinatal and reproductive outcomes.

Kelly Anders, MAL, is a research associate working on national and international research projects with Maria Dinis, PhD, MSW, associate professor at the Division of Social Work, California State University Sacramento in Sacramento, California, United States. Ms. Anders does research in the area of leadership studies. Her interests are organizational sociology, leadership, international studies, and educational policy. She received her master's of arts in leadership from Augsburg College in Minneapolis, Minnesota.

Thomas Beers, PhD, graduated from the University of Cincinnati in Cincinnati, Ohio, United States, with an MA and PhD in clinical psychology. Following graduation he worked as a clinical psychologist at the Alcohol Counseling Program at a CMHC in Pensacola, Florida, United States. Dr. Beers was director of the Chemical Dependency Recovery Program with Kaiser Permanente, San Diego, California, United States, from 1981 to 2003. Since 2003, Dr. Beers has served as clinical director of the California Screening, Brief Intervention, Referral and Treatment program (CASBIRT). He has also supervised US Navy addictions counselors for the last 25 years. Dr. Beers is a licensed psychologist in California and holds APA Certification for Proficiency in Treatment of Substance Disorders.

Robert K. Brooner, PhD, is a professor of medical psychology and psychiatry in the Department of Psychiatry and Behavioral Sciences at the Johns Hopkins University School of Medicine in Baltimore, Maryland, United States. He received a BA at the University of California–Santa Cruz and a PhD at the California School of Professional Psychology, both in California, United States. He completed an internship in medical psychology at The Johns Hopkins University School of Medicine in Baltimore Maryland, United States, and one

year of additional postdoctoral training. He is a licensed clinical psychologist and director of Addiction Treatment Services at the Johns Hopkins Bayview Medical Center. Current research interests include: assessment of substance use disorder with and without other psychiatric comorbidity; testing interventions for substance dependent patients with specific types of psychiatric comorbidity; testing of combination treatments that incorporate behavioral reinforcement to motivate adherence; and the development and testing of adaptive treatment models to improve treatment-seeking behaviors and maximize therapeutic response in substance-dependent patients with and without other psychiatric and medical comorbidities.

James Burns, PhD, is a senior staff psychologist and senior research fellow at the Danielsen Institute of Boston University in Boston, Massachusetts, United States. He also holds appointments at the University of St. Thomas Graduate School of Professional Psychology in Twin Cities, Minnesota, United States, and as an instructor at Harvard Medical School in Boston, Massachusetts, United States. He currently coordinates consultation services for clergy, their families, and congregations. He was ordained as a priest in 1993 and holds a double diploma in behavioral medicine and counseling psychotherapy. He is a licensed psychologist and has received various awards for clinical expertise having completed clinical education at Yale School of Medicine, McLean Hospital/Harvard Medical School, the Center for the Study of Religion and Psychology, and the Boston Psychoanalytic Society. He holds a PhD in counseling psychology from Northeastern University. Dr. Burns's research to date has examined the relationship between levels of anger and aggression in adolescent males and their levels of spirituality, as well as general mental health issues and risk factors in adolescence and the relationship of these issues to religion and spirituality. Additional research studies currently underway are examining the way the sexual abuse crisis in the Catholic Church and church closings have affected morale of priests, pastoral leadership, and community dynamics. He has been involved in studying the impact that Catholic schools in inner cities have on the lives of youth and their communities. His international studies engage questions of peace and conflict particularly as these impact globalization and mental health resources.

Giuseppe Carrà, MD, MSc, PhD, consultant psychiatrist and research fellow at University College London, (UCL), England, studied Medicine at Milan University, and did his psychiatric training at Pavia University in Pavia, Lombardy, Italy. He has a PhD in public mental health from the University of Pavia. Dr. Carrà did an MSc in psychiatric research at UCL. Since 1995, he has been a consultant psychiatrist at S. Paolo University Hospital Trust,

Milan, Italy. Since 2004 Dr. Carrà has been a research fellow at UCL. He is a board member of the International Society of Addiction. His governmental and institutional appointments include: member of Guideline Development Group for Schizophrenia at the Italian National Institute of Health; member of Addiction Panel at Italian Department of Health; member of the Panel of Independent Experts assisting the European Commission at Directorate General of Justice, Freedom and Security in the priority field "Prevent Drug Consumption and Inform the Public," July 2007–June 2010. His research interests include dual diagnosis of psychosis and substance misuse; psychoeducational interventions in schizophrenia; and adaptation and implementation of local guidelines.

Massimo Clerici, MD, PhD, studied medicine and did his psychiatric training at Milan University, Milan, Italy. He has a PhD in psychiatry and relational sciences from the University of Milano in Italy. Since 1991, he has held the position of assistant professor (university researcher) at the University Hospital of S. Paolo in Milan, Italy, and of associate professor at the University of Milano Bicocca, also in Italy, (second University of Milan) from the academic year of 2007–2008. He is now the president of the Italian Society of Addiction Psychiatry (SIP. Dip, special section of the Italian Society of Psychiatry) since 2002, vice president of the Association of Research on Schizophrenia (ARS, member Society of WPA) from 2007 and board member at several professional and scientific societies. He is also the editor of the Addiction's Book Collection of one of the most important Italian publishers. Dr. Clerici also serves as a member of the National Department for Politics against Drugs, National Scientific Committee against Addictions of the Italian Government; and the Italian Panel of Scientific and Professional Societies against Addictions.

Jana Cook, MD, PhD, joined the Center for Criminality and Addiction Research, Training and Application (CCARTA) in San Diego, California, United States, in 2006 as assistant project scientist. She trains the workforce of substance abuse counselors and criminal justice professionals on addiction treatment issues in custody and community-based treatment programs in the state of California and serves as a member of the Executive Committee of the Forensic Addictions Corrections Treatment (FACT) Board of Directors. Dr. Cook graduated from the Medical School at the Comenius University, Bratislava, Slovakia. She is trained in general psychiatry and specialized in substance abuse treatment and forensic psychiatry and is certified by the Ministry of Justice of the Slovak Republic as an expert witness in psychiatry. Jana worked as assistant professor of psychiatry at the Comenius University, Bratislava. She is a member of the World Council of Young Psychiatrists and one of the found-

ers of the World Association of Young Psychiatrists and Trainees, and she has worked with the Council of Europe as consultant.

Ann N. Dapice, PhD, is director, Education and Research, of T. K. Wolf, Inc., a nonprofit American Indian organization in Tulsa, Oklahoma, United States. With a PhD in psychology, sociology, and philosophy from the University of Pennsylvania, United States, she has served as professor and administrator at a number of universities in the United States, including the University of Pennsylvania, Widener University, Penn State University, and Goddard College, teaching social sciences and Native American studies. Her cross-cultural research has been reported in professional journals, books, and academic presentations regionally, nationally, and internationally. Her speaking engagements include topics related to addiction, stalking, and American Indian issues. She has served on the Elders Council for the American Indian Chamber of Commerce, is a member of the Board of Directors of Mental Health Association in Tulsa, and the Tulsa Metropolitan Ministry/Domestic Violence Intervention Services Committee. She consults with the University of Pennsylvania on Native American issues, where she is founder/chair of the Association of Native Alumni.

Maria Dinis, PhD, MSW, is an associate professor for the Division of Social Work at California State University Sacramento (CSUS), in Sacramento, California, United States. Dr. Dinis is the admissions director for the Master's of Social Work Program at CSUS. Dr. Dinis is the chair of the CSUS Committee for the Protection of Human Subjects (CPHS) during every spring term and is a member of the California Health and Human Services Agency, a CPHS committee. She has published in the areas of alcohol/drug treatment, policy, and prevention. Her interests are in multicultural issues in regards to alcohol/drugs, women, and global social work. Dr. Dinis received her PhD from the School of Social Welfare at the University of California, Berkeley, in Berkeley, California, United States.

Nady el-Guebaly, MD, is professor and head, Division of Addiction, Department of Psychiatry at the University of Calgary in Calgary, Alberta, Canada, and past chair of the department. He is the founding medical director of the Calgary Health Region's Addiction Centre and Program in Canada. Currently, he is also board chair of the Alberta Gaming Research Institute, also in Canada; third term chair, Addiction Psychiatry Section of the World Psychiatric Association; and executive medical director and past founding president of the International Society of Addiction Medicine. He holds recognition awards from the American Society of Addiction Medicine, the Mexican Psychiatric Association, the Italian Society of Addiction Psychiatry, the University of Calgary's Guenther Distinguished Achievement Award in International Health, a Queen Elizabeth II Golden Jubilee medal and an Alberta

Centennial medal. Major research interests have resulted in 200 peer-reviewed papers and chapters, 450 abstracts, and 60 past and current research grants.

Ann Fabean, PhD, of Greenburg, Pennsylvania, United States, holds her PhD in family studies, an MA in counseling and BS in psychology. A licensed marriage and family therapist, she is now retired from practice. Her extensive work in the drug and alcohol field has been with addicts and their families in inpatient and outpatient settings, and in advocacy, prevention, and on various mental health boards.

Harris Friedman, PhD, is research professor in the Counseling Psychology program at the University of Florida in Gainesville, Florida, United States. He is also professor emeritus at Saybrook Graduate School and holds a number of other academic appointments. He received his PhD from Georgia State University in Atlanta, Georgia, United States, and Diplomate from the American Board of Professional Psychology, both in clinical psychology. He has taught at a number of colleges and universities as well as chaired a doctoral clinical psychology program and served as a graduate school academic dean. He is also retired from private practice as a clinical and consulting psychologist, where he specialized in humanistic-transpersonal psychotherapy and community-organizational change psychology. He serves as associate editor of *The Humanistic Psychologist* and editor of the *International Journal of Transpersonal Studies*, and has published over 100 professional papers and books.

Hamid Ghodse, MD, PhD, DSc, is professor of psychiatry and international drug policy at the University of London, England, the director of the International Centre for Drug Policy at St. George's University of also in London, England, medical director of the National Advisory Committee on Clinical Excellence Awards (ACCEA) for England and Wales, UK, nonexecutive director of the UK National Patients Safety Agency (NPSA), and the chairman of the RCPsych Honours Committee in the UK. He is a distinguished leader in the fields of psychiatry and addictive behavior from the perspective of research and policy development and implementation. He was awarded the highest honor of the Royal College of Psychiatrists in the UK, by being elected an honorary fellow in 2006. He has published over 300 papers and chapters and a number of books, of which those on legal and clinical aspects have become standard works, both in their 3rd edition. His new book, *Addiction at Work*, is another groundbreaking work. He has been an advisor on analgesic and psychotropic medication to the British National Formulary in the UK since 1982. His research paper won the SIGP 2004 Prize for the best psychopharmacological paper in the *British Journal of Psychiatry*. He was awarded CBE in 1999.

Sean R. Hogan, PhD, MSW, is assistant professor in the Department of Social Work at California State University Fullerton, California, United States. In 2005, he received his doctorate from the School of Social Welfare at the University of California, Berkeley, Berkeley, United States. Dr. Hogan's teaching interests are in the areas of substance abuse and social welfare policy. He also has an interest in the effectiveness of service learning as a pedagogical method for teaching substance abuse education to social welfare students. Dr. Hogan's research focuses on the effects of welfare reform legislation on marginalized populations, with a specific interest in the effects of eliminating welfare benefits to low-income substance abusers. He also has an interest in the history and construction of substance abuse policy in the United States and its relationship to social inequality.

Melinda Hohman, PhD, is a professor at the School of Social Work, San Diego State University, San Diego, California, United States, where she has worked since 1995. Dr. Hohman teaches courses in substance abuse treatment, research, and social work practice. Her research interests include substance abuse assessment and treatment services and the overlap of substance abuse treatment and child welfare services. She has been a trainer in motivational interviewing (MI) since 1999, training community social workers, child welfare workers, probation officers, and addiction counselors across southern California. Dr. Hohman is the Co-PI/evaluator on two substance abuse and mental health services expansion grants for women receiving drug treatment in a residential setting. She serves as a consultant on the California Screening Brief Intervention, Referral and Treatment Services (CASBIRT) project.

Rev. Robert Davis Hughes, III, PhD, is Norma and Olan Mills Professor of Divinity and Professor of Systematic Theology at the School of Theology, University of the South (Sewanee), Sewanee, Tennessee, United States, where he has taught since 1977. His degrees are from Yale, Episcopal Theological School, and St. Michael's College, University of Toronto. During this time he was a National Merit Scholar and a Kent Fellow of the Danforth Foundation. He is a graduate fellow of the Episcopal Church Foundation and a member of the Fellows' Forum planning group. He also serves on the General Board of Examining Chaplains and publishes frequently in *Sewanee Theological Review*, *Anglican Theological Review*, and elsewhere. He has served parishes in the Dioceses of Southern Ohio, Ohio, United States, and Toronto, Canada. He is past president and chair of the Missions Committee for Global Outreach for Addiction Leadership (GOAL) Project, www.goalproject.org, an ecumenical mission society that takes Twelve-Step recovery where it is not and supports it where it is new. Bob's wife, Barbara, is a noted sculptor, completing the new per-

manent crèche for the National Cathedral. They have two sons and two grandchildren.

Michael Kidorf, PhD, is an associate professor of psychiatry and behavioral sciences at Johns Hopkins University School of Medicine in Baltimore, Maryland, United States. He received a BA at Emory University and a PhD in clinical psychology at Florida State University. He also completed an internship at Brown University and postdoctoral training at the Behavioral Pharmacology Research Unit of the Johns Hopkins University. He is a licensed psychologist and associate director of Addiction Treatment Services at Johns Hopkins Bayview Medical Center. His current research interests include the study of stepped care approaches to improve the treatment response of drug users and the study of motivational interventions to encourage out-of-treatment drug abusers to enroll in substance abuse treatment.

Van L. King, MD, is an associate professor of psychiatry and behavioral sciences at the Johns Hopkins University School of Medicine in Baltimore, Maryland, United States. He received a BS at the University of Wisconsin–Madison and an MD at the University of Rochester School of Medicine. He completed postdoctoral psychiatry residency training at the Massachusetts General Hospital and is board certified by the American Board of Psychiatry and Neurology. He has been the medical director of Addiction Treatment Services at Johns Hopkins Bayview Medical Center since 1993. His research interests have focused on co-occurring psychiatric disorders in patients with substance use disorders and integration of co-occurring psychiatric disorder treatment with substance use disorder treatment. More recently, he has developed adaptive treatment strategies to extend the continuum of care for patients requiring long-term substance use treatment to minimize the intrusiveness of treatment while ensuring adequate monitoring and treatment response.

Eli Kolp, MD, received the MD degree from Moscow Medical Stomatological Institute in Moscow, Russia, and received residency training in both surgery and psychiatry in Russia, as well as additional residency training in psychiatry at the University of Texas Medical School in Texas, United States. In 1994, he began researching ketamine psychedelic psychotherapy while on staff at the James A. Haley Veterans Hospital in Tampa, Florida, United States, where he continued his work through 1999. He also was a fellow in geriatric psychiatry at University of South Florida College of Medicine. He is board certified in psychiatry and presently maintains a private practice in the Tampa Bay area of Florida, United States, specializing exclusively in ketamine psychedelic psychotherapy.

Igor Koutsenok, MD, MS, is assistant professor of psychiatry at the University of California San Diego (UCSD) School of Medicine in San Diego, California, United States, and director of the Center for Criminality and Addiction Research, Training and Application (CCARTA) also in San Diego. He has an MD from the University in Kiev (1982) in Kiev, Russia. In 1990 he received a degree as psychiatrist from the Medical University in Sofia in Bulgaria. In 1994–1996 he worked at the University of London, UK, Department of Addictive Behavior and Psychological Medicine, where he received a master's degree in addictive behavior. During the last 20 years, he served as an expert for many international organizations such as the Council of Europe, European Union, and the United Nations. Dr. Koutsenok joined UCSD in 1997. He is the Forensic Addiction Treatment Certification Board of Education director and director of the Offender Substance Abuse Treatment Institute. He has authored and coauthored over 30 scientific publications and book chapters, such as *Substance Abuse: A Comprehensive Textbook* (4th edition, 2004), and *Treatment of Drug Offenders* (2007).

Evgeny Krupitsky, MD, PhD, DMedSci, received an MD from Leningrad Institute of Hygiene and Sanitation, in Leningrad, Russia, a PhD from Leningrad Institute of Experimental Medicine in Psychopharmacology, also in Leningrad, and a DMedSci in psychiatry from St. Petersburg Bekhterev Research Psychoneurological Institute in St. Petersburg, Russia. He is the chief of the Laboratory of Clinical Pharmacology of Addictions at St. Petersburg State Pavlov Medical University and the chief of the Department of Addictions at the Bekhterev Research Psychoneurological Institute, as well as the main specialist in Addiction Medicine of the Health Care Committee of the Government of the Leningrad Region in Russia. In 1996–1997, he was visiting scientist in the Department of Psychiatry, Yale University School of Medicine in New Haven, Connecticut, United States. He has more than 150 publications dealing with the treatment of various forms of addictions and alcoholism.

Scot Lord, CATC, FACT, is a senior learning skills counselor at the University of California San Diego (UCSD) Center for Criminality and Addiction Research, Training and Application (CCARTA), in San Diego, California, United States. He is a certified addiction treatment specialist with over three years of frontline experience working with substance-addicted individuals. He has provided treatment services for the Mental Health Systems East County Drug Court program and was the lead counselor at a San Diego County Proposition 36 diversionary treatment program. Scot has extensive background and knowledge with evidence-based addiction treatment approaches, criminality, and addictive behaviors. Most recently, Scot was the lead trainer in

the CMC peer mentor training program in which he taught long-term prison inmates the therapeutic community treatment model, fundamentals of addiction science, and cross-trained correctional officers with prison inmates in order to develop an entirely inmate-driven therapeutic community.

Julian G. Martins, MA, MB, BS, qualified in medicine from the University of Cambridge, Cambridge, England, (BA [Hons], MA pharmacology) with first-class honors and from the Royal London Hospital (MBBS) in London, England, with honors in surgery and further prizes in medicine, surgery, and therapeutics. He obtained both the MRCP and MRCPsych and worked for many years as a university lecturer and consultant psychiatrist. He is currently the director of an independent academic research company, the Dr. Julian G. Martins Academy of Nutritional Medicine, Cambridge, England.

Scott E. McClure, PhD, is currently employed as a senior learning skills counselor with the University of California San Diego (UCSD), Department of Psychiatry, Center for Criminality and Addiction Research, Training, and Application (CCARTA) also in San Diego. At CCARTA, he provides technology transfer of the most current evidence-based treatment procedures for substance use disorders to substance use treatment staff throughout the state of California. Scott has over seven years of experience working with individuals who have co-occurring mental health and substance use issues across a broad scope of populations ranging from the severally mentally ill to university students. He has facilitated groups on posttraumatic stress disorder (Seeking Safety), adult attention deficit hyperactivity disorder, dialectical behavior therapy, as well as implemented motivational interviewing and life skills groups while employed at the UCSD Co-occurring Disorder Outpatient Clinic. Scott's clinical and research interests include criminality and addiction, trauma, ADHD, and multicultural issues.

Patrick McNamara, PhD, is an associate professor of neurology and psychiatry at Boston University School of Medicine in Boston, Massachusetts, United States. He is based at the Department of Neurology at the Veterans Administration New England Healthcare System. He has received U.S. Veterans Administration (VA) Merit Review Awards (2000–2003) there as well as two U.S. National Institute of Health (NIH) awards (current) to fund his research in neurology and evolutionary psychology. He is the cofounder (with Wesley Wildman) of the nonprofit research Institute for the Biocultural Study of Religion (www.ibcsr.org). The institute's most recent venture is the launching of a new scientific journal called *Religion, Brain and Behavior,* which will be devoted to publishing new studies in the field. He has authored several publications on religion and brain and related topics including addictions. In 2005–2006 he edited a three-volume series of books on evolutionary, cognitive, and neurological associations of religiousness (Praeger Press). Prior

to joining the VA's Neurology Department he taught experimental design, research methods, and neuropsychology at SUNY College Buffalo and Keene State College. He graduated with honors in psychology at Boston University in Massachusetts, United States, and received a PhD in behavioral neuroscience from Boston University in 1991.

Joseph R. Merighi, PhD, MSW, is an associate professor of human behavior at Boston University School of Social Work in Boston, Massachusetts, United States. Dr. Merighi is the Co-editor-in-Chief of the *Journal of Nephrology Social Work* and he serves as a consulting editor for *Social Work* and the *Journal of Social Work Education*. His research focuses on social work practice in health care settings, with an emphasis on renal social work, and cross-national comparisons of job-related well-being of social work practitioners. In addition to his research and teaching, Dr. Merighi has served as a consultant for organizations such as the National Kidney Foundation's Council of Nephrology Social Workers and United Cerebral Palsy. Dr. Merighi received his MSW and PhD from the School of Social Welfare at the University of California, Berkeley in Berkeley, California, United States.

Lorraine T. Midanik, PhD, is dean and professor in the School of Social Welfare at the University of California at Berkeley in Berkeley, California, United States. She received her PhD from the School of Public Health at the Johns Hopkins University in Baltimore, Maryland, United States. Following graduation, she was a postdoctoral fellow at the School of Public Health at U.C. Berkeley and a health evaluation analyst at Kaiser Permanente. Dr. Midanik has an extensive career in research and publication in the alcohol field beginning as a clinician, then as a researcher and teacher. Her work has focused primarily on the epidemiology of alcohol use and alcohol-related problems and on methodological issues—primarily in the area of self-report validity. In 2004, she received a Fulbright Fellowship to examine alcohol research policy at Stockholm University in Sweden. In 2006, she wrote *Biomedicalization of Alcohol Studies: Ideological Shifts and Institutional Challenges*, published by Aldine Transaction.

Karin J. Neufeld, MD, MPH, is assistant professor of psychiatry and behavioral sciences at Johns Hopkins University School of Medicine in Baltimore, Maryland, United States. She received her BS and MD from the University of Manitoba, Canada, completed postdoctoral psychiatry residency training at the Johns Hopkins University, School of Medicine, and an MPH at the Johns Hopkins School of Public Health. She is board certified by the American Board of Psychiatry and Neurology and a fellow of the Royal College of Physicians and Surgeons of Canada. Since 2002, she has been an associate medical director

of Addiction Treatment Services at Johns Hopkins Bayview Medical Center. Her research interests have focused on co-occurring psychiatric and medical disorders in patients with substance use and the ways in which appropriate care can be integrated. Currently she is developing innovative strategies for patients with severe and persistent drug use problems who are not responding to routine treatment.

Jessica Peirce, PhD, is assistant professor of psychiatry at Johns Hopkins University School of Medicine in Baltimore, Maryland, United States. She received a BA from University of Chicago in Chicago, Illinois, and a PhD in biological psychology from University of Oklahoma Health Science Center, Oaklahoma, United States, respecialized in clinical psychology at Oklahoma State University, and completed internship and postdoctoral training at the Boston VA Medical Center. She is a licensed psychologist and associate director of the Addiction Treatment Services program at Johns Hopkins Bayview Medical Center. Dr. Peirce's research and clinical interests are in gender differences and comorbidity of substance use with other psychiatric problems, particularly trauma and posttraumatic stress disorder.

Flavio Poldrugo, MD, PhD, received his MD at Trieste, Italy (1975), the specialization in psychiatry at Zagreb, Croatia, 1979, and the PhD in pharmacology in Birmingham, Alabama, United States, 1985. Dr. Polgrugo has held numerous academic positions, including: assistant professor of psychiatry (Trieste, 1975), visiting professor of neuroscience (Birmingham, 1980), associate professor of psychiatry (Trieste, 1985) and visiting professor of social psychiatry (Zagreb, 1992). His research interests span from preclinical research on alcoholism to prevention of alcohol problems, pharmacological and nonpharmacological treatment of alcoholism, and utilization and cost-effectiveness of alcohol treatment. Dr. Poldrugo has been very active in international relationships: he was a founding member of the Association of the Alcoholics under Treatment (1979), the Association for the Study and Treatment of Alcoholism in Europe (1991), the International Society of Addiction Medicine (1999), chairman of Section of the International Council on Alcoholism and Addictions (1995), board member of the International Society of Addiction Medicine Journals (2000), past president of the Addiction Section of the European Psychiatric Association (2006) and secretary of the same section in the World Psychiatric Association (2005). Dr. Poldrugo is deputy editor of the journal *Alcoholism: Journal on Alcoholism and Related Addictions* (1992) and serves in the scientific board of seven other international journals. He is author of more than 200 articles in international journals and 15 chapters of books.

Basant K. Puri, MA, PhD, MB, BChir, MRCPsych, MMath, of the Medical Research Council (MRC) Clinical Sciences Centre (CSC), Hammersmith Hospital and Imperial College London, England, received his primary and postgraduate degrees in medicine from the University of Cambridge, England, and carried out postdoctoral work in molecular genetics at the MRC and University of Cambridge, and in imaging at the Royal Postgraduate Medical School at Hammersmith Hospital, London. He also has a first-class honors degree in mathematics and postgraduate degrees in mathematics and is a member of the Royal College of Psychiatrists in the United Kingdom.

Kathleen Sciacca, MA, of Sciacca Comprehensive Service Development for Mental Illness, Drug Addiction and Alcoholism (MIDAA) in New York City, New York, United States and on the Web at http://users.erols.com/ksciacca/, has been a forerunner in the development of treatment methods and programs for mental illness, drug addiction, and alcoholism (MIDAA) since 1984, when there were no program models or attention given to this population. Her programs have been replicated across New York state, Alaska, Delaware, Georgia, Tennessee, North Carolina, Louisiana, Connecticut, Michigan, Minnesota, Washington, DC, Texas, Virginia, and other states, cities, counties, and agencies in the United States and internationally. She has lectured in colleges and universities; participated in national reports; authored the MIDAA service manual; produced video invited into the Library of Congress; and has been reviewed by *Time* magazine. She is an international consultant, lecturer, and trainer. She is former director of the MICAA Training Site for Program and Staff Development, statewide for the New York State Office of Mental Health (1984–1992). Ms. Sciacca is a trainer and consultant on motivational interviewing.

Ramadugu Shashikumar, MD, is a consultant psychiatrist based in Jallandhar, Punjab, India. He graduated from one of the most prestigious colleges of India, the Armed Forces Medical College Pune, in December 1991. After having done service obligations, he received an MD in psychiatry in 1999. He has been working on treatment and prevention of alcoholism at a community level since 1999. Apart from this he has worked in child psychiatry. He has been awarded the best paper award for the paper titled "Best Paper Presentation on Psychosocial Co-relates of Service Personnel's Children with Recurrent Abdominal Pain." He is a keen wildlife enthusiast. He has been instrumental in creating information booklets for use by general public and patients on subjects like alcoholism, substance abuse, and child psychology in multiple languages. He has authored a chapter on psychological aspects of a cold environment in a textbook on environmental emergencies published by the Department of Medicine of Armed Forces Medical College.

Daniela Sisneros, MSW, received her master's degree in social work, with an emphasis in administration, from San Diego State University, San Diego, United States. Ms. Sisneros has worked in nonprofit and academic settings for six years and is currently the center coordinator at the Center for Alcohol and Drug Studies and Services. The programs she has served on have specialized in: alcohol and drug prevention; child welfare–related research and program evaluation; consensus organizing; screening; brief intervention and referral to treatment services; and short-term psychiatric rehabilitation treatment. Ms. Sisneros has made presentations at scientific meetings and currently educates on substance abuse and cultural competency issues.

Katharine Slack, MSW, received a BS in psychology from Guilford College in Greensboro, North Carolina, United States, and an MSW from San Diego State University in San Diego, California, United States. Katie Slack currently works as a brief treatment counselor for the California Screening Brief Intervention, Referral and Treatment Services (CASBIRT) Project. Her work history includes nearly 10 years of experience in the social services field, including several years of case management and program management for an independent living skills program working with teenagers and young adults in foster care. She also worked for nearly three years doing community education and outreach on domestic violence and sexual assault. Additionally, she held a one-year internship placement offering individual therapy for persistently mentally ill adults, as well as an additional one-year internship placement conducting individual, family, and child therapy with survivors of domestic violence and sexual assault.

Ray B. Smith, PhD, received his doctorate at the University of Texas in Austin, Texas, United States, in physiological psychology in 1976. Since then he has taught at the State University of New York at Cortland, the University of Virginia Graduate School, the Washington Theological Coalition, and has served as adjunct advisor for doctoral dissertations at several universities, including the University of Michigan. Since 1972 he has researched CES in major addiction treatment programs in Washington, DC, Dallas/Ft. Worth, Santa Barbara, Los Angeles, Seattle, and St. Louis. After serving as research consultant on CES at the veterans hospital in Houston, Texas, he presently serves as a consultant based in Forestville, Maryland, United States, as research advisor to a CES research project in a field army hospital in Iraq, and as a member of a scientific board of a major pharmaceutical company. He has presented papers at national and international conferences on CES, and in 2007 published a research monograph on CES. He presently serves as a private research consultant for research projects around the nation.

Kenneth B. Stoller, MD, is an assistant professor of psychiatry and behavioral sciences at the Johns Hopkins University School of Medicine in Baltimore, Maryland, United States. He received his medical degree from Johns Hopkins in 1992. He completed his residency in psychiatry at the Johns Hopkins Hospital, followed by a two-year postdoctoral fellowship in addiction psychiatry at the Behavioral Pharmacology Research Unit at Johns Hopkins. He then joined the faculty group at Addiction Treatment Services at Hopkins Bayview, where he is an ABPN-certified psychiatrist and associate medical director. Dr. Stoller's research interests center on cost issues as they relate to drug abuse and treatment, methods of enhancing treatment adherence, managed care organization approaches to members with drug abuse, and co-occurring psychiatric, medical, and substance use disorders.

Mary Theresa Webb, PhD, is the founder and past Director of the Global Outreach for Addiction Leadership and Learning (GOAL) Project based in Aliquippa, Pennsylvania. She was one of the founders of the International Substance Abuse and Addiction Coalition (ISAAC), based in the UK, and the OPORA Training Center in Moscow, Russia. (*Opora* is the Russian word for *support*. Moscow-based nongovernmental OPORA, which works with the Russian government to fight addiction, has trained more than 3,000 persons in addiction and 12 Step programs, and implemented 60 recovery groups in 31 cities in Russia.) As a global educator, she has personally and with others facilitated addiction trainings in the United States, Russia, Romania, Tajikistan, Bulgaria, Kenya, Tanzania, Honduras, and Egypt. Currently, Dr. Webb is the Project Director of the Kenya-based, USAIDS-funded Substance Abuse Rehabilitation and HIV/AIDS (SARAH) Network in Kenya. Dr. Webb holds a master's in Education from the University of Pittsburgh and a Doctor of Philosophy Degree in Family Systems/Addiction Intervention from the University of America. She is the author of *Tree of Renewed Life, Church Training Manual*, and coauthor of *Codependence in Family Systems*.

Michael Winkelman, MPH, PhD (University of California-Irvine), MPH (University of Arizona), is an associate professor at Arizona State University in Tempe, Arizona, United States. He served as president of the Anthropology of Consciousness Section of the American Anthropological Association and was the founding president of its Anthropology of Religion Section. Winkelman has engaged in cross-cultural and interdisciplinary research on shamanism, focusing principally on the cross-cultural patterns of shamanism and identifying the associated biological bases of shamanic universals and altered states of consciousness. His principal publications on shamanism include *Shamans, Priests and Witches* (1992) and *Shamanism: The Neural Ecology of Consciousness*

and Healing (2000). He has also addressed the role of psychedelic medicines in shamanism, developing neurophenomenological perspectives that link the experiences to the underlying physiological processes (*Sacred Plants, Consciousness and Healing* [1996] and *Psychedelic Medicine* [2008]). He has also explored the applications of shamanism to contemporary health problems of addiction.

Susan I. Woodruff, PhD, is a professor at San Diego State University School of Social Work in San Diego, California, United States. She is an epidemiologist with over 20 years of experience in the area of health research, much of it with underserved, high need, and understudied populations. She has a master's degree in experimental psychology and a doctorate in epidemiology from the University of California San Diego/San Diego State University both in San Diego, California. Her areas of expertise include substance use epidemiology and intervention, adolescent health, program evaluation (i.e., pre-post change analysis), Latino health promotion, measurement/methodological issues, research design, and univariate/multivariate statistical data analysis. Dr. Woodruff has served as investigator, statistician, and data analyst on several large epidemiological and intervention studies, and has authored and coauthored over 150 articles in scientific journals. Currently she is the evaluator on the California Screening Brief Intervention, Referral and Treatment Services (CASBIRT) project.

M. Scott Young, PhD, received an MS in management information systems, an MA in clinical psychology, and a PhD in experimental psychopathology from University of South Florida in Florida, United States. He works as coordinator of statistical research in the Department of Mental Health Law and Policy at the Louis de la Parte Florida Mental Health Institute, University of South Florida in Tampa, Florida, United States. His research currently focuses on substance abuse treatment program evaluation, alternatives to incarceration for nonviolent drug offenders, and coerced substance abuse treatment. He has published a number of articles and book chapters on substance abuse and mental health program evaluation, and he has received grant and contract funding to analyze mental health and substance abuse treatment provider administrative data sets.

Series Foreword

Tragically, most people across the globe have either struggled with a health- and relationship-damaging addiction or know someone who has. Addictions, broadly defined, have touched the lives of the majority of people in multiple cultures and locations. For centuries, numerous people have suffered with their addictions to alcohol and drugs as well as with other addictions, with often devastating outcomes. Sadly, important relationships, jobs and careers, and many lives have been lost due to the destructive power of addiction. These tragedies not only occur for those who suffer from addiction, but for their loved ones, coworkers, and community members, and for innocent victims who are perhaps in the wrong place at the wrong time when an addiction-related accident, crime, or violence occurs. The enormous cost of addiction in health care, traffic accidents, crime, violence, loss of workplace productivity, and broken families is too large to quantify. The global spread and success of organizations such as Alcoholics Anonymous (as well as related organizations such as Narcotics Anonymous, Sexoholics Anonymous, and Overeaters Anonymous) is a testament to the numerous people trying to recover from their addictions. Sadly, for every person seeking help for his addiction problem, there are likely to be many more people who never do. Clearly we need help to better understand, evaluate, treat, and cope with those who suffer from addictions.

In this remarkable four-volume set, *The Praeger International Collection on Addictions,* Angela Browne-Miller, PhD, DSW, MPH, has assembled an all-star and diverse team of leading experts from across the globe to provide a state-of-the-art understanding of the various facets of addiction. Each chapter

is written in a manner that is suitable for professionals working in the field as well as educated lay readers and those who either struggle with addictions or live or work with someone who does. What is especially remarkable about the four-volume set is its emphasis on addiction from around the globe, examining multicultural and international issues in addiction, as well as its coverage of so many multifaceted aspects of diverse addictions. For example, it certainly makes sense to cover fully addiction topics such as alcohol abuse and illegal drug use of, say, cocaine and heroin, yet chapters are also offered that examine addictions to caffeine, Internet pornography, work, television, intimate relationship abuse, and shopping. The chapters highlight biological, psychological, social, spiritual, and public health perspectives, with chapter authors who are psychologists, psychiatrists, other physicians, nurses, social workers, counselors, clergy, and other professionals. Dr. Browne-Miller is uniquely qualified to assemble this project as she is someone who has worked in the field of addiction for many years and has training in a unique blend of both the policy and the clinical sides of psychology, social work, education and public health.

The set is complete, state of the art, and highly informative and engaging. There is something for everyone interested in the field of addiction for professional or personal reasons. It is hoped that professionals and lay readers will greatly benefit from this important work and, in doing so, will find a way to improve the lives of those touched by addiction. It is my hope that both research and practice in the field of addiction will be greatly improved thanks to this set. The lives of those who either struggle with addiction or live with those who do will ultimately be improved thanks in part to this critical series. I am grateful to Dr. Browne-Miller and her assembled contributors for providing us all with such important and high-quality volumes that are now available to the public and professional communities. If only one life is saved or improved thanks to this set, it will be a great success in my view; yet I expect that many lives will ultimately be saved or greatly improved thanks to *The Praeger International Collection on Addictions*.

Praeger Series Editor, Abnormal Psychology

Preface

Angela Browne-Miller, PhD, DSW, MPH

Welcome to *The Praeger International Collection on Addictions,* addressing the insidious, pervasive, worldwide problem of human addiction. Addiction is clearly a global issue, touching every population, every nation, and every age group, people from all walks of life everywhere, directly or indirectly. Indeed, we are talking about an affliction of epic and epidemic proportions. We cannot look away. This is the health of the human species we are talking about.

The World Health Organization (WHO, 2008, p. 1) reports that "psychoactive substance use poses a significant threat to the health, social and economic fabric of families, communities and nations. The extent of worldwide psychoactive substance use is estimated at 2 billion alcohol users, 1.3 billion smokers and 185 million drug users" (p. 1). The WHO has estimated there to be at least 76.3 million persons with alcohol use disorders worldwide, and at least 15.3 million persons with drug use disorders worldwide. Alcohol use and abuse as well as the use and abuse of other psychoactive substances contributes to substantial individual and public health costs. Alcohol is but one substance playing a major role in this global addiction epidemic, but clearly there are many others, despite efforts to prevent new addictions and addicts, and to contain world drug markets (UN, 2008, p. 7).

For example, cocaine shares the stage with other abused drugs. Its prevalence is estimated to be up to 3 percent of the population in developing countries, with severe medical, psychological, social, and economic consequences including, but not limited to, the spread of infectious diseases (e.g., AIDS, hepatitis, and tuberculosis), plus crime, violence, and neonatal drug exposure.

Amphetamine-type stimulant (ATP) abuse is more widespread than cocaine abuse in at least 20 countries. Methamphetamine is presumed to lead in ATP addiction rates, with massive meth epidemics affecting several whole countries and entire regions of others. Social and public health costs of methamphetamine production and use via smoking, sniffing, inhaling, and injecting are staggering and growing in many regions. Additionally, there has been a global increase in the production, transportation, and use of opioids, especially heroin, with worldwide heroin production doubling or even tripling since the mid-1980s. Global estimates are that 13.5 million persons consume opioids, with 9.5 million of these being heroin users who face health risks including hepatitis, HIV, and death. And cocaine, meth, and heroin are just one piece of the picture.

The hotly debated drug cannabis—or the *Cannabis* family of drugs with the euphoric tetrahydrocannabinols, or THCs, including marijuana and hashish preparations—is said to be the most widely abused drug. Research is now suggesting the risk for acute health effects of long-term, chronic cannabis use, including potential impairment of cognitive development, learning, memory, recall, attention, and coordination. (Certainly the presence and extent of long-term effects of casual, of regular and of chronic use are as yet not entirely ascertained.) Both casual use of marijuana and medical use of forms of what is termed medical marijuana (e.g., dronabinol sold as Marinol, the cannabidiols, or CBDs) are subsets of all forms of cannabis use. There are legitimate therapeutic uses of this substance, and these uses make it all the more difficult to regulate marijuana drugs fairly and effectively.

We have here, and in the use of any psychoactive medication for therapeutic purposes, a gray area in which illicit and licit use overlap and can confuse many adult and youth consumers, researchers, and policy makers, among others. In the emergence (or reemergence in history, some will argue) of cannabis as medicine, we have a model for asking which, if any, abused substances may, and perhaps should, be repurposed for medicinal or treatment purposes, and how this is best done against the backdrop of the global addiction epidemic.

Regarding marijuana, we are confronted with the age-at-first-use issue, which suggests that early onset of regular cannabis use may affect not only the academic and social performance of children and teens, but also their future susceptibility to addictions. It was in the 1960s that the hotly debated label "gateway drug" was applied to marijuana, perhaps to scare off its use, and only in the decades since have we understood better what this might actually mean to us. It may not be that marijuana provides the training wheels for drug addiction, but rather that it may serve as an indicator of future use of the same or other drugs. Of course, today, with so many young people having access, and taking advantage of their access, to the whole range of psychoactive substances,

the question of which drug might be a gateway to which other drug dissolves into the fury of the countless addiction conundrums of our constantly changing times.

There is always a new, or rediscovery of an old, addiction on the horizon. There is also always a new (or rediscovered) psychoactive substance for exploratory, research, and perhaps even treatment purposes emerging (or re-emerging). Labeling all of these substances as addictive right out the gate may or may not serve science or even humanity itself. How can we be certain the approach we take will be a constructive one? With new legal (where licensed for development and experimentation) and illegal (where not being utilized under protection of law) so-called designer drugs emerging at a staggering rate, we must admit that we cannot know what is coming, nor whether the new compound will be addictive, or popular, or of medicinal value, or even accessible. We can only imagine what the brave new world of chemistry will continue to bring and whether any benefits can be made available without accompanying risks and detriments.

Moreover, the desire to explore and achieve various altered states of consciousness in religious, spiritual, ritual, and perhaps even treatment settings, is unfolding into debates about rights (Browne-Miller, 1989, pp. 258–260). When there is no demonstrated risk to self or others, we have to ask ourselves whether this right should be protected, especially in circumstances of traditional uses for religious purposes. Again, this dilemma arises against the backdrop of the global and runaway epidemic of substance addiction. How do we balance pressures from opposite directions (freedom protecting the right to use versus control to stop injury and costs of using), when these pressures are not balancing themselves?

Also against the backdrop of global addiction levels, is the massive level of addiction to legal drugs, many of which are heavily marketed to consumers. The legal drug tobacco is said to be the substance causing the most damage globally, with at least one-third of the global population smoking. While smoking rates may be dropping in some countries, the reverse is true globally. As just one of its effects, smoking accounts for some 90 percent of all lung cancer in men and 70 percent of all lung cancer in women. And yet tobacco use is overwhelmingly viewed as being "the single most avoidable cause of disease, disability and death" in the United States (CDC, 2008, p. 2).

And perhaps nothing here has touched so many lives as the regularly consumed, legal drug caffeine, perhaps because coffee drinking is considered so very normal and acceptable, even necessary, in everyday life. However, we must ask whether there is a level of caffeine use that is abuse—or perhaps self-abuse. Surely we do not want to throw caffeine use onto this list of substance abuses

and addictions. Still, a collection on addiction would not be complete without at least touching on this matter, and therefore we do address caffeine herein.

And then there are also the addictions to prescription drugs (such as Vicodin, Percocet, OxyContin, and Darvon), which we find increasing rapidly and already a worldwide phenomenon, with the most commonly abused prescription drugs being opiates. The U.S. National Institute of Mental Health characterizes prescription drug addiction as the second most common illegal use of drugs in the United States, second only to marijuana.

We must also note that unusual, virtually invisible psychoactive substances are working their way into our everyday lives. Household and workplace products contain many volatile substances, exposure to which can be not only damaging, but also intoxicating, and perhaps addicting. Although this domain of substance use and abuse is not specifically addressed herein, we must acknowledge the severe and perhaps largely unmeasured effects of this domain of even routine, legal substance use as well as unintentional and intentional abuse.

So as not to exclude nonsubstance addictions in this overview of addiction today, the fourth volume in this collection on addiction reminds us that work, television, shopping, food (with its particularly difficult-to-call-addiction nature), intimate partner relationship, gambling, Internet, and even pornography addictions make their marks in our lives, either indirectly or directly. These behavioral, nondrug addictions, which occur alone and co-occur with each other, also do co-occur with substance uses, abuses, and addictions. Every human being is in some way affected by the prevalence of behavioral addictions, either directly or indirectly. The study of behavioral addictions teaches us a great deal about addiction itself.

All this suggests the picture of an addiction-prone and largely chemically dependent human species. And this is just the tip of the iceberg. With this truly incomplete laundry list of human fallibilities—or better stated, perhaps, human *vulnerabilities*—this four-volume collection on addiction is truly that: a collection of perspectives, approaches, and findings. Each chapter is a snapshot of the work and thinking taking place in many fields of addiction. Contributors to this collection work with addiction on the various social, philosophical, psychological, spiritual, policy, political, economic, biological, and even cellular levels, all places where this thing we call "addiction" lives. Certainly this collection would have to comprise hundreds of volumes, rather than the four that it does, to address addiction in all its iterations.

Here we give voice to a diverse cross section of perspectives on addiction. This is in no way an exhaustive cross section (of either perspectives or addictions); rather, this collection suggests the diversity of perspectives, theories, practices, and types of addiction in the field—or better stated, *fields*—of addiction. The four volumes of this collection represent the voices of those who have

graciously and even bravely stepped forward from their numerous countries and arenas of work to contribute their ideas, research, and experiences. Certainly there are many others out there, many other aspects of addiction, and many other drugs and objects of addiction not addressed in these volumes.

This work is divided into four volumes, with the first three addressing addictions to substances and the fourth addressing behaviors that show characteristics of addiction. Volume 1, *Faces of Addiction, Then and Now,* offers a sampling of the depth and breadth of addiction today and in the past; volume 2, *Psychobiological Profiles,* surveys some of the interlinked psychological and biological aspects of addiction; volume 3, *Characteristics and Treatment Perspectives,* samples the range of addiction treatment perspectives and approaches; and volume 4, *Behavioral Addictions from Concept to Compulsion,* gives the reader a glimpse of behavioral addictions other than substance addictions.

Readers will observe that the content of these volumes is indeed diverse and in no way represents any one view or theory of addiction. There are many other voices out there who must also be heard, and only in the interest of time and space are we stopping here, at these volumes. The content of these volumes in no way expresses the opinion of this editor, nor of this publisher, regarding what is right, best proven, or even most en vogue in the addiction world; rather, this *International Collection on Addictions* seeks a display of, a sampling of, the diversity of effort to quell the detrimental effects of addiction on individuals, families, communities, societies, economies, and international relations; on ecologies; and in fact, on the human population of planet Earth.

Introduction to Volume 4: Behavioral Addictions from Concept to Compulsion

Angela Browne-Miller, PhD, DSW, MPH

This is volume 4, *Behavioral Addictions from Concept to Compulsion*, of *The Praeger International Collection on Additions*, where we see among the many faces of addiction the nonsubstance addictions. Here we move into the tangled territory of evolving and expanding definition. We can ask whether nondrug addictions are actually addictions. If so, why? If not, why not? We can argue all sides of this matter. Yet, where there is continued engagement, excessive engagement, in the face of harm to self or others, in an activity generating temporary and too often lasting shifts, changes, adaptations, even damages—on social, psychological, biological, even biochemical levels—we encounter *addiction-like* behavior that, for all intents and purposes, is indeed addiction. Certainly we may label these as *non*substance addictions, yet we are in so many ways talking about drug-like effects where there is *excessive engagement in* working, television viewing, shopping, intimate partner abusing, food consuming, as well as in pornography, Internet, and gaming and gambling activities. As our contributors will show, engagement in these activities to excess shows symptoms of addiction such as trigger-response, urge-craving, reinforcement, tolerance, and withdrawal.

Part I, "Compulsions," opens with a penetrating look at something to which we may all be vulnerable, that is, work addiction. Ronald J. Burke, PhD, of the Schulich School of Business, York University, in Toronto, Ontario, Canada, contributes chapter 1, "Work Addiction: Causes, Consequences, and Choices." Working hard and working long hours are highly respected activities signifying (at least to onlookers) dedication and commitment. Yet, working hard—

excessive working—may be an addiction to working or workaholism. While employers may even reward workaholism, workaholics may or may not be productive. Symptoms of workaholism have been seen as parallel to those of other addictions, with workaholics often being unhappy, obsessed, exhibiting a reluctance to disengage from work (e.g., a tendency to work, to think about work, and to talk about work far more than others do), with willingness to work anytime and anywhere, to choose work over leisure, to lose sight of boundaries between work and the rest of life. Burke reviews definitions of workaholism, the term itself first being used in 1971, when a workaholic was defined as "a person whose need for work has become so excessive that it creates noticeable disturbance or interference with his bodily health, personal happiness, and interpersonal relationships, and with his smooth social functioning." The workaholic gradually becomes "emotionally crippled and addicted" as this "progressive, potentially fatal disorder" consumes him or her. Burke encourages employers to assist in the development of workplace values and to promote healthy lifestyles among employees, which will support the "workaholism types" in addressing their addiction. However, intervention in a workaholic pattern may be quite challenging because "work addicts almost always are in denial." We might add that their employers may be as well.

Chapter 2, "Addiction to Television: With Commentary on Dependence on Video Games and the Internet," by Robert W. Kubey, PhD, of the Center For Media Studies at Rutgers University in New Brunswick, New Jersey, United States, adds another face to behavioral addiction. Kubey notes that "The time people spend viewing is nearly astonishing. People throughout the industrialized world, from the United States and Latin America to Europe and parts of Asia, the Middle East, and Africa, typically devote about three hours a day to watching television. In many societies, this easily constitutes half of all a person's leisure time or, calculated another way, 9 full years of a 75-year lifespan." Kubey adds that "the three hour figure *is* an average. . . . 'addicted' or so-called 'heavy viewers' . . . might watch five or six hours a day . . . about 30% to perhaps 38% of their waking time watching TV, or as many as 20 years of the 50 years they will be awake if they live to 75." That television viewing can indeed be self-perpetuating, and can indeed produce a dependency, is of grave concern. Addiction to television can produce effects such as aggression, obesity, poorer academic performance, and impaired imagination. Kubey does not decry all television viewing, as there are significant cultural, educational, and entertaining programs. "Television also surely provides much needed distraction and escape. Still, "viewing begets more viewing" and "one must generally keep watching in order to keep feeling relaxed." Note that where television is used for relaxation,

the "quick onset of relaxation is particularly telling when compared to that produced by certain drugs that are known to be habit forming or 'addictive.'"

Chapter 3, "Excessive Buying as a Genuine Addictive Behavior" by Paul Rose, PhD, and Dan J. Segrist, PhD, of Southern Illinois University, Edwardsville, Illinois, United States, turns to "hyperconsumption." Here the case for "classifying excessive buying as a genuine behavioral addiction" is presented. The benefit of such a classification is a better understanding of, and therefore treatment of, this condition as an addiction. Rose and Segrist define excessive buying through a review of the literatures on compulsive, impulsive, and nonfrugal purchasing. Only in the past few decades has research begun to establish a demographic of this worldwide problem—shopping addiction. Excessive buyers are more likely to experience feelings of depression after shopping, rather than pleasure after a new purchase. The emotional pathway is mapped something like this: the individual may be driven to shop for any of a variety of reasons, then shop excessively, and then feel out of control, then afterward experience guilt and shame, negative self-views, and depression. Shopping exposes the excessive buyer to numerous mental health problems. The sensation of "diminished impulse control" is seen as parallel to that found in other addictions. Preceding excessive buying is any number of states of mind including low self-esteem and narcissism—likely serving as classical triggers.

Offering another look at compulsive buying, we shift in chapter 4 to perspectives from another part of the globe, exemplifying the universality of the conditions we read about in this collection on addictions. "Compulsive Buying Disorder" is contributed by Mamta Sood, MD, and Meera Vaswani, PhD, both of the All India Institute of Medical Sciences in New Delhi, Delhi, India. Sood and Vaswani accept that buying is a "universal, everyday human experience and has been practiced since ancient times." As we have progressed through history, our awareness of, and labeling of, a buying disorder—the *compulsive* buying disorder—have emerged. As long ago as the early twentieth century, terms such as *oniomania* (for sale—mania) have focused on impulsiveness in shopping. Compulsive buying has been conceptualized as various disorders including impulse, obsessive-compulsive, mood, and substance abuse disorders. Sood and Vaswani describe the "increasing sense of arousal or tension prior to the act and an experience of pleasure, gratification, or release of tension at the time of committing the act." Sood and Vaswani also note that, while they find no formal guidelines being emphasized, there are psychotherapeutic, pharmacological, and other treatments available. Long-term outcome studies and the establishment of the reliability and validity of diagnostic criteria are called for.

At this point, we pause to consider which of the compulsive and addictive behaviors are indeed criminal and which of these are mistaken for criminal behaviors. To this end, chapter 5, "Association with Criminality of Habit and Impulse-Control Disorders," is contributed by Ian H. Treasaden, MB, LRCP, MRCS, FRCPsych, LLM, of the Three Bridges Medium Secure Unit, West London Mental Health NHS Trust, Middlesex, England, and Basant K. Puri, MA, PhD, MB, MRCPsych, MMath, of the Medical Research Council (MRC) Clinical Sciences Centre, Hammersmith Hospital and Imperial College, London, England. Treasaden and Puri emphasize that "Impulse-control disorders are a disparate group of conditions with different characteristics and epidemiologies." The authors establish the parameters of the debate, or better stated, perhaps, of the confusion, surrounding impulse control disorders: "whether the urges and impulses and resulting criminality are irresistible is open to question. Perhaps no impulse is irresistible, if an individual is motivated to try hard enough to resist." If an impulse is generally controlled and then not controlled in an instance of "momentary excitement," or heightened stimulation (triggering), the question may be as follows: is this a "disordered function" or merely an "irresistible impulse?" Treasaden and Puri note that the psychopathologies of the many conditions included in habit and impulse-control disorders are not identical. "Pathological gambling is a more complex condition, requiring attention to the whole person, than an impulse-control disorder such as tricotillomania. A pathological gambler shows features akin to substance addiction, with characteristic histories of escalation from use, abuse, and then addiction with tolerance and withdrawal symptoms, with gambling becoming the center of a sufferer's life, unlike . . . pyromania or tricotillomania."

Surely at this point numerous other detrimental habitual behaviors come to mind. The next chapter, chapter 6, "Troubled IPR Addiction: Habitual Attraction, Abuse, and Violence in Intimate Partner Relationships," which I, Angela Browne-Miller, PhD, DSW, MPH, contribute here, addresses an addiction-like behavior that may be seen for political, philosophical, and perhaps even emotional reasons as being in the "gray zone" of unproven and debated addictions. The existence of some degree of intimate partner relationship (what I call IPR) addiction is virtually a given, in that even emotional and sexual attractions can, and do, in their extremes bear habitual, even compulsive and disturbingly addictive, components. After all, if excessive working, television viewing, and shopping can be described as addictions or addiction-like behaviors, we must look at other excesses in which large portions of our species might engage. These might be emotional, sexual, or otherwise violent, cruel, or excessive extremes. Most troubling perhaps is the reality that interpersonal violence, when between two intimate partners, may exhibit addiction-like

characteristics. As I note in chapter 6, "In fact, the intimate partner relationship (IPR) itself—or its dynamics—can become habitual, can under certain circumstances turn not only sour but detrimental to one or both partners, the family around them including child witnesses, the surrounding community including the workplace, and beyond to the economy, in the form of not only lost productivity and lost work days but also ongoing . . . mental and physical health care costs. And, at its extreme, one possible outcome of a troubled IPR is that of intimate partner violence (IPV), which can be quite dangerous, even lethal." That the various emotional and physical abuses and violences found under the umbrella of intimate partner violence can be addictive is perhaps obvious and at the same time controversial. I emphasize that this is in no way what is called a "blame the victim" approach to intimate partner violence. Still, we are best able to assist persons (persons being abused and persons doing the abusing) at risk for being caught in, or stuck in, or returning to, detrimental and even dangerous patterns when we can tell it like it is: these are patterns that one might be at risk of "getting hooked on." Add in any form of co-occurring addiction (such as substance abuse), and both IPR and IPV addiction can be magnified exponentially.

Part II, "Eating as a Special Issue," is set apart from the other chapters in this volume, as eating "disorders," "compulsions," and "habits" are so variable in etiology and in interpretation when it comes to "addiction" itself. For what is and is not a medical and or psychological condition, while often the central question in the fields of addictions, is key to deciphering eating extremes, whatever these may be. Thus, we have chapter 7, "Craving Pizza? This Is Your Brain on Drugs: Eating Disorders as Addiction," written by Amanda Ruiz, MD, of the University of San Francisco, San Francisco, California, United States; Hugo Barrera, MD, and Norman Jackson, MS, both of the Center for Criminality and Addiction Research, Training and Application (CCARTA) in San Diego, California, United States. Ruiz, Barrera, and Jackson look at the areas of the brain that are "involved in this addictive process," to better establish eating disorders as addictions. Opening with a review of the various types of eating disorders, the authors demonstrate that "Multiple similarities exist between the neurotransmitters that regulate eating disorders and addiction." Eating disorders are bio-psycho-social conditions. Where the genetic explanation with regard to the human obesity gene appears to account for some 20 percent of variation in the basal metabolic index (BMI) in young women (for example), this may leave 80 percent not explained by this gene.

We then turn to what Cynthia Kalodner, PhD, at Towson University in Baltimore, Maryland, United States, has to say on this matter of eating disorders and addictions in chapter 8, "Eating Disorders and Disturbances: The

Continuum of Eating Disturbances." Kalodner discusses eating "disturbances" as a *continuum of eating behavior*, with normal eating at one end, eating disturbances in the middle, and eating disorders at the far end. Dieting, binge eating, and forms of purging can occur in the middle of this continuum and of course at the disorder end. Certainly, not every behavior taking place along this continuum is habitual, compulsive, or addictive; and Kalodner does not make the case that any or all of these are. Yet, within the context of the chapters in this and the other volumes of this collection on addiction, we cannot help but see that there are parallel patterns.

From here, we move into Part III of this volume, "Pornography, Internet, Gaming, and Gambling," which opens with chapter 9, "Addiction to Pornography and Its Psychological and Behavioral Implications," contributed by Robert Kubey, PhD, who, as noted earlier, is at the Center for Media Studies, Rutgers University, New Brunswick, New Jersey, United States. Pornography is, Kubey tells us, a phenomenon often said to be addictive, both in its print media forms and in its video and newer "interactive erotic" forms. Pornography is virtually all around us and is worldwide. Adults and children everywhere are exposed to pornography either directly or indirectly. Certainly, not all uses of pornography are excessive. However, sexual media can be addicting; they can be used excessively and in the face of harm to self or others. Yet, the "harm" quotient is perhaps most hotly debated. Note that when pornography addiction co-occurs with Internet addiction, the harm can be magnified exponentially.

Chapter 10, "Assessment and Treatment of Internet Addiction," is contributed by Kimberly S. Young, PhD, of St. Bonaventure University's Center for Internet Addiction Recovery, in St. Bonaventure, New York, United States. Young delineates the troubled category of Internet addiction: "In contrast to chemical dependency, the Internet offers several direct benefits as a technological advancement in our society . . ." The Internet differs from chemical dependence as "chemical dependence is not an integral part of our professional lives, nor does it offer any direct benefit." The tug of war over the true meaning of addiction surfaces again here: "many researchers argue that the term *addiction* should be applied only to cases involving the ingestion of a drug." However, "pathological Internet use" is continued use in the face of harm. It can cause addicts to hurt or lose significant real-life relationships, to feel worthless and unlovable; plus it can occur with depression, obsessive-compulsion, and likely even substance abuse. Cyberpsychology has its work cut out for it.

Next we move to chapter 11, "Gambling Addictions," by Mark Griffiths, PhD, of the International Gaming Research Unit, Nottingham Trent University, Nottingham, England. Griffiths tells us that "the majority of people have gambled at some time in their life" and that "The introduction of national lotteries

and new casinos, the proliferation of electronic gaming machines, and the introduction of remote gambling (e.g., Internet gambling, mobile phone gambling, interactive television gambling), has greatly increased the accessibility and popularity of gambling all over the world." And certainly impulses to gamble are up as a result of growing opportunities to gamble. Gambling behavior and "maladaptive gambling" are complex, "a multifaceted rather than a unitary phenomenon." Excessive gambling is harmful to self or others. These symptoms manifest (in some mix) as follows: being chronically and progressively unable to resist impulses (to gamble); compromising and disrupting one's life and the lives of those around one to support gambling; being arrested for any number of crimes including forgery and fraud to obtain money for gambling; disrupting family and significant other relationships due to gambling; borrowing money from illegal sources; and more.

Adding to this investigation of gambling and Internet addictions, is chapter 12, "Youth Gambling Problems: An International Perspective," by Isabelle D. Lussier, MA, Jeffrey L. Derevensky, PhD, and Rina Gupta, PhD, all at the International Centre for Youth Gambling Problems and High-Risk Behaviors, McGill University, Montreal, Quebec, Canada. "Recent reviews suggest that upwards of two-thirds of underage North American youth have gambled in regulated and licensed gambling venues . . . with adolescents having been reported to have pathological gambling prevalence rates two to four times those of adults." The problem of gambling too often begins in the latency age. Moreover, "excessive gambling among adolescents has been shown to be positively correlated with participation in increased delinquency and criminal behaviors, substance use, and antisocial behaviors. The serious nature of gambling problems is especially disconcerting considering that gambling is perceived to be a highly socially acceptable activity among adults and adolescents, with little recognition of the inherent risks."

The four volumes of this *Praeger International Collection on Addictions* has looked at the many faces of addiction. The authors have considered addiction as a moral problem, a social problem, a medical problem—akin to an allergy, a brain disease, and more. We have also discussed the marketing of alcohol and other drugs as an example of great business interest in addicting consumers. Here, in this part of volume 4, we are looking at addiction not only as a business but as a huge *industry*—the gambling industry. Gambling is so internationally pervasive that we have dedicated a significant portion of this volume to it. The above chapter is therefore followed by three chapters, providing examples of the global gambling invasion, written by Richard A. McGowan, MA, MDiv, ThM, DBA, associate professor at the Carroll School of Management at Boston College and Research Associate at Harvard Medical, Division on Addictions in

Boston, Massachusetts, United States. These chapters, as discussed below, are chapter 13, "Macau: China's Entry into the World Of Gambling;" chapter 14, "Native American Gambling: Economic Development or Dependence?" and chapter 15, "The Current Climate of Gambling in the United States."

In chapter 13, McGowan reports on what we will call the "addiction industry" in Macau. Gambling is not a new phenomenon, as it can be traced back at least hundreds of years, if not as far back as recorded history. Virtually no nation remains untouched. "Recently, Macau has been dubbed the 'Monte Carlo of the Orient.' This nickname is becoming well deserved." With the marked growth in the Macau gambling industry, the economy affected by it is booming. "This increase in casinos and hotels has resulted in a similarly strong increase in visitors to the island. In 2005, Macau welcomed 10.5 million visitors from China, 2.5 times as many as it had seen in 2002. Chinese visitors accounted for 56 percent of all visitors in 2005, up from 37 percent in the same time frame. . . . [At the same time], local authorities have been citing a sharp increase in casino-related crimes, such as money laundering. . . . Many companies are vying for a strong foothold in Macau, and some have a set strategy already."

In chapter 14, McGowan then turns to what we are calling the "addiction industry" in "Native America": "Tribal gaming is a $19.6 billion per year industry, and it is getting larger. . . . The number of tribes with gaming facilities grew about 3 percent in 2004 (from 221 to 228), and the number of Indian gaming facilities saw growth at about 5 percent in 2004 (from 385 to 405). Although they are highly correlated with the development of new gaming facilities, the numbers of gaming tables and gaming machines have seen tremendous growth as well. . . . Therefore, in coming years, we can only hope that the size and power of the Indian gaming industry influences public and private parties to engage in further studies of the effects that Indian gaming has had on the Native American population as well as the American population at large."

And third, in chapter 15, McGowan discusses this "addiction industry" in the United States: "A look at how gambling revenues stack up against revenues from other recreational/leisure time activity sectors reveals not only that the gambling revenues outweigh both music sales and movies combined, but also that the gambling industry is the only one of the industries in this study to have shown consistent growth in each of the last three years." Moreover, "The rise of Internet gambling has been the primary driver of the intensifying levels of competition within the industry. No longer is consumers' ability to place wagers limited by their geographic proximity to gambling operators. . . . Internet gambling operators can serve a truly global customer base, and with the financial barriers to entry relatively low in comparison with the huge profits

being reaped through Internet gambling, new entrants can enter at will and attempt to compete with the market leaders."

From McGowan's overview of this addiction-based industry, we move to chapter 16, contributed by Kimberly S. Young, PhD, as noted earlier of the Center for Internet Addiction Recovery, St. Bonaventure University in St. Bonaventure, New York, United States. Young discusses "Online Gaming Addiction: Symptoms, Risk Factors, and Treatment." Note the ongoing use of the broader term, "gaming," which can include gambling but is not limited to gambling. Young presents her definition for purposes of her chapter: "Online gaming addiction is an addiction to online video games, role-playing games, or any interactive gaming environment available through the Internet. Online games such EverQuest, the Dark Age of Camelot, or Diablo II—dubbed 'hero-inware' by some players—can pose much more complex problems. Extensive chat features give such games a social aspect missing from offline activities, and the collaborative/competitive nature of working with or against other players can make these games a hard habit to break." Interactive gaming addiction, like so many of the other global addictions, is pervasive. Its consequences are increasingly apparent. Interactive gaming can lead to divorce, job loss, and health problems. Not yet as prevalent as addictions to cyberporn and online chatting, interactive online gaming is already reaching millions of users. "Globally, recent reports have indicated that interactive online gaming has reached addictive proportions in China, Korea, and Taiwan. About 10 percent of China's more than 30 million Internet gamers are said to be addicted." The global picture is bleak; however, efforts are being made to stem the tide. "To battle what has been called an epidemic in some reports, Chinese authorities regularly shut down Internet cafes, many illegally operated, in crackdowns that also include huge fines for their operators. The Chinese Government . . . in 2005 opened the first treatment center for Internet addiction in Beijing. Online gaming addiction continues to raise such serious concerns that the first detox center for video game addiction has opened in Amsterdam, and . . . the American Medical Association, at its annual policy meeting, has considered calling video game overuse an addiction."

We complete this volume with chapter 17, "Youth Gambling Prevention and Resilience Education: A Harm Reduction Approach," by Isabelle D. Lussier, MA, Jeffrey L. Derevensky, PhD, and Rina Gupta, PhD, all of the International Centre for Youth Gambling Problems and High-Risk Behaviors, McGill University, Montreal, Quebec, Canada. Lussier, Derevensky, and Gupta remind us that "Gambling, in its many forms, has permeated every society and culture all the way back to ancient times. While gambling has been a source of entertainment for countless people, a minority of people exhibit compulsive

gambling behaviors that lead to personal harm and suffering." Young people are reported to be at greatest risk from gambling behavior and addiction. Programs and initiatives seeking to quell this mounting predicament recognize the "significant overlap in risk and protective factors for youth with respect to problem gambling and other problem behaviors." This "has led to the creation of prevention initiatives that target multiple risk behaviors." The authors call for "resilience research regarding youth gambling behaviors," as "resiliency skills have long been incorporated into prevention programs for a wide variety of risky behaviors." However, the authors note, "resilience researchers have become increasingly cautious in using the term resilience, opting instead for more specific terms such as *educational resilience*, *emotional resilience*, and *behavioral resilience*."

We hear the hope in the work of these authors and the other contributors to the four volumes in this *International Collection on Addictions*. It is in their work, their solutions, and the work and solutions of their colleagues around the world, that we can envision an ever more, rather than an ever less, resilient human species, one that faces, understands, and overcomes detrimental addictions of all forms everywhere. In the face of daunting addictions data from around the globe, this may seem an impossible dream. However, with the talent and vision of the cadre of persons fighting this war on addictions internationally, the paths to healing and cures for people everywhere can become realities.

Part I

COMPULSIONS

Chapter 1

Work Addiction: Causes, Consequences, and Choices

Ronald J. Burke, PhD

Workaholism and long working hours have positive connotations such as dedication, commitment, and organizational citizenship behavior as well as negative connotations such as ill health and damaged family relationships (Killinger, 1991). The number of hours worked per week, while obviously an element of workaholism, does not capture one's degree of work involvement, psychological state, or attitude. Hours worked per week, however, are a behavioral manifestation of workaholism (Ng, Sorensen, & Feldman, 2007). Although the popular press has paid considerable attention to workaholism, very little research has been undertaken to further our understanding of it (McMillan, O'Driscoll, & Burke, 2003). It should come as no surprise, then, that opinions, observations, and conclusions about workaholism are both varied and conflicting (McMillan, O'Driscoll, Marsh, & Brady 2001). Some writers view workaholism positively from an organizational perspective. Machlowitz (1980) conducted a qualitative interview study of 100 workaholics and found them to be very satisfied and productive. Others view workaholism negatively (Fassel, 1990; Killinger, 1991; Oates, 1971). These writers equate workaholism with other addictions and depict workaholics as unhappy, obsessive, tragic figures who are not performing their jobs well and are creating difficulties for their co-workers (Porter, 1996). The former would advocate the encouragement of workaholism; the latter would discourage it.

McMillan and O'Driscoll (2006) see workaholism as a value system regarding the importance of working and achieving that typically does not meet the scientific criteria for addiction. They propose an integrated model of workaholism that includes antecedents, behaviors, and consequences. Antecedents

include a reluctance to disengage from work, an obsessive style, and a strong enjoyment of work, driven by internal positive reasons. Behaviors include working more than others, thinking about work more than others, talking about work more than others, and stability in these areas over time. Consequences include working anytime and anywhere, choosing work/chores over leisure, and unclear work/relationship boundaries. Workaholism, to McMillan and O'Driscoll may in fact represent an approach to work (with intensity) rather than a frequency captured only by hours.

DEFINITIONS OF WORKAHOLISM

Oates (1971), generally acknowledged as the first person to use the word *workaholic*, defined a workaholic as "a person whose need for work has become so excessive that it creates noticeable disturbance or interference with his bodily health, personal happiness, and interpersonal relationships, and with his smooth social functioning" (Oates, 1971, p. 4). Killinger (1991, p. 61) defines a workaholic as "a person who gradually becomes emotionally crippled and addicted to control and power in a compulsive drive to gain approval and success." Robinson (1998, p. 81) defines workaholism "as a progressive, potentially fatal disorder, characterized by self imposed demands, compulsive overworking, [and an] inability to regulate work to the exclusion of most other life activities." Porter (1996, p. 70) defines workaholism as "an excessive involvement with work evidenced by neglect in other areas of life and based on internal motives of behavior maintenance rather than requirements of the job or organization." Most writers use the terms *excessive work*, *workaholism*, and *work addiction* interchangeably.

Spence and Robbins (1992, p. 162) define the workaholic as a person who "is highly work involved, feels compelled or driven to work because of inner pressures, and is low in enjoyment at work." Most writers view workaholism as a stable individual characteristic (Scott, Moore, & Miceli, 1997; Spence & Robbins, 1992). Most definitions of workaholism portray it in negative terms.

TYPES OF WORKAHOLICS

Some researchers have proposed the existence of different types of workaholic behavior patterns, each having potentially different antecedents and associations with job performance, work outcomes, and life outcomes (Burke, 1999b; Naughton 1987; Scott et al., 1997; Spence & Robbins, 1992). The existence of different types of workaholics might reconcile conflicting views as to whether workaholics are productive and satisfied or tragic and unfulfilled.

Scott et al. (1997) suggest three types of workaholic behavior patterns: compulsive-dependent, perfectionist, and achievement oriented. They hypothesize that compulsive-dependent workaholism will be positively related to job performance and job and life satisfaction. Perfectionist workaholism will be positively related to levels of stress, physical and psychological problems, hostile interpersonal relationships, low job satisfaction and performance, and voluntary turnover and absenteeism. Finally, achievement-oriented workaholism will be positively related to physical and psychological health, job and life satisfaction, job performance, low voluntary turnover, and pro-social behaviors.

Spence and Robbins (1992) propose three workaholic patterns based on their workaholic triad notion. The workaholic triad consists of three concepts: work involvement, feeling driven to work because of inner pressures, and work enjoyment. Data were collected in Spence and Robbins's study from 368 social workers holding academic appointments. Profile analysis resulted in the same six profiles for women and men—three workaholic types and three nonworkaholic types. These profiles were as follows. Work addicts (WAs) score high on work involvement, high on feeling driven to work, and low on work enjoyment. Work enthusiasts (WEs) score high on work involvement, low on feeling driven to work, and high on work enjoyment. Enthusiastic addicts (EAs) score high on all three workaholism components. Unengaged workers (UWs) score low on all three workaholism components. Relaxed workers (RWs) score low on feeling driven to work and work involvement and high on work enjoyment. Disenchanted workers (DWs) score high on feeling driven to work and low on work involvement and work enjoyment.

RESEARCH FINDINGS

The following sections of this chapter will review research findings that compare the personal demographics, job behaviors, work outcomes, extrawork outcomes, and psychological health of the three types of workaholics proposed by Spence and Robbins (1992).

Personal Demographic and Work Situational Characteristics

A critical question involves potential differences between the three workaholism types on both personal demographic and work situation characteristics including hours worked per week. If the workaholism types were found to differ on these (e.g., organizational level, marital status, hours worked per week), these differences would account for any differences found in work and health outcomes.

A number of studies (Bonebright, Clay, & Ankenmann, 2000; Burke, 1999d; Burke, Burgess, & Oberklaid, 2002; Spence & Robbins, 1992) have reported essentially no differences between the three workaholism types on a variety of personal and work situation characteristics. The workaholism types work the same number of hours and extra hours per week; the workaholism types work significantly more hours per week and more extra hours per week than the nonworkaholism types.

Job Behaviors

There has been considerable speculation regarding the work behaviors likely to be exhibited by workaholics (see Mudrack, 2007). This list includes hours worked per week, extra hours worked per week, job involvement, job stress, nondelegation of job responsibilities to others, high (or low) levels of job performance, and high levels of interpersonal conflict and lack of trust. There is empirical research that examines some of these hypothesized relationships.

Burke (1999d) considered these relationships in a large sample of Canadian MBA graduates. Comparisons of the three workaholism types on a number of behavioral manifestations provided considerable support for the hypothesized relationships. First, there were no differences between WAs, EAs, and WEs on hours worked per week or extra hours worked per week; workaholism types worked significantly more hours and extra hours per week than did the three nonworkaholism types. Second, EAs devoted more time to their jobs in a psychological sense than did both WEs and WAs. Third, WAs reported greater job stress than did EAs, both reporting greater job stress than did WEs. Fourth, both EAs and WEs reported greater job involvement than did WAs. Fifth, WAs exhibited greater inability and unwillingness to delegate than both WEs and EAs. Sixth, EAs were more perfectionistic than were WEs.

Spence and Robbins (1992) found that WAs reported higher levels of job stress, perfectionism, and unwillingness to delegate job duties to others than did WEs. Kanai, Wakabayashi, and Fling (1996), using the Spence and Robbins measures, reported that WAs and EAs scored higher than WEs on measures of job stress, perfectionism, nondelegation, and time committed to job.

In summary, WAs reported higher levels of work stress, more perfectionism, and greater unwillingness or difficulty in delegating than one or both of the other workaholism types.

ANTECEDENTS OF WORKAHOLISM

Four potential antecedents of workaholism have received some conceptual and research attention. Three of these, family of origin, Type A behavior, and

personal beliefs and fears, are the result of socialization practices within families and society at large. The fourth, organizational support for work–personal life imbalance, represents organizational values and priorities.

Family of origin. Robinson (1998) has written about work addiction as a symptom of a diseased family system. Work addiction, like other addictive behaviors, is intergenerational and passed on to future generations through family processes and dynamics. In this view, work addiction is seen as a learned addictive response to a dysfunctional family of origin system.

Personal beliefs and fears. Burke (1999g) examined the relationship between personal beliefs and fears and workaholism. Beliefs and fears are a reflection of values, thoughts, and interpersonal styles. Three measures of beliefs and fears developed by Lee, Jamieson, and Early (1996) were used: "Striving against others," "No moral principles," and "Prove yourself." Burke compared the three workaholism types on these measures of beliefs and fears. WAs scored significantly higher than WEs and EAs on the measures of striving against others and no moral principles, as well as on the composite measure. In addition, WAs scored higher on the need to prove self than did WEs. Workaholism thus emerges as work behaviors in response to feelings of insecurity and low self-worth. This is best reflected in managers' feelings of being driven to work. Paradoxically, these beliefs and fears were also found to be associated with lower levels of work enjoyment.

Kaiser and Kaplan (2006) offer some observations on the wellsprings of "overdoing it" at work, based on their coaching and consulting work with executives. They emphasize intrapersonal issues, describing how psychological wounds sensitize managers to be anxious about being hurt again. When managers feel threatened, their behavior frequently goes to the extreme, either overdoing or underdoing. Kaiser and Kaplan propose the following sequence: first one's sensitivity becomes activated; this influences (or distorts) one's perceptions of resources and demands in the environment, precipitating feelings of threat that in turn promote compulsion—overdoing, leading to working extreme hours, striving to prove oneself, impatience with the performance of others, overcontrolling, nondelegating and micromanaging. This list reads like a template for the work addict.

Type A Behavior

Zhdanova, Allison, Pui, and Clark (2006), using meta-analysis, provided support for Type A behavior as an antecedent of workaholism. Type A behavior has been shown to be associated with levels of job stress, psychological distress, and coronary heart disease. Pred, Helmreich. and Spence (1987) factor analyzed the Jenkins Activity Survey, a self-report measure of Type A behav-

ior, producing two independent factors: Achievement Striving (AS), which they found to be predictive of positive work attitudes and performances, and Impatience-Irritation (II), found to be predictive of psychological distress.

Burke, Richardsen, and Martinussen (2004), in a study of 171 Norwegian owners and senior managers of construction companies, found that WAs scored higher than WEs on Impatience-Irritation; EAs scored higher than WEs on Achievement Striving, both being dimensions of Type A behavior. Impatience-Irritation has been shown to be predictive of psychological distress.

Organizational values. Burke (1999f) compared perceptions of organization culture values supporting work–personal life imbalance across the three workaholism types. Organizational values encouraging work-family imbalance were measured by scales developed by Kofodimos (1993). Organizational values encouraging balance were measured by nine items (e.g., "Setting limits on hours spent at work"). Organizational values supporting imbalance were measured by eight items (e.g., "Traveling to and from work destinations on weekends"). A total imbalance score was obtained by combining both scales, reversing the balance scores. WAs reported higher imbalance values than both WEs and EAs. Thus, WAs see their workplaces as less supportive of work–personal life balance than do the two other workaholism types.

Johnstone and Johnston (2005), using two of the three Spence and Robbins workaholism components (work enjoyment, feeling driven to work because of inner pressures), examined the relationship of these to four aspects of organizational climate: work pressures, involvement, supervisor support, and co-worker cohesion. Data were collected in two occupation groups: business services (law firms, management consulting, accounting firms) and social services (schools, social workers in government agencies, workers in a hospice). Involvement, supervisor support, and co-worker cohesion were positively related to work enjoyment while work pressures were negatively related to work enjoyment. Only work pressures were significantly related (positively) to feeling driven.

Regression analyses including age, occupation type, and hours worked along with the four organizational climate measures showed that only co-worker cohesion and supervisor support predicted work enjoyment. Age, work pressures, and occupational type were significant predictors of feeling driven. Those in business services had higher levels of feeling driven and lower levels of work enjoyment.

Work Outcomes

The relationship between workaholism and indicators of job and career satisfaction and success is difficult to specify. It is likely that different types

of workaholics will report varying work and career satisfactions (Scott et al., 1997).

Burke (1999a) compared levels of work and career satisfaction and success among the workaholism profiles observed by Spence and Robbins (1992). Four work outcomes, all significantly intercorrelated, were used. Intent to quit was measured by two items (e.g., "Are you currently looking for a different job in a different organization?"). Work satisfaction was measured by a seven-item scale developed by Kofodimos (1993). One item was "I feel challenged by my work." Career satisfaction was measured by a five-item scale developed by Greenhaus, Parasuraman, and Wormley (1990). One item was "I am satisfied with the success I have achieved in my career." Future career prospects were measured by a three-item scale developed by Greenhaus et al. (1990). One item was "I expect to advance in my career to senior levels of management."

WAs scored lower than WEs and EAs on job satisfaction, career satisfaction, and future career prospects, and higher than WEs on intent to quit. It should be noted that all three workaholic profiles (WAs, EWs, WEs) worked the same number of hours per week and had the same job and organizational tenure.

WORKAHOLISM TYPES AND FLOW AT WORK

Csikszentmihalyi (1990) uses the term *optimal experience* to refer to times when individuals feel in control of their actions and masters of their own destinies. Optimal experiences commonly result from hard work and meeting challenges head on. Would the workaholism types differ in the experience of flow? In a study of 211 Norwegian journalists, Burke and Matthiesen (2004) found that journalists scoring higher on work enjoyment and lower on feeling driven to work because of internal needs indicated higher levels of flow or optimal experience at work. In this same study, Burke and Matthiesen found that WEs and EAs indicated higher levels of flow than did WAs.

PSYCHOLOGICAL WELL-BEING

There is considerable consensus in the workaholism literature on the association between workaholism and poorer psychological and physical well-being. In fact, some definitions of workaholism incorporate aspects of diminished health as central elements. It is not surprising that this relationship has received research attention.

Burke (1999e) compared the three workaholism types identified by Spence and Robbins (1992) on three indicators of psychological and physical well-being

in a sample of 530 employed women and men MBA graduates. Psychosomatic symptoms were measured by 19 items developed by Quinn and Shepard (1974). Respondents indicated how often they experienced each physical condition (e.g., "headaches") in the past year. Lifestyle behaviors were measured by five items developed by Kofodimos (1993). One item was "I participate in a regular exercise program." Emotional well-being was measured by six items developed by Kofodimos (1993). One item was "I actively seek to understand and improve my emotional well-being."

Once again, the comparisons of the workaholism types on the three measures of psychological and physical well-being provided considerable support for the hypothesized relationships. WAs had more psychosomatic symptoms than both WEs and EAs and poorer physical and emotional well-being than WEs.

In a study of 171 Norwegian construction company owners and senior managers, Burke et al. (2004) found that WAs reported higher levels of emotional exhaustion than both WEs and EAs; the three workaholism types were similar on levels of cynicism and personal efficacy.

EXTRA-WORK SATISFACTIONS AND FAMILY FUNCTIONING

A number of writers have hypothesized that workaholism is likely to impact negatively on family functioning (Killinger, 1991, Porter 1996; Robinson, 1998). Burke (1999c) considered the relationship of the three workaholism types identified by Spence and Robbins (1992) with extrawork satisfactions. Three aspects of life or extrawork satisfaction were included, using measures developed by Kofodimos (1993). These aspects were family satisfaction, relationship satisfaction, and relationship satisfaction and community satisfaction. The comparisons of the workaholism types on the three measures of life or extrawork satisfactions provided moderate support for the hypothesized relationships. WAs reported less satisfaction on all three extrawork satisfaction measures than did WEs and less satisfaction on one (family) than did EAs.

"GOOD" AND "BAD" WORKAHOLICS

Schaufeli, Taris, and Bakker (2007) make a distinction between "bad" workaholics, exhibiting a negative psychological state, and "good" workaholics, characterized by high levels of work engagement. They differentiate between work addiction and work engagement. Engaged workers work hard because it is fun; work addicts work hard because they are compulsively driven. They conducted a study in the Netherlands, involving 2164 employees in a wide variety

of jobs who participated in an Internet survey They developed a measure of workaholism having two components: working excessively, and working compulsively (also see Taris, Schaufeli & Verhoeven, 2005). Scores on these two components were related to measures of overwork, employee well-being, and job performance. Both measures of workaholism were significantly and positively correlated with indicators of overwork, Working excessively correlated with these at a slightly higher level. Both workaholism components were also significantly and negatively correlated with psychological health and happiness. Work engagement was positively correlated with indicators of overwork and psychological health and happiness, and negatively correlated with absenteeism. And somewhat surprisingly, both work addiction components and work engagement were positively related to indicators of job performance.

Schaufeli, Taris, and Bakker (2008), again using their two-component measure of work addiction (working excessively and working compulsively), report the results of two further studies. In the first study, involving 7594 Dutch workers, hours worked were correlated with both work addiction scales, and different occupational groups differed on the two work addiction scales. Managers and entrepreneurs scored higher on both, as did men when compared to women.

In the second study, data were collected from 2115 medical residents. Although there were a few differences in the predictors of working excessively and working compulsively, the majority of relationships between these two components and other variables (e.g., job demands, job resources, burnout recovery, life satisfaction) were statistically significant. Schaufeli and his colleagues conclude that both working excessively and working compulsively formed a syndrome —two characteristics that occur together and are associated with potential predictors in the same way.

They also divided their sample into four groups based on either high or low scores on the two workaholism scales. These groups were labeled workaholics, hard working, compulsively working, and relaxed. These four groups were then compared on 22 variables with significant group differences found on all but one. Workaholics (those residents scoring high on both components) had the poorest scores on 16 of the 21 variables on which significant group differences were found.

The work of Schaufeli and his colleagues has highlighted the distinction between work engagement and work addiction, between good and bad workaholics, and put the spotlight on different motivational systems. Workaholics are motivated by performance goals; engaged workers are motivated by mastery goals. The former are external; the latter internal. Workaholics work hard to prevent themselves from feeling bad—an avoidance motivation; engaged workers work hard for learning and development —an approach motivation.

PASSION VERSUS ADDICTION

Why do people work hard, and does their motivation for working long hours matter in terms of their satisfaction and well-being? Several streams of research bear on these questions. First, a growing body of research on workaholism has shown that different types of workaholics exist (Scott et al., 1997; Spence & Robbins, 1992) and that some types seem to be work satisfied and psychologically healthy while other types are dissatisfied with their jobs and careers, are dissatisfied with their family relationships, and are in psychological distress (Buelens & Poelmans, 2004; Burke, 2007; Kanai et al., 1996; Machlowitz, 1980; Robinson, 1998; Spence & Robbins, 1992).

Second, extensive research on sources of motivation (e.g., the effects of intrinsic versus extrinsic goals) and different processes or motivations for realizing these goals (e.g., internal versus external motivations)—the "what" and "why" of goal pursuits—has shown that individuals motivated by extrinsic goals and external sources of motivation report lower levels of satisfaction and psychological health (Deci, Koestner, & Ryan, 1999; Deci & Ryan, 1985, 2000; Ryan & Deci, 2000; Srivastava, Locke, & Bartol, 2001). Burke (2006) has shown that different types of workaholics are motivated by different beliefs and fears about people and their larger social and work environment.

Third, although working long hours has generally been associated with more negative work and health outcomes, dramatic exceptions to this trend have also been observed. Hewlett and Luce (2006) reported some work and family experiences of men and women working in "extreme jobs," jobs in which they worked 70 or more hours per week and under high work intensity (e.g., an unpredictable flow of work, responsibility for clients 24/7, and a fast-paced flow of work). Respondents were senior level managers and executives in large U.S. and international based corporations earning huge salaries and working in prestigious jobs having lots of perks. Their respondents indicated great work satisfaction resulting in part from the challenge, meaning, and rewards from their jobs. They were passionate about their work and their jobs. Respondents did indicate, however, that they hoped to work a few fewer hours in the future, and some were concerned about potential negative effects of their work hours on personal and family lives. Brett and Stroh (2003), in a sample of alumni of a prestigious U.S. business school, also reported positive reasons among both men and women for working over 61 hours per week.

Fourth, it is only recently that passion in the workplace has begun to be explored. Vallerand and his colleagues (Vallerand et al., 2003; Vallerand et al., 2007) have proposed a dualistic approach to passion. Passion is defined as a strong inclination toward an activity (e.g., work in our case) that is important,

liked, and involves investing considerable time in its pursuit. They distinguish between a harmonious passion (HP) that is well integrated into one's identity and undertaken freely and willingly and an obsessive passion or addiction (OP) that is not well integrated into one's identity and is the result of internal pressure (e.g., to increase one's self-esteem in the eyes of others). The activity controls the person under OP; the person controls the activity under HP. Vallerand and colleagues hypothesized and found that HP leads to more positive affect, less negative affect, and higher levels of flow, while OP produces the opposite effects. Because the activity is freely chosen under HP, the individual is engaged in the activity more fully and flexibly, leading to greater concentration, absorption, flow, and positive affect. Vallerand and colleagues developed measures of both types of passion and found they were significantly and positively correlated with each other, and similarly and positively correlated with evaluations of and liking for a self-chosen activity. They also found that levels of HP were higher than levels of OP for the chosen activity. They further suggest that HP would likely be correlated with psychological health and OP with psychological distress. Thus, passion can create motivation, increase well-being, and provide meaning in one's life, but it can also lead to negative emotions, rigid persistence, and an unbalanced life.

Fifth, two of the three workaholism components in the most widely used measure of workaholism developed by Spence and Robbins (1992), feeling driven to work because of inner pressure(D) and work enjoyment (WE), have been found to relate in different directions and to different outcomes (see Burke, 2006, for a review). WE, not surprisingly, was shown to be positively related to various work outcomes whereas D was shown to be negative related to many of these work outcomes. On the other hand, D was found to be negatively related to measures of psychological health, while WE was unrelated to these health indicators. In addition, WE and D related differently to potential antecedents of workaholism, such as perceptions of organizational climate supporting work–personal life balance and perceptions of people and their motives and how to succeed in the world. Other researchers have also reported different relations between WE and D and a number of different work and well-being outcomes (e.g., Graves, Ruderman, & Ohlott, 2006; Johnstone & Johnston, 2005; Schaufeli et al., 2007; Virick & Baruch, 2007).

These studies indicate different patterns of correlations, both antecedents and consequences, of WE and D. WE and D represent different underlying motivations or orientations to work and therefore have different effects in terms of both work and well-being outcomes. D is likely to hamper performance. WE is likely to facilitate performance (Vallerand et. al., 2003, 2007). D is likely to be associated with persistence, rigidity, perfectionism, and heightened levels

of job stress. D is likely associated with working harder, not smarter. D may also be associated with the setting of unrealistic performance expectations and deadlines. The positive emotions of WE are likely to spur higher levels of performance through increasing social resources and creativity, building trust with colleagues, and reducing levels of debilitating stress.

Vallerand and his colleagues (Vallerand et al., 2003; Vallerand & Houlfort, 2003; Vallerand et al., 2007) suggest four hypotheses relating to their two types of motivation, passion and addiction. First, passion and addiction are likely to be positively correlated. Second, respondents will generally score higher on passion than on addiction. Third, passion is likely to be related to positive work outcomes and psychological health. And fourth, addiction is likely to be associated with negative work outcomes and psychological distress.

Burke and his colleagues conducted three exploratory studies involving different occupational groups and conducted in different countries that examine the four hypotheses suggested by Vallerand and his colleagues (Vallerand et al., 2003, 2007)

Study 1—Managers and Professionals in Canada

Mail questionnaires were sent to about 1,000 male and 1,000 female MBA graduates of a single university in Canada. Responses were received from 591 individuals, a response rate of about 35 percent, with elimination of questionnaires returned because the person had moved. The sample decreased to 530 when individuals who indicated they were no longer working full-time were excluded. A fairly wide range of response was present on most personal demographic items.

Measures included single-item measures of personal and work situation characteristics; the measures of passion and addiction (Spence & Robbins, 1992); potential antecedents of passion and addiction including beliefs and fears (Lee et al., 1996) and organizational values supporting work–personal life imbalance (Kofodimos, 1993); four indicators of work investment including hours worked; extra hours worked; job involvement (Spence & Robbins, 1992), and one's psychological sense of *time committed to the job* (Spence & Robbins, 1992), two job behaviors—perfectionism and nondelegation—both measured by scales developed by Spence and Robbins (1992), four work outcomes including measures of job satisfaction (Kofodimos, 1993); career satisfaction (Greenhaus et al., 1990); future career prospects (Greenhaus et al., 1990); and job stress (Spence & Robbins, 1992), three extra work satisfactions—family, friends, and community—using measures developed by Kofodimos (1993); and three indicators of psychological well-being including

emotional and physical health (Kofodimos, 1993) and psychosomatic symptoms (Quinn & Shepard, 1974).

The following results were obtained. First, passion and addiction were significantly and positively correlated ($r = .25$, $p<.001$, $N = 524$). Second, respondents indicated similar levels of passion and addiction, the mean scale values being 2.5 and 2.7, respectively, contrary to predictions .Third, the correlations between the measures of both passion and addiction with four indicators of investment were positive and significantly different from zero ($p<.001$). As hypothesized, managers and professionals scoring higher on passion, and on addiction, were more involved with their jobs and work (e.g., worked more hours, more extra hours, more job involved). Fourth, both passion and addiction were significantly correlated with the two potential antecedents. Managers scoring higher on passion scored lower on the measure of beliefs and fears and lower on the measure of organizational support for work–personal life imbalance; managers scoring higher on addiction also scored higher on the measure of beliefs and fears and higher on the measure of organizational support for work–personal life imbalance. As hypothesized, the pattern of correlations was the direct opposite. Fifth, let us now consider the correlations between passion and addiction and the two job behaviors. All correlations were significantly different from zero ($p<.001$). Managers scoring higher on passion and managers scoring higher on addiction also scored higher on perfectionism; however, managers scoring higher on passion scored lower on nondelegation, whereas managers scoring higher on addiction scored higher on nondelegation. These findings provide partial support for our hypotheses. Sixth, let us turn to the correlations between passion and addiction and the four work outcomes. Most correlations were significantly different from zero. Managers scoring higher on passion also indicated more favorable work outcomes across the board (more satisfaction, lower levels of stress); managers scoring higher on addiction also indicated less job and career satisfaction and higher levels of stress. Scores on addiction were not correlated with perceptions of future career prospects. Once again, as hypothesized, the pattern of correlations was in the opposite direction. Seventh, let us consider the correlations of scores on passion and addiction with three indicators of extrawork satisfaction. All correlations were significantly different from zero ($p<.05$). Managers scoring higher on passion were also more satisfied in all three extrawork areas; managers scoring higher on addiction were less satisfied in all three areas of extrawork satisfaction. As hypothesized, the pattern of correlations was in the opposite direction, but weak. Finally, let us consider the relationship of passion and addiction with three indicators of psychological health. All correlations between passion and addiction were significantly different from zero ($p<.001$). Managers

scoring higher on passion reported higher levels of psychological health, whereas managers scoring higher on addiction reported lower levels of psychological health.

In summary, the pattern of findings shown provides strong support for the proposed hypotheses. In almost all instances, passion and addiction showed opposite relationships with the antecedent and outcome variables under investigation.

Study 2—Female Psychologists in Australia

Mail questionnaires were sent to 35,61 members of the Australian Psychological Society in the state of Victoria. A total of 658 completed surveys were returned, a 19 percent response rate. Respondents were similar to the total membership of the Australian Psychological society on some dimensions (age, sex) for which data were available. Only female respondents were chosen for this analysis. A wide range of response was again present on most demographic items.

The measures used were identical to those employed in the study of Canadian managers and professionals discussed above. Let us now consider the results. First, passion and addiction were significantly and positively correlated (r = .25, p<.001). Second, levels of passion and addiction were similar, mean values being 2.7 and 2.5, respectively. Third, scores on both passion and addiction were significantly and positively correlated with each of the four measures of work investment (e.g., work hours, job involvement). Fourth, scores on passion were significantly negatively correlated with beliefs and fears and organizational values supporting work–personal life imbalance, whereas scores on addiction were significantly positively correlated with scores on these two measures. Fifth, correlations of passion and addiction with the two job behaviors (perfectionism, nondelegation) were significant but in opposite directions, passion being negative and addiction being positive. Sixth, almost all the correlations of passion and addiction with the four work outcomes were significantly different from zero. Female psychologists scoring higher on passion also indicated more favorable work outcomes across the board (more satisfaction, lower levels of stress); female psychologists scoring higher on addiction indicated less job satisfaction and higher levels of stress. However, scores on both passion and addiction were positively correlated with perceptions of future career prospects. Once again, as hypothesized, the pattern of correlations was generally in opposite directions. Seventh, most of the correlations of passion and addiction with the three measures of extrawork satisfaction were significantly different from zero (p<.05). Female psychologists scoring higher on passion were also

more satisfied in two extrawork areas; female psychologists scoring higher on addiction were less satisfied in all three areas of extrawork satisfaction. Finally, almost all the correlations of passion and addiction and the three indicators of psychological health reached statistical significance. Female psychologists scoring higher on passion reported higher levels of psychological health, whereas female psychologists scoring higher on addiction reported lower levels of psychological health.

In summary, these findings were generally consistent with our hypotheses and almost identical to those obtained in a large Canadian sample of female and male managers and professionals.

Study 3—Journalists in Norway

Data were collected from 211 journalists working in the city of Bergen, Norway, using anonymously completed questionnaires, representing a response rate of 43 percent. Five hundred questionnaires were sent out by the journalists' union, and completed questionnaires were returned to a university address. Measures originally appearing in English were translated into Norwegian by members of the research team using the back-translation method; other measures (e.g., the Maslach Burnout Inventory) had already been translated into Norwegian from English and used by others in their research projects.

Measures included a number of personal and work situation characteristics. The same measures of passion and addiction used in the two previous studies, two measures of work investment (hours worked, work-family conflict; Lindstrom et al., 1997), four work outcomes including intrinsic motivation (Lindstrom et. al., 1997), intrinsic motivation (Lindstrom et al., 1997); organizational commitment (Lindstrom, et al., 1997) and flow (Jackson & Marsh, 1996), and psychological health including three scales from the Maslach Burnout Inventory (Schaufeli, Maslach, Leiter, & Jackson, 1996), and measures of positive and negative affect—the PANAS scales (Watson, Clark, & Tellegen, 1988).

Let us now consider the findings. First, passion and addiction were significantly and positively correlated ($r = .29$, $p<.001$). Second, levels of both passion and addiction were generally similar, mean values being 2.8 and 2.6, respectively. Third, passion tended to be positively correlated with hours worked ($p<.10$) and with work-conflict; addiction was significantly correlated with both hours worked and levels of work-family conflict. Thus, as predicted, both passion and addiction were significantly related to level of work investment. Fourth, six of the eight resulting correlations between passion and addiction and the four work outcomes were significantly different from zero ($p<.05$), and the

direction of these correlations was opposite in the two work motivation sources. Journalists scoring higher on passion also scored higher on flow, organizational commitment, and intrinsic motivation; passion was uncorrelated with levels of extrinsic motivation (but negative in sign). Addiction was negatively correlated with flow and organizational commitment and positively correlated with level of intrinsic motivation, and tended to be positively correlated with level of extrinsic motivation. Thus, passion and addiction were differentially correlated with flow, organizational commitment, and extrinsic motivation (but in the latter case, only one correlation approached statistical significance) and similarly correlated with levels of intrinsic motivation. Finally, 7 of the 10 correlations between passion and addiction and the five indicators of psychological health reached statistical significance ($p<.01$). Journalists scoring higher on passion also scored lower on exhaustion, cynicism, and negative affect and scored higher on positive affect. Journalists scoring higher on addiction also scored higher on exhaustion and cynicism and lower on positive affect. Neither passion nor addiction was correlated with levels of efficacy; addiction was also uncorrelated with levels of self-reported negative affect.

In summary, the pattern of findings reported here were both consistent with our hypotheses and very similar to those obtained in two other studies employing different samples obtained in different countries. In almost all instances, passion and addiction showed opposite relationships with the outcome variables under investigation. These findings show rather convincingly that different sources of work motivation—passion and addiction—had dramatically different relationships with a range of job satisfactions, work outcomes, and indicators of psychological health. Though themselves moderately and positively correlated, passion and addiction had opposite relationships with these outcomes.

As predicted, both passion and addiction were significantly correlated with job and work investment (e.g., hours worked, job involvement).

There were also widespread differences in the direction of correlation of passion and addiction with antecedents, job behaviors, work and extrawork satisfactions, and indicators of psychological well-being. Passion was always correlated with favorable work, extrawork, and psychological well-being outcomes and less obsessive job behaviors. These findings were consistent with an emerging view that positive emotions are likely to be associated with favorable outcomes (Fredrickson, 1998, 2001; Lyubormirsky, King, & Diener, 2005; Pressman & Cohen, 2005) Addiction was almost always correlated with less favorable work, extrawork, and psychological well-being indicators, and with less constructive job behaviors (e.g., more difficulty delegating). In summary, our results suggest significant differences in the effects of a healthy commit-

ment to one's work versus a harmful, psychologically and physically damaging compulsion to work.

ADDRESSING WORKAHOLISM

There is a large speculative literature suggesting ways to reduce levels of workaholism. One part of this work focuses on individual and family therapy (Killinger, 1991, Robinson, 1998); a second part emphasizes organizational and managerial interventions.

Individual counseling. Workaholics Anonymous chapters have sprung up in some North American cities. These groups, patterned after Alcoholics Anonymous self-help groups, endorse the 12-step approach common to the treatment of a variety of addictions. Killinger (1991) and Robinson (1998) include chapters outlining actions an individual might pursue to reduce levels of workaholism; Seybold and Salomone (1994) offer suggestions on counseling approaches. Chen (2006) shows how the use of rational emotive behavior therapy (REBT) can be effective in lessening work-life balance concerns and ameliorating the effects of workaholism.

Chen (2006) applied rational emotive behavior therapy (REBT) to the treatment of work addiction. Several factors likely cause work addiction. However a negative self-concept and related self-perceptions (e.g., lack of self-confidence, low self-worth) are the essential sources. An external environment that supports and reinforces work addiction interacts with these intrapersonal factors to produce the addiction to work (see Killinger, 1991). REBT addresses this distorted sense of self, irrational beliefs and emotions concerning self-worth and self-image; REBT seeks to build a confident and positive inner self. Work addicts are informed of the hazards of work addiction and ways of coping with it. Cognitive intervention lies at the heart of REBT: irrational beliefs are examined—the musts and shoulds that spur and sustain work addiction; individuals are also taught to use different language—there are other ways to think and behave. Individuals explore the emotional imagery of being less work addicted (i.e., working fewer hours); role playing is used to further examine feelings and thoughts.

Behavioral strategies are also part of REBT applied to work addiction. Individuals learn how to relax, to slowly desensitize the exhibition of particular behaviors (engaging in more or less), to improve self-management, to reorganize their workloads, to set clear boundaries, and to spend time in valued non-work activities.

Burwell and Chen (2008), in more recent writing, position their approach to treating work addiction within the broader field of positive psychotherapy

(PPT). Then they discuss therapeutic approaches stemming from quality of life therapy (QOLT).

Work addiction has its roots in the individual, the family, organizations, and the broader society. Work addicts are almost always in denial. The typical interventions for addressing work addiction are individual treatment (Fassel, 1990; Killinger, 1991; Robinson, 1998) and workplace changes (Fassel, 1990; Munck, 2001).

PPT encourages work addicts to increase positive emotions, engagement, and meaning in their lives. QOLT encourages individuals to identify, pursue, and fulfill their most valued needs and aspirations in important areas of their lives. Relationships and play are typically addressed as goals for change in QOLT.

Family therapy. Robinson and his colleagues, consistent with their clinical and consulting perspective, focus on treatment, both individual and family. This is not surprising given the central role they give to both family of origin and current family functioning in the development, maintenance, and intergenerational transmission of workaholism. The treatment recommendations Robinson offers (1998) are similar to those offered to alcoholic families.

Thus, denial is common among workaholics and their family members. Family members are reluctant to complain. Workaholics define their behavior and symptoms in a favorable light (Killinger, 1991; Porter, 1996). Parental expectations of children, often unrealistic, must be addressed. Family structures need to be identified. How do family members collude with the workaholic parent? Family members need help in expressing their negative feelings to the workaholic. Families need to learn to set boundaries around the amount of time they spend working together and talking about work. Family members can set goals to improve family dynamics (e.g., communication, roles, expression of feelings).

Workplace interventions. How can employers help workaholics and workaholics help themselves? Schaef and Fassel (1988) offer the following ideas. Employers should pay attention to the performance and work habits of employees and be alert to warning signs of workaholism. They should ensure that employees take vacation time away from work. Finally, job insecurity, work overload, limited career opportunities, and lack of control can make employees feel compelled to work longer. If these factors exist, employers should try to minimize their impact on the atmosphere within the organization.

Haas (1991) also highlights the role that managers can play in assisting their workaholic employees to change. Workaholic employees should be referred to an employee assistance program or a recovery program to start treatment processes. Managers should help prioritize projects for employees as long-term and

short-term assignments (Cartwright, 2000). Workaholics must be encouraged and helped to delegate their work. At the end of each day, the manager should meet with the employee to discuss what has been accomplished during that day and to plan (down to short intervals) for the following day. The employee should be given specific times to take breaks and to leave work. It may also be possible to reduce the negative effects of workaholism, particularly the well-being and health consequences, through stress-management training.

The development of workplace values that promote new, more balanced priorities and healthier lifestyles will support those workaholism types that want to change their behaviors (Austin Knight, 1995; Messenger, 2006; Munck, 2001). More people today want a life beyond work. Employees can work more effectively if they can integrate their work, families, and personal lives in more satisfying ways—they want "just enough success" (Nash & Stevenson, 2004a, 2004b). This becomes a win-win situation for all involved (Friedman, Christensen, & DeGroot, 1998).

ACKNOWLEDGMENTS

Preparation of this chapter was supported in part by York University, Toronto, Ontario, Canada. Several colleagues participated in the design and conduct of the research program: Lisa Fiksenbaum, Astrid Richardsen, Stig Mattheisen, Graeme McDermid, Mustafa Koyuncu, Zena Burgess, and Fay Oberklaid.

Chapter **2**

Addiction to Television: With Commentary on Dependence on Video Games and the Internet

Robert W. Kubey, PhD

When a person becomes chronically dependent on a stimulus that is enjoyable but that in the long run is harmful, people often speak of addiction. This is not a precise scientific term, because what we think about certain activities is relative and depends on value judgments.

For this and other reasons, the official manual used by psychotherapists throughout North America, the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders,* fourth edition (1994; *DSM–IV*) and fourth edition text revision (2000; *DSM–IV–TR*),[1] no longer uses the term *addiction*. Instead, the committees that wrote the *DSM* use the term *substance dependence*. This does not resolve the problem, because of course we are all dependent on substances like oxygen, water, and dietary protein without being considered addicts.

For years, the addiction term has been extended to a whole host of behaviors from gambling and sexuality to video gaming and Internet use. My aim here is to bring some clarity to the question of how people develop the television viewing habits that now absorb so many hours of daily life in nearly all developed societies.

The time people spend viewing is nearly astonishing. People throughout the industrialized world, from the United States and Latin America to Europe and parts of Asia, the Middle East, and Africa, typically devote about three hours a day to watching television. In many societies, this easily constitutes half of all a person's leisure time or, calculated another way, 9 full years of a 75-year life span. Unless one does something else during commercials, two of those nine

years will be devoted to viewing advertisements; this viewing constitutes about 20 percent of all commercial television viewing time.

And of course, the three-hour figure *is* an average after all. For the "addicted" or so-called heavy viewers who may watch five or six hours a day, we may well be talking about 30 percent to perhaps 38 percent of their waking time watching TV, or as many as 20 years of the 50 years they will be awake if they live to 75.

If television viewing is indeed self-perpetuating, as will be suggested in the pages ahead, and if it indeed *can* produce a dependency, this is a matter of considerable significance, because this effect may be seen as perhaps the most powerful link in a chain of other effects. Indeed, many effects of television—from aggression and obesity to poorer academic performance and the impairment of imagination—are presumed to be effects of heavy or prolonged viewing.

Most people believe television viewing can be addictive. In North American surveys, roughly 10 percent of adults believed that *they* were addicted, but 65 to 70 percent reported believing that *others* were addicted. And many millions experience misgivings about how much they view. In a 1990 Gallup Poll (Gallup & Newport, 1990), 42 percent (up from 31 percent in the late 1970s) of adult Americans reported believing that they spent too much time watching television.

It needs to be stated at the outset that television viewing needn't be seen as purely problematic, or necessarily problematic at all. There are fine entertainment and information programs on television. One can learn and derive enjoyment from television. The author personally watches some escapist programs, and a fair amount of news, historical and scientific documentaries, HBO dramas, and bio-dramas that he thinks quite worthy.

The new television environment of 300 channels and DVD and downloadable films and other programs has made for a viewing world that is extraordinarily rich for adults and children alike and quite different from the one in which some of the data were collected, data that will be cited in this chapter and that date back to the television world of 1975, before most homes even had a VCR and when most homes only had the usual 8–15 channels. Readers should keep in mind that in citations to some of my work, or my work with Csikszentmihalyi, the research being drawn on was collected in that media environment, though not all of the research was conducted in the United States, as will be seen.

Furthermore, my book, *Creating Television* (Kubey, 2004), examines the personal creativity of many television artists involved in the creation of many programs that I consider very good or great and classic programs over the first 50 years of the medium's history. Moreover, I am something of a film buff. I regularly expose my sons to everything from early Buster Keaton and *One Flew*

Over the Cuckoo's Nest to Hitchcock and foreign works such as *Blow-Up* and Ingmar Bergman. Not to go on too long about this—and these are *films* after all—but they are viewed on a television monitor, and though I watch them commercial free, many people watch them over cable or broadcast television complete with commercial interruptions. These offerings, too, can be seen as television and some of them were available when my earliest data were collected in 1974–75.

Television also surely provides much-needed distraction and escape. Still, there is little doubt that a great many millions of people around the world have developed very significant viewing habits that might be deemed problematic and even a risk to mental and physical health.

So, first, what accounts for such a devotion to television, a devotion greater than to any other activity, save sleep and work?

HOW THE VIEWING HABIT IS FORMED

One of the first things to know is that television viewing typically involves less concentration and alertness—and is experienced more passively—than most other daily activities. This is known from my own studies and others using the same methodology with children, adolescents, adults, and the aged in the United States (see Kubey, 1984; Kubey & Csikszentmihalyi, 1990). Other researchers have confirmed these findings using the same method in other countries.

The findings are based on people's responses to a random signaling method, the Experience Sampling Method (ESM), that permits researchers to study human behavior and emotions as they occur naturally in the normal course of everyday life

The ESM involves having research subjects report what they are doing, and how they are feeling, each time they are signaled with a radio controlled, or preprogrammed, signaling device, or beeper. In most studies, each respondent is signaled six to eight times each day, from morning till night, for a week. The timing of the signals is predetermined by the research team to occur at random intervals, and participants do not know when to expect a signal.

The method has proved very useful in studying the contours of everyday life in a wide variety of populations around the world. Studies have focused on everything from worker satisfaction and the ways in which one spouse's mood affects the other spouse to student performance in school, eating disorders, and drug and alcohol abuse.

Along with the beepers, participants also carry a small booklet of self-report forms. After each signal, the individual stops to fill out a short report form

telling researchers how she felt on a number of standard psychological measures of mood and mental activity.

When people report how they are feeling and thinking when watching television, they report feeling relaxed and, as noted, exerting little mental effort or concentration. It is these related aspects of the experience, while perhaps obvious, that are key among the reasons why so many people watch for so many hours a day, why their habits are so well established, and why it is generally hard for people to reduce their viewing.

The ease with which viewing is accomplished is especially pronounced when compared with reading. And while it is not as dramatic as popular press accounts would have us believe, others' studies with the EEG show that reading *does* produce more beta activity ("fast waves" associated with increased mental activity and attention) than does television viewing, which causes somewhat more alpha activity ("slow waves" associated with relaxation and less mental arousal). Unlike reading, with its constant provision of moving images and sound, television can be thought of as doing the work of attention for us. Research also indicates that lower cortical arousal coincides with prolonged viewing.

Part of what holds our attention to television is the *orienting response*. First described by Pavlov in 1927, the orienting response is our instinctive, visual (or auditory) reaction to any sudden or novel stimulus in the environment. A well-functioning orienting response is necessary to the survival of almost every species.

Once stimulated, organisms orient their sensory receptors toward the stimulus that caused the response. The typical response set includes vasodilation of the blood vessels to the brain, decrease (or blocking) of the EEG alpha frequency, slowing of the heart, and vasoconstriction of blood vessels to major muscle groups. In other words, the attentional capacities of the organism are put on high alert, with stimulus intake rapidly becoming the first priority while the rest of the body quiets.

Byron Reeves of Stanford University and Esther Thorson of the University of Missouri and their colleagues (1986) first used the EEG in 1985 to test whether the simple *formal features* of television (cuts, edits, zooms, pans, sudden noises, and so on) might activate the orienting response, thereby causing attention to be drawn to the screen. While an increase in alpha frequency coincides generally with viewing, *alpha blocking* is associated with orienting responses. Reeves and Thorson and their team concluded that the formal features of cuts, edits, and movement did indeed command involuntary responses that may well "derive their attentional value through the evolutionary significance of detecting movement." "It is the form, not the content, of television that is unique."

Since 1985, various teams of researchers have delved deeper into how and when television's formal features affect encoding, storage, and message retrieval. The work has been extended to look at lighting levels, slow motion, animation, graphics, music, and narrative structure, and there is a growing literature on the formal features of Web sites as well. Researchers don't use the EEG as much now, preferring observation of the drop in heart rate that comes immediately after the orienting-eliciting stimulus and that continues for 4–6 seconds. Annie Lang's research teams at Indiana University have been among the most active (see Lang, 2000). Lang and her colleagues repeatedly show heart rate decelerations in response to cuts, edits, and video graphics. Recently the list has expanded to voice changes and special effects in radio messages.

The use of formal features to sustain attention isn't all bad. Many involved in the production of educational television for children have done research on the formal features of the medium so they know how edits, movement, slow versus fast zooms, or changes in volume can help hold attention on the screen for the purpose of learning. (Edits and slow zooms, for example, help.) The problem lies in how often such techniques are used (too often, in the opinion of some, in a program such as Sesame Street) to merely hold viewers so they don't channel surf or miss the next ad.

Lang shows improved recognition memory with increasing edits (changes from one camera to another in the same visual scene, i.e., giving different views of the same phenomenon). Increases in cuts (changes from one scene to a new visual scene) also improve recognition, but only to a point. A sharp drop-off in recognition occurs if the number of cuts exceeds 10 in 2 minutes. Lang concludes that the increase in resources allocated to encoding new information can't keep up with the increase in processing load, and, as a result, memory decreases.

Music videos and other forms of advertising that frequently use rapid intercutting of generally unrelated scenes are thus particularly well designed to hold attention, but they also overload the system, resulting in a decrease in overall memory for specific elements, despite the fact that more attentional resources have been activated by the scores of unrelated scene changes and jump cuts. Still, the name of the product may be well remembered, but the detail of the ad or video itself may be less well remembered.

The cost appears to be an overworked orienting response, one that continues to work, with the result that we still attend to the screen, but there is also an accompanying tired and worn-out feeling with little attendant psychological reward. Yale psychologist Jerome Singer expresses his concern about the exploitation of the orienting response in this way: "The TV set, and particularly commercial television with its clever use of constantly changing short sequences,

holds our attention by a constant sensory bombardment that maximizes orienting responses. . . . We are constantly drawn back to the set and to processing each new sequence of information as it is presented. . . . The set trains us to watch it" (1980, pp, 50–51).

It is the orienting response that may best explain typical viewer reports such as the following: "If a television is on, I just can't keep my eyes off it"; "I don't want to watch as much as I do but I can't help it. It makes me watch it"; and "I feel hypnotized when I watch television."

No one should think this is only a problem for those who are not well educated. Research psychologists such as Milton Rosenberg (1978) of the University of Chicago and Percy Tannenbaum (1980) of the University of California at Berkeley have reported on the strong attraction and hold of the small screen. Says Rosenberg, "When I've got television on in my home and I have to get up for one of the conventional reasons . . . I feel temporarily unfulfilled. Some part of the total sensory experience has suddenly been subtracted and I'm left in some slight state of tension until I can turn my gaze back to the screen" (1978).

Tannenbaum writes: "Among life's most embarrassing moments have been countless occasions when I am engaged in conversation in a room while a TV set is on, and I cannot for the life of me stop from periodically glancing over to the screen. This occurs not only during dull conversations but during reasonably interesting ones just as well. Judging from the behavior of the people with whom I was talking at the time and from reports of friends and colleagues, I am far from alone in this behavior and its accompanying chagrin" (1980, p. 112).

The embarrassment and chagrin, however, *may* be something of a class phenomenon. Indeed, research going back nearly four decades in the United States, England, and Japan has shown that TV viewing passivity often is associated with mild feelings of guilt and self-contempt (Bower, 1973; Furu, 1971; Himmelweit & Swift, 1976; Steiner, 1963)—especially among more affluent and educated viewers. The feelings of guilt in each study were associated with self-recrimination about the passivity of viewing and appear to be part of a sense among middle class individuals that they ought to use their time more productively.

Along with the overworked orienting response, I have also found evidence that the longer people view in a given period, the less satisfaction they report deriving from television (concentration also becomes more difficult) (Kubey, 1984). Perhaps like drug users who don't quite get the same response from the same dose as time goes on, in my studies, heavier viewers also report enjoying viewing less, on average, than do light viewers. And if viewers are middle class, a slight twinge of unease or guilt may also accompany prolonged viewing.

The natural attraction to television's sound and bright, colorful, and changing images starts very early. Israeli researcher Dafna Lemish (1987) documents neonates at six to eight weeks of age attending to television. I've observed slightly older infants, when lying on their backs on the floor, turning their necks around nearly 180 degrees to catch the light from a TV screen.

Of course, the ability of the television medium to attract and hold our attention is by no means purely a function of biology. Television provides ready opportunities to vicariously visit exotic places and experience high drama and suspense, view the most beautiful people in the world, and enjoy myriad forms of entertainment. Just as importantly, television producers are masters at finding clever ways to get people to view longer than they had originally intended. Cliffhangers are as common as ever, and some one-hour and most two-hour television dramas are written in seven acts with a rise in the action before each of the commercial breaks to hold viewers for advertising.

The set of programs that will follow those at present being viewed are also routinely "teased" with titillating suggestions that spike viewer interest and increase the possibility that we will view beyond the single program that we may have planned to watch. While the blame cannot all be laid at the feet of television producers, viewers do frequently report that they will sit down to watch one program, say, from 9 to 10 p.m., but then find themselves still watching beyond midnight.

Furthermore, there is a whole host of psychosocial variables to consider. Those who live alone and who feel lonely are especially vulnerable to developing dependence on the quasi-social experience the medium affords. Heavy viewers report having more time on their hands generally, and they also spend more time alone than do light viewers. Not surprisingly, among the demographic groups with higher proportions of heavy viewers in their ranks are the old, the unemployed, and those with more free time

One of the primary positive experiences people report while viewing is "relaxation," and associated with relaxation are consistent reports of passive bodily and mental states. But the benefit of relaxation appears to occur only while viewing, not afterward, whereas the feelings of passivity and lowered alertness associated with viewing seem to continue, spilling over into how people report feeling after they stop viewing—what I have called the "passive spillover effect" (Kubey, 1984). In this same research, I also found that people reporting more difficulty concentrating after viewing. In contrast, they appear to concentrate easily after reading.

These findings raise concerns about whether the quality of thinking after viewing is affected and whether viewing reduces the likelihood of engagement in more active cognitive and behavioral activities after viewing. Indeed, it is not

uncommon for people to report that television somehow absorbs or sucks out their energy. Author Marie Winn (1977) quotes this recollection from a college English teacher: "I find television almost irresistible. When the set is on, I cannot ignore it. I can't turn it off. I feel sapped, will-less, enervated. . . . So I sit there for hours and hours. . . . I remember that feeling of tiredness and anxiety that always followed those orgies, a sense of time terribly wasted. It was like eating cotton candy; television promised so much richness, I couldn't wait for it, and then it just evaporated into air. I remember feeling terribly drained after watching for a long time" (pp. 21–22).

People regularly use television to escape and distract themselves from negative and unpleasant moods, normal stress, and mild tension. In one study, the distraction function of TV was found to effectively reduce patients' reports of pain during dental procedures.

Dependence on the medium appears to develop for many as a result of a need to escape negative feelings or to help fill an emotional vacuum. In repeated studies by Robert McIlwraith (1991, 1998) of the Department of Psychiatry at the University of Manitoba, the 10 percent of university students and adults who call themselves "TV addicts" on surveys are shown to be significantly more likely than the 90 percent of self-reported "nonaddicted" viewers to report using television to cope with negative moods such as loneliness, sadness, anxiety, and anger. McIlwraith also reports finding self-proclaimed addicted viewers to be significantly more neurotic and introverted. On a measure called the Short Imaginal Processes Inventory (SIPI), McIlwraith finds the TV addicts to be more easily bored and distractible, and to have poorer attentional control than the nonaddicted. The addicted also often report using TV to distract themselves from unpleasant thoughts and to fill time. Interestingly, self-proclaimed addicts are significantly more likely to eat junk food but are significantly less likely than nonaddicts to drink alcohol (McIlwraith, Jacobvitz, Kubey, & Alexander, 1991).

My research using the ESM finds much the same thing. By comparison with light viewers in my research who watch less than two hours a day, heavy viewers (more than four hours) reported feeling significantly worse when they are alone, in unstructured situations such as waiting in line, or between activities. Heavier viewers appear to be particularly prone to fill up unstructured time or escape loneliness with a flick of the switch.

Using the American Psychiatric Association's (APA's) *Diagnostic and Statistical Manual* (*DSM–IV–TR;* 2000, http://psych.org/MainMenu/Research/DSMIV.aspx), I have suggested that were television a substance (and it may be—light is both particular and wavelike and *something* is taken into the body when people view), many people could be given a diagnosis of

dependence. Indeed, Allen J. Frances (as quoted in Goleman, 1990, p. C8), who oversaw the most recent revision of the manual, concluded that "Under the broader definition, many kinds of compulsive behavior could be considered addictive, including obsessive sex or compulsive television viewing."

APPLYING *DSM–IV* AND *DSM–IV–TR* SUBSTANCE DEPENDENCE CRITERIA

Though it is tempting to use the term addiction when referring to individuals who report upwards of 60 hours of viewing each week, the term connotes different things to different people. It seems likely that less confusion will result if we are more careful in the words we choose.

Indeed, the prime diagnostic manuals used by psychotherapists throughout North America, the American Psychiatric Association's *DSM–IV* and *DSM–IV–TR*, do not use the term addiction, nor did the previous edition published in 1987. Instead, the committees that wrote the *DSM* prefer the term substance dependence to conceptualize what others might call addiction. Still, there remain researchers and clinicians who use the term addiction, especially with regard to pornography. As a result, in some of these pages I have used the addiction term from time to time.

Using the *DSM* as a guide for making a diagnosis of television dependence is instructive. It is noteworthy that in the most recently revised edition of 2000, the word *drug* is explicitly used in the preface, perhaps to discourage those who have applied the diagnostic criteria to think about or conceptualize dependence on things that are not drugs, as have I since 1990.

DSM–IV lists seven possible criteria for making a diagnosis of substance dependence. Three of the seven must apply in order to make a diagnosis of dependence. Diagnosis also involves a time dimension wherein three (or more) criteria occur at any time in the same 12-month period.

In considering these criteria and the relevant literature on television viewing, it seems to me that perhaps all seven diagnostic criteria could be seen as applicable to television viewing habits in some people, along with their concomitant behaviors and effects. Each criterion is followed by observations regarding the way in which known television behaviors are related to it.

Criterion #1 in the DSM.: "Tolerance is defined by either of the following: (a) a need for markedly increased amounts of the substance to achieve intoxication or desired effect" or "(b) markedly diminished effect with continued use of the same amount of the substance" (p. 181).

Notably, viewers appear to obtain the benefit of relaxation only when they are viewing. It is for this reason, among others, that viewing often continues for

as long as it does. Heavier viewers also *enjoy* their viewing less on average than do light viewers (Kubey, 1984).

Criterion #2: Withdrawal is "manifested by either of the following: (a) the characteristic withdrawal syndrome for the substance" or "(b) the same (or a closely related) substance is taken to relieve or avoid withdrawal symptoms." Withdrawal includes "a maladaptive behavioral change" and it is noted that "withdrawal symptoms vary greatly" (p. 178).

This criterion is a bit more difficult to apply to television viewing behaviors because we are largely limited to anecdotal reports and a small number of social science studies of withdrawal-like symptoms. Still, such reports are not hard to find.

Reports of withdrawal. Steiner (1963), for example, presented individuals' reports of a variety of behaviors of psychological interest that occurred following the loss of a television set. He was quite clever in his research approach, going to television repair shops in the early 1960s when many households still had only one TV set. Then he would interview those families who were without TV for a week or so while their TV set was in the shop.

Here are three examples: "The family walked around like a chicken without a head"; "It was terrible. We did nothing—my husband and I talked"; "Screamed constantly. Children bothered me and my nerves were on edge. Tried to interest them in games, but impossible. TV is part of them" (p. 99).

In her informal interviews, Winn has presented many similar anecdotes (1977, pp. 21–22). Today, such reports are less frequent, in part because most homes have more than one set. To be completely without a television set today is unusual, which is perhaps still another sign of how entrenched television viewing has become. So difficult is this sort of research to conduct that in the early 1970s, Tannis MacBeth Williams (1986) went to great lengths to study a small town in Canada that had been blocked by the Rocky Mountains before it was wired for cable. She was able to study the town before, during, and after the introduction of television in what I consider the most ambitious and convincing research on television's effects ever conducted—and all in a natural environment. Furthermore, Williams compared the small town, "No-Tel," to two other demographically matched towns of similar size that had television. Her book-length treatment is a classic in the field.

Like Steiner, Winick (1988) also offers a valuable review of studies of families whose television sets were being repaired:

> The first 3 or 4 days for most persons were the worst, even in many homes where viewing was minimal and where there were other ongoing activities. In over half of all the households, during these first few days of loss, the regular routines were disrupted, family members had difficulties in dealing with the newly avail-

> able time, anxiety and aggressions were expressed, and established expectations for the behavior of other household members were not met. People living alone tended to be bored and irritated. Over four-fifths of the respondents reported moderate to severe dislocations during this period. . . . The fifth to eighth day represented, in many cases, some form of readjustment to the new situation. By the second week, a move toward adaptation to the situation was common. (pp. 221–222)

Daley (1978) offers a similar account of his family's difficulties when they stopped viewing, also showing how easily the habit reformed itself after six months of abstinence. A number of newspapers, in the United States and elsewhere, have offered money as an incentive to get individuals or families to stop viewing television for some limited period of time, often a week or a month (reviewed in Condry, 1989; Kubey, 1984; Winick, 1988). Increased tension among family members has been described, and many families could not complete the period of abstinence agreed upon (Ryan, 1974). In a German study, it was reported that there was increased verbal and physical fighting after viewing stopped.

If a family has been spending the lion's share of its free time together over a period of years watching television—as is the case for many families today—it may take some days or weeks, or longer, for the family to reconfigure itself around a new set of activities. Particularly because watching television is so easy to do, family members may have become less imaginative about other ways to spend their time together.

Anecdotal reports from families that have tried the annual TV-turnoff week in the United States tell much the same story, with the early days being most difficult and some accommodation reached after a week, accompanied by a sense that it was a good experience for the family to have lived without TV if only for a week and that they had learned from the experience. Some families change their habits for good ,but most don't, typically returning to their former levels of viewing very quickly. The habit of viewing is readily formed, and socially sanctioned and supported within the context of the home and family, and thus the habit can be very difficult to break (see tips for reducing viewing, below).

A Television reduction program that worked. Perhaps the most successful group attempt to help get a number of children to successfully reduce their viewing was recently developed by Barbara Brock and described in her book, *Living outside the Box: TV-Free Families Share Their Secrets* (2007)

Bock, a teacher in eastern Washington State, worked with 130 fourth-, fifth- and sixth- graders from six different classrooms in 2003 and 2005. The experiment in giving up television for a full month worked better than Brock

or anyone, in advance, would have dreamed possible. There was a tremendously high compliance rate—keep in mind how hard, historically, it has been to get people, adults or children, even to try to give up the box for a week.

Hardly any of the children quit after a full month, and some continued on afterward and reported great benefits, all recounted in Brock's book. And it is clear to me, at least, that the group camaraderie and the knowledge of being part of the project are what made the difference. Had just one or two children tried to do it, they might not have succeeded and it wouldn't have been so easy to accomplish as it turned out to be.

Barbara Brock is to be given great credit for conducting this experiment and taking measurements before, during, and after the TV-free month. The most important finding, however, is that it was the group morale that made her experiment work. That hadn't really been a big part of her expectations, but now that the results are clear and to my knowledge unprecedented, in my opinion, the message can go forth that there *is* a way for children and families, since siblings and parents also participated to greater or lesser extents, to learn what it is like to go without television for an extended period of time.

I'm not a Luddite and I've never advocated that people stop viewing; after all, I love many television programs (see, e.g., Kubey, 2004). I just believe that we need to be more discriminating in how we use television and all other media. But families and children can rediscover strengths, activities, and hobbies that they didn't know they had or had forgotten about when they try a TV-turnoff week, or even a few days, and see how life changes in comparison with life when viewing four to five hours a day every day.

In sum, although there is not a great deal of hard empirical evidence, it does seem likely that some individuals—and perhaps entire families—go through something akin to withdrawal if television suddenly disappears. Furthermore, in congruence with section "b" of this criterion, other enjoyable leisure and media activities are typically used to replace TV viewing for those trying to give it up. It is also interesting to note that television is sometimes used by individuals seeking to withdraw from drugs such as heroin, cocaine, and alcohol as a less harmful means of escape and distraction (personal communication from Dyznskyi, October 20, 1994; Kubey & Csikszentmihalyi, 1990, pp. 184–185).

Criterion #3: "The substance is often taken in larger amounts or over a longer period than was intended" (p. 181).

It is common for viewers of all ages to report sitting down to watch just one program but ending up watching much more than was planned. Thus, this diagnostic criterion may fit many viewers.

In a Gallup Poll, 42 percent of the 1,241 U.S. adults who were surveyed reported that they spent too much time watching television (Gallup & Newport, 1990). Mander (1978) reported that some of the typical viewers he interviewed said things such as, "If a television is on, I just can't keep my eyes off it" and "I don't want to watch as much as I do but I can't help it. It makes me watch it" (p. 158).

Indeed, the viewing habit is so entrenched in many people that the choice to view is made almost automatically (Kubey, 1990a). Once dinner is done—or the dishes washed—many individuals sit down to watch television regardless of what programs are on.

Criterion #4: "There is a persistent desire or unsuccessful efforts to cut down or control substance use" (p. 181).

As noted above, it is common for people to report that they believe they spend too much time viewing. This belief itself appears to be on the rise. The percentage of adults in the United States who felt that they watched too much television in the late 1970s was 31 percent, 11 points lower than the 1990 figure of 42 percent (Gallup & Newport, 1990).

It is also relatively common for people to report that they feel powerless to stop viewing on their own, without abandoning the set altogether or interfering with it electronically (Daley, 1977). Some people have told me that they have given up their cable subscriptions precisely so that they have less choice and will thereby watch less. And as stated in *DSM–IV*, *technically* one need only have a "persistent desire . . . to cut down or control substance use" for the criterion to apply. Presumably, some of the Gallup Poll respondents would qualify.

Criterion #5: "A great deal of time is spent in activities necessary to obtain the substance . . . [or] . . . use the substance (e.g., chain smoking), or recover from its effects" (p. 181).

Clearly, with the vast majority of Americans spending two to four hours daily with television, or over half of all their leisure time, a great deal of time is spent using television.

Criterion #6: "Important social, occupational, or recreational activities are given up or reduced because of substance use." "The individual may withdraw from family activities and hobbies in order to use the substance in private" (p. 178).

There is a good deal of research showing that television can bring family members together, but also that it can reduce familial contact (Bronfenbrenner, 1973; Kubey, 1990b, 1990c; Maccoby, 1951; National Institute of Mental Health [NIMH], 1982). Not a few adults (e.g., so-called football widows) feel neglected by their partners who use television heavily. People have reported to

me that they feel that they must regularly compete with television personalities for the attention of family members (Kubey, 1994).

Many people also use television (not to mention other media) purposely to avoid contact with their family. Particularly disturbing is the suggestion that some children may be emotionally, and perhaps even physically, neglected because their caregivers are too engaged in television programs to attend to their needs (Desmond, Singer, & Singer, 1989; Shanahan & Morgan, 1989).

With regard to recreation, some viewers will necessarily engage less in other activities if they are spending three, four, or more hours each day watching television. For example, Williams (1986) found that adolescents and adults participated much less in community activities and sports when TV was available than when it was not.

As for occupational activities, there are undoubtedly people who bring work home from the office but do not do as much as they might (or perhaps do a lower-quality job) because of a television habit that is not under control.

Criterion #7: "The substance use is continued despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by the substance" (p. 181).

As will be noted below, there may be a small percentage of people to whom this criterion could be applied, but the reference in the criterion to "knowledge" demands *awareness,* and awareness of having a significant physical or psychological problem due to TV use is probably rare. Still, it is almost certainly the case that *some* individuals recognize that their television viewing habit interferes with their social relations, level of physical exercise, or work habits. In these instances, television could be seen as exacerbating physical or psychological problems.

There *is* evidence that children and adolescents who view a great deal of television tend to be more obese than those who view less (Dietz & Gortmaker, 1985; Taras, Sallis, Patterson, Nader, & Nelson, 1989). And there is growing evidence now that a child's metabolism slows down when watching television. Furthermore, consumption of junk food by adult self-labeled TV addicts is higher than for nonaddicts (McIlwraith, 1991). Some people also report feeling more passive after viewing than before, and this passivity may decrease the likelihood that viewers will become involved in more active and potentially rewarding activities (Kubey, 1984; Kubey, 1990a: Kubey & Csikszentmihalyi, 1990).

There is also very strong evidence that children and adolescents who view a great deal of television tend to be more obese than those who view less. A study by researchers at Harvard, Tufts, and the New England Medical Center shows perhaps the strongest statistical relationships known among the thousands of studies on television viewing (Dietz & Gortmaker, 1985). This research dem-

onstrates a strong dose-response relationship between television viewing and weight. Even when controlling for a myriad of critical demographic variables, children ages 10–15 who watch over five hours each day were shown to be over five times more likely to be overweight than those who watch less than two hours. Put another way, 60 percent of this population's excess weight is attributed to viewing. Reduced exercise and more consumption of junk food (often advertised on TV) are implicated, as is the finding that a child's metabolism slows down when watching television.

SUMMING UP

As can be seen, when *DSM-IV* or the identical *DSM–IV–TR*'s diagnostic criteria are applied to television viewing habits, a diagnosis of substance dependence can be made for many people. The key missing feature, it would seem, is that we are not accustomed to thinking of television as a substance: it is neither a liquid (alcohol) nor a solid (a pill). Not to go too far, but technically, the viewing of television does, in some way, involve taking *something* into the body, even if that something is only light and sound, and even if no residue of the substance can later be found in the body. Though TV may not be a substance, millions of people nonetheless believe that they, or people they know, need to gain better control of their use of the medium. It is to that end that we next turn our attention. And it is the case that physicists believe that light is both wave-like and *particular*, that is, that it has particles.

One important caveat. Robert McIlwraith (1998) an experienced clinician, is dubious about actually including television dependence in the *DSM*, pointing out that there has yet to be a demonstration of a significant clinical impairment due directly to so-called television dependence. For McIlwraith, while a person not engaging in certain other activities due to their television habit may be social significance, it may well fall short of needing diagnosis. McIlwraith also points out that the establishment of a new diagnosis requires that we rule out more parsimonious explanations for the observed phenomenon in terms of already existing diagnoses such as depression, social phobia, agoraphobia, or avoidant personality disorder.

But the evidence that television is itself causative with regard to some behavioral or psychological phenomena cannot be denied. The comprehensive inventory of three Canadian communities in the early 1970s, two that had television and one that was just beginning to receive it, led Tannis MacBeth Williams and her colleagues to conclude that the use of television "seems unlikely to encourage the ability to tolerate aloneness with one's thoughts and ideas" (1986, p. 125). Williams's team also found that adolescents and adults participated

much less in community activities and sports when TV was available than when it was not. Again there is the indication of viewing leading to isolation and less activity and of viewing perpetuating itself.

In short, television viewing habits are often self-perpetuating. Viewing may lead to more viewing and may also elicit what has been described as *attentional inertia*, that is, the longer people look at television, the greater is the probability that they will continue to look.

Viewing begets more viewing, because one must generally keep watching in order to keep feeling relaxed (Kubey, 1984; Kubey & Csikszentmihalyi, 1990). A kind of psychological and physical inertia may develop. Although paying the bills might not have seemed difficult immediately after dinner, after two or three hours spent with TV, viewers become accustomed to having their experience effortlessly and passively structured. Getting up and taking on a more demanding task may begin to seem more formidable.

Within moments of sitting or lying down and pushing a TV set's power button, many viewers will report feeling more relaxed than they did before. And because relaxation occurs quickly, people readily learn to associate viewing with relaxation. The association is positively reinforced through simple operant conditioning because viewers remain relaxed throughout viewing, and it is negatively reinforced via the stress and dysphoric rumination that occurs during idle time or once the set is turned off.

The quick onset of relaxation is particularly telling when compared to that produced by certain drugs that are known to be habit forming or addictive. As Alvin Swonger and Larry Constantine (1976) have written: "The attribute of a drug that most contributes to its abuse liability is not its ability to produce tolerance or physical dependence but rather its ability to reinforce the drug-taking behaviors" (p. 235). This is why both the speed of a drug's effect and the speed with which it leaves the body are often critical factors in whether or not dependence develops. And, of course, reinforcement needn't be consciously experienced at all for it to occur or to be a powerful motivator of behavior.

Some tranquilizers, for example, whose half-lives are very short—half the drug leaves the body more rapidly compared to other drugs—are much more likely to cause dependence precisely because the user is more prone to become aware that the drug's effects are wearing off. In decades past, some attentive physicians were inclined to prescribe a less well-known tranquilizer, a benzodiazepine called Tranxene (clorazepate) because it was so slow-acting and much less likely than faster-acting benzodiazepines like Valium (diazepam), and especially Ativan (lorazepam), to be habit forming.

When a person starts to feel anxious more quickly while a tranquilizer with a short half-life's effect is on the wane, the tendency to turn to the drug again for relief will be that much greater than if its effects wear off more slowly.

Returning to the use of television, the change in mood that one experiences from the time of viewing to the time when one suddenly stops viewing may be key. The vague experiential knowledge on the part of viewers that one will feel less relaxed if one stops viewing may be a significant factor in not turning the set off.

And relative to other means available to bring about distraction and relaxation, television is perhaps the quickest, most readily available, and least expensive ever invented. Unlike conversation or games, one does not need anyone else to watch TV. And viewing provides more immediate and cheaper relaxation than that involving drugs or alcohol.

As with any activity, too much of the same thing may not always be best, especially for children. If other activities and experiences are not occurring with the frequency that a caregiver or parent deems to be appropriate because of a television, video game, or Internet habit, then, in my opinion, it is surely the right and responsibility of the caregiver to limit such activities. We must also encourage children to develop their own internal self-monitoring abilities so that they can increasingly make these determinations for themselves.

And we should encourage media education, which has been required in schools nationwide across Canada and Australia for two decades now. We need to encourage children's ability to critically analyze the media and to make them more mindful the use of all media (Kubey, 1991; Macedo & Steinberg, 2007).

Is viewing addictive? If we only mean by the term that one can easily develop dependence on the activity, the answer would be "yes." But to be more properly classified as a true dependence or addiction, an activity must also be harmful, interfering with the quality of the rest of one's life. And so, on this score, the answer is "it depends." Most people can benefit from viewing without the activity interfering with the rest of their lives. In its easy provision of relaxation and escape, in small doses it can be beneficial. For lonely people without other resources, it may be wonderful; I have heard this from many older individuals or people stricken with an illness that makes it hard or impossible for them to read.

But when the viewing habit interferes with the ability to grow, to learn new things, to lead an active life, then viewing indeed becomes an obstacle in life.

VIDEO GAMES, COMPUTER GAMES, AND THE INTERNET

Parents are often concerned about their children's heavy use of computers, video games, and the Internet. We can readily apply many of the same explanations offered earlier, as to how television dependence develops, to help explain the attraction of these games, and in some instances the attraction of the Internet. As with television, they offer escape and distraction, and as with

television, players quickly learn that they feel better when playing, hence a kind of reinforcement loop develops.

But computer and video games also pose challenges and the opportunity to overcome them—something largely or entirely missing from much television viewing—and most importantly, many games are designed to minutely increase in difficulty along with the increasing ability of the player.

In being programmed to constantly challenge a player's current ability, video and computer games offer a nearly perfect level of difficulty for the player who enjoys such challenges. And psychic pleasure—what Csikszentmihalyi (1990) has called flow—does accompany the improvement of one's skills and increased mastery of almost any human endeavor (the application of flow to video game play was first discussed by Kubey & Csikszentmihalyi (1990, pp. 143–144).

Before the introduction of video and computer games, one could search for months to find another tennis or chess player of comparable ability, but many programmed games immediately provide a near perfect matching of the challenges with one's skills. Thus, computerized games make extended play extraordinarily common because one is feeling neither bored by too easy an opponent nor too frustrated by an inability to match the level of competition. Plus, players are highly motivated to keep playing to achieve a new personal best score and are being psychologically rewarded throughout the game as they see themselves succeeding.

In computer play, as with sports, musical performance, and other activities that induce flow, the feedback is quick and clear, and insofar as it often occurs at the height of one's own personal level of performance, it is little wonder that the games are extremely engaging and, hence, for some they feel addictive.

The latest media addiction to emerge is so-called Internet addiction As with video and computer games, the Internet is also interactive *and,* importantly, it can be readily used to sustain or form social relationships.

Being connected with others when one is alone, any time of day, and so inexpensively is very attractive, and there can be little doubt that some individuals have grown dependent on the Internet for social contact. A small minority of new college students—perhaps 5 percent—are using the Internet so much that it appears to interfere with their social adaptation to college life, and for some, with their academic performance (Kubey, Lavin, & Barrows, 2001). New students can readily use the Internet to stay in touch with their old high school friends, and in maintaining these safe and familiar social links, or engaging in other parasocial activities on the Internet, a handful of students may be avoiding making new friends on campus.

Indeed, for growing numbers of us, the life we lead online may seem more important, more immediate, and more intense than the life we lead face-to-face.

We're not prepared to draw the conventional conclusion that being with people in real time is absolutely better than being with people on the Internet, but as with other activities, Internet activity can begin to eclipse the rest of life for some, and wisdom suggests that we at least raise the possibility that some of us have developed a habit of some significance that might be interfering with the quality of our relationships with those immediately around us.

CONTROLLING VIEWING AND OTHER MEDIA HABITS

There are ways in which individuals and families can achieve better control of their viewing habits, if that is their goal.

Raising awareness. As with other habits and dependencies, an early critical step is to become aware of how entrenched the viewing habit has become, how much time it absorbs, and the limited rewards of viewing. One way to do this is to keep a diary for a few days of all programs viewed. Some people may be assisted by also rating the quality of their experience with TV, noting how much they enjoyed or learned from various programs. Adding up the hours at the end of the week can be quite sobering. Multiplying by 365 can be even more so.

Promoting alternative activities. All too many individuals and families view automatically: that is, as soon as dinner is done, they watch television. To help break the repetitive, habitual, and self-perpetuating nature of the habit, people need to replace television viewing with other activities. Generating a list of enjoyable and/or constructive activities that can be done in or around the home may prove particularly helpful. The list might be posted on the refrigerator. (Not on the television if using a magnet, lest you harm the cathode ray tube.) Using such a list of enjoyable leisure activities has proved effective for patients suffering from mild depressive episodes. Instead of reflexively going to the television as soon as dinner is done, those interested in reducing their viewing can go to the list. (See the section above on a viewing reduction program for children that worked.)

Exerting willpower. Viewers often know that a particular program or movie is not to their liking within the first few minutes, but instead of switching off the set, they view for the full two hours. It can be helpful to consider that just five or ten minutes after turning off an only somewhat interesting mystery story, most viewers will rarely care what was going to happen next.

Enforcing limits. In addition to setting overall limits on viewing for one's self or one's children, one tip that works particularly well with younger children's video game or computer play is to tell a child, and his or her friends, that they may only play for some specific period. This might be 20 to 40 minutes. It

can be very effective to use a kitchen timer to set the time deemed appropriate. When it rings, the kids know to stop. For some parents, this works much better than announcing the deadline themselves. The kids may actually take the bell more seriously than the parent's words. For an extended discussion of parental responsibility for children's viewing habits, please see the section below.

Blocking channels/v-chip. Viewers can block particular channels or content. Nowadays, television sets come equipped with microchips that can be used to program the set to avoid violence. There are also electronic devices that can be attached to a television set and can be set to count how many hours each family member has viewed and not to permit access beyond a particular level.

Viewing selectively. Using a television guide can be helpful in cutting down on TV viewing. One chooses specific programs to watch ahead of time and then watches only those programs that have been preselected.

Using the VCR or recording device. A VCR, DVD-R, or Tivo can be very effective in time shifting and reducing time spent viewing. Many viewers never return to much of the material they've recorded.

Making television less available or going cold turkey. Many families have succeeded in substantially reducing viewing by limiting the household to one TV set and placing it in a remote room, often one with less than ideal seating. Others keep a set in a closet and bring it out only a few times a year for a particular event. Others end their cable subscription or disconnect the set from an antenna, only using the set to watch videotapes. And thousands of people jettison the set altogether. A group called TV-Free America will send a kit of free information about how to encourage complete abstinence or organize one's school or community for a TV-turnoff week.

Parental Responsibility for Children, with Regard to Dependent and Heavy Viewing

In making decisions and judgments about what is in the best interests of a child, and especially about children and media, it is critical to remember that every child is simultaneously unique and changing—often rapidly. Furthermore, every medium is different, and TV shows, video games, movies, and books offer an enormous range of content, form, and style. Still, there are some similarities among most children at different ages and across media and programs, games, and stories. So while idiosyncratic judgments with regard to each child are critical, there are also some general observations that can be made.

Today, we probably have more children at risk for developing a dependency on television than ever before. I have observed, as have others (personal com-

munication from James Hutchinson, M.D., April 1994), that a substantial number of parents do not believe that they can, or should, control their children's viewing. Some believe that there is no potential harm in anything that a child might watch. They believe that children can negotiate the television text on their own.

Many parents have reported to me that it is beyond their ability to limit their children's viewing. None of us wants to be a dictator, but in my opinion parents should not back off making decisions with regard to what their children may view on television. If parents are not in reasonable control of their households, and their children and their activities, we might conclude that the socialization process is, at best, undergoing change. At worst, we might expect all manner of social problems to ensue (Kubey, 1994, 1996).

Parental monitoring of children's viewing is important because there are many programs and materials that are unsuitable for some children, young children in particular. I am especially concerned about reality programming and news programs that often engender unnecessary and substantial fear. Indeed, I am as concerned about the fear-induction effects of violence as I am about the potential modeling effects (Kubey, 1987).

Children sometimes need to be supervised in their use of television, video games, computers, and other media, just as they sometimes need supervision when carving a pumpkin, walking downstairs, or riding a bicycle on the street. The idea that a great many different children's activities need to be monitored from time to time but somehow only media activities can be completely unsupervised is thoroughly illogical to me, yet some hold to such a position.

What I have just written will strike most readers as obvious. I have made these points for two reasons. The first is that some media scholars and researchers, most often those allied with the cultural studies approach to media studies—an approach that has made many important contributions to our understanding of how audiences experience and understand the media—believe that parents ought never to censor a child's media experience or prohibit a child from partaking in any medium that she might wish to experience. Some believe it is a presumptuous and arrogant act for a parent to intrude on or censor the media experience of a child.

For theoretical, political, and pedagogical reasons, some theorists have concluded that the media are a different kind of stimulus or phenomenon from things such as fire, dangerous strangers, candy, and unguarded cliffs and stairs. Television shows, books, and video games are all cultural products and can be actively negotiated by audience members, it is argued. Notably, much of the research on such negotiations, or readings, of media texts has been done with adolescents and adults, not children.

Indeed, some developmental psychologists have been criticized by some cultural studies advocates for being too proscriptive in their views about appropriate media content for children. There are leading cultural studies scholars who seem to suggest that the only media effect with which we need to concern ourselves is what these theorists see as the negative effect of developmental psychologists and other authorities pontificating to the culture at large through the media and causing moral panic about the potential harmfulness of media (Buckingham & Sefton-Green, 2001).

My second reason for emphasizing the need for caregivers to supervise children's media use is that many parents report that they were not restricted in their own viewing when they were young and yet they often watched a lot of violence on television. Insofar as they believe *they* were not psychologically harmed in any way, they now believe that they can safely permit their children to watch whatever they like.

Regardless of this belief, one only has to go to a movie rated PG-13 or R to observe parents or other caregivers with three- and four-year-old children on their laps or in the seat beside them witnessing material that is by most measures incredibly violent, frightening, and horrific. There is material that I myself turn away from on a large-screen film and I am in my mid-50s. I am doubtlessly being judgmental here in the view of some readers, but it is my view that young children should not be exposed to horrific violence or graphic sex when they are highly impressionable.

With regard to the idiosyncrasies of different children and the differences among media, let me relate a final story. My older son, now 23, was six when he first watched *The Wizard of Oz* on TV, a favorite movie of mine that his mother and I concluded was now appropriate for his viewing, even though it contains frightening scenes of flying monkeys and melting witches. But with another child we might have been wrong. During one commercial break, at around 7:30 p.m. CBS promoted a story to be shown a few days hence on its popular program *60 Minutes*. The ad included both a voiceover and words on screen promoting a story entitled "Kids Killing Kids?" The promotion was dominated by news footage of a child being rushed into a hospital emergency room on a stretcher, wrapped in gauze and bleeding. My son was frightened by what he saw and heard, and no wonder. He wanted to know whether or not kids really killed kids. We talked about it for a while, though it meant missing Dorothy's initial meeting with the cowardly lion.

I am not recommending that children be constantly supervised, only that for many children, today's media offerings—from television to video games and the Internet—demand more vigilance on the part of parents than was the case 30, 40, or 50 years ago.

ACKNOWLEDGMENTS

I wish to thank Hartmut Mokros, PhD, and James Hutchinson, MD, for their helpful suggestions on the application of the *DSM* to this work in the first public presentation of these ideas at the 98th annual meeting of the American Psychological Association, Boston, August 1990.

NOTE

1. Page numbers cited here for the *DSM* refer to the 1994 edition but it is important to note that the wording has gone unchanged in the 2000 edition. It can be obtained online.

Chapter **3**

Excessive Buying as a Genuine Addictive Behavior

Paul Rose, PhD, and Dan J. Segrist, PhD

Addiction scientists have not always agreed on what is and is not an addictive behavior. Although there has been some longstanding consensus that particular substances can be addictive (e.g., alcohol, cocaine, heroin), cultural and technological evolution has forced us to reconsider whether the concept of addiction can also apply to certain behaviors. Can work be addictive? What about viewing soap operas, gambling, or playing video games? Anecdotal evidence suggests that these behaviors might sometimes reach "out of control" levels that produce clinically significant dysfunction or distress, but if the list of addictive behaviors is not carefully limited, the most dangerous addictive behaviors risk being trivialized by their association with less serious self-control problems.

The primary purpose of this chapter is to present the case for classifying excessive buying as an addictive behavior. While presenting this case, we wish neither to understate nor to overstate the gravity of the problem. In fact, we recognize that there may be several addictive behaviors that have worse consequences than excessive buying. But the primary issue with which we are concerned is whether the existing literature warrants the grouping of excessive buying with other behaviors that are widely accepted as addictive. To present the case for classifying excessive buying in this way, we first describe the nature of excessive buying and the general characteristics of people who are prone to it. We then present well-accepted definitions of addiction and demonstrate "goodness of fit" between existing definitions of addiction and excessive buying as it is presently understood. Following this, we emphasize that classifying excessive buying as a genuine behavioral addiction may stimulate considerable progress

in our understanding by facilitating knowledge transfer between the study of other addictive behaviors and the study of excessive buying.

WHAT IS EXCESSIVE BUYING?

Excessive buying is an enduring purchasing pattern that has reached a level so high that it is deemed problematic by either the consumer or people close to the consumer (such as family and friends). There are many reasons why such behavior might be experienced as problematic. Excessive buying can undermine a consumer's financial security (which has the potential to erode well-being; Drentea, 2000; Drentea & Lavrakas, 2000; Hatcher, 1994) but may also have harmful effects on relationships (Andersen, 2005; see also Dean, Carroll, & Yang, 2007) and mental health (Christenson et al., 1994). This behavior also has obvious negative consequences for the earth's ecosystem and may have indirect effects on other, international-scale problems, but in this chapter our focus is on excessive buying as an individual and interpersonal problem. We use the term *excessive buying* because this term is relatively free of unnecessary assumptions about the essence of the behavior (cf. Dittmar, 2004a; Swan-Kremeier, Mitchell, & Faber, 2005).

In empirical studies, excessive buying is most often operationalized with measures of "compulsive buying" (e.g., Edwards, 1993; Faber & O'Guinn, 1992; Valence, d'Astous, & Fortier, 1988). However, questionnaires labeled as indices of "impulse buying" (Mick, 1996; Rook & Fisher, 1995), "addictive buying" (Scherhorn, Reisch, & Raab, 1990), and (low levels of) "frugality" (Lastovicka, Bettencourt, Hughner, & Kuntze, 1999) appear to capture the same construct. Indeed, although each of these measures has been labeled differently, all of them measure the propensity to buy at high levels in spite of negative consequences. For example, the Valence et al. compulsive buying measure contains the item "When I have money, I cannot help but spend part or the whole of it"; the Rook and Fisher (1995) impulsive buying measure contains the item "Sometimes I am a bit reckless about what I buy"; and the Lastovicka et al. (1999) frugality measure contains the item "I believe in being careful in how I spend my money." As this sample of items suggests, the differing names of these scales belie the possibility that the scales assess a common latent construct.

Although no formal assessment of whether these various measures are actually measuring different constructs has been conducted, the evidence of which we are aware is consistent with a common-construct view. In unpublished data (Rose & Segrist, 2008), we have observed (with data obtained from a sample of 183 undergraduates) that scores on measures of impulse buying (Mick, 1996), compulsive buying (Faber & O'Guinn, 1992), and frugality (Lastovicka et al.,

1999) substantially intercorrelate (all *r*'s > |.42|; see also Troisi, Christopher, & Marek, 2006). (Frugality correlated negatively with impulse and compulsive buying, which correlated positively with each other.) All three measures also produced correlations of magnitude (*r*'s ranging from |.37| to |.43|) similar to those of scores from Eysenck, Pearson, Easting, and Allsopp's (1985) Impulsiveness Questionnaire. At this point, therefore, it seems justified to assume that measures labeled as indices of compulsive buying, impulse buying, addictive buying, and frugality are at least approximately assessing the same construct.

Having stated this, an appreciation of the equifinality principle should compel us to recognize that there may be several very different routes by which consumers arrive at an excessive level of buying (cf. DeSarbo & Edwards, 1996). For instance, it has been repeatedly observed that compulsive buying is related to low self-esteem (e.g., d'Astous, 1990; Faber & O'Guinn, 1992; Scherhorn et al., 1990; cf. Valence et al., 1988), but it has also been observed that compulsive buying is related to narcissism (Rose, 2007). These findings may seem somewhat surprising in light of ample evidence that trait narcissism and trait self-esteem are positively related (Campbell, Rudich, & Sedikides, 2002; Rhodewalt & Morf, 1995; Rose, 2002). (Initial evidence, based on clinical speculations, that people with narcissistic personalities might dislike themselves "deep down" [i.e., beyond the reach of the questionnaires; Jordan, Spencer, Zanna, Hoshino-Browne, & Correll, 2003] has recently been contradicted by additional evidence [Campbell, Bosson, Goheen, Lakey, & Kernis, 2007].) These and other findings suggest that excessive buying, like many other addictive behaviors, may arise from a variety of different traits.

WHO BUYS EXCESSIVELY?

Until recently, little was known about the demographic and personality characteristics of excessive buyers. But primarily within the last two decades, numerous studies have provided a clearer picture of the background characteristics of these consumers.

Gender. In a recent review of compulsive buying research, Dittmar (2004b) noted that many studies suggest that compulsive buying is far more common among women than among men (e.g., d'Astous, 1990; Faber & O'Guinn, 1992; Scherhorn et al., 1990). However, she also acknowledged that the gender difference that has emerged in some studies may be exaggerated because of the sampling techniques that some researchers have used. Many researchers have recruited participants who self-identified as having buying problems, and because participants often volunteer for such studies with the hope of receiving

some help with their problem, women may have been especially likely to volunteer. After all, research has consistently demonstrated that women hold more favorable attitudes toward seeking help, including help for their psychological problems (see Mosher, 2002). For example, with regard to gambling problems, Ladd and Petry (2002) found that, among first-time treatment seekers, women sought treatment significantly sooner than men did. In addition, with regard to alcohol problems, Thom (1986) found that women were less likely than men to report that the belief that one should be able to resolve one's own problems was a barrier to seeking treatment (a finding that further attests to women's greater willingness to seek help for their problems).

Given that women generally seem more prone to seeking treatment than men do, and given that many research participants volunteer for studies with the hope of eventually getting help with their problems, it seems likely that earlier studies may have overestimated the degree to which excessive buying is more common among women than among men. Indeed, a recent phone survey conducted with a random sample of Americans indicated that 6.00 percent of women and 5.50 percent of men could be classified as compulsive buyers using Faber and O'Guinn's (1992) screening instrument (Koran, Faber, Aboujaoude, Large, & Serpe, 2006). Furthermore, in two nationally representative surveys conducted in Germany, women scored only moderately higher (i.e., .31 of a standard deviation higher) than men on Scherhorn et al.'s (1990) addictive buying scale (Neuner, Raab, & Reisch, 2005). The most reasonable conclusion at this point is that women are somewhat more prone to excessive buying, but the difference is not nearly as dramatic as some small-sample studies previously suggested. The magnitude of the gender difference may also vary across cultures.

Age. Existing data support the commonly held idea that young adults and teenagers experience more buying problems than older adults. In Neuner et al.'s (2005) surveys, Germans between 14 and 32 years of age scored higher in addictive buying than Germans between 33 and 49 years of age, and this middle-aged group scored higher than Germans older than 49. Using a sample of 190 Canadians (ranging in age from under 20 to over 74), d'Astous (1990) observed a negative association between age and compulsive buying. Similarly, in two surveys of British adults (with a few adolescents included in the first survey), Dittmar (2005) also found negative associations between age and compulsive buying. Negative correlations have also emerged in U.S. samples (Koran et al., 2006; Troisi et al., 2006). Dittmar (2005) uncovered evidence that materialistic values mediate the age-compulsive buying relationship, which suggests that teenagers and younger adults are the most susceptible to excessive buying because they are more materialistic than older adults.

Socioeconomic status (*SES*). In the United States, Canada, and Germany, it appears that excessive buying is negatively related to SES. In Koran et al.'s (2006) American survey, compulsive buyers were more likely to have incomes lower than $50,000 per year than to have incomes above that amount. In a study of 135 adult (nonstudent) Americans, Rindfleisch, Burroughs, and Denton (1997) observed a small negative relationship between socioeconomic status and compulsive buying. In d'Astous's (1990) Canadian survey, a negative relationship also emerged between socioeconomic status and compulsive buying, although the very lowest SES group scored no higher than the second-lowest group. In addition, Scherhorn et al. (1990) reported a negative correlation between addictive buying and SES in their sample of German participants (who were not preselected for having buying problems).

Values. Values guide behavior toward desired ends (Rokeach, 1973) and may play an important, and perhaps underappreciated, role in the development of addiction problems (see Rose, 2007). Materialistic values are the most obvious values connected to excessive buying, and research confirms that measures of compulsive buying (Dittmar, 2005; Yurchisin & Johnson, 2004), impulsive buying (Rose, 2008), and frugality (Lastovicka et al., 1999) are all predictably correlated with materialism. Further insight into the values of excessive buyers comes from research on the broader values of materialistic consumers. Materialism is negatively correlated with the valuation of family, community, religion, universalism (care for all living things), and benevolence (concern for the welfare of close others); it is also positively correlated with the valuation of power, pleasure, achievement, and work (Burroughs & Rindfleisch, 2002). In addition, fame and image values (i.e., the valuation of popularity and looking good) are also positively correlated with materialism (Grouzet et al., 2005). These associations have been observed with *materialism*, however, so additional research is needed to determine whether excessive buying itself yields a similar pattern of correlations.

Personality. Because excessive buying is relatively stable over time, researchers have devoted substantial attention toward identifying how it is related to enduring aspects of personality. Excessive buying may be related to all of the big five personality traits (the basic traits thought to underlie all major dimensions of personality; Wiggins & Trapnell, 1997) except openness to experience (Mowen & Spears, 1999; Troisi et al., 2006). Several studies indicate that neuroticism, the tendency to consistently experience a variety of negative emotions, is positively related to excessive buying (Mowen & Spears, 1999; Stone, 2002), although the relationship is sometimes weak (e.g., Verplanken & Herabadi, 2001). As previously mentioned, excessive buying is also negatively related to self-esteem (d'Astous, 1990; Faber & O'Guinn, 1992; Scherhorn et al., 1990;

cf. Valence et al., 1988), and self-esteem is strongly negatively related to neuroticism (Robins, Tracy, Trzesniewski, Potter, & Gosling, 2001). Impulsivity, which is considered a component of neuroticism (Jang, Livesly, & Vernon, 1996), may be the personality trait to which excessive buying is most strongly related (Rose, 2007; see also Eysenck et al., 1985). The association between neuroticism (and its components) and excessive buying is consistent with the hypothesis that, in the absence of strong inhibitions, buying is sometimes used as a means of escaping distress (cf. Kyrios, Frost, & Steketee, 2004; Valence et al., 1988;).

Evidence of a relationship between extraversion and excessive buying is mixed. Although some studies indicate a positive relationship (e.g., Stone, 2002; Verplanken & Herabadi, 2001), others suggest no relationship (Mowen & Spears, 1999). This mixed evidence may be reasonably attributed to researchers' use of different extraversion measures in different studies. Sensation seeking, which is a component of extraversion (Jang et al., 1996; Olino, Klein, Durbin, Hayden, & Buckley, 2005) but is not captured to the same degree by all extraversion measures, correlates positively with impulse buying (Troisi et al., 2006). In contrast, extraversion measures that primarily emphasize sociability tend to yield near-zero correlations with compulsive buying (Mowen & Spears, 1999). In short, whether there is a significant association between extraversion and excessive buying may depend on how extraversion is measured and defined.

Although the relationship is weak and does not emerge in all studies (cf. Verplanken & Herabadi, 2001), there appears to be a positive relationship between agreeableness (i.e., kindness) and excessive buying (Mowen & Spears, 1999; Stone, 2002). Strange as this association may initially seem, it is understandable in light of evidence that excessive buyers are highly susceptible to others' influence (d'Astous, 1990; see also Yurchisin & Johnson, 2004). The desire to gain others' approval is a characteristic of materialistic consumers in general (Rose & DeJesus, 2007), and an orientation toward pleasing others may make resisting marketing messages particularly challenging.

Of all of the big five personality traits, conscientiousness appears to be the only one that is negatively related to excessive buying (Mowen & Spears, 1999; Verplanken & Herabadi, 2001). Conscientious people probably tend to plan their purchases carefully, and considering established plans when confronted with a buying impulse may be an effective strategy for resisting the temptation to buy (cf. Dholakia, 2000). Consistent with this possibility, Bearden, Money, and Nevins (2006) have demonstrated that their measure of planning tendencies is positively related to frugality and negatively related to compulsive buying.

Beyond the big five, recent research has established that trait narcissism is positively related to compulsive buying (Rose, 2007), apparently because narcissists tend to be both materialistic and impulsive. Several motivational variables have also been linked to excessive buying. Mowen and Spears (1999) have established that the need for arousal (similar to sensation seeking) is positively related to compulsive buying, possibly because people with a strong desire to experience excitement tend to be more materialistic (Troisi et al., 2006). Furthermore, Verplanken and Herabadi (2001) have observed that the need for structure (i.e., the motive to simplify and reduce ambiguity) and the need to evaluate (i.e., the motive to assess things positively and/or negatively) are both inversely related to the cognitive aspects of impulsive buying, such as buying with little forethought. A cogent account of the reasons behind these associations will require additional research.

In summary, although people who buy excessively vary widely in their characteristics, it seems that women, adolescents and young adults, and people of lower socioeconomic status are somewhat more prone than others to excessive buying. However, personality traits and values may be more important risk factors than any of these demographic variables. All of the big five personality traits (except openness to experience) seem to be related to excessive buying, with neuroticism (and especially the more specific neuroticism facet, impulsivity) being the most consistent trait predictor that researchers have uncovered thus far. Among values, materialism clearly stands out as the value most closely related to excessive buying, and numerous research studies confirm that these two variables are positively associated.

WHAT IS AN ADDICTIVE BEHAVIOR?

To fairly assess whether excessive buying should be categorized as an addictive behavior, it is necessary to carefully consider how addiction should be defined. Shaffer (1996) noted that the addictions field is marked by "conceptual chaos" and that "clinicians, researchers, and policy makers are without a shared definition of addiction" (p. 463). Similarly, Doweiko (2002) observed that "there is no single definition of addiction and a universally accepted, comprehensive theory of addiction has yet to be developed" (p. 21, cited in Coombs & Howatt, 2005). Traditionally, however, addiction has been conceptualized as a phenomenon reserved only for psychoactive substances (Coombs, 2004; Holden, 2001; Orford, 2001; Shaffer & Freed, 2005), whereby an individual demonstrates tolerance and withdrawal as well as a variety of negative consequences subsequent to the increased use of a drug. Consequently, similarly problematic behaviors that are now known as behavioral or process addictions

(such as compulsive gambling) were excluded from the traditional framework of addictive behaviors. M. B. Walker (1989), for example, argued that gambling should not be considered an addictive behavior because, he contended, there is insufficient evidence of dependency or withdrawal, and dissimilar biochemical mechanisms are at work.

Peele (1995) pointed out that even the traditional conceptualization of addiction is a relatively recent phenomenon: "addiction was not applied especially to narcotics or alcohol until well into this century. Until the twentieth century, *addiction* simply meant liking to engage in a habit" (p. 22). Furthermore, Shaffer (1996) has argued that physical dependence is not a requisite indicator of addiction, and Smith and Seymour (2004) assert that physical dependence is "no longer our sole definition of addiction" (p. 26). In fact, while the current editions of the *International Classification for Diseases* (*ICD-10;* World Health Organization, 1990) and the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM–IV–TR;* American Psychiatric Association, 2000) include tolerance and withdrawal as potential symptoms, neither is required for the diagnosis of substance dependence.

Unfortunately, the traditional view of addiction precludes many behaviors—behaviors that manifest dynamics quite similar to substance abuse and dependence—from fitting under the addiction umbrella. Orford (2001) asserts that because of the exclusive focus on drugs within the addictions field, "other forms of excessive appetite have been marginalized" (p. 2). Arguing against the narrow, traditional view of addiction, many authors have advocated that the concept of addiction can be generalized to other problem behaviors (e.g., Internet use; Young, 1996). For example, Peele (1995), a staunch critic of the disease model of addiction, suggests that in comparison with narcotics, activities such as gambling are more likely to be associated with a loss of control. Whelan, Steenbergh, and Meyers (2007) have also argued that gambling can be genuinely addictive. They noted that "Like other addictions, problem gambling includes loss of control, preoccupation, tolerance, withdrawal, escape, cravings, and other concomitant biopsychosocial problems" (p. 20).

Grant and Potenza (2005) point out that "mounting evidence supports phenomenological, clinical, epidemiological, and biological links between behavioral and drug addictions" (p. 303). Although M. B. Walker (1989) argued that the biochemistry underlying drug addiction is dissimilar to that of behavioral addictions such as gambling, the differences may be diminishing, as increasing evidence points to similarities between the neurological mechanisms implicated in substance-based addictions and behavioral addictions (Coombs & Howatt, 2005). For example, gambling has been shown to increase dopamine activity (Shizgal & Arvanitogiannis, 2003) and activate the brain's pleasure center (Coombs & Howatt, 2005). Within the area of eating disorders, Marrazzi and

Luby (1986) detail an "auto-addiction" model of anorexia implicating increases in endogenous opioids associated with starvation behaviors. They argue that this process contributes to the intractable nature of the disorder by creating an addictive cycle.

Other researchers have also pushed for a broader conceptualization of addictive behavior. Shaffer (1996) has asserted that "It is the relationship of the addicted person with the object of their excessive behavior that defines addiction" (p. 465), and Orford (2001) has argued that behaviors such as gambling, sex, and eating should be considered addictive behaviors because they "can get sufficiently out of hand" and "spoil the lives of many people" (p. 3). Coombs and Howatt (2005) have also conceptualized addictive behaviors broadly; they describe these behaviors as actions characterized by compulsive use, loss of control, and continued use in the face of harmful consequences. Consistent with these broader views, Grant and Potenza (2005) have outlined several similarities between drug and behavioral addictions: "(1) repetitive or compulsive engagement in the behavior despite adverse consequences; (2) diminished control over the problematic behavior; (3) an appetitive urge or craving state prior to engagement in the problematic behavior; and (4) a hedonic quality during the performance of the problematic behavior" (p. 304). With these perspectives in mind, we believe that one of the most reasonable definitions of addiction has been offered by Goodman (1990), who wrote that addiction is "a process whereby a behavior, that can function both to produce pleasure and to provide relief from internal discomfort, is employed in a pattern characterized by (1) recurrent failure to control the behavior (powerlessness) and (2) continuation of the behavior despite significant negative consequences (unmanageability)" (p. 1404).

A perusal of several major addiction journals attests to the fact that the zeitgeist within the addictions field is changing, leading to a more flexible characterization of what constitutes an addictive behavior. It is noteworthy that *Psychology of Addictive Behaviors*, a peer-reviewed journal of the American Psychological Association, reviews and publishes "articles on the full range of addictive behaviors, including alcohol use and addiction, drug use and misuse, eating disorders, tobacco and nicotine addiction, and *gambling and other excessive behavior patterns*" (emphasis added). Similarly, the leading journal *Addiction* "publishes peer-reviewed research on alcohol, illicit drugs, tobacco and *behavioural addictions*" (emphasis added).

DOES EXCESSIVE BUYING FIT WITHIN CURRENT CONCEPTUALIZATIONS OF ADDICTIVE BEHAVIOR?

Given the ways in which addictive behavior is now defined by many leading addiction scientists, we suggest that a behavioral pattern can be fairly classified

as addictive to the extent that the behavioral pattern (a) can produce pleasure (i.e., a "high") at least some of the time; (b) has reached an "out of control" level; and (c) persists in the face of harmful consequences (cf. Goodman, 1990). In this section, we demonstrate that excessive buying meets these criteria.

People who buy excessively experience buying as pleasurable. Many people seem to believe that buying can be a pleasurable experience, and both theory (Holbrook & Hirschman, 1982) and research (e.g., Cox, Cox, & Anderson, 2005) confirm that it can be a pleasurable experience in some circumstances. Some purchasing activities can even evoke excitement (Wakefield & Baker, 1998) and elation (Mano & Oliver, 1993). Indeed, the mere perception of a preferred product is associated with activation of the nucleus accumbens (Knutson, Rick, Wimmer, Prelec, & Loewenstein, 2007), a conglomeration of neurons in the forebrain that are involved in the experience of pleasure.

Consumers who buy excessively, however, seem especially prone to experiencing a rush of pleasure while purchasing. Faber and O'Guinn (1988) have demonstrated that compulsive buyers are much more likely than other consumers to report feeling high while shopping, and Lejoyeux, Mathieu, Embouazza, Huet, and Lequen (2007) have similarly shown that compulsive buyers find purchasing more gratifying than other consumers do. The strong high experienced by excessive buyers seems to stem from the purchasing act itself; both Valence et al. (1988) and Faber and O'Guinn (1988) have demonstrated that excessive buyers derive little satisfaction from owning the things they purchase.

People who buy excessively experience their buying as "out of control." A feeling of diminished volitional control is a cardinal feature of excessive buying. Qualitative studies have repeatedly documented that consumers who buy excessively feel as if their consumption is out of control (e.g., Dittmar, 2004b; Rook, 1987), and several measures of excessive buying include items that assess this experience. To provide a few examples (with italics added), Valence et al.'s (1988) compulsive buying measure includes the item "When I have money I *cannot help* but spend part or all of it"; Verplanken and Herabadi's (2001) impulsive buying measure contains the item "I sometimes *cannot suppress* the feeling of wanting to buy something"; and Lastovicka et al.'s (1999) frugality scale contains the item "There are things *I resist* buying today so I can save for tomorrow." Also, Faber and O'Guinn (1988) have demonstrated that, much more than other consumers, compulsive buyers report going on buying binges and feeling unable to stop.

The diminished sense of control experienced by excessive buyers seems very similar to that of people who experience other addictions. A substantial body of research suggests that diminished impulse control is associated with a wide variety of addictive behaviors (e.g., Acton, 2002; Miller & Brown,

1991), including excessive buying (Rose, 2007; Spinella, Yang, & Lester, 2007). Impulse control is partly heritable (Jang et al., 1996) and seems to be associated with prefrontal cortical functioning and the functioning of the orbitofrontal circuit in particular (Grace, Stout, & Malloy, 1999; Spinella, 2004). Indeed, O'Doherty, Kringelbach, Rolls, Hornak, and Andrews (2001) have demonstrated that experiencing hypothetical financial rewards and losses activates the orbitofrontal cortex. Given the existing research, therefore, we may hypothesize that suboptimal orbitofrontal functioning predisposes people to excessive buying and other impulse-control problems.

People who buy excessively persist in their purchasing in spite of adverse consequences. A third way in which excessive buying fits within current conceptualizations of addictive behavior is that it persists even when the consumer experiences harmful consequences from his or her buying. To provide evidence of this, in the section that follows, we document some of the negative consequences of excessive buying that research has uncovered thus far. Thereafter we demonstrate that excessive buyers persist in their extreme buying habits in spite of these negative consequences.

WHAT ARE THE ADVERSE CONSEQUENCES OF EXCESSIVE BUYING?

Financial stress and its sequelae. The most obvious negative consequence of excessive buying is that it undermines financial security (Faber, 2004). Financial problems may seem trivial in comparison to the negative effects of some other addictive behaviors, but in fact, such problems are likely antecedents of a wide range of health-, family-, and work-related problems. Financial strain is associated with general psychological distress (Whelan, 1992) and depressive symptoms in particular (Mills, Grasmick, Morgan, & Wenk, 1992). It has also been linked to smoking (Siahpush, Borland, & Scollo, 2003) and increases in alcohol consumption over time (when financial support from others is low; Peirce, Frone, Russell, & Cooper, 1996; see also Moos, Fenn, Billings, & Moos, 1989). Peirce et al.'s (1996) longitudinal study is an especially important contribution to our knowledge about the consequences of financial stress, because it rules out the possibility that financial problems are linked to alcohol use merely because purchasing large quantities of alcohol strains people's budgets. Peirce et al.'s (1996) study demonstrates increased drinking *following* financial strain (among people who have little financial support from others), suggesting that in some circumstances money problems may cause greater substance abuse.

Several studies also link financial difficulties with family problems. Financial strain among married people is associated with lower marital satisfaction,

both for the person reporting financial problems and for that person's spouse (Dean et al., 2007). Parents experiencing financial strain report higher levels of depression, as do their adolescent children (Clark-Lempers, Lempers, & Netusil, 1990). Moreover, children of parents with high levels of financial stress also experience more impulsive and antisocial behavioral problems (Takeuchi, Williams, & Adair, 1991).

Financial stress also seems to affect a variety of health problems. In O'Neill, Sorhaindo, Xiao, and Garman's (2005) survey of consumers participating in a debt management program, self-reported improvements in participants' financial situations were associated with reports of improved overall health. Although this finding (like all of the correlational findings in this section) raises questions about which way the causal arrow might point (because health problems might cause financial problems and vice versa), there are reasons to believe that financial stress might cause poorer health. For instance, Rosengren et al. (2004) found that compared to control patients, patients who had experienced a heart attack were more likely to report severe financial stress in the 12 months *prior* to their hospital admission.

Financial stress may also affect people's work lives, because employees experiencing greater financial stress exhibit lower job satisfaction (Bailey, Woodiel, Turner, & Young, 1998), lower organizational commitment (i.e., sense of attachment to the organization), and higher absenteeism (Kim & Garman, 2003). In short, financial stress seems to produce many of the same detrimental effects that other types of stress do, and these consequences are far from trivial. Because excessive buying has an obvious negative effect on many consumers' financial security, it may have an indirect effect on a wide variety of occupational, familial, and personal problems.

Affective distress. Excessive buyers seem to be highly prone to guilt and shame (Edwards, 1993; O'Guinn & Faber, 1989; Valence et al., 1988), emotions that are often classed with other "self-conscious" emotions (Tangney & Fischer, 1995). Studies suggest that guilt and shame are both related to hostility, anxiety, and depression as well as psychotic, paranoid, and obsessive-compulsive symptoms (Tangney, Wagner, & Gramzow, 1992). Shame in particular has been linked to posttraumatic stress symptoms and somatization symptoms, although guilt may also be indirectly related to these symptoms through shame (Pineles, Street, & Koenen, 2006). These findings are consistent with research on both substance-based addictive behaviors (see Marlatt & Witkiewitz, 2005) and other behavioral addictions such as gambling (see Shaffer & LaPlante, 2005), in which people with addiction problems have elevated rates of mood disorders. It is important to note that among people with substance use prob-

lems, negative emotional states are strongly linked to relapse (see Marlatt & Witkiewitz, 2005). In future research, it would be helpful to examine whether this link between negative states and relapse might also exist for people who are in treatment for excessive buying.

One reason why excessive buyers may be prone to aversive self-conscious emotions is that they have some awareness that their buying is a serious personal problem (cf. Scherhorn et al., 1990). Self-report measures of excessive buying, and the many studies that employ them, clearly suggest that many compulsive buyers recognize that their buying habits are problematic. For example, the Rook and Fisher (1995) impulsive buying scale includes the item "Sometimes I am a bit reckless about what I buy"; and the Valence et al. (1988) compulsive buying scale includes the item "There are some things I buy that I do not show to anybody for fear of being perceived as irrational in my buying behavior ('a foolish expense'). These and similar items require the respondent to admit that he or she may have a buying problem, and suggest that excessive buyers are prone to feeling guilty about their purchases and ashamed of themselves. As suggested above, these feelings may predispose people to a wide variety of mental health problems.

Consistent with evidence that excessive buying is linked to affective distress (see also Scherhorn et al., 1990), Faber and O'Guinn (1988) have demonstrated that excessive buyers are more likely than other consumers to feel depressed after shopping. (It may seem that these consumers should be especially happy with their new purchases, but as previously mentioned, several studies suggest that compulsive buyers gain little satisfaction from the objects they buy. It is the buying act itself that thrills them; Faber & O'Guinn, 1988; O'Guinn & Faber, 1989; Scherhorn et al., 1990.) Although no research has clearly delineated the reasons for a link between excessive buying and depression, existing studies lead us to tentatively propose a model of how excessive buying might contribute to such distressing feelings. First, when a consumer buys something he believes should not have been bought, he should experience guilt (as people often do when they act contrary to their personal standards). Once guilty feelings arise, the bad act (buying when one shouldn't have bought) may be interpreted as evidence of a bad self; thus, guilt may give rise to shame (cf. Tangney et al., 1992). When shame arises, depressive thoughts and feelings may naturally follow, because negative self-views are central to the experience of depression. Although we provide this as a possible (and as yet untested) explanation for how excessive buying might contribute to depression, we recognize that depression might also engender excessive buying (especially among consumers who believe that buying can make them feel better).

DO PEOPLE WHO BUY EXCESSIVELY PERSIST IN SPITE OF ADVERSE CONSEQUENCES?

By definition, excessive buying is an enduring pattern of buying, and as we have shown above, adverse consequences follow from this enduring pattern. The question posed in the heading of this section is thus easily answered by reflecting on the definition of excessive buying and why it is considered a problem. If excessive buyers persist in their extreme buying habits even after they experience harmful repercussions, it seems clear that excessive buying, like other addictive behaviors, is characterized by maladaptive persistence. Indeed, items commonly used to measure excessive buying suggest that excessive buyers frequently fail to factor adverse consequences into their buying choices. "How often have you bought things even though you knew you couldn't afford them?" (from Faber and O'Guinn's [1992] compulsive buying measure) captures a tendency to keep spending at high levels in spite of negative outcomes. Other items that suggest a disregard for adverse consequences include "I have often bought a product that I did not need, while knowing that I have very little money left" (from Valence et al.'s [1988] compulsive buying measure) and "When I see something that really interests me, I buy it without considering the consequences" (from Weun, Jones, and Beatty's [1997] impulsive buying measure). The failure to consider the deleterious consequences of purchasing decisions is clearly central to the experience of persistent buying in the face of harmful consequences.

Qualitative data also reveal a pattern of maladaptive persistence among people who buy excessively. Excessive buyers interviewed by Dittmar (2004b) mentioned an awareness of having a problem, but a perceived inability to stay below the limit on a credit card, to cut up a credit card, or to pass by a store without buying anything. Similarly, O'Guinn and Faber (1989) interviewed an excessive buyer who said she could not stop even though (she believed) her husband and children hated her for her problem. Given the desperate tone of some of these statements, it seems that many excessive buyers do have a goal of reducing their buying, but the temptation to buy overpowers this goal.

FUTURE DIRECTIONS IN THE STUDY OF EXCESSIVE BUYING

One of the substantial benefits of recognizing that excessive buying should be classed among other behavioral addictions is that it may facilitate knowledge transfer between our currently rudimentary understanding of excessive buying and our more mature understanding of some other addictive behaviors. As fur-

ther research identifies similarities between excessive buying and other addictive behaviors, clinicians should have better knowledge to draw upon as they seek to help people who experience excessive buying problems. Toward this end, we suggest that researchers investigating excessive buying would do well to model lines of research that have already produced valuable insights into substance abuse and dependence. In the paragraphs that follow, we highlight just a few constructs from substance use research—several of which draw from Marlatt and Gordon's relapse prevention model (see Larimer, Palmer, & Marlatt, 1999; Marlatt & Donovan, 2005; Marlatt & Gordon, 1985)—that might be profitably applied to research on excessive buying. We stress that the concepts that follow are only a limited sample of the ideas from substance abuse research that could be used to build a better understanding of excessive buying.

Outcome expectancies. Research on alcohol consumption has demonstrated that outcome expectancies—"anticipated effects that an individual expects will occur as a result of alcohol or drug consumption" (Marlatt & Witkiewitz, 2005, p. 10)—are predictive of use (e.g., Brown, 1985; Smith & Goldman, 1994), beverage selection (Corcoran & Segrist, 1993), and consequences related to use (e.g., Blume, Lostutter, Schmaling, & Marlatt, 2003). Goldman, Del Boca, and Darkes (1999) note that since the late 1980s there has been "an explosion of research applying the expectancy concept to alcohol use" (p. 205). An important aspect of expectancies, as pointed out by Walters and Baer (2006), is that "Whether accurate or not, these beliefs are related to drinking" (p. 38). For example, despite the fact that alcohol can impair sexual desire and performance (e.g., Miller & Gold, 1988), individuals may *believe* that alcohol can increase their sexual prowess and behave accordingly.

Measures of alcohol expectancies typically include anticipated physiological, psychological, and social outcomes that serve as potential predictors of use. Some of the alcohol expectancies that have been researched are positive (e.g., those assessed by the Alcohol Expectancy Questionnaire; Brown, Goldman, Inn, & Anderson, 1980), whereas others are negative (such as those assessed by the Negative Alcohol Expectancy Questionnaire; Jones & McMahon, 1994). Some studies, such as those employing the Comprehensive Effects of Alcohol Scale (CEOA; Fromme, Stroot, & Kaplan, 1993) have examined alcohol expectancies that are both positive (e.g., tension reduction: *I would feel calm*) and negative (e.g., self-perception: *I would feel guilty; my problems would seem worse*). The expectancy concept has been applied to other substance behaviors, including expectations and motivations for smoking (e.g., Copeland, Brandon, & Quinn, 1995; Gilbert, Sharpe, Ramanaiah, Detwiler, & Anderson, 2000), as well as expectations about marijuana (Gaher & Simmons, 2007) and cocaine use (Schafer & Brown, 1991).

Recently, the expectancy concept has been used to build knowledge of non-substance addictive behaviors such as eating disorders (see Collins, 2005; Collins & Ricciardelli, 2005) and gambling (e.g., Raylu & Oei, 2004). Nevertheless, to our knowledge, the study of outcome expectancies associated with buying has been relatively neglected. One relevant study (Babin, Darden, & Griffin, 1994) involved the development of a scale to assess what participants expected to gain from their shopping. Results indicated that the measure assessed two factors: hedonic value (e.g., "While shopping I was able to forget my problems.") and utilitarian value (e.g., "I accomplished just what I wanted on this shopping trip."). Although the hedonic factor correlated with compulsive buying, it is important to note that the scale developed in this study assessed participants' experience of a *specific* shopping occasion, not the experience of shopping in general. Furthermore, there are undoubtedly many other outcome expectancies that predict excessive buying. Given the contribution that the expectancies construct has made to the assessment and treatment of other addictive behaviors, further exploration of buying-related outcome expectancies would seem a particularly fruitful avenue for future research.

High-risk situations. In summarizing Marlatt and Gordon's (1985) relapse prevention model, Larimer, Palmer, and Marlatt (1999) describe situations that "pose a threat to the person's sense of control and, consequently, precipitate a relapse crisis" (p. 153). These high-risk situations are typically characterized by any or all of the following components: negative affect, interpersonal conflict, pressure from others to engage in the problem behavior, and positive mood states (Larimer et al., 1999). The identification of high-risk situations, as well as the development of strategies for navigating them, is an important focus of treatment within the relapse prevention model.

How might applying the concept of high-risk situations to excessive buying be useful? At least some (if not all) of the high-risk situations described by Larimer et al. (1999) may precipitate buying binges, but none of these situations (other than negative affect) have been investigated as antecedents of excessive buying. Knowledge about such high-risk situations would be extremely valuable, as clinicians might need to help clients recognize and respond appropriately to situations that are high risk. If a client with an excessive buying problem is to successfully overcome a buying addiction, it seems crucial that he develop a repertoire of strategies for handling such high-risk situations.

Seemingly unimportant decisions. An element of Marlatt and Gordon's (1985) relapse prevention model centers around the decisions an individual makes that place her in a high-risk situation. Some of these decisions are referred to as seemingly unimportant decisions (SUDs; e.g., Wheeler, George, & Stephens, 2005) or apparently irrelevant decisions (AIDs)—"a series of covert decisions or choices, each of them seemingly inconsequential, which in combination set

the person up for situations with overwhelmingly high risk" (Larimer et al., 1999, p. 154). For example, at first glance, Cindy's seemingly unimportant decision to take a different route from work to her home may appear unrelated to her ultimately buying $900 worth of new clothes. But Cindy's choice of a different route actually led Cindy to drive by the mall, the sight of which gave her an overwhelming urge to buy, which ultimately led her to make several unplanned and unneeded purchases at considerable expense.

Individuals with excessive buying problems face a multitude of opportunities for SUDs (e.g., deciding to go to a Wal-Mart supercenter, instead of a grocery store, for a gallon of milk). In future research, it may be insightful to focus on the role of such decisions in triggering or sustaining excessive buying, with the ultimate goal of helping clients identify and appropriately respond to the subtle but powerful precursors to high-risk situations that lead to buying binges. Such research may eventually enable clinicians to help clients prone to excessive buying reconceptualize "impulse purchases" as acts preceded by a series of decisions that only *seemed* unimportant.

Stages of change. Prochaska, DiClemente, and Norcross (1992) proposed that individuals pursuing treatment for addictive behaviors progress through a series of stages: precontemplation, contemplation, preparation, action, and maintenance (also see Prochaska & Norcross, 2007). At the precontemplation stage, an individual has no interest in changing her behavior or is not aware of the potential consequences of the behavior (Dimeff, Baer, Kivlahan, & Marlatt, 1999). The contemplation stage entails the recognition of a problem, but no consistent dedication to change. The preparation stage is characterized by an intention to make changes soon. During the action stage, a client makes changes in his behavior or environment. Finally, a client in the maintenance stage works to sustain positive changes he has previously made and prevent relapse.

The stages of change model has been applied to several addictive behaviors including gambling (Petry, 2005; Shaffer & LaPlante, 2005), marijuana use (Walker, Roffman, Stephens, Berghuis, & Kim, 2006), eating disorders (Collins, 2005), smoking (Schuman et al., 2005), and others (Prochaska et al., 1994). However, we are not aware of any research on stages of change for people pursuing treatment for buying problems. Such research might be extremely useful to therapists, because as Blume (2004) has noted, "by establishing at what state of change a person might be, therapists can determine what might be the best therapeutic strategies to use with the patient" (pp. 89–90). Global measures to assess stages of change have been developed (e.g., University of Rhode Island Change Assessment: Long Form; McConnaughy, Prochaska, & Velicer, 1983) and so have specific measures designed to assess stages of change across a variety of behaviors (see *Cancer Prevention Research Center Measures*), including those of alcohol use (Alcohol Stages of Change: Short Form; Laforge,

Maddock, & Rossi, 1998), smoking (Smoking: Stage of Change, Short Form; DiClemente et al., 1991; Velicer et al., 1995), and health activities (General Health Survey; Nigg et al., 1999). Because understanding a client's motivation level has implications for treatment, creating measures to assess and further our understanding of stages of change in the context of excessive buying makes sense from both a research and treatment standpoint.

Social norm perceptions. The social norms framework has become an important approach for understanding substance use, particularly alcohol use (see Perkins 2003). Substance use research has consistently demonstrated a tendency among adolescents and young adults to believe that others use psychoactive substances more frequently and in greater quantities than oneself (e.g., Perkins, Meilman, Leichliter, Cashin, & Presley, 1999; Segrist, Corcoran, Jordan-Fleming, & Rose, 2007). These perceived norms, even though they are often inaccurate, are predictive of greater consumption (Perkins, Haines, & Rice, 2005). Consequently, social norms interventions seek to correct misperceptions of peer drinking behaviors (Perkins, 2003). Given the extremely high level of exposure people usually have to marketing messages that promote buying, it would not be surprising if many consumers similarly hold an inflated perception of how much buying is actually occurring among their peers. Furthermore, previous research on the association between perceived norms and substance use suggests that perceptions of high peer consumption may lead to greater personal consumption. From a treatment standpoint, an understanding of the role of norm perceptions in sustaining excessive buying may be particularly valuable, because these beliefs may need to be addressed and corrected before a client is ready to make significant changes in her buying.

In summary, a considerable benefit of recognizing that excessive buying is a genuine addictive behavior is that hypotheses that have already proven useful in the study of other addictive behaviors might be fruitfully applied to increasing our understanding, recognition, and treatment of excessive buying. The brief list of potentially applicable concepts that we have reviewed above could provide much-needed direction in the excessive buying literature, as could many other concepts in the addictions literature that researchers of excessive buying have yet to exploit. Ultimately, an extensive analysis of the ways in which excessive buying is similar to and different from other addictive behaviors should be helpful as therapists seek to develop effective and specific treatments for excessive buying.

CONCLUSION

Our primary objective in this chapter has been to demonstrate that excessive buying should be classed with other addictive behaviors. Toward this end, we

have briefly reviewed some of the characteristics of people who buy excessively, considered how addictive behaviors should be defined, and established that excessive buying fits within contemporary definitions of addictive behavior. To illustrate one potential benefit of classifying excessive buying as an addictive behavior, we have emphasized that considerable progress in theory construction and treatment might be made by applying concepts developed in the study of other addictive behaviors to research on excessive buying.

Chapter **4**

Compulsive Buying Disorder

Mamta Sood, MD, and Meera Vaswani, PhD

Buying is a universal, everyday human experience and has been practiced since ancient times. Besides being recognized for its primary function of acquiring an essential item, it is also recognized as a leisure activity. The ability to buy saw the emergence of monetary power as a significant determinant of social status. Excessive buying is sometimes not uncommon, especially in situations such as those of holidays, festivals, marriage, and so on. However, such occasional buying sprees are not recognized as a problem. In some individuals, indulgence in buying behavior is excessive and extreme, so much so that it results in significant psychological, interpersonal, financial, and legal difficulties. Since the beginning of the twentieth century, a clinically significant problem of buying behavior has been recognized. Kraepelin (1915) referred to it as *oniomania*, a term that is derived from the Greek words *onios*—for sale, and *mania*—insanity. Kraepelin based this on Esquirol's concept of monomania (Esquirol, 1838). Bleuler (1924) recognized impulsiveness as its core feature and classified it with pyromania and kleptomania. Subsequently, interest in this disorder remained limited to psychoanalysts and consumer behaviorists. The situation changed in the early 1990s, when independent research workers published three case series and interest in this condition was rekindled. Data on the demographics and phenomenology of 24 compulsive buyers in comparison to normal buyers was reported (Christenson, Faber, & de Zwann, 1994). For the first time, diagnostic criteria for compulsive buying disorder (CBD) were proposed, and data on 20 consecutive diagnosed patients with problematic buying behavior were published (McElroy, Keck, Pope, Smith, & Strakowski, 1994). In

addition to clinical features, overall lifestyle, comorbidity, and other problems in 46 compulsive buyers were studied (Schlosser, Black, Repertinger, & Freet, 1994). Since then, reports of compulsive buying have started to emerge from all parts of the world. "Uncontrolled problematic buying behavior has been referred to as uncontrolled buying, compulsive buying, compulsive shopping, addictive buying, excessive buying, and spendaholism" (Koran, Faber, Aboujaoude, Large, & Serpe, 2006, p. 1806).

Research in this field in the last decade and a half has witnessed progress from descriptions of compulsive buying behavior to the proposal of diagnostic criteria for compulsive buying disorder. Robins and Guze (1970) proposed five phases for establishing the diagnostic reliability and validity of a psychiatric disorder: clinical description, exclusion of other disorders, follow-up, family studies, and laboratory study. The focus of research has been on identifying and delineating these phases so as to establish the reliability and validity of diagnosis of CBD. Based on all this, there is a proposal to include compulsive buying disorder as a diagnostic category in future revisions of classificatory systems. Currently, it is not included in the *Diagnostic and Statistical Manual of Mental Disorders*. fourth edition, text revision (*DSM–IV–TR;* American Psychiatric Association, 2004) or the *International Classification of Diseases*, 10th edition (*ICD-10;* World Health Organization [WHO], 1992) as a separate diagnostic category.

The researchers in the field have conceptualized compulsive buying disorder as being linked to impulse control disorders, obsessive-compulsive spectrum disorders, mood disorders, and substance and behavioral addiction disorders. It is linked to impulse control disorders (Black, 2007), based on similar clinical features like failure to resist an impulse to perform an act of buying, an increasing sense of arousal or tension prior to the act, and an experience of pleasure, gratification, or release of tension at the time of committing the act. It is also considered close to the obsessive-compulsive disorders (Hollander et al., 1996). The repeated idea of buying is conceptualized as an obsession. When this idea is resisted, it results in anxiety. which is relieved by a compulsive act in the form of buying. In fact, some researchers consider it to be a compulsive-impulsive disorder (Dell'Osso, Altamura, Allen, Marazziti, & Hollander, 2006), as it is proposed that impulsive features initiate the behaviors, and the compulsive drive causes the behaviors to persist over time. Its relationship to mood disorders, mainly depression (Lejoyeux, Ades, Tassain, & Solomon, 1996), is suggested by elevated scores on depression rating scales. Also, the concept of behavioral addiction (Krych, 1989) is applied to compulsive buying disorder because buying produces the same sequence of events as those produced by addictive substances. Buying behavior gains increasing significance despite

adverse consequences. Attempts to cut down the behavior result in restlessness. The conceptualized link to one of these disorders has an important role in deciding under which section of classificatory systems compulsive buying disorder will be included. Conversely, attempts to categorize compulsive buying as an illness are seen as a part of a trend to medicalize behavioral problems that may be better understood within the wider social context of the consumption-driven economy (Lee & Mysyk, 2004).

This chapter aims to present an overview of compulsive buying disorder based on research carried out in the last 15 years, in epidemiology, etiology, clinical features, diagnosis, comorbidity, and treatment.

EPIDEMIOLOGY

Prevalence

Faber and O'Guinn (1992) estimated the prevalence of CBD to be 2–8 percent in the adult general population by administering Compulsive Buying Scale (CBS) to 292 respondents in Illinois. Recently, in a nationwide random telephone survey in the United States, (using a large general population sample), CBS embedded in a computer assisted telephone interview was administered to 2,513 adult respondents. The point prevalence was calculated by using scores on CBS as two standard deviations below the mean and was found to be 5.8 percent. Using a stricter criterion, (three standard deviations below the mean), 1.4 percent of individuals were reported to have this disorder (Koran et al., 2006).

A hospital-based study examined the frequency of co-occurring impulse control disorders including CBD in 204 consecutively admitted psychiatric inpatients. Using the Minnesota Impulsive Disorders Interview, it was found that 30.9 percent had at least one current impulse control disorder. A total of 9.3 percent of patients with impulse control disorders had CBD, which was also the commonest diagnosis (Grant, Levine, Kim, & Potenza, 2005).

An interesting study (Lejoyeux, Mathieu, Embouazza, Huet, & Lequen, 2007) on women consumers in a famous department store found that 32.5 percent exhibited compulsive buying. Further analysis revealed that in comparison to controls, they considered purchases as opportunities not to be missed, used purchased items less often, made purchases to impress others, considered purchases as personally gratifying, and stayed connected to online shopping sites longer.

Gender

Compulsive buying is seen mostly in women and it is ascribed to the appeal of risky and exciting situations by some of them (Bleuler, 1924; Kraepelin,

1915). In the clinical case series referred to above, 80–94 percent of compulsive buyers are reported to be women (Christenson et al., 1994; McElroy et al., 1994; Schlosser et al., 1994). However, the nationwide community survey (Koran et al., 2006) found that point prevalence is almost equal in both sexes; 6.0 percent for women and 5.5 percent for men, thereby refuting the notion that it is more common in women. The difference in clinical and community settings is probably due to the willingness of women to seek treatment. It is also possible that the recruitment strategies, for example, daytime television ads or contact with self-help groups, might have resulted in a larger number of women in the clinical cases.

Age of Onset

The onset of compulsive buying is reported to be in the late teens or early twenties, which correlates with the time when the individual is establishing separation from the nuclear family. Also, this is the age when a person can first establish credit. By the time the behavior is recognized as problematic, individuals are in their thirties (Black, 2007a). Compulsive buying in adolescents is likely to be associated with several risky behaviors like cigarette smoking, alcohol use, drug use, and early sex (Roberts & Tanner, 2000), as seen in a survey conducted among 111 adolescents between the ages of 12 and 19 years.

ETIOLOGY

There is no single cause of compulsive buying disorder. However, psychological, sociocultural, neurobiological, and genetic factors may contribute toward its causation.

Psychological and Sociocultural Perspective

From a psychodynamic perspective, compulsive buying forms a specific complex with common developmental precursors of pathological narcissism (Kruger, 1988). Positive associations emerge between narcissism, materialism, and compulsive buying in young graduates. Personal values and impulse control are important correlates of addictive buying. Relatively narcissistic persons are poor self-regulators and may be at risk of developing a variety of addictive behaviors (Rose, 2007).

Dittmar (2005) found endorsement of materialistic values to be the strongest predictor of individuals' compulsive buying; such endorsement significantly mediated the observed age differences. In-depth interviews with persons

exhibiting compulsive buying suggest that the behavior serves a variety of functions for them; it improves their mood and increases their ability to match their perceptions of socially desirable appearances. This behavior is located in the context of postmodern fragmentation, where personal identity is manifested in a reliance on emotionally charged experiences (Elliott, 1994).

Black (2007) hypothesized that sociocultural mechanisms are necessary for the development of CBD, as evidenced by the fact that the disorder largely occurs in developed countries. A market-based economy, the availability of a wide variety of goods, a disposable income, and significant leisure time are necessary for the development of compulsive buying.

Neurobiological Perspective

Disturbed neurotransmission, specifically of the serotonergic, dopaminergic, and opioid systems has been hypothesized to have a role in the causation of CBD. This causation is presumed because the drugs used in the treatment of CBD act on these neurotransmitter systems. However, there are no studies that have directly examined these hypotheses. The serotonergic system is implicated because selective serotonin reuptake inhibitors (SSRIs) have been used in its treatment based on its closeness to obsessive-compulsive disorder (Ninan et al., 2000). In behavioral addictions like CBD and pathological gambling, the changes in dopaminergic pathways have been implicated. Reward-seeking such as buying in CBD, triggers the release of dopamine and produces feelings of pleasure (Grant, 2003).

Limited research on genetics suggests that compulsive buying may run in families. McElroy et al. (1994) studied family history data on 18 compulsive buyers; 17 had one or more first-degree relatives with a mood disorder, 11 had alcohol or substance abuse, three had an anxiety disorder and three exhibited compulsive buying. In a larger study (Black, Repertinger, Gaffney, & Gabel, 1998), 137 first-degree relatives of 31 compulsive buyers were interviewed; 9.5 percent of them had CBD. In comparison with controls, first-degree relatives of compulsive buyers reported significantly more depression, alcoholism, and drug abuse. However, relatively small sample sizes remain an important limitation of these studies.

Two genetic studies have also been reported. Significant correlation between a polymorphism in the promoter region of the D1 receptor gene and the association of Tourette's disorder with compulsive buying disorder have been reported. However, no association was reported with the serotonin transporter gene promoter polymorphisms (Comings et al., 1997). In another study, 21 patients diagnosed with compulsive buying were compared with 38 normal

controls with regard to two DNA sequence polymorphisms in the gene that encodes the serotonin transport (5-HTT); no significant difference was seen (Devor, Magee, Dill-Devor, Gabel, & Black, 1999).

CLINICAL FEATURES

The onset of compulsive buying disorder is mostly in the teens. By the time the behavior is recognized as problematic, individuals are in their twenties or thirties (see Box 1).

BOX 1

Clinical Features

- Onset is in teens.
- Seen more commonly in women.
- Preoccupation with thoughts about shopping.
- Rising levels of anxiety and tension followed by act of shopping, which leads to tension relief.
- Clothing, shoes, jewelry, makeup, and compact discs are usual items purchased.
- Leads to significant psychological, interpersonal, financial, and legal difficulties.
- Course is either chronic or recurrent.

Compulsive buyers are preoccupied with repetitive and intrusive thoughts like shopping and spending, which they try to resist, usually without much success (Bernik, Akerman, Amaral, & Braun, 1996; Christenson et al., 1994). Compulsive buyers are supposed to have high urge combined with low control (Nataraajan & Goff, 1991). Typically they engage in compulsive buying behaviors by spending many hours in a week buying, year round or in binges.

There is an increasing level of anxiety and tension. The actual shopping experience is intense. The act is completed with the purchase, which leads to tension relief. Attempts to resist urges to buy are present in the majority of subjects with compulsive buying disorder, but invariably they are unsuccessful, as is illustrated by the fact that, most often, 1–5 hours pass between the urge to buy and the purchase (Christenson et al., 1994; Schlosser et al., 1994).

Black (2007) described four phases of compulsive buying disorder: anticipation, preparation, shopping, and spending. In the first phase, a person with compulsive buying disorder is preoccupied with the thought of a specific item

and the act of shopping. Then the preparation for shopping and spending starts. This involves deciding on the time and venue for shopping, the outfit to be worn, and so on. This phase is followed by the actual shopping experience. Negative emotions (Miltenberger et al., 2003) such as anger, anxiety, boredom, and self-critical thoughts are the most common antecedents to shopping binges in individuals, while euphoria or relief from the negative emotions is the most common consequence.

Shopping is generally done alone; it may be in upscale department stores, consignment shops, a garage sales. Internet and catalog shopping are also used. Generally, clothing, shoes, jewelry, makeup, and compact discs are purchased. These items seem to address personal and social identity needs. Shopping provides a sense of recognition and acceptance for people with low self-esteem. Once a purchase is made, its outcome varies; the item may be returned or sold, given away, or not even removed from the package (Schlosser et al., 1994).

Income does not seem to be a factor in developing CBD. A person with low income preoccupied with shopping and spending will tend to shop at a smaller store. However, the presence of CBD may result in interpersonal problems in both groups (Black, 2007).

Adverse consequences include guilt or remorse, excessive debt, bankruptcy, family conflict, divorce, illegal activities, such as writing bad checks and embezzlement, and even suicide attempts.

Compulsive buying occurs along a spectrum of severity. Greater severity is seen in low the income group; they tend to purchase nonsale items, spend a lower percentage of income on sale items (Black, Monahan, Schlosser, & Repertinger, 2001), and give maladaptive responses regarding their consumer behavior (Koran et al., 2006).

In a transnational study, treatment-seeking female compulsive buyers were compared (38 Germans from Bavaria and 39 Americans from North Dakota) by using CBS and the Yale-Brown Obsessive Compulsive Scale-Shopping Version (YBOCS-SV). However, with regard to age and scores on the above scales, the researchers did not find statistically significant differences (Mueller et al., 2007).

Although, there are no long-term follow-up studies, the disorder is either chronic or recurrent (Schlosser et al., 1994; Christenson et al., 1994). In one study, treatment with citalopram in CBD was followed up for a year, which resulted in a good response in 71 percent of subjects. However, an acute response predicted a greater likelihood of continued remission (Aboujaoude, Gamel, & Koran, 2003). This study highlights the impact of treatment on the course of CBD in terms of initial and maintained improvement.

DIAGNOSIS AND ASSESSMENT

Diagnosis

While making a diagnosis, questions regarding individuals' attitudes toward shopping and their specific shopping behaviors and patterns are generally asked. Preoccupation with buying, time spent in desires, urges, fantasies, or behaviors related to buying should be looked into. To judge the dysfunction, feelings of distress and guilt, and financial, legal or interpersonal problems need to be looked into. A history of past psychiatric and medical illness, surgical procedures, and past treatment needs to be incorporated. However, bipolar disorder should be ruled out as a cause of excessive buying.

The diagnostic criteria for CBD proposed by McElroy et al (1994) have been used for research (see Box 2). These include (1) uncontrollable problematic buying behavior characterized as being frequently preoccupied with buying or subject to irresistible, intrusive, and/or senseless impulses to buy; (2) shopping for periods longer than intended; (3) experiencing adverse consequences such as markedly distressing, time consuming, and/or resulting in family, social, vocational, and/or financial difficulties; and (4) not occurring only in the context of hypomanic or manic symptoms.

BOX 2

Diagnostic Criteria for Compulsive Buying Disorder
(McElroy et al., 1994)

1. Uncontrollable problematic buying behavior
2. Shopping for periods longer than intended
3. Experiencing adverse consequences
4. Not occurring in the context of hypomanic or manic symptoms

Assessment Instruments

1. Compulsive Buying Scale
2. Yale Brown Obsessive-Compulsive Scale—Shopping Version
3. Minnesota Impulsive Disorders Interview

Differential Diagnosis

CBD needs to be distinguished from normal buying behavior. Frequent shopping in itself does not warrant a diagnosis of compulsive buying disorder. Normal buying can also sometimes be compulsive and episodic, specifi-

cally around special holidays or birthdays. The distinction is not made on the grounds of the amount of money spent or the income level, but on the extent of the preoccupation with buying behavior, the level of personal distress, and the presence of adverse consequences. Typically, excessive buying in a manic patient arises out of euphoric and cheerful mood, grandiosity, and unrealistic plans, and the duration of the shopping invariably corresponds to the duration of the manic episode. Although a preoccupation with buying behavior is present most of the time in compulsive buying disorder, it lacks the periodicity seen in bipolar disorder.

Assessment Instruments

Several rating instruments have been used for identifying as well as for rating the severity of CBD (see Box 2).

The Compulsive Behavior Scale (CBS) consists of seven items representing specific behaviors, motivations, and feelings associated with compulsive buying disorder. The seven scale items assess the need to spend money, awareness that spending behavior is aberrant, loss of control, and buying things to improve mood and financial problems (Faber & O'Guinn, 1989). Studies have established that subjects meeting the two standard deviation criterion on this scale always meet the clinical diagnostic criteria (Black et al., 1998; Christensen et al., 1994).

The Yale Brown Obsessive-Compulsive Scale has been modified to form the Yale Brown Obsessive-Compulsive Scale-Shopping Version (YBOCS-SV). The 10-item scale rates time spent, interference, distress, resistance, degree of control for cognitions, and behaviors typical of compulsive buying disorder, yielding scores ranging from 0 to 40 (Monahan, Black, & Gabel, 1995).

The Minnesota Impulsive Disorders Interview is a semistructured interview to assess the presence of compulsive buying disorder, kleptomania, trichotillomania, intermittent explosive disorder, compulsive sexual behavior, pathological gambling, and compulsive exercising. However, an 82-item module has been developed specifically for those screening positive for compulsive buying disorder (Christenson et al., 1994).

COMORBIDITY

The presence of comorbid disorders has far-ranging implications for the understanding of CBD. The initial presentation may be changed or may be more severe. There may be shared underlying etiological factors, treatment may need modification, and the future course may be altered. High rates of psychi-

atric comorbidity have been reported in persons having CBD. Various studies have reported higher lifetime prevalence of mood disorders, obsessive-compulsive disorders, anxiety disorders, alcohol abuse, eating disorders, and impulse control disorders on Axis I, and obsessive-compulsive, borderline, avoidant, antisocial, and narcissistic personality disorders on Axis II (Black, 2007).

In Christenson's case series, compulsive buyers had a higher lifetime prevalence of anxiety disorders, substance use disorders, and eating disorders as compared to controls. It was found that buying behavior resembled obsessive compulsive disorder in 66.7 percent of subjects, whereas impulse control disorder was seen in 95.8 percent. In McElroy's case series, 95 percent of the compulsive buyers had lifetime diagnoses of major mood disorders, 80 percent had anxiety disorders, 40 percent had impulse control disorders, and 35 percent had eating disorders. In Schlosser's case series, more than two-thirds met lifetime criteria for Axis I psychiatric disorder, anxiety disorders, substance abuse, and mood disorders were common. Nearly 60 percent met the criteria for personality disorder on Axis II, most commonly the obsessive-compulsive, borderline, and avoidant types. Lejoyeux, Haberman, Solomon, and Ades (1999) studied the effect of the concomitant presence of compulsive buying disorder in depressed subjects. Their results indicated that these patients had significantly more recurrent depression, bipolar disorder, kleptomania, bulimia, suicide attempts, and benzodiazepine abuse as compared to control subjects with depression only.

It is reported (Mueller et al., 2007) that many compulsive buyers also suffer from compulsive hoarding. Hoarding compulsive buyers report severe buying symptoms and obsessive-compulsive symptoms with a higher psychiatric comorbidity, especially with regard to affective, anxiety, and eating disorders. The prevalence of compulsive buying among patients presenting with obsessive-compulsive disorder was 23 percent. Subjects having both disorders also showed more depression and drank more alcohol (Lejoyeux, Bailly, Moula, Loi, & Ades, 2005).

In the transnational study comparing German and American female compulsive buyers, nearly all participants met the criteria for at least one lifetime Axis I disorder. However, the German compulsive buyers showed higher rates of affective disorder, anxiety disorder, and somatoform disorder. In addition, the German compulsive buyers were more likely to have more than one Axis I disorder (Mueller et al., 2007).

TREATMENT

There are no guidelines for treatment; multiple modalities of therapies have been tried in clinical settings. Pharmacotherapy, psychotherapies, and some other treatments are also available (see Box 3).

BOX 3

Treatment

- No treatment guidelines
- Selective serotonin reuptake inhibitors and partial opiate antagonists
- Cognitive-behavioral techniques of cue exposure and response prevention
- Group cognitive-behavioral intervention
- Self-help books
- Debtors Anonymous
- Marital and financial counseling

Pharmacotherapy

Selective serotonin reuptake inhibitors (SSRIs) and partial opiate antagonists have been tried in the treatment of CBD on the basis of its conceptualized closeness to obsessive-compulsive spectrum disorder, mood disorders, and addictive disorders.

The results of open label studies using SSRIs are promising. In McElroy's cases, almost 50 percent experienced full or partial remission to SSRIs or in combination with a mood stabilizer. In most cases, the observation period was limited to a few weeks or months. Treatment with fluvoxamine showed benefit, suggesting that improvement is independent of the treatment of mood symptoms in 9 out of 10 nondepressed subjects with CBD (Black, Monahan, & Gabel, 1997). In an open-label trial with citalopram, it was reported that 17/24 subjects improved in specific measures of buying behavior and global functioning (Koran, Chuang, Bullock, & Smith, 2003). However, treatment with escitalopram showed little effect in an identically designed trial carried out by the same group.

Two randomized-controlled trials using fluvoxamine have been conducted. The results have not been promising. A 12-week trial with 37 subjects found no difference between fluvoxamine and placebo in an intent-to-treat analysis (Ninan et al., 2000). A nine-week trial of 23 nondepressed subjects with compulsive buying disorder reported 50 percent of subjects in the fluvoxamine group and 64 percent in the placebo group being rated as improved (Black, Gabel, Hansen, & Schlosser, 2000). However, in these studies, subjects kept a log of their shopping. Keeping logs is a therapeutic intervention in itself, which may have led to these findings (Dell'Osso et al., 2006). Grant (2003) described cases in which persons with CBD improved with naltrexone, suggesting that opiate antagonists might play a role in the treatment.

Psychotherapy

Psychoanalytic treatment based on early experiences has been used (Kruger, 1988). Recently, Cognitive-behavioral models using techniques of cue exposure and response prevention have been found to be effective in treatment (Bernik et al., 1996; Lejoyeux et al., 1996). The efficacy of a group cognitive-behavioral intervention designed for the treatment of 28 subjects with compulsive buying was compared with 11 subjects on waiting list control. At the end of treatment, the results indicated significant advantages for cognitive-behavioral therapy over the waiting list in terms of reductions in the number of compulsive buying episodes and time spent in buying, as well as in scores on YBOCS-SV and the CBS. Improvement was well maintained at six-month follow-up (Mitchell, Burgard, Faber, Crosby, & de Zwaan, 2006).

Other Therapies

Self-help books are available and have been reported to be beneficial. Debtors Anonymous is patterned after Alcoholics Anonymous. It is a voluntary group that provides mutual support and encouragement for those with substantial debts. Simplicity circles are available in some U.S. cities; voluntary groups encourage people to adopt a simple lifestyle. Marital counseling may be helpful in cases where interpersonal relations are strained. Persons with financial difficulties may benefit from financial counseling (Black, 2007).

CONCLUSION

In the past decade, the focus of research in the field of compulsive buying disorder has been on identifying and delineating its characteristic features. This has resulted in a better understanding of its epidemiology, phenomenology, family history, and treatment. The disorder is not uncommon and is associated with important comorbid psychiatric disorders. Proposals to include this as a diagnostic subcategory in *DSM–V* are the subject of debate. Various researchers have argued for its inclusion under impulse control disorders, substance use disorders, mood disorders, and obsessive compulsive disorders in *DSM–V*. At present, opinion favors its inclusion under impulse control disorders. Its inclusion in classificatory systems will help in routine screening for compulsive buying disorder by mental health professionals and in community-based incidence prevalence studies. It will also help in the identification of vulnerability, precipitating and perpetuating factors, and in the development of effective psychosocial and pharmacological therapies.

At present, there are conflicting reports regarding gender-related differences. Different underlying diatheses have been proposed in the etiology of compulsive buying disorder. Neurobiological studies employing brain imaging and other techniques need to be conducted to clarify these issues. Cognitive-behavioral strategies and medications have been used for treatment with partial success.

Future research needs to focus on establishing the reliability and validity of diagnostic criteria. So, there is a need for large-scale community studies in order to understand the epidemiology. Studies need to be planned for identifying efficacious treatments, type of treatment, short- and long-term outcome, and duration of treatment. Long-term follow-up studies are needed for charting the course of the disorder, identifying various prognostic factors, and identifying their relationship to other psychiatric disorders.

Chapter **5**

Association with Criminality of Habit and Impulse-Control Disorders

Ian H. Treasaden, MB, LRCP, MRCS, FRCPsych, LLM, and
Basant K. Puri, MA, PhD, MB, MRCPsych, MMath

Impulse-control disorders are disorders in which a person acts on an impulse that is potentially harmful and which he or she fails to resist. The impulses are usually perceived as pleasurable (egosyntonic). There is an increasing sense of wishing to commit the act with a sense of pleasure occurring once the act has been committed. These disorders have also been conceptualized as non–substance-related addictions. They do not represent personality disorders. They are described in the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (fourth edition, text revision, 2000; *DSM–IV–TR*) as impulse-control disorders, and in the World Health Organization's *International Classification of Diseases and Related Health Problems* (1992; *ICD-10*) as habit and impulse disorders.

In *DSM–IV–TR*, their essential features include the following:

- The failure to resist an impulse, drive, or temptation to perform an act that is harmful to the person or to others.
- For most disorders, the individual feels an increasing sense of tension or arousal before committing the act and then experiences pleasure, gratification, or relief at the time of committing the act.
- Following the act there may or may not be regret, self-reproach, or guilt.

Included are the conditions of pathological gambling, pyromania, kleptomania, and tricotillomania.

ICD-10 (World Health Organization, 1992) has a similar definition for this group of disorders, which it terms "Habit and Impulse Disorders," but also includes intermittent explosive (behavior) disorder. *ICD-10* points out that these disorders have no clear rational motivation.

Pathological gambling, pyromania, and intermittent explosive (behavior) disorder are more common in men, while kleptomania and tricotillomania are more common in women. There is an absence of epidemiological studies of the prevalence of these disorders, but rates among psychiatric inpatients may be higher than in the general population. Using the Minnesota Impulsive Disorders Interview (Christenson et al., 1994), Grant, Levine, Kim, and Potenza (2005) found the following rates, mainly comorbid with depression, among inpatients:

- Kleptomania 8 percent
- Pathological gambling 7 percent
- Intermittent explosive (behavior) disorder 6.4 percent
- Tricotillomania 3.4 percent.

Overall, such impulse control disorders are probably underdiagnosed.

Other disorders, such as pathological buying (oniomania or shopaholism), characterized by buying items that are not needed and often storing them unopened, and workaholism, have also been considered to be impulse-control disorders, but are not classified as such in *DSM–IV–TR* or *ICD-10*. Such behaviors may be motivated by a need for compensation or as a substitute for something missing in life or as a depressive equivalent.

Crime is law-breaking behavior. Impulse-control disorders may lead to offending either directly, for instance, in pyromania, or indirectly, for instance, for financial gain in a pathological gambler. Individuals who commit crimes due to such a disorder have, however, usually been deemed legally culpable for their actions, even though their propensity is psychiatrically considered to be irresistible. It has been argued, however, that this may be a legal injustice, as such individuals clinically apparently have little or no control over their actions.

The interface between impulse-control disorders and offending raises philosophical questions, including questions about the nature of free will and whether all behaviors are determined by the effects of genes, environment, and background. Are those with impulse-control disorders less responsible for their behavior and should they therefore be punished less than those of normal responsibility? Even if impulse-control disorders have a biological basis, in clinical practice the aim is, however, to encourage the sufferer to take responsibility for his or her actions.

HISTORY

During the eighteenth century, the concept of "monomania with propensity" developed, referring to the fact that apparently insane, incomprehensible

actions did not always appear to be the result of delusional thinking. This and subsequent historical developments have been discussed by Gibbens and Prins (1962), who cite the following historical landmarks:

- Philippe Pinel (1745–1826), in the eighteenth century, refer to "mania without delirium" as being a disease of the willpower.
- Esquirol referred in 1885 to instinctive monomanias, including homicide, fire-setting and alcoholism, that is, respectively, homicidal monomania, pyromania, and dypsomania, where the individual acts "without passion or motive but only under involuntary instinctive impulse."
- Referring to some cases of theft and homicide, Rush in 1810 described them as an illness of the moral willpower and equated this illness with the involuntary movements of convulsions.
- Mathey coined the term klepemnia (theft) to add to the list of other manias including dipsomania and pyromania.

As noted by Topp (1973), it was the Frenchman Marc in 1833 who first used the term kleptomania when describing a number of wealthy individuals who carried out bizarre, worthless thefts in which they had little intrinsic interest and to which they confessed spontaneously when challenged.

Subsequently it has been considered that instinctive monomanias such as kleptomania are very rare and, indeed, it has been questioned whether they, in fact, exist. Terms such as pyromania and kleptomania have indeed tended to be increasingly discarded. Neustatter (1953) doubted whether kleptomania existed as an entity, but, if it did, he suggested that it was part of a psychopathic personality that gives way to impulses.

Differentiation from Obsessive-Compulsive Disorder

An important differentiation in this area is between compulsions and impulses. Compulsions, as seen in obsessive-compulsive disorder, are characterized by nonsituational preoccupation with subjective compulsion despite conscious resistance, such preoccupations being thoughts (ruminations or obsessions) or acts (rituals or compulsions). Where there is poor impulse control, impulses are poorly resisted, and this is much more common than compulsions. In the case of obsessive-compulsive disorder, sufferers in general do not act on their ruminations, unlike those with poor impulse control. The key difference between impulse-control disorders and obsessive-compulsive disorder is that while both may lead to relief of anxiety and tension, in obsessive-compulsive disorder the thought of carrying out the act must not in itself be pleasurable, that is the thought must be egodystonic.

PATHOLOGICAL GAMBLING

This is defined in *ICD-10* as persistently repeated gambling that continues and often increases despite social consequences. Gambling involves risking something of value, not necessarily money, in a game or other uncertain event, with the aim of achieving greater value. There is a range of gambling behaviors from the culturally normal to hazardous, professional, problematic, and pathological gambling. In contrast to professional gamblers, who may carefully plan their gambling and base it on information to decrease the risk, pathological gamblers will myopically gamble despite repeated and heavy losses resulting in adverse family and social consequences and financial ruin, to which they appear hyposensitive. Four phases may be distinguished: winning, losing, desperation, and eventual giving up. Problems do not arise from the gambling itself but from the consequences, as seen in alcoholism. Indeed, pathological gambling shows features characteristic of an addiction, with loss of control, extremes of emotions reflecting autonomic nervous system changes, and withdrawal phenomena when not gambling.

DSM–IV–TR defines the essential feature of pathological gambling as a chronic and progressive failure to resist impulses to gamble, with behavior leading to much damage to personal and family life. Evidence suggests this to be a valid and reliable diagnosis (Stinchfield, 2003). Efforts to control, resist, or stop gambling generally fail, and the behavior has been equated to an addiction, with withdrawal symptoms of irritability and restlessness if the person is unable to gamble and an escalation in the size and frequency of bets or other stakes to achieve a desired level of excitement. Such individuals will tend to respond to repeated losses by gambling further to "chase" their losses, in spite of increasing debts, marital breakdown, and law involvement. They anticipate losses as shown in fMRI studies (reduced activity in the ventromedial prefrontal cortex), even while their appetite for gambling and their impulsivity increase, and they will continue gambling until they have lost their available resources. Psychodynamically, they appear unconsciously to aim to lose their money. They tend to focus on their winnings, disavow or deny their losses, lack the courage to own up to losses, and gamble more to break even. This is a pattern also seen in stock market "rogue" traders.

Pathological gambling may also lead to disturbances in eating and sleeping and in sexual relationships, as well as to difficulties in sustaining employment. Lying to and relying financially on friends is also characteristic. Some gamblers steal to finance their habit, and pathological gambling may only come to light following a court case regarding an acquisitive offense such as theft, fraud, or embezzlement.

Some individuals present following an overdose or self-harm, which occurs in 10 percent of pathological gamblers, or with depression. Suicide occurs in 2 percent of attendants of Gamblers Anonymous. Legg-England and Gotestam (1991) and Raylu and Oei (2002) have reviewed pathological gambling in detail.

Epidemiology

Gambling itself is common, with estimates of prevalence around 40 percent of the British population and 60 percent of the United States population (Moran, 1983). Even these figures may now be underestimates, given the current availability of national television and other lotteries. Wardle et al. (2007) found the prevalence of gambling in the United Kingdom (UK) to be 68 percent, but 48 percent when the UK National Lottery was excluded. It is said to be more common among Chinese and less common among Scandinavians. It is more common in men, those with a past history of psychiatric disorder, and criminals. Problem gamblers cause themselves or others to suffer. It is of course possible to lose control and bankrupt oneself through gambling in just one day. Pathological gambling is associated with tolerance and withdrawal phenomena and has been found to have a prevalence of 0.25 percent in Australia (Dickerson, 1988) and 0.77 percent in the United States. Shaffer and Korn (2002) reviewed 120 studies and suggested a lifetime rate of 1.6 percent, a figure not dissimilar to that for schizophrenia. Wardle et al. (2007) in the UK estimated that 0.5–0.6 percent of the population were problem gamblers. The Royal College of Psychiatrists in the UK in 1977 described around 10 percent of prisoners as suffering from pathological gambling.

Pathological gambling is certainly more obvious but probably also more common among those, especially men, who indulge in horse and dog racing, in which losses soon become apparent. Women pathological gamblers, on the other hand, have been reported to be more likely to make use of specialized helplines (Potenza, et al., 2001). In the UK, it is said that women prefer bingo, which may lead to less pathological gambling and in which losses tend to be smaller.

Etiology

The predominant motivation for pathological gambling is the sense of thrill and pleasure at the risk taking, as reflected in changes of heart rate demonstrated during gambling. Winning produces euphoria, said to be comparable to the effects of amphetamines, and helps individuals switch from negative inter-

nal mood states, including despondency and loneliness. Dostoyevsky, in his autobiographical novel *The Gambler*, described the reward of a sense of power obtained from gambling. Freud (1928), commenting on this, considered that Dostoyevsky did his best writing after a big loss from gambling as he was then freed from unconscious guilt feelings concerning patricidal urges that inhibited his creativity. Gambling has also been described as serving to gratify oedipal wishes, for example, wishing to defeat a tyrannical father or woo a mother (Frosch, Frosch, & Frosch, 1985; Greenson, 1947). Moran (1983) cited social pressures, early exposure to gambling, and a father who gambled or drank alcohol as etiological factors among male gamblers, while having an alcoholic spouse who was often absent was characteristic more of women who gamble. Gambling increases with the number of gamblers in one's social network, being initially a social activity, but when pathological, it is usually undertaken alone.

Learning theory has suggested that the pattern of intermittent (variable ratio) reinforcement, the most potent schedule for conditioning, particularly applies to gambling, where repeated losses with frequent near misses are combined with occasional random wins with immediate payouts. The prospect of small but immediate rewards is preferred to higher but delayed rewards. Evidence of psychological dependence may become manifest by the appearance of what can be considered withdrawal symptoms and craving following the stopping of such activity.

Biological factors may also be important (Sharpe, 2002). The orbitofrontal cortex and anterior cingulate gyrus are involved in reward mechanisms. Potenza et al. (2003) undertook an fMRI study of pathological gamblers that showed, compared with controls, decreased activation of the orbitofrontal cortex, basal ganglia, and thalamus, which have been linked to impulsivity and disinhibition.

Pathological gambling has been suggested to be associated with low central serotonin levels, as seen in other impulse-control disorders, and low central dopamine activity, as seen in other addiction disorders. Serotonin is involved in mood and impulse control and dopamine in reward, pleasure, and motivation. Of note is the increasingly recognized phenomenon of individuals with Parkinson's disease, who have low levels of the neurotransmitter dopamine, presenting for treatment of gambling after having been treated with pro-dopaminergic agents such as L-dopa (Driver-Dunkley, Samanta, & Stacy, 2008). Norepinephrine (noradrenalin), which is involved in arousal and excitement, and opioids, involved in urges and pleasure, may also be important.

Comorbidity

While pathological gambling often arises in the absence of other psychiatric disorders, personality disorder, especially antisocial, narcissistic, and borderline

types, and depression may also be present. The presence of personality disorder will, however, only explain part of the excess of impulsivity. Hypomanic or manic episodes of bipolar disorder, which may be associated with general overspending and grandiose beliefs about one's wealth and ability to make money, including the ability to counter losses, may also lead to excessive gambling. Problem gambling is associated with attention deficit hyperactivity disorder (ADHD), delinquency, and recidivist offenders, and is especially high among young offenders.

Risk Factors

These include being male, over 45 years of age, cigarette smoking, alcohol abuse, low income, having debts, being a foreign national, depressive disorder, flat affect, having the metabolic syndrome, and sleep difficulties in females. A history of previous treatment for gambling is self-evidently an important risk factor.

Assessment

This should include eliciting when gambling started and when it became regular, who introduced the individual to gambling or encouraged the individual to gamble, the circle of gambling friends, and the history of escalation in patterns of gambling. Is gambling increased when the individual is despondent and/or by alcohol consumption?

The onset and presence of symptoms of pathological gambling should be noted, for example, inability to stop despite debts, withdrawal symptoms such as restlessness and irritability when not gambling, chasing losses, and raising stakes for the thrill.

The motivation to change should also be assessed. Stages of change include the following:

- Precontemplation, when the need to change is recognized
- Contemplation, when the problem is acknowledged and the individual is willing to change
- Action taken to change
- Maintenance to sustain control of or abstinence from gambling.

Screening instruments such as the South Oaks Gambling Screen (SOGS; Lesieur & Blume, 1987) can be useful, especially in screening populations at risk (a score of 3 to 5 out of 10 indicates problem gambling, while a score of over 5 indicates pathological gambling). The SOGS may produce excessive false-positives compared with the National Opinion Research Center DSM Screen

for Gambling Problems (NODS; Gerstein et al. 1999) which was developed as a population-based telephone screening tool to identify gambling problems according to *DSM–IV* criteria (Hodgins, 2004). Stinchfield (2002) found that the SOGS demonstrated good to excellent classification accuracy in his large gambling treatment sample, but had poorer accuracy in the general population sample with a 50 percent false positive rate; the SOGS overestimated the number of pathological gamblers in the general population, compared with *DSM-IV* diagnostic criteria.

A further tool is the Canadian Problem Gambling Severity Index (Ferris & Wynne, 2001), which contains 9 items of the 30-item Canadian Problem Gambling Inventory (CPGI).

Management

Health promotion to populations at risk as identified by screening to counter excessive gambling before problems develop is, of course, ideal. However, pathological gambling may not always follow a chronic and persisting course. Slutske (2006) reported that among individuals with a lifetime history of pathological gambling, 36 to 39 percent did not experience any gambling-related problems in the past year, even though only 7 to 12 percent had ever sought either formal treatment or attended meetings of Gamblers Anonymous. About one-third of the individuals with pathological gambling disorder in her study of two nationally representative U.S. samples were characterized by natural recovery.

Comorbid psychiatric disorders should be excluded or treated, for example, depression. As with other addictive behaviors, selective serotonin reuptake inhibitor (SSRI) antidepressants at high doses have been recommended (Grant & Kim, 2002), and the opioid antagonist naltrexone has been recommended. The selective norepinephric (noradrenergic) reuptake inhibitor (SNRI) venlafaxine, the 5-HT1A partial agonist buspirone, the stimulant cognitive enhancer modafinil, and the psychostimulant methylphenidate have all been used.

Cognitive-behavioral therapy, which concentrates on reducing the preoccupation with gambling and can involve motivational interviewing and risk/harm reduction strategies, has been successfully used and has also been combined with a 12-step group program (Petry & Roll, 2001). There is no real evidence for the efficacy of psychodynamic psychotherapy or aversive behavioral therapy in this disorder. Dickerson (1989) described 22 uncontrolled studies offering a variety of management approaches, including most forms of psychotherapy. Support and counseling for the family, which can include brief focal marital counseling. may also be required.

Help is often only sought as a result of the consequences of gambling, such as debt, deteriorating marital and other relationships, and law involvement, rather than as a result of a primary desire to stop gambling itself. Most gamblers cannot contemplate complete abstinence, though some may consider as a reasonable goal stopping gambling for a number of months with a view to continuing controlled gambling thereafter.

One approach is for the family income to be paid into an account over which only the spouse has control (Moran, 1983). Gamblers Anonymous adopts the approach used by Alcoholics Anonymous and may be more helpful than standard traditional psychiatric approaches. For relatives, Gam-Anon is available for mutual support, akin to Al-Anon for relatives of those suffering from alcoholism. Local citizens advice bureaus and money advisory services may assist with resulting financial difficulties.

Few pathological gamblers will consider a goal of total abstinence. In spite of management approaches, the prognosis is generally considered poor, although 10 percent stop spontaneously and progression and chronicity are not inevitable. Relapse rates after treatment vary from two-thirds to 70 percent. Duration of the disorder and neurocognitive measures of disinhibition and decision-making are powerful predictors of relapse in pathological gambling (Goudriaan, et al., 2008).

Clearly, as the ease of availability of gambling increases, so does the risk of developing pathological gambling. Legislation, for example, controlling casinos and society's hedonistic attitudes, for instance, to national lotteries and so on, may be important in prevention, although a study by Bondolfi, Jermann, Ferroero, Zullino, and Oseic (2008) in Switzerland showed no increase in pathological gambling following an increase in the opening of casinos.

PATHOLOGICAL FIRE-SETTING (PYROMANIA)

ICD-10 defines this as repeated fire setting without any obvious motive. There is an intense interest in watching fires burn and feelings of increasing tension before the act and intense excitement immediately after it.

In *DSM–IV–TR*, it is also classified as an impulse disorder. There is deliberate and purposeful fire-setting on more than one occasion. Tension or affective arousal is present before the act. There is intense pleasure, gratification, and/or relief when setting fires or when witnessing or participating in their aftermath. Such individuals, also referred to as fire bugs, are fascinated with, curious about, and attracted to fire.

This group of fire-setters includes those who are described as having an irresistible impulse and a repeated urge to set fires, which they do not fully

understand and about which they are often inarticulate. They are often isolated and inadequate people who set a number of fires impulsively and who may escalate the seriousness of their fire-setting. This group also overlaps with those who set fires for tension or depression reduction, that is, as an anxiolytic or an antidepressive act. Such individuals discover that fire-setting relieves feelings of despondency or tension. An analogy can be made with the calming effect normal individuals report when observing and sitting in front of a glowing coal fire.

In the past, fire-setting by men was considered to be frequently associated with direct sexual arousal by such an act, that is, the use of fire as a fetish, and there was considerable psychodynamic interest in the symbolism of fire, for example, flames of passion, burning desire, blazing rows, and so on. Freud (1932) described the glow of fires as reflecting sexual excitement and the motion of flames as symbolic of the phallus in action. However, while a number of fire-setters may indeed obtain a sense of excitement from their actions, those who are specifically sexually aroused and who may even masturbate after setting fires are rare.

Pathological fire-setters are a subset of those who tend to set more fires and to whom the fire is a thing of interest in itself. Individuals have a fascination with fire and hence the arson appears outwardly motiveless. There may also be an associated fascination with fire engines and calling out the fire service. The making of false telephone calls to the emergency services can result in a charge of "wasting electricity" in the UK.

Other clinical features include evidence of advanced preparation and indifference to the consequences of fire-setting to property or life.

It is rare in children, but more common in male adolescents, particularly those with poor social skills and learning difficulties.

The Offense of Arson

Arson is the offense associated with fire-setting and is the unlawful and malicious (willful) destruction of or damage to property by setting a fire. Legally, the more serious charge is arson with intent to endanger life or being reckless as to whether life was endangered. Owing to problems of detection, only 5 percent of cases of arson end in successful prosecution in the UK. In the UK, one school in eight is subject to arson each year.

If an individual is charged with arson, it is important to reconstruct in detail what happened at the time of the offense, for example, reading witness statements related to the case, and not just depending on the actual legal offense category. For instance, arson may be the setting fire to a waste paper bin in a busy

hospital ward in front of observing staff and fellow patients, or an impulsive or planned serious fire, in circumstances unlikely to be detected, with intent to kill. Of psychodynamic note is the fact that fire almost uniquely can make things disappear, including evidence. Historically, one reason individuals were burnt at the stake was to avoid spilling blood.

Epidemiology of Arson

Approximately 40 percent of all serious fires are started deliberately. Six percent of fires in the UK are recorded as arson. Arson is responsible for 1 percent of all serious crimes in the UK. However, as the evidence is often burnt, only about a quarter of arson offenses result in conviction. The peak age for arson is 17 years for men and 45 years for women. Eighty percent of those convicted are men. There is increased incidence of arson among those with learning disabilities and those who suffer from alcohol dependence syndrome. Fifty percent of cases of arson follow alcohol abuse, especially binge drinking of alcohol.

Clinical Classification of Arson

Numerous attempts have been made to classify arson clinically, for example, by Puri, Baxter, and Cordess (1995).

There is no typical arsonist. Psychiatric difficulties are common, but the most common diagnoses are personality disorder and substance abuse, in up to two-thirds of cases, with about 8 percent suffering from a psychosis. Pure pyromania appears rare (1 percent) among convicted arsonists (Ritchie & Huff, 1999).

A classification based on these studies is as follows:

1. Fire as a means to an end (motivated). This includes the following:

   (a) Those who set few fires:

   - *Psychosis*, such as schizophrenia. Such individuals may set fires, for instance, to burn out the devil or evil, or in response to hallucinatory voices.
   - *Displaced revenge, anger, or jealousy*. Rather than overt direct aggression against an individual, aggression may be displaced into setting fire to that individual's property. For instance, an employee of a warehouse or supermarket is told off by his boss, but rather than retaliate directly, physically, aggressively, the employee returns after business hours to set fire to his boss's property. This is the commonest reason (in almost 50 percent cases) found by psychiatrists among arsonists referred to them.

- *Cover-up of other crimes*, for example homicide. Modern forensic science, however, usually overcomes such attempts at a cover-up.
- *For insurance*. This has become increasingly common in recent years; for instance, french-fry fires to finance the redecoration of a kitchen.
- *Political motivation*. For example, to further their rise to power, Nazi storm troopers set fire to the Reichstag in 1932 in Berlin.
- *Adolescent gangs*. Individuals are generally more likely to be disinhibited and behave antisocially in a group than when alone. This group is associated with a low rate of recidivism, except among gang leaders.

(b) Those who set more fires:

- *Desire to be powerful or a hero*. Members of this group often have inadequate personalities. Their low self-esteem is bolstered by the sense of power they feel at the results of their having set fires, for example, the panic and the emergency services with flashing lights rushing to the scene. Sometimes this is combined with a desire to be a hero, so that after setting a fire the individual may rush into the premises and rescue pets or the elderly or infirm. On occasions they are caught owing to being seen repeatedly or even photographed, for instance, seen in a local newspaper at the scenes of the fires.
- *To earn money*. This occurs when part-time firemen on call-out rates set a fire. It is a particular problem in rural areas and in some countries such as France. Some individuals may be drawn to the fire service because of their fascination with fire, and psychodynamic associations have been made regarding the phallic symbolism of hoses. Anthropologists and evolutionists have suggested that females may have been impressed by the ability of males to put fires out by urinating.
- *As a cry for help*. To bring attention to a distressed emotional state.

2. Fire as a thing of interest

   This includes the following:

   - Pathological fire-setting (pyromania).

Differential Diagnosis of Pyromania

This includes conduct, adjustment, affective, and psychotic disorders.

Comorbidity of Pyromania

This may include substance misuse, past history of sexual or physical abuse, and personality disorder, especially antisocial personality disorder. High rates

of previous sexual abuse in women who set fires have been frequently described in clinical practice.

Assessment of Arsonists

This depends not only on a careful, detailed history and mental state examination but also on the gathering and study of objective information such as witness statements related to a case. It is important to determine the presence or absence of psychiatric abnormality, especially at the time of the offense, and its relationship with the offense itself. It is clearly important to determine whether there is a history of previous fire-setting and to examine precipitants.

It should be noted that suicide by fire is particularly associated with schizophrenia, perhaps explaining the choice of this most painful means of suicide. Historically, it has been described in the early nineteenth century among Hindu widows in India (suttee) and among monks protesting in Vietnam during the mid-twentieth-century war.

Management

This should clearly address any underlying or comorbid psychiatric disorders. Psychological intervention, for example, with cognitive-behavioral therapy, may be helpful.

The potential dangers of fire-raising must always be borne in mind. The fire service view is that a large fire is merely a small fire not brought under control.

In cases where an individual is charged with arson, the courts will be particularly concerned with the protection of the public and it is likely to be unwilling in serious cases of arson to consider outpatient care or placement in an open psychiatric ward. Ordinary psychiatric hospitals are also inevitably reluctant to admit those who have set fires, so if hospital treatment is required it is frequently undertaken under conditions of medium or maximum security. In the absence of a psychiatric disposal, the courts usually impose a custodial sentence. In England and Wales, under the Criminal Damage Act 1971, a maximum sentence of life imprisonment can be imposed for arson (Section 1) or arson endangering life (Section 2).

Prognosis

Further offenses of arson are increasingly likely if there has been a history of previous arson and if the offender continues to have an irresistible impulse to set fires or to relieve tension or obtain pleasure or sexual excitement from such fire-setting. Increased risk of further fire-setting is seen in individuals who

suffer from psychosis, learning disability, or dementia. However, in an individual case, it may be difficult to tell whether that individual will reoffend. The risk of further serious offending after a period in prison or hospital is low; however, the risk of reoffending may not be apparent in the short term but only on longer follow-up. For example, Soothill and Pope (1973) found a 4 percent recidivism rate over a 20-year period, and Sapsford, Banks and Smith (1978) reported a range over time of 2 to 20 percent.

PATHOLOGICAL STEALING (KLEPTOMANIA)

In *ICD-10*, this is defined as repeated failure to resist impulses to steal objects that are not required for personal use or monetary gain. Objects may be discarded, given away, or hoarded. The person may even later offer to pay for items stolen. An increasing sense of tension before and a sense of gratification during and immediately after the act are seen.

Epidemiology

This is usually seen in women of a mean age of 36 years with a mean duration of illness of 16 years (often after an onset in childhood) (McElroy, Pope, & Hudson, 1991).

The term kleptomania comes from the Greek for stealing madness. The disorder is generally said to be rare, with fewer than 5 percent, according to *DSM–IV–TR*, of arrested shoplifters giving a history consistent with kleptomania. However, such individuals rarely seek psychiatric help and often avoid detection, so that estimates of kleptomania's prevalence have been variable, even up to a quarter of all shoplifters. Up to a quarter of those suffering from bulimia nervosa are said also to meet the diagnostic criteria for kleptomania. This condition is certainly more prevalent in females than males, unlike other impulse-control disorders such as intermittent explosive disorder and pyromania, where males predominate. Onset is around 20 years of age. However, diagnosis is usually made one or two decades later. The individuals concerned are typically married. Males may be underrepresented because they are more likely to receive custodial sentences precluding reoffending in the community during periods of imprisonment.

Clinical Features

Stealing is perpetrated without much planning and without the assistance of others. The objects taken are not needed for personal use or for their monetary

value and may be given away, discarded, or returned surreptitiously, or kept and hidden. The individual invariably has enough money to pay for the stolen objects, but the theft is not committed to express anger or vengeance. Typically, when diagnosed, such individuals have appeared in court several times, feel guilt or remorse, but have not sought psychiatric treatment. There is often a history of a number of years of chronic dysphoric mood, and of the display of signs of depression and anxiety. Individuals' relationships and marriages are often unhappy. There is frequently a history of sexual difficulties and dysfunction and a past history of a turbulent childhood. Individuals often show poor impulse control generally and evidence of personality disorder, but the stealing is not primarily the result of conduct disorder or antisocial personality disorder. They share similarities, therefore, with those who have a past history of childhood sexual abuse.

Differential Diagnosis of Kleptomania

In ordinary shoplifting the act is usually well planned, although it may be impulsive, but it is motivated by need or monetary gain and the objects taken are for individuals' use or monetary gain. Some individuals who shoplift may attempt upon arrest to simulate kleptomania; they are then referred to as malingering.

Shoplifting may also occur in conduct disorder, antisocial personality disorder, depression, manic episodes, schizophrenia, or organic mental disorders, but in such circumstances the act is related to the primary diagnosis.

Comorbidity of Kleptomania

This includes eating disorders or substance abuse disorders. Kleptomania may be precipitated by major stressors such as life events. Depression is common and bipolar disorder may not be infrequent (Lejoyeux, Arbarataz, McLoughlin, and Adès, 2002).

Etiology

There is no definite evidence of a specific genetic or inherited predisposition, although a biological basis has been suspected; for example, Grant, Correia, & Brennan-Krohn (2006) found decreased white matter integrity in the inferior frontal brain regions in women with kleptomania.

Kleptomania has been viewed as a variant of depressive disorder. Those suffering from kleptomania often have depressive symptoms, and the thieving

itself may produce a stimulating excitement that has an antidepressive effect. It has also been viewed as a variant of obsessive-compulsive disorder, but only about half of cases experience with stealing the relief or tension characteristic of that disorder, and in obsessive-compulsive disorder there is not typically the sense of gratification seen in kleptomania.

Psychodynamic Theories

These have included the following:

- *Loss substitution*, in which kleptomania provides symbolic compensation for threatened or actual loss (Cupchik & Atcheson, 1983).
- *Drive theory*, which considers kleptomania in terms of a forbidden activity, engaged in secret and thus having a sexual basis.
- *A perversion*, in which stolen objects represent fetishes as defined by Fenichel.
- *A defensive strategy*. used by females, for example, to acquire a symbolic penis to counter castration fears.
- *Self-psychological theory*, in which kleptomania is seen as a response to narcissistic injuries and a means to counter fragmentation of self.

Management

In keeping with a view that kleptomania may be an equivalent of depressive or obsessive-compulsive disorder, kleptomaniac individuals often respond well to antidepressant medication, especially SSRIs such as fluoxetine. Cognitive-behavioral therapy has also been found to be effective (Gudjonsson, 1990). Psychotherapeutic approaches, including family therapy, have also been reported. A self-imposed ban on shopping may, however, be required where treatment fails.

Prognosis

The condition tends to be chronic but waxes and wanes.

The Offense of Shoplifting

The technical offense is theft, that is, from shops, an offense that, as with all offenses of theft, requires the intent permanently to deprive, as well as the act, for the offense to be proved in court. Intent would clearly be indicated if an individual were seen to be hiding an object in his coat and to be looking around

to make sure he was not being observed. In absent-minded shop-lifting, there would theoretically be no intention to deprive.

Epidemiology

In the UK, about 5 percent of all shoppers shoplift (Buckle & Farrington, 1984). However, up to 50 percent of goods taken from shops may be taken by the staff of those shops, as is the case with many thefts from businesses. Sociologists have viewed shoplifting as a social disorder created by a consumer society and precipitated by the visual provocation of shop displays. Open shelves increase sales and reduce the requirement for staff, as in supermarkets, but they are associated with increased shoplifting, with such businesses having to take this into account in their business planning. Some items are left near the checkout till for impulse buying and, in addition, provide easy but inexpensive objects to be shoplifted. Objects are often taken suddenly on impulse and are of trivial value or useless. Some individuals appear to regard shoplifting as an accepted perk of shopping and may pay for other items.

Up to the early 1970s, most shoplifters in the UK were women, who then undertook more of the shopping than now, and 50 percent showed evidence of psychiatric disorder. Ninety percent did not reoffend after conviction (Gibbens & Prins, 1962). However, the majority of shoplifters in the UK are now male and between the ages of 10 and 18 years, as reflected in signs on shops limiting the number of children allowed in at one time. Males are now more likely than females to have previous convictions. The incidence of psychiatric disorder has been reduced to about 5 percent, and it is questionable now whether shoplifting deserves more psychiatric attention than other thefts (90 percent of all offenses are acquisitive). The previous predominance of female offenders coincided with the view that female offenders tended to be psychiatrically disordered, which may explain the courts' requests for psychiatric reports more often in shoplifting offenses than in other, male-dominated, offenses.

Classification of Shoplifters

Shoplifters have been subject to lay and legal stereotyping as needy, greedy, or seedy. Bluglass (1990) distinguished three groups of shoplifters: professional, amateur, and associated with psychiatric disorder. Building on Bluglass' work, a more detailed classification is as follows:

1. Shoplifting for simple gain, plus excitement with or without associated marked antisocial attitudes:

The principal motivation is excitement, and such individuals are responsible for a significant proportion of shoplifting in large cities. Individuals often feel less constrained by another country's laws when abroad. This category also includes organized gangs and those with chaotic lives who steal impulsively and commit other offenses. They may come from antisocial families and be subject to relative poverty. Such shoplifting may be associated with resentment and feelings of bitterness associated with individuals' lifestyles.

2. Shoplifting associated with psychiatric disturbance:

   The commonest association in this group is with depression in people of previous law-abiding personality. These may include isolated younger women with children, but they may also include middle-aged women isolated from their families, who have lost children, who have experienced the loss of a husband (including loss owing to his career), and who also may have significant physical complaints or ill-health and/or be chronically depressed. Shoplifting may be an early symptom of depression. The depression may also be associated with acute losses. Law involvement, including court appearances and associated publicity, can precipitate self-harm or suicide where offenders are depressed.

   In cases of shoplifting and depression, the motivation may arise from feelings of guilt, a desire to be caught and punished, a cry for help, or represent an act of self-comfort or a treat. Other dynamics include secondary gain, in the newly poor to keep up appearances and to steal something for oneself that is not purchased with money from parents or a husband. In married female offenders, there may particularly be sexual difficulties or rejection and marital problems. Shoplifting may be an act of revenge on a husband or a partner to induce shame or punishment. For instance, it may result in the female having to be accompanied by her husband when shopping in future or alternatively in the husband having to undertake the shopping from which the wife can then opt out. For such individuals, a prison sentence may at one level be a relief from their marital or family situation.

   Other psychiatric disorders associated with shoplifting include anorexia and bulimia nervosa, which may reflect both hunger for food and impulsivity, and early dementia, which is associated with disinhibited behavior, lower resistance to temptation, poor judgment, and late onset offending. Shoplifting may also occur on occasion in association with other psychotic mental illnesses, alcoholism, and learning disability.

3. Absent-minded shoplifting:

   This implies no intent permanently to deprive and, if successfully argued in court, a not guilty verdict will result. Such shoplifting may result from undue preoccupation, distractions or harassment, for example, caused by the shopper's own accompanying children. Other causes cited include

claustrophobia in shops and various medical or psychiatric drugs that impair concentration or cause confusion. It is the prescribing doctor's responsibility to warn of such side effects from medication. Although a defense based on medication side effects, including the effects of benzodiazepines, is not infrequently put forward in court by shoplifters, in reality it is rarely a primary cause.

4. Shoplifting in children:

   This peaks around 14 to 15 years, with boys being predominant. Boys steal candy and books. Girls tend to steal cosmetics and clothes. The items stolen are usually of little value. The commonest group is in fact that of "normal" children stealing for excitement. However, child shoplifting may occur owing to subcultural standards or as an expression of emotional disturbance, for example, as an act of defiance against parents, as a cry for help, or in association with feelings of depression, worthlessness, and a sense of guilt.

Assessment of Shoplifters

An examination of the history and mental state of the individual should elucidate motives and detect any evidence of formal psychiatric disorder. The motive may often initially appear obscure, with useless objects or objects of trivial value taken suddenly on impulse, sometimes as a treat or arising from concealed resentment. Alcohol or drug abuse is often associated with shoplifting. Additional information should be obtained if possible, for example, from the arresting police officer. It is often useful to discuss the case with the probation officer if one has been requested by the court to prepare a social enquiry report, which should also be read. It is essential to establish whether there is a history of previous convictions for shoplifting and any past psychiatric history and its relationship to offending.

Management

If it is argued on psychiatric grounds that there was no intent to shoplift and the patient pleads this successfully, a finding of not guilty will result. However, individuals are often deterred from such a defense, for example, a defense involving absent-minded shoplifting, as it will often require a number of court appearances and considerable legal expense, including payments to lawyers, to plead this successfully, and it may well involve local publicity.

Where the court accepts that intent permanently to deprive was present, the individual is legally convicted of theft. If the individual does suffer from a psychiatric disorder, including kleptomania, requiring treatment, psychiatric

evidence may be used in mitigation with a view to altering the sentence: for example, a psychiatric recommendation of outpatient psychiatric treatment may be made as part of a probation order.

TRICOTILLOMANIA

This is a habit and impulse disorder characterized by noticeable hair loss resulting from recurrent failure to resist impulses to pull out the hair. Hair-pulling is usually preceded by mounting tension and followed by a sense of relief or gratification. It is not itself directly associated with criminality, although it can be associated with personality disorder, which in turn may be associated with offending. It has been well reviewed by Walsh and McDougall (2001).

INTERMITTENT EXPLOSIVE (BEHAVIOR) DISORDER OR EPISODIC DYSCONTROL SYNDROME

This is included in *ICD-10* under habit and impulse disorders, but not in *DSM–IV–TR,* and is characterized by episodes of sudden unprovoked violence. Onset is in adolescence, and males outnumber females in a ratio of 4:1. It was originally conceptualized as a form of limbic epilepsy, but this has not been borne out. The syndrome may, however, be associated with soft neurological signs and temporal lobe electroencephalogram (EEG) abnormalities, and may be helped by anticonvulsants such as carbamazepine and sodium valproate. Mood stabilizers may also be used, and lithium and SSRI antidepressants may also help, suggesting a link to mood (affective) disorder. This disorder, in fact, usually occurs in those with a severe, often explosive, personality disorder with a propensity under stress to intemperate outbursts of anger and impulsive violence when frustrated, which equates to the emotionally unstable impulsive-type personality disorder of *ICD-10* and falls within the antisocial personality disorder of *DSM–IV–TR*. It is of note that half of persistently aggressive offenders in general are said to have an abnormal EEG record, often an immature record (persistence of excess posterior slow-wave activity), characteristic of those with psychopathic disorder and not diagnostic of epilepsy.

NONPARAPHILIC SEXUAL ADDICTIONS

These are culturally acceptable sexual interests and behaviors so intense or frequent that they interfere with sustained intimate relationships. They include, for example, compulsive masturbation, repetitive promiscuity (using people as sex objects and often involving prostitutes), and dependence upon anonymous

sexual outlets such as pornography or telephone sex. These have been conceptualized as addictions, compulsions, or hypersexuality, or as disorders of impulse control (hence their inclusion here).

Nonparaphilic sexual addictions may be depressive equivalents, especially in the presence of affective disorder that causes disorder of sexual regulation and that, in turn, increases nonconventional sexual interests. There are similarities to bulimia nervosa, which also shares comorbidity with depression and responds to antidepressants. Such sexual addiction has also been viewed as an obsessive-compulsive disorder variant. It has been criticized as a concept for being used too loosely and defensively and as including those merely with a high sex drive or those who are prone to marital infidelity. The concept has gained increasing public awareness through celebrities who have cited such a diagnosis and been admitted to private institutions for treatment. Successful treatment has been undertaken with the SSRI fluoxetine at 20–60 mg a day, which would be in keeping with such sexual addiction's being either a depressive equivalent or an obsessive-compulsive disorder variant.

Comparison of Nonparaphilic Sexual Addiction and Paraphilias

Nonparaphilic sexual addictions should be differentiated from paraphilias or disorders of sexual preference, in which there is a persistence of and preference for such behavior over normal adult sexual behavior, which may then lead to sexual offending, although in both there may be feelings in keeping with addiction, for example, a sexual "high" and tolerance with an escalation of the stimulus intensity needed to attain the same level of pleasure.

Those with paraphilias often feel they are addicted to such behaviors or view such behaviors as compulsions. They experience their paraphilic urges as instant, demanded, and fixated. They describe feeling in an altered state during paraphilic acts and unable to stop such behavior unless others intervene. Once caught, they may say they will never behave so again but they do, in spite of law involvement and risk to self or others. This may reflect dissociation due to high sexual arousal. Those with paraphilias often want acceptance from professionals rather than increased self-understanding or change.

The Internet

The majority of sites on the Internet are sexual in content and estimates suggest that up to 1 in 200 of such sites concern child pornography. Such sites may be used by those with nonparaphilic sexual addiction and those with paraphilias.

However, most adults are sexually curious. Among those who access the Internet for sexual reasons, some may be predisposed to use such sites, some may have lifelong paraphilias, and some may discover nonparaphilic or paraphilic interests owing to images seen on Internet sites being etched in the mind. The Internet allows easy access and apparent anonymity, and most sites are now free or affordable. It is unclear whether the Internet has increased the prevalence of paraphilias, but it has certainly led to an increase in the detection and conviction of those viewing child pornography there, in comparison with the past, when such images were viewed in private in magazines. The Internet also makes it easier omnipotently to summon at will and find rare sexual fantasies being carried out in reality, with the illusion of a real object relationship with another; this distances the individual from associated feelings of guilt.

CONCLUSIONS

Impulse-control disorders are a disparate group of conditions with different characteristics and epidemiologies. Whether the urges and impulses and resulting criminality are irresistible is open to question. Perhaps no impulse is irresistible, if an individual is motivated to try hard enough to resist. Certainly in practice, impulse-control disorders appear to be controllable at times but uncontrollable at others, when momentary excitement leading an individual to act on the impulse appears to overwhelm control. A disordered function of control may better describe the situation than an irresistible impulse. Indeed, the impulse to act is often combined with a desire not to act.

The conditions included in habit and impulse-control disorders do not real an identical psychopathology. Pathological gambling is a more complex condition, requiring attention to the whole person, than an impulse-control disorder such as tricotillomania. A pathological gambler shows features akin to substance addiction, with characteristic histories of escalation from use, abuse, and then addiction with tolerance and withdrawal symptoms, with gambling becoming the center of a sufferer's life, unlike the situation in pyromania or tricotillomania.

Impulse-control disorders are at least as prevalent as schizophrenia, but the research interest in such disorders and the evidence base for treatments are limited. Current treatments demonstrated to be effective include cognitive-behavioral therapy and SSRIs. Other treatments for impulsivity with a weaker evidence base include an SNRI, anticonvulsants, stimulants such as methylphenidate, and the cognitive enhancer modafinil. Other approaches being currently considered and researched include biofeedback, repetitive transcranial magnetic stimulation, deep-brain stimulation, and stererotactic neurosurgery.

Chapter **6**

Troubled IPR Addiction: Habitual Attraction, Abuse, and Violence in Intimate Partner Relationships[1]

Angela Browne-Miller, PhD, DSW, MPH

The intimate partner relationship (what I will herein call the IPR) is an intricate, wondrous system of processes and functions between people who come together largely by way of two highly "rewarding" and "reinforcing" processes—various forms of attraction and of social norm fulfillment. Sadly, a large subset of the population of IPRs is that of troubled IPRs, which are too frequently undetected, or unadmitted via denial functions—or accepted as "normal" (the norm), or worse, simply ignored. Within the domain of the troubled IPR reside habitual detrimental attractions, and various abuses and violences—potentially addictive patterns of attraction, abuse, and violence. These patterns offer insights into behavioral addiction tendencies, functioning on multiple macro and micro levels ranging from overarching species and sociocultural to micro level interpersonal and interactive psychological, psychoneurological and biochemical processes. The psychological, psychoneurological, and biochemical components of patterns of intimate partner abuse and violence parallel patterns of substance abuse and addiction.

Habitual attraction itself, founded upon attraction and/or social norm, is not in itself problematic, and may in fact be some of the glue that keeps well-functioning couples and their families together. While eventually the relationship can become almost a habit, this can be a good habit. It is when this function runs awry that patterns of troubles, risks, and dangers common to runaway addictions emerge (Henry, 2006; Sethi, Marais, Seedat, Nurse, & Butchart, 2004; Weitsman, 2000).

A substance addiction involves continued use of the substance in the face of harm to self or others. Similarly, ongoing habitual attraction-interaction can devolve into detrimental forms including but not limited to ongoing emotional abuse, obsession, masochism, sadomasochism, violence against the self or the other, and co-occurring disorders including substance addiction. (Berliner, 1947; Browne-Miller, 2007; van der Kolk, 1989; see also Dingfelder, 2007 and Gorman, 2007). Troubled habitual attraction—what we might better describe as *mal*attraction—reaches past emotional and physical states of healthy love to the realm of addiction. Here, the triggering of addictive emotional and physical swings, with the wide-swinging roller coaster ride of emotional and physical highs and lows, can go runaway and spin to extremes. Or it can spin until it reaches a relatively stable destructive state where there are no further highs and lows, only increasingly lower lows. In these realms lurk the patterns of self and interpersonal abuse and violence to which too many people become addicted, and at the hands of which too many lives are damaged.

The troubled relationship is addressed by researchers and practitioners in several fields, although rarely addressed as an addiction (Family Violence Prevention Fund, 2007; Hendy, Eggen, Gustitus, McLeod, and Ng, 2003). Many intimate partners, as well as professionals treating and researchers studying them, do not choose to say that destructive relationship patterns such as intimate partner abuse and violence can exhibit habitual and addiction-like characteristics. Still, the IPR itself—or its dynamics—may be a habit that under certain circumstances can turn not only sour but immensely detrimental to one or both partners, the family around them including children, the surrounding community including the workplace, and beyond to the economy, in the form of not only lost productivity and lost work days but also ongoing, even long-term, mental and physical health care consequences and costs (Salber & Taliferro, 2006; Scaer, 2005, Tjaden & Thoennes, 2000; Tjaden & Thoennes, 2000; UNICEF, 2000; USDHHS, 1999). And, at its extreme, one possible outcome of a troubled IPR is that of extreme intimate partner violence (extreme IPV), which can be quite dangerous, even lethal (Rennison & Welchans, 2000; Rivara, Mueller, Somes, Mendoza, Rushforth, & Kellerman, 1997).

As troubled IPR addiction can be so damaging and dangerous, it is only responsible behavior for all who are, will be, or have been in and around IPRs (everyone), and for helping professionals and the researchers who guide them, to consider what positive and also what negative elements of IPR behavior may indeed be habitual, even addicting. I come to this work from a long background in several fields including but not limited to clinical aspects of substance abuse, domestic violence (working with persons abused, persons abusing, and their family members), family dynamics, trauma, family systems theory, and related social policies. This work has converged to bring me to make the following

commentary (addressed to professionals as well as to lay persons, thus written in language aimed at being accessible to a broad range of readers[2]) on IPR pattern addiction and what is best labeled intimate partner *abuse and* violence (IPAV) (Browne-Miller, 2007). The frequently applied acronym for intimate partner violence, IPV, is quite relevant here, although perhaps limited when discussing the full range of abuse and violence patterns, whether or not these are physical. Other terms for IPV may include domestic violence (DV) and gender-based violence (GBV), which can be but are not always subsets of IPV (or in my schema, IPAV).

ELEMENTS OF TROUBLED IPR ADDICTION

Troubled IPR patterning addiction has many faces, and it is perhaps best summarized as falling into three inextricably linked categories: deep neuropsychological elements; powerful behavioral patterning; and overarching social norms to which entire subpopulations and populations are not only committed but are themselves virtually and even actually addicted (applying the broader definition of addiction being used herein).

Deep Neuropsychological Programming.

As is true for substance addiction and other behavioral addiction, troubled IPR addiction contains a powerful biological—neuropsychological—component. Of course, even without the running awry found in an addictive pattern, a healthy love (and or sexual) relationship can parallel a drug "high," especially in its early stages. As Louis Cozolino explains in *The Neuroscience of Human Relationships*, "Love is a drug . . . that includes endorphins and dopamine and results in similar patterns of brain activation as taking cocaine" (Cozolino, 2006, p. 316). This addictive rush of attachment chemicals brings with it the distress at their withdrawal.

Building on Cozolino's observation, we can add that the search for, and the actual or presumed reinstatement of, this or another replacement love sensation poses the risk of the high-low roller coaster ride, of the repetition of highs and lows of love, and in runaway situations, of the extreme highs and lows of love. Desperation in, and distortion of, the search may misinterpret replacement sensations as love when these are not love. This distortion is an all too common component of the troubled IPR addiction pattern (which can even leap from relationship to relationship), and can be said to be self-sustaining. self-fueling, *auto-perpetuating*.

The risk of neuropsychological addiction to such patterns is emotional-biochemical and it is also a factor of present-time social experience. As Cozolino

points out, "we never experience a person as totally new but as some blend of our expectations, implicit schema, and who he or she really is. [Note however that reaction to this experience] . . . results from the fact that implicit memory processes are faster, automatic, and guide explicit memory and conscious experience. . . . Although it takes our brain 400–500 milliseconds to bring sensations to conscious awareness, it takes only 14 milliseconds to implicitly react to, and categorize visual information" (Cozolino, 2006, p. 133).

Again building on Cozolino's viewpoint, we can formulate the notion of a sort of *neuropsychological investment* in a relationship pattern, even one of abuse: We respond to what our implicit memories are responding to, until we have time to reason with ourselves—to see what is happening in the now—if we get a chance at all to do this before impulsively reacting to a stimulus or trigger, as by then we may be neuropsychologically invested in the process. We may also be interpersonally committed to the process, as action has already been taken, without advance review of its outcome. Implicit memory has, in a sense, been socialized (and even traumatized) to the point where it reacts to present-day triggers as if these were harbingers of past events. *Past comfort may seem to be present comfort; past safety may seem to be present safety. Past danger may seem to be present danger; past pain may seem to be present pain.* For example, take a person who has been hit in the face many times as a child, and has grown to cower and fear these repeated assaults. Many years later, in adulthood, there is nothing like this in that person's life. One day someone reaches to adjust the cap on that person's head and that person flinches and raises a fist, almost hitting the hat-adjusting friend. Had the person not been so rapidly placed on automatic by the implicit memory, then the explicit memory could have warded off this behavior.

The effect of this difference in speed of access to implicit and speed of access to explicit memory is powerful, as both memory pools are being accessed almost (in real world—everyday—time) simultaneously. For my purposes here, I will call this the *reaction differential factor*, or RDF. It is in the realm of this RDF that the IPR is vulnerable to on-the-spot, immediate responses, reactions—without the benefit of conscious integration and review of the stimulus or trigger. And almost concurrently the IPR is vulnerable to the next wave of responses, somewhat more conscious responses to the actions taken on impulse.

In is in the first, brief 14-millisecond interval that hurtful and even threatening verbal and physical outbursts, actions, can be initiated. Once in process, implicit triggers work like an avalanche. Where intimate partner violence, physical IPV, takes place, this 14-millisecond response zone is loaded with physical risk. This RDF characterizes much of extreme IPAV. I add the *A* in here, as nonphysical abuses such as impulsive emotional abuse can also arise out of, be triggered by, the implicit memory (Browne-Miller, 2007; Loring, 1998).

Stretching the definition of implicit memory somewhat, we can see that implicit memory reaches back in time—into the memory of the individual, and of the IPR, as well as of the species. The latter is where instinct lives. Here is where the instinct known as the fight or flight response arises. When the individual is threatened, species-honed instinct works in the millisecond space to initiate a rapid impulse response to danger: either fight or take flight.

Powerful Behavioral Patterning

Implicit memory calling back, right into the present, responses to old events and traumas is a driving force in many troubled IPR reactions. However, we need not reach only into the far past to find powerful behavioral patterning. We can search the term, the span, of the RDF, look into the space between reaction out of implicit memory response and reaction out of explicit memory response. We can also search more recently formed implicit memory responses. A long- and even short-term IPR may repeat the same pattern often enough that its characteristics, actions-reactions and triggers-responses, move into implicit memory enough to put certain behaviors onto automatic. This process can also take place in a healthy IPR and likely does. (Do we wish our partner's and our own taking out the garbage and cleaning up in general were guaranteed implicit memory–directed automatic behaviors?) However, in a troubled IPR, troubled patterns are established, maintained, protected, and often even amplified, with repetition. Reinforcement of a problem behavior takes place (even in "the now").

Addiction to these learned patterns is common, and works on both the neuropsychological level and the level of current social interaction and expectation. All sorts of present-time reinforcements of these patterns occur, and we have the addiction scenario arising again and again. The discussion here focuses on this category, powerful behavioral patterning in the troubled IPR, not to the elimination of the other two categories (instinct-driven neuropsych and culturally-driven social norm), but as the locus of interaction between them.

Powerful Social Norms

I add this third layer to my discussion of troubled IPR addiction: the social norm. Where much of the following discussion focuses on the individual's and the couple's potential for addiction to a troubled relationship pattern, everything discussed here takes place within the larger sociocultural context. The social norm as a concept is accepted as a phenomenon found in broad, overarching social and cultural settings and their subpopulation subsets. We tend not to think of the social norm as addictive but rather as an overarching

contextual dictum under which all else takes place. Here I do refer to *addiction* to social norms, and use this reference both lightly and as profoundly as I can. My assertion here is not only that the individual can become addicted to something or some behavior but that an entire population or subpopulation can as well. While some social norms are explicit as givens, others are implicit, virtually invisible while they do their work on all levels including the neuropsychological and behavioral.

The power of the social norm is in its characteristic transferring of expectations regarding values, beliefs, behaviors and attitudes to a broad population. The weakness of the social norm is that is has evolved over a long period of time and that it does not change quickly even when such a change is needed. Where social norms are misinterpreted and resistant to change while being abused or at least misinterpreted, behaviors of individuals can be negatively affected. As an example, the condoning of, or at least the minimizing of the gravity of, violence against women, is still prevalent in many cultures and subcultures around the world. While this chapter does not focus on social-norm-supported, and even social-norm-promoted, violence against women or GBV per se (I choose to do this elsewhere), the role of powerful underlying social norms in interpersonal and relationship violence is the context in which much of the IPAV discussed herein occurs.

EXTENT OF THE PROBLEM

Data-established pieces of the puzzle are available; however, we have no measure of the extent of addiction to troubled IPR patterns or of addiction to IPV or IPAV patterns. The prevalence of such *pattern addiction* would be difficult to measure. Certainly, we cannot prove that all IPV is the result of addiction to individual and social IPAV patterns, as many instances of assault upon an intimate partner may not be the product of addiction to a pattern. The data that are available do tell us that intimate partner violence is significant in scope and impact worldwide, suggesting the relevance of all three factors: social norm, behavioral patterning, and neuropsychology. We pause here to note some basic IPV incidence-prevalence data.

In terms of what is being reported, which is truly only the tip of the iceberg, counted intimate partner violence results in well over a million injuries and a thousand deaths each year in the United States alone, and this is without adding data regarding rape and other forms of sexual molestation and assault, which are not always considered events taking place between "intimate" partners (Centers for Disease Control [CDC], 2002; see also Bugarin, 2002). Given abused persons' general reluctance to report the abuse and violence, especially

when the context is a formal or semiformal marital or pair-bond situation, these are likely vast understatements. And, given what we know from hotlines and shelters (Campbell, Sullivan, and Davidson II, 1995; Rennison, & Welchans, 2000), these are surely vast underestimates. Note that this data just represent rates in the United States; global data echo all this and more.

The World Health Organization (WHO) "Multi-Country Study on Women's Health and Domestic Violence against Women" (WHO, 2005) found that in 10 countries it studied, at least half of all women reported that they had been physically or sexually assaulted since the age of 15, and at least half of these assaults had been inflicted upon them by a "male intimate partner." Of the ten countries in this WHO study (Bangladesh, Brazil, Ethiopia, Japan, Namibia, Peru, Samoa, Serbia, Montenegro, Thailand, and the United Republic of Tanzania), 10 percent of women reported *current* violence by a current intimate partner. In terms of IPV during their lifetimes, reports ranged from "15% in Japan city to 71% in Ethiopia province, with prevalence estimates in most countries ranging from 30% to 60" (WHO, 2005, WHO, 2004).

Again, these data alone say nothing about addictive *patterns*. Much of these violence events are crimes—assault, rape, homicide—that may or may not have occurred as part of a pattern (Coker, Smith, McKeown, & King, 2000; Rivara, et al., 1997; Simon, 2003). Where women are the victims of such violence, this is frequently described as the gender-based violence (GBV) referred to earlier. (Note that IPV is not always violence against women.) When this violence is embedded within overarching cultural norms, including tolerance of violence against women, this violence is not only tolerated and even accepted but in some cases expected. Here, the addiction may be that of a population or subpopulation to a general social norm of toleration (of tolerance of, and programming for, this form of violence) rather than to an individual's addiction to a pattern. Similar social or population phenomena are seen in substance addictions. For example, a subculture or subpopulation may accept, encourage, and virtually require heavy alcohol consumption. The line between a social pressure and a social given as a population addiction blurs.

TERMINOLOGY AND CONCEPTUAL CAVEATS

A few caveats here. First and foremost, nothing about this discussion is in any way a blame the victim approach to intimate partner abuse and violence. All too often, the victim is somehow construed as the cause of the violence of which the victim is the victim—the clearly injured party, clearly at another's hands. Without entering into any contemporary (and quite common in the United States) "who is really the victim" debate here, it is important that the

following material not be used to serve one side or the other of the debate. And where this material may indicate that both partners who are involved in ongoing IPAV are either at risk for, or already are, addicted to IPAV patterns, this in no way says that this addiction to patterning excuses the abuse and violence. Similarly, even addiction to abuse and violence itself does not excuse this abuse and violence. Persons committing the abuse and violence must be accountable for their actions, to their victims, to their families, and to their communities.

Another important note. Clearly, substance abuse (SA) and IPAV co-occur at an alarming rate (Saint-Jacques, Brown, Caplan, & Werk, 2006). Nevertheless, there is no definite and entirely predictable causal direction; neither one nor the other is certain to always come first:

Neither the rule, SA → IPAV,
nor the rule, IPAV → SA,
can be held gospel.

Instead this co-occurrence itself takes myriad forms and directions, and it never takes place in isolation from countless other factors. Nevertheless, with far too great a frequency, SA is often said to be the whole cause of IPAVs, especially domestic violence. This risks a transfer of focus entirely onto the SA element in lieu of delving into the complexities of the IPR itself and of the IPAV addiction where this is present. Calling SA the cause of IPAV also risks absolving the members of the relationship, especially the perpetrators of the abuse and violence, of direct responsibility for their actions.

The definition of the intimate partner relationship, or what here is called the IPR, has itself been debated with regard to the requisite degree of formality of the relationship. Some will say that the sanction of marriage permits sexual intimacy and therefore is the official IPR. Others will disagree, of course. However, whether or not the relationship is official or sanctioned, or long term, troubled patterns of relating and of abuse and violence can emerge. Also note that there are many forms of casual relationships that involve intimacy—thus, intimate partners. We will not differentiate here as we are looking at IPR interaction patterns wherever they may emerge.

A word here about the use of terms such as *domestic violence survivor* and *batterer* or *perpetrator*. Various terms are used for these and similar roles in this dance of pain seen in too many intimate partner relationships. In fact, different professions tend to select different labels for these roles (as in Catalano, 2006; Chu, 2006; Dahlberg & Krug, 2002; McCormick, & Sacks, 2007; NCIPC, 2006; Roberts, Hegarty, & Feder, 2006; see also Meyers, 2007; DeWolfe, & U.S. Department of Mental Health Services, 2004; Rosen, 2007; Simon. 2003). For example, law enforcement tends to respond to what are called vic-

tims of violence, while persons who work with those who have managed to triumph over being abused in their intimate partner relationships may tend to prefer other terms, such as survivor, for the same persons. And the person seen as having committed the act or acts of violence is often described as the batterer or perpetrator, in keeping with the law enforcement and judicial labels for this person. Nevertheless, simplifying the role of this individual to that of batterer is erroneously collapsing the complex role of this person in the troubled IPR or its IPAV. Labeling one party as batterer reduces the role of both parties in the pattern to the point that one is the good guy or girl victim and one is the bad guy or girl batterer. (That there is no gender preference in these labels is purposeful here. Gender is a very important overlaying factor that must be studied separately.) While in many instances, one is the victim and the other is the batterer, for the analysis of addiction to patterns of relating and abusing, these distinctions are at times secondary.

Rather than take a stand on these terms and their utility, we focus here on the likely to be seen as controversial condition and experience of being habitually "stuck" in these roles—*addicted to them*—however they may be labeled. Therefore, here, in about half the instances in which I describe the roles found in intimate partner violence, "people first language" is used, to some extent allowing us to think past labels—to take one step back from a final label. The "abuser" can be the "*person* who is abusing" and the "abusee" can be the "*person* who is being abused." (Note that this also allows for role switching, for role matching, and also for the implicit self abuse that all too frequently attends the IPAV scenario.) Terms such as abuser and abusee are also used, and more rarely are terms such as perpetrator and victim used. Looking past these roles allows honest consideration of mutual abuse, plus self-abuse, plus dominant abuser roles in destructive addictive patterns. And this allows us to look deeply at addictive IPR patterning.

The patterns of hurt we are talking about have many complex dimensions. These dimensions include nonphysical types of abuse and violence that can be precursors to physical violence or can be extremely hurtful, miserable, and destructive even in the absence of physical violence. These nonphysical forms of violence are easily mislabeled and can be missed altogether. For example, emotional abuse can be so subtle that even the participants do not consciously realize it is taking place. And, where they do realize it, they may not recognize this as emotional abuse or emotional violence, let alone as a pattern of such, let alone addiction to such. Another form of non-violent abuse, that is, financial abuse, can seem so natural to the participants that it remains unlabeled. These and other nonphysical abuses—*hidden violences*—must be recognized and addressed to halt them. So must the patterns—all too often addictive patterns—in which these abuses and violences occur. We will return to addictive patterns of emotional abuse and of self abuse later.

Additionally, there are other dimensions of IPAV addiction and patterning that include but are not limited to the earlier mentioned co-occurring substance abuse, as well as stress, psychological and health disorders, and the partners' separate personal histories of substance, self, relationship, and child abuse prior to the marriage or coupling. These conditions, only some of which can be described as co-occurring disorders, or even causal preceding disorders, can be so intertwined with relationship addiction (including any sex addiction or obsession, any abuse and violence), that it is unrealistic to see and to treat one of these to the exclusion of the other. We return to particular elements of co-occurring IPAV and SA at the close of this discussion.

There are those who prefer to separate these conditions out, not to link them in any way. This is understandable because they want to prevent persons who are abusing from passing the buck for their abuse and violence onto conditions such as stress, mental illness, having been abused as a child, and as noted above, alcohol or drug abuse and addiction (of note where etiology of adult problems is relevant are Burgess, Hartman, & Clements Jr., 1995; ICAN, 2000; Schwartz, Hage, Bush, & Burns, 2006). This point of view is taken to help persons doing the abusing take responsibility for their actions no matter what has contributed to them. While this is a noble approach, and persons abusing should be helped to take this responsibility no matter what contributes to their violence, treating their violence without treating the co-occurring conditions is limiting the power of the work being done with and for persons who wish to stop their detrimental and abusive behaviors.

PATTERNS OF ABUSE AND VIOLENCE IN RELATIONSHIPS

That IPAV may be addicting becomes clear when its various levels are included in the delineation of its patterns. The many faces of relationship abuse and violence are frequently categorized along these lines: emotional abuse; verbal abuse; physical abuse. These types of abuse and violence can be placed along a spectrum like this, depicting the pattern found in much relationship abuse and violence, in that it flows from one end of this spectrum to the other, working its way through perceived levels of escalation from nonphysical to physical:

emotional abuse → verbal abuse → physical abuse.

We should add in threats of physical abuse. These can be threatening words or threatening gestures, or implied, hidden but very real threats, and should have their own category (as underlined here):

emotional abuse → verbal abuse
→ *threats of physical abuse* → physical abuse.

As these patterns tend to be cyclic, they are perhaps best diagrammed around a circle, or perhaps as an oscillating or roller coaster sort of line, with the extremes of no violence and then of physical violence at the highest and lowest parts of the "ride." Many other patterns form around IPR abuse and violence, and some patterns devolve to a single ongoing flow of abuse and violence with no, even temporary, de-escalation or relief:

abuse and violence → abuse and violence → abuse and violence → etc.

A great deal of emotional and verbal abuse is very subtle, and not seen for what it is by its recipients or by its perpetrators. In some relationships, there is never physical violence but there is a great deal of other violence taking place. Sadly, these often damaging patterns can be entirely overlooked because there is no physical violence taking place.

VIOLENCE CAN BE HABITUAL, ADDICTIVE

And while there is surely growing understanding that sometimes emotional and verbal abuse are signs of physical abuse, or signs that physical abuse is coming, there is less understanding of the matter of addiction to abuse and violence. The truly addictive nature of actual patterns of attraction, abuse, and violence in relationships remains largely hidden to us, perhaps because we shy away from this understanding. Understanding could be disturbing, could call far too many behaviors into question. Bottom line: we must admit that people can become addicted to intimate partner abuse and violence in the way they can become addicted to just about anything else repeated over time—anything that has positive and negative sensations and reinforcements associated with it. Even where this pattern is experienced on a frequent basis

emotional abuse → verbal abuse
→ *threats of physical abuse* → physical abuse.

it has its built-in pleasurable sensations (such as relief of built-up tension). These built-in sensations can function as rewards—things that may seem to feel good—positive reinforcements that are typical in addictive patterning. These so-called rewards are easy to reap, in that they are natural parts of the cycle.

An example of positive reinforcement of a dangerous habit is the habit of make-up sex after a dangerous level of intimate partner violence has taken place. Some couples have even been known to engage in their habit of make-up sex after extreme physical violence instead of going to the doctor or the hospital for stitches (and then to return to the violence after the sex). How very much like the picture we have of severe drug addiction—craving the drug during withdrawals—then using and getting high and using again despite the damage and injury this is causing (even using while needing to get medical attention for a wound inflicted while high or while desperately seeking the drug). The general script reads like this: undergo suffering, feel relief and/or pleasure, undergo suffering, feel relief and or pleasure, undergo suffering, feel relief and/or pleasure, and so on.

Habitual Rewards

People go for rewards, and for cycles that include rewards, for many reasons. When it comes to intimate partner violence, the reward can tie deeply into the addiction to the pattern, even becoming central. First, there is a potentially addictive *pain—no pain—pain* cycle. As noted above, the cycle of abuse and violence often (but not always) ebbs and flows, and when it does, may bring with it the simple reward that there will at least be breaks—whether moments or hours or weeks long—from cyclic extremes such as physical violence and possibly from the physical pain it brings (although sometimes it is only after the violence stops that the physical injury and pain it causes is felt). Suddenly, the person abusing stops hurting the person being abused and there is new relief—the beating has ceased. This fleeting so-called relief is a form of reward (albeit a cheap reward), a positive reinforcement for this pattern. It is also a shift through the range of the RDF, to the somewhat slower reaction time end of the spectrum.

Let's be very clear here: there is nothing in these words that says the person being abused likes being abused. Instead, these words say, first, that even momentary relief from abuse can be looked forward to or longed for; that tolerating abuse from which there seems to be no escape is facilitated by the anticipation of even brief relief; that when this situation becomes a pattern, both the person abusing and the person being abused can become programmed to it.

Second, there is potential addiction to a specific reward. Where patterns of abuse include what has been called the hearts and flowers or make-up stage, this stage may serve as the reward, the reinforcement, and itself be craved as a drug high would be craved. During this time, no matter how long- or short-lived it may be, there can be politeness, or emotional caring, or gift giving, or

make-up sex. Each of these reinforcing reliefs brings with it not only the positive effect of the respite from the violence but also the positive experience of the make-up activity.

Third, addiction to the highs and lows themselves—to the very behavioral pattern—is quite natural. IPAV addiction's highs and lows are experienced as something like the experience of drug addiction—a roller coaster ride. This ride itself can become addictive, as it can produce sets of biochemical shifts that in themselves produce something similar to these common cycles:

- Seeking stimulation—then relief by excitement, adrenalin rush;
- Tension building—then relief from tension in some form;
- Pain building—then relief from pain in some form;

and even

- Longing for, craving, the sense of contact with someone or something—then contact with something or someone in some form.
- Longing for, craving, relief from discomfort—then comfort in some form;
- Longing for, craving, relief from pain—then relief from pain in some form.

In an abusive relationship (abusive to the other member of the relationship and/or abusive to the self while in the relationship), addiction to a pattern of highs and lows has distinctly detrimental effects. Prolonged addiction to roller coaster rides of stress and violence increases the probability of desensitization to the danger and to the pain that the violence presents. Increasingly severe violence may not be experienced as such. Prolonged addiction to these roller coaster rides also increases the probability of more and more damage and more and more severe instances of damage and injury, with the potential of these *additional* last phases being added onto the spectrum above:

physical abuse → physically damaging abuse
→ *physically disabling abuse* → *death*

Checkpoints Along the Path to Violence

Somewhere along the line, usually from the very start when attraction and/or love is intensely biochemical, we may unwittingly cross checkpoints on a path that could be traveling from *interaction*, to *habitual non-physical abuse*, to *habitual physical violence*, to *addiction to the highs and lows of the pattern of relationship abuse and violence*. This is not to say that all or even a majority of relationships follow this path. This is to emphasize that everyone in a past, present, or future relationship can benefit by knowing about these paths, warning signs, and

checkpoints. To say that anyone having a relationship should not look at this issue is to say we support denial.

Tolerance Can be Dangerous

Sometimes people experiencing patterns of relationship violences—whether these be emotional or physical or both—grow numb to the pain. This numbing to pain takes place because the emotional and physical pain is too much to bear, and also as a result of developed tolerance. This numbing behavior, whether tolerance or a coping skill, is terribly dangerous. This numbing makes all involved miss protective, even life-saving cues. They may not see how serious the situation is, and/or not feel the intensity of the pain—even while in great distress or being maimed or nearly being killed (or being killed). Contrary to programmed safety instincts (pain aversion or pain avoidance), safety is compromised by numbing to the very pain that would allow the sensing of the true level of danger. The IPAV addict moves in surrender of a basic survival instinct for what is in this instance an acquired, maladapted, survival instinct: tolerance. (Again note, this discussion does not stem from a blame-the-victim approach. Rather, this is an *alert and educate* the victim, and all players in the process, stance.)

When our moral, emotional, or basic survival responses to inflicting or receiving abuse and violence diminish, we have developed a *tolerance* to the abuse and violence. This tolerance can emerge much as a person addicted to a drug may eventually take in more and more of the drug to feel or achieve the same effects, and also much as a child who has watched thousands of hours of violence on television may grow accustomed to witnessing violence and may be less and less shocked or morally taken aback by it. The former example raises another matter. We must dare to ask here whether some instances of tolerance to IPAV pain include subconsciously requiring increasingly painful and dangerous violence in order to feel by contrast the longed for relief when the seemingly safe part of the roller coaster ride, the hearts and flowers stage as it is sometimes called, comes around—if it does.

What tolerance can look like in intimate partner abuse and violence is a numbing to the experience of being abused as well as to the experience of abusing. Again, we must remember that numbing to violence does not prevent the damage it causes; rather, it can allow the violence, danger, and damage to continue and even get worse. Addiction to a neurostimulant (such as cocaine, methamphetamine, or even caffeine) offers a standard example of tolerance. A person addicted to a drug with stimulating effects will crave the stimulation and energy increase when not high on the drug. Over time, when not high,

the energy drop will become increasingly low and misery inducing. Each time the stimulant is taken to relieve the low, brain cells may open more receptor sites that fit the stimulant. Tolerance emerges. These sites eventually expect the stimulant, and during phases when there is no stimulant available, the brain cells are hungry for the stimulant, more and more of the stimulant, while the individual is very tired, more and more tired, without it. Tolerance means, in this case, that the highs get lower and the lows get lower. The brain cells require more and more of the same stimulant to feel the high. Even with more and more and more of the same drug, the highs eventually get lower.

Conflicting Experience

We might suggest that while the intensity of the violence may increase, the conscious sensation of receiving the violence (or of giving the violence) decreases over time. The word "conscious" is used here as the person being abused may turn off to conscious awareness of the pain, grow more and more numb to it, while suffering immensely but very deep inside. The suffering is taking place whether or not it is consciously recognized.

People can give themselves such conflicting messages. And this applies to both persons abusing and persons being abused, and of course to situations of mutual abuse and violence. Being either the cause of the pain or the recipient of the pain is painful. Again, this does not in any way say that an abuser who on some level suffers as much as the abusee is therefore off the hook for the damage and injury caused.

Establishing and Maintaining Healthy Patterns

With the great risk of deteriorating into troubled patterns, can an IPR avoid these? Certainly, most relationships can establish a healthy holding pattern, a way of life that stabilizes and promotes not only stability for the relationship but also safety and healthy living for its members and for the people, including the children, around them. However, some relationships stabilize in holding patterns that on the surface work but are laden with risks lingering like time bombs waiting to go off. For example, a "little bit of hitting," or "getting mad and throwing things sometimes," may be alright for partners and may work for quite a while. Still, if behind this there are time bombs lurking, *predispositions to detrimental patterns*, it is generally best to detect and defuse these before they become more damaging and dangerous. Members of IPRs can be assisted or assist themselves in preventing the emergence of troubled patterns. They can be encouraged or encourage themselves to do the following:

- Choose to protect the relationship from deteriorating into problem patterns that once in place are more difficult to change.
- Try to spot, in the early stages of their formation, inherited or acquired, learned, patterns that could grow into problems.
- Weigh the risks of doing nothing preventive about patterns that may eventually become problem patterns.
- See the risk of certain potentially abusive behaviors and patterns, spotting these before they exacerbate into clear abuse and violence.
- When spotting abusive behaviors, even very subtle ones, be ready to call them—admit they are—abusive.
- Recognize the importance of impulse control, even of the time out, and of counting to 10 to go off automatic before speaking or acting.
- Understand that even emotional abuse is violence.
- Direct and change patterns and behaviors in a direction away from potential and/or actual abuse and violence.
- Be highly alert to the process of numbing to pain, and of avoiding, not seeing, and not feeling pain. Pain is a signal that must be addressed.
- Do not let the relationship tolerate certain levels of abuse and violence, as there is no appropriate level.
- If consciously exiting each other's company, temporarily or permanently, have a clear plan and agreement about a clear plan for so doing.
- If a clear plan for so doing is not possible, the individual member or members of the relationship and the children, if any, whose safety is in question or peril must get away.
- Do not sacrifice personal or children's safety for the preservation of the relationship or of a relationship pattern. While ongoing harm may be part of the pattern, this harm does not justify the pattern.

PROGRESSIONS

Warding off the incursions into love of negative psycho-neuro, behavioral, and social programming requires being able to recognize any progression toward detrimental pattern addiction. Most important to see is the simple addictive progression so well recognized in the substance addiction treatment field. An addiction to a behavior frequently begins with *casual behavior.* Casual behavior is brief, occasional, a sort of emotional experiment, seemingly without deep consequences. For example, where there is stress in one's intimate partner relationship, one of the partners may on occasion get into bed with someone else outside the relationship, thinking that this is coping. Of course, this and other casual (and casual escape) behavior can become regular behavior:

Casual Behavior → Regular Behavior

Where there are detrimental present-time or future consequences of this repeated behavior, it at some point may become troubled behavior, a pattern of negative or detrimental behavior:

Regular Behavior → Troubled Behavior

People who are exhibiting troubled behavior continue to do so in the face of adverse effects to themselves (their health, their mind, their work), their families, their businesses, their communities, and/or their societies. It is easy to slip from regular behavior to troubled behavior because the early signs of troubled behavior are subtle and often go undetected.

Again, consider drug use the example. Someone who snorts lines of cocaine to experiment, and then moves into casual social use, and then moves into regular social use, then into increased regular use, likely enters addiction without recognizing this. This is a simple progression, and quite common:

Casual → Regular → Troubled → Addicted Behavior

Fortunately, not everyone who tries a behavior that might be addictive travels this tragic path. Some of these persons, these *casual behav*ORS, (behavORS being the word here for the people exhibiting behavIORS), try a behavior once or a few times and then consider the experiment completed. Or they engage in the casual behavior very rarely and feel this works. But all too commonly, casual behavORS unwittingly slip into regular behavior. We hear people confidently tell themselves, "It can't happen to me. I'm too much in control of my life to develop an addiction to any behavior." However, some do go from casual to addicted behavior in the blink of an eye.

BLEEDING EYE STORY

In the midst of a loud verbal argument, as S yelled at J, "You stupid idiot, you know I'm right!" S raised one arm as if S would hit J if J did not agree.

J jumped back and yelled, "Don't you dare hit me; you look so stupid doing that!"

In that moment, as J was doing and saying this, S leapt forward, right at J, S swinging an arm, this time hitting J in the face, tearing the skin of the side of the head near the eye, and leaving a red mark that would later become a black eye.

Stunned and flinching in pain, J fell to the ground, cowering, saying, "Stop! That's the last time you'll ever hit me!"

S grumbled back, "Oh yeah? Who's going to stop me?"

"I'll call the police."

"No, you won't. You stupid idiot, get up and go wash your face, it's bleeding all over the carpet. And then clean this mess up."

"You clean it up; you hit me."

"This is your fault; you do it," J said, but J finally cleaned it up anyway, as was the pattern.

THE WAY IT SHOULD BE (THE NORM) PATTERN

Shifting the unit of analysis away from the patterns of the individual and the couple, the larger context in which a troubled IPR addiction occurs is highly determinative of the path of that addiction. Given that I am suggesting that entire populations and subpopulations are addicted to the particular social norms in which they are immersed, these norms are here cast as elements of IPRs including troubled IPRs. Social norms themselves, particularly those norms relating to intimate partner relationships, may not only be guiding and comforting but may also be confining and, either way, addicting. Clearly, relationship building and maintenance is not a simple undertaking. It is easier for many to just do it, to rely on the norm for just being involved, and avoid delving into what is happening while they are doing it. And there is a strong social directive to just do it, have a relationship, don't look too closely, don't question the process. There are those who will say. "That is how it is supposed to be" and "That's life." Recall the old rhyme: "[So and so], sitting in a tree, K-I-S-S-I-N-G. First comes love, then comes marriage. Then comes the baby in the baby carriage." This picture—love then marriage then baby—slips into many young minds as early as the nursery rhyme stage of life, forming a sort of directive, a norm—or "normal" pattern—that young people come to feel is most acceptable and most normal.

This basic norm is itself so complex that while it is evolved, adapted, and transmitted from generation to generation via nursery rhymes, fairy tales, spoken expectations, laws and religious codes, media of the times, and modeling done by older generations, no one can say what all goes into it. No one can say for sure that this is truly how it is supposed to be now (today if ever), or what it is that is supposed to be. No one can promise that good and wonderful experiences are normal in and can be expected of this arrangement, nor whether the abuse and violence that can take place in some of these arrangements is alright, part of the plan. However, what becomes clear is that this pattern, instilled via the K-I-S-S-I-N-G message and other traditions, can go awry. Norms work to resist this. Embedded within the nature of the norm is what sustains it, protects it, and wards off threats to its dominance over behavior. The norm reserves for itself the role of dominant, unquestioned imperative—a hypnotic,

addictive, given—*reality* so ubiquitous and self-preserving it is frequently invisible—even when flawed in its intended implementation. While social norms can and do change over time, deviation from a norm prior to its full change can bring ostracism, suffering, and harm to the deviator (Browne-Miller, 2007; Chandler, 2005).

Transaction Habits

There are many hidden trades that take place almost every day, and sometimes almost every minute of a relationship. Each time there is an interaction, a choice to do or not do something, a passage in time in which one or the other puts either the relationship first or the self first, there is a tiny transaction taking place. There is also memory of the pattern of this interaction and its rewards and reinforcements.

These transactions—what we can describe as compromises and trades—are not in themselves sources of pain; they can be wonderfully convenient. And they can be navigated with sensitivity and appreciation for the process of balancing the give-and-take required to keep a relationship functional. Many couples achieve this sort of balance without working hard to do so, and this is ultimately the goal where possible: perceived stability, safety. and sanity. At the same time, too many couples never reach this balance. Then, as time goes by, they trap themselves or at least one of their members into ongoing sacrifice of self and compromise of at least one of their senses of stability, sanity, and safety, all within the comfortable bounds of social norms or (subnorms). It is then that the vows some couples take can become troubled patterns—traps, licenses to cause pain, hurt, and damage.

Progress of Bonds

IPRs form bonds and frequently pursue preservation of these bonds. The pattern of intense bonding, even in a very new love relationship, is natural. Love can form a beautiful bond and a deep emotional engagement and commitment, a truly rich experience making life all the more meaningful. Of course, entering into and then existing as an individual while in an intimate partner relationship is a never-ending process. The relationship changes, just as its members do, as time goes by. The relationship develops a history of its own, a deeper meaning and identity of its own. It truly can take on a personality of its own—not only in the eyes of outsiders who may even come to call the partners in the relationship the "Smiths" or the "couple next door" or "those two"—but in the eyes of its members. Now the relationship is itself a pattern.

When the members of the couple both feel the evolution of their relationship is generally positive, then the progression or pattern moves something like this although not always precisely in this order: from *initial attraction*, to *deeper connection*, to *intersection of lives*, to *identification with the relationship*, to *formalization of the relationship*, to *perpetuation of the relationship*, to *preservation of the relationship*, to *ongoing deepening of the relationship and of the commitment to it.*

Some Bonds Progress Negatively

Of course, there are other less than desirable paths a bond may take. It is important for persons in intimate partner relationships to track, or at least be aware of, the progression of their relationships, the evolution of their bonds, over time. This way, the relationship and its members can maintain an awareness of the direction (or directions) their relationship is taking. They can even influence the direction, if paying close attention—relating consciously and recognizing signs such as those suggesting there may be a need for work on the relationship.

For example, a watchful eye early in a new relationship, when both love hormones and sexual passion can run very high, may help to prevent a relationship from taking the path of a negative progression, which can take many forms. The deterioration of a bond may fluctuate between periods of positive progression and periods of negative progression, as well as experience reversals.

Then, denial finds its way in through every crack in the wall, chink in the armor, of the troubled relationship. Denial creeps in and wants to stay in. Denial itself becomes the glue holding things together. The composite, the whole picture, is a façade not a relationship—an *act* covering over a lack of awareness . . . buttressed by denial upon denial . . . facilitating the *not seeing* of the steps toward participating in, allowing . . . anything needed to preserve the relationship. Frequently this transition into denial is relatively innocuous.

THE COMPLEX MATTER OF EMOTIONAL ABUSE PATTERNING

Patterns of emotional abuse are underway all around us, affecting almost everyone of us, at least in a minor form, at some time in our lives. Emotional abuse patterns are so very common that they are taken for granted, as normal and acceptable. Emotional abuse tends to take a back seat to physical abuse, as physical abuse is seen as more damaging, more dangerous, and more specific. In fact, many persons who are being abused emotionally but not physically do not recognize this abuse as there is no distinct physical sign of it. And of those

being abused physically, many do not include emotional abuse in their descriptions of the abuse they are experiencing. However, the effects of emotional abuse can be as powerful as the effects of physical abuse.

This discussion deals only with emotional abuse of adults by adults. When children experience abuse, and far too many do, a host of highly critical factors not addressed in this chapter are present and require specific attention. Here the discussion focuses on what is, or is supposed to be, behavior taking place between two adults.

Signs

Even adults experiencing emotional abuse may not see that this is taking place. Feelings of discomfort such as those listed here may not be attributed to emotional abuse, even in instances of high levels of emotional abuse; however, these are quite common responses to emotional abuse in intimate partner relationships: embarrassment; confusion; instability; identity doubts, not feeling like oneself; worthlessness, low self-esteem; no level or low level of confidence; sense of complete or extreme failure; depression; isolation; no sense of control over what happens; all-encompassing self-blame—for every problem; humiliation; and pessimism, a negative outlook on the future. And eventually, persons being emotionally abused by a partner over long periods of time can add to this list: feeling that the criticisms of oneself being made by a significant other are correct, believing (or buying into) them; and even . . . defending these criticisms to others. And sadly, sometimes these self-abusing behaviors arise: joining in on the emotional abuse of oneself, hurting oneself emotionally or physically; amplifying the abuse being experienced by working to hurt oneself even more than the abuser does; hiding the pain in substance abuse or other detrimental habitual behavior; possible tendencies to suicidality; bottling up of rage. And of course, what deserves entire volumes and is reported in depth elsewhere, is the risk that the abuse being experienced is then transferred onto others such as children.

DENIAL PRESERVES A PROBLEM RELATIONSHIP

Does denial about harmful patterns preserve a troubled relationship? Yes. Does denial about being in denial further help to preserve this troubled relationship? Yes, for a time. Sometimes too long a time. Relationships can establish an uneasy form of stability by living in denial. However, when the denial is actually camouflaging or burying ongoing suffering, the damage festers and grows. The damage may grow for years, even decades, before it reveals itself

in unusual ways—utilizes unexpected outlets—or simply becomes so extreme that it is finally addressed. Some people are even willing to take their denial to their graves! This is how very scary truth may seem to some.

Sometimes we engage in this denial out of lack of information about the signs of these patterns, sometimes out of insecurity and fear of change, sometimes out of actual fear for our safety. Recognizing and addressing the truth can be unsettling, especially in an environment where truth is repressed and punished if told. We see this scenario many times around us, where someone speaks up about abuse or other interpersonal problems that were expected to remain secret, and the person speaking up is the one who suffers and pays! The role of what we can call the truth teller, perhaps better described as truth revealer, may be a dangerous role to play in a relationship, a family, or a community where abuse and violence is not supposed to be revealed. Powerful unspoken agreements "not to let outsiders know things" are made and can even be carried from generation to generation. Rocking the boat can be risky for the boat rocker. The boat, the troubled relationship system, will fight to stay afloat, to resist change. The sea of social norms in which the boat is immersed may even keep the boat from sinking, supporting the troubled relationship itself.

In that denial serves to preserve many a relationship, even many wonderful, high-functioning relationships, perhaps denial is not in itself always so bad. If the only challenge in a relationship is that one partner wears a plaid shirt, or maybe a particular color of nail polish, that the other partner thinks is a little out of style, it may be that letting this matter go helps. However, far greater issues can be ignored in relationships. Ignoring, not seeing problems so as not to rock the boat, may feel like the only option, the only thing to do. And again, the matter of remaining in denial out of fear of the truth steps forward.

Denial can indeed have a stabilizing effect, preserving what is—the relationship and the patterns that have become the relationship. Denial can also prioritize issues and postpone, back-burner, or simply eliminate attention to problems. Again (and again), when these problems are serious and potentially damaging problems, denial itself is a problem. People can see the black eyes and bruises on their own or their partner's faces and say nothing about these for years and years! When asked, even when looking right at these wounds, people (both persons being abused and those doing the abusing) say they do not see, or actually do not see, them! How much of this is a conscious lie and how much of this is a subconscious lie?

Rocking the boat rocks the boat. And the tendency is to avoid shaking things up, to preserve the status quo, good or bad, whatever this may be. Lies keep the boat from rocking, yes, until the boat springs a leak or sinks, and one or more of its passengers drown.

NUMB TO PAIN STORY

Having been beaten many times, eyes now closed, the burning slaps to the face and the hard knocks to the side of the head feel like more of the same; almost all the hits and slaps and kicks feel the same now. And here comes more and more of the same. And then a fist to the stomach, and a slug to the shoulder, then a hit so hard somewhere—where?

Eyes flicker open and shut. Things start to spin and get darker. Down, falling to the floor. Being kicked now, again and again and again. Each impact making every cell in the body shudder, each cell echoing the thud. Every cell takes each hit and kick, every cell takes it in.

Feeling like nothing but a slab of meat, a beaten, bruised slab of meat. But then, wait, I'm not here, I'm not in here. This doesn't hurt. Hurt is too much to take now. No pain. This isn't happening, I don't feel it. I don't feel anything but the jarring impacts through and through. . . .

Hit, hit, hit. Wait, I'm being beaten as I curl into a ball on the floor. I can make it through this, I can. Again.

HOLLOWING TO PATTERNS

Patterns abound. Patterns are normal. Patterns are a way of life. We need to establish patterns in order to live. Similarly, relationships need to establish patterns in order to live. Relationships build patterns of relating and eventually become dictated by these patterns. In fact, some relationships hollow to nothing but their patterns, losing all defining characteristics and identities outside these patterns, functioning on automatic. Some degree of patterning can work for partners, especially partners in and for life. Establishing healthy patterns can be healthy, so it is good we have this pattern-establishing instinct and capability. But there is a fine line between preserving what is good and preserving what is. Preserving something just to preserve it (no matter what it is) takes a particular mind set, especially when what is being preserved is detrimental or dangerous to the self or others. This is how much we can resist change. This is how continued participation in a troubled IPR can cross into addiction—continued behavior, excessive IPAV behavior, in the face of harm to self or others.

Conflict of Interests

We all engage in some not seeing of patterns, whether desirable or less than desirable patterns, because instinct tells us to go onto automatic. Now another conflict of instincts looms: the powerful instinct to establish and then to pre-

serve patterns may override the instinct to avoid danger! Basically, when we are receiving two conflicting messages from ourselves, we might let one override the other. Amazingly enough, we can endure exposure to a negative experience better when this negative experience is part of an ongoing pattern. When the negative experience is part of a pattern we have grown used to, we are less shocked by it.

Hollowing to Deteriorating Patterns

This function—enduring something simply because it is part of a pattern—allows us to slip unaware into deteriorating patterns, patterns that start out positive and deteriorate into destructive ones, even dangerous ones. For example, if the pattern is one of intimate partner violence in which one partner hits the other repeatedly and continues to do so over time, the intensity and danger of the violence may increase. Little by little, or maybe abruptly, the situation can become dangerous, perhaps even life threatening. Neither party sees the danger of serious injury increasing, even when the danger is there right before their very eyes.

Hollowing to Patterns of Dominance

It is similarly quite easy to slip into relationship arrangements where one partner dominates certain decisions or processes. This dominance may feel quite natural to both members of the partnership, as one may be more of a leader or more extrovert than the other, or may have more knowledge about something than the other, or perhaps be more experienced in certain decision areas than the other. There is nothing wrong with a person who has knowledge or skill in a particular area offering to take the lead there. This can be both efficient and logical.

What can take place, though, when partners are not aware of the permission being given and the power being allocated in this process, is a general transfer of overall power from two people to one of them. This is quite a subtle step, and one which is frequently not seen. A pattern of dominance can grow into an addictive pattern of dominance and control.

Unlike the situation in a town meeting, there are fewer people, usually only two, in the intimate partner relationship. Here, if the overall transfer of power becomes an overall transfer of power and control, we have a potentially dangerous situation. Of course, intimate partner relationships are run like democracies where everyone is supposed to have equal respect, voice, value, and say, right? Wrong. There are no guarantees that intimate partner relationships guarantee

anything close to equal respect, voice, value, and say to the members of this relationship. This is up to each participant in the relationship and is something that deserves conscious monitoring as patterns are being established.

DANGERMOUS DENIAL STORY

High-powered advertising couple, a real alpha or power couple, Vitz and Kat, had been married 15 high-speed years. By the time Kat realized how serious their situation was, both Vitz and Kat were testing HIV-positive. Kat had been entirely monogamous, and also, by the way, drug-free all 15 years. Vitz, on the other hand, had been, for several years, exploring bisexuality —mostly on the sly when high, but not keeping this activity entirely from best friend and partner in civil marriage, Kat. Indeed, Kat knew about Vitz' activities to some extent, and felt Vitz was behaving like this as a result of a tendency to overuse certain drugs rather than out of a desire to cause pain or threaten their relationship. However, Kat just trusted that Vitz would practice safe sex extramaritally. Oh, and by the way, Kat also just assumed Vitz would use sterile needles when shooting up.

EMOTIONAL SADOMASOCHISM

A special discussion of the emotionally sadomasochistic relationship is useful at this point in this discussion of emotional and physical abuse. A sadomasochistic relationship may or may not be one that includes physical-sexual sadomasochism, but it does include elements of emotional sadism and or masochism. Emotional sadomasochism is a relationship pattern that is often hidden although existing right before our eyes, with major components of the sadomasochistic process themselves invisible, nonphysical, emotional, and even non- or pre-emotional (still buried deeply enough in the subconsciousness that they are not registering consciously with any emotional or recognizable impact). In fact, these unseen elements play powerful roles, far more powerful than we give them credit for. These hidden patterns are composed of intricate and often quite subtle energy exchange processes.

Quicksand

Immediately, we step into the quicksand of definition, a sort of now you see safe ground, now you don't, situation. There are several understandings of this concept. Among these are the special definitions of hurt and of the overlap between pleasure and pain. First, the definition of *hurt*. Many readers have heard

the phrase "but it hurts so good" used either jokingly or seriously or both. Here the shifty overlap between the sensation of pain and the sensation of pleasure is identified. Basically, for some, feeling anything, anything at all, is preferred to feeling nothing. Therefore, whether pain or pleasure, both of these experiences fall into the category of feeling something, and thus are thrown together.

Second, sexual relationships—upon and around which many intimate partner relationships are built—can generate both pleasure and pain: at the same time; and/or in such close sequence that they are felt to go together; and/or, in a sequence that places one as a threshold to the other; frequently with some degree of pain being the precursor to some degree of pleasure, and or the reverse.

This is an especially troubled area, as many find discussion of this sort of thing difficult and even offensive. Yet, whether the pain-pleasure linkage is played out physically, emotionally, or in some combination of both, it is safe to say that many emotional relationships play out these sequences in their own, varied ways.

The perpetual compromise and trade process found even in healthy intimate partner relationships can color entire experiences for each member of the couple. Even the way an individual chooses to register an experience as pleasurable or painful can be influenced or even dictated by the compromise and trade process. How frequently these internal decisions are quietly made: "That's not so good for me, but it's great for the other person, and that is good, so it's great for me." "That hurts some, and even when it doesn't it's not fun, even boring, but it gives my partner so much pleasure, so why not?"

What sheer irony it is that while we are compromising and trading—interacting in any way—with our intimate partners, we are actually living in our own worlds, experiencing our own perceptions—not anyone else's—of what is taking place. Hence, we travel through our own personal emotional cycles all alone, even when keeping company with another who may or may not be on the same emotional ride! Take, for example, the comfort-discomfort cycle and the longing for contact cycle (referred to earlier). Clearly, an individual can be taking these cyclic rides—addicted to these patterns—virtually alone. The longing for contact and discomfort-comfort relationship experiences may not be anything like what the other member of the relationship would know or say is taking place.

Like is Too Simple a Word

Another reason why discussion of sadomasochism is touchy is that, quite rightly, there is a concern that some will say persons who are being abused by their intimate partners "like it," and therefore stay. This is not the case. "Like"

is too simple a word here. For example, longing for contact is not liking abuse; taking any form of contact as a form of comfort is not liking abuse.

Emotional sadomasochism involves the overlapping of emotional abuse with perceived consent. "Permission to hurt me, even to break my heart, to destroy me," may seem to have been granted although it has not. Hearing that consent has been given is just thinking that it has, or pretending that it has. This confusion or distortion of reality can become quite perilous. Content and intent blur, their very meanings abused, in these patterns (Atkinson, 2005; Blackwell, 2004; Browne-Miller, 2007; Coker, Smith, McKeown, & King, 2000; Corbett, 2007; see also Asad, 1996).

When Relationships Kill

The majority of abusive, violent relationships do not end in death by accident, murder, or suicide. Yet, ultimately, there is always a risk of actual physical harm once an abusive relationship becomes physical. By degrees, some relationships become so out of control that murder is an actual risk, and where it is not, death by accident during violence is. And where severe depression and/or other psychological problems result from exposure to abuse and violence, there may be risk of suicide.

Swimming in the murky waters where intent and consent are blurred by those who are engaged in not seeing what these are, some people drown. Being repeatedly beaten over time, with the risk of serious injury increasing, involves risk of death. To deny this risk is to not see the problem. To be in a violent relationship where this risk is not acknowledged is to be in a dangerous mix of denial and physical danger. There is no guarantee of accurate prediction regarding when out of control abuse may go too far. (In the extreme, some persons who are suicidal could tend to prefer to kill themselves rather than be murdered, or rather than be wondering when they might be killed during IPV.)

Stages of Change

Models such as the Stages of Change (SOC) model have been proposed to describe the stages people experience as they recover from conditions, frequently moving quite gradually from engaging in harmful behaviors to engaging and maintaining engagement in healthy behaviors. These stages of change, most frequently focused on stages of overcoming and or recovering from addictive behaviors such as drinking, smoking and drug use, are labeled as precontemplation, contemplation, preparation, action, and maintenance (Dunn,

Hungerford, Field, & McCann, 2005; Prochaska, Velcier, Rossi, et. al., 1994; see also Scaer, 2005).

Although there are indeed significant differences between intimate partner abuse (for both its recipients and its perpetrators) and substance addiction, these stages of change can be useful in understanding the process of overcoming and/or recovering from this abuse and violence, especially given that abuse and violence cycles themselves tend to be habitual. This model tells clinicians and others working with those experiencing intimate partner abuse that behavior change occurs in steps, and an abrupt intervention into a habitual situation including ongoing intimate partner abuse is not necessarily effective and in fact is often countereffective. To move as quickly and effectively as possible toward behavioral change away from habitual or compulsive behaviors, we must first slow down to help people explore the why of changing before trying to impress them with the how. (Of course there are situations so severe that life-saving intervention must preempt this approach.)

Trapped in an Unfinished Experience

Ideally, there will be a deeper understanding of therapies that help recognize and release trauma in safe settings, allowing persons who have experienced the trauma to understand its ongoing impact and know the signs and triggers of this impact. Too many victims of trauma experience a deep lack of closure (which is often unseen for years) (Cozolino, 2006; Gazmararian, Spitz, Goodwin, Saltzman, & Marks, 2000; Hammer, Finkelhor, & Sedlak, 2002; NRC, 1996). Even when victims have been treated for the trauma, there can be a lingering sense of being stranded in a space that suggests closure—says that closure has taken place—but in which actual closure has never actually occurred.

Too many persons who have experienced trauma, including traumatic intimate partner abuse and violence, remain profoundly affected for life, with the effects reappearing or taking new forms sometimes years later (Asad, 1996; Bower, 2006; Briere, & Scott, 2006). Furthermore, too often, the effects of this sort of trauma surface in forms not identified with partner violence trauma. This makes the effects all the more difficult for persons experiencing them to address. A sense of free-floating anxiety, fear, disconnection from natural emotional sequences, and other lingering emotional conditions can haunt people and be triggered for no clear reason even years later. Hence, when one thinks the memories of intimate partner abuse and violence are healed, and that one is years past the problem, the dead hand of this abuse and violence may reach out and touch that person. *Traces, almost invisible traces, of patterns, can linger on.*

The sense of being trapped in an unfinished experience, stuck in a lack of closure state, troubles many persons who have experienced intimate partner vio-

lence and abuse. The sense that the trauma is not complete, that the impact of the trauma lingers and is relived—cycled back into—at the slightest reminder or trigger, must be addressed. We must see these sometimes vague but nevertheless profound effects as a serious outcome of intimate partner abuse and violence. Certainly, there is a profound posttraumatic stress component here, in this case a component with many faces. The ghosts of intimate partner violence can float through the subconscious forever, trapped in what seems to be a no-exit pattern (like this):

→ NO EXIT ←

Forgetting, Trauma, and Dissociation as Coping

Numbing while enduring abuse and violence is a coping as well as a tolerance mechanism, as is forgetting. Forgetting can indeed be coping; however, this forgetting of the experience is actually burying the experience deep in the subconscious mind. It lingers there, its pattern's sensations blocked but not erased. Forgetting serves as a barrier to remembering what has taken place, a profound form of not seeing, but, again, a not seeing.

The mind deals with traumatic experience in various ways, the processes of numbing and forgetting being two of them. The mind is skilled at internal protective camouflage, and has the ability to convince, in this case, not the outside world but itself, that the camouflaged, distorted, reality it serves up to its consciousness is real. Mental processes such as *dissociation*, in which the mind separates out normally connected mental processes from each other and from the rest of the mind, are a way of not seeing or processing these as connected experiences, as whole events. Painful memories, taken apart and served back up to ourselves fractured, are possibly less painful than when served up as a whole. This memory-fracturing process as a coping skill is then transferred to experience in the here and now, dissociating the mind from the experience of present-time reality. Memories and current experiences become incompletely perceived and reacted to.

While the person traumatized by intimate partner violence may not be formally diagnosed as dissociating, there may likely be a certain degree of dissociation in any storage of the memory of intimate partner violence trauma. When calling up and addressing these fractured memories, the expression of them as a whole is naturally going to be more reflective of fragmented memories of the experience than of whole ones. The traumatized individual, who is perhaps long over the physical pain the violence may have caused (its physical wounds and even visible trauma), may live forever with the lingering and subconscious sense of incomplete expression of something too vague to label. Being, on a

deep, hidden level, frozen in this unfinished state, the person is done with it all only on the surface.

There can be a deeply buried need for a sense of closure when living with a history of intimate partner abuse and violence, even after the visible, conscious sense of closure has been reached. Sometimes the trauma of violent experience lingers, hidden but present, and subtly affects all aspects of one's existence for years, maybe decades. Pretending this is not the case does not make it not the case; rather, it subjects some traumatized people to half-lives, never being entirely themselves. Given that we are indeed forever changed, on a very deep neurological level, by trauma, we help not only to rebuild what can be salvaged of the self, but to construct a new self, is essential.

Trauma Upon Trauma Upon Trauma

In instances of long-term relationships in which abuse and violence is ongoing, there may be trauma upon trauma upon trauma, continuously compounding the effects of trauma-induced neurological change while burying conscious realization that one is actually traumatized. Not only is violence-related trauma in the face of ongoing violence difficult to detect, but the related need for closure (for something suggesting the closing of the shattering experience of violence and its long-term effects) is buried.

Persons who are being abused may even cling to a dangerous pattern of relationship violence, not realizing that it may be the trauma itself perpetuating the pattern and the addiction to the pattern. The hunger for closure can leave the traumatized individual stuck in a pattern whose cycles may fool all those involved and feel somewhat like closure each time the cycle ends, when the individual takes a break from the violence and "enjoys" a sweet moment of relief.

PASSING ON THE PATTERN

The trauma does not reside in the victim and only the victim. Others around are also affected and may also be traumatized.

The Unaddressed Injuries

Volumes can be written about the impact of intimate partner violence on children who witness it, feel that they are to blame for it, may find role-modeling in it, and when caught in the fray are hurt emotionally as well as physically. Although this discussion is in large part not focused on children,

this is by no means a message that what happens to these child witnesses does not matter.

Carriers of Patterns

These children are the carriers into the future of our values and knowledge. They will likely (and fortunately) want to improve upon their parents' values and expression of these, and this is good. So much can be done better. These precious people, their parents' offspring, deserve a great deal of caring and intelligent assistance in identifying, and recovering from, their exposure to adults' intimate partner violence—and their parents' pain. To break the cycle of intimate partner violence—as well as its long-term health and mental health effects, pain, and trauma—we must understand that all of this can spill over from generation to generation in some form unless a conscious and visible effort to stop the violence is made. Breaking pattern addiction can be multigenerational work.

It is also important to see that, when adults repeat patterns of emotional and physical violence and abuse around children, they are including children in these patterns. Any detrimental habits, negative addictions, played out around children bring the children right into these patterns. The compulsive, destructive, abusive cycles of intimate partners include any children who are apparently on the sidelines. They cannot be unaffected. Nor can be they saved from the roller coaster rides of cycles played out by adults who are likely, in some difficult to explain (to a parent let alone a child) way, addicted to the patterns they have established. No matter how much a parent believes a child is insulated from the parent's ongoing involvement in intimate partner violence and abuse, there is little protection from this reality for the child. Children see and hear—*and feel*—even the smallest signs of this problem. They ride the emotional and physical roller coaster ride with their parents.

Teaching Denial

To pretend to children and teens that there is no abuse and violence when there is abuse and violence is not only absurd but cruel. Young people do perceive something, feel it, usually also hear and see it and the injuries. When the feeling, hearing, and seeing is not validated by the parent, this denial of an actual reality is disturbing, confusing, and distressing. Why drive a child into denial-like patterns, teaching that denial of a serious problem is normal, alright, a fine way of life? Why add lessons in denial to a child's pain and roller

coaster experience? Why fuel children's addictions to detrimental patterns such as IPAV?

Harsh and Painful Reality

The harsh and painful reality is that these children are dependent upon adults who are abusing and being abused. They have no way of ending the relationship with these adults, and they have no way of choosing not to need these adults. This dependence upon disturbed adults, coupled with the mixed messages that children in these situations typically receive (such as, it is bad to hit people even though you see this happening here at home), can be highly stressful and emotionally disturbing for these children.

Riding the roller coaster of fight, feel better, fight, feel better, fight, feel better, and so on, children absorb elements of abuse and violence cycle patterning. Moreover, they absorb the ride itself—high low high low high low—fear safety fear safety fear safety—again and again. For some children, especially those who do not know what patterning is, or what is happening to them as witnesses (which is most children in these instances), these unsettling, terrifying (potentially show-stopping in terms of developmental impact) patterns can become deeply buried inside them. These hidden time bombs tick for years, sometimes many years. Much, much later, or maybe not so much later, a trigger may fire the pattern into action, and the child is at risk of continuing the cycle. Or the child is at risk of playing out the cycle of abuse and violence in another way, such as via alcohol and drug addiction, food addiction, or other detrimental and dangerous behavioral patterns.

Adults seeking to rewrite the programming they may have instilled in their children (when they allowed their children to witness emotional and physical violence) must teach their children the same thing they themselves need to learn: how to recognize and change patterns of abuse and violence. Not to teach these things, out of concern that the material to be taught is too much for children's ears and eyes, is illogical. These children have already been exposed to intimate partner violence and abuse. Now they have a right to a recapturing of this information in a way that prepares them to avoid their parents' experiences. The material presented here, for example, is material young people can learn and many indeed have a hunger for. Young adults forming young intimate partner relationships are especially in need of this sort of information. Knowing how relationships work, knowing how to spot compromises and trades as they are being made, knowing the slippery definitions of intent and consent, is all very important. Children can be taught to recognize patterns of malattraction when they see them.

Tolerance

Of course it is not only fighting parents who teach abuse and violence as a way of life, an acceptable medium of exchange. The media and the world around children teach this as well. Yes, we live in a world where violence is virtually normal. Everything they see, and a large part of what they learn in school, tells children that violence works, that violence is part of life and part of history. The tolerance of violence is instilled so deeply in children, and yet so invisibly. Children's nervous systems react to violence and record their reactions to violence. Repeated exposure to violence dulls some of the response, and generates a mental and biochemical system of incorporating this reality, perhaps a desensitization as the brain cells open receptor sites that are hungry for the addictive roller coaster ride the adults' (and the world's) patterns take them on.

Parents can counter this trend by visibly practicing *positive conflict resolution* processes and telling their children this is what they are doing. Rising above violence can be done and can become a way of life, first in the home. No, we cannot turn back the hands of time, but we can start now, and teach our children well—or at least better than we have done so far. IPAV addiction is rampant, yet it can be halted. The stability, sanity, and safety pattern need devolve no further.

COMPOUNDING IPAV WITH SA PATTERNS

This discussion has delved into the nature of troubled IPR behaviors. Of course, little of the above occurs in isolation or free of other influences such as substance use, abuse, and addiction. Clearly there is frequent co-occurrence of domestic violence, substance abuse, and chemical dependence. Data on this co-occurrence are everywhere, with 20 percent to 80 percent of all instances of battering co-occurring with substance use/abuse. Common data find alcohol use involved in 50 percent of instances of violent behavior.

Characteristics of Co-Occurrence

Particular circumstances bring IPR troubles and SA together (Department of Peace, 2006; Lang, 1993; Leonard, 2000; Nace, 2007). These include: the desire to self-medicate to cope with physical and emotional pain; the learned (in childhood) association of IPAV and SA; the practice of disavowal in using one behavior as an excuse for the other (SA excuses IPAV and vice versa). Characteristics associated with substance abuse can fuel IPAV: disinhibition, in which alcohol and or other drugs reduce inhibition of socially unacceptable

behaviors such as violence; distortion, in which there is a blunting or disturbing of cognitive regulators resulting in misinterpretation and/or distortion of the abusee's remarks and behavior; and paranoia, in which distrust and jealousy and other emotions that can trigger abuse and violence are present.

Patterns of SA can parallel and even cross-trigger IPAV. The basic pattern

$$\text{trigger} \rightarrow \text{urge} \rightarrow \text{response}$$

is seen in both SA and IPAV pattern addictions. So representative of each other are these trigger-urge-response cycles that they can even be confused and that confusion can even be acted upon. Triggers for the SA pattern can be triggers for the IPAV pattern and vice versa. Cravings for a drug of "choice" can be cravings for an abusive interaction of "choice." Moreover, triggers for one pattern may be initiated with the conscious or subconscious intent to trigger the other pattern: SA might be engaged in not only as a response to an IPAV pattern but also as an excuse for it, and vice versa.

Intimate partner violence is often blamed on substance abuse. For example, the person who is abusing may blame the abuse on drugs and or alcohol; the person who is abusing may blame the abuse of the victim on the victim's substance abuse; the victim may claim that the battering is excusable because of either the victim's SA or the batterer's SA.

Persons who are being abused often tend to increase their substance use and abuse in response to IPAV, typically calling this "necessary self-medication" of physical and emotional pain. Many persons being abused are pressured into drug and or alcohol use by the persons abusing them as a mechanism of control and/or abuse. Any treatment of either the IPV or the SA must address this dual condition. As noted earlier, alcohol and drug addiction cannot be said to be the primary cause of IPAV. Once SA and IPAV are in process, then providing only substance abuse/substance addiction treatment will not stop IPV. (Nor will only IPV treatment stop SA.) Note that IPV may be likely to increase once abstinence from drugs and alcohol begins, and to increase as abstinence continues. The same is true for IPAV, as the verbal and emotional violence (threats, manipulation, etc.) are likely to increase as well. Therefore, the safety of the person who has been abused can be quite fragile and must be monitored during and after substance addiction treatment. Many victims in addiction treatment are facing forms of abuse typically unlabeled, overlooked. or downgraded in significance (e.g., the abuser preventing the victim of the IPAV abuse from attending or succeeding in substance addiction treatment—and/or using threats of or even violence itself to interfere with the victim's addiction treatment—and/or even offering the drug/alcohol of addiction to the victim. In other words,

abuse here can include working to keep the person being abused from getting better, from receiving and participating in SA treatment.

Key here is the recognition that in treating IPAV, legitimate safety and survival strategies sometimes conflict with SA recovery strategies. For example, addiction treatment professionals are naturally focused on the involvement of family and significant others in addiction treatment. Addiction treatment quite rightly discourages behaviors and attitudes such as dishonesty, resistance, and noncompliance. However, these same behaviors and attitudes may be essential to protect the person who has been emotionally and/or physically abused via IPAVs and who may still be at risk of being abused, attacked, or killed.

EXAMINATION OF IPR *MAL*ATTRACTION PATTERNS: CONCLUSION

This general discussion of addiction to IPAV patterns with and without accompanying SA identifies what is merely the tip of the iceberg. Patterns of malattraction, abuse, and violence wear many faces and mask themselves in countless ways. Revealing to ourselves the multitude of malattractions and their physical and nonphysical abuse and violence patterns—the IPAV addictions in which too many engage—may be immensely disturbing, chillingly honest, perhaps even repulsive. Yet, removing this mask to unveil and examine troubling personal and interpersonal patterns—addictions that can emerge in relationships—may be profoundly illuminating and have far-reaching benefits to the individuals involved and to the children, communities, and worlds around them.

EATING AS A SPECIAL ISSUE

This page intentionally left blank

Chapter **7**

Craving Pizza? This Is Your Brain on Drugs: Eating Disorders as Addiction

Amanda Ruiz, MD, Hugo Barrera, MD,
and Norman Jackson, MS

The relationship between eating disorders and other more established forms of addiction (i.e., alcoholism, substance abuse) is becoming better understood as the science on the brain—specifically the reward centers—develops. In this chapter, the research on brain physiology is explored to distinguish the areas in the brain that are involved in this addictive process.

There are various forms of eating disorders. The three most common are anorexia nervosa, bulimia, and compulsive eating. Eating disorders are marked by extremes. Eating disorders are present when a person experiences severe disturbances in eating behavior, such as extreme reduction of food intake or extreme overeating, or feelings of extreme distress or concern about body weight or shape.

Anorexia nervosa (AN) is a potentially fatal condition. People with anorexia are so afraid of gaining weight or losing control over their bodies that they diet to the point of starvation. Even when they are very thin, anorexics see themselves as fat (Bulik, et al., 2008). In recent studies, the human life cost of AN is startling. Among young women with AN, the rate of suicide is eight times higher than among young women in general (Bulik et al., 2008).

Bulimia nervosa is a condition characterized by repeated episodes of binge eating followed by attempts to purge food from the system through vomiting, laxative or diuretic abuse, exercising, or fasting. *Compulsive eating* is like bulimia, except that the compulsive eater does not try to purge the food he or she has eaten. The compulsive eater will often consume large quantities of high-calorie

foods in a short period of time, often leading to feelings of shame and an increase in body weight. Eating disorders can affect people from all walks of life regardless of age, race, religion, gender, and so on. As with all addictions, the substance is never the issue; the issue is the underlying causes that people are attempting to cover up or control.

According to the National Institute on Mental Health, the prevalence of eating disorders in the United States has increased steadily over the last 30 to 40 years. Over 90 percent are adolescent girls and young women. Eating disorders has the highest mortality rate of any mental illness—up to 20 percent. Two to five percent of males and females suffer from binge eating disorder. A total of 1.1 to 4.2 percent of females from bulimia nervosa. The first year of college can be especially challenging, with both females (4.5 percent) and males (0.4 percent) reporting bulimia.

In a recent study among gay or bisexual men, the rate of eating disorders has been found to be more than 15 percent higher than among heterosexual men (Columbia University's Mailman School of Public Health, 2007). The cause for this discrepancy is unknown, according to the authors of the study. The higher rate may be attributed to more body-centered focus norms within the gay/bisexual community. Young athletes, particularly gymnasts, runners, bodybuilders, rowers, wrestlers, jockeys, dancers, and swimmers, are especially vulnerable to developing eating disorders. Unfortunately, many of these disorders go underdiagnosed because of the complexity of symptoms and the lack of forthrightness of patients giving their medical histories.

The desire of athletes to be in elite shape may cause heath challenges, but that should not undermine the importance of incorporating exercise into our lives. The benefits of exercise on the human body are well understood, and numerous scientific studies support the notion that regular exercise can prolong life. This is evidenced in numerous chronic conditions (i.e., in the prevention and/or lowering of high blood pressure). Regular exercise boosts high-density lipoprotein (HDL), or "good" cholesterol, while decreasing low-density lipoprotein (LDL), or "bad" cholesterol. In addition, regular exercise can benefit type II diabetes patients and can elevate mood. This health benefit can be attained with a brisk 30-minute daily walk. These types of interventions can be difficult to adapt initially, but once adopted can lead to easier adherence.

The role of diet is very important in maintaining a healthy weight and preventing chronic illnesses. Proper nutrition has become increasingly difficult with higher-stress lifestyles and the common inclusion of readily available processed foods in the Western diet. For adolescents, being adequately nourished is essential to ensure that their growth and development progresses normally and continuously. Unfortunately, this time of our development is the time when most eating disorders develop.

Rapid physical growth and development in adolescence constitute the unique background to the development of eating disorders at this stage of life. For example, self-esteem problems intensify in many normal young women in the process of doubling their body weight, increasing the percentage of body fat, gaining about four inches in height, developing breasts, and acquiring other features of the mature female body, as well as experiencing menarche. Given that this development occurs within a six- to eight-year period, the rapidity of change contributes to the difficulty of the task of acceptance of the change.

The intensity of physical growth and development also accounts for the vulnerability of adolescents to long-term consequences if they experience semi-starvation. All organisms are subject to the greatest harm from food deprivation at periods when they are synthesizing tissue; they need nutrients to build into tissues and food the energy to fuel the process. Human teenagers are no exception to this basic biological rule.

Adapting a mental image of one's unique body—the body image—is basic to adolescent development. Body image distortion is a core characteristic of anorexia and bulimia nervosa. Thus, these disorders are commonly seen in adolescence, the period when young people are vulnerable to body image problems, and the progress of adopting a positive body image is interrupted for the teenager with an eating disorder.

THE BIOLOGY OF ADDICTION MODELS

One of the most hotly contested issues in models of addiction, no matter the type, is the notion that an addiction is a disease. Because society defines disease as a "condition of the living body that impairs normal functioning and is typically manifested by distinguishing signs and symptoms," (Merriam Webster, 2008) many associations come tied in with the definition, including value judgments.

For example, it seems fitting that persons that are medically ill receive assistance with requisite everyday responsibilities. As such, persons in poor health are nursed back to health while they regain strength.

This argument has not held true as ubiquitously for drug addicts (or food addicts) as well as it has, for example, for poststroke patients. Yet, each of these individuals increases their potential for meaningful recovery when she/he accepts responsibility for her/his health. A poststroke patient that actively engages in physical therapy typically improves more rapidly than the patient that is unmotivated to do so. Similarly, the overweight person that exercises generally gains strength and well-being relative to those persons who do not exercise and choose food-restriction alone.

Using the example just briefly outlined, each of the persons mentioned—the drug addict, the food addict, and the stroke patient—have the following in common:

Each person has evidence of disease on fMRI.
Each person has options for medical treatment, which may be beneficial.
Each person should take responsibility for prognosis and treatment, including diet and exercise for optimal recovery.

Ethical issues aside, our argument is not one that is based on wishful thinking or the desire that everyone get a second chance; it is one that is grounded in science. This chapter hopes to explain our point.

PET/MRI AS APPLICABLE TO ADDICTION MODELS

As we launch into an examination of brain imaging, we should first explain what we are looking at and why.

Brain imaging is useful in many specific ways. For example, in individualizing treatment with newer medications or implementing new medication, a knowledge of affected circuitry can point to chemical dysfunction that may be helped by medication (Freese, 2006). The design of behavioral treatments can tell you the types and severity of deficits and dysfunctions in the brain and the possible areas of the person's general strengths and deficits (Freese, 2006). Finally, brain imaging can potentially show how much viable tissue there is to work with; it can show the response of efficacy of treatment (Freese 2006).

IMAGING BEFORE AND AFTER

The brain is a complex organ with many complex circuits running through it. The circuits that coordinate our drive or "pleasure centers" are outlined below:

The main circuits for mediating reward behaviors are as follows:

Fronto-amygdalar pathway. This pathway connects the amygdala and prefrontal cortices *and* the limbic circuit. It integrates the amygdala with the hypothalamus and septal nuclei. The amygdala and cortico-limbic areas have conventionally been the "anatomical substrates" of eating disorders as described in a case report (Cerrato et al., 2004).

Papez circuit. This pathway joins the hypothalamus with the hippocampus and thalamus.

Why is all this important? We explain below.

The limbic circuit is primarily concerned with unconditionally rewarding stimuli like food, water, and sex. This is supported by the fact that the limbic system is connected to ancient, hard-wired structures in the brain. Other important players within your brain include the hypothalamus. Simply speaking, it is the master control of the autonomic function of the body. Stimulation or lesions of the hypothalamus result in systemic responses, such as increased or decreased appetite, including hyperphagia or anorexia, or change in sexual functioning (Goldberg, 1994). The thalamus is a sensory relay center. It is capable of sensing pain, but not pinpointing it. The hippocampus (or hippocampi, since there are two of them) has important functions related to both memory and mood. The nucleus accumbens relates to the motivation properties of food/palatability. The dorsal striatum regulates the caloric requirements necessary for survival.

Dopamine and Hedonism

Positron emission tomography (PET) and functional magnetic resonance imaging (fMRI) have been used in the study of brain activity related to reward processing in both animal as well as human models for years (James, Gold & Liu, 2006; Martin-Soelch, et al., 2001, pp. 139–149; Spiegel, et al., 2005; Wang, Volkow, Thanos, & Fowler, 2004). Most of these studies have indicated that dopamine has a role in reward processing and motivation.

In other words, persons of all shapes and sizes may be driven by a thought or an idea. This thought or idea is then chemically reinforced by a swell of neurotransmitters and neuromodulators, which bathe the brain, making the person feel wonderful. The "craving" is born.

In one study, rodents were used to measure their dopamine output in response to natural incentives. In comparison to basal output, food and sex generated well over 150 percent and 200 percent, respectively, of the resting output of dopamine in the system (Fiorino & Phillips, 1999, 19). This "extra-extra" is nature's way of making sure we return for more.

NATURAL REWARDS AND THEIR IMPACT ON DOPAMINE

As we apply the same concept to substances of abuse, we see that other studies have demonstrated a correlation between the intensity of the "high" induced by various drugs and the level of dopamine that was released (Wang, et al., 2004).

For example, in another study, , the various substances were administered and then the basal rate of release dopamine was measured in the nucleus

accumbens of rodents. Cocaine and methamphetamine had striking peaks, at 350 percent and 1150 percent, respectively, over the baseline dopamine level (DiChiara, Tanda, & Frau, 1993, 112). Based on these findings, it becomes easier to understand why individuals pursue the substance of their addiction despite medical, legal, economic, and other adverse consequences.

NEURO-IMAGING AND ITS APPLICATION TO FOOD

Studies demonstrating that drug abuse involves reward circuitry in the brain have led to interesting research primarily pioneered by Dr. Nora Volkow at the National Institute of Drug Addiction. She was among the first to use imaging technology to investigate neurochemical changes associated with addiction. Similarly, Dr. Volkow has been at the forefront of research that appears to demonstrate that compulsive eating involves many of the same circuits that drug abuse does (Volkow, 2007; Volkow & O'Brien, 2007; Volkow & Wise, 2005).

Further, research has indicated that compulsive eating is reinforced by fat-laden and high-sugar foods. The pizza you love and cannot get enough of, particularly when you have had a long hard day? It is hard wired, believe it or not. The truth is that high-calorie food packs a lot of energy. When viewed from a historical perspective, it likely offered an advantage in terms of survival. In other words, it was palatable, high energy, and reinforcing.

Viewed from this perspective, it should not be shocking, then, to learn that compulsive overeating appears to share many of the same characteristics as drug addiction. In fact, in one study, both methamphetamine abusers and obese subjects were found to have significantly lower measures of striatal dopamine D2 receptors available than did control subjects. Low levels of endorphins have been associated with cravings for fatty foods and chocolates. Further, serotonin, "the happy neurotransmitter," has been linked to sugar cravings; low levels of serotonin lead persons to crave sugar and gain weight as a result. Even more shocking, the newest word related to eating disorders is "drunkorexia," shorthand for a disturbing blend of "self-imposed starvation or bingeing and purging, combined with alcohol abuse." It describes a phenomenon in which persons, typically women, some even middle-aged, refrain from eating throughout the day in order to offset the calories in the alcohol they consume at after-work or college functions including a cocktail hour (CBS News, 2008).

The age of onset of eating disorders, like waistlines, has been steadily increasing, partially in response to mid-life stresses such as divorce, career changes, remarriage, blended families, the empty nest syndrome, slowing metabolisms, and the ever-present pressures of the fashion industry push against us. Two polymorphisms of the "human obesity gene" account for 20 percent of the variance in basal metabolic index (BMI), especially in young women. This finding

is also consistent with frequent binge eaters who have low dopamine metabolite concentrations in their cerebrospinal fluid. Further, a high prevalence of binge eating disorder has been reported among the morbidly obese subjects who have undergone gastric bypass, a subject that is discussed in the following segment on treatment modalities for compulsive overeaters.

KEY POINTS ON BIOLOGY OF ADDICTION MODELS

Enter again our three subject examples: the substance addict, the food addict, and the stroke victim. Each has evidence of brain dysfunction on fMRI. Each has the option of medical treatment modalities. Each is also to some degree responsible for diet and exercise, that is, for making the right choices and taking little steps, one at a time. That is what every person in recovery does.

Some points to note are as follows:

1. Multiple similarities exist between the neurotransmitters that regulate eating disorders and addiction.
2. Although further research needs to be conducted, recent imaging studies indicate that modalities that have been useful in the treatment of compulsive disorders such as substance abuse may also be useful in the treatment of compulsive eating disorders (see Table 7.1).

Table 7.1
Neuromodulators Mediating Response to Cues/Craving

Neurotransmitter or Neuromodulator	Effect	Evidence/ Reference	Comment
Dopamine (D2) receptor antagonist	Enhances meal size Increases meal duration	Study performed on rodents(Clifton, Rusk, & Cooper, 1991, 105)	Dopamine decrease
Long-term administration D2 antagonists	Increased feeding Increased body weight	Study performed on female rats (Baptista, Parada, & Hernandez, 1987, 27)	Dopamine decrease
Patients receive D2 receptor antagonists	Increased weight gain	Human subjects (Allison & DE, 2001; 62 Supplement 7) (Wetterling, 2001, 24)	Ex. Antipsychotic medications
D2 agonists	Anorexigenic effect Weight loss	Human subjects (Scislowski, Tozzo, & Zhang Y, 1999, 23) Anecdotal reports	Dopamine increase

Table 7.1 (continued)

Neurotransmitter or Neuromodulator	Effect	Evidence/ Reference	Comment
Long-term drug addiction & obese persons	Reduced number D2 dopamine receptors in the striatum	Human subjects (Wang et al., 2004) Anecdotal reports	Dopamine increase
Neuropeptide Y (NPY)	Stimulates food intake	Wang et al, 2004	DA inhibits NPY in the hypothalamus
Opioid	Increases food palatability when mod-high	Animal models (Yeomans, 1996, 27) Anecdotal reports	Excessive levels of opioids result in stupor & anorexia
GABA/benzodiazepines	Increases food palatability Increases food consumption	Mammal models (Yeomans, 1996, 27)	GABA is an inhibitory neurotransmitter; the tongue and gustatory zone of the brain also have GABA receptors
Melanocortin	Regulation of food intake through hypothalamic receptors	F:\Eating as Addiction\ NGFN-Science Neuroimaging of hunger and satiety and assessment of sympathetic nerve activity in carriers of a MC4-R gene mutation.mht	Increased activation of limbic/paralimbic areas in obese individuals during apperception of palatable food
Ghrelin	Increases hunger and food intake	Acts on hypothalamus, but there is increasing evidence that it also acts directly on other areas: dopamine neurons, hippocampus (Malik, 2008)	Peripheral peptide
Leptin	Modulates the synthesis & release of dopamine	Wang et al., 2004	Peripheral peptide
Serotonin	Decreases appetite when high; low levels cause sugar cravings	Case report(s)	SSRI

Compiled by Amanda Ruiz, MD.

THE PRACTICAL ASPECTS OF TREATING ADDICTIVE EATING DISORDERS: TREATMENT MODALITIES AND MEDICAL TREATMENT OPTIONS

Ah, that there were a magic bullet for the treatment of exogenous obesity. The diet industry is a multi-billion-dollar market in the United States, and indeed around the world. Medications and herbs that tout the ability to reduce fat and increase weight loss are developed or released weekly. Yet, while millions of dollars are spent annually on weight loss medications, creams, drinks, and other diet elixirs, few if any of the items marketed deliver the promised results.

The medications listed below are currently approved by the United States Food and Drug Administration for the treatment of obesity (FDA, 2008). These medications typically fall into one of two categories: they are either appetite suppressants or they are metabolic stimulants. Similar to the neurotransmitters outlined above, they effectively increase dopamine.

- Dextro amphetamine
- Phentermine
- Sibutramine

Other medications that have not received a specific indication for the treatment of exogenous obesity but have been found to be helpful in the treatment of such disorders, either in case reports or in anecdotal reports of personal experiences with the medications, include the following:

Topiramate: This has been effective in the treatment of alcohol and nicotine dependence (and possibly food abuse?).

- Possible method: decreased impulsive eating/side effect weight loss.
- Increases Gamma-aminobutyric acid (GABA) (using a mechanism different from that used by barbiturates), thereby decreasing anxiety and possibly "comfort eating."

Rimonabant: This has been effective in the treatment of alcohol and nicotine dependence, as well as obesity. There is some evidence of efficacy for both smoking and weight loss in Europe; it is unapproved for use in the United States. Side effects including severe depression have limited its use in the United States.

Other antiepileptic medications and serotonin reuptake inhibitors, either alone or in combination, may also have potential in the treatment of exogenous obesity and other eating disorders related to addictions. However, without further study of these combinations to assess their safety in this population, it is premature to apply them here without a detailed risk-benefit analysis on a case-

by-case basis. Further, the value of medication as treatment is dwarfed when not coupled with an appropriate exercise, diet, and supportive psychotherapy program, as needed.

SURGICAL TREATMENT OPTIONS/METABOLIC SURGERY

With the advent of more efficient, inexpensive food production following World War II, the prevalence rate of obesity in the United States and the world at large began to increase. By the 1950s, surgeons began encountering obese patients with increasing frequency, stimulating, partially surreptitiously, the search for a surgical cure for this condition.

A well-known condition, the short-gut syndrome, results from a catastrophic loss of the nutritional absorptive capacity of the small intestine, usually following vascular compromise. Most patients with this condition become nutritionally impaired, but obese patients, though losing body mass, are better able to cope in the aftermath of the illness. This observation led pioneering surgeons to consider a small bowel bypass, by which a significant portion of the small intestine is functionally excluded from participating in nutritional absorption, as an operation that might result in loss of excess weight in the obese.

A jejunoileal bypass was the first operation performed for the purpose of weight loss in the morbidly obese. And not surprisingly, the operation was very successful in achieving this goal. With long-term follow-up of these patients, however, it became clear that the side effects arising from this rearrangement in the gut anatomy led to life-threatening complications, and within a generation, this resulted in the abandonment of this operation for weight loss.

The search for a surgical cure for obesity was further stimulated by these initial attempts, however. Approximately 20 different operations since have been described for weight loss. Validation and endorsement for surgical treatment for obesity arrived in the National Institutes of Health's (NIH's) Consensus Conference Statement in 1991, which found that in patients deemed morbidly obese, surgical intervention resulted in the only long-term successful treatment for weight loss and maintenance of weight. Morbid obesity, defined as a body mass index (BMI) greater than 40kg/m^2 or a BMI of 35kg/m^2 with associated comorbid conditions, was deemed primarily to arise out of an organic disruption. In the absence of an effective medical cure for the morbidly obese, surgery gained momentum.

From a general perspective, surgical weight loss procedures deal with weight loss from a gross or macro level, resulting in a reduction in absorptive capacity (*malabsorptive procedures*), or a reduction in caloric intake (*restrictive pro-*

cedures), or a combination of both (*restrictive-malabsorptive procedures*). Many of the metabolic effects of the anatomical rearrangements of the particular operations are slowly becoming better understood, surpassing in complexity the mechanisms originally attempted by physicians.

MALABSORPTIVE PROCEDURES

From a simplistic view, the difference between caloric intake and caloric expenditure is the formula that determines weight gain or loss. Obviously, the two terms are affected by a multitude of variables, intrinsic and extrinsic, organic and psychological, genetic and acquired. In the history of bariatric surgery, as we have seen, the initial surgical approaches were directed toward altering absorption, or more accurately, inducing malabsorption.

Absorption of nutrients in the gut occurs primarily in the small intestine, an organ that is 20 feet or more in length. Intestinal villi, finger-like projections of the mucosa or lining of the intestine, greatly expand the absorptive area. As briefly alluded to, short-gut syndrome arises from a situation, as the name implies, in which a significant amount of length and area of the small intestine is lost, usually as a result of vascular compromise or iatrogenic injury. The result is a syndrome of nutritional deterioration in an individual whose remaining intestinal area can no longer support adequate absorption of required calories in the immediate term. With time, some level of compensation can occur in the small intestine in the form of an increase in the height and number of the villi in the mucosa with a resulting increase in the absorptive area. During this transitional period, it was observed that obese individuals, with their excess stores of fat, could better adapt as they lost the excess weight. The connection between short-gut syndrome and obesity is what led to the creation of the first bariatric procedure, an operation that deliberately induced a short gut.

The jejunoileal bypass, performed first by Dr. Richard Varco in 1953 at the University of Minnesota, resulted in an anatomical change in the gut in which a significant portion of the small intestine was excluded from contact with nutrients. As the name implies, the intestine was *bypassed* but not removed, affording a certain level of safety in the form of reversibility. And after extensive study and time, reversal became necessary in the vast majority of patients, as the effects of this form of anatomic alteration became obvious. As a result of physiologic changes in the bypassed segment, including bacterial reflux, overgrowth, and translocation into portal venous flow, the liver became progressively affected in a presumed inflammatory mechanism. The consequence was hepatic failure in approximately 5 percent of patients in the first year following surgery and up to a 50 percent occurrence of cirrhosis in patients within 25 years of surgery

(O'Leary, 1992). For this reason, the jejunoileal bypass has all but been abandoned, with the added recommendation that previously performed bypasses be reversed to avoid the subsequent complications.

In the interim, other varieties of weight loss procedures were being developed, stimulated by the great success of these initial attempts. But this did not mean the end to *malabsorptive* operations. A second generation of such procedures was developed, including the biliopancreatic bypass and the biliopancreatic diversion with duodenal switch, technically more complex surgeries. These operations resulted in effective weight loss without the attendant side effects and complications inherent in the first-generation procedures. Though less common today, these operations have strong adherents who advocate these procedures in the "super morbidly obese" (BMI >60). The common thread is still that decreasing exposed surface area to nutrients leads to less absorption, and, therefore, the intake portion of the caloric formula is decreased, resulting in weight loss.

RESTRICTIVE/MALABSORPTIVE PROCEDURES

From a physiological standpoint, altering absorptive capacity is more complicated, with potentially more complex consequences, than simply decreasing the amount of calories that enter the body. It was with an eye to this concept, that of restricting the quantity of nutrients that enter the body in the first place, that the gastric bypass model of weight loss surgery came into existence. Dr. Edward Mason at the University of Iowa developed the first gastric bypass procedure in 1966, and within 10 years, following some technical modifications, it became the dominant bariatric procedure in the United States.

The initially described procedure involved partitioning the stomach into a small proximal pouch isolated from the remainder of the distal stomach and duodenum. This proximal gastric pouch was then attached to the proximal jejunum. Intake was therefore restricted by the small size of the pouch, which could handle only a certain volume of food before the patient experienced satiety. In addition, as the food exited this proximal pouch, it bypassed the distal part of the stomach and the whole of the duodenum, a situation that results in important hormonal changes that appear to play significant roles not only in weight loss but in the ameliorative effects on certain comorbidities associated with morbid obesity, such as type II diabetes mellitus. Moreover, these effects appear to occur independent of the weight that is lost.

Dr. Ward Griffin at the University of Kentucky modified the original Mason gastric bypass by converting the loop gastrojejunostomy to a Roux-en-Y gastrojejunostomy in order to eliminate bile-induced gastritis and esophagitis. He

also compared this procedure to the original small bowel bypass procedure, finding equivalent weight loss with significantly decreased complications in the gastric bypass group. With the advent of laparoscopy, the Roux-en-Y gastric bypass, performed laparoscopically, has dominated the bariatric landscape in the United States. Change, however, is continuing, and a new generation of purely restrictive procedures is gaining ground, primarily due to the ease of the newer procedures.

RESTRICTIVE PROCEDURES

The concept of a restrictive operation for weight loss arose primarily from the potential simple mechanistic alteration in the gut anatomy that would be required to achieve restriction in caloric intake. In the context of the physiological alterations that resulted from bypassing the small bowel in the first-generation jejunoileal bypass, which led to life-threatening complications, a way to restrict intake became attractive as a manner in which to achieve weight loss.

The Mason gastric bypass had a significant restrictive component but was still a hybrid procedure, with a bypass and malabsorptive component as an integral part for the subsequent weight loss and metabolic effects. But the bypass component also encompassed the creation of connections between different parts of the gut, with the attendant possibility of leaks at these connection sites. Technically, the creation of these connections can be challenging, especially laparoscopically, but also in the traditional open method. And finally, the metabolic changes resulting from bypassing the distal stomach and duodenum were not fully understood early on, but it was suspected that potentially troublesome complications could arise from such rerouting of the nutrient stream.

The purely restrictive procedures address these concerns by essentially simplifying the anatomical changes required. The gastroplasty procedure, described in 1973 by Dr. Mason, is one in which the proximal portion of the stomach was divided horizontally, leaving a narrow channel between the proximal and distal portions of the stomach, slowing the transit time of nutrients between the two areas, yet leaving the nutrient stream directionally intact. This procedure resulted in restriction of flow, but was not consistently effective due to stretching of the proximal gastric pouch or enlarging of the channel between the two areas. Weight loss with this procedure was, therefore, not consistent.

Subsequent experimentation with the concept of gastric restriction led to the development of a modification of the gastroplasty procedure, namely, the vertical banded gastroplasty, using a silastic band or mesh material to maintain the caliber of the narrowed channel. These modifications have led to more stable

weight loss results, though not quite at the levels achieved with the Roux-en-Y gastric bypass."

The implantation of an adjustable gastric band is a relatively new procedure that is purely restrictive in function and technically easy to perform, even laparoscopically. The idea of utilizing a synthetic implant to restrict intake for weight loss arose out of a similar device, the Angelchik ring, a synthetic ring that was employed at the esophagus for prevention of esophageal reflux. Marcel Molina, MD, of the Spring Branch Medical Center in Houston, Texas, first described wrapping a polypropylene mesh around the upper stomach. Adjustability was soon found to be desirable, and obesity surgeons, L. Kusmak, MD, and G. Hellers, MD, developed an adjustable band connected to a port under the skin that could be subsequently accessed in the office with a needle and inflated or deflated as the situation dictated. This procedure is now becoming one of the fastest growing procedures for weight loss in the world and the United States. The speed of the weight loss is slower than with gastric bypass, and follow-up for continued weight loss and maintenance of lost weight is imperative. Nevertheless, the technical ease, speed of recovery, reduction in serious complications, and reversibility has spurred its growing popularity among patients and surgeons alike.

METABOLIC SURGERY

As alluded to earlier, researchers are learning that the bypass portion of the Roux-en-Y gastric bypass procedure appears to contribute to almost immediate improvement in type II diabetes mellitus through complex interactions between "fore-gut "and "hind-gut" hormonal changes. The improvement in this form of diabetes occurs with weight loss and is, therefore, associated with other forms of bariatric surgery, but it is the immediacy of this effect, independent of actual weight lost with gastric bypass, that has led to a new conceptualization of bariatric surgery, in particular gastric bypass, as a form of metabolic surgery. This concept has even been extended to the point where in the near future it may not be unheard of to consider metabolic surgery for nonobese patients suffering from type II diabetes mellitus.

SELECTION PROCESS

The surgical treatment for morbid obesity is not a panacea, and the results can be dramatically affected by the behavior of the patient postoperatively. Surgery, therefore, needs to be viewed as a tool that the patient needs to use effectively in order to achieve weight loss and maintenance of weight. This tool can easily be misused and does not work in an automatic fashion.

Examples of behaviors that negatively impact the postbariatric patient include "grazing" (eating small quantities of food throughout the day), not adhering to the high protein/low carbohydrate diet (usually prescribed for gastric bypass patients), and ingesting high-caloric drinks. It is hoped that psychological evaluation will detect issues of noncompliance or compulsive behavior so as to either address these issues with the patient before surgery or eliminate the patient as a good candidate for surgery.

Unfortunately, failures in detection of important psychological issues result in a great many of the failures of weight loss in patients who have had bariatric surgery.

THE FUTURE

Only a small proportion of the patients who are potential candidates for bariatric surgery are actually availing themselves of this option. The estimates are that 1–2 percent of morbidly obese patients undergo bariatric surgery every year. In part, this is due to availability and insurance coverage for this type of surgery, though this situation is improving as more surgeons become adept at the procedures and coverage for these surgeries is expanded. Part of the problem, however, is educational, on the part of patients as well as referring physicians. This also appears to be improving, as both patients and physicians are realizing the beneficial effects of weight loss surgery, not only in dealing with the issue of excess weight but also in dealing with associated comorbid conditions.

SUMMARY

Our brain is a complex organ that regulates much more than we realize. It seems odd to think that addiction may come in so many various forms, as indicated by the neuro-imaging studies introduced above. Addictions include the traditional vices such as addiction to cocaine and alcohol, and yet may also include compulsive overeating and, its opposite, stringent fasting. For many persons, eating pizza produces a high, just as fasting produces anorectic euphoria. Alarmingly, the idea that certain age groups were out of the typical age of onset no longer holds true: our population is growing more obese; at the same time, more women are crossing the line from being thin social drinkers to binge-alcohol anorexics, regardless of their age.

Medications and metabolic surgery may prove to be an option for many, yet even these advances must be approached with caution. Up to 20 percent of postbariatric surgery patients experience suicidal ideation after the opera-

tion, requiring strict screening beforehand. The reasons for this phenomenon have yet to be studied academically; the possible risk factors are numerous and beyond the scope of this chapter. Thus despite marvelous advances in neuroimaging, medication, surgery, rehabilitative psychotherapy, and diet/exercise, and the implications these advances hold for treatment tomorrow, the best medicine teaches us that it is through a careful coordination of these modalities that we offer our patients and ourselves optimal results on a long-term basis.

Chapter **8**

Eating Disorders and Disturbances: The Continuum of Eating Disturbances

Cynthia R. Kalodner, PhD

> *I did not think of myself as having an eating disorder, yet I could intimately understand the pain of these women. I was clearly not anorexic or bulimic, yet I definitely used food to soothe myself, was uncomfortable with my body, and shared the same struggle for wholeness.*
>
> (Radcliffe, 1993, p. 138)

Anorexia nervosa and bulimia nervosa are eating disorders, well known in popular culture since the media has identified and publicized them through articles, movies, and books. However, when considering eating disorders, limiting discussion to anorexia and bulimia is inaccurate since there are other eating disorders and problems that do not fit the criteria for anorexia or bulimia. In this book, the term *eating disorders* refers to psychiatric illnesses with specific criteria; these include anorexia nervosa, bulimia nervosa, and eating disorder not otherwise specified, which is a special category used for people who have eating disorders that meet most, but not all, of the criteria for anorexia or bulimia.

Eating disorder not otherwise specified is a very heterogeneous category, with six different types. The "not otherwise specified" part of the name might be misunderstood as somehow less serious or not as important as anorexia or bulimia, however, as we will see later in this chapter, eating disorders not otherwise specified are clinically significant eating disorders that require treatment. People with an eating disorder not otherwise specified do not have less body dissatisfaction than do people with anorexia or bulimia. Furthermore, there

may be a progression from eating disorders not otherwise specified to anorexia or bulimia (Herzog & Delinsky, 2001).

In addition to the three major types of eating disorders, there is a large group of people who are dissatisfied with body image and practice unhealthy eating practices, but they may not fit the criteria for any eating disorder. They engage in disordered eating, but do not meet the criteria for an eating disorder. These people have *eating disturbances*. In fact, there are many, many people who are dissatisfied with their body, have a fear of gaining weight, and may be anxious or stressed about weight and body shape. People with eating disturbances may skip meals, restrict food choices to a few acceptable things, and avoid foods that contain fat. They may binge eat occasionally and self-induce vomiting but do not have an eating disorder.

ASYMPTOMATIC, SYMPTOMATIC, AND EATING DISORDERS

One way to think about the definition of various types of eating disorders and disturbances is to use the terms "asymptomatic," "symptomatic," and "eating disordered" (Mintz, O'Halloran, Mulholland, & Schneider, 1997). Those who are asymptomatic do not have any symptoms of any eating disorder. Those who are symptomatic have symptoms of eating disorders, but do not meet the criteria for anorexia, bulimia, or eating disorder not otherwise specified; in the language of this book, they have eating disturbances. Finally, those who have anorexia nervosa, bulimia nervosa, or eating disorders not otherwise specified are considered to have an eating disorder.

THE CONTINUUM OF EATING DISTURBANCES

The eating disorders continuum is a way to think about the various kinds of eating problems. The continuum of eating disorders places normal eating at one end of the spectrum (asymptomatic), eating disorders at the opposite end, and eating disturbances at intermediate points. On the normal end of the continuum, people have normal eating behaviors whereas those on the eating disordered end have significant eating and body image problems. The groups between normal and eating disordered display some eating disordered behaviors such as dieting, binge eating, and various methods of purging. The phrase "continuum" was first used in regard to eating disorders in 1971 (Nylander), and it continues to be a useful way to explain eating disturbances and eating disorders.

BRIDGE—BUILDING THE RELATIONSHIP BETWEEN BODY IMAGE AND DISORDERED EATING GRAPH AND EXPLANATION

BRIDGE (Russell & Ryder, 2001a) is a graphical presentation of the relationship between body image attitudes and disordered eating behaviors that can provide a framework for connecting attitudes (such as body satisfaction or dissatisfaction) and behaviors (such as exercise, healthy eating, binge eating) on the continuum of eating disturbances and disorders. The BRIDGE concept is consistent with the continuum concept since it does not dichotomize between normal and abnormal behaviors and attitudes, but rather presents a continuum of attitudes and behaviors (see Figure 8.1). The developers of BRIDGE highlight the need to be concerned about a wide range of disordered eating behaviors and attitudes and emphasize the importance of discussing eating disorders in the context of a continuum (Russell & Ryder, 2001).

The graph shows how an eating disorder may develop when unhealthy attitudes and behaviors meet. The horizontal axis is a continuum of body image that ranges from healthy to unhealthy. It is the axis of attitudes and feelings about bodies; the healthiest attitudes are on the left near the intersect point on the graph. As you move to the right on the horizontal line, attitudes become increasingly unhealthy. At the extreme, a person may not see himself or herself accurately, seeing the body as larger than it is. The vertical axis ranges from healthy to unhealthy in terms of different behaviors. The healthiest behaviors start at the bottom of the graph near the intersect point and become less healthy as you go up the vertical line. Anorexia and bulimia are at the extreme of this axis.

The shaded areas on the graph represent the intersection of attitudes and behaviors. The "Body Awareness and Acceptance" ellipse holds the part of the horizontal and vertical axes associated with the healthiest attitudes and behaviors. People who fall into this area have healthy attitudes about their bodies and engage in healthy behaviors. They are asymptomatic. They accept their bodies and understand that the way they look is only one part of who they are. Primary prevention programs are designed to promote these healthy attitudes and behaviors are recommended for people who fit into this ellipse (Russell & Ryder, 2001a, 2001b).

The "Body Preoccupation" ellipse is much larger, and it encompasses restrictive dieting/overeating, binge eating, compulsive exercise, and disordered eating. The people who fall into this ellipse are overly concerned about their bodies and are engaging in behavior that is not healthy. This shaded area may include

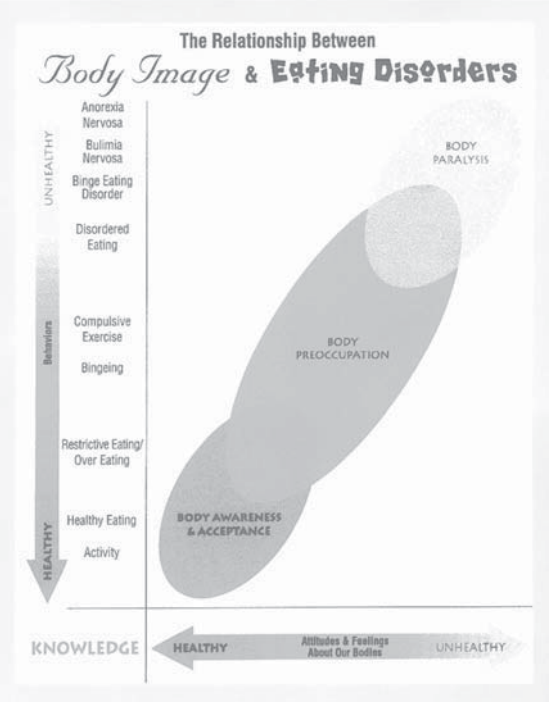

FIGURE 8.1. The Relationship between Body Image and Eating Disorders. Copyright 2001 from Shelly Russell and Sabine Ryder, "BRIDGE: A Tool for Parents and Professionals." Reproduced by permission of Taylor & Francis, Inc., http://www.routledge-ny.com

people who would benefit from secondary prevention or early intervention (such as psycho-education or counseling) to help them change their unhealthy attitudes and behaviors (Russell & Ryder, 2001a, 2001b). Some people in this area have eating disturbances.

The third ellipse is called "Body Paralysis" and is characterized by extremely disordered attitudes and behaviors. People in this ellipse are obsessed with their bodies to such an extent that it becomes the most important thing in life. This ellipse includes people who have anorexia or bulimia, or eating disorders not otherwise specified. These individuals need treatment or specialized services to help them recover from their eating disorders (Russell & Ryder, 2001a, 2001b).

A CLOSER LOOK AT THE EATING DISORDERS CONTINUUM—CROSS-SECTIONAL, RETROSPECTIVE, AND LONGITUDINAL RESEARCH

The continuum conceptualization provides a background for understanding how eating disturbances and disorders may develop and change as time passes. Individuals may progress from a less serious problem to a more severe one over time. Or, it is possible that some people may move from the more severe end of the continuum toward the normal end.

There are three kinds of research that can be used to study this issue: cross-sectional, retrospective, and longitudinal studies. Cross-sectional studies compare different groups of people along the continuum on eating attitudes and behaviors and other variables of interest. Retrospective studies are based on asking people who developed an eating disorder about events that happened to them before the beginning of their eating disorder. Longitudinal studies determine if there is a progression from one point on the continuum to another in the same individual as time passes. Different types of information can be obtained from studies of these sorts.

A Survey of the Cross-Sectional Research

Most of the cross-sectional studies were published in the late 1980s and early 1990s when the field was just beginning to explore the idea of the continuum of eating disorders. The older studies (i.e., Mintz & Betz, 1988; Scarano & Kalodner-Martin, 1994) are cross-sectional studies, since they involved collecting data from a large group, assigning the individuals to a group on the continuum based on their responses to a questionnaire, and then making comparisons between the groups on the continuum. Cross-sectional studies are a way to determine if there are differences between the groups on the continuum.

In one continuum from normal eating to bulimia nervosa (anorexia was not included in this work), six groups were used (Scarano & Kalodner-Martin, 1994). These include normal eaters, weight preoccupied, chronic dieters, purgers, subthreshold bulimia, and clinically diagnosed bulimia. In this continuum, the groups were defined as follows:

- Normal eaters do not binge eat, restrict eating, or use any method of purging.
- Weight preoccupied individuals express significant concern about body weight and shape, but they do not engage in any kind of binge eating, restricting, or purging.

- Chronic dieters engage in repeated dieting behavior at least once a week, including the use of diet pills, fasting, or overexercising.
- Purgers self-induce vomiting, fast, or use diuretics at least once a month.
- Individuals with subthreshold bulimia or bulimia are characterized by both binge eating and purging behaviors, but differ in the frequency of these behaviors; bulimia nervosa is defined by binge episodes at least eight times a month, while those with subthreshold bulimia do this less than eight times a month (Scarano & Kalodner-Martin, 1994).

In several studies based on this continuum with six groups, the groups differed from each other on a variety of eating attitudes and behaviors. For example, a measure of behaviors associated with bulimia showed a linear increase from normal eaters through those with bulimia. A linear increase means that with increasing levels of eating disturbances, there is also an increase in measures of eating related problems, such as binge eating or body image dissatisfaction (Mintz & Betz, 1988; Scarano, 1991; Scarano & Kalodner-Martin, 1994). Other findings that support the linear increase are (1) individuals who meet the criteria for bulimia were more weight preoccupied than those who meet the criteria for subthreshold bulimia, (2) purgers were more weight preoccupied than normal eaters and chronic dieters, and (3) body dissatisfaction increased from normal eaters through the group with bulimia in an incremental way. Similar patterns exist for thinking about appearance and food, feeling fat, and fearing becoming fat.

In another more recent cross-sectional study of the continuum, the three groups of asymptomatic, symptomatic, and eating disordered were used (Mintz, O'Halloran, Mulholland, & Schneider, 1997). A study of college students using this three-group continuum indicated that a continuum existed for the issues most closely associated with eating disorders, such as body dissatisfaction. Scores on a measure of body dissatisfaction increased from 37.9 to 75.9 to 76.2 for asymptomatic, symptomatic, and eating disordered groups respectively (Tylka & Subich, 1999). This kind of linear increase supports the idea that a continuum exists. However, Tylka and Subich also found that some variables did not differentiate between the three groups in this way. Some measures of psychological and behavioral variables (such as extraversion, openness to experience, agreeableness, and conscientiousness) did not distinguish the three groups in any meaningful way. These variables may be less relevant to the eating disorders continuum.

A Survey of the Retrospective Research

Shisslak and Crago (2001) reviewed the studies that used a retrospective model and summarized the findings by saying that people who develop eating

disorders are more likely than other psychiatric patients to have experienced greater parental pressure, high expectations or abuse, more health problems, childhood obesity, more familial criticism about their weight, shape, or eating habits, and a more negative self-evaluation. In contrast, the death of someone close, a loss of relationship with a friend or family member, and work or school problems were not factors that were reported more often by those who developed an eating disorder than those who had another psychiatric problem.

An example of retrospective research is provided by Fairburn, Welch, Doll, Davies, & O'Connor (1997). In this study, 102 people with bulimia were compared with 204 control group participants, and 102 psychiatric patients with disorders other than eating disorders. All participants were British females between 16 and 35 years, and they were matched for age and social class. The participants with bulimia reported exposure to twenty-nine risk factors, but only 4 of the 58 were at greater levels than those who developed another psychiatric problem. This led the researchers to conclude that risk factors for bulimia are similar to those factors that lead to the development of psychiatric problems in general.

There has been no study of the groups on the continuum using a retrospective approach, thus it is unclear if asymptomatic, symptomatic, and eating disordered groups would provide different data on the factors that preceded the development of eating problems. It is also worth noting that retrospective studies are subject to the bias of recall of stressful events. For example, some events that participants may report occurred before their eating problems began, may actually have developed at the same time, or even as a result of the eating disorder. In addition, individuals vary in their perception of what is stressful; that is, what creates a great deal of stress for one person may not be as stressful to another. Even in light of these limitations, retrospective research adds to our understanding of the differences between groups of people who develop a problem and those who do not.

A Survey of the Longitudinal Research

Longitudinal studies can be used to study how individuals change from less severe to more severe eating disturbances in the same individual over time (Shisslak & Crago, 2001). This type of study is based on collecting data from a large sample of individuals and following their development to see who develops eating problems and what precedes or is associated with the development of eating disorders. According to Shisslak and Crago, twenty-six studies have been published that fit into this category; the first one was published in 1989 (Attie & Brooks-Gunn). Since longitudinal studies take much more time to

complete (because you have to wait for people to get older and see how their attitudes and behavior change), and there can be problems with attrition (participants drop out of the study or cannot be reached to provide data), they are quite expensive to conduct.

Longitudinal research suggests that low self-esteem, weight concerns, dietary restraint, body dissatisfaction, depression, negative emotionality, early maturation and being overweight are risk factors for the development of eating disorders and disturbances (Shisslak & Crago, 2001). The four factors that are associated most strongly with the development of eating disorders are weight concerns, dietary restraint, body dissatisfaction, and early maturation, while the other factors are associated with the development of other psychiatric disorders as well. This is consistent with a two-track approach to the continuum that is discussed below.

An example of a longitudinal study of 800 children and their mothers is provided by Kotler, Cohen, Davies, Pine, & Walsh (2001). The procedures involved interviewing mothers and children between the ages of 1 and 10 (childhood), then again in adolescence (mean age 13.9), late adolescence (mean age 16.3), and early adulthood (mean age 22.1). It can be expected, at childhood, there were no children who met the criteria for anorexia or bulimia. In early adolescence, 1 (.2 percent) male and no females met the criteria for anorexia, and 7 (1.4 percent) females met the criteria for eating disorder not otherwise specified Type 1 (anorexia nervosa without the criteria of amenorrhea). There were 6 (1.2 percent) females and 1 male (.2 percent) with bulimia. In late adolescence, 4 (1 percent) males and no females met the criteria for anorexia, and 4 (1.1 percent) females met the criteria for eating disorder not otherwise specified as Type 1. There were 12 (3.2 percent) females and 2 (.5 percent) males with bulimia. In early adulthood, no males or females met the criteria for anorexia, and 2 (.5 percent) females met the criteria for eating disorder not otherwise specified as Type 1. There were 4 (1.1 percent) females and 4 (1.1 percent) males with bulimia. These data fit with the data that suggest there is a low prevalence of anorexia and bulimia.

Relevant to the notion of the continuum and understanding what factors may lead to the development of these eating disorders, Kotler et al. (2001) indicated that the adolescents who scored highest on a measure of symptoms of bulimia developed bulimia at a much higher rate than those with no symptoms when they were younger (7.9 percent more likely); having severe symptoms of anorexia or bulimia in early or late adolescence predicted severe symptoms of these disorders in young adulthood. In addition, certain childhood eating problems, such as conflicts over eating, struggles with meals, and unpleasant meals (as rated by mother) increased the risk for the later diagnosis of anorexia

nervosa. Additional research of this type that includes more psychological assessments may add considerably to our understanding of the risk factors for the development of eating disorders and help understand how eating disturbances develop into eating disorders.

A longitudinal study based on twenty-one female college students who were symptomatic of eating disorders during their college years was conducted to see what happened to their eating attitudes and behaviors after they graduated from college (Hesse-Biber, Marina, & Watts-Roy, 1999). In this interview-based study, it was noted that 11 women experienced reductions in their eating problems, whereas 10 other women remained at risk of developing an eating disorder. The group that reduced eating problems reported better interpersonal relationships and more adaptive means for coping with stress, whereas the group that continued to experience eating-related difficulties described feelings of isolation and discontent with relationships with family and friends and had less satisfying relationships with men.

The results of a longitudinal study involving a ten-year long follow-up of 509 women and 206 men who completed a questionnaire about eating attitudes and behaviors when they were in college has implications for the continuum of eating disturbance and the natural progression among the continuum as people mature and become adults (Heatherton, Mahamedi, Striepe, Field, & Keel, 1997). The first questionnaire was collected in 1982, and the follow-up was in 1992. The ten years after college are ones in which people generally settle down, get married, have children, and establish careers. The researchers wanted to know how their eating attitudes and behaviors would change during that time. A large percentage of the initial respondents returned the follow-up questionnaire (82 percent of the women and 76 percent of the men). During the ten years, the women gained an average of 4 pounds, while men gained 12 pounds.

The groups on the continuum used in this research included nondieters, dieters, problem dieters, and those with subclinical eating disorders and clinical eating disorders. The percentage of women classified as having any sort of eating problem (problem dieter, subclinical, or clinical) dropped from more than 40 percent in 1982 to just over 15 percent in 1992. Thus, it was found that 46 percent of the women moved to a lower category of eating disorder, while 41 percent stayed in the same category and 14 percent moved to a more disordered category. Overall, this study found that body dissatisfaction, chronic dieting, and eating disorder symptoms declined for women in the 10 years after college. Rates of eating disorders dropped by more than half and the prevalence of binge eating and purging declined as well. Maturing into adulthood seems to help women stop dieting and abnormal eating. Some participants wrote notes

to the researchers saying that dieting was much less important to them as they gained some distance from the college experience. So even though it may be normative for women to have some degree of problem eating while in college, it may also be normative for the problems to diminish as the person moves into adulthood. Unfortunately, some of the women continued to have eating related problems after college. About 1 person in 5 who met the clinical criteria for an eating disorder in college still met the criteria ten years later.

For men, the data suggest something quite different. Men gained more than ten pounds from 1982 to 1992, and they also reported increases in body weight concerns, desire to lose weight, and dieting behavior. These changes were associated with increases in attitudes consistent with eating problems. The data suggest that it was the men who were most concerned about being thin who actually got heavier in the ten years.

DOES THE CONTINUUM REALLY EXIST?

Whether eating disorders actually exist on a continuum has been the subject of a great deal of study. Based on many studies, it appears that there is a continuum of food and body image issues, but there may not be a continuum of the psychological aspects of eating disorders (Connors, 1996). There may be meaningful differences on psychological variables between those who have eating disorders and those who do not. In other words, there may be a continuum for some aspects of eating disorders, but not for others. The eating disorders continuum holds true for variables that are more closely related to eating and body image, rather than the psychological issues that may be associated with anorexia and bulimia.

The continuum of food and body image includes body dissatisfaction and negative body image, weight preoccupation, and dieting. The food and body image issues (which include intense concern with weight, appearance, and body shape) may be common among people who diet and those who have eating disorders. The second set of concerns refers to psychological issues such as problems with affect (mood), low self-esteem, and insecure relationships with parents. The second set of issues may be deeper and more complex and may be issues that affect those with the more serious eating disorders—not those who do not have a diagnosis of any eating disorder.

A summary of the state of the art of the continuum follows:

> The data suggest that the normative levels of body dissatisfaction and dieting so prevalent in the current sociocultural context may be differentiated from clinically significant eating disorders on the basis of emotional disturbance.

> Body dissatisfaction and dieting behaviors could be viewed as spanning a continuum from slight to very intense. Individuals may have mild to moderate levels without other life impairment. Women with more symptoms of eating disorders seem to have high levels of body dissatisfaction and disturbed eating attitudes and behaviors in conjunction with other psychological problems, including greater levels of depression, feelings of ineffectiveness, self-criticism, impulsivity, emotional reactivity, and life impairment. (Connors, 1996, pp. 289–290)
>
> This quote means that it may take eating and body image problems along with other psychological problems to lead to the development of eating disorders. Connors (1996) also indicates that when a person has both body dissatisfaction and certain psychological issues (such as depression or a high degree of self-criticism), an eating disorder may develop, but that when body dissatisfaction occurs without psychological issues, an outcome might be normative discontent dieting. The term normative discontent is a classic phrase because it is used so often in the literature. It was first used by Rodin, Silberstein, and Striegel-Moore in 1985 to describe the pervasiveness of women and their dissatisfaction with appearance. Authors continue to describe the problem differentiating between pathological concern associated with eating disorders and cultural norms of thinness. (Herzog & Delinsky, 2001)

THE CONTINUUM AND IMPLICATIONS FOR TREATMENT OF EATING DISTURBANCES

The two aspects of the continuum (food/body issues and psychological concerns) are consistent with a two-track approach for counseling clients who have eating disturbances and disorders (Garner, Vitousek, & Pike, 1997). The first component to treatment is concerned with weight and body image, while the second track involves the psychological and emotional disturbances. Track one issues refer to weight preoccupation, body image, and eating, including binge eating and methods of purging. Track two refers to the psychological issues such as self-esteem, anxiety, depression, and family issues.

These two tracks can be used to describe treatment for all groups on the eating disorders continuum. For example, people who fall into the category of weight preoccupied may benefit from track one interventions to target unhealthy attitudes toward weight and body image. If these attitudes are not modified, individuals are likely to begin to diet. Social pressures to be thin may be addressed in a media literacy kind of intervention for people who are in the weight-preoccupied group. The two tracks of treatment may also be applied to repeat or chronic dieters. Treatment for repeat dieters should include psychoeducation about the negative effects of chronic diets.

DO NORMAL EATERS NEED TREATMENT?

In the first article to address this topic, Polivy and Herman (1987) raised the idea that treatment may be necessary for "normal eaters"; they wrote about this in an article with the provocative title, "The Diagnosis and Treatment of Normal Eating." This highlights the fact that what is societally normal eating may be quite abnormal, depending on the definition of normal. Does normal mean normative, in that it is what most people are doing? If that is true, then what is normal may include concern with weight and use of repeated diets. People who are of normal weight may feel as if they are overweight. Chronic dieting is normal in some groups. The important point of this article is that just because behavior is normal does not mean that it is okay; in fact, chronic dieting is not healthy. Dieting is the single most common factor in developing an eating disorder (Ghaderi, 2001). Many professionals in the eating disorders field have addressed the problems associated with dieting as a risk factor for the development of eating disorders.

Since dieting is a common eating style, it may be that this seems like normal eating, though it is quite a bit like disordered eating and therefore it may require treatment. Physiologically normal eating requires eating in response to hunger, which means that people must be able to accurately determine if they are truly hungry. Normal eating, simply put, is eating when you are hungry and stopping when you are full and satisfied. To learn (or relearn) to respond to hunger and satiety (being full), one must perceive them accurately. Dieters learn to ignore these normal cues; as part of their diets, they learn not to eat when hungry and to stop eating before they are full. Ignoring hunger and satiety cues creates a kind of distorted regulation of eating. Dieters fear that when they eat naturally the result will be uncontrollable binge eating and weight gain. However, uninhibited eating does not lead to overeating and binge eating. Sometimes dieters who stop dieting actually lose weight by stopping their diets. The reversion to physiologically (rather than cognitively) controlled eating ends obsessions with dieting and allows dieters to recognize that normal eating is not a threat to well-being. In *Full Lives*, Hutchinson (1993) said, "It was dieting, and not some intrinsic neurosis, that made me into a compulsive overeater. Therefore, it was dieting, not compulsive overeating, from which I really needed to recover" (p. 97).

Dieting behaviors are associated with a drive for thinness and body dissatisfaction. Reduction in dietary fat is one way in which people may attempt to lose weight. This is a strategy that is viewed as positive; there is an inherent assumption that fat avoidance is desirable and consistent with improved health. However, fat avoidance behaviors have also been associated with high levels

of eating pathology and psychosocial problems (Liebman, Cameron, Carson, Brown, & Meyer, 2001).

DOES DIETING LEAD TO BINGE EATING?

Polivy and Herman (1985) were among the first to study the relationship between dieting and binge eating. Their initial work provided a great deal of evidence that suggests that dieting causes binge eating. Recently, Stice (2001) summarized a great deal of research on the temporal relationship between dieting and binge eating, indicating that in prospective longitudinal studies dieting does seem to predate bulimic behaviors. This may be due to the "abstinence-violation effect," which means that although someone may create a set of rules about eating and restrict intake of food, when these rules are broken, it may lead to overeating or binge eating. The abstinence-violation effect means going on a diet, breaking a rule of the diet, and then binge eating.

Several experiments in which subjects were put on diets and then developed binge eating behaviors provide additional support for the idea that dieting causes binge eating. The famous Keys study (of starvation in male volunteers) showed that when people are placed on a restrictive diet, they "exhibited a persistent tendency to binge, gorging at meals to the limit of their physical capacity" (Polivy & Herman, 1985, p. 195). Successful dieting demands that physiological controls, which by themselves are conducive to a "desirable" weight level, be replaced with cognitive controls designed specifically to achieve a lower weight in line with the dieter's personal aspirations (Polivy & Herman, 1985, p. 198).

Why does dieting precede binge eating? A physiological reason is that binge eating might be the body's attempt to restore weight to a more appropriate level. This relates to the idea of set point, which holds that a person has a range of weight that is determined for them biologically. When a person gets much lower than the set point, the body may respond by developing a binge eating style. However, there may be other reasons to explain this relationship. As indicated earlier, dieting is a cognitive (thinking) kind of activity. Cognitive factors may be more important determinants of intake on a given occasion than are physical factors. In the final comment of the article, Polivy and Herman (1985) suggest that dieting is the disorder that we should be attempting to cure.

EATING DISORDER NOT OTHERWISE SPECIFIED

Serious eating problems exist in individuals who do not meet the criteria of anorexia or bulimia. In addition to understanding anorexia and bulimia, it is important to attend to those eating disorders that are assigned to the category

eating disorder not otherwise specified. This is a poorly defined large "catch-all" category (Striegel-Moore & Smolak, 2001) with 25 percent–60 percent of people presenting for treatment fitting in the "not otherwise specified" group (Andersen, Bowers, & Watson, 2001). Individuals with an eating disorder not otherwise specified can be quite distressed and need attention to the eating issues and associated psychological concerns.

As you can see, the types are defined by "falling just short of full criteria" (Herzog & Delinsky, 2001, p. 36). Type One includes females who meet all the criteria for anorexia except the individual has regular menses. Type Two is for people who meet all criteria for anorexia except that, despite significant weight loss, the individual's weight is in the normal range. Type Three includes people who meet all criteria for bulimia except that binge eating and purging or other ways to control weight gain occur at a frequency of less than twice a week or for less than three months. In Type Four, individuals of normal weight vomit after eating a small amount of food or use other inappropriate compensatory behavior. Type Five is for people who repeatedly chew and spit out food (they do not swallow it). Type Six is called binge eating disorder and is described below.

People may move from one type of eating disorder not otherwise specified to another, and from an eating disorder not otherwise specified to anorexia or bulimia. For example, in Marya Hornbacher's (1998) book *Wasted*, about her personal struggle with eating, she wrote, "I became bulimic at the age of nine, anorexic at the age of fifteen. I couldn't decide between the two and veered back and forth from one to the other until I was twenty, and now, at twenty-three, I am an interesting creature, an eating disorder not otherwise specified" (p. 2).

Eating disorder not otherwise specified is a category that concerns researchers and clinicians for several reasons. First, the large number of people who are diagnosed with eating disorders not otherwise specified makes one wonder if the criteria for anorexia and bulimia may be too restrictive. Second, insurance companies may restrict coverage for people with this diagnosis, assuming that it is less serious than anorexia or bulimia (Andersen et al., 2001). Third, some clinicians who treat eating disorders have expressed uncertainty of the methods that they should use with eating disorders not otherwise specified since the research is based on anorexia and bulimia, but rarely mentions eating disorders not otherwise specified. In fact, the Practice Guidelines for the Treatment of Patients with Eating Disorders does not make specific treatment recommendations for people with eating disorders not otherwise specified (APA, 2000b).

If there were changes that broadened the diagnostic criteria for anorexia and bulimia, there could be a significant reduction in the number of people assigned to an eating disorder not otherwise specified. Redefining anorexia and bulimia would result in an increase in the cases of both of these disorders. For

example, one criterion for the diagnosis for anorexia requires an absence of menstruation for three months. Forty-seven percent of a group of eating disorders not otherwise specified fit into this category, thus with a revision in the criteria for anorexia, they would no longer be considered eating disorders not otherwise specified. When adjustments to the criteria for anorexia and bulimia were made, only 18 percent of people with a diagnosis of eating disorder not otherwise specified remained in this category. Since the majority of influence of reducing eating disorders not otherwise specified is due to changes in the criteria for anorexia nervosa, this is described in the chapter on anorexia.

INCIDENCE AND PREVALENCE OF EATING DISTURBANCES AND DISORDERS

Epidemiology concerns the number of people who are diagnosed with a specific disorder. Here, we are concerned with the number of people who have eating disorders or disturbances of various types. Both incidence and prevalence data are available to provide estimates of the number of people who have eating disorders or disturbances. Incidence is defined as the frequency of the occurrence of a disorder; it may refer to the number of new cases of a disorder. Prevalence is defined as the number of cases of a disorder in a specific population at a specific point in time.

Eating disturbances and disorders occur in children, adolescents, adults, and the elderly, but the majority of the research has focused on people between the ages of twelve and twenty-two. In the sections s that follow, data are presented to demonstrate the number of children, adolescents, and young adults with eating disturbances. In chapters 3 and 4, data are provided on the frequency of occurrence of anorexia and bulimia. Briefly, anorexia has a lifetime prevalence of .05 percent and the prevalence reported for bulimia ranges from 1 percent to 3 percent (APA, 2000a). For bulimia nervosa, the prevalence rate is 1 to 3 percent (APA, 2000a).

Eating disorders not otherwise specified occurs in 4 percent to 6 percent of the general population (Herzog & Delinsky, 2001), thus, the prevalence of eating disorders not otherwise specified is approximately twice that of anorexia and bulimia. In addition, eating disorder not otherwise specified is the appropriate diagnosis for more than 50 percent of patients with eating disorders who present for treatment (APA, 2000b). Major epidemiological studies of eating disorders have shown that by adopting subthreshold criteria, defined as meeting all but one of the diagnostic criteria for anorexia or bulimia, the number of cases of anorexia or bulimia would more than double (Garfinkel, 1996; Garfinkel, Lin, Goering, Spegg, Goldbloom, Kennedy, Kaplan, & Woodside,

1995). Those who meet all but one of the diagnostic criteria for bulimia do not differ from those who have been diagnosed with bulimia in terms of demographic characteristics, psychiatric comorbidity, family history, or early childhood experiences (Garfinkel, 1996; Garfinkel et al., 1995). Since those with an eating disorder not otherwise specified may engage in all the same disturbed eating behaviors as those with the diagnosis of anorexia or bulimia, it is an important group that requires attention.

As for eating disturbances, studies suggest that unhealthy eating and weight-related behaviors and body image dissatisfaction exists in vast numbers of young females, as well as college students and adults. In addition, there is also increasing emphasis on eating disturbances in males (Andersen, Cohn, & Holbrook, 2000).

COLLEGE STUDENTS

College students have been the subjects in a great deal of prevalence research. For example, a group of researchers using the same instrument in four different studies of the prevalence of eating disorders in college students revealed that the prevalence of bulimia ranged from 0 percent to 3 percent, eating disorder not otherwise specified ranged from 2 percent to 5 percent and symptomatic eating issues ranged from 19 percent to 23 percent (Mintz, O'Halloran, Mulholland, & Schneider, 1997; Mulholland & Mintz, 2001). In a prevalence study of African American women enrolled in a predominately Caucasian university, 2 percent met criteria for eating disorders, 23 percent were symptomatic, and 75 percent were asymptomatic (Mulholland & Mintz, 2001). In a sample of 330 female undergraduates enrolled in psychology classes at a public university, Tripp and Petrie (2001) reported 7.6 percent met criteria for an eating disorder, 72.7 percent were symptomatic, and only 19.7 percent were asymptomatic. Likewise, using a different measure, Franko and Omori (1999) reported that in their sample of 207 female students enrolled in psychology classes, 2.4 percent fell into a group they called "probable bulimic," 6.7 percent were dieters, 23 percent were called intense dieters, 17 percent were termed casual dieters, and 51 percent were not dieters.

CHILDREN AND ADOLESCENTS

In the introduction to a book entitled *Body Image, Eating Disorders and Obesity in Youth* published in 2001, Thompson and Smolak reviewed the most recent prevalence data for children and adolescents. Three recent large surveys

of children have been conducted to assess the number of children and adolescents who have symptoms of eating disturbances.

Dieting prevalence was studied by the Heart, Lung and Blood Institute (Schreiber, Robins, Striegel-Moore, Obarzanek, Morrison, & Wright, 1996) in a study of over 2,000 black and white 9- and 10-year-old girls.

Among the 9-year-olds, 42 percent of the black girls and 37 percent of the white girls reported that they were trying to lose weight. For the 10 year olds, the corresponding percentages are 44 percent and 37 percent.

Another study that is cited often because of the large number of participants and the data available from adolescents of varying ethnic backgrounds yielded higher percentages of adolescents who report weight loss attempts of varying kinds (Serdula, Collins, Williamson, Anda, Pamuk, & Byers, 1993). Of Caucasian female adolescents, 47.4 percent were trying to lose weight, while 30.4 percent of African American and 39.1 percent of Hispanic American adolescents were also trying to lose weight. For males, the percentages were Caucasian 16.2 percent, African American 10 percent, and Hispanic 16.7 percent. Interestingly, this survey also assessed desire to gain weight and found that 26 percent of boys wanted to gain weight, along with 6.6 percent of the girls.

Field and colleagues (1999) studied a very large sample of more than 16,000 9- to 14-year-old boys and girls (93 percent of the sample was white) and found that the 44 percent of the older girls were trying to lose weight. However, they also found that 20 percent of the 9-year-old girls were trying to lose weight. Girls reported that they exercised to lose weight rather than dieted. Of the boys in this study, 17 percent of the 9year-olds and 19 percent of the 14-year-olds were trying to lose weight.

These studies suggest that there are a large number of children and adolescents who are dissatisfied with their bodies and attempting to lose (or, in some cases, gain) weight. It is important to remember that these high rates of dieting may not indicate that these individuals have eating disorders. Rather, the data suggest that many adolescents and some children have weight concerns that may be associated with unhealthy behaviors. Some of these individuals may develop symptoms of eating disorders.

After reviewing the information on prevalence on the various types of eating disorders, one might ask the question: Why is it so difficult to provide precise figures that represent the prevalence of these problems? It is impossible to come up with exact percentages for several reasons. First of all, the current percentages provided by the American Psychiatric Association are based on documented, or reported, cases of eating disorders. These numbers represent people who are receiving treatment for their eating disorder. It is very likely that many

cases go unreported or undiagnosed, which could make this number inaccurate. Second, oftentimes, young women are asked to fill out questionnaires to indicate whether they meet criteria for an eating disorder. As with any kind of self-report questionnaire, this may not be the most accurate method of determining who has an eating disorder. For example, people who have an eating disorder may be uncomfortable filling out questionnaires or may be ashamed to answer the questions honestly. Another reason is that the numbers may not accurately reflect the prevalence of the disorder in different populations. Whenever we read about percentages or prevalence rates, we should ask the question: What group did they use to get this information? For example, if we know that a group of athletes were used, with an equal percentage of African American, Hispanic, Native American, Asian American, and white females, we may have a pretty good idea that the results represent athletes from various racial backgrounds. If, on the other hand, a group of white swimmers were used, we can say that those numbers represent that population only. Some groups may be more at-risk than other groups. For example, sorority members and athletes may be more prone to develop eating problems than other populations. For this reason, we must always be aware of the group upon which results are based.

BINGE EATING DISORDER

Binge eating disorder, in the eating disorder not otherwise specified category, involves recurrent episodes of binge eating in the absence of regular use of purging, fasting, or excessive exercise, which are also characteristic of bulimia (see criteria). Binges are characterized by some of the following: rapid eating, eating until uncomfortably full, eating when not hungry, eating alone to avoid embarrassment about how much food is eaten, and feeling disgusted, depressed, or guilty when overeating. People with binge eating disorder are concerned about their binge eating, including concern about the long-term effects of binge eating on the body. In addition, in order to have binge eating disorder, the binges must occur an average of two times a week for at least six months. Finally, binge eating disorder is not diagnosed when the person meets the criteria for anorexia or bulimia.

Binge eating disorder is also more prevalent than anorexia or bulimia. The overall prevalence of binge eating disorder taken from weight-control programs is 15 percent to 50 percent (with a mean of 30 percent; APA, 2000a). Less is known about the prevalence of this disorder in the general population. In samples taken from the general community, the prevalence of binge eating disorder ranged from .7 percent to 4 percent (APA, 2000a), though some researchers believe that the number is much greater. Some researchers say that there is no

doubt that binge eating will be increasingly recognized as a clinical problem and will be the object of additional research.

There has been more attention to binge eating disorder than any of the other types of eating disorder not otherwise specified. Although binge eating disorder is not common in adolescents or college students, a few paragraphs are included to define and describe this eating disorder. Binge eating disorder may be associated with depression and anxiety (APA, 2000a). It appears that binge eating disorder often begins following a significant weight loss from dieting. Some people report that they feel numb or spaced out by the binge episodes. Binge eating disorder is associated with obesity; this makes sense when you remember that this is a disorder of binge eating without any kind of purging or other way to compensate for the calories consumed in the binges. Many people with binge eating disorder have been struggling with weight issues for many years and have repeatedly dieted and experienced failure in their ability to lose weight and keep the weight off. Females are 1.5 times as likely to have binge eating disorder than males but note that the female/male ratio in binge eating disorder is much closer to even than in either anorexia or bulimia. The onset of binge eating disorder occurs more frequently in adults than in adolescents (APA, 2000a). Binge eating disorder appears to be a chronic kind of disorder, which means that it recurs in the lifetime.

Case of Binge Eating Disorder

Mr. Cohen is a thirty-seven-year-old man who weighed 272 pounds at 5 feet 9 inches tall. He sought therapy for weight loss related to a job promotion. Mr. Cohen indicated that he had gained 60 pounds in a year and he "ate all the time." He explained that he dieted and could lose weight in the past, but now he could not generate the willpower. Mr. Cohen thought that having someone weigh him each week would help him to start to lose some weight. Mr. Cohen had some interesting things to say about guilt. "My guilt drives me here, but why do I feel so guilty? Why is it so out of proportion to what I have done? It is not that terrible to overeat and yet I feel it is." Through counseling, it was difficult to discover what triggered Mr. Cohen's overeating. It seemed as though he ate when he was frustrated and also ate when he felt like he had made a significant achievement. He did manage to lose some weight and began to feel better. The weekly weigh-in and attention in psychotherapy may have been helping. But, after New Year's Day, Mr. Cohen reported a food binge—after he cashed his paycheck, he kept $100 and "everything just seemed to go blank . . . all of my good intentions just seemed to fade away I . . . just said 'what the hell' and started eating and what I did then was an absolute sin." He ate a

cake, several pieces of pie, and several boxes of cookies, which he ate while he drove his car around town. He ate quickly, in a kind of frenzy. Then he visited a series of restaurants, eating a little bit in each. When he described this binge, he said that he didn't enjoy it but that he couldn't stop it. He said that a part of him just blacked out (Stunkard, 1993, pp. 18–21).

These food binges described in this case were part of Mr. Cohen's food problems. They also became a part of the history of binge eating disorder, since the therapist that he saw was Dr. Albert Stunkard, who is now well known for his work in binge eating disorder.

SUMMARY

The eating disorders continuum is a way to think about the various kinds of eating problems. The continuum of eating disorders and disturbances places normal eating at one end of the spectrum (asymptomatic), eating disorders at the opposite end, and eating disturbances at intermediate points. The continuum continues to be a useful way to explain the difference between eating disturbances and eating disorders and how people may move from eating disturbances to disorders. BRIDGE (Building the Relationship between Body Image and Disordered Eating Graph and Explanation) is a graphical presentation that links attitudes and behaviors on the continuum of eating disturbances and disorders. In addition to understanding these well-known eating disorders, it is important to attend to those eating disorders that are assigned to the category called eating disorder not otherwise specified. Anorexia nervosa, bulimia nervosa, and eating disorder not otherwise specified (including binge eating disorder) are all disorders of eating.

DSM-IV-TR Criteria for Eating Disorder Not Otherwise Specified

The Eating Disorder Not Otherwise Specified category is for disorders of eating that do not meet the criteria for any specific eating disorder. Examples include:

1. For females, all of the criteria for anorexia nervosa are met except that the individual has regular menses.
2. All of the criteria for anorexia nervosa are met except that, despite significant weight loss, the individual's weight is in the normal range.
3. All of the criteria for bulimia nervosa are met except that the binge eating and inappropriate compensatory mechanisms occur at a frequency of less than twice a week or for a duration of less than 3 months.

4. The regular use of and inappropriate compensatory behavior by an individual of normal body weight after eating small amounts of food (e.g., self-induced vomiting after the consumption of two cookies).
5. Repeatedly chewing and spitting out, but not swallowing large amounts of food.
6. Binge eating disorder: recurrent episodes of binge eating in the absence of the regular use of and inappropriate compensatory behaviors characteristic of bulimia nervosa. (APA, 2000, p. 594 Reprinted with permission from the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision.* Copyright 2000 American Psychiatric Association.)

DSM-IV-TR Criteria for Binge Eating Disorder

A. Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following:

   (1) eating, in a discrete period of time (e.g., within any 2-hour period), an amount of food that is definitely larger than most people would eat during a similar period of time and under similar circumstances
   (2) a sense of lack of control over eating during the episode (e.g., a feeling that one cannot stop eating or control what or how much one is eating)

B. The binge-eating episodes are associated with three (or more) of the following:

   (1) eating much more rapidly than normal
   (2) eating until feeling uncomfortably full
   (3) eating large amounts of food when not feeling physically hungry
   (4) eating alone because of being embarrassed by how much one is eating
   (5) feeling disgusted with oneself, depressed, or very guilty after overeating

C. Marked distress regarding binge eating is present.
D. The binge eating occurs, on average, at least 2 days a week for 6 months.
E. The binge eating is not associated with regular use of inappropriate compensatory behavior (e.g., purging, fasting, excessive exercise) and does not occur exclusively during the course of anorexia nervosa or bulimia nervosa. PORNOGRAPHY, INTERNET, GAMING, AND GAMBLING

Chapter **9**

Addiction to Pornography: Its Psychological and Behavioral Implications[1]

Robert W. Kubey, PhD

In addition to the Internet and video games another form of media content often claimed to be addictive is pornography. Nonprint pornography has experienced an enormous growth in recent decades, and the opportunities for serious habits involving these materials have clearly increased. Where once only a small minority of interested parties could afford to buy or rent films, or venture into public theaters of dubious quality and atmosphere, for nearly three decades there has been an explosion in the availability of pornography. Here, the use of the word "explosion" is hardly hyperbolic. This is now a huge, multi-billion-dollar growth industry, and even a five-year old child staying with his parents in a hotel room can see signs that it exists from the ads sitting atop the TV, unless a vigilant parent puts them in a drawer the minute the family checks into the room.

With the advent of interactive pornography and live, visual, sexual chat rooms and live video sites, the debate over the value or harm of pornography has heated up over and over again in the last decades, yet it is questionable whether the research literature has been able to keep pace. When we get to the quality of research, the issue becomes more problematic, as at least in the opinion of this observer, some researchers appear to have found it difficult to steer clear of the political controversies surrounding this highly volatile topic.

It can also be very hard to obtain good, unbiased, and honest data from people who use pornography, who potentially have a problem with it, or who have committed sex crimes. Sexuality is always a challenging area for researchers, and clearly determining whether someone is addicted to pornography may not

be so simple. As I have done in applying the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (*DSM–IV–R)* to understanding so-called television addiction (see chapter 2 in this volume), readers might wish to consult Irons and Schneider (1996), who have adapted the *DSM* for the analysis of sexual addictions, though they have little to say about pornography.

The federal government sometimes funds studies in order to inform lawmakers and set policy on pornography, but going back at least to the Nixon administration, the government or party in power, at least in the U.S. situation, sometimes appears to wants to see certain results emphasized in research or official government studies, and in some instances certain findings that disagree with administration policy may be disowned or eschewed and, some believe, even suppressed. This politicization of media effects issues has been evident for an even longer period in the debate over the impact of violence in film and television, and in many of the same ways.

That said, I will review some of the alleged effects of pornography and the ways in which an addiction to pornography may develop. This chapter will focus as well on concerns that I believe are raised by the delivery of new media forms and interactive erotica.

As with other media effects debates, it is very difficult to disentangle cause from effect. Still, a number of researchers and clinicians report both negative effects *and* evidence for dependence, or in their words, *addiction*, with regard to the use of pornography (Oddone-Paolucci, Genuis, & Violato, 2000; Zillmann, 2004). As will be seen, some of the negative effects are thought to be intertwined with pornography addiction. Those interested in a dissenting research view, one that holds that pornography might be a much more benign influence in people's lives, might consult Daniel Linz's (2004) work.

Now to some of the claims. One claim is that large private pornography collections are often found by authorities in the residences of persons arrested for sexual crimes (Cline, 1994; Reed, 1994), especially pedophiles (Lanning & Burgess, 1989). There is also evidence indicating that some rapists and child molesters use sexually explicit materials both before and during sexual assaults (Marshall, 1988). At a minimum, it does seem that there is a relationship between the frequent use of pornography and problematic sexual disorders for some individuals. Whether the pornography is merely symptomatic of the disorder, or plays a causal role, is much more difficult to establish.

Still, for some, there is little doubt that both negative effects and pornography addiction do indeed occur. Reed (1994), a practicing psychiatrist, is explicit in his presentation of specific criteria that he believes would constitute an addiction to pornography. He notes that the *DSM* itself recognizes that

many *paraphilias* (compulsive sexual deviances) frequently involve the use and collection of pornography. Reed lists 13 paraphilias and the ways in which they are related to the use of pornography.

Cline (1994), a clinical psychologist who has treated hundreds of people with sexual disorders, describes a four-step process in the involvement of his patients with pornography. First described is an "addiction effect," in which the person comes back repeatedly for more material because it provides "a very powerful sexual stimulant or aphrodisiac effect followed by sexual release most often through masturbation" (p. 233).

Cline goes on to describe an "escalation effect," in which there is an "increasing need for more of the stimulant to get the same effect" obtained initially (p. 233). Third, he observes "desensitization," in which things that might have once seemed shocking become less so and are thereby legitimized. Fourth, Cline claims that there is an "increasing tendency to act out sexually the behaviors viewed in the pornography" (p. 234).

A number of psychological and physiological mechanisms have been posited to explain how pornography addiction might develop. Among the most common is sexual gratification as a powerful reinforcer (Lyons, Anderson, & Larson, 1994). This is the "addiction effect" described by Cline, in which learning is made all the more powerful by virtue of the sexual release that attends pornography's use. Here, Cline draws on McGaugh's (1983) memory research suggesting that experiences that co-occur with high emotional and physical arousal may be better remembered. Reed (1994) suggests the possibility that some such learning might be occurring on the biological as well as the psychological level when he points out that "the neurotransmitters that are activated by pornography use may trigger similar neural pathways as cocaine or heroin" (p. 265).

Of note is a trade book by Dodge (2007), arguing that the neuroplasticity of the brain can enable an addiction to Internet- or other-mediated pornography that can leave the user with a typical pattern of less enjoyment over time, as a result of which the user looks for new forms of excitement (pp. 102–112).

In my chapter on television addiction, I applied an operant conditioning approach to the role relaxation plays in the development of the television viewing habit. It certainly makes sense that the pleasure accompanying orgasm may increase the potential for a habit to develop for some users of pornography, especially those who have few other outlets for sexual gratification. The early literature on sexual behavior points to strong associations developing between the particular ways in which first or early sexual gratifications were obtained and the object or means of that gratification (Ellis, 1906/1936). According to Ellis and the research he cites in this early, seminal work, well before Kinsey's,

if one's primary means of sexual gratification at an early and impressionable age is via a particular technique or a particular object of desire, then there may be a kind of fixation on that technique and/or object.

Cline argues further that if sexual problems can be alleviated in sex-counseling clinics with the use of sexual films, books, and videos as tools in therapy, then one must suspect that exposure to pornography can also have an effect. For Cline, and for many other observers, pornography provides powerful occasions on which modeling and imitative learning can occur.

Zillmann and Bryant (1988b) have made an important experimental contribution to the addiction hypothesis by showing that prolonged exposure to pornography can decrease some people's level of satisfaction with their partners and with the quality of their sex lives. Zillmann (1994) has gone on to propose that in many instances, "initial sexual dissatisfaction drives exposure to pornography" and a vicious circle ensues. With the consumption of pornography, the dissatisfaction grows stronger and draws the person into further consumption. For Zillmann, consumption of pornography invites comparisons that help drive dissatisfaction: "consumers compare what they have, by way of sexual intimacy, with what pornography tells them they might and should have" (1994, p. 210).

I have proposed, similarly, that the frequent presentation of highly romanticized and sexually arousing material on television, and elsewhere in our mainstream contemporary media, may fuel similar dissatisfactions and a propensity toward invidious comparison in a much broader spectrum of the population than was previously the case (Kubey, 1994, 1996; see also Bryant & Rockwell, 1994).

Other effects of pornography, aside from dependence—or addiction—and modeling, have .been studied and merit comment. Weaver (1994) has reviewed evidence indicating that exposure to pornography increases sexual callousness toward women. This callousness includes increased aggressivity toward women as well as a desensitization to the injury that violence or sexual assault causes.

Zillmann and Bryant have been interested in the degree to which so-called family values may be on a collision course with pornography, and they again offer experimental evidence. These studies (see Zillmann, 1994, for a review) typically expose an experimental group of adults to pornographic videos over a number of weeks (often six). Then, a week after the exposure, the group's answers to survey questions are compared with those of a control group that was not exposed.

The researchers' studies show that experimentally produced prolonged exposure to pornography results in a greater acceptance of both male and female promiscuity, and that as promiscuity is presumed to be more natural, adults also begin to assume that faithfulness among sexual intimates is less

common than is assumed by those in the control group. The participants in the experiment also report being more accepting of nonexclusive sexual intimacy for themselves.

In one study, when asked, "Do you feel that the institution of marriage is essential to the well-functioning of society?" 60 percent of the control group answered in the affirmative, but this was true for only 38.8 percent of the group exposed to pornography. Zillmann and Bryant (1988a) have also reported that exposure to pornography reduced the desire of their research participants, male and female, student and nonstudent, to want to have children. Zillmann (1994) suggests that this finding may

> Support the contention that prolonged consumption of pornography makes having children and raising a family appear an unnecessary inconvenience—presumably because pornography continually projects easy access to superlative sexual gratification, these gratifications being attainable without emotional investment, without social confinements, without economic obligations, and without sacrifices of time and effort. (p. 208)

In this regard, the immediate gratification that standard commercial television drama and film so frequently offers and promotes may in its own right be in conflict with the values of constancy and commitment so necessary to the healthy functioning of family life (Kubey, 1994). While this research is intriguing, I can't help but editorialize and wonder how internal review boards at universities permit research to be conducted on undergraduate populations if a propensity toward promiscuity is the known, and expected (from prior research trials), result in the experimental group. This work has been replicated; it is interesting to ponder the ethics of such work, and yet its importance, and the challenge of how to do this work without exposing people to the very material that one might hypothesize will be injurious.

As noted, new technologies have led to an explosion in pornography. And, if a pornography habit—or addiction—can indeed develop, it would seem more likely to develop if pornographic materials can be easily obtained.

It is not difficult to imagine how young people can come into contact with such materials. Even if a 12-year-old boy cannot rent a pornographic video on his own, it may well be that his friend's older brother, who is 16 but looks 18, can. And, of course, an increasing number of parents own such materials and keep them in their homes. In addition, such materials are available on many cable channels, if parents do not block them or if the child wishes to order material and suffer the consequences, if there are any, later.

While I do not personally frown on all uses of pornography, I do believe that it is not to be recommended for certain audiences. I believe it is unwise for

a 12-year-old boy to experience hard core pornography, especially as it is likely to be one of his very first exposures to sexual intimacy and such intense sexual experiences at a young age may constitute powerful early occasions for learning and impression formation.

Zillmann and Bryant's work suggests that such materials might also prove detrimental in the formation of a boy's impressions of female sexuality, since most such pornography depicts women as sexual objects whose primary goal is to serve the sexual desires of men. An occasional viewing of such materials by a pubescent or prepubescent boy might not have any strong or deleterious effects. But when we recognize that some boys may view such material every few days, or even more often, and if we add that some boys typically seek and obtain sexual release upon viewing, I believe we raise the possibility not only that a strong habit or "addiction" may develop, but also that it may be one we would not want to encourage, especially when we consider that this same boy is likely to begin having his first real sexual experiences with a girl or young woman in the not so distant future.

These concerns are multiplied when we consider the arrival of interactive erotica. An early interactive offering was called Virtual Valerie. Here, computer-generated, movie-quality images of young women take their clothes off at the command of the viewer. Women on the screen can also be programmed at the touch of a button to say arousing things to the viewer, as well as to perform a variety of sexually suggestive acts before the viewer's eyes.

Let's return again to our 12-year-old boy. Imagine that he has obtained some interactive video products like Virtual Valerie. Imagine that he interacts with them while masturbating several times a week, typically spending 10 to 30 minutes in each encounter, off and on, for a few years before, at age 15, he has his first intimate encounter with an *actual, real-life* young female of the same age. Might his expectations of how she will act and how he should act if they become intimate have been altered by the many hours spent with his interactive pornography disks?

I don't believe we know the answer. Conceivably, this form of pornography may have positive effects. Perhaps it will help some people fantasize and obtain sexual release in such a way that there is a reduction in the commission of sexual crimes (see Linz and Malamuth, 1993, for a review of research on the positive, cathartic effect of traditional pornography). Still, combining common sense with what we know about the learning of sexual behavior, I must say that I am concerned about young people, as well as some adults, overusing, and perhaps becoming dependent on or "addicted" to, such a form of entertainment.

Chapter **10**

Assessment and Treatment of Internet Addiction

Kimberly S. Young, PhD

Notions of technological addictions (Griffiths, 1996) and computer addiction (Shotton, 1991) have previously been studied in England. However, when Internet addiction was first introduced in 1996 at the American Psychological Association meeting (Young, 1996), it sparked a controversy among clinicians and academicians alike.

In contrast to chemical dependency, the Internet offers several direct benefits as a technological advancement in our society, rather than a device to be criticized as addictive (Levy, 1997). These benefits range from practical applications including conducting research, performing business transactions, accessing libraries, communicating with colleagues, and making vacation plans. Books have been written outlining the psychological as well as functional benefits of the Internet in our daily lives (Rheingold, 1993; Turkle, 1995). By comparison, chemical dependence is not an integral part of our professional lives, nor does it offer any direct benefit.

Furthermore, many researchers argued that the term *addiction* should be applied only to cases involving the ingestion of a drug (e.g., Rachlin, 1990; Walker, 1989). However, defining addiction has moved beyond this to include a number of behaviors that do not involve an intoxicant: these include compulsive gambling (Griffiths, 1990), video game playing (Keepers, 1990), overeating (Lesuire & Blume, 1993), exercise (Morgan, 1979), love relationships (Peele & Brodsky, 1975), and television viewing (Winn, 1983). Over the past decade, a growing body of peer-reviewed literature has adopted the term *Internet addiction,* and its acceptance as a legitimate disorder has grown (e.g., Ferris, 2001; Greenfield, 1999; Hansen, 2002).

DIAGNOSIS

The Internet is a highly promoted technological tool, making the detection and diagnosis of addiction difficult. Therefore, it is essential to understand the criteria that differentiate normal from pathological Internet use. Proper diagnosis is often complicated by the fact that there is currently no accepted set of criteria for addiction listed in the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, fourth edition (*DSM–IV*, 1994). Of all the diagnoses referenced, pathological gambling was viewed as most akin to compulsive Internet use, being defined as an impulse-control disorder that does not involve an intoxicant. In what is known as the Internet Addiction Diagnostic Questionnaire (IADQ), Young (1998a) developed the first screening instrument, which outlined the following criteria:

1. Do you feel preoccupied with the Internet (think about previous online activity or anticipate next online session)?
2. Do you feel the need to use the Internet with increasing amounts of time in order to achieve satisfaction?
3. Have you repeatedly made unsuccessful efforts to control, cut back, or stop Internet use?
4. Do you feel restless, moody, depressed, or irritable when attempting to cut down or stop Internet use?
5. Do you stay online longer than originally intended?
6. Have you jeopardized or risked the loss of significant relationship, job, educational or career opportunity because of the Internet?
7. Have you lied to family members, therapist, or others to conceal the extent of involvement with the Internet?
8. Do you use the Internet as a way of escaping from problems or of relieving a dysphoric mood (e.g., feelings of helplessness, guilt, anxiety, depression)?

When using the IADQ, only nonessential computer/Internet use (i.e., use that is not for business purposes or academically related) should be evaluated, and addiction is present when clients answer "yes" to five (or more) of the questions over a six-month period. This list of questions offers a workable definition of Internet addiction to help us differentiate normal from compulsive Internet use, but the warning signs can often be masked by cultural norms that encourage and reinforce Internet use. Thus, even if a person meets all eight criteria, signs of abuse can be rationalized away as "I need this for my job" or "It's just a machine," when in reality the Internet is causing significant problems in a user's life.

While time is not a function in diagnosing Internet addiction, addicts are generally are excessive in their online usage, spending anywhere from 40 to

80 hours per week on the Internet, with sessions that could last up to 20 hours at a time. Sleep patterns are disrupted due to late night log-ins, and addicts generally stay up surfing until two, three, or four in the morning despite having to wake up early for work or school. In extreme cases, caffeine pills are used to facilitate longer Internet sessions. Such sleep depravation causes excessive fatigue, impairing academic or occupational performance, and may affect the immune system, leaving the addict vulnerable to disease. Sitting at the computer for such prolonged periods also means that addicts aren't getting the proper exercise, and sometimes addicts are at increased risk for carpal tunnel syndrome.

Like alcoholics who need to consume greater levels of alcohol in order to achieve satisfaction, addicts routinely spend significant amounts of time online. Furthermore, addicts will go to great lengths to mask the nature of their online activities, primarily to conceal the extent and nature of the behavior. In most cases of impulse-control disorder, an individual's compulsion is often associated with increasingly painful states of tension and agitation that is relieved through the completion of the act. For example, an alcoholic is driven to drink or an overeater is driven to binge on food during moments of tension. In each case, the compulsive behavior serves to reduce the underlying emotional tension and serves to reward behavior. In the same manner, an Internet addict's use of the computer is less about using it as an information tool and more about finding a psychological means to cope with life's problems.

SUBTYPES OF ONLINE ABUSE

The Internet is a term denoting a variety of functions accessible online, such as the World Wide Web (WWW), chat rooms, instant messaging systems, interactive games, virtual casinos, online auction houses, news groups, and databases. Internet addicts typically become addicted to a particular application that acts as a trigger for excessive Internet use. Internet use becomes focused on a particular chat room, a particular online game, a particular virtual casino, or a particular set of adult sites. Early attempts to categorize the behavior suggested that the patterns of use fall into four major subtypes: online abuse, cybersex addiction, online affairs, online gaming, and Internet gambling. An overview of each is provided below.

Cybersex Addiction

Individuals who suffer from cybersex addiction are typically engaged in viewing, downloading, and trading online pornography or are involved in

adult fantasy role-play rooms. Adult Web sites comprise the largest segment of online development and electronic commerce, catering to a wide variety of sexual interests. Given the extensive availability of sexually explicit material online, cybersex addiction has been the most common form of problem online behavior among new users (70%) and has a high relapse rate among prior sexual compulsives (55%) (Young, 2001).

Young (2001, p. 36) stated that "computer-enabled fantasies are highly reinforcing and the addict's preoccupation with sexual arousal stems from his own imagination and fantasy history." The association of the Internet with sexual arousal is so potent that it transforms the Internet from a practical business or research device into a modern-day sex toy. Sometimes, just recalling the potent images of one's last online episode triggers arousal and reinforces the notion that cyberspace is an open gateway to immediate sexual fulfillment; as one addict explained, "I get a major erection just clicking on my computer." Based upon her studies, Young describes five interdependent stages of cybersex addiction that highlight how users utilize the Internet as a progressive means of escape as part of an addiction cycle: discovery, experimentation, escalation, compulsivity, and hopelessness.

In the discovery stage, the discovery that adult Web sites and chat rooms exist is made by the user. A man doing research online may accidentally bump into a pornographic Web site or a woman may enter a social chat room and meet a man who entices her to have cybersex. In either case, the person discovers the sexual thrill of the act, which opens the door for further exploration. In the experimentation stage, the user may secretly begin to explore and experiment online without the fear of being caught. Users feel encouraged and validated by acceptance of the cyberspace culture, especially when, cloaked in the anonymity of the computer screen, they may feel less accountable for their actions over the Internet (Cooper, Putnam, Planchon, & Boies, 1999). Within the anonymous context of cyberspace, conventional messages about sex are eliminated, allowing users to play out hidden or repressed sexual fantasies in a private lab.

In the experimentation stage, a curious person may be completely unprepared when she steps into one of many sites specifically designed for the purposes of facilitating sexual experimentation. Web site names such as the "Hot Sex Room," the "Fetish Room," or the "Bisexual Room" may intrigue the casual browser, who is initially shocked but at the same time titillated by the permissiveness of others engaged in virtual sex. Such virtual environments may be more seductive than most users anticipate, providing short-term comfort, distraction, and/or excitement. Users begin to dabble in darker or more deviant types of sexual material online. Furthermore, online experiences occur in the privacy of one's home, office, or bedroom, facilitating the perception of anonymity and the idea that Internet use is personal and untraceable.

In the escalation stage, the behavior becomes more chronic and pronounced, such that the addict becomes saturated with a continuous stream of sexual content that can take on riskier and riskier forms. Most people do not yet realize that there is any risk involved in engaging in online sexual pursuits. While in some ways such engagement may seem like a journey into foreign territory, online sexual behaviors occur in the familiar and comfortable environment of home or office, thus reducing the feeling of risk and allowing even more adventurous behaviors (Young, 2001).

In the compulsivity stage, the user engages in more constant sexual behavior online, downloading hundreds or thousands of pornographic images, or meeting people for the sole purpose of having cybersex in online sex chat rooms. Just as the alcoholic requires larger doses of the drug to achieve the same sensation and pleasure from the experience, the online addict now looks for the next big virtual thrill, perhaps engaging in more extreme sexual fantasies online.

In the hopelessness stage, in order to deal with the double life that develops, the addict often rationalizes the behavior and disowns what he says or does online with self-statements as, "It's just a computer fantasy" or "This isn't who I really am." Addicts detach themselves from the online sexual experience and perceive their secret fantasy world as a parallel life that is completely separate from their identity in real life. They may also progress into more sexually deviant topics that they would normally find reprehensible but that over time become acceptable as they become increasingly desensitized to the experience. The addict becomes preoccupied with the computer, attempts to conceal the nature of his online activities, and continues to engage in the activity despite its known potential risks, including possible job loss, divorce, or arrest. In one such case, a 34-year-old minister arrested for possession of child pornography obtained from the Internet explained, "I soon discovered the vast array of pornography, including child pornography, available on the Internet. My attraction to pornography on the computer was born of sheer amazement at the volume of available material and this amazement turned to fascination and ultimately to obsession. I knew it was wrong. My life became a lonely, isolated mess. I realized that I could lose my job, my marriage, and the respect of everyone I love if I was caught. I have two daughters and would never think about doing anything inappropriate with them, but I could not bring myself to stop, despite knowing the consequences of my actions."

Online Affairs

Individuals who become overinvolved in online relationships through instant messaging, chat rooms, voice-over Internet, and e-mail are at risk for developing an addictive pattern in these relationships. Online friends quickly become

more important to an individual, often at the expense of real-life relationships with family and friends. Among married couples, this can lead to online affairs. Married users may utilize interactive online environments to seek out support, comfort, and acceptance that provide them with a sense of belonging in a non-threatening manner.

Online affairs are among the most common consequences of online addiction. At an alarming rate, long-term and previously stable marriages are destroyed by intimate words shared over the computer. An online affair can be defined as a romantic and/or sexual relationship that is initiated via online contact and maintained predominantly through electronic conversations that occur through e-mail, chat rooms, or interactive games (Young, 1999). These virtual communities allow strangers from all over the world to meet instantly 24 hours per day, seven days a week, creating a breeding ground for online affairs. Young (1998b) found that serious relationship problems were reported by 53 percent of Internet addicts surveyed that led to marital discord, separation, and even divorce. However, the scope of the relationship problems caused by the Internet can be undermined by its popularity and advanced utility.

Online affairs differ dynamically from real-life affairs and are potentially more seductive. Given the global nature of the Internet, online affairs can be culturally diverse and consequently seem more glamorous than the people one already knows in day-to-day living (Greenfield, 1999). Electronic communication allows individuals to feel less inhibited, which accelerates perceived intimacy. Online, people are more likely to be open, honest, and forthright, revealing personal truths, and the intimacy that might take months or years to develop in an offline relationship may only take days or weeks online (Cooper & Sportolari, 1997). A friendly online conversation can quickly turn erotic, allowing users to share private sexual fantasies with one another; this can be accompanied by self-stimulation to heighten the sexual experience (Young, 1998a).

Seemingly harmless online relationships can easily progress to secret phone calls, letters, and offline meetings, and getting one's needs met through an online affair can adversely impact one's marriage. Clinicians are increasingly seeing cases of couples seeking counseling to deal with an online affair (Young, 2004), and online infidelity has accounted for a growing number of divorce cases. According to the American Academy of Matrimonial Lawyers (Quittner, 1997), 63 percent of lawyers surveyed reported that the Internet has played a significant role in the divorces they have handled during the past year (AAML, 2002). Unlike affairs that happen outside the home, online affairs occur in the home, often while an unsuspecting spouse is sitting in the next room. The warning signs of an online affair are often masked with the claim of legitimate

or necessary use of the computer. For instance, a spouse may begin to come to bed in the early morning hours or they leap out of bed an hour or two early to use the computer for a prework e-mail exchange with a new romantic partner. If a spouse begins an affair, whether online or offline, that spouse will usually go to great lengths to hide the truth from a partner. In the case of an online affair, the attempt to hide the truth usually leads to a need for greater privacy and secrecy surrounding computer use. The computer may be moved from a visible den to a secluded corner of a locked study, or the password may be changed. If disturbed or interrupted when online, unfaithful spouses may react with anger or defensiveness to conceal the extent of their online involvement (Young, 1998a).

Some online affairs can evolve into phone sex or real-life meetings, but even the process of sharing one's sexual fantasies online can alter patterns of sexual interest. If chats with an online lover also include masturbation, a person may suddenly show a reduced interest in sex with a real-life partner; this may be one of the signs that an individual has found another sexual outlet online. Often, people who engage in online affairs are less enthusiastic, energetic, and responsive with regard to lovemaking with a real-life partner and prefer the newness and excitement of virtual sexual stimulation (Young, 2004).

Online Gaming

Massive multiuser online role-playing games, or MMORPGs as they are often called, are one of the fastest growing sub-areas of Internet addiction among children and teens. Parents across the globe are increasingly concerned about their sons' and daughters' online gaming habits (Young, 2004). They are sure that there is a problem, but counselors unfamiliar with online gaming addiction often do not understand how seductive such games can be. As one parent explained, "I had gone to my son's guidance counselor, the school psychologist, and two local addiction counselors. None of them ever heard of World of Warcraft, much less someone becoming addicted to it. They told me it was a phase and that I should limit my son's game playing. They didn't understand that I couldn't. He had lost touch with reality. He lost interest in everything else. He didn't eat, sleep, or go to school. The game was the only thing that mattered to him."

Parents often feel alone and scared as their children become hooked on something that no one seems to understand. "I couldn't believe it when my therapist told me to just turn off the computer. That was like telling the parent of an alcoholic son to tell him to just stop drinking. It wasn't that simple. We felt like no one was taking us seriously, that our son had a real problem."

Like those addicted to alcohol or drugs, gamers show several classic signs of addiction. They become preoccupied with gaming, lie about their gaming use, lose interest in other activities just to game, withdraw from family and friends to game, and use gaming as a means of psychological escape (Young, 1998b). Because of their addiction, gamers become defensive about their need to play the game and angry when forced to go without it. Parents who try to put time limits on the game describe how their sons and daughters become angry, irrational, and even violent. Gamers who can't access the game experience a loss. They want to be on the game and they miss playing the game. This feeling can become so intense that they become irritable, anxious, or depressed when they are forced to go without the game (Young, 1998b). They can't concentrate on anything except going back online to play. Their minds become so fixated on the game that they can experience a psychological withdrawal from the game. As their feelings intensify, they stop thinking rationally and begin to act out toward other people in their lives, especially a parent or anyone who threatens to take the game away.

Internet Gambling

Online casinos have practically overnight sprung up and turned into a multi-million-dollar business, attracting a large number of gamblers worldwide. Compulsive gambling has been around for decades, but now access and opportunity have greatly increased with the invention of Internet gambling, bringing with it a new form of addictive behavior. The global nature of the Internet, combined with the limited, if not nonexistent, ability of local governments to effectively regulate or ban online gambling, will have profound psychological and social consequences. "It's fun. It's exciting. It's glamorized on TV and in the media in a way that other addictions are not," states the National Council on Problem Gambling (2008), referring to the traditional gambling that takes places in casino-rich places like Las Vegas and Atlantic City. Today, all anyone needs is a computer and the Internet to access the thousands of online casinos.

There are now an estimated 1,700 gambling Web sites on the Internet. As well as using the Internet, users can gamble through interactive television and mobile phones. The convenience of gambling at home, the ease of setting up an online gambling account, and the variety of Internet gambling opportunities, ranging from traditional betting to casino gambling and lotteries, makes online gambling very appealing (Petry, 2006).

However, while many people gamble online without developing any problems, several factors make online gambling more seductive for teens, increasing their risk of developing a gambling problem:

- The ability to gamble 24 hours a day.
- The access underage children have to gambling sites.
- The absorbing nature of computers, leading teens to online casinos in the first place.
- The decrease in perception of the value of cash—i.e., players forget that they are spending money.

According to the National Gambling Impact Commission (1998), the national lifetime gambling population is no less than 1.2 percent of the total population (2.5 million). That would make gambling twice as prevalent as cancer among Americans. In mature gambling markets such as Nevada, more than 5 percent of the population will develop some problem with gambling, a prevalence rate about five times that of schizophrenia and more than twice that of cocaine addiction. According to the National Coalition against Legalized Gambling, young children and teenagers are at the greatest risk of developing a problem with Internet gambling. Some recent estimates they suggest are as follows:

- 16–24-year-old males comprise 4% of Internet gamblers; and
- 11–18-year-old males comprise 4–7% of Internet gamblers

Teen gambling has a special appeal as television shows promote the fun associated with poker or Texas Hold Um. Teenagers' access to these televised poker shows makes them believe that gambling is harmless fun and not potentially addictive.

Teens experiencing a problem with Internet gambling start to become preoccupied with gambling, causing disruptions in their personal, family, and social lives. Petry (2006) found that teen Internet gamblers were more likely to have a serious problem with gambling than other gamblers. Furthermore, teen Internet gamblers were more likely to suffer from health and emotional problems such as substance abuse, circulatory disease, depression, and risky sexual behaviors. As teens and preteens go online with greater frequency, the risk of addiction in various forms becomes greater. Old favorites such as sports betting and casino games still dominate the Internet, but in the future there will be more opportunities that could draw new gamblers into the fold. People can go online and bet about whether Brad Pitt and Angelina Jolie will get married or whether Tom Cruise and Katie Holmes's marriage will last. They can bet on the outcome of the Oscars or who will win on *Survivor*. These are the new kinds of bets that are placed by people who might not normally visit a gambling site.

RISK FACTORS

While most agree that the Internet is a productive tool, research findings document serious negative consequences when it is used in an addictive

manner. In particular, recent research suggests that compulsive use of the Internet is associated with increased levels of social isolation, increased depression, familial discord, divorce, academic failure, job loss, or significant financial debt as a result of obsessive online gambling, shopping, or gaming (e.g., Cooper, Putnam, Planchon, & Boies, 1999; Cooper, Scherer, Boies, & Gordon, 1999, Orzack, 1999).

Despite the consequences, addictions accomplish something for the person, however illusory or momentary the benefits may actually be. Underlying Internet addiction is the anonymity of electronic transactions, which provide a virtual context that cultivates a subjective escape from emotional difficulties (e.g., stress, depression, anxiety) or problematic situations or personal hardships (e.g., job burnout, academic troubles, sudden unemployment, marital discord).

As the addiction cycle grows, the Internet becomes a way for the addict to self-medicate in order to temporarily run away from life's problems. Over time, however, this coping mechanism proves to be unproductive and potentially harmful, as the issues hidden by the addictive behavior develop into larger and larger problems. While not everyone becomes addicted to the Internet in the same way for the same reason, some general patterns have emerged with regard to why people become hooked and the ways in which they use the Internet to escape from or cope with underlying problems in their lives.

Emotional Problems

Like a craving for a cigarette or the desire to have a drink, emotions such as stress, depression, loneliness, anxiety, or burnout can lead to an addict's need to go online, which serves as a temporary distraction to fill an emotional void (Peele & Brodsky, 1979). Consistently, Internet addicts explain that they feel a difference between their online and offline emotions. They feel frustrated, worried, angry, anxious, and depressed when offline. When online, they feel excited, thrilled, uninhibited, attractive, supported, and more desirable. These strong positive emotions reinforce the compulsive behavior (Young, 1999). The addictive behavior itself acts as a way to temporarily avoid negative or unpleasant feelings. Under the influence, the alcoholic feels as if all the other problems in his life disappear, and when eating, the overeater experiences a sense of peace and relaxation, lessening the overwhelming stress and frustration he feels.

Interpersonal Difficulties

Individuals who suffer from low self-esteem and feel lonely, restless, or withdrawn can use cyberspace connections with others to make them feel better

about themselves and their circumstances. Internet sex offers a fantasy world in which there are endless numbers of people who appear to be interesting to—and interested in—the individuals concerned. Young, socially awkward, or emotionally troubled individuals may find it easier to engage in Internet "relationships" than risk face-to-face rejection by a real person. As the addict becomes more immersed in this shadow world, denial takes hold and she comes to view these "friends" and "partners" as more real than an actual spouse or family member.

The anonymity associated with electronic communication and the general milieu of the Internet often facilitates more frank and open communication with other users (Cooper and Sportolari, 1997). Anonymity can also increase the online user's feeling of comfort, since it is less easy for the user to detect signs of insincerity, disapproval, or judgment than it is in face-to-face interactions. The distance afforded by cyberspace enables a person to share intimate feelings often reserved for a significant other, thus opening the door for bonding and an accelerated sense of intimacy, which in turn can disrupt real-life relationships. This can in turn lead to greater problems in the addict's marriage or family (Young, 2004). Partners often feel hurt, betrayed, rejected, abandoned, devastated, jealous, and angry, as well as experiencing a loss of self-esteem at the discovery of the user's activities. Being lied to repeatedly is a major source of distress. Partners will feel angry and jealous of the computer and view it as a source of conflict, pain, and stress in the relationship as the addict withdraws deeper into the virtual life.

Relapse from Prior Addictions

For those in recovery from prior addictions, the Internet becomes another way to engage in compulsive or addictive behavior (Greenfield, 1999). Recovering addicts who feel overwhelmed, experience work or money problems, or experience life-changing events such as divorce, relocation, or a death in the family can absorb themselves in a virtual world full of fantasy and intrigue. They can lose themselves in online pornography, Internet gambling, or online gaming, and once they are online, the difficulties of their lives fade into the background as their attention becomes completely focused on the Internet. Those in recovery from prior addictions look to the Internet as a new way of escaping without really dealing with the underlying problems causing their addictive behavior. Without the crutch of their prior addiction, say, to alcohol or drugs, the stress that comes from a job or a marriage or relationships in general can trigger sexually addictive online behavior. Using the Internet becomes a quick fix and an instant way to wash away troubling feelings or difficult situations that they really don't know how to deal with (Young, 2004).

Students Most At Risk

The Internet has been touted as a premier educational tool driving schools to integrate Internet services into their classroom environments. However, one survey revealed that 86 percent of responding teachers, librarians, and computer coordinators believe that Internet use by children does not improve performance (Barber, 1997). They argue that information on the Internet is too disorganized and unrelated to the school curriculum to help students, and can even serve as a distraction. Young (1998b) found that 58 percent of students suffered from poor study habits or poor grades, or failed school due to excessive Internet use. Increasingly, college administrators are recognizing that they have put a great deal of money into an educational tool that can easily be abused.

Colleges are starting to see the potential impact of student Internet use. At Alfred University in Alfred, New York, Provost W. Richard Ott investigated why normally successful students with scores of 1200 to 1300 in the SATs had recently been dismissed. His investigation found that 43 percent of these students failed school due to extensive patterns of late-night log-ins to the university computer system (Brady, 1997). Counselors at the University of Texas at Austin began seeing students whose primary problem was an inability to control their Internet use, and in one of the first campus studies of Internet abuse they found that 14 percent met the criteria for Internet addiction (Scherer, 1997).

College counselors have argued that students are the most population most at risk of developing an addiction to the Internet because campuses, computer labs, wired dorms, and mobile Internet devices access possible anytime, day or night (Scherer, 1997). The University of Maryland even started an Internet addiction support group to help students who abused Internet use (Murphey, 1996), and gradually more such support groups are developing across campuses.

TREATMENT ISSUES

Our computerized society makes it difficult to simply go "cold turkey" from Internet sex. Today, most people need to use the computer every day for work, making abstinence from Internet sex more complex than abstinence from drink or drugs. As more jobs involve computers and as more homes have computers, complete abstinence from the Internet may be impossible, forcing the Internet addict to use self-control to achieve corrective action and abstinence from problematic Internet applications. In food addiction, recovery can be objectively measured through caloric intake and weight loss; in the same way, online addicts can objectively measure success through maintaining abstinence from problematic online applications and increasing meaningful offline activities.

But how can addicts learn that kind of willpower and self-discipline when any contact with the computer feels like a temptation?

In *Caught in the Net*, Young (1998a) provides an integrated recovery approach that combines cognitive-behavioral and insight-oriented therapies. She postulates that recovery from Internet addiction is most akin to recovery from food addiction. Food addicts cannot simply abstain from food as part of their recovery; instead they must discover healthier ways to live with food in their lives. Similarly, online addicts must discover healthier ways to live with the Internet in their lives. To make this discovery, the addict must be willing to identify and understand the underlying emotional, cognitive, or situational factors that trigger the addictive behavior, such as depression, anxiety, loneliness, stress, marital troubles, divorce, or career problems, and learn to cope with those underlying issues in a more adaptive manner.

Cognitive-Behavioral Therapy

Researchers have likened Internet addiction to addictive impulse-control disorders on the Axis I scale in the *DSM* (Beard & Wolf, 2001; Orzack, 1999), and they have utilized various forms of *DSM–IV*-based criteria to define Internet addiction. Cognitive Behavioral Therapy (CBT) has been shown to be an effective treatment for compulsive disorders such as intermittent explosive disorder, pathological gambling, and trichotillomania (Hucker, 2004). CBT has also been effective in treating substance abuse, emotional disorders, and eating disorders (Beck, 1979; Beck, Wright, Newman, & Liese, 1993).

CBT is a familiar treatment based on the premise that thoughts determine feelings. Patients are taught to monitor their thoughts and identify those that trigger addictive feelings and actions while they learn new coping skills and ways to prevent a relapse. CBT usually requires three months of treatment or approximately 12 weekly sessions. The early stage of therapy is behavioral, focusing on specific behaviors and situations in which the impulse control disorder causes the greatest difficulty. As therapy progresses, there is more of a focus on the cognitive assumptions and distortions that have developed and the effects of these on behavior. This involves assessment of the type of distortion, training in problem-solving skills and coping strategies, modeling in therapy, use of support groups, and keeping thought journals (Beck, 1979).

Behavior Change

In cases of Internet addiction, abstinence recovery models are not practical, as computers have become such a salient part of our daily lives. Therefore, clinicians have generally agreed that moderated and controlled use of the Internet

is most appropriate as a means to treat Internet addiction. Behavior therapy is the initial focus of recovery, examining both computer behavior and noncomputer behavior (Hall & Parsons, 2001). Computer behavior deals with actual online use, with a primary goal of abstinence from problematic applications while retaining controlled use of the computer for legitimate purposes. For example, a lawyer addicted to Internet pornography would need to learn to abstain from adult Web sites, while still being able to access the Internet to conduct legal research and to e-mail clients. Noncomputer behavior focuses on helping clients develop positive lifestyle changes for life without the Internet. Life activities that do not involve the computer are evaluated and may include relationship function, social function, or occupational function.

Young (2001) suggests using a daily internet log to evaluate computer behavior and establish a baseline for clinical treatment. Once a baseline has been established, behavior therapy is used to relearn how to use the Internet to achieve specific outcomes, such as moderated online use and more specifically abstinence from problematic online applications and controlled use for legitimate purposes. Behavior management for both computer usage and adaptive noncomputer behavior focuses on present and overt behavior. The techniques involved may include assertion training, behavioral rehearsal, coaching, cognitive restructuring, desensitization, modeling, reinforcement, relaxation methods, self-management, or new social skills.

Cognitive Restructuring

Addictive thinkers, for no logical reason, will feel apprehensive when anticipating disaster (Twerski, 1990). While addicts are not the only people who worry and anticipate negative happenings, they tend to do this more often than other people. Young (1998a) suggested that this type of catastrophic thinking might contribute to compulsive Internet use by providing a psychological escape mechanism to avoid real or perceived problems. Subsequent studies hypothesized that other maladaptive cognitions, such as overgeneralizing or catastrophizing, negative core beliefs, and cognitive distortions also contribute to compulsive use of the Internet (Caplan, 2002; Davis, 2001; LaRose, Mastro, & Easton, 2001). Young hypothesized that those who suffer from negative core beliefs may be the ones who are drawn the most to the anonymous interactive capabilities of the Internet in order to overcome their perceived inadequacies. She suggested that cognitive restructuring should be used to address underlying negative core beliefs, cognitive distortions, and rationalizations such as "Just a few more minutes won't hurt" for effective management of the patient's primary symptoms.

Developing Support Systems

Young suggests that addicts must first assess their current use of the Internet to examine the extent of Internet use and identify high-risk situations, feelings, or events that trigger the behavior. Most importantly, for continued recovery and relapse prevention, they need to avoid high-risk situations that can lead to relapse and they need to repair relationships hurt by their addiction.

Due to their addiction, addicts often hurt or lose significant real-life relationships, such as relationships with a spouse, a parent, or a close friend. Often, these were individuals who provided the addict with support, love, and acceptance before the Internet addiction, and their absence only makes the addict feel worthless and reinforces past notions of being unlovable. The addict must amend and reestablish these broken relationships to achieve recovery and find the support necessary to fight the addiction. Young (1998a) emphasizes that the recovery process is an ongoing self-exploration that must separate the behavior from the person, relieve shame about the behavior, correct maladaptive cognitions, and promote opportunities to learn from mistakes. The recovery process must also build relationships, provide new ways to relate to others, and allow amends to be made. Involving loved ones in the recovery process can be a rich source of the nurturing and sponsorship needed to help a client maintain sobriety and abstinence. Finally, the recovery process should provide continuous support and affirmation that creates a positive self-image.

FUTURE AREAS OF RESEARCH AND PRACTICE

Over the last decade, acceptance of Internet addiction has grown in the mental health field, and new journals such as *CyberPsychology and Behavior,* which focus on Internet behavior and addiction, have emerged. It is difficult to predict the results of these early endeavors. However, it is quite possible that with years of collective effort, Internet addiction may be recognized as a legitimate impulse-control disorder worthy of its own classification in future revisions of the *Diagnostic and Statistical Manual of Mental Disorders*. Until then, there is a need for the professional community to recognize and respond to the threat of its rapid expansion.

With the growing popularity of the Internet, the mental health field needs to develop an infrastructure of treatment programs specifically designed to care for the Internet addicted. Since this is a new and often laughed at addiction, individuals are reluctant to seek out treatment, fearing that clinicians may not take their complaints seriously. Drug and alcohol rehabilitation centers, community mental health clinics, and clinicians in private practice should avoid

minimizing the impact to addicts whose complaint involves Internet addiction and offer effective recovery programs. Advertisement of such programs both online and within the local community may encourage timid individuals to come forward to seek the help they need.

Finally, to pursue such effective recovery programs, continued research is needed to better understand the underlying motivations of Internet addiction. Future research should focus on how psychiatric illness such as depression or obsessive-compulsive disorder plays a role in the development of compulsive Internet use. Longitudinal studies may reveal how personality traits, family dynamics, or interpersonal skills influence the way people utilize the Internet. Outcome studies are needed to determine the efficacy of specialized therapy approaches to treat Internet addiction and to compare these outcomes with traditional recovery modalities.

Chapter **11**

Gambling Addictions

Mark Griffiths, PhD

Gambling is an activity that is popular across many cultures. Surveys of gambling on a national level have tended to conclude that there are more gamblers than nongamblers, but that most participants gamble infrequently (Abbott, Volberg, Bellringer, & Reith, 2004; Wardle et al., 2007). Estimates based upon survey data from countries all over the world indicate that the majority of people have gambled at some time in their life (Griffiths, 2007; Orford, Sproston, Erens, & Mitchell, 2003).

The introduction of national lotteries and new casinos, the proliferation of electronic gaming machines, and the introduction of remote gambling (e.g., Internet gambling, mobile phone gambling, interactive television gambling) have greatly increased the accessibility and popularity of gambling all over the world. As a consequence, the number of people seeking assistance with gambling-related problems has increased (Abbott et al., 2004). Government-commissioned studies in a number of countries including the United States, the United Kingdom (UK), Australia, and New Zealand have all concluded that (in general) increased gambling availability has led to an increase in problem gambling, although the relationship is complex and nonlinear (Abbott, 2007).

Despite the recognition of the complexity of gambling behavior, most research in the area has been confined to narrow areas of specialization. Singular theoretical perspectives tend to be adhered to (e.g., behaviorism, cognitivism, addiction theory), with few attempts to establish links or draw contrasts with other research programs (Griffiths & Delfabbro, 2001). Singular perspectives assume that a single explanation or theory is sufficient to explain every aspect

of gambling behavior and that rival perspectives are thereby misguided. Yet, as a number of authors assert, this may not be so (e.g., Griffiths, 2005; Griffiths & Larkin, 2004; Shaffer et al., 2004).

A number of authors have noted that gambling is a multifaceted rather than a unitary phenomenon (Griffiths & Delfabbro, 2001; Shaffer et al., 2004). Consequently, many factors may come into play in various ways and at different levels of analysis (e.g., biological, social, or psychological) (Griffiths, 2008). Theories may be complementary rather than mutually exclusive, which suggests that the limitations of individual theories might be overcome through the combination of ideas from different perspectives. This has often been discussed before in terms of recommendations for an eclectic approach to gambling (Griffiths, 1995) or a distinction between proximal and distal influences upon gambling (Walker, 1992). However, for the most part, such discussions have been descriptive rather than analytical, and so far, few attempts have been made to explain why an adherence to singular perspectives is untenable. There are generally three specific levels of analysis: social, psychological, and biological. This chapter will focus on the psychological aspects.

Central to this eclectic view, no single level of analysis is considered sufficient to explain either the etiology or the maintenance of gambling behavior. Moreover, this view asserts that all research is context bound and should be analyzed from a combined, or biopsychosocial, perspective (Griffiths, 2005, 2008). Variations in the motivations and characteristics of gamblers and in gambling activities themselves mean that findings obtained in one context are unlikely to be relevant or valid in another. In each of the following sections, broad details of each level of analysis are provided, followed by discussions of the limitations and interdependence of each theoretical approach and the implications for research and clinical interventions.

PATHOLOGICAL GAMBLING: PREVALENCE AND HISTORY

Estimates of the number of probable adult pathological gamblers vary from just under 1 percent in the UK to 1.1–1.9 percent in the United States and 2.3 percent in Australia (Wardle et al., 2007). These surveys have also indicated that pathological gambling is twice as common among males as it is among females, that nonwhites have higher rates than whites, and that those with low levels of education are more likely to be pathological gamblers (Abbott et al., 2004; Griffiths, 2007). In 1980, pathological gambling was recognized as a mental disorder in the third edition of the *Diagnostic and Statistical Manual* (*DSM–III*) under the section titled "Disorders of Impulse Control," along

with other illnesses such as kleptomania and pyromania (American Psychiatric Association, 1980). Adopting a medical model of pathological gambling in this way displaced the old image that the gambler was a sinner or a criminal.

Before the appearance of *DSM-III* (1980), the subject of pathological gambling had produced an expanding body of literature by psychiatrists, psychologists, psychoanalysts, and social workers, and the subject had appeared under a variety of labels including "neurotic," "compulsive," "addictive," "excessive," and "pathological" (Griffiths, 2007). There now seems to be an increased preference among professionals for the terms "problem" or "pathological gambling," as opposed to terms like "compulsive" or "addictive," which might suggest specific and homogenous etiologies.

In diagnosing the pathological gambler, *DSM–III* states that the individual is chronically and progressively unable to resist impulses to gamble and that gambling compromises, disrupts, or damages family, personal, and vocational pursuits. The behavior increases at times of stress, and associated features include lying to obtain money, committing crimes (forgery, embezzlement, fraud, etc.), and concealment from others of the extent of the individual's gambling activities. In addition, *DSM–III* stated that, for a diagnosis of pathological gambling, the gambling must not be due to antisocial personality disorder (see Table 11.1).

As Lesieur (1988) pointed out, these criteria were criticized for (1) a middle class bias, that is, that the criminal offences like embezzlement and income tax evasion were middle class offences, (2) a lack of recognition that many com-

Table 11.1
***DSM–III* Criteria for Pathological Gambling**

The criteria state that maladaptive gambling is indicated by the following:

A. The individual is chronically and progressively unable to resist impulses to gamble.
B. Gambling compromises, disrupts, or damages family, personal, and vocational pursuits, as indicated by at least three of the following:
   1. Arrest for forgery, fraud, embezzlement, or income tax evasion due to attempts to obtain money for gambling
   2. Default on debts or other financial responsibilities
   3. Disrupted family or spouse relationships due to gambling
   4. Borrowing money from illegal sources (loan sharks)
   5. Inability to account for loss of money or to produce evidence of winning money if this is claimed
   6. Loss of work due to absenteeism in order to pursue gambling activity
   7. Necessity for another person to provide money to relieve a desperate financial situation
C. The gambling is not due to antisocial personality disorder.

Source: American Psychiatric Association, 1980.

Table 11.2
DSM–III–R Criteria for Pathological Gambling

The criteria state that maladaptive gambling is indicated by at least four of the following:

1. Is frequently preoccupied with gambling or obtaining money to gamble.
2. Often gambles larger amounts of money or over a longer period than intended.
3. Needs to increase the size or frequency of bets to achieve the desired excitement.
4. Exhibits restlessness or irritability if unable to gamble.
5. Repeatedly loses money gambling and returns another day to win back losses ("chasing").
6. Makes repeated efforts to cut down or stop gambling.
7. Often gambles when expected to fulfill social, educational, or occupational obligations.
8. Has given up some important social, occupational, or recreational activity in order to gamble.
9. Continues to gamble despite inability to pay mounting debts, or despite other significant social, occupational, or legal problems that the individual knows to be exacerbated by gambling.

Source: American Psychiatric Association, 1987.

pulsive gamblers are self-employed, and (3) the exclusion of individuals with antisocial personality disorder. Lesieur recommended the same custom be followed for pathological gamblers as for substance abusers and alcoholics in the past, that is, to allow for simultaneous diagnosis with no exclusions. In addition, the criteria leave out the "problem gambler," who by self-admission, or by others' testimony, spends a disproportionate amount of time gambling but has yet to produce the serious consequences laid down in *DSM–III*. The new criteria were subsequently changed, in the *Diagnostic and Statistical Manual*, third edition, revised (*DSM–III–R*) (see Table 11.2), taking on board the criticisms and modeled extensively on substance abuse disorders, due to the growing acceptance of gambling as a bona fide addictive behavior (American Psychiatric Association, 1987).

However, Rosenthal (1989) conducted an analysis of the use of the *DSM–III–R* criteria by treatment professionals. It was reported that there was some dissatisfaction with the new criteria and that there was some preference for a compromise between *DSM–III* and *DSM–III–R*. As a consequence, the criteria were changed for the *Diagnostic and Statistical Manual*, fourth edition (*DSM–IV*; American Psychiatric Association, 1994; see Table 11.3). Preparations are already under way for *DSM–V*.

PHASES OF THE PATHOLOGICAL GAMBLER'S CAREER

The acquisition, development, and maintenance of pathological gambling is an area that is continually disputed. The exact causes and reasons for continu-

Table 11.3
DSM–IV–TR Criteria for Pathological Gambling

A. Persistent and recurrent maladaptive gambling behavior is indicated by five (or more) of the following:
   1. Is preoccupied with gambling (e.g., preoccupied with reliving past gambling experiences, handicapping or planning the next venture, or thinking of ways to get money with which to gamble).
   2. Needs to gamble with increasing amounts of money in order to achieve the desired excitement.
   3. Made repeated unsuccessful efforts to control, cut back, or stop gambling.
   4. Is restless or irritable when attempting to cut down or stop gambling.
   5. Gambles as a way of escaping from problems or of relieving a dysphoric mood (e.g., feelings of helplessness, guilt, anxiety, depression).
   6. After losing money gambling, often returns another day to get even ("chasing" one's losses).
   7. Lies to family members, therapist, or others to conceal the extent of involvement with gambling.
   8. Has committed illegal acts such as forgery, fraud, theft, or embezzlement to finance gambling.
   9. Has jeopardized or lost a significant relationship, job, educational, or career opportunity because of gambling
   10. Relies on others to provide money to relieve a desperate financial situation caused by gambling.

B. The gambling behavior is not better accounted for by a manic episode.

Source: American Psychiatric Association, 1994.

ing gambling behavior seem to be dependent upon the individual, but there do seem to be some general underlying factors and recurring themes. Problem gambling generally begins in adolescence and may start following a major life stress, for example the death of a parent or birth of a first child (Griffiths, 2003a). Such events may induce a need to escape from the problems of reality.

Lesieur and Custer (1984) concluded that pathological gambling behavior consists of three stages—the winning phase, the losing phase, and the desperation phase. The winning phase normally begins with small but successful bets in adolescence. Early wins prompt more skillful gambling, which usually leads to larger winnings. Most social gamblers stop at this stage. However, after a considerable win maybe equaling or exceeding the individual's annual salary, the gambler accepts the thought that this can happen again.

The next stage—the losing phase—is characterized by unrealistic optimism on the gambler's part, and all bets placed are in an effort to recoup losses: this has been termed "the chase" by Lesieur (1984) . The result is that instead of cutting their losses, gamblers get deeper into debt, preoccupying themselves

with gambling, certain that a big win will repay their loans and solve all their problems. Family troubles (both marital and with relatives) begin, and illegal borrowing and other criminal activities usually start to occur, in an effort to get money (Lesieur, 1984). At this point in the pathological gambler's career, family and/or friends may bail out the gambler. Alienation from those closest to the pathological gambler characterizes the appearance of the final stage—the desperation phase. In a last-ditch, frenzied effort to repay debts, illegal criminal behavior reaches its height, and when there are finally no more options left, the gambler may suffer severe depression and have suicidal thoughts.

It is, then, usually at the insistence of the family (if not the courts) that the gambler must seek help. Because the pathological gambler is impatient, requiring immediate results, help should be aimed at priority areas, that is, the lessening of legal and financial difficulties, counseling to resolve family and marital problems, and most importantly hospitalization for desperate patients who are depressed and suicidal. In addition to this, Rosenthal (1989) has described a fourth phase called the hopeless or giving up phase. This is a phase in which gamblers know they cannot possibly retrieve their losses and they do not care, leading to play for play's sake.

EXPLANATIONS OF GAMBLING INVOLVEMENT

In general, research has consistently shown a positive relationship between the availability of gambling and both regular and problem gambling (Abbott, 2007; Griffiths, 2003b). Whenever new forms of gambling are introduced, or existing forms become more readily available, there is an increase in gambling, suggesting that the demand for gambling products is closely linked to their supply—although there are exceptions to this (Griffiths, Parke, & Rigbye, 2008). The larger the gambling industry infrastructure that is established (e.g., new venues), the larger the range of gambling products (e.g., through the application of new technologies), and the greater the industry's marketing efforts, the more likely people will be to gamble in the first place.

But why is gambling so popular? According to sociologists, gambling is an inherent component of human society (Goffman, 1967) and human beings have a natural penchant for play, risk, and competition. Gambling, they argue, fits easily with cultural values, virtues, and lifestyles, so that when gambling becomes more accessible and socially acceptable, more people will gamble (Abt, Smith, & McGurrin, 1985). As a form of social interaction, gambling provides a means by which people can escape the boredom of everyday life, adopt new roles, and enjoy the excitement of the action, namely, the suspense, anticipation,

and social reinforcement resulting from taking risks and being rewarded for one's daring (Abt & Smith, 1984).

Almost all surveys of gambling have shown that these broad motivational factors are central to gambling and that attitudes toward gambling are positively related to availability and cultural acceptability. However, this perspective fails to take into account many key findings and observations in gambling research. Research has consistently shown that people often gamble for reasons other than broad social and economic reasons (Griffiths, 1996). These other motivations may vary according to the personal characteristics of the gambler and the type of gambling activity. Finally, broad social and economic theories fail to explain why certain gambling activities are more popular or "addictive" than others.

Demographic variations in gambling participation have been observed since surveys were first administered. Typically, gambling has been more popular in lower socioeconomic groups, among Catholics rather than Protestants, among unmarried people, in younger age groups, and in men (Griffiths, 2007). Consistent with trends observed in overall participation rates, research has found that the incidence of gambling-related problems is considerably higher in lower socioeconomic groups and in younger people, and it is more likely to be associated with slot machines, one of the few activities that attract similar numbers of men and women (Griffiths & Delfabbro, 2001; Griffiths, 2007). Accordingly, understanding demographic variations in overall participation is vital if one is to estimate the likely social effects of expansion or product changes in existing gambling markets.

Variations in gambling preferences are thought to result from differences in both accessibility and motivation. Older people tend to choose activities that minimize the need for complex decision making or concentration (e.g., bingo, slot machines), whereas gender differences have been attributed to a number of factors, including variations in sex-role socialization, cultural differences, and theories of motivation (Delfabbro, 2000; Griffiths, 2007; Griffiths & Delfabbro, 2001).

Variations in motivation are also frequently observed among people who participate in the same gambling activity. For example, slot machine players may gamble to win money, for enjoyment and excitement, to socialize, and to escape negative feelings (Griffiths, 2002). Some people gamble for one reason only, whereas others gamble for a variety of reasons. A further complexity is that people's motivations for gambling have a strong temporal dimension; that is, they do not remain stable over time. As people progress from social to regular and finally to excessive gambling, there are often significant changes in their reasons for gambling. Whereas a person might have initially gambled to

obtain enjoyment, excitement, and socialization, the progression to problem gambling is almost always accompanied by an increased preoccupation with winning money and chasing losses.

STRUCTURAL AND SITUATIONAL CHARACTERISTICS OF GAMBLING ACTIVITIES

Another factor central to understanding gambling behavior is the structure of gambling activities. Griffiths and colleagues (Griffiths, 1993a, 1999; Parke & Griffiths, 2006, 2007) have consistently argued, gambling activities vary considerably in their structural characteristics, including the probability of winning, the amount of gambler involvement, the amount of skill that can be applied, the length of the interval between stake and outcome, and the magnitude of potential winnings. Structural variations are also observed within certain classes of activities, such as slot machines, where differences in reinforcement frequency, colors, sound effects, and machines' features can significantly influence the profitability and attractiveness of machines. Each of these structural features may (and almost certainly does) have implications for gamblers' motivations and the potential "addictiveness" of gambling activities.

For example, skillful activities that offer players the opportunity to use complex systems, study the odds, and apply skill and concentration appeal to many gamblers because their actions can influence the outcomes. Such characteristics attract people who enjoy a challenge when gambling. They may also contribute to excessive gambling if people overestimate the effectiveness of their gambling systems and strategies (see discussion of cognitive theories, below). Chantal and Vallerand (1996) have argued that people who gamble on these activities (e.g., racing punters) tend to be more intrinsically motivated than lottery gamblers in that they gamble for self-determination (to display their competence and to improve their performance). People who gamble on chance activities, such as lotteries, usually do so for external reasons (to win money or escape from problems) (Griffiths, 2007).

Although many slot machine players also overestimate the amount of skill involved in their gambling, other motivational factors (such as the desire to escape worries or to relax) tend to predominate. Thus, excessive gambling on slot machines may be more likely to result from people becoming conditioned to the tranquilizing effect brought about by playing rather than from just the pursuit of money (Griffiths, 2002).

Another vital structural characteristic of gambling is the continuity of the activity: namely, the length of the interval between stake and outcome (Parke & Griffiths, 2007). In nearly all studies, it has been found that continuous activi-

ties (e.g., racing, slot machines, casino games) with a more rapid play-rate are more likely to be associated with gambling problems (Parke & Griffiths, 2006). The ability to make repeated stakes in short time intervals increases the amount of money that can be lost and also increases the likelihood that gamblers will be unable to control their spending. Such problems are rarely observed in noncontinuous activities, such as weekly or biweekly lotteries, in which gambling is undertaken less frequently and in which outcomes are often unknown for days. Consequently, it is important to recognize that the overall social and economic impact of expansion of the gambling industry will be considerably greater if the expanded activities are continuous rather than noncontinuous.

Other factors central to understanding gambling behavior are the situational characteristics of gambling activities. These are the factors that often facilitate and encourage gambling in the first place (Griffiths & Parke, 2003). Situational characteristics are primarily features of the environment (e.g., accessibility factors such as the location of the gambling venue, the number of venues in a specified area, and possible membership requirements) but can also include internal features of the venue itself (e.g., décor, heating, lighting, color, background music, floor layout, refreshment facilities) or facilitating factors that may influence gambling in the first place (e.g., advertising, free travel and/or accommodation to the gambling venue, free bets or gambles on particular games) or influence continued gambling (e.g., the placing of a cash dispenser on the casino floor, free food and/or alcoholic drinks while gambling) (Abbott, 2007; Griffiths & Parke, 2003).

These variables may be important in both the initial decision to gamble and the maintenance of the behavior. Although many of these situational characteristics are thought to influence vulnerable gamblers, there has been very little empirical research into these factors, and more research is needed before any definitive conclusions can be arrived at on the direct or indirect influence on gambling behavior and on whether vulnerable individuals are any more likely to be influenced by these particular types of marketing ploys (Griffiths, 2007).

THEORIES OF GAMBLING BEHAVIOR

Although sociological, situational, and demographic factors can explain why some people are more likely to gamble than others, these theories cannot explain why some people gamble more than others or what factors contribute to behavior maintenance in gambling. Psychological theories become important at this level. Research in this area is remarkably diverse. Almost every major branch of psychology (e.g., cognitivism, behaviorism, Freudian theory, addiction theory) has been utilized in an attempt to understand gambling. Despite this diversity,

it is possible to distinguish two broad, general perspectives: first, theories that attribute ongoing behavior and excessive gambling to habitual processes that are the consequences of gambling; second, theories that state that variations in behavior result from variations in the characteristics or makeup, of individual gamblers (Griffiths & Delfabbro, 2001). In other words, whereas the first places a stronger emphasis upon psychological determinants of gambling, the second emphasizes biological differences between individuals.

Central to psychological explanations is the idea that every person who gambles has the potential to become a problem gambler. This is because gambling activities are difficult to resist by their very nature: excitement, risk taking, and the possibility of monetary gains. The more a person gambles, the more difficult it becomes to resist the temptation to commence a gambling session or stop once gambling has commenced (Dickerson, 1989). Accordingly, it has been suggested that there is no neat distinction between problem gambling and normal gambling; rather, there is a continuum from social gambling to regular gambling to problem gambling.

People who gamble regularly may display many of the same behaviors as people with gambling problems, although to a lesser degree. This view gives rise to conceptualizations of problem gambling that emphasize the developmental and habitual nature of problem gambling behavior rather than individual pathology. This perspective avoids terms such as compulsive, addiction, or pathology, in preference for terms such as impaired control (Dickerson & O'Connor, 2006). Although researchers' views differ concerning the psychological mechanisms behind loss of control, three general classes of theory will be used to illustrate the limitations of psychological accounts. They are behaviorist theories that explain persistent gambling as a conditioned process; need-state models that see gambling as a form of psychological or physiological dependence; and cognitive theories that attribute excessive gambling to erroneous beliefs about the potential profitability of gambling.

BEHAVIORIST APPROACHES

Both classical and operant conditioning principles have been applied to the study of gambling. In operant explanations for problem gambling (Delfabbro & Winefield, 1999), persistent gambling is seen as a conditioned behavior maintained by intermittent schedules of reinforcement, most likely a variable-ratio schedule. This involves the provision of infrequent rewards after varying numbers of responses. On the other hand, proponents of classical conditioning models argue that people continue to gamble as a result of becoming conditioned to the excitement or arousal associated with gambling, so that they feel

bored, unstimulated, and restless when they are not gambling. Both the classical and operant perspectives have been central to the development of measures of impaired control over gambling (Dickerson & O'Connor, 2006) and clinical interventions using desensitization, aversive conditioning, and satiation techniques. In each of these examples, it is assumed that the more a person gambles, the more a person's behavior is dictated by factors beyond the person's control.

Despite evidence supporting both theories, neither is entirely satisfactory on its own. Classical conditioning theory seems useful in explaining people's motivation to commence a gambling session but appears less useful in explaining persistent gambling behavior. Conversely, while operant conditioning might explain ongoing behavior, it appears less useful in explaining why people commence gambling or recommence gambling after a prolonged period of abstinence (Griffiths, 1995). Researchers have also raised questions about the extent to which gambling behavior adheres to operant theory at all, since gamblers lose more than they win and because reinforcement magnitudes are not independent of player responses, for example, stake sizes (Delfabbro & Winefield, 1999). Nevertheless, the importance of subtle variations in machine characteristics in influencing behavior reinforces the role of operant conditioning in the maintenance of behavior, although perhaps in more subtle ways than has been envisaged.

It is important to recognize that these theories cannot stand in isolation. As with other psychological theories, conditioning theories cannot explain why people exposed to similar stimuli respond differently; why some gamble whereas others do not; or why some people gamble more than others. In addition, the effectiveness or strength of the conditioning effect may be a function of motivational factors and type of activity. Some but not all people gamble for excitement or relaxation, and as discussed above, people satisfy these needs by engaging in different activities. Thus, it is unlikely that classical conditioning will affect all types of gambling or gamblers. Similar difficulties plague attempts to develop general operant theories of gambling. Some activities appear to suit this form of explanation more than others. Examples include slot machines and scratch tickets, where there is a short time interval between stake and outcome, and where outcomes are entirely determined by chance. It seems more difficult to apply these principles to skilled gambling games such as blackjack, poker, and sports betting, where player decisions can significantly influence outcomes.

NEED-STATE MODELS AND THEORIES OF ADDICTION

Much of the discussion relating to classical conditioning also applies to need-state theories of gambling, which assume that people gamble to escape unpleasant

feeling states such as anxiety, depression, and boredom. These perspectives have been applied to all facets of gambling, including involvement, ongoing behavior, and excessive gambling. They are incorporated into the *DSM–IV* classification of pathological gambling (i.e., gambling as a way of escaping from problems or intolerable feeling states). Although not all researchers agree that these motivations signify the existence of a physiological addiction (Walker, 1989), most agree that people can become psychologically addicted to gambling.

The concept of arousal has been studied most extensively (e.g., Coventry & Hudson, 2001; Diskin & Hodgins, 2003; Griffiths, 1993b), but the results have not been consistent. Arousal increases have been observed in some studies but not in others, and most increases have been relatively small. Variations in arousal have co-varied reliably neither with the persistence of behavior nor with the onset of gambling sessions. Walker (1992) has questioned the explanatory value of arousal theories, arguing that the excitement of gambling is unlikely to be independent of people's desire to win money.

Similar problems have plagued attempts to associate gambling with anxiety and depression. While a considerable number of studies (Blaszczynski & McConaghy, 1989; Blaszczynski, McConaghy & Frankova, 1990; Dickerson, Cunningham, Legg England, & Hinchy, 1991; Dickerson, Hinchy, Legg England, Fabre, & Cunningham, 1992; Ramirez, McCormick, Russo, & Taber, 1984) have revealed that negative mood states commonly accompany gambling or predict the duration of gambling sessions, most analyses have been confined to problem gamblers and high-frequency gamblers. For this reason, it is unclear whether these mood states are also associated with less frequent gambling. Moreover, it is not possible to determine whether mood states precede gambling or arise as a consequence of gambling. Indeed, as Walker (1992) points out, it may be that gamblers become depressed as a result of losing more money than they can afford.

Again, the temporal dimension suggests that the role of mood states is unlikely to be independent of the gambler's characteristics. As with arousal, it is unlikely that avoidance of negative feeling states will be common to all activities or all gamblers. For example, slot machines appear to reduce anxiety, whereas racing provides arousal and excitement. In addition, variations in gambling motivation among participants involved in the same activity suggest that not all people gamble to satisfy unfulfilled needs. It is also unclear why some people apparently have a greater need for arousal or relaxation than others, and whether this is sufficient to explain differences between normal and excessive gambling. It is important to place behavior in a social context in order to understand how gambling compensates for, or assuages, problems or deficits experienced in other areas of life. Alternatively, as will be suggested later in this

chapter, it may be useful to look for dispositional or biological differences to explain the varying motivations and behavior of individual gamblers.

COGNITIVE THEORIES

Despite the fact that the odds for almost all activities are weighted strongly in favor of the house, gamblers continue to believe they can win money from gambling. This observation leads to the conclusion that gambling may be maintained by irrational or erroneous beliefs. For example, people overestimate the extent to which they can predict or influence gambling outcomes and tend to misjudge how much money they have won or lost. This hypothesis has been confirmed in numerous studies (Langer, 1975; Langer & Roth, 1983) showing that people overestimate the degree of skill or control that can be exerted in chance activities, and also in studies using the so-called thinking aloud method (Griffiths, 1994), which reveal high levels of irrationality in verbalized statements made during gambling sessions. These findings have been confirmed not only under laboratory conditions but also in ecologically valid gambling settings, using regular gamblers (Griffiths, 1994; Ladouceur, Gaboury, Bujold, Lachance, & Tremblay, 1991).

Based upon these findings, it has been suggested that irrational thinking may be related to problematic gambling behavior (Ladouceur & Walker, 1996; Wagenaar, 1988), with persistent behavior thought to be the result of people's overconfidence in their ability to win money (Wagenaar, 1988; Walker, 1992). Evidence suggests that problem gamblers frequently overestimate the amount of control and skill involved in gambling (Griffiths, 1994). Unfortunately, some of these observations have also been made using students with no gambling experience, indicating that irrational beliefs are not positively related to level of gambling involvement (Ladouceur et al., 1991). A further problem is that irrationality does not appear to co-vary with other observable facets of gambling, such as the level of risk taking or reinforcement frequency. Alternatively, where irrationality relates positively to involvement, few differences in behavior have been observed. Consequently, Dickerson and Baron (2000) have concluded that irrational thinking is probably more a reflection of demand characteristics than a rational underlying behavior. A lot of what people say may result only from the difficulty of trying to come up with rational, meaningful statements in chance-determined situations.

In additional to these conceptual difficulties, it is also possible that contextual factors play a role in cognitive research. For example, Griffiths (1994) found that regular players had greater difficulty than occasional players in verbalizing their thoughts while they were gambling. Regular players seemed capable of gambling

without attending to what they were doing, suggesting (a) that cognitive processes did not play a major role in the maintenance of their behavior, or (b) that the original justifications or rationales for behavior were less accessible. In either case, Griffiths's observations suggested that temporal factors (namely, how long a person has been gambling) appear to be important. Therefore, all other things being equal, it appears that valid comparisons cannot be drawn between gamblers with differing levels of gambling experience, because what holds for infrequent gamblers might not hold for regular players, and vice versa.

Finally, it is again important to observe that cognitive theories need to take structural variations in activities into account. Many cognitive processes thought to underlie gambling behavior (e.g., overestimations of control, biased attributions) are more likely to be observed when activities are perceived as having some skill component (Griffiths, 1995). In some activities, there is a genuine possibility for skillful play (e.g., racing, blackjack, table poker). The more people play or know about these activities, the greater is their awareness of the skills involved. Thus, beliefs about control and skill are neither completely irrational nor consistent across players. Instead, in these situations, researchers must examine the quality of play: for example, looking at the extent to which the person adheres to optimal strategies rather than looking for evidence of irrational thinking (Keren & Wagenaar, 1985).

Even in activities where outcomes are chance-determined, there are likely to be variations in the extent to which gamblers perceive that the outcomes are solely chance-determined (e.g., roulette and craps are probably more likely to be perceived as skillful than Australian slot machines, because of the greater complexity of the rules and the possibility for variations in playing strategy). Therefore, it may be ineffective to compare results across studies using different chance activities without controlling for variations in perceived skill.

It should also be noted that social and psychological explanations are insufficient to explain the full complexity of gambling behavior; that there are many other theoretical accounts examining problem gambling and ambling addictions, including those using biological and dispositional theories, sociological theories, and economic theories (Griffiths & Delfabbro, 2001), and that an unified theory of addiction will be complex and biopsychosocial (Griffiths, 2005, 2008). Whether ongoing behavior is explained in terms of behaviorism, need-state models, or cognitive theories, it remains unclear why one person gambles more heavily than another. In other words, while it seems likely that increased involvement with gambling is likely to contribute to loss of control over behavior, development of irrational beliefs, and greater psychological dependence, it is important to determine what makes some gamblers more susceptible to these outcomes than others. It is here that research into biological and personality

factors becomes important. Central to this research is the effort to ascertain whether pathological gamblers possess qualities that would predispose them to excessive gambling.

Biological and dispositional accounts assume that such factors should override environmental or contextual factors and allow for the development of a general theory of gambling addiction. However, this is clearly not so. Apart from the conceptual difficulties associated with determining a causal relationship between characteristics and behavior, dispositional theories are unable to account for the full diversity of gambling patterns and behavior. They fail to explain demographic differences in preference for activities and variations in motivation. Neither can they explain why some activities are more "addictive" than others and why the structural characteristics of specific activities (e.g., slot machines) can influence behavior. Therefore, it appears that excessive gambling is likely to result from both dispositional and psychological factors and the complex interaction between them. Psychological explanations must play a role because of the obvious importance of external factors (e.g., environmental and situational variables) in the development of gambling habits. However, it is also clear that internal factors influence the way in which certain individuals respond to these situations. The implications of this observation for the study and treatment of problem gambling are discussed below.

PATHWAYS INTO GAMBLING ADDICTION

Blaszczynski and Nower (2002) postulated a "pathway" model of the determinants of problem gambling based upon a series of clinical observations with problem gamblers and integration with the literature. They argued that there are common influences that affect all problem gamblers, such as availability and access, classical and operant conditioning reinforcements, arousal effects, and biased cognitive schemas. However, they suggested that there are three distinct pathways into problem gambling, representing three primary motivating forces that drive different problem gamblers to gamble. The members of the first group of gamblers, *behaviorally conditioned problem gamblers*, are not pathologically disturbed but instead gamble excessively as a result of poor decision-making strategies and bad judgments. Any features such as preoccupation with gambling, chasing, depression, anxiety, and related substance abuse are seen as the consequence, not the cause, of their excessive gambling. These gamblers are usually motivated to seek and attend treatment, and to reestablish controlled levels of gambling posttreatment.

The members of the second group, *emotionally vulnerable problem gamblers*, are characterized by a predisposition to be emotionally susceptible. This group

uses gambling as a means of modifying mood states and/or in order to meet specific psychological needs. These gamblers display higher levels of premorbid psychopathology including depression, anxiety, substance dependence, and deficits in coping or managing stress. They tend to engage in avoidant or passive aggressive behavior and to use gambling as a means of emotional relief through dissociation and mood modification. The psychological dysfunction in these gamblers makes them more resistant to treatment and not suitable for controlled gambling. Treatment must focus the underlying vulnerabilities as well as the gambling behavior.

The members of the third group, *antisocial impulsivist' problem gamblers*, have biological dysfunctions, either neurological or neurochemical. They also possess psychosocial vulnerabilities similar to the second group of gamblers mentioned above. However, they are characterized by antisocial personality disorder and impulsivity and/or attention-deficit disorders. It is argued that these gamblers have a propensity to seek out rewarding activities (such as gambling) in order to receive stimulation. They tend to be clinically impulsive and display a broad range of problems independent of their gambling. These problems include substance abuse, low tolerance for boredom, sensation seeking, criminal acts, poor relationship skills, family history of antisocial behavior, and alcoholism. Gambling usually begins at an early age, has a rapid onset, and occurs in binges. The members of this third group are less motivated to seek treatment, have poor compliance rates, and respond poorly to all interventions. All three groups are affected by environmental variables, conditioning effects, and cognitive processes. However, in terms of treatment intervention, each group will have specific needs.

FURTHER IMPLICATIONS FOR RESEARCH AND INTERVENTIONS

In summary, it seems that gamblers are first influenced by sociological factors: for example, the availability of gambling opportunities and the attitudes and habits of parents, friends, and peer groups as well as a lack of alternative activities. During the middle stages of development, there are many factors that heavily influence the maintenance of gambling behavior. Three of these factors are schedules of reinforcement, the escape qualities of gambling, and cognitive biases, all of which have been summarized in this chapter. While it remains unclear exactly how some people come to gamble excessively, it is agreed that persistent gambling eventually leads to a desperate "spiral of options" (Lesieur, 1984), in which gambling is largely maintained by the desire to win money, recover losses, and pay back debts. Gambling is thus a complex, multidimen-

sional activity that is unlikely to be explained by any single theory. Instead, research into this subject is best served by a biopsychosocial model that stresses the individual and idiosyncratic nature of the development of gambling problems and emphasizes the role of contextual factors internal and external to the process of gambling (Griffiths, 2005, 2008).

Recognition of this complexity has important implications for gambling research, in terms of both the selection of samples and the data analysis. First, the existence of structural variations in activities suggests that results obtained using one activity cannot be generalized to other activities that are not structurally equivalent. Existing research suggests that continuity and the element of skill involved are two factors that must be similar in order for valid comparisons to be made. Second, studies of gambling motivation are unlikely to be valid unless both individual and situational factors are taken into account. Since motivations differ across demographic groups (e.g., different genders and ages), across activities, and over time, studies must ensure that these factors are controlled for before conclusions are drawn. Samples should contain equal numbers of men and women of a similar age with similar levels of gambling experience. In situations where this cannot be achieved, gender, age, and experience should be used as co-variants or as the first variables in regression analyses.

Third, in recognition that personality may influence the strength of experimental effects, it is important that researchers match comparison groups in terms of these variables. For example, cognitive experiments investigating the illusion of control should include measures of desirability for control, whereas arousal experiments should include measures of gambling motivation (Griffiths & Delfabbro, 2001). In addition, researchers should not assume that biological differences or psychological factors will explain all gambling behavior. Instead, it may be useful to explore the interaction between these different levels of analysis, for example, by examining whether variations in the structural characteristics of activities (e.g., reinforcement frequency) affect people with, or without, the characteristic under observation.

IMPLICATIONS FOR PREVENTION, INTERVENTION, AND TREATMENT

Since sociological factors appear to be critical in the acquisition of gambling behavior and subsequent gambling addiction, prevention needs to be aimed at the social and situational antecedents. These can be approached from a number of levels (e.g., societal, school, family, individual), some of which may be more practical than others. Since problem gamblers start gambling at a significantly earlier age than nonpathological gamblers, an obvious step would be for

governments to legislate against young people gambling (i.e., below 18 years of age). A blanket ban on gambling would, in most cases, reduce acquisition until at least late adolescence. Both parents and peers may model gambling; therefore, the family's role in maintaining gambling behavior should be addressed in therapy, and prevention plans should aim to increase the gambler's contact with nongambling peers. Also, evidence or knowledge of a gambler's own negative thoughts or feelings about gambling behavior and irrational biases may provide useful cues for behavior modification.

These findings have led to suggestions designed to enhance educational awareness of the dangers of gambling, not only among children and adolescents but also among parents, guardians, and teachers. Although recommendations of this nature typically tend to focus upon the need for greater awareness of the true odds and the nonprofitability of gambling, this approach needs to be applied with caution. It is quite possible for education to have the opposite effect, namely, to increase students' knowledge of how to gamble. In addition, it is questionable whether knowing the true odds has a significant effect upon dissuading people from gambling, given that many problems gamblers are well educated and have, in some cases, some knowledge of basic mathematics. For many, the belief that they are inherently lucky or different from others helps maintain their interest in gambling. Accordingly, educational campaigns that focus upon the negative consequences of gambling and alternatives to it may have greater success. While these sorts of campaigns are unlikely to prevent gambling in all young people, they might reduce (a) the total number of adolescents who start to gamble and (b) the amount of time an adolescent spends gambling.

The fact that some gamblers are socially rewarded for gambling cannot be altered directly, but more adaptive personal and social skills can be taught as responses to stress (i.e., emotional antecedents), for example, relaxation, assertion, and social skills training. Alternatively, where people seek the company of other gamblers as a way to escape from unpleasant feeling states or life stress, the development of alternative interests, hobbies, and social networks should be afforded priority during intervention. This approach could also be extended to people who gamble alone. An essential aspect of treatments should be to identify and address the factors that are antecedents to gambling, those that provide the underlying motivation and social and cultural context in which the behavior has developed. Only when these are addressed can treatment be extended to more specific psychological aspects of the behavior itself. This is because these broader social and structural factors influence a person's exposure to gambling, opportunities to gamble. and ability to recover. Detailed analysis of the person's daily schedule and the nature and extent of available social supports is essential during this phase of treatment.

Viewing problem gambling as a biopsychosocial process recognizes the diversity of psychological factors involved in maintaining the behavior as well as the fact that problem gamblers are not a homogeneous group; in fact, there appear to be a number of subtypes (Griffiths, 2005). This has major treatment implications. For instance, Griffiths (1995) outlined two very different types of gamblers. The first type appeared to be addicted to gambling itself and played to test skill, to gain social rewards, and mostly for excitement (i.e., the "buzz" or "high"). This was termed a primary addiction and appears to be a mixture of subcultural and impulsivist types of gamblers (Moran, 1970; Blaszczynski & Nower, 2002). Identifying the environmental, situational, or emotional factors that precede a gambling session are important to know in administering any therapeutic intervention. Imaginal desensitization, counterconditioning, and situational exposure are methods that have been used to teach people to resist the urge to gamble. Of course, therapists differ in their views concerning the factors underlying this urge. Whereas some emphasize the learned or conditional quality of the behavior and emphasize the role of stimulus control, others may emphasize irrational beliefs or the gambler's desire to obtain physiological stimulation from the activity.

Furthermore, as emphasized by Griffiths (1995), a second type of gambler may gamble for the reasons described earlier, such as escape. These gamblers are usually depressed and socially isolated, and could be described as having a secondary addiction, in that the player uses gambling as an escape from a primary problem (e.g., broken home, relationship crisis, etc.). It seems that this type of escape gambler is not confined to the United Kingdom. This type appears to be a mixture of neurotic and symptomatic"(i.e., emotionally vulnerable) types (Moran, 1970; Blaszczynski & Nower, 2002). If the primary problem is resolved by excessive gambling, then playing should disappear. This distinction between types of gamblers obviously has clinical usefulness and may also help explain conflicting research, some of which states that gambling is a social activity and some of which states that it is a solitary activity. As discussed above, addicted gamblers are likely to benefit from any intervention that tries to find alternative activities to take the place of gambling. Like Griffiths's writing, more recent writings by Blasczcynski and Nower (2002), suggest there are different subtypes of gamblers that follow different pathways.

CONCLUSIONS

Examining gambling and gambling addiction as a biopsychosocial behavior makes it evident that individual differences and broader contextual factors must be considered and not ignored (Griffiths, 2005). This chapter provides

evidence that a narrow focus upon one theoretical perspective in research and clinical interventions may, in many cases, not be justified. Such an approach fails to consider the interrelationships between different levels of analysis. It would be of limited value to many gamblers whose problems have a different etiology, which may be multifaceted. As Gambino and Shaffer (1979) pointed out nearly three decades ago, individuals are self-determining agents, and therefore, a taxonomy of situations must be developed to describe the vast majority of contexts and conditions in which people use substances or engage in habitual behaviors to alter their perceived experience.

Gambino and Shaffer also make the important point that these behaviors are not completely self-developed or understood by the people themselves and should be examined more broadly. This is because gambling becomes a habitual behavior. Since the perceived experience of the individual can change over time, it is possible that focusing upon the self-reported factors currently maintaining the behavior does not provide insights into the factors that led to the development of the behavior. Thus, when one takes a biopsychosocial view, it becomes possible to perceive individual gambling in terms of its broader social and cultural context. This approach also suggests that different perspectives and approaches may be beneficial, as long as they appear to apply to the particular gambler concerned. Moreover, it indicates that a variety of treatments could be beneficial simultaneously.

Chapter **12**

Youth Gambling Problems: An International Perspective

Isabelle D. Lussier, MA,
Jeffrey L. Derevensky, PhD, and Rina Gupta, PhD

Gambling involves the wagering of money on games of chance and is a popular pastime for people in most parts of the world. The literature on gambling behavior indicates that children and adolescents enjoy and frequently participate in gambling despite legal restrictions on underage gambling (Derevensky & Gupta, 2000; Gupta & Derevensky, 1998a). Recent reviews suggest that upwards of two-thirds of underage North American youth have gambled in regulated and licensed gambling venues (Jacobs, 2000, 2004), with adolescents having been reported to have pathological gambling prevalence rates two to four times those of adults (Gupta & Derevensky, 1998a; National Research Council [NRC], 1999). In fact, there is growing evidence that a small but identifiable proportion of adolescents in many countries exhibit excessive gambling behavior (Becoña, 1997; Delfabbro & Thrupp, 2003; Fisher, 1993; Johansson & Götestam, 2003; Ólason, Sigurdardottir, & Smari, 2005; Skokauskas, 2007).

Current research supports the notion that problem gambling behavior often begins early, between the ages of nine and eleven years of age (Gupta & Derevensky, 1998a; Jacobs, 2000, 2004), an age of onset that is earlier than that for most illicit substances (Gupta & Derevensky, 1998a). As well, excessive gambling among adolescents has been shown to be positively correlated with participation in increased delinquency and criminal behaviors, substance use, and antisocial behaviors (Derevensky & Gupta, 2004a; Ladouceur, Dubé, & Bujold, 1994). The serious nature of gambling problems is especially disconcerting considering that gambling is perceived to be a highly socially acceptable

activity among adults and adolescents, with little recognition of its inherent risks (Azmier, 2000; Gupta & Derevensky, 1997).

For a long time, adolescent gambling dependency went unnoticed compared with other addictions given that gambling dependence is not always directly observable in youth, that the negative consequences for youth may not be perceived to be as severe as those for adults, and that gambling behavior is prevalent and currently widely accepted (Derevensky, 2007, and Derevensky, in press; Derevensky & Gupta, 2004a; Hardoon & Derevensky, 2002). In fact, gambling is so widely acceptable in our society that unregulated forms of gambling frequently occur in the home and begin as a family activity (Felsher, Derevensky, & Gupta, 2003; Gupta & Derevensky, 1997). Parents are often aware of their children's gambling activities and many children's first gambling experience occurs in the home with a family member. However, as children get older, they tend to gamble less with family members and more with peers (Gupta & Derevensky, 1997).

Recently, a pathways model has been formulated, suggesting that there are several subtypes of adolescents who meet the criteria for probable pathological gambling behavior, but who demonstrate different antecedents and related symptoms (Nower & Blaszczynski, 2004). Further sharpening our understanding of gambling problems, Abbott, Volberg, Bellringer, and Reith (2004) point out that the scientific investigation of gambling problems must address nuances inherent to the broad subject of gambling. For example, the popularity of certain types of gambling appears to vary from country to country, and some forms of gambling are likely more strongly associated with gambling problems (Abbott et al., 2004). However, it is equally important to note that apparently less problematic forms of gambling (for example, the lottery) may be a gateway to more harmful types of gambling (Felsher, Derevensky, & Gupta, 2004).

MEASUREMENT ISSUES

The most widely used categories to represent youth gambling behavior are based upon a continuum and diagnostic screens that include designated cut-off scores for problem and pathological gambling, at-risk gambling behaviors, and social gambling (Derevensky, Gupta, & Winters, 2003). Adolescents who meet the criteria for pathological gambling demonstrate a pervasive pattern of excessive gambling behaviors and experience severe gambling-related problems. Derevensky and Gupta (2004b) contend that the adolescent classification of *pathological gambler* is in itself problematic since pathological behavior, as it is currently operationalized, implies a long history of gambling behavior. As such, they have argued that it may be premature to apply this term to young

populations, and they recommend the use of the term *probable pathological gambler* instead. The category *at-risk gambler* refers to adolescents who do not yet meet sufficient criteria to be classified as probable pathological gamblers on gambling screens, but who remain at risk for the development of severe gambling problems should their behaviors and the negative consequences of excessive gambling escalate (Shaffer & Hall, 1996). In contrast, *social gamblers* most often gamble occasionally, appear to have no difficulty controlling their gambling behavior (in terms of setting money and time limits) and have no negative consequences associated with their gambling.

Despite advances in our understanding of the development, acquisition, and maintenance of youth gambling problems, most adolescent gambling screens are adaptations of adult instruments, with items having been modified to make them more developmentally appropriate. Several of the most commonly used instruments include the South Oaks Gambling Screen—Revised for Adolescents (SOGS-RA) (Winters, Stinchfield, & Fulkerson, 1993), the DSM-IV-J (Fisher, 1992), and its revision the DSM-IV-MR-J (Fisher, 2000) (see Derevensky & Gupta, 2004b for a detailed description of each instrument and its criteria). Currently, the Canadian Centre for Substance Abuse and the Ontario Problem Gambling Research Centre are in the final stages of developing a new adolescent instrument, the Canadian Adolescent Gambling Inventory. Further testing of this instrument will be necessary, but this will in fact be the first instrument specifically designed for adolescents.

Although no gold standard for the measurement of adolescent problem gambling currently exists (Derevensky et al., 2003), concordance between the DSM-IV, DSM-IV-MR-J, and the SOGS-RA is reportedly high, particularly for identifying gambling problems among boys (Derevensky & Gupta, 2000). The DSM-IV-MR-J appears to be a slightly more conservative measure than the SOGS-RA (Derevensky & Gupta, 2000; Ólason et al., 2005). However, variations in cut score criteria, omissions and/or insertion of items, and translation problems have led to serious difficulties in reliably estimating the prevalence rates of adolescent problem gambling and comparing study outcomes (Derevensky & Gupta, 2006). As well, Gambino (2006) has emphasized the need for community-specific validation of youth gambling scales, given the variability in accessibility to different forms of gambling.

PREVALENCE

Gambling and problem gambling have been described as "moving targets" (Abbott et al., 2004), because gambling activities and venues for gambling continue to change (e.g., Internet gambling; mobile gambling), and because the

criteria for classifying individuals with gambling problems continue to evolve with each new release of the classificatory system in the *Diagnostic and Statistical Manual* (*DSM*), thus making comparisons between outcomes in prevalence studies over time difficult. Although little is known regarding best practices in gambling research, increasingly governments are establishing systems to monitor the impact of gambling over time (e.g., in Australia, Canada, New Zealand, South Africa, and the United States) (Abbott et al., 2004).

The fact that the discrepant variability in prevalence rates for youth problem gambling is generally larger than the variability in prevalence rates for adults (e.g., NRC, 1999) has elicited some debate among researchers (Derevensky & Gupta, 2006; Derevensky et al., 2003; Ladouceur et al., 2000). Aside from the possibility that adolescent reports are simply more variable than adult reports (Derevensky & Gupta, 2006), it has been postulated that the larger variability in youth gambling prevalence studies may be due to various situational and measurement variables including sampling procedures, the use of different instruments (including varying cut-point scores, the use of modified instruments, and unverified translations), gender distributions within samples, the age of the population being assessed, cultural and ethnic differences, the availability and accessibility of different forms of gambling, the existing statutes concerning regulated forms of gambling, and the time frame used for assessing gambling behavior (see Derevensky & Gupta, 2000; Derevensky et al., 2003; Shaffer, LaBrie, LaPlante, Nelson, & Stanton, 2004; Stinchfield, 2002). In addition, the variability in terminology used to identify adolescents with gambling problems (e.g., pathological gamblers, probable pathological gamblers, compulsive gamblers, problem gamblers, level 3 gamblers, disordered gamblers) further obscures comparisons among outcomes in prevalence studies and has led to a need for greater standardization in nomenclature and terminology in youth gambling research (Derevensky & Gupta, 2006; Shaffer et al., 2004).

North America

The onset of gambling experiences occurs early among North American youth, with a median age ranging between 11 and 13 years (Jacobs, 2000). This age of onset is younger than the expected age of onset for cigarette use, consumption of alcohol, and substance use (Gupta & Derevensky, 1998a; Jacobs, 2000). Among North American youth, the lottery appears to be the preferred legalized/regulated form of wagering (Jacobs, 2000, 2004), likely due to the lax regulations concerning selling to underage minors and the perception of the lottery as a nonaddictive form of gambling.

Youth gambling behaviors are often dependent upon the availability and accessibility of games and gaming locations, gender and type of game (males more frequently report sports wagering as a preference, whereas girls more frequently report bingo), age (older adolescents are more likely to play video lottery terminals and to engage in casino gambling), and cultural and ethnic background (Chevalier, Deguire, Gupta, & Derevensky, 2003; Derevensky, in press; Ellenbogen, Gupta, & Derevensky, 2007; Gupta & Derevensky, 2004).

Meta-analyses and reviews that look at youth gambling behaviors and problems in North America reveal lifetime gambling rates among adolescents that range from 39 percent to 92 percent, prevalence rates for serious youth gambling problems that range from 4 percent to 8 percent, and prevalence rates for youth at risk for developing or returning to serious gambling problems that range from 10 percent to 15 percent (Jacobs, 2000, 2004; NRC, 1999; Shaffer & Hall, 1996). Gambling participation and problematic gambling behavior among youth appear to have increased substantially between 1984 and 2002 (Jacobs, 2004). Based on findings from an examination of 20 prevalence studies, Jacobs (2000) estimated that 2.2 million North American adolescents experience gambling-related problems. The National Research Council (NRC, 1999), designed to assist the United States National Gambling Impact Study Commission, reported that the proportion of adolescents exhibiting pathological gambling behavior in the United States could be more than three times that of adults (5.0 percent vs. 1.5 percent) (NRC, 1999). Several recent studies conducted in the United States describe findings similar to those of these large reviews and early meta-analyses (Gealt & O'Connell, 2006; Langhinrichsen-Rohling, Rohde, Seeley, & Rohling, 2004).

In Canada, recent studies also demonstrate that approximately 3–7 percent of adolescents surveyed in prevalence studies meet the criteria for pathological gambling using the DSM-IV or DSM-IV-MR-J screens (Derevensky & Gupta, 2000 [3.4 percent], 2001 [3.4 percent]; Gupta & Derevensky, 1998a [4.7 percent], 2000 [6.7 percent]; Hardoon, Gupta, & Derevensky, 2002 [4.9 percent]; Lussier, Derevensky, Gupta, Bergevin, & Ellenbogen, 2007 [3.2 percent]; Ste-Marie, Derevensky, & Gupta, 2002 [4.4 percent]). While most of these surveys have been conducted in Quebec and Ontario, a large-scale prevalence study in four Atlantic provinces of Canada was conducted in 1998. The sample design was a single-stage cluster sample of randomly selected and stratified classes (grades 7, 9, 10, and 12) (Poulin, 2000). Broad definitions of problem gambling and at-risk gambling led to prevalence rates of 6.4 percent and 8.2 percent, respectively, whereas narrow definitions of problem gambling and at-risk gambling revealed prevalence rates of 2.2 percent and 3.8 percent, respectively.

Europe

During the 1960s and 1970s, many European countries legalized various forms of gambling, including electronic gaming machines (Becoña, Labrador, Echeburúa, Ochoa, & Vallejo, 1995). Early studies suggested that per capita spending on gambling in Germany, Holland, and Spain was among the highest in European countries (Becoña et al., 1995). Further, it was estimated that at least half of the people with pathological gambling problems in Holland, Spain, and Germany were under the age of 30 (Becoña et al., 1995). Despite these statistics, there remains a dearth of information regarding gambling behavior and problem gambling estimates among children and adolescents in these countries. Most published research on youth gambling in Europe has been conducted in the United Kingdom (UK), the Nordic countries, Spain, Iceland, and more recently Eastern Europe. The findings of these studies are summarized by region below.

United Kingdom

Research on youth gambling problems in the UK has focused mostly on amusement machines, commonly referred to as fruit machines (Fisher, 1993, 1995; Fisher & Griffiths, 1995; Yeoman & Griffiths, 1996), lottery and scratchcards (Griffiths, 2000; Wood & Griffiths, 1998, 2002, 2004; Wood, Griffiths, Derevensky, & Gupta, 2002; Wood, Griffiths, Stevens, Bartlett, & Pye, 2006), and more recently, video games and the Internet (Chappell, Eatough, Davies, & Griffiths, 2006; Griffiths & Wood, 2000; Wood, Griffiths, & Parke, 2007). Although most forms of commercial gambling are reserved for adults (18+), no age restriction has been placed on low-stakes fruit machines, and the lottery and sports pools have long incorporated an age restriction to the age of 16 years and above (Fisher, 1999). The UK is currently the only country in the world that allows juveniles to legally wager on fruit machines, for which the government has been subject to criticism (Orford, 2003). From 1997 to 1998, more than 82 percent of problem-related calls from adolescents placed to a gambling helpline in Britain were from individuals who gambled on fruit machines (Griffiths, Scarfe, & Bellringer, 1999).

Fruit machines, found in seaside arcades, cafés, and restaurants, are easily accessible to many youths in the UK and represent a serious problem (Griffiths, 2000). As such, it is not surprising that there has been a proliferation of research and proposals for the elimination of fruit machines and for raising the minimum age at which to gamble. Similarly, given the wide variety of gambling opportunities and the social acceptability of gambling, it is not surprising that

the rates of youth problem gambling in the UK remain relatively high. The first national prevalence study, conducted by Fisher (1999), examined youth gambling behaviors among 10,000 adolescents in England and Wales, aged 12–15. The study focused on fruit machines and scratchcards. Based on DSM-IV-MR-J scores, findings revealed an overall problem gambling prevalence rate of 5.6 percent. Males were more likely to be problem gamblers than females, and children identified as problem gamblers were more than three times as likely to report that their parents gambled too much. As well, problem gambling was reported to be more prevalent among seaside residents than among those that lived inland, likely due to the popularity of seaside arcades (Fisher, 1999). Similarly, using an adapted version of the DSM-IV-J, Wood and Griffiths (1998) explored the psychosocial effects of the lottery and scratchcards among 1,195 adolescents (aged 11–15). A positive correlation was found between parental and child gambling, with most lottery tickets and scratchcards being bought for juveniles by their parents. Of the 6 percent of participants who met the criteria for pathological gambling, the majority were male.

More recently, Wood and his colleagues (2006) conducted a large-scale national prevalence study, which included 8,017 adolescents aged 12–15. Overall, lifetime participation in gambling activities in this age group had fallen to 73 percent. Most notably, the prevalence of problem gambling had declined to 3.5 percent (based on DSM-IV-MR-J cut scores). Although prevalence of problem gambling on scratchcards and/or fruit machines in particular had also declined, it remained relatively high at 6.0 percent compared with international rates. As might be expected, boys were more likely to participate in gambling activities and to demonstrate problematic gambling behaviors. As well, youth living in coastal areas were more likely to exhibit problems with fruit machine gambling compared to those that lived inland (4.7 percent vs. 2.9 percent). This last-mentioned finding was attributed to the wide availability and easy accessibility of fruit machines in coastal areas. It is also important to note that this prevalence study did not include older adolescents.

In Scotland, Moodie and Finnigan (2006) conducted a study of the prevalence of gambling behavior and problems in Scotland among 2,043 adolescents aged 11–16. This was the first prevalence study of its kind in the country. Using the DSM-IV-J as a gambling screen, findings revealed a striking 9.0 percent probable pathological gambling rate with an additional 15.1 percent reported as being at risk for developing or returning to a serious gambling problem. The most popular gambling activity was the use of fruit machines. Males were more likely to meet the criteria for probable pathological gambling (3.5:1), and 76 percent of all adolescents reported that they had gambled in the past. Also, youth with gambling problems were more likely to report having friends and

family members who gambled. The age of onset for gambling was young, at 10.3 years of age for nonproblem gambling, 9.5 years for at-risk gambling, and 9.3 years for probable pathological gambling. More than a third of the sample considered gambling a "good" or "very good" way to make money. Despite the high rates of problem gambling in Scotland, treatment options remain scarce (Moodie & Finnigan, 2006).

Nordic Countries

Prevalence estimates indicate that the rate of problem gambling in Nordic countries may be lower than those obtained in North America and the UK (Johansson & Götestam, 2003; Ólason et al., 2005; Ólason, Skarphedinsson, Jonsdottir, Mikaelsson, & Gretarsson, 2006; Volberg, Abbott, Ronnberg, & Munck, 2001). However, further research must be conducted within Nordic countries to confirm these results, particularly in Denmark and Finland where no published studies of adolescent problem gambling were found.

In Iceland, there is no age restriction on scratch cards, lotteries, sport pools, and bingo. However, electronic gaming machines (EGMs) are restricted for youth under the age of 16, and wagering on horse races is illegal for anyone under the age of 18 (Ólason et al., 2005). Two adolescent prevalence studies in Iceland have examined youth gambling rates amongst 13–15-year-old and 16–18-year-old adolescents (Ólason et al., 2005, 2006). The survey for youth aged 13–15 was distributed among 25 primary schools in Reykjavik (N = 3,511). The DSM-IV-MR-J and the SOGS-RA screening items were both administered, with results indicating prevalence rates of 1.9 percent (DSM-IV-MR-J) and 2.8 percent (SOGS-RA) for problematic gambling, and an additional 3.7 percent (DSM-IV-MR-J) and 4.1 percent (SOGS-RA) for being at risk of developing or returning to serious gambling problems (Ólason et al., 2006). Of the full sample, 70 percent of adolescents reported that they had gambled in the past year, and 93 percent reported that they had gambled at least once in their lifetime. The age of onset for gambling was 9.5 years, and boys were again more likely than girls to demonstrate gambling problems. In addition, those classified as exhibiting a gambling problem were more likely to report that their parents and peers gambled. EGMs, which are widely available, were the most popular form of gambling among youth with gambling problems (41 percent). The survey for youth aged 16–18 found similar rates, with 2 percent (DSM-IV-MR-J) and 2.7 percent (SOGS-RA) of youth identified as having gambling problems, and an additional 3.2 percent (DSM-IV-MR-J) and 4.4 percent (SOGS-RA) being at risk for gambling problems (Ólason et al., 2005).

In Norway, a study conducted by Johansson and Götestam (2003) included 3,237 youths aged 12–18 that were solicited via telephone and postal interviews. Using selected DSM-IV criteria to classify problem gamblers, 1.8 percent of adolescents were identified as exhibiting problematic gambling behavior, while another 5.2 percent were at risk of developing or returning to serious gambling problems. Boys were four times as likely as girls to exhibit gambling problems. Slot machines were rated as the most popular form of gambling, and 82 percent of youth reported that they had gambled in the past. Interestingly, the age of onset for gambling in this study was 9 years with an onset age range of 4–18 years of age, indicating that while the age of onset in Norway is low, problematic gambling rates also remain relatively low.

In a study carried out by Statistics Sweden, 2 percent of adults were identified as exhibiting gambling problems (Volberg et al., 2001). Individuals in the sample ranged in age from 15 to 74 years (N = 9,917). Analyses carried out on the younger participants (15–24) revealed that youth had a 151 percent higher risk than those over 25 years of exhibiting lifetime problem gambling behavior. Unfortunately, the prevalence rates for adolescents (15–17) were not reported in this study, and only adult gambling screens were administered.

Spain

Spain is believed to be among the countries in Europe that spends the most money per capita on gambling (Becoña et al., 1995; Hand, 1992). In Spain, type A machines, known as amusement machines or more colloquially as *comecocos,* are available to youth under the age of 18. Although they offer no cash prizes, they do offer free games and publish the winner's name and score (Becoña et al., 1995). A study conducted by Becoña (1997) estimated the prevalence rates to be 2.2 percent and 1.6 percent for problem gambling among adolescents aged 11–16 in two northern regions of Spain (Galicia and Asturias) (N = 2,185). More recently, Becoña and Miguez (2001) surveyed a sample of 2,790 adolescents using the SOGS-RA. Their findings revealed that overall, 5.6 percent of the participants met the criteria for problem gambling and another 8.2 percent were at risk of developing or returning to serious gambling problems.

Eastern Europe

Research conducted in Lithuania and Romania has recently emerged regarding youth gambling behavior. During Soviet control, access to gambling was largely prohibited. However, there appears to have been a rapid expansion of gambling venues and opportunities since that time (Lupu, Onaca, & Lupu,

2002; Skokauskas, 2007). In the early 1990s, slot machines, initially registered as computer games or gaming machines, were made available to the public in Lithuania (Skokauskas, 2007). Due to inadequate controls, youth were free to engage in these forms of wagering. In 2002, gambling was legalized in Lithuania and youth became exposed to a wider variety of gambling activities (Skokauskas, 2007). A recent prevalence study in Lithuania using the DSM-IV-MR-J identified 4.2 percent of youth (aged 10–18) as exhibiting probable pathological gambling behavior. An additional 9.1 percent were classified as being at risk of developing or returning to severe gambling problems. Overall, 82.6 percent of adolescents had engaged in some form of gambling. Six characteristics that were found to be associated with problem gambling included being male, having cognitive distortions regarding gambling, having parents who gambled, using alcohol, and smoking (Skokauskas, 2007). In Romania, a prevalence study of youth gambling based on the Gamblers Anonymous 20 questions in three districts identified 6.8 percent of youth (aged 14–19) as exhibiting gambling problems (Lupu et al., 2002). Males were found to be almost five times more likely to meet the criteria for problem gambling than females. The most frequent forms of gambling were pool (56%), poker (35%), and bingo (32%).

Australia

In Australia, gambling activities are generally available only in licensed establishments and are restricted to adults (Delfabbro & Thrupp, 2003). Most gambling among Australian youth occurs privately (individually or with peers and/or parents), which has been presented as support for the notion that regulatory provisions are working well in the country (Delfabbro, Lahn, & Grabosky, 2005). In terms of prevalence estimates in Australia, early research by Moore and Ohtsuka (1997) revealed that 3 percent of youth aged 14–25 in Melbourne were identified, using a modified version of the SOGS, as having a gambling problem. Approximately 75 percent of the sample had gambled in the past, with higher prevalence estimates among boys. Further research by Moore and Ohtsuka (1999, 2000) supported these findings, with 3.8 percent of youth being classified as having gambling problems based on scores from the SOGS in two studies of 14–25-year-old and 15–18-year-old participants. As well, findings from a sample of 505 adolescents aged 15–17 by Delfabbro and Thrupp (2003), revealed that 62.5 percent had gambled in the previous year, and that 3.5 percent could be classified, based on scores from the DSM-IV-J, as having a gambling problem. Lotteries, scratch-tickets, and sports betting were identified as the most popular gambling activities, and youth with gambling

problems were more likely to have friends and family members who approved of their gambling and/or gambled themselves. Most recently, Delfabbro and his colleagues (2005) identified 4.4 percent of youth aged 11–19 as exhibiting gambling problems (based on DSM-IV-J scores), indicating a slightly higher prevalence rate of gambling problems than was revealed by prior studies in the country.

RISK AND VULNERABILITY FACTORS

Among adolescents, there appears to be a rapid movement from social to problem gambling (Derevensky & Gupta, 1999). There are many factors involved in the acquisition, development, and maintenance of youth gambling problems. Although gambling does not involve the ingestion of a substance, and is unique in its emphasis on attributions of luck, skill, and attitudes about money, pathological gambling and drug dependency share common consequences including tolerance, dissociative states, and physiological arousal (APA, 2000; Felsher, 2007). Stinchfield and Winters (1998) have identified commonalities between risk factors identified in the substance abuse and youth gambling literature, including family history of the respective problem, low self-esteem, depression, family norms (e.g., attitudes that promote the problem), physical or sexual abuse, poor academic performance, delinquency, community norms (e.g., promotion and access related to drug use or gambling), and early onset. Similarly, Dickson, Derevensky, and Gupta (2002) demonstrated a large degree of overlap in risk factors shared by people exhibiting problem gambling and those exhibiting other addictions over a wide breadth of domains including individual, social/familial, and neighborhood/societal (Dickson et al., 2002). The overlap in risk factors identified in the gambling and substance abuse literature has led clinicians to adopt Jacobs' (1986) general theory of addictions as a framework for conceptualizing problem gambling behavior and commonalities across addictions (Gupta & Derevensky, 1998b; Winters & Anderson, 2000). Unique risk factors and overlapping risk factors between youth gambling problems and other youth addictions are described in greater detail below.

Individual Factors

Individual factors such as physiological, personality, emotional, coping, values and attitudes, and chronic problem behaviors have been shown to be associated with excessive youth gambling behavior (Derevensky & Gupta, 2004a; Dickson et al., 2002; Hardoon & Derevensky, 2002). Adolescents meeting the criteria for pathological gambling are also more likely to report difficulty in

school, exhibit truancy, and have poor grades (Hardoon, Gupta, & Derevensky, 2004; Lesieur et al., 1991). Current research regarding individual risk correlates among adolescents with gambling problems suggests that probable pathological gambling is more prevalent in males than females (NRC, 1999), with males being more likely to gamble larger amounts of money (Derevensky, Gupta, & Della-Cioppa, 1996), to begin gambling at an earlier age (Derevensky & Gupta, 2001), to gamble more frequently (Jacobs, 2000, 2004), and to exhibit a wide variety of gambling-related problems (Derevensky & Gupta, 2004a).

Adolescents with gambling problems often report higher levels of risk-taking behaviors (Gupta, Derevensky, & Ellenbogen, 2006), impulsivity (Nower, Derevensky, & Gupta, 2004; Vitaro, Arseneault, & Tremblay, 1999), anxiety (Ste-Marie, Gupta, & Derevensky, 2006), depression, suicide ideation, and suicide attempts (Gupta & Derevensky, 1998b; Kaufman, 2004; Nower, Gupta, Blaszczynski, & Derevensky, 2004). As well, youth with gambling problems are more likely to have a history of delinquency (Magoon, Gupta, & Derevensky, 2005) and/or to engage in other maladaptive behaviors including substance and alcohol abuse (Hardoon et al., 2004; Winters & Anderson, 2000). Adolescents have been reported to be four times more likely to gamble daily or weekly if they also consume drugs on a regular basis (Winters & Anderson, 2000).

Familial/Social Factors

Many youth who exhibit severe gambling problems report that their first gambling experience occurred at home with a family member (Gupta & Derevensky, 1997). They are also more likely to have a parent who struggles with an addiction (Gupta & Derevensky, 1998a; Wood & Griffiths, 1998). Although youth gambling frequency appears to be related to both parents' gambling frequency and gambling problems, youth gambling problems appear to be linked mostly to fathers' severity of gambling problems (Vachon, Vitaro, Wanner, & Tremblay, 2004). In addition, research findings indicate that even after controlling for socioeconomic status (SES), gender, and impulsivity-hyperactivity problems, significant associations remain between youth gambling problems and poor parental monitoring and disciplinary strategies (Vachon et al., 2004).

More recently, the combination of being in a family that interacts infrequently and concurrently feeling a lack of bond to one's family was found to contribute to the prediction of problem gambling (Lussier et al., 2007). Although these findings require replication and further study, they indicate the possibility of a curvilinear relationship between familial interaction and gambling

behavior. A curvilinear relationship for parental control/monitoring has been demonstrated in adolescent sexual behavior research (Miller, McCoy, Olson, & Wallace, 1986). As well, it has been noted that drug-using adolescents often report their parents as being overcontrolling (Meschke & Patterson, 2003).

There is some evidence that peer modeling and social learning are involved in the onset of gambling problems (Gupta & Derevensky, 1997; Hardoon & Derevensky, 2001). Many adolescents report that they gamble because their friends engage in this behavior (Griffiths, 1990). As well, adolescents with gambling problems commonly replace old friends with individuals who share their interests in gambling (Gupta & Derevensky, 2000).

Neighborhood/Societal Factors

Despite the lack of formal prevalence studies for youth problem gambling among various socioeconomic groups, preliminary data demonstrate that low SES youth may be at higher risk for gambling problems compared to other youth (Fisher, 1993; Kaufman, 2004; Schissel, 2001; Vitaro et al., 1999). As well, ethnic/racial minority youth appear to be at greater risk for developing and maintaining gambling problems (Lesieur et al., 1991; Schissel, 2001; Volberg et al., 2001). Interestingly, compared with Francophone (French-speaking) or Anglophone (English-speaking) youth, Allophone (neither English nor French is their mother tongue) adolescents made up the greatest proportion of youth with gambling problems in a community sample of over 1,000 Quebec adolescents (Ellenbogen, Gupta, & Derevensky, 2007).

First Nation youth appear to be at particularly high risk for gambling problems (Delfabbro et al., 2005; Peacock, Day, & Peacock, 1999; Schissel, 2001; Stinchfield, Cassuto, Winters, & Latimer, 1997). In a review of literature concerning aboriginal populations and problem gambling, Wardman, el-Guebaly, and Hodgins (2001) concluded that aboriginal adolescent problem gambling and adult problem and pathological gambling rates were considerably higher, ranging from 2 to 16 times those of non-Aboriginal populations, although they caution that there are concerns regarding the validity and reliability of these rates.

Situational and environmental risk factors may interact with individual risk factors through the availability and accessibility of gambling activities and venues to further augment the possibility of developing and maintaining gambling problems (Felsher et al., 2003, 2004; Fisher, 1999; Gupta & Derevensky, 1998a; Jacobs, 2004). More specifically, game features and technological advances have been associated with problem gambling. Structural characteristics of games that encourage continued, repetitive play such as high event

frequencies and intermittent reinforcement schedules (e.g., electronic gambling machines and scratchcards) as well as qualities that create a favorable ambience for play, such as vivid colors, sounds, music, and lights (e.g., electronic forms of gambling) are believed to enhance the availability, accessibility, and addictive potential of games (Abbott et al., 2004; Derevensky, 2007; Felsher et al., 2003; Griffiths & Wood, 2004). Technological advances continue to provide enticing gambling opportunities in the form of Internet gambling, interactive lotteries, keno and television wagering, mobile gambling (via cell phones), and novel slot machines (Griffiths & Wood, 2000). Recent research indicates that a large number of youth have gambled on Internet sites without money (Byrne, Gupta, & Derevensky, 2004), leading to a growing concern that such sites may be training youth to gamble with money once they obtain their own means to do so (Derevensky, 2007).

YOUTH GAMBLING BEHAVIOR AND RESILIENCY

Clearly, bio-psycho-social factors are involved in the acquisition, development, and maintenance of gambling behavior. Despite the existence of much literature on factors that predispose youth to problem gambling, very little research has addressed the identification of moderating variables that serve to mitigate the development and maintenance of severe gambling behavior (Dickson, Derevensky, & Gupta, 2008; Lussier et al., 2007). Youth gambling researchers have specified a need for effective ways to strengthen resiliency traits in children (Derevensky, Gupta, Dickson, & Deguire, 2004; Dickson et al., 2002, 2008; Winters, Arthur, Leitten, & Botzet, 2004). Educating children to develop the capacity and resources required to resist and overcome adversity is a rational and increasingly effective approach. The research that has focused on adolescent resilience has demonstrated a strong relationship between healthy, resilient behaviors and successful outcomes (Werner & Smith, 1992).

Dickson and colleagues hypothesized that the protective factors that apply to other addictive behaviors would also buffer against the acquisition, development, and maintenance of excessive youth gambling (Dickson et al., 2008). Using a community sample of adolescents, Lussier and colleagues (2007) examined whether youth identified as resilient (high risk exposure/high internalized protection scores) were as likely as those identified as vulnerable (high risk exposure/low internalized protection scores) to engage in excessive gambling behavior. Their findings demonstrated that resilient and vulnerable youth differed significantly in their self-reported gambling severity. As well, youth identified as resilient were not found to be statistically distinguishable from low-risk exposure groups in terms of their gambling severity. Lussier and colleagues also

examined the relative contribution of various risk (family, peers, neighborhood, substance use) and resiliency traits (social bonding, personal competence, social competence) domains in relation to problem gambling behavior and reported that environmental risk and resiliency traits each provided a unique contribution to the prediction model of gambling problems, with low levels of social bonding being the greatest predictor (Lussier et al., 2007).

SUMMARY AND FUTURE DIRECTIONS

While caution is necessary in comparing prevalence rates from different studies, it appears that the prevalence of youth gambling problems in Nordic countries (Johansson & Götestam, 2003; Ólason et al., 2005, 2006) and Australia (Delfabbro & Thrupp, 2003) is lower than in North America (Derevensky & Gupta, 2000; Jacobs, 2000, 2004; NRC, 1999) and the UK. However, in all countries, adolescents and young adults appear to have higher prevalence rates than older adults (Abbott et al., 2004), boys appear to have higher prevalence rates than girls, and youth whose parents endorse gambling activities have higher prevalence rates than youth whose parents do not. Also, a small but identifiable proportion of the adolescents in all countries where prevalence estimates exist reported significant gambling-related problems.

In Europe, electronic gambling machines appear to be more easily accessible and more popular among adolescents than in North America. The fact that they are often widely distributed in public places in Europe has led some policy experts to suggest that their popularity is related in part to easy access, where enforcement of age limits is lax (Ólason et al., 2006). In fact, accessibility and availability of gambling activities and venues are increasingly identified as significant risk factors that may interact with individual risk factors to further augment the chances for certain youth to acquire and maintain problematic gambling behavior (Abbott et al., 2004; Derevensky, 2007). For this reason, it has been suggested that legislation and policies that increase access to gambling activities will likely create higher problem gambling prevalence rates and in turn generate social and economic costs to families and communities (Abbott et al., 2004).

It is estimated that active participation in Internet gambling among youth may continue to rise significantly as accessibility becomes easier and as popularity of and familiarity with such gambling venues increase (Derevensky, 2007). Internationally, there is ample indication that individuals having significant gambling problems do not seek or acquire treatment for their symptoms, indicating a need for better prevention and intervention programs that reduce the barriers for individuals seeking help.

Adolescent problem gambling remains an important social policy issue in need of appropriate prevention and responsible social policies (see chapter 17 in this volume for more information regarding prevention strategies). The study of youth gambling research supports and broadens contemporary theories of typical and atypical development and provides information concerning risk and protective factors that may be applicable to the development of prevention and intervention initiatives for a targeted gender, or for age groups, cultures, or adolescents as a whole.

Chapter **13**

Macau: China's Entry into the World of Gambling[1]

Richard A. McGowan, MA, MDiv, ThM, DBA

Gaming in Macau is not a new phenomenon. Its history traces back to before the Portuguese colonized the island in the sixteenth century. When the Portuguese did arrive, they did not attempt to change the customs of the indigenous people. However, gaming was not officially legalized until the 1850s, and the industry did not start booming until the end of the nineteenth century.

In 1930, the decision to auction off a monopoly on gaming was made by the Portuguese Colonial rulers to the Hou Heng Company, headed by Fok Chi Ting.[2] It was then awarded in 1937 to the Tai Heng Company, which narrowly lost the right to it in 1962 to STDM. The Portuguese government contemplated four special licenses in 1982, which would have given groups a specific geographic region over which they would have a monopoly. However, this proposition did not pass, and STDM's monopoly existed until 2002. In 2002, Portugal handed over control of Macau to the Chinese government. Since 2002, the Chinese government has made many concessions and subconcessions to gaming companies. The first resort to open as a result of these moves was the Sands in May 2004. Another achievement in 2004 for the gaming companies was the new law that gave them the ability to grant credit and enforce gaming debts, a practice previously not allowed because of the cultural ideals of the residents. However, this new law was so important that Steve Wynn (owner of a premier Las Vegas casino) announced that he would not plan on buying property or opening a casino in Macau until the law was in effect.

MACAU'S GAMBLING EXPLOSION

Recently, Macau has been dubbed the "Monte Carlo of the Orient."[3] This nickname is becoming well-deserved. There were only 11 casinos in 2002. As of August 2006, there were 21 casinos operating on the island. This number was expected to more than double, to 45, in the subsequent three years. As of 2006, 60 new hotels were being planned or built to provide rooms for the upcoming influx of gamblers. However, according to locals, only two of the casinos are actually flourishing. Despite these reports, Macau's gross domestic product (GDP) grew 14.2 percent in 2003 and 28.3 percent in 2004. These factors help the younger locals to be optimistic about Macau's future.

This increase in casinos and hotels has resulted in a similarly strong increase in visitors to the island. In 2005 Macau welcomed 10.5 million visitors from China, 2.5 times as many as it had seen in 2002. Chinese visitors accounted for 56 percent of all visitors in 2005, up from 37 percent in the same time frame. Macau has growth potential in a variety of areas. According to the American Gaming Association, the acronym MICE describes the facets on which Macau should concentrate: meetings, incentives, conventions, and exhibitions. Almost every hotel planned for Macau is looking to specialize in at least one of these growth areas. For instance, the Venetian Macau plans on having 35 percent of its rooms filled by conventioneers. The Macau government has stated publicly that it intends to double its number of visitors to approximately 37–38 million by 2010.[4] Although most indicators are positive, many difficulties need to be addressed. First, there are still various issues with the Chinese government, mainly China's strong tendency to have inconsistent policies. Also, locals have some major concerns for Macau. One obvious concern is that they will become, if they have not already, too dependent on casinos. In a similar vein, they are somewhat bothered by their overreliance on gamblers coming from the Chinese mainland. Also, they realize that the rapid growth of the casino industry in Macau in the recent past and near future cannot continue given restrictions on not only demand, but also, and more importantly, land. Last, local authorities have been citing a sharp increase in casino-related crimes, such as money laundering, but others feel that the numbers are inflated because the grouping "casino-related crimes" is vaguely defined. Clearly, there is a fair amount of unease about Macau's long-term development.

Many companies are vying for a strong foothold in Macau, and some have a set strategy already. There are two basic strategies that casino-hotels can follow, embodied by two Hong Kong–listed companies. First, Melco International Development will compete directly with the U.S. gambling heavyweights Wynn

Resorts, Las Vegas Sands, and MGM Mirage on the basis of grandiose luxury.[5] Melco is planning on building Macau's first six-star hotel, the Crown Macau, in 2007, as well as the City of Dreams (a series of casinos that Macau hopes to rival the Las Vegas strip) marketed to both VIP and mass-market gamblers, in 2008, in a joint venture with Australia's Publishing and Broadcasting. Melco has a leg up in the race for supremacy in Macau because of the familiarity of its CEO, Lawrence Ho, the son of the casino monopolist Stanley Ho, with the gaming industry in Macau.

Galaxy Entertainment Group, on the other hand, intends to pursue casual visitors from mainland China who are on a budget. This is the less popular of the two strategies, but it has its advantages because there is less competition with the U.S. companies, and Melco is looking for higher-end customers. With this strategy, Galaxy does not have to invest as much in extravagant architecture and other amenities. However, Galaxy cannot afford to save on real estate, so the company is investing heavily in some of the best real estate on Macau. Either way, any new casino must have a good conception, a good location, and imagination because copycat casinos will suffer.

The growing popularity of the Macau gaming industry is aided in many ways. First, the government is improving the infrastructure in the hope, as noted earlier, of doubling visitation from 18.7 million in 2005 to 37 million in 2010. Second, the most profitable game, slots, is surprisingly popular with the Asian gamblers in Macau. Also, they have taken a liking to electronic table games, which are preferred by casinos over live table games because they take up less space and do not require paying dealer salaries. This is a key point because there are currently major labor shortages, including for dealers, in Macau, and this could signify a shift in Macau into Vegas-style gaming. This shortage of a labor supply exists because Macau's population is less than 500,000, but its residents protest the hiring of Chinese and Philippine workers, slowing the growth ability of the gaming industry in Macau. Many new casinos now poach some of the best employees from competing casinos and start wage wars. All of these developments are creating growing concerns about wage inflation among gaming companies. The average Macau gambler is searching for convenience and value. Most of them will not travel beyond the Macau peninsula center of mass, and despite the cheap hotel rates (US$20–40 per night), a decent percentage will stay just off the island for the slightly cheaper rates and then commute to the casinos, making Macau extremely dependent on gaming revenues. Because this market is geared to a low-end gambler, Macau's government does not want any permanent residents, but would like to see some time shares, second homes, and vacation suites.

COTAI—THE RICH MAN'S ALTERNATIVE

Currently, Macau is generating the majority of buzz in the gaming industry, but much of that attention may soon be shifting to its neighbor island, Cotai. Right now, Cotai mainly attracts "Macau rejecters"[6] and some conventioneers, but the island plans on attracting more developers and gamblers from Macau beginning around 2009. These "Macau rejecters" are affluent gamblers who have already become disinterested in Macau and want Cotai to become a high-end resort. The geographical area that Cotai would target has 120 million residents, giving it a large population from which to draw. This target audience will travel great lengths and pay premium prices (approximately US$200 per night) for a quality product. Also, nearby Hangquin Island is waiting for government approval to begin development of residential and leisure resorts. It is hoped that by 2010, Cotai can reach its full potential with many high-quality casinos and improved access to the area.

However, many pitfalls could arise and lessen Cotai's ability to match or surpass Macau's gaming potential. There is currently a lack of critical mass of casino venues on and access to Cotai, which will not be improved until at least 2008. This means that only "must see" casinos will have any chance to succeed. The most difficult of these problems to improve is the projected extra nine million land visitors coming through already saturated border crossings and congested roadways. Once the critical mass and access issues are resolved, the casinos of Cotai have to convince the gamblers of Macau to change their preferred casino, so that they can add them to the current group of "Macau rejecters." The optimistic view points to the surprising change in Asian preferences toward slots as a possible precedent for gamblers switching from Macau to Cotai. A bad sign for Cotai is that the opening of the Grand Waldo Cotai fell short of all expectations and has spooked investors for other potential Cotai casinos. However, optimists in this case focus on the differences between the unsuccessful opening of the Grand Waldo Cotai and the successful opening of the Venetian Macau. A few of the reasons for these differing results are that the Grand Waldo Cotai did not have as strong of a marketing strategy and it also lags behind the Venetian Macau in size and amenities. Many companies, including Wynn, are taking a wait-and-see approach to get a better feel for the market, its customers, and the progress on Cotai's infrastructure, delaying many openings until 2009 or 2010. The casinos are not the only industry struggling on Cotai. As in Macau, the short supply of land in Cotai has started a land scramble that is sending real estate prices through the roof.

If all of Cotai's needed changes occur in a timely fashion, and the pitfalls are avoided, then Cotai has the ability to become one of the top casino resort locations in Asia. The projections for Cotai predict that it could have double or triple the number of casinos that Macau has, sometime between 2012 and 2015.[7] This could make it the dominant casino resort destination in the world.

Another potential revenue driver is the availability of retail on both Macau and Cotai. Many investors are skeptical because of the difficulty that the Fisherman's Wharf is having. However, this area has some of the lowest rents on the island and attracts a low-end shopper. Two planned casinos will court high-end retailers, in order to be attractive to high-end customers. The Wynn Macau is planning on opening 10,000 square feet of retail space to satisfy its gamblers. The Venetian Macau is pulling out all of the stops to open up a retail mall that will rival its Grand Canal Shoppes in Las Vegas. However, many retailers do have reservations, so they are signing short-term leases, to take a wait-and-see approach toward the viability of retail at the Venetian Macau before signing a long-term lease. Most indicators suggest that both of these retailing endeavors will thrive, and investors should not be concerned with the Fisherman's Wharf struggles.

QUESTIONS

Clearly, Macau has achieved the greatest growth of any recent market for additional gambling. Yet some interesting questions need to be asked about whether this growth can be sustained. The first consideration is, of course, the attitude of Chinese officials. If they fear that they are losing control of these islands, they can easily deny the remaining available land parcels on both Macau and Cotai. This could easily happen, given their fear of being too dependent on one industry—namely, casino gambling. And after all, the Chinese government has made no firm commitment to the concept of private property, especially for casino operations.

Another concern of Chinese officials is the possibility of wage inflation because of the labor shortage on the island. Finally, it will be interesting to see how the governing Communist Party will reconcile its previous ban of all types of gambling in China with this establishment of another Las Vegas. If the party's authority is ever threatened on the mainland, would the Communist Party crack down on gambling on Macau in an effort to reestablish its "purity" and authority? So far, the Chinese government has "tolerated" this gambling exception, but whether or not it would sacrifice Macau as its gambling capital in times of need has yet to be tested.

Chapter **14**

Native American Gambling: Economic Development or Dependence?

Richard A. McGowan, MDiv, ThM, DBA

There are over four million Native Americans living in the 567 federally recognized Indian Tribes in the United States. Over the past 20 years, the quality of life for American Indians living on reservations has increased tremendously. However, the economic welfare statistics of these tribes still consistently place them far behind the rest of the American population. Although the cultural and historical reasons for this discrepancy are important, they will not be the focus of this chapter. This chapter concentrates purely on the rationale for Native American gambling. More specifically, this chapter concentrates on the effects that the Indian Gaming Regulatory Act (IGRA, 1988) has had on the Native American population in the United States.

This issue is of importance because many financial and political effects must be considered during development of plans for new casinos, creation of tax codes, or drafting of federal legislation, for example. States cannot impose taxes on American Indian casinos, but the IGRA allows states to negotiate compacts for exclusive rights with tribes for a share of their revenues. One-third of the 22 states that permit "Las Vegas–style" games on American Indian land receive significant revenue from the tribes.[1] Although certainly many other aspects must be considered when these political tasks are undertaken, the effects that tribal casinos have had on the welfare of the Native American population, if significant, should be weighed heavily. And if not, then the claims that tribal casinos have been a huge success need to be examined more closely. Although the data available limit the scope of this study, it should be recognized that concerns over the social welfare of Native Americans since the passing of the

IGRA (drafted as a direct result of the decision of the *California v. Cabazon* case) have even served as an impetus for a recent push for Congress to draft further legislation. Some of the proposed bills call for more closely measuring the negative effects that casinos have had on Native Americans, altering the legal uses for Indian casino revenue and changing the way the oversight committee operates. Further, in light of the recent Jack Abramoff lobbying scandals, the political associations of tribal leaders have been called into question, thereby implicating the casinos that they run.[2]

Tribal gaming is a $19.6 billion per year industry, and it is getting larger,[3] as reports from February and June 2005 indicate with headlines such as, "Tribal Casino Takes Are Soaring, Surpassing Those in Nevada."[4] According to excerpts from Dr. Alan Meister's study on Indian gaming, the growth rate of Indian casino revenues from 2003 to 2004 exceeded 15 percent[5] The number of tribes with gaming facilities grew about 3 percent in 2004 (from 221 to 228), and the number of Indian gaming facilities saw growth at about 5 percent in 2004 (from 385 to 405).[6] Although they are highly correlated with the development of new gaming facilities, the numbers of gaming tables and gaming machines have seen tremendous growth as well. In 2004, the number of gaming machines grew by 10.7 percent, and the number of table games grew by 9.4 percent. These numbers are significantly larger than the percentage of growth we see in new gaming facilities; therefore, the currently existing gaming facilities clearly are continuing to grow. In 2004, for instance, in California there were no new tribes with gaming facilities, and there were no additional Indian gaming facilities in the entire state. However, California saw a 4.5 percent growth in gaming machines and saw 16.9 percent growth in the amount of table games within its already existing 54 Indian casinos.[7]

Even nongaming revenue at Indian gaming facilities saw significant growth in 2004. This revenue includes money spent by casino patrons on food, beverages, hotel stays, retail purchases, and other entertainment at the gaming facilities. If it were possible to measure the contribution these patrons made to neighboring facilities as a direct result of their visits to the casino, then this revenue would be included as well. However, because this data is practically nonexistent, the reported nongaming revenues have the effect of underestimating the total economic contribution of expenditures at casinos. Nongaming revenue grew by 7.6 percent in 2004 or from $1.79 billion to $1.93 billion dollars. However, as discussed in the following sections, the stipulations of the IGRA are less strict about nongaming revenue than they are about revenue directly created by and received from gaming expenditures at casinos. Therefore, the effects that these revenues have on Native American welfare are much less than the effects of revenues received from gaming. Also, nongaming revenues make up less than

10 percent of gaming revenue. In general, it can be asserted that noncasino revenue does not play an important role for Native American casinos.

Furthermore, in the economic impact analysis that Dr. Alan Meister performed, he estimated several effects that tribal gaming has had on the overall economy. In total, the claim is that Indian gaming in the year 2004 contributed about $53.1 billion in output, $19.7 billion in wages, and 545,000 total jobs and helped create about $6.3 billion in tax revenue. Indian gaming in the year 2003 saw about $45.3 billion in output, $17.3 billion in wages, 489,000 jobs, and $5.7 billion in tax revenue. When the revenue-sharing agreements that each state has developed are considered, totaling $889 million, the total tax revenue garnered in 2004 reaches $7.2 billion. Of the 545,000 jobs supported by Indian casinos in 2004, 279,000 of those jobs were directly induced, and 266,000 were indirectly supported, by the output of Indian gaming. The $6.3 billion of tax revenue mainly comes from secondary economic activity as estimated by the input-output analysis that Dr. Alan Meister conducted. In his study, Meister used the Impact Analysis for Planning (IMPLAN) method, which has been in use since 1979 and is used by the Federal Emergency Management Agency (FEMA) and the Bureau of Economic Analysis; it is also very similar to the format used by the United Nations. For most of the economic estimations such as tax revenue, jobs created, and wages distributed, IMPLAN came into use.

Figure 14.1 shows the amount of revenue shared by the tribes and states according to their agreements in 2004. As one can see, states such as Connecticut, Wisconsin, and California have reasonably substantial revenue-sharing agreements with their tribes, whereas the governors of states such as Minnesota and Washington often receive flak for failing to negotiate successful compacts for their states. At this time, the IGRA does not explicitly mandate that states receive a portion of the revenue from the tribes. However, it is pervasively assumed that changes to the IGRA will be made in the future and that among those changes will be an additional clause that provides the framework for adopting revenue-sharing agreements in new compacts.[8]

The issue surrounding revenue-sharing agreements is a tricky one. From the states' perspective, they are permitting such activity to go on within their borders, and most likely their residents are the patrons of Indian casinos on reservations in their state. Therefore, as with any other commercial activity, the states should have the right to receive some portion of the profit from these casinos. However, from the Native American viewpoint, they are a sovereign nation and not subject to the laws and taxation principles of the states in which they are located. Also, a fear often expressed by politicians who side with Indian tribes is that the states will basically coerce the tribes rather than meet them

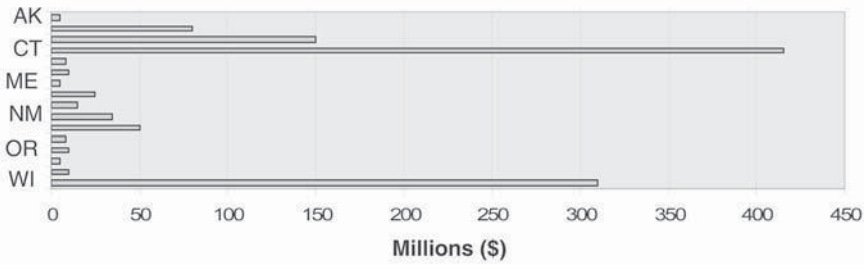

FIGURE 14.1 Revenue sharing between states and Native American casinos. Source: Analysis of the Economic Impact of Indian Gaming in 2004, National Indian Gaming Association (January 2005).

as equals at the bargaining table.[9] Hence the issue is once again whether the tribes are truly sovereign or have become merely wards of state government. Two well-versed political scientists have raised the question of whether compacts are "*compromises*, or are they *compromised?*"[10] The focus of Steven Light and Kathryn Rand's work is the political consideration of the impact of Indian gaming, mainly on sovereignty of the tribes. Light and Rand's work is considered further throughout this chapter and more specifically when we consider the pros and cons of tribal gambling.

Clearly, given the preceding facts and figures, Indian gaming is becoming a significant factor in the U.S. economy, in addition to being the most significant contributor to the Native American economy. Although commercial casinos brought in just under $30 billion in revenue last year, Indian casinos grew to nearly $20 billion. The growth rate of Indian casinos has also significantly outpaced commercial casino development—even since the year 2000—as the establishment of Indian casinos has become more complete. Dr. Alan Meister sees no reason to assume that the growth of Indian casinos will stop and even predicts that they will continue to grow faster than their commercial counterparts. Obviously, as the markets mature and the base of revenue becomes much larger, Indian growth rates will have to decline. However, as more and more states begin to negotiate casino development with the tribes located within their states, continued expansion is to be expected.[11] Another reason it is important to consider the influence of casinos on Indian welfare is that at first glance there appears to be a significant relationship between casinos and expedited improvement in quality of life. Table 14.1 shows a chart created by a group at Harvard when they looked at some of the simple observable results from the 2000 U.S. census.

Table 14.1.
Changes on Reservations Other than Navajo (Changes 1990–2000 presented in points unless indicated as %; OTSAs excluded)

	Nongaming	Gaming	United States
Real per capita income	+21%	+36%	+11%
Median household income	+14%	+35%	+4%
Family poverty	−6.9	−11.8	−0.8
Child poverty	−8.1	−11.6	−1.7
Deep poverty	−1.4	−3.4	−0.4
Public assistance	+0.7	−1.6	+0.3
Unemployment	−1.8	−4.8	−0.5
Labor force participation	−1.6	+1.6	−1.3
Overcrowded homes	−1.3	−0.1	+1.1
Homes lacking complete plumbing	−4.6	−3.3	−0.1
Homes lacking complete kitchen	+1.3	−0.6	+0.2
College graduates	+1.7	+2.6	+4.2
High school or equivalency only	−0.3	+1.8	−1.4
Less than ninth-grade education	−5.5	−6.3	−2.8

These numbers suggest that there might be a significant correlation between gaming and a stronger performance of welfare improvement over time. In 13 of the 15 categories, gaming tribes performed better than nongaming tribes. Although at first glance it is apparent that Native Americans' lives have improved since the inception of the IGRA, will advances and growth in Indian gaming result in comparable gains in Native American welfare in the future? Does this improvement in the lives of Native Americans justify the costs of gambling in the communities that surround these casinos? Are states using Native American casinos as agents for revenue while leaving these casinos largely unregulated?

INDIAN GAMING REGULATORY ACT (IGRA)

The impetus to address the Indian gaming situation came from a court case involving a tribe of Native Americans from California called the Cabazon Band of Mission Indians. In 1953 Congress passed a law that authorized states to

extend state criminal laws to Native Americans. This law, known as Public Law 280, was often used by the state to justify regulation of activity on reservations. However, when states began to impede the rights of tribes to operate gaming facilities on their reservations, the Cabazon tribe forced the state of California to take them to the Supreme Court. In *California v. Cabazon* (1987), the Supreme Court ruled that Indian tribes had the inherent right to self-rule and that Public Law 280 applied only to limited circumstances, particularly when criminal activity was taking place between Indians and non-Indians. Specifically, the courts ruled that Public Law 280 was not enough justification for states to impede on tribal sovereignty in civil terms.[12] Noticing this glaring legal omission, Congress quickly acted to draft legislation that would help fill the void of confusion, whence came the Indian Gaming Regulatory Act.

In the time between the *Cabazon* decision and the adoption of the Indian Gaming Regulatory Act (IGRA), gaming sprang up nationwide on tribal reservations. This helped charge the atmosphere surrounding the debate on the IGRA. In drafting the IGRA, Congress sought to balance tribal rights to sovereignty with the right of a state to regulate what sort of activity takes place within its borders, thereby affecting its citizens. One of the major considerations and justifications for federal intervention in this matter was the issue of organized crime. One major fear that came in discussions of gambling was the concern about organized crime gaining a foothold in the casino industry. Because the business involves transactions with large amounts of cash, many spectators were suspicious that Indians, without private-run management interference or federal intervention, would turn to the realm of organized crime to help them run their businesses and gain political influence. This was definitely something that legislators kept in mind when drafting earlier forms of the bill and that influenced legislators' decision to allow private firms to help run Indian casinos.[13]

According to the opening section of U.S. Code Title 25 Chapter 29, Congress had five main things in mind when considering the IGRA: (1) tribes had begun to utilize the revenue drawn from casinos to generate governmental funding; (2) tribes had turned to outside management, but existing law provided no standards by which those management contracts could be regulated or approved; (3) existing federal law did not provide any clear stipulations for regulation of Indian gaming; (4) at that time, the goal of federal policy involving Indians was to "promote tribal economic development, tribal self-sufficiency, and strong tribal government"; and (5) Indian tribes had the right to wholly regulate any gaming activity on their land that was neither prohibited nor strictly regulated by the state or federal governments.

The major provisions of the IGRA sought to create three separate classes of gaming, and a different regulatory scheme for each class, and put stipulations

on the use of casino revenue. The first thing that the IGRA established, the three classes of gaming, are still used today to define various types of gaming in both commercial and Indian casinos. Class I gaming refers to traditional social games with minimal prizes, clearly targeted toward ceremonial Native American forms of gaming. The regulatory authority over these types of games is vested exclusively in tribal governments and is not subject to any of the requirements in the IGRA. Class II gaming refers to bingo and other similar games of interplayer chance, such as lotto, pull-tabs, and punchboards, if played at the same location as bingo. Also included in this are card games where the establishment is not banking any of the money. The regulatory authority over these types of games is vested in the tribal governments insofar as the state in which the tribe is located permits such gaming for any purpose and the tribal government adopts a gaming ordinance that is approved by the National Indian Gaming Commission (which is also established later in the IGRA). Class III gaming refers to every other type of gaming, including slot machines, banked card games, and typical casino games such as blackjack, roulette, craps, any wagering games, and electronic facsimiles of any game of chance. There are three main clauses regarding the regulatory authority of such gaming: the particular form of gaming must already be permitted by the state in which the tribe is located, the tribe must negotiate a contract with the state and have it approved by the Secretary of the Interior, and the tribe must have a tribal gaming ordinance that has been approved by the National Indian Gaming Commission.

Further, the IGRA limits the use of any casino revenue to three major categories: (1) to fund tribal government operations or programs; (2) to provide for the general welfare of the Indian tribe and its members; or (3) to promote tribal economic development. Of course, the tribes are also allowed to make donations to charitable organizations or help fund the operations of local government agencies.

The tribal compacts described in the text of the IGRA are very vaguely outlined. The IGRA does not require the compacts to have any specific terms except that both parties approach the negotiations in good faith—particularly the state, given that the Indian tribe is the party that initiates the negotiations. If this disposition of good faith is in question, the Indian tribe has the right to sue the state in federal court. Many procedures detailed in the IGRA are in place to handle these types of situations as they develop. The procedures are not as important as the implications for tribal and state sovereignties, but in general, government mediators step in and utilize loosely constructed general principles, the goal of which is to establish a well-balanced compromise between both parties. It is through these mediums that states are able to negotiate revenue-sharing agreements and other issues of taxation. Although these

work on a state-by-state basis, as is evident by the disparity among revenues collected by states, in general they provide a means to mitigate the cost that the casinos incur to the state, and they often times go above and beyond this inferred cost.

In particular cases, it is in the Indian tribe's interest to agree to pay more if the state will promise to help keep commercial casinos banned or kept far away from the prime location of the tribal casino. For instance, in 1992, the Mashantucket Pequot tribe negotiated such a contract with the state of Connecticut. In exchange for the tribe's promise to share with the state 25 percent of the revenue generated from the Foxwoods Resort Casino's slot machines, Connecticut effectively guarantees them exclusive rights (along with Mohegan Sun, which now has the same contract) to operate slot machines within the state. Since the precedence of this revenue-sharing agreement, many other tribes have offered similar terms and come to settlement on them. Quite recently, Harrah's Entertainment offered similar commercial revenue-sharing terms with the states of Rhode Island and Pennsylvania if they grant Harrah's exclusive slot machine rights. In Rhode Island, Harrah's has agreed to pay 25 percent of slot revenue up if revenues do not surpass $400 million and a higher percentage to be determined if revenues exceeded $400 million, while in Pennsylvania, Harrah's has agreed to pay a whopping 53 percent excise tax on slot revenue.[14] The justification that this commercial entertainment giant offers to Rhode Island legislators is that the facility to be developed in Rhode Island is more of a resort; therefore, it needs fewer taxes to operate its smaller casino. Harrah's Entertainment assists in the management of as many as nearly 200 Indian casinos in North America.

Also established by the IGRA was the National Indian Gaming Commission (NIGC). As an oversight committee on tribal gaming in the United States, with limited regulatory powers, the NIGC was to be funded by a minuscule tax on the revenues of Indian casinos. With the commission's funding limited to 2.5 percent of the first $1.5 million in revenues and 5 percent thereafter, with a cap of $8 million, the effectiveness of the commission has been questioned at every level of government (U.S. Code Title 25). In 2005, Senator John McCain (R-AZ), then chair of the Senate Indian Affairs Committee, introduced the legislation regarding the NIGC. This bill, S.1295, would have forced the NIGC to be held more accountable and would also provided an increased amount of funding, to the tune of .08 percent of Indian casino revenue without any cap. Under this setup, the revenues received by the commission would have increased to about double what they are now, and then would have proportionally increased relative to the growth of the industry. This bill would have also allow the NIGC to crack down on off-reservation gaming, which is often seen

as a scam that allows the tribes to illegitimately profit by creating and supporting commercial casinos under the guise of tribal sovereignty. In 2006, this bill passed the Senate Indian Affairs Committee but still remains on the agenda of the House Resources Committee awaiting approval for vote.[15]

PRO–INDIAN CASINO ARGUMENTS

There is a lot of literature supporting the propagation of Indian casinos. The study with the most data to back its conclusions was conducted by the Harvard Project for American Indian Economic Development. Authored primarily by Jonathan Taylor, a leading research expert on Indian welfare, *American Indians on Reservations: A Databook of Socioeconomic Change between the 1990 and 2000 Censuses* provides a summary glimpse into the changes in welfare that American Indians experienced during the explosion of tribal casinos. Basically providing two snapshot images of the state of Native American welfare, this study looked at the empirical census data from both 1990 and 2000, breaking it down by every single federally recognized reservation. But aside from the fact that this study neglected to use econometric analysis or examine the revenue-side data, the institution that funded this study receives massive donations from the National Indian Gaming Association (NIGA) to run its research. The NIGA is a nonprofit organization of all the Indian tribes that have casinos—it is clearly in their best interest to promote the expansion and growth of the Indian casino industry. Therefore, the research that the NIGA conducts, though mainly objective, often has suspect results that appear to maintain an optimistic outlook on Indian gaming. The *Cabazon* project, one that specifically focuses on economic development with regard to Indian gaming and of which the Harvard Project study is a part, on the whole manifestly supports the expansion of tribal sovereignty and rights—issues that are not so clearly defined on the national political stage. "Essentially, the research of the Harvard Project finds that poverty in Indian Country is a political problem—not an economic one."[16] Their claim is that the economic development of the tribes, which is bolstered by Indian gaming, is merely the means to the end of achieving full tribal sovereignty and self-reliance. In 2004, the NIGA produced its *Analysis of the Economic Impact of Indian Gaming*. This report details much of the alleged success that tribes have had with casinos. Although much of the evidence is anecdotal or qualitative, the report does provide some firm statistical support for its very optimistic outlook for Indian gaming. The NIGA touts statistics such as the fact that in 2005, 69 percent of Americans thought that Indian nations deserve their help, or that 86 percent of Americans thought that Indian tribes benefit from having casinos.[17] The *Analysis of the Economic Impact*

of Indian Gaming clearly states that the mission of NIGA is to "protect and preserve the general welfare of tribes striving for self-sufficiency through gaming enterprises in Indian Country."[18] Also included in the association's analysis is a mention of every positive outcome that Indian gaming could have ever possibly influenced, from jobs to roads to schools. In order to further garner sympathy and support, the NIGA points out that there are various shortfalls among the Native American community when it comes to keeping up with national norms and includes notations of various education, poverty, health, and crime statistics.

Other published books that may give the reader a clearer picture of the effects of Native American gambling are *Gambling and Survival in Native North America* by Paul Pasquaretta (2003) and *Indian Gaming and Tribal Sovereignty* by Steven Andrew Light and Kathryn R. L. Rand (2005). The latter provides a very thorough analysis of the political implications of casinos through the lens of tribal sovereignty. Again, the researchers behind *Indian Gaming* clearly favor the expansion of tribal sovereignty, and their book is predominately anecdotal and historically based.

ANTI–INDIAN CASINO LITERATURE

Legalized Gambling (2006), edited by David Haugen, provides a collection of abridged articles on various gambling topics, such as Indian gaming, Internet gaming, social consequences, personal stories, and a general overview of gaming in the United States. Although not every article in this collection is anti-casino—in fact, it attempts to provide an equal amount of articles for each side—it is one of the only available sources that clearly try to present this point of view. In these articles, once again, we see that the evidence provided is largely anecdotal and subjective. Although this is clearly an important component of the consideration as to whether casinos are a viable and good option for Indian tribes to gain economic independence, anecdotal evidence is very difficult to include in any quantitative analysis or econometric study. Some of the interesting things for legislatures and concerned citizens to keep in mind about Indian casinos are the alleged social burdens that they place on the public: costs to local communities in the form of upkeep, roadway paving, and police patrols and other implied public costs. There are claims that casinos lead to increased crime in the surrounding areas, that the people who are drawn to visit communities with casinos are not the most upstanding citizens of this country, and finally, that the harmful effects on addicted gamblers and ordinary, but excessive, gamblers are not nearly outweighed by the benefits that Indian casinos receive from the economic independence they gain. And these concerns do not

consider the larger moral question as to whether gambling should be legalized in the first place, which as a democratic society, America has determined it should, viewing it as an acceptable form of business practice.

Finally, there is the story about the famous Mashantucket Pequot founder who, on his marriage license, claimed to be "white." Many people point to this as evidence of Native Americans simply taking advantage of a crooked system that seeks to pay reparations to a people that no longer necessarily deserves them. It is true that there were only four registered members of this tribe in 1990; today, however, there are several hundred members. The Mashantucket Pequots now host the largest Native American casino in the country and hence are flourishing as operators of one of the most successful casinos in the world. There are two sides to every story. The next section gives the reader a chance to ascertain whether the advent of Native American casino gaming has really made a difference in the welfare of tribal members.

COMPARING GAMING AND NONGAMING TRIBES IN 2005

One fundamental question that needs to be addressed is this: has Native American gambling improved the plight of Native Americans? One way to explore this question would be to test different sets of welfare statistics on two groups: those with gaming and those without. The method that was utilized to determine whether or not there was a statistically significant difference exists is called the unpaired (independent) samples "t" test. The categories (which refer to American Indians on reservations, including Navajo, unless otherwise noted) to be tested included:

1. median income,
2. family poverty, unemployment,
3. percentage of houses that lack kitchen facilities,
4. actual number of houses that lack kitchen facilities,
5. aggregate income of tribe,
6. average aggregate income,
7. percentage over the age of 25 who are college graduates,
8. percentage over the age of 25 who have a high school degree,
9. percentage over the age of 25 who have less than a ninth-grade education,
10. the actual numbers for each of the preceding three statistics,
11. percentage of families living in poverty, percentage of population that owns houses,
12. percentage of occupied houses that are actually owned by the Indians occupying them,

13. percentage of homes that are occupied by American Indians that are overcrowded,
14. percentage of all races on reservations that are self-employed, and
15. percentage of American Indians that live in deep poverty.

RESULTS OF INDEPENDENT SAMPLES TESTS

Out of the various categories that were tested, only six of them came out statistically significant (a "t" test value of 2 or greater), with a seventh one reasonably close. Median income produced t-scores of 3.086 and 3.094; percentage of houses lacking kitchen facilities produced t-scores of –2.391 and –2.304; average aggregate income produced t-scores of 1.797 and 1.873; actual number of college graduates came really close, producing a t-score of 1.320; percentage of American Indians over the age of 25 with a less than a ninth-grade education produced t-scores of –2.045 and –1.991; percentage of occupied homes that are owned by American Indian residents produced t-scores of –2.370 and –2.346; and percentage of population of all races on reservations that are self-employed produced t-scores of 2.069 and 2.049. The rest of the statistics produced t-scores that ranged from .344 to .998, none of them being significant at even the 10 percent level.

CONCLUSIONS

From these analyses, it appears as though the only welfare statistic that has been significantly influenced by casino revenue in the past 16 years is average aggregate income of American Indians. When you take this result and compare it with the fact that median income has not seen an equivalent impact, it appears as though a lot of the money could be staying at the top. If some of the wealthiest tribal members were keeping a lot of the profits for themselves, it would explain why the average income is much higher than the median. This is being addressed in various political circles. In particular, Senator John McCain's bill addresses the issue of tribal casinos using profits to reinvest in commercial casinos or build other casinos in off-reservation locations. Although tribal leaders argue that, oftentimes, building a casino away from their reservation can provide opportunities that otherwise would not be economically feasible, opponents of this argue that it also has the potential to cause a great deal of trouble. No one imagined that Indian casinos would have expanded to the extent that they already have, and this is just one more way that they could grow even more—which is undesirable to many.[19]

Whereas commercial casinos grew at a rate of 6.7 percent in 2004, according to the American Gaming Association,[20] Dr. Alan Meister's numbers show us that Indian casino revenue grew at 15.2 percent.[21] This beats even Las Vegas's growth rate of about 10 percent. These significant increases mean that the influence that Indian tribes have on politics and the welfare of their citizens is only going to increase over time. In 1999, Indian tribes donated a total of $2,000 to politicians in the United States. In 2004 that number had surged to $7 million.[22] Although in the wake of the Jack Abramoff scandals, this tremendous increase should slow down, the contributions are not expected to stop any time soon. As their economic well-being increases, Indian tribes are going to become steadily more influential. Real per capita income of gaming tribes increased 36 percent between 1990 and 2000, whereas the income of nongaming tribes and the rest of the nation grew at 21 percent and 11 percent, respectively, during that same time period. This seems significant considering that American Indians received the lowest amount of per capita income assistance out of all Americans.[23] Obviously, it is also possible that the tremendous growth we see is merely a result of the historical setbacks that American Indians have faced over time—that any improvement we see is a result of the relative weakness of their starting point. However, this is not always the case, and if one looks at mere percentage point changes in the census data, there are still significant differences on the surface between the data for Indian reservations and the data for the nation as a whole.

Between the years 1990 and 2000, Indian tribes on the whole increased their overall income at an astoundingly higher rate than the rest of the United States, as described earlier in this chapter. Yet the differences between Indian tribes with gaming and without do not seem to be significant at this time. There are many things to consider when recognizing the lack of influence that gaming has had in 17 years. Many of the effects that are calculated would take much longer than these 17 years to have a massive measurable impact on the Indian population as a whole. Welfare statistics that are related to education and housing, for example, would take a lot longer to be affected by casino income than the aggregate incomenumbers. The time it takes to receive an education must be considered, and additionally, the investment in infrastructure and way of life definitely does not occur successfully over night. Aside from the fact that it took about 8 years for Indian casinos to take off and about 10 years for those tribes to gain any significant political influence, schools have to be built, a culture of education has to be established, and pupils that are of the appropriate age need to pass through the newly established learning systems. For instance, take the Mashantucket Pequot Tribal Nation; this tribe profits so substantially

from its world-renowned Foxwoods Resort Casino that it pays for any tribal member to attend college. Assuming that a person begins high school at the age of 14, that same person probably decides whether he or she is going to attend college by about age 17. Because the education statistics are not measured for anyone under the age of 25, at which age education levels become standardized and typically no longer change, this effect would take anywhere from 8 to 11 years to have any significant effect and much longer to make up a significant portion of the 25-and-older population. Considering this, it is not hard to see why the positive effects that many claim economic independence is having on the tribes might not yet be showing themselves . Either this is the case, or tribal leaders are, to date, making poor investment decisions or restricting the flow of money downward to the rest of the members of their tribes.

Finally, it is always important to look at the big picture when critiquing policy decisions. It is therefore difficult to gauge the specific impact that casinos have had—even more so for the Indian gaming industry because of its perceived isolation on reservations and mysterious reporting practices that are not subject to the same transparency laws as commercial casinos in the rest of the country. More specific to this chapter, it is even more difficult to estimate the negative effects that casinos have had on the Native American populace. Although studies may provide hard statistical evidence of negative effects in the future—one such study is soon due to produce the results of research on the use of methamphetamines by Indians on reservations—currently there is no such evidence.

Therefore, in coming years, we can only hope that the size and power of the Indian gaming industry influences public and private parties to engage in further studies of the effects that Indian gaming has had on the Native American population as well as on the American population at large.

Chapter **15**

The Current Climate of Gambling in the United States[1]

Richard A. McGowan, MA, MDiv, ThM, DBA

A look at how gambling revenues stack up against revenues from other recreational/leisure time activity sectors reveals not only that the gambling revenues outweigh both music sales and movies combined, but also that the gambling industry is the only one of the industries in this study to have shown consistent growth in each of the last three years.

—Joseph Greff, "U.S. Gambling" (Bear, Stearns, January 2005)

With a few notable exceptions, it is a great time to be in the gambling industry. The year 2005, for example, was a record-breaking one for Las Vegas casinos, which took in $11 billion from gamblers in casino revenues—excluding hotel, restaurant, and bar revenues.[2] In 2004 alone, U.S. gamblers spent $78.6 billion on commercial gambling, a 7.6 percent increase over the year before.[3] Lottery sales increased by an average of 12.5 percent throughout the United States.[4] Tribal gambling and Internet gambling experienced double-digit growth, a rate not seen anywhere else within the gambling industry.

But can discussions about the gambling industry be painted in such broad, sweeping terms? Can one really talk about "the" gambling industry as a whole without generalizing to the point that trends become half-truths and facts and figures become meaningless? What similarities are there between an Internet sports book based on the Isle of Man and the Massachusetts state lottery's daily operations? Given the explosive rate of growth in Internet gambling and the gradual decline of horserace betting, can one ignore the fact that the various segments within the industry are at different stages in their life cycles and

should therefore expect very different opportunities and threats in coming years? It is obvious that each segment deserves (or, more accurately, demands) its own assessment in order for any analysis to be fully developed, relevant, and—most important—meaningful.

There are, however, recurring themes that weave throughout each segment of "the" gambling industry and that merit special attention. The most obvious, and perhaps most important, of these themes is that of regulation. Regardless of what type of gambling is being discussed—be it Internet poker, slot machines in Vegas, or a sports book in the United Kingdom—each and every one of these various business enterprises faces some sort of regulation. In some instances, regulation creates state-held monopolies through special gambling licensing. In other jurisdictions more lax regulations allow for numerous firms to compete for consumer dollars. Finally, in the United States, ambiguous legislation and inconsistent activity by the courts regarding Internet gambling create a legal gray area. In this type of environment, sites enjoy a surplus of consumers and a scarcity of competitors, often resulting in huge profits for the more daring Internet gambling site operators.

Monopolies in the industry, however, are becoming things of the past. A second recurring and universal theme throughout "the" gambling industry is increasing levels of competition. The forms in which this competition manifests itself are as diverse as ever. California's tribal casinos now compete with the Las Vegas Strip. Las Vegas bookmakers compete with Internet sports books based in the United Kingdom. These Internet sports books diversify their product offerings and allow users to play poker online, competing with other Internet poker sites. In many instances, gambling operators compete not only with other operators within the same segment (for example, a casino competing with another casino) but with *every other form of gambling readily available to customers*.

INTERNET GAMBLING

The rise of Internet gambling has been the primary driver of the intensifying levels of competition within the industry. No longer is consumers' ability to place wagers limited by their geographic proximity to gambling operators (nor, in some instances, are they limited by the legislation of their country's jurisdiction—for example, China). Internet gambling operators can serve a truly global customer base, and with the financial barriers to entry relatively low in comparison with the huge profits being reaped through Internet gambling, new entrants can enter at will and attempt to compete with the market leaders. As discussed earlier, these online operators compete not only with each other

but with traditional land-based operators as well. Although both land-based and Internet gambling operators have done fairly well in recent years, given the explosive growth and successful initial public offerings (IPOs) of several online-only firms, it appears that the Internet sites will ultimately come out ahead. Indeed, players in the gambling industry must be ready to compete in the "borderless global marketplace the Internet has created."[5]

Regardless of which segment of the gambling industry a particular firm is involved in, be it market leader or new entrant, no firm can afford to underestimate the impact that the Internet will have on its business. Internet gambling has revolutionized the gambling industry, and what we have seen thus far is only the tip of the iceberg. Estimates vary, but for discussion's sake, one expert estimates that consumers spent over $8 billion on Internet gambling in 2004, and he expects that number to more than triple by the end of the decade.[6] Although this sum represents only a small portion of global expenditures on commercial gambling, certain indicators point toward a bright future for Internet gambling operators. A case in point: PartyGambling plc, operator of PartyPoker, executed a highly successful IPO and listed on the London Stock Exchange with a market cap of almost $8.5 billion. Its shares have appreciated significantly since then, and PartyGambling now has a market capitalization larger than Harrah's Entertainment.[7] In light of the fact that Harrah's Entertainment is the world's largest casino operator, the true potential of Internet gambling has become apparent.

The landscape of the online gambling industry is undoubtedly the most challenging to navigate of any of the gambling industry's segments. In no other segment must an operator navigate such a web of legislative snarls or compete so ferociously for revenues. Unlike for traditional land-based gambling operators, for online casinos, poker tables, and bookmakers, barriers to entry are extremely low. With relatively little initial capital, a firm can purchase third-party software at minimal cost (royalties included) and apply for a license in any of a number of jurisdictions throughout the world. As a result, "given the portability of pure online services,"[8] jurisdictions now compete to draw online operators, resulting in attractive tax regimes for firms willing to be flexible in their location. This leads to increasing levels of competition for consumers, driving up marketing spending. The added complexity of the various legal issues regarding the jurisdiction of the consumers themselves further muddles the legal waters.

The following is a short summary of the various issues surrounding Internet gambling. Current legislation in various countries runs the gamut from complete prohibition of Internet gambling to its legalization and regulation. In the United States, the Department of Justice (DOJ) holds that all Internet

gambling is illegal, under the 1961 Federal Wire Act, which prohibits bets made over telephone and other "wires."[9] Although the DOJ has no intention of prosecuting casual gamers, it is adamantly opposed to allowing firms located within U.S. jurisdiction to run online gambling sites. Harrah's and MGM Mirage, for example, both formed Internet casinos, only to shut them down under pressure from the DOJ.[10] The DOJ's strategy has been to put pressure on financial intermediaries, fining them for processing illegal online gambling transactions. For example, the DOJ fined PayPal $10 million in 2003 for such violations.[11]

Interestingly enough, the legality of certain actions by the Department of Justice in restricting online gambling subsequently came under scrutiny. A case filed by the island of Antigua, a small Caribbean center for offshore Internet gambling, charged that the Department of Justice had restricted the "cross border supply of gambling and betting services" in violation of U.S. obligations under the General Agreement on Trade in Services (GATS) and World Trade Organization (WTO) regulations. The outcome proved ambiguous, with both sides claiming victory. Nevertheless, it appears that the United States ultimately will have to acquiesce to the WTO ruling—either through "total prohibition, including currently legal forms of online gambling . . . or liberalization [*sic*] and permissive regulation of online gambling."[12]

Unlike U.S. legislation, legislation within the United Kingdom was updated following passage of the Gambling Act in 2005. Although online betting had not previously been illegal in the United Kingdom, the Gambling Act explicitly legalized online gambling and clarified a number of issues regarding advertising to the UK audience.[13] But although the United Kingdom's stance on Internet gambling is quite clear (permissive regulation), the greater European landscape is still divided. The 1957 Treaty of Rome established free trade principles regarding services, yet the European Court of Justice "has wrestled with the conflicting claims of member state laws predicated on sovereign power over gambling and free trade principles."[14] The political structure and conflicting interests of greater Europe are immeasurably complex, but research analysts at Deutsche Bank believe that the European market ultimately "will open up to cross-border online gambling . . . through rulings from the EU (European Union) courts rather than through a directive."[15]

Regardless of the short-term developments in global regulation, the expansion of Internet gambling is inevitable in the long term. The blistering growth rates of online revenues, seemingly endless consumer demand, and market capitalization figures usually reserved for blue-chip stocks all point in one direction: Internet gambling will continue to grow as more firms enter the industry and cater to "an audience that is discovering that it actually quite enjoys casual gambling."[16] In regard to the future of Internet gambling, the competition will

eventually be whittled away until, as the industry matures, only the most successful operators remain. Consolidation is also likely as smaller sites are bought up by major firms, several of which, after very successful IPOs, now have plenty of acquisition currency.

What, therefore, is in store for traditional land-based gambling operators, given the unfettered explosion of Internet gambling in the United States—despite legislation aimed at preventing American gamers from utilizing online services? Like many things in life, it all depends on whom you ask, and even then, the answer you get today is likely to change over the course of the next few years. One study that analyzed the relationship between the increasing prevalence of Internet gambling and states' casino revenues came to the conclusion that "Internet gambling has not had a statistically significant negative impact on the gambling revenues of . . . Nevada and New Jersey."[17]

Yet by the close of this first decade of the twenty-first century, the advent of Internet gambling will have had a significant impact on traditional land-based revenues, negatively *or positively*. One scenario foresees Internet gambling reducing revenues through a substitution effect. The UK Treasury currently holds a different view, stating that the "assumption of a substitution effect between traditional based gambling offerings and remote gambling is false. Remote gambling is a unique customer experience."[18] Although the experience is indeed different, this does nothing to imply that casual gamers will not choose one form of entertainment over the other. Internet gambling cannot replicate the experience of a weekend in Vegas, but online gambling sites offer betting services from the home. For consumers looking only to place a bet—with no interest in luxurious hotels, restaurants commanded by world-renowned chefs, or bustling nightlife—the online gambling experience may be preferable to what traditional casinos have to offer. In order to succeed in a post-Internet environment, casinos and other traditionally based gambling operations will have to evolve from being merchants of gambling services to merchants of *entertainment* services. This process has already begun, with certain casinos on the Las Vegas Strip earning less than half their revenues from gambling activities. If online gambling does negatively impact traditional operators, those operators will have to adapt their product offerings in order to replace lost revenues.

A second possible outcome scenario would find Internet gambling actually benefiting traditionally based games operators. Internet gambling—online poker, specifically—has introduced a record number of Americans to casual gambling. The stigma attached to gambling by moral authorities is diminished every time a consumer visits an online gambling site. The trend was started when Las Vegas shed its image as a seedy gambling hotspot and began to be perceived as a more family-friendly destination. What the Internet has done is

accelerate a shift in public opinion about gambling as a form of leisure, from a vice to an acceptable, and oftentimes enjoyable, pastime. Should this scenario hold true, casinos would see increases in their gambling revenues *as well as* in their other operating revenues. According to this "rising tide lifts all boats" view, casinos would see not only higher room occupancy rates *but also a greater percentage of guests actually sitting down to play at gambling tables*. Not only is there the opportunity to draw more people to casinos and other traditional gambling sites, but the opportunity also exists to encourage them to gamble more. Whereas Americans spend an average of 1 percent of after-tax earnings on gambling, Australians, for example, spend approximately 3.5 percent on gambling.[19] Clearly, the market for American gambling services is far from saturated.

For horseracing in particular, with declining purses caused by years of declining race attendance, Internet gambling may be the last hope for survival. Simulcast races and off-track betting offer two ways to stimulate the sluggish industry by increasing purse sizes. Not everyone is embracing Internet gambling, though. Betting exchanges, which operate by matching a gambler who sets odds with another willing to take the bet (the operator of a betting exchange site takes no risk), can offer better prices than traditional bookmakers. Traditional bookmakers must manage their risk exposure and are also subject to higher taxes. Therefore, traditional bookmakers are unambiguously harmed by the existence of betting exchanges, because betting exchanges reduce the margins bookmakers can hope to earn.

To say that the Internet has revolutionized the gambling industry is far from an overstatement. If anything, the word "revolution" has been so overused that it fails to capture the tremendous impact Internet gambling will have on the industry for years to come.

NATIVE AMERICAN GAMBLING

Although online gambling has taken the globe by storm, it is not the only segment of the gambling industry to experience double-digit growth in recent years. Within the United States, gambling ventures operated under the Indian Gambling Regulatory Act have proven highly lucrative for Native American tribes as well as for investors lucky enough to have gotten in on the action. Collectively, the tribes now have the largest gambling industry segment in the United States, having surpassed the gross gambling revenues of the state of Nevada in 2001.[20] The climate of tribal gambling in the United States has become increasingly political, a fact that will shape the future of tribal gambling to come.

The most heated political debates revolve around tribal recognition and off-reservation casinos. Formal recognition of a tribe's legitimacy can mean the difference between financial success and poverty, and the political maneuverings employed by tribes seeking recognition, the investors backing them, casino operators, and other tribes who fear competition demonstrate the varied interests at play in tribal gambling. In 2005, the U.S. Senate Committee on Indian Affairs met to discuss the recognition process for Indian tribes. As one commentator noted, "Connecticut's governor, both its senators, and three of its congressmen showed up to testify on a matter none would have cared much about a decade or so ago."[21] Connecticut already has two well-established tribal casinos, and those in office are not interested in a third.

Senator John McCain, who then chaired the Senate committee, noted that wealthy investors have a vested interest in helping tribes win recognition because the tribes would, in turn, provide the investors with profitable investment opportunities.[22] Indeed, lobbying expenditures by tribes—whose poverty-stricken members are purportedly among the poorest in America—can total in the millions of dollars. As a matter of illustration, the Schaghticoke tribal nation spent approximately $12 million in its efforts for recognition, financed in part by the founder of the Subway restaurant chain, and the Eastern Pequots of Connecticut were supported financially by none other than Donald Trump.[23] Although it would be nice to consider these acts as particularly altruistic, partnering with Native American casino operators can prove highly profitable. Witness a recent partnership between the Creek Indians and Harrah's Entertainment Inc. in trying to expand gambling in Rhode Island.[24]

Off-reservation casinos are also a hot-button issue within the scope of tribal gambling. Whereas landless tribes maintain that restricting off-reservation gambling deprives them of opportunities to raise their socioeconomic status by opening a casino, opponents of off-reservation casinos, led by Senator McCain, argue that Congress (in passing the Indian Gaming Regulatory Act in 1988) never intended Native Americans to build off-reservation, Vegas-style casinos.[25] Opposition can even come from a seemingly unlikely source—other Indian tribes. Many tribes oppose off-reservation casinos strictly for fear of competition with their own tribal casinos.

Future prospects for Indian gambling are similar to those for traditional land-based casinos and other gambling sites. Although rapid expansion continues, the market segment is already showing signs of slowing growth rates as tribal casinos face increased competition from private casinos, state-run gambling operations, online gambling sites, and other tribal casinos themselves. As tribal casinos become established in their marketplace, fewer tribes will seek to enter a saturated market, especially if casinos are restricted to reservations not

frequented by the majority of the public. Though tribal gambling's fantastic rate of growth has been second only to that of Internet gambling, according to one economist, the "double-digit growth is over."[26]

THE EXPANSION OF GAMBLING BY STATES: SLOTS, SPORTS GAMBLING, AND PRIVATIZATION

The final segment of the gambling industry to be discussed is the state of gambling in traditional gambling operations within the United States, including casinos, lotteries, and slot machines. As mentioned at the opening of this chapter, 2005 was a banner year for brick-and-mortar casinos throughout the country. Despite the threat posed by Internet gambling and tribal gambling, casinos in Las Vegas and Atlantic City are positioned to continue their financial success of recent years into the near future. The gambling industry as a whole will benefit from a favorable demographic shift in the U.S. population. "The average gambling patron is 49 years old, placing the average U.S. gamer in an age category that is growing three times faster than the overall U.S. population."[27] It is also noteworthy that the Las Vegas Strip tends to be a supply-driven economy, in that increasing the number of rooms available in effect increases the demand for said rooms. With the addition in 2005 of the $2.7 billion Wynn Las Vegas, revenues from the hotel side of Vegas casinos could reach an all-time high.

Moving away from Las Vegas, casinos become less about profits and more about tax revenues. Permitting slot machines has become a favorite tactic of legislators seeking to raise revenue for state treasuries without raising taxes. Oftentimes, states vie for each other's residents' gambling dollars, building casinos just across their borders in hopes of luring revenues from out of state. As an example, Maryland is currently considering the legalization of slot machines in the state. James Browning, former executive director of Common Cause Maryland, which oversees campaign spending by the gambling industry, makes a deft comparison:

> If you look at the other states, Pennsylvania got slots. West Virginia is talking about table gambling. It's like an arms race between the states, and campaign contributions and lobbying expenditures are the weapons to win.[28]

Although the analogy may seem a bit overblown, it does bring to light an underlying theme of state-run gambling. The initial success of many of the first movers was a result of an inflow of out-of-state money into state-run casinos. Indiana, for example, has taken advantage of differences in legislation by allowing riverboat gambling near the border of two states that do not, those states

being Ohio and Kentucky.[29] In effect, Ohio and Kentucky residents are subsidizing lower taxes for residents in Indiana—a politician's dream come true.

In a similar vein, states such as New Jersey are considering legalizing sports gambling in order to protect their current flow of gambling revenue. In 1976, New Jersey became the first state besides Nevada to legalize casino gambling. Casino gambling was confined to Atlantic City in the hope that Atlantic City would recover some its cachet as a resort community. It has been a success in that Atlantic City is the second-largest casino gambling market in the United States, yet Atlantic City casino gambling has experienced slow growth from 2001 to 2006. With bordering states such as Delaware, Pennsylvania, and New York permitting slot machines at racetracks as well as other venues, Atlantic City's prospects appear bleak. Hence, legalized sports gambling is seen as the newest weapon in New Jersey's arsenal to protect its gambling revenues by reinvigorating Atlantic City as a casino destination. This is a highly controversial move on New Jersey's part. Many professional sports leagues, such as the National Football League and the National Basketball Association, as well as the National Collegiate Athletic Association, are adamantly opposed to legalizing sports betting.

Finally, the state of Illinois, among others, has proposed selling its lottery to private operators. Currently, the state lotteries are owned and operated as government agencies. This proposal does gives rise to two series of questions: (1) Why should government have a monopoly over lotteries? Isn't our entire economy built on the merits of competition? Wouldn't the bettor be better off with competitors offering a variety of games and odds? and (2) Why is gambling regulated by government at all? If so, what is the appropriate amount of regulation, and can government really regulate an industry from which it draws so much revenue?

Of course, all of the these questions have one common denominator: revenue! As the reader proceeds to examine all of the various facets of gaming, Tables 15.1, 15.2, and 15.3 should provide an idea as to why gambling has been become such an important topic for public policy officials.

Although the threads of competition and regulation run through any discussion regarding any segment of the gambling industry, it is a daunting task to make any statement summarizing the present climate or future outlook of "the" gambling industry, for the industry is manifested in many distinct forms. What *can* be said about the gambling industry in its entirety is that each part is connected to the whole more deeply than ever before. Consumers enjoy gambling, and firms are just scratching the surface in terms of developing innovative service offerings to cater to the gambling public. Yet although the public enjoys additional forms of gambling, opposition to the expansion of gambling remains quite strong.

Source: Statistical Abstract of the United States for 2004–05, State Regulatory Agencies.

This chapter has focused on the current state of the various segments of the gambling industry, on why states compete for expanded gambling revenues, and on the forces expected to shape how that competition will take place. There are various ethical concerns that public policy officials need to take into account before they develop a coherent gaming strategy for their states. How states formulate and implement these strategies will, of course, determine whether they are successful in achieving the goal of a delicate balance between the revenue needs of the state and the social costs that invariably accompany the expansion of gambling activity.

Chapter **16**

Online Gaming Addiction: Symptoms, Risk Factors, and Treatment

Kimberly S. Young, PhD

My son is a sophomore in high school and he appears to be addicted to online video games. I think his ideal life would be sitting in front of a computer monitor with an IV in his arm to deliver enough nutrients and caffeine that he wouldn't have to eat or sleep. He also has started to lie to his father and me—and to his teachers—about his schoolwork to maximize his access to the video games, particularly those on the web. He has some friends, but they are limited to other "gamers" and he went from being a straight "A" student to failing out of school. In one sense, I'm glad he isn't out on the streets getting into drugs or other forms of trouble. But I fear his life has become so one-dimensional that he will be damaged as a result of this obsession.

—Linda, a concerned mother in California

Adolescents are encouraged to utilize the Internet to enhance school performance and competitiveness; however, heavy use has several negative consequences. Internet addiction is one of the most serious problems (Young, 1998a; Griffiths et al., 2003; Kelly, 2004). Adolescents who are addicted to the Internet also usually suffer from problems in their daily routine, school performance, family relationships, and mood (Leung, 2004; Ng & Wiemer-Hastings, 2005). It is important, therefore, for mental health professionals to develop effective intervention strategies for preventing Internet addiction among adolescents. It is also important to examine the warning signs, risk factors, and treatment strategies associated with gaming addiction, to aid in detection and prevention.

WHAT IS ONLINE GAMING ADDICTION?

Online gaming addiction is an addiction to online video games, role-playing games, or any interactive gaming environment available through the Internet (Young, 1998b). Online games such as EverQuest, the Dark Age of Camelot, or Diablo II—dubbed "heroinware" by some players—can pose much more complex problems. Extensive chat features give such games a social aspect missing from offline activities, and the collaborative/competitive nature of working with or against other players can make these games a hard habit to break (Ducheneaut & Moore, 2004).

"I really want my life back," explained one gaming addict. "Three years ago I was one of the most popular kids at school. I got invited to all the parties, got lots of girls, had too many friends. Then I discovered an online game called Counter-Strike. It's very hard for me to stop. I wake up in the morning, no shower, get on the computer, stay on till the wee hours of the mornings, go to sleep, repeat. I don't know how to get off, I've tried. . . . It's just too hard. I heard this is a very common problem but I really want to get my life back and I'd give anything."

In the early days of the Internet, interactive online games were a takeoff on the old Dungeons and Dragons games, often known as Multi-User Dungeons, or MUDs, that drew upon power, dominance, and recognition within a role-playing, make-believe virtual world. Young men traditionally gravitated toward these role-playing games to assume a character role associated with specific skills, attributes, and rankings that fellow players would acknowledge and treat accordingly (Turkle, 1998). MUDs differed from traditional video arcade games in that instead of a player's hand-eye coordination improving, the actual strength, skills, and rankings of the character improved. MUD players earned respect and recognition from fellow players (Turkle, 1998), and younger men, especially those with low self-esteem and weak interpersonal skills, were at greatest risk of becoming addicted if they developed a powerful persona within the game (Young, 1998b).

Interactive gaming has taken on new themes beyond Dungeons and Dragons that are easier to learn and appealing to those who are more mainstream. In several documented cases, interactive gaming has led to divorce, job loss, and health problems among those suffering from an addiction. While online gaming addiction is not as prevalent as addictions to cyberporn or online chatting, online gaming has grown substantially over the last few decades, reaching millions of users. Gaming also encompasses traditional board games such as YAHZEE or Bingo, which have taken on an interactive and social nature when

played online, and virtual casinos have also grown rapidly, especially among teenagers and college-aged populations who now easily access black jack, roulette, or poker tables online.

Globally, recent reports have indicated that interactive online gaming has reached addictive proportions in China, Korea, and Taiwan (Lee, 2007). About 10 percent of China's more than 30 million Internet gamers are said to be addicted. To battle what has been called an epidemic in some reports, Chinese authorities regularly shut down Internet cafes, many illegally operated, in crackdowns that also include huge fines for their operators. The Chinese government has also instituted laws to reduce the number of hours adolescents can play online games (BBC News, 2007) and in 2005 opened the first treatment center for Internet addiction in Beijing. Online gaming addiction continues to raise such serious concerns that the first detox center for video game addiction has opened in Amsterdam (CBSNews.com, 2006), and most recently the American Medical Association, at its annual policy meeting, has considered calling video game overuse an addiction (Tanner, 2007).

SIGNS OF ONLINE GAMING ADDICTION

As online gaming becomes more popular, more parents discover how addictive it can be for their children. "My son has completely withdrawn from his family and from all reality," explains one mother. "At first, his father and I were happy that he seemed interested in the Internet. He had no other hobbies and he seemed to make friends online, but soon, the game took over his life. He didn't shower, didn't eat, and didn't leave his room. My husband and I became worried and tried to set time limits, but he just got mad. I mean angry and hateful towards us. It was a side of our son we had never seen. All he wanted was the game. We are so scared and don't know where to turn. Counselors we have talked to just tell us it is a phase and to ignore it, but we can't. His whole life is the game. This is more than a phase—it is an obsession. We are desperate to find him help."

Parents often feel alone and scared as their children become hooked on something that no one seems to understand. Parents search for information and help of any kind as they helplessly watch their children become absorbed in the computer and begin to see the warning signs of a dangerous pattern. Gamers who become hooked show clear signs of addiction. Serious gamers, who play for extended periods of time (over four hours at a time), get restless or irritable if they can't play, and sacrifice other social activities just to game, are

showing signs of addiction (Griffiths, Davies, & Chappell, 2003). Other common warning signs include the following:

- A preoccupation with gaming
- Lying or hiding gaming use
- Disobeying time limits
- Loss of interest in other activities
- Social withdrawal from family and friends
- Psychological withdrawal from the game when forced away from it
- Using gaming as an escape
- Continuing to game despite its consequences

Preoccupation with Gaming

The addiction process begins with a preoccupation with gaming. Gamers will think about the game when offline and often fantasize about playing the game when they should be concentrating on other things. Instead of thinking about the paper that needs to be completed for school, or going to class, or studying at the library, the gamer becomes completely focused on playing the game. Gamers start to miss deadlines and neglect work or social activities, as being online and playing the game becomes their main priority.

Lying or Hiding Gaming Use

Some gamers spend days and nights online. They don't eat, sleep, or take showers because of the game. They lie to family and friends about what they are really doing on the computer. Students tell their parents that they are doing their homework, spouses tell their family that they are using the computer for work, and friends will make up excuses for why they can't go out—all to find more time to play the game.

Loss of Interest in Other Activities

As the addiction grows, gamers become less interested in hobbies or activities that they used to enjoy and become more fascinated by the game. One mother told me about her son who loved baseball and played Varsity on his high school team until he discovered XBox Live. "His grades plummeted after he discovered the game, but it wasn't until he quit the baseball team that I knew that something was seriously wrong. He loved baseball too much. He even won

a baseball scholarship for college and dreamed about playing professionally. Now, nothing else matters to him except the game."

Social Withdrawal

Some gamers experience personality changes the more addicted they become. A once outgoing and social daughter withdraws from friends and family only to spend more time alone in front of the computer. A normally happy son becomes withdrawn, preferring to make friends in the game as the people that were once important in real life become less important. As one mother explained, "If no one else existed, he would play all day." If children do have real-life friends, they are usually fellow gamers. In some cases, gamers are introverts who have problems making social connections in real life and turn to the game for companionship and acceptance.

Disobeying Time Limits

Because of their addiction, gamers become defensive about their need to play the game and angry when forced to go without it. Parents who try to put time limits on the game describe how their sons and daughters become angry, irrational, and even violent. In one case, a mother told me about her son who spent his nights gaming and his days sleeping. "When I took away his computer, he pushed me, slammed the door to his room, and wouldn't come out all night. When I came home from work the next day, he took a sledgehammer to my computer, which was off limits to him. This isn't my son. He was a good kid and never gave me a moment's trouble until I lost him to the game."

Psychological Withdrawal

Gamers who can't access the game experience a loss. They want to be on the game and they miss playing the game. This feeling can become so intense that they become irritable, anxious, or depressed when they are forced to go without the game. They can't concentrate on anything other than going back online to play. Their minds become so fixated on the game that they can experience a psychological withdrawal from the game such as depression and irritability. Their feelings intensify and they stop thinking rationally and begin to act out toward other people in their lives. All that they can think about is getting back to the game, and they become vent their anger and bitterness against anyone who threatens to take it away.

Using Gaming as an Escape

Gaming addicts use the online world as a psychological escape. The game becomes a safe means to cope with life's problems. It is a legal and inexpensive way to soothe troubling feelings and can quickly become a convenient way to instantly forget stresses and pains. Like drug addicts or alcoholics who use drugs or alcohol as a way to escape problems that they aren't able to deal with, gaming addicts use the game to avoid stressful situations and unpleasant feelings. They escape into the gratification of the game and the feelings they associate with playing it. Gamers who feel socially awkward, isolated, and insecure in real life can transform themselves into people who feel socially confident, connected, and self-assured in interacting with others through the game. As gamers progress further into the game, they make friends (or maybe their friends were the ones who first introduced them to the game) and these social relationships with other players become highly significant. While playing, gamers feel more accomplished, more accepted, and better about themselves. Through their characters, gamers live out a fictional life that is more satisfying and interesting than their own.

Continuing to Game despite Its Consequences

Gamers often want to be the best at the game. In order to grow in the game, they need to play. Especially in quest-type games that include a shared activity, they hunt for items together, and can take several hours to complete one quest. Gamers who become hooked become obsessed with the need to be the best at the game. They want to feel powerful and to be recognized by other players; in order to do this they must spend time in the game. They continue to use the game despite its effects on their lives. Adolescents may fail out of school, lose a scholarship, break up with a girlfriend or boyfriend, and ignore basic hygiene, just to be online. Adults may lose a job or a relationship, or their marriage may be on the brink of divorce, but still they remain loyal to the game.

PSYCHOSOCIAL RISK FACTORS

People of all ages are quickly becoming immersed in the virtual fantasy world in which they can easily escape problems in their real lives (Kolo & Baur, 2004). "For me, gaming was a way of coping with my divorce," said Susan, a regular player of the game EverQuest. "A guy I talk to has been through three girlfriends and even more jobs because of the game." Like other players, Susan struggles to find a workable balance between gaming and the responsibilities

in her life. She spends nearly eight hours a day online and often questions her devotion to the game. "I think of quitting all the time," she said. "I'm neglecting my kids and my husband but the game is so powerful I feel helpless to stop." Recent research has explored several potential risk factors associated with addictive online gaming behavior.

Low Self-Esteem

Individuals who suffer from low self-esteem or other emotional problems are at greater risk for developing an addiction to online gaming. Recent studies suggest that hardcore players may have a tendency toward neuroticism or may suffer from emotional problems or low self-worth and esteem (Yee, 2007). The studies suggest that individuals who have other emotional problems may be more at risk of developing an addiction to interactive gaming. In the game, the interactive environments allow individuals to experiment with parts of their personality: they can be more vocal, try out leadership roles, and try out new identities. The problem comes when players rely upon these new online personae and the distinction between reality and a fantasy role-play game becomes blurred. Kevin was a 21-year-old from Rochester, NY, who was dismissed from college because of his gaming habit. When I asked him about the game, he said that his life seemed to be important when he was playing the game. He was important in the game, but in real life he was a person who couldn't make friends and wasn't meeting his parent's expectations. He had failed in school, not so much because he couldn't pass the tests but because he couldn't make it to class. He didn't have a direction in his life, and because of this, he didn't feel good about his life. But in the game, all that changed. He was good at the game, had a network of fellow gamers who, he felt, were his closest (and only) friends, and he felt validated and confident when playing the game.

Poor Social Relationships

A large part of gaming is about making social relationships. Gamers often make friends with other gamers (Kolo & Baur, 2004). Ultimately, online gaming is a social activity. Most online games include copious amounts of chatting, allowing players to interact with each other in the guise of the characters they represent. The social aspect is a primary factor in many game addictions (Leung, 2007). Many adolescents have trouble with social relationships and feel lonely, as if they have never truly belonged. Adolescents can develop a sense of belonging in the game. In some cases, the game provides the only friends they interact with. Gamers can become hooked on the social aspect of the game.

They may join guilds that provide a strong sense of community and accomplishment when they take out monsters or strategize about their next online session. Through quests or nightly turns playing the game, gamers can form close bonds and friendships with fellow players that provide the social contact that has been missing from their lives.

Highly Intelligent and Imaginative Individuals

Gaming provides players with an outlet for their imaginations (Turkle, 1998). Adolescents who are academically bright and who feel understimulated in school turn to the game as a place for adventure and intellectual stimulation (Kelly, 2004). Games also lure players with complex systems of goals and achievements. The players are drawn into the virtual fantasy world of the game; they internalize the game as a real place, and other characters are seen as real people, not fictional characters. Especially in goal-oriented games such as EverQuest**,** players engage in activities designed to develop their characters and compete to find valuable in-game elements such as armor and weapons. Players can find themselves wrapped up in the game for hours as they struggle to gain one more skill or weapon.

Need for Recognition and Power

Turkle (1998) describes how gamers often achieve recognition and power through online gaming. "I'd say the most addictive part for me was definitely the gain of power and status," explained Mark, a gamer hooked on Diablo II. "The way you progressively gain power you become more of an object of awe to the other players. . . . each new skill isn't enough." Among most multi-user gamers, each goal leads to another goal, and gamers make critical choices along the way. They invest significant time and thought in developing a character. They feel they have wasted their time unless they reach the next goal. For example, Mark, a college sophomore, explained, "By day I am a mild-mannered student, but at night, I become the most aggressive warrior online." Mark had always been a loner. He described how, growing up as a middle child, he felt ignored by his parents, who gloated over his older sister, a medical doctor, and his younger sister, a freshman at Brandeis, while he attended a state university. He had built up a great deal of resentment toward his siblings, and deep down he resented his parents for their neglect. "On the outside, I looked like the perfect child and no one knew of the anger and resentment that I felt inside," Mark explained. "I was afraid to give into my anger, yet within the game, I confronted my fears and liked dominating other players. I became known as the most powerful and the

most respected player in the game, and I needed that. The game was the only place in my life where I felt important."

The Younger They Start

Some research has suggested that the younger children start to use the Internet, the more they are at risk of developing an addiction to online gaming (Yee, 2007). Dan started gaming by age 12. He was drawn to Gameboy, Sony Play Station, and Nintendo with his friends, and gradually progressed to XBox. He was able to manage the time he spent gaming until he went on XBox Live. "It was like a whole other world opened up to me," he explained. Suddenly, he was able to interact with fellow players instead of sitting beside friends while playing the game. Gaming had already become a large part of his personal identity, and despite suffering from attention deficit disorder (ADD) he was able to sit in front of the computer for hours. His parents became concerned when his gaming habit turned into an obsession. "He went into a trance-like state every time he went online but unlike other hobbies, he never lost interest in this," his mother explained. "When he quit the track team, which he loved, we knew he had a serious problem and the game took over his life." Interestingly, children with ADD have been prone to gaming addiction and are more likely to form an addiction to gaming due to the stimulation that the interaction with other online players and the challenge of the game can provide.

Family History of Addiction

Recent studies in Taiwan suggest that family factors also increase risk for developing online gaming addiction (Yen, Yen, Chen, Chen, and Ko, 2007). Adolescents from households of lower economic levels, whose parents are separated or divorced, whose families have high parent-adolescent conflict, or whose families have a history of addiction are at greater risk of developing gaming addiction. Many addictions stem from a history of addiction in the family as a way of coping with painful feelings and difficult situations. Seeing that an aunt, uncle, or other relative copes with problems through drinking, drug use, gaming, or smoking might indicate to an adolescent that this is the way to cope with all problems. Gamers who become addicted, especially adolescents, often use the game as a way of escaping conflict or turbulence in their lives. Adolescents experiencing a traumatic transition such as divorce, or family relocation, or the acquisition of a new step-parent face a personal crisis and learn to cope through the Internet. Adolescents addicted to gaming explain that they feel alone, feel emotionally removed from others, or feel that their parents are somehow

disappointed with them (Young, 1998b). Like those addicted to drugs or alcohol, they use the game to escape these painful feelings and momentarily feel a sense of acceptance and accomplishment in their lives.

TREATING GAMING ADDICTS

As in any treatment program, the primary step to take in the path to recovery is to accept and not refute "denial," a defense mechanism that addicts frequently employ and that effectively stops them from accepting treatment. Once this obstacle is overcome, treatment can be more effective. It is important to understand that compulsive online gaming is treatable. It affects the gamers, their families, their schoolwork or employer, and their community. For players who do admit they have a problem, the most common response is a guilt-and-purge cycle, which is common to many addictions (Kelly, 2004). Many players who realize that they are addicted will kill their characters and delete the game software with no regrets; however, many other game addicts aren't as successful in doing this. For most players, true recovery involves looking at the issues underlying the game habit. Addicted players need to examine the emotional motives that prompt them to play a game excessively and look for alternate ways to satisfy those needs.

Knowing the Clinical Signs

It is important to be able to recognize the symptoms of online gaming addiction and possible warning signs. The sooner one seeks help for an adolescent experiencing online gaming addiction, the more beneficial it will be. Consistent patterns of addiction in adolescence are in most cases a sign that there are prevalent issues in the adolescent's immediate environment that need to be addressed. Some warning signs that an adolescent may be abusing games include change of friends, change in physical health, behavioral problems, academic problems, change in attitude, indifference, increased irritability and hostility, frequent changes in mood, eating, and sleeping patterns, and depression and isolation. Young (2007) developed an eight-item screening test based upon the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*) to help clinicians identify the most common signs of compulsive behavior related to online games:

1. Do you need to play for increasing amounts of time?
2. Are you preoccupied with gaming (thinking about it when offline, anticipating your next online session)?

3. Have you lied to friends and family members to conceal the extent of your gaming?
4. Do you feel restless or irritable when attempting to cut down or stop online gaming?
5. Have you made repeated unsuccessful efforts to control, cut back, or stop online gaming?
6. Do you use gaming as a way of escaping from problems or relieving feelings of helplessness, guilt, anxiety, or depression?
7. Have you jeopardized or lost a significant relationship because of your online gaming habit?
8. Have you jeopardized a job, educational, or career opportunity because of your online gaming habit?
9. Do you suffer from eye strain, back strain, or lack of sleep because of the amount of time you spend at the computer?
10. Do you suffer from carpal tunnel syndrome or other repetitive stress injuries because of the amount of time you spend at the computer?

Answering "yes" to give or more of questions without the response being better accounted for by a manic episode suggests that a client may suffer from online gaming addiction. These signs suggest that a client has lost control, lied, risked a relationship or job, or possibly suffered from physical problems because of online gaming.

Symptom Management

Understanding how and when a gamer uses the computer is an initial step in the recovery process. Keep a daily log to track how the gamer actually uses the Internet, then take a few minutes to consider his or her current online habits. On what days of the week does he typically log online? At what time of day does she usually begin? How long does he stay online during a typical session? Where does he usually use the computer? Does a pattern emerge? Now, using the daily log, construct a new schedule, or what Young (1998b, 56) refers to as "practicing the opposite." The goal of this exercise is to disrupt the client's normal routine and construct new patterns of time use in an effort to break the online habit. Let's say the client's Internet habit involves playing the game from 5 a.m. until after midnight. Instead of going online, the client should take a shower or start breakfast first instead of logging on. Or, perhaps, a client uses the Internet only in the evening, and has an established pattern of coming home and sitting in front of the computer for the remainder of the evening. Instead, he should wait until he has had dinner and watched the news before logging on. Practicing the opposite will disrupt clients' normal Internet patterns and increase their ability to effectively manage their online time.

Online gaming is an emotionally draining and time-consuming activity, and to create more time for the computer, addicts neglect sleep, diet, exercise, hobbies, and socializing. The initial loss of online gaming means an increase in idle time or boredom, which only increases the temptation to surf, making it vital for clients to create positive lifestyle changes to fill the void created by time no longer spent at the computer.

Symptom management also involves creating positive lifestyle changes that take clients away from the computer and improve their emotional and physical well-being (Young, 2007). This varies, depending upon the client's specific situation. Some strategies may involve finding spiritual fellowship in the form of personal prayer or pastoral counseling as part of spiritual wellness and daily recovery (Young & Klausing, 2007). Clients may practice mediation to focus their energy during recovery and use prayer and scripture to improve their ability to fight the temptation to return to the computer. Other activities include getting the proper rest, going to bed at a reasonable hour, joining a gym, and improving diet to manage overall physical health.

As in food addiction, symptom management is an essential part of recovery. In food addiction, certain foods trigger binge behavior. Chocolate or potato chips will trigger binges but celery sticks will not, so avoidance of the trigger foods is a necessary part of recovery. This means that recovery from binge eating is about relearning how to eat in order to make more informed and healthier food selections, with success being measured through objective goals such as changes in caloric intake and weight loss. The same logic is applied to addictive online gaming. In part, recovery involves relearning how to use the computer, making better choices about its use. Reducing the number of hours a gaming addict spends online is an important first step, but to move toward full recovery, the addict must also address the underlying issues that led to gaming (Young, 1998b).

Addressing Underlying Issues

The ability to mentally absorb oneself in a virtual environment that seems more exciting and more interesting than one's real life reinforces the addictive behavior and can be used as a coping mechanism to deal with missing or unfulfilled needs. That is, gaming momentarily allows the gamer to forget his or her problems. In the short term, gaming may be a useful way to cope with the stress of a hard situation; however, addictive behaviors used to enable the individual to escape or run away from unpleasant situations in the long run only make the problem worse. For the gaming addict, situations such as a death of a loved one, a divorce, or a job loss may trigger using the game as a mental distraction that

temporarily makes such problems fade into the background. Since the escape is only temporary, addicts return to gaming as a means of making themselves feel better without dealing with and resolving the underlying feelings of depression or anxiety in their lives.

The game produces a "high" that provides an emotional escape, altered state of reality, or mental rush (Ng & Wiemer-Hastings, 2005). That is, online gaming, through the excitement of becoming someone new in a role-playing game, the challenge of winning the quest, and the pleasure of making new friends through the game, provides an immediate mental escape from problems and serves to reinforce future behavior.

Therefore, treatment requires addressing those needs that the game fulfills. For James, a 21-year-old college freshman addicted to XBox Live, the hardest part of getting better was finding something else in life that mattered as much as the game. "At 21, I was going nowhere fast," James explained. "I didn't like school, I didn't have any friends except those I knew in the game, but yet I saw others around me moving on with their lives. The friends that I had during freshman year were going to graduate while I got myself kicked out of school because I couldn't stop gaming. My older brother was graduating from graduate school, had a girlfriend and was getting married in the fall, while I did nothing and felt completely stuck in the game. I tried quitting the game so many times, but I felt there was nothing important enough in my life to really quit it for."

James repeatedly relapsed into the game because he still wasn't dealing with his feelings about his career goals. Each time he thought of registering for classes, taking a course, or studying for a test, he felt the pressure and internal judgment of feeling like a failure. He constantly compared himself to his friends and his brother, and relapsed into the game as a way to relieve his underlying feelings of depression and self-doubt.

As part of his recovery, James started taking night classes at a community college, taking one or two classes to see what type of work or vocation he wanted to pursue. He liked finance, a far cry from his major in engineering at the University of Buffalo, and with the financial and emotional support of his parents, he re-enrolled full-time at the university and graduated with a degree in business and financial management. His interest in online gaming diminished as he spent his free time studying, going to classes, and making new friends—and he was finally doing something he loved.

Whatever the situation, confronting the issues that initially drove a client toward the addiction will not be easy, but it is the only way to achieve the personal growth necessary to maintain long-term recovery. In our work together, James gained a deeper sense of why he gamed. Important questions to ask clients, in order to help them understand their gaming behavior are as follows:

What types of needs does gaming fulfill? Does gaming give you a sense of power, but offline, do you still feel out of control? Does gaming make you feel better about yourself, but offline, do you still feel unsure about the choices you have made in life? Instead of using gaming to avoid difficult feelings, therapists should work with their clients to learn how and why gaming has become a way to deal with what hasn't been working in people's lives.

Family Therapy

Adolescent gaming addiction continues to be a major issue in our society as teen gaming abuse is growing at an alarmingly high rate. Adolescence alone, regardless of involvement in the Internet, is an extremely challenging and complex transition for young individuals. Exploring and attempting to discover one's identity as an adolescent can be an overwhelming stage in one's life. In the event that an adolescent is using online games, it is more than likely that many more obstacles will be encountered and as a result a teen will struggle with unmanageable physical and emotional consequences (Kelly, 2004).

Peer pressure and environmental stresses are the main influences on an adolescent who becomes involved with gaming. Friends are often gamers, and, as discussed above, family dynamics can play a role in the development of online gaming addiction. Furthermore, children of substance-abusing parents have been shown to have an increased risk of using gaming as a means to cope with problems such as developmental issues, school problems, health problems, delinquency, sexual problems, mental issues, and family problems.

It is very hard for a teen to recover from gaming addiction, especially when the computer is often a necessary component of the teen's home and school environments. Effective treatment requires that the dynamics of the family should be assessed and that family members must also be helped to achieve health, or relapse is much more likely.

For most adolescents, referral to treatment is involuntary and is usually mandated by parents, teachers, or the judicial system. When asked at the intake stage what the problem is, adolescents' most common answers are "Don't know" or "Somebody [family, teacher, policeman] just overreacted." When pressed, most adolescents say they are doing nothing different from their peers or explain that they aren't online as much as other friends who game.

Successful treatment must not only address the gaming behavior but also help an adolescent navigate the normal developmental tasks of identity formation that are often neglected while gaming is being used as a means of coping with life's problems. Treatment should focus on effective problem solving and the social skills necessary to build self-esteem. Many gamers lack a strong sense

of self, using gaming as means to form their identities. However, their self-esteem in real life is fragile or nonexistent. Family therapy must focus on ways to build or rebuild their identities within a nongaming environment.

Gamers often minimize the extent to which they game and avoid dealing with the family issues that may be driving their desire to game. It is important to consider an adolescent's specific family situation when treating the addiction. Comprehending the teen's immediate environment in most cases enhances the understanding of the addiction's causes. It is necessary to look at family dynamics, such as family history of addiction, background, communication dynamics, or conflict and to look at the ways in which these factors may be impacting a teen's developmental stages, emotional well-being, and self-esteem.

Finally, family therapy needs to include educating the family on ways in which they can help the addict, whether or not he or she is in individual counseling or treatment. This may include counseling for family members, education on problem/compulsive gaming for the family, strategies on how to cope with the addict's anger and loss of trust, and education on the emotional costs of online gaming. Often, gaming addiction is addressed as a part of a weekly family program. Each week, topics related to addiction are addressed, to help family members understand the process of recovery, the possible relapse triggers, and the importance of maintaining healthy boundaries. This is especially important for parents as they struggle to understand a son or daughter's compulsive need to game and the underlying dynamics associated with the addiction.

Communication Skills

Communication skills may also need to be learned. Many gamers cannot communicate well in face-to-face situations (Leo Sang-Min, 2003). This one reason why children game in the first place. Communicating online seems safer and easier for them. However, a lack of communication skills can cause poor self esteem and feelings of isolation and create additional problems in life among adolescents, so therapy needs to address the way they communicate with others offline. Some basic guidelines for therapists include the following:

- Enlisting the aid of an older child who may help to engage your client in short conversations to help develop skills.
- Engaging as many of your client's senses as you can during a conversation and teaching the client to do the same. The client's interest in the discussion will remain higher.
- Using books, magazines, and television to talk to your client about facial expressions and what they mean, and to enable the client to watch for body

language so as to improve the understanding of what the other person is feeling.

- Using role-playing conversations to build the client's confidence. You should start one on one and introduce other children one at a time as the client begins to build confidence in his abilities. Older siblings, cousins, or neighbors might be more than willing to help.
- Taking the time to tell to your clients what you think they meant. If needed, you should help them find ways to better explain themselves.
- Asking your client to tell you what she thinks you said. This will help you see how well your client listens during a conversation.
- Using regular eye contact and having your client practice using eye contact when speaking to other people.

Residential Care

Residential care may be required to provide intensive therapy when the effects of the game have become severe. Often gamers refuse treatment until they become deeply depressed, are dismissed from school, are terminated from a job, are threatened with divorce and separation, or are thinking about suicide. Once the problems have become this severe, it is important to seek professional help in evaluating the situation. Residential treatment programs often last for four to six weeks of intensive treatment. Some gamers may require more or less time, so recommendations will be made following an initial assessment.

In most cases, the treatment program of a residential care facility is specifically designed to fit the needs of the client, and most sessions focus on individual treatment, educational groups, and family therapy where appropriate to best manage and address the intense feelings surrounding the addiction. Often, parents will initiate residential care for a child addicted to online gaming. It may be difficult to find a facility that understands the special requirements in treating compulsive online gaming, but gradually more inpatient addiction rehabilitation centers are learning about this new form of addictive behavior.

Chapter **17**

Youth Gambling Prevention and Resilience Education: A Harm Reduction Approach

Isabelle D. Lussier, MA,
Jeffrey L. Derevensky, PhD, and Rina Gupta, PhD

Gambling in its many forms, has permeated every society and culture all the way back to ancient times (Caltabiano, 2003). While gambling has been a source of entertainment for countless people, a small but identifiable minority of people exhibit compulsive gambling behaviors that lead to personal harm and suffering (Abbott, Volberg, Bellringer, & Reith, 2004). Over the last two decades, an unprecedented growth has occurred in the legalization, availability, and accessibility of gambling activities and venues. Internationally, the legitimacy and popularity of gambling continue to rise, and technological advances continue to evolve, attracting both young and old to participate (Abbott et al., 2004; Derevensky, 2007).

Of particular concern is the fact that young people are consistently reported to be at higher risk of demonstrating compulsive gambling behavior (Gupta & Derevensky, 1998; National Research Council [NRC], 1999). It is estimated that 3–8 percent of adolescents meet the criteria for pathological gambling, while another 10–15 percent of adolescents are at risk for the development of severe gambling behavior (Derevensky & Gupta, 2000, 2004; Jacobs, 2000, 2004; NRC, 1999; Shaffer & Hall, 1996). Probable pathological gambling is more prevalent among males than females (NRC, 1999), and the onset of gambling problems occurs early, between the ages of 11 and 13 (Jacobs, 2000), indicating a need for targeted public education and awareness campaigns (Abbott et al., 2004).

As well, there appears to be a large degree of overlap between risk factors that predispose youth to severe gambling problems and those that predispose youth

to other risky behaviors such as delinquency and substance abuse (Derevensky & Gupta, 2004; Ladouceur, Dubé, & Bujold, 1994). These bio-psycho-social risk factors, (e.g., familial attitudes and history of gambling problems, depression, abuse, school failure, delinquency, availability of and access to gambling opportunities, and early onset) span individual, peer, familial, neighborhood, and societal domains (Dickson, Derevensky, & Gupta, 2002; see chapter 12 in this volume for a more comprehensive review of international youth gambling prevalence rates and risk and protective correlates).

The harm reduction/minimization approach, prevalent among alcohol and substance prevention initiatives, has recently attracted considerable attention from youth gambling researchers (Derevensky, 2007, and Derevensky, in press; Dickson, Derevensky, & Gupta, 2004; Gupta & Derevensky, 2008). These researchers advocate the adoption of harm reduction prevention programs (HRPPs) in targeting youth gambling behaviors, but they recommend that these strategies also emphasize the promotion of resiliency traits, by reducing the negative effects of risk factors while enhancing the beneficial moderating effects of protective factors and resiliency traits (Derevensky, 2007, and Derevensky, in press; Dickson et al., 2004; Dickson, Derevensky, & Gupta, 2008). The significant overlap in risk and protective factors for youth with respect to problem gambling and other problem behaviors (Dickson et al., 2002, 2004) has led to the creation of prevention initiatives that target multiple risk behaviors (Jessor, 1998), including problem gambling (Dickson et al., 2002, 2004; Jacobs, 2004). To date, very little resilience research regarding youth gambling behaviors has been conducted (Lussier, Derevensky, Gupta, Bergevin, & Ellenbogen, 2007). However, resiliency skills have long been incorporated into prevention programs for a wide variety of risky behaviors (Jessor, 1998). It is therefore important to extend resilience research, especially in an area such as youth gambling, which has received such little attention (Dickson et al., 2002).

RESILIENCY

Traditionally, the major focus of prevention research has been to identify risk factors and high-risk individuals (Leshner, 1999). However, it is evident that many youth exposed to high levels of risk never develop the anticipated negative problem behavior(s), and many thrive in spite of them; a concept referred to as *resilience*. Although there is substantial variation in the definition of resilience, two central constructs exist in most definitions, that is, *risk* or *adversity*, and *positive adaptation* or *competence* (Luthar, 1997). A widely accepted, simplified definition of resilience therefore relates to the presence of manifest competence despite exposure to significant adversity (Rolf & Glantz, 1999). Manifest

competence generally refers to internal states of well-being and/or effective functioning in the environment (Masten, Best, & Garmezy, 1990). Individuals may be resilient in one domain or several, but rarely in all (Luthar, 1997). For example, resilient adolescents who demonstrate high social competence despite much adversity in their lives may also report depressive symptoms. In light of these findings, resilience researchers have become increasingly cautious in using the term resilience, opting instead for more specific terms such as *educational resilience, emotional resilience,* and *behavioral resilience* (Luthar, Cicchetti, & Becker, 2000).

Resilience research has to date experienced three waves (O'Dougherty Wright & Masten, 2005). In the first wave, early studies on resilience focused mostly on the identification of protective factors. Influenced by Urie Bronfenbrenner's ecological (1979) and bioecological (2005) models, a second wave of resilience research emphasized relationships and systems, and integrated biological, social, and cultural processes across time. Ecological theory is conceptualized by Urie Bronfenbrenner as

> the scientific study of the progressive, mutual accommodation, throughout the life course, between an active, growing human being and the changing properties of the immediate settings in which the developing person lives, as this process is affected by the relations between these settings, and by the larger contexts in which the settings are embedded. (2005, p. 107)

According to this model, there are four environmental levels including the *microsystem* (the actions and interactions within the environment that a child is behaving in, at any given moment in time, e.g., home and school); the *mesosystem* (the interrelations among the child's microsystems, e.g., the relationship between a child's parents and school); the *exosystem* (the environmental factors that indirectly influence the child's behavior and development, e.g., parental workplace), and the *macrosystem* (broad social factors and cultural values that influence other settings, e.g., public social policies) (Bronfenbrenner, 2005; Kaminski & Stormshak, 2007).

Risk and Vulnerability Factors

The term *risk* commonly refers to early predictors of probable negative outcomes and to descriptions of negative life conditions such as family conflict and poverty (Kaplan, 1999). Probable negative outcomes may include psychopathology, excessive gambling, drug or alcohol abuse, dropping out of school, and so on. Two terms commonly used in reference to risk include *vulnerability factors* and *risk factors*. Risk and vulnerability factors may include individual attributes,

characteristics, situations, or contexts within the environment that increase the likelihood of acquiring and maintaining maladaptive behaviors (Kaplan, 1999). However, vulnerability factors suggest variables that increase the chances of negative outcomes within the context of adversity, while risk factors refer to variables that increase the chances of negative outcomes regardless of the occurrence of adversity (Rose, Holmbeck, Millstein Coakley, & Franks, 2004).

Researchers and clinicians have long recognized that the relationship between risk and maladaptive behaviors is such that as the co-occurrence and accumulation of risk factors over time increases, so too do maladaptive behaviors (Jessor, 1998; Jessor, Van Den Bos, Vanderryn, Costa, & Turbin, 1995; Rutter, 1990). In other words, the more risk factors an individual is exposed to, the less likely the individual will be to build internal or external assets (Benson, Galbraith, & Espeland, 1995). Risk is often described on a continuum, with a positive end associated with positive outcomes and a negative end associated with negative outcomes (e.g., socioeconomic status) (Masten, 2001). However, not all risk factors may be conceptualized in this manner. For example, teen pregnancy and cigarette use have been shown to be associated with negative outcomes, but the lack of pregnancy or smoking is not necessarily associated with positive outcomes.

Protective and Resource Factors

The term *protection* commonly involves conditions that improve an individual's resistance to negative outcomes. Two terms commonly used in reference to protection include *protective factors* and *resource factors*. Protective factors include variables that decrease the chances of negative outcomes in the context of adversity, whereas resource factors refer to variables that positively influence outcome independent of the occurrence of adversity (Rose et al., 2004). Protective factors may include personal attributes (e.g., temperament, intelligence, social bonding, personal competence, social competence), familial factors (e.g., encouragement of trust, autonomy, and initiative), and community characteristics (e.g., external support systems including church, youth groups, and school) that *moderate* a person's reaction to adversity in a positive manner (Dickson, Derevensky, & Gupta, 2008; Werner, 1995; Werner & Smith, 1992). Fostering the growth and presence of protective factors thus moderates the undesired effects of risk in such a way that development is more positive than if the protective factors had not existed (Masten et al., 1990).

To summarize, when a variable promotes or impedes adaptive outcomes within the context of adversity, it may be conceptualized in terms of protective or vulnerability factors, serving a moderating role. However, when a variable

promotes or impedes adaptive outcomes regardless of the context of adversity, it may be conceptualized in terms of resource or risk factors (Rose et al., 2004).

Most researchers now agree that a child may be identified as resilient at one point in his development but not in another. Similarly, a child may be competent in one context or aspect of life but not in another (O'Dougherty Wright & Masten, 2005). A second wave of research has sought to search for mediating and moderating processes that ultimately lead to resilience. Although this wave of research is far from complete, a third wave of research has already begun, with a focus on intervention strategies designed to promote resilience.

PREVENTION EFFORTS

The importance of resilience research rests in its applicability to the field of prevention. Researchers have begun to incorporate resilience research into prevention and intervention programs for high-risk youth (Coie et al., 1993; Leshner, 1999). The focus in prevention research was initially to identify risk and vulnerability factors and at-risk populations (Garmezy, 1971; Pasamanick & Lilienfeld, 1956). However, the identification of risk and vulnerability factors by themselves has not been of great use to prevention efforts since many of these factors are difficult to minimize (e.g., poverty) or identify (e.g., sexual abuse) (Leshner, 1999) and since many high-risk youth never actually develop the anticipated negative behaviors. As a result, an attempt to identify variables and interactions between variables that might act as buffers or protective factors to counteract the risks associated with aberrant behavior has begun.

Dickson and her colleagues (2004) have integrated adolescent gambling behavior into Jessor's (1998) adolescent risk behavior model. Jessor's model follows current trends in resilience research, where risk and protection are seen as interacting across various domains (biological, social environment, perceived environment, personality, and behavior) and high-risk behaviors. Further, the protection variables listed in each of the domains of the model correspond to broad resiliency traits including *social bonding* (pro-social ties to one's school, family, and community), *personal competence* (one's individual identity and sense of personal development), and *social competence* (one's ability to adjust in social situations) (Springer & Phillips, 1992).

HARM REDUCTION

There are certain risky behaviors, such as alcohol consumption, that, though potentially harmful, have nonetheless become part of the fabric of our society.

This has led certain prevention specialists to reevaluate abstinence models as being unrealistic and impractical (Beck, 1998; Dickson et al., 2004; Poulin & Elliott, 1997). Rather, a movement toward responsible, controlled involvement has led to a harm reduction approach versus an abstinence approach. Harm reduction strategies are designed to limit the harmful effects that may result from involvement in risky behaviors without demanding abstinence per se. Such strategies were first developed to curb alcohol and illicit substance abuse (Erickson, 1997). More recently however, a youth gambling risk prevention model based on a public health perspective has been proposed (Messerlian, Derevensky, & Gupta, 2005). Within this model, primary prevention strategies are designed to prevent the onset of risky gambling behavior by educating youth, parents, professionals, and the public regarding the risks and consequences of problem gambling. As well, based on the assumption that it is not realistic to expect youth to abstain from gambling altogether (especially unregulated forms of gambling), secondary prevention strategies are designed to prevent juveniles at risk of developing serious gambling problems from escalating toward problem gambling. These harm reduction strategies include early identification of gambling problems by educating primary health care workers to identify some of the risk and warning signs of excessive gambling. Finally, tertiary prevention strategies within this model, designed for youth exhibiting excessive gambling behaviors, seek to augment the access to and availability of treatment, services, and support (Messerlian et al., 2005).

HARM REDUCTION AND RESILIENCE EDUCATION INITIATIVES

Given the increasing availability, accessibility, and popularity of gambling, the utility of a harm reduction approach to prevent probable pathological gambling among youth is promising. Based on a harm reduction approach, the International Centre for Youth Gambling Problems and High-Risk Behaviors at McGill University in Montreal has developed a number of prevention initiatives including *The Amazing Chateau* and *Hooked City* (interactive CD ROM games for children and adolescents aged 11–18), prevention workshops for youth, and *Clean Break* (a DVD/VHS docudrama designed for adolescents 13–18) (Derevensky, in press). Although there are very few evaluated outcomes of harm reduction prevention initiatives for youth gambling (Petry, 2005), parents (Ladouceur, Vitaro, & Côté, 2001; Côté, Vitaro, & Ladouceur, 2003) and educators (Ladouceur, Ferland, Côté, & Vitaro, 2004) in Quebec, Canada, are reportedly becoming increasingly aware of the potential risks involved in youth gambling behavior, indicating that primary prevention efforts may be having a

beneficial effect. As well, estimates from a large-scale national prevalence study in the United Kingdom (UK) indicate that lifetime participation in gambling activities and rates of problem gambling among youth have been on a steady decline since 1997 (Wood, Griffiths, Stevens, Bartlett, & Pye, 2006). The authors suggest that this decline may be an indication of the beneficial effects of prevention measures put in place in the country.

Resilience education programs have received some evaluative attention, supporting the plausibility of translating resilience research into effective practice-based prevention and intervention programs (Battistich, Schaps, & Wilson, 2004; Lynch, Geller, & Schmidt, 2004). For example, Battistich and colleagues (2004) examined the effects of an elementary-school intervention program aimed at reducing risk and promoting resilience among youth. Students exposed to the program experienced greater levels of pro-social behavior and engaged in fewer problem behaviors than did the control group. Similarly, social-emotional competence, positive coping skills, and suppression of antisocial and aggressive behavior were strengthened by a carefully designed, research-based resilience program for children (Lynch et al., 2004).

Nation and colleagues (2003) have identified nine qualities that are consistently displayed in effective prevention programs. These principles include (a) comprehensive programming, (b) varied methods of teaching, (c) adequate exposure to the intervention in terms of duration, (d) theory-driven programming, (e) promotion of strong relationships between adults and participants, (f) developmentally sensitive programming such that exposure occurs early enough to have an impact on the problem behavior, (g) sociocultural relevance, (h) clear goals and objectives and documentation of results relative to these goals, and (i) well-trained personnel. Resilience programs that are grounded in research and theory tend to be multifaceted in nature and include multiple strategies designed to strengthen protective factors while concurrently reducing or minimizing risk.

Concluding Remarks

Gambling activities have entertained people across cultures for thousands of years (Caltabiano, 2003). However, over the last 20 years there has been a proliferation in the legalization and expansion of various forms of gambling. Consequently, a reevaluation of how best to prevent youth from developing and maintaining serious gambling problems has fostered the adoption of a harm reduction approach (Dickson et al., 2002; Gupta & Derevensky, 2008; Messerlian et al., 2005). Although such efforts are currently in their infancy, environmental micro-, meso-, exo-, and macrosystems should be taken

into consideration in the design, implementation, and evaluation stages of such initiatives, as these four systems are increasingly recognized as important transactional variables that significantly influence human development (Bronfenbrenner, 2005; Kaminski & Stormshak, 2007).

Despite the promising potential of resilience education programs, various concerns have been raised regarding the hazards of applying such programs in schools. In particular, Pianta and Walsh (1998) delineate numerous cautions to bear in mind regarding the immaturity of the study of resilience, and they draw a parallel between resilience education programs and historical fads such as the e*ffective schools movement*that was popular in the 1970s and early 1980s. During the period of popularity of this movement, schools were identified that had students doing better academically than could be expected, given their high-risk backgrounds. These schools were then used to derive lists of factors that could improve the performance of students in schools with an overrepresentation of high-risk youth. Pianta and Walsh (1998) point out that despite the promise of early findings, methodological flaws in early evaluative studies, eventual lack of evidence, and lack of theory led to the downfall of the movement. They suggest a parallel between the rise and fall of the effective schools movement and the proliferation of recent success stories arising from the resilience movement. Although Pianta and Walsh's article was originally published in 1998, their concerns remain poignant today, as new articles reporting on resilience theory and education programs are published in greater numbers than ever before. Pianta and Walsh caution that a heavy focus on stories of success may deter individuals from appreciating that success is a process that develops over time, and that such a focus may deflect attention away from the harsh realities that high-risk youth are exposed to (Pianta & Walsh, 1998). Similarly, Cantinotti and Ladouceur (2008) caution that harm reduction initiatives for gambling behavior require adherence to the integrity of the original term, harm reduction (i.e., the reduction of negative effects related to gambling, without reducing gambling participation per se), lest the term become so broad as to lose its utility.

Ultimately, the successful prevention of gambling and other problems among youth and the treatment of youth with gambling problems and other addictions is the desired outcome of youth gambling research. Today, it is generally acknowledged that gambling problem prevention efforts, as well as public and industry policies, must be empirically science based (Abbott et al., 2004; Dickson et al., 2002, 2004). The efficacy of programs is largely dependent upon commitment from stakeholders to work together and on conceptually driven research on risk and resilience theory (Abbott et al., 2004; Gupta & Derevensky, 1997; Luthar et al., 2000).

The lack of recognition by youth, parents, educators, and primary health care workers of the prevalence and negative effects of problem gambling is disconcerting, considering that estimates for problem gambling among youth are predicted to rise as gambling activities increase in accessibility, availability, and popularity (Abbott et al., 2004; Derevensky, 2007). Though more complex and controversial in terms of its goals than an abstinence model, the notion of a harm reduction approach that promulgates self-control and responsible involvement may thus become increasingly realistic and palatable as a way of protecting our adolescents.

About the Editor and Contributors

EDITOR

Angela Browne-Miller, PhD, DSW, MPH, is the Set Editor of the *Praeger International Collection on Addictions* (2009), Director of Metaxis Institute for Personal, Social, and Systems Change, based in northern California, United States; Director of Browne and Associates Violence, Substance Abuse, and Trauma Treatment and Prevention Program, also in northern California; has been a keynote speaker at conferences around the world on addiction, violence, and behavior change; and is the author of numerous books, including *To Have and to Hurt: Seeing, Changing or Escaping Patterns of Abuse in Relationships* (2007) and *Rewiring Your Brain to Change Your Behavior* (2009). Dr. Browne-Miller earned two doctorates and two master's degrees at the University of California, Berkeley, where she lectured in three departments for 14 years, and has served as a National Institute of Mental Health Postdoctoral Fellow, a U.S. Department of Public Health Fellow, the public relations director for Californians for Drug Free Youth, the Research Education and Treatment Director for the Cokenders Alcohol and Drug Program, a member of the board of directors of the Employee Assistance Society of North America, an advisor to addiction treatment programs in the United States and several other countries, and project director on three California Department of Health violence prevention projects.

CONTRIBUTORS

Hugo Barrera, MD, completed his internship and general surgery residency training at the University of California, San Diego from 1992 until 1997. Since 1997, he has been with Coast Surgical Group in Chula Vista, California, United States, where he became a partner in 2000. Dr. Barrera's special interests in surgery include surgery for the correction of heartburn using minimally invasive techniques (laparoscopic Nissen fundoplication), advanced laparoscopic surgery including removal of the colon and spleen, and cancer surgery. Dr. Barrera is the Medical Director of the Bloodless Medicine and Surgery Program at Sharp Chula Vista Medical Program. This is a program focusing on the implementation of specialized techniques to minimize operative blood loss and decrease the use of blood transfusions.

Ronald J. Burke, PhD, University of Michigan, is currently professor of organizational behavior, Schulich School of Business, York University, Toronto, Ontario, Canada. His research interests include gender in organizations, work and health, work hours and work addiction, and the use of human resource management research to build more humane and more effective organizations.

Jeffrey L. Derevensky, PhD, is professor in the School of Applied Child Psychology, Department of Educational and Counseling Psychology, also professor in the Department of Psychiatry, McGill University, Montreal, Quebec, Canada. He is codirector of the McGill University Youth Gambling Research and Treatment Clinic and the International Centre for Youth Gambling Problems and High-Risk Behaviors. He is a child psychologist who has published widely in the field of youth gambling. Dr. Derevensky remains on the editorial board of several journals and is an international consultant on responsible gambling practices.

Mark Griffiths, PhD, is a chartered psychologist and professor of gambling studies at Nottingham Trent University, Nottingham, England, and director of the International Gaming Research Unit. He has spent over two decades in the field, is internationally known for his work on gambling and gaming, and has won seven national and international awards for his research. He has published over 200 refereed research papers, two books, 50 book chapters, and over 550 other articles. He has served on numerous national and international committees and gambling charities (e.g., [the] Society for the Study of Gambling, Gamblers Anonymous General Services Board, National Council on Gambling, and as national chair of GamCare). He has won eight national and international awards for his work, including the John Rosecrance Prize (1994), the CELEJ Prize (1998), and the Joseph Lister Prize (2004). He also

does a great deal of freelance journalism and has appeared on over 1,800 radio and television programs.

Rina Gupta, PhD, is a clinical child psychologist and assistant professor of school/applied child psychology, Department of Educational and Counseling Psychology at McGill University, Montreal, Quebec, Canada. She has published widely and has focused her research and social policy work in the area of youth high-risk behaviors. Her early work testing a general theory of addictions was recognized with the doctoral dissertation award of the National Council on Problem Gambling. Most recently, Dr. Gupta was named the National Centre for Responsible Gambling's young researcher of 2006. Dr. Gupta is the founder and codirector of the International Centre for Youth Gambling Problems and High-Risk Behaviors, where her research focus is on prevention. She has worked hard to effect social change and has been invited to provide expert testimony before a number of governmental committees internationally.

Norman Jackson, MS, is a senior learning skills counselor with University of San Diego (UCSD) Center for Academic Research and Training in Anthropogeny (CARTA) in San Diego, California, United States. Prior to working at UCSD, he worked for the Information and Education Section in the California Department of Health Services Immunization Branch as an educational specialist. He was awarded an academic fellowship from the Andrus Foundation and completed a master's of science degree from San Diego State University's College of Health and Human Services. He has over 14 years of health promotion and education work experience in the nonprofit and government sectors. He is committed to working to decrease the health disparities in populations of color, historically disadvantaged populations, and the aged.

Cynthia R. Kalodner, PhD, is professor of psychology at Towson University in Baltimore, Maryland, United States. She teaches graduate and undergraduate courses in abnormal psychology, group counseling, and counseling techniques. Aside from her work in eating disorders, Dr. Kalodner is well known for her work in group counseling and psychotherapy. She coedited a book entitled *The Handbook of Group Counseling and Psychotherapy* (2004). She also writes fiction for young adults.

Robert W. Kubey, PhD, is director of the Center for Media Studies and professor of journalism and media studies at Rutgers University in New Brunswick, New Jersey, United States. Professor Kubey received his doctorate from the Committee on Comparative Human Development at the University of Chicago. Dr. Kubey has been an Annenberg Scholar in Media Literacy at the University of Pennsylvania, and a National Institute of Mental Health research fellow in

the Program in Social Ecology at the University of California at Irvine. He has been a visiting professor at Stanford University. Professor Kubey's books include *Creating Television* (2004), *Television and the Quality of Life* (1991), coauthored with Mihaly Csikszentmihalyi, and *Media Literacy in the Information Age* (1997/2001). Dr. Kubey has written articles for the *New York Times, Scientific American, Newsweek*, and the *Christian Science Monitor* as well as for numerous other major newspapers and magazines. News reports on his research have been carried by all of the world's major wire services and news outlets.

Isabelle D. Lussier, MA, PhD candidate, is a doctoral student in the School/Applied Child Psychology Program, Department of Educational and Counseling Psychology, McGill University, Montreal, Quebec, Canada. Her master's thesis examined youth gambling problems and resilience, and was recognized by the National Council on Problem Gambling with its master's thesis award. Her current research explores personal resiliency traits as moderators of the relationship between environmental risk and gambling problems among low socioeconomic status youth.

Richard A. McGowan, MA, MDiv, ThM, DBA**,** is associate professor in the Carroll School of Management at Boston College in Boston, Massachusetts, United States, and research associate at Harvard Medical, Division on Addictions also in Boston. The focus of his research is on the interaction of the business and public policy processes, especially as they relate to the gambling, tobacco, and alcohol industries. Father McGowan has published five books, entitled *State Lotteries and Legalized Gambling: Painless Revenue or Painful Mirage* (1994); *Business, Politics and Cigarettes: Multiple Levels, Multiple Agendas* (1995); *Industry as a Player in the Social and Political Arenas* (1996); and *The Search for Revenue and the Common Good: An Analysis of Government Regulation of the Alcohol Industry* (1997). He has also published 48 referred articles in various academic journals and made over 80 academic and professional presentations.

Basant K. Puri, MA, PhD, MB, MRCPsych, MMath, of the Medical Research Council (MRC) Clinical Sciences Centre, Hammersmith Hospital, and the Imperial College in London, England, received his primary and postgraduate degrees in medicine from the University of Cambridge and carried out postdoctoral work in molecular genetics at the MRC and the University of Cambridge, and in imaging at the Royal Postgraduate Medical School at Hammersmith Hospital, London. He also has a first-class honors degree in mathematics and postgraduate degrees in mathematics and is a member of the Royal College of Psychiatrists.

Paul Rose, PhD, is an assistant professor of psychology at Southern Illinois University, Edwardsville, Illinois, United States. His current research is focused on consumer behavior. He has also published on the self and romantic relationships.

Amanda Ruiz, MD, trained in psychiatry at the University of California San Diego, in San Diego, California, United States. She also completed a fellowship in forensic psychiatry at the University of California, San Francisco. Dr. Ruiz currently provides consultation services to physicians, attorneys, and companies on mental illness and risk management.

Dan J. Segrist, PhD, is an assistant professor of psychology at Southern Illinois University, Edwardsville, Illinois, United States. His research interests include college student alcohol use, clinical practice issues, and the teaching of psychology.

Mamta Sood, MD, earned her MD degree from Ranchi University in India, followed by a diploma in psychiatry. She has been elected as a fellow of the Indian Association for Social Psychiatry in India. She worked as a psychiatric specialist in the Army Medical Corps of India and subsequently joined the All India Institute of Medical Sciences, New Delhi, Delhi, India as an assistant professor. She has several publications and has received the award for the best paper in military psychiatry and industrial psychiatry.

Ian H. Treasaden, MB, LRCP, MRCS, FRCPsych, LLM, is head of forensic neurosciences, Lipid Neuroscience Group, Imperial College, London, England, and, since l984, he has been consultant forensic psychiatrist at the Three Bridges Medium Secure Unit for mentally disordered offenders, West London Mental Health NHS Trust, where he has also been clinical director. He qualified in medicine in 1975 from the London Hospital Medical College, University of London, where he was awarded the James Anderson Prize in Clinical Medicine. He undertook training in forensic psychiatry at the Maudsley and Bethlem Royal Hospitals in London and Broadmoor Special Hospital, Berkshire, England, between 1982 and 1984. He is the author of papers on forensic psychiatry, and he is also coauthor of the *Textbook of Psychiatry and Mental Health Law: A Practical Guide*. His current research interests include the relationship between mental disorder and offending, including violence among those with schizophrenia and associated lipid neuro-imaging abnormalities.

Meera Vaswani, PhD, earned her PhD degree from Delhi University, a leading university in India. She is a member of the All India Institute of Medical Sciences in New Delhi, Delhi, a prestigious and internationally recognized

institute in India, where she was first a postdoctoral fellow, subsequently became a lecturer, and rose to be a professor. During this time, she was elected as a fellow of the Royal Society, London, and member of the National Academy of Medical Sciences, India. She was selected for a United Nations fellowship, during which she worked in the University of Glasgow, in Scotland, UK. She was one of three scientists in the world selected for the Distinguished International Scientist Collaborative Award (DISCA) from the U.S. National Institute on Drug Addiction (NIDA), the U.S. National Institutes of Health (NIH), 2007. She has completed several projects on addiction (alcohol and heroin) and published many papers in both national and international journals. She has been a guest speaker at several national and international forums. She was the only delegate invited by Japan to represent India in the Asia Pacific Society of Biological Research in Alcoholism. Subsequently, she was elected as a member of the board of directors of the Asia Pacific Society for Alcohol and Addiction Research (APSAAR).

Kimberly S. Young, PhD, is an internationally known expert on Internet addiction and online behavior. She serves as the director of the Center for Internet Addiction Recovery, founded in 1995, and travels nationally conducting seminars on the impact of the Internet. She is the author of *Caught in the Net* (1998), the first book to address Internet addiction, which has been translated into six languages; *Tangled in the Web* (1998); and her most recent, *Breaking Free of the Web: Catholics and Internet Addiction* (2009). She is a professor at St. Bonaventure University in St. Bonaventure, New York, United States, and has published over 40 articles on the impact of online abuse. Her work has been featured in media outlets such as the *New York Times*, *USA Today*, *Newsweek*, *Time*, CBS News, Fox News, *Good Morning America*, and ABC's *World News Tonight*. Dr. Young received the Psychology in the Media Award from the Pennsylvania Psychological Association, and in 2000 she received the Alumni Ambassador of the Year Award for Outstanding Achievement from Indiana University at Pennsylvania in Pennsylvania, United States.
