THE PRAEGER INTERNATIONAL COLLECTION ON ADDICTIONS

Volume 1, 2, 3 and 4

Angela Browne-Miller

Greenwood
PUBLISHING GROUP

How to go to your page

This eBook contains four volumes. Each volume has its own page numbering scheme, consisting of a volume number and a page number, separated by a colon.

For example, to go to page 5 of Volume 1, type vol1:5 in the “page #” box at the top of the screen and click “Go.” To go to page 5 of Volume 2, type vol2:5 in the "page #" box… and so forth.

Series Foreword

Tragically, most people across the globe have either struggled with a health- and relationship-damaging addiction or know someone who has. Addictions, broadly defined, have touched the lives of the majority of people in multiple cultures and locations. For centuries, numerous people have suffered with their addictions to alcohol and drugs as well as with other addictions, with often devastating outcomes. Sadly, important relationships, jobs and careers, and many lives have been lost due to the destructive power of addiction. These tragedies not only occur for those who suffer from addiction, but for their loved ones, coworkers, and community members, and for innocent victims who are perhaps in the wrong place at the wrong time when an addiction-related accident, crime, or violence occurs. The enormous cost of addiction in health care, traffic accidents, crime, violence, loss of workplace productivity, and broken families is too large to quantify. The global spread and success of organizations such as Alcoholics Anonymous (as well as related organizations such as Narcotics Anonymous, Sexoholics Anonymous, and Overeaters Anonymous) is a testament to the numerous people trying to recover from their addictions. Sadly, for every person seeking help for his addiction problem, there are likely to be many more people who never do. Clearly we need help to better understand, evaluate, treat, and cope with those who suffer from addictions.

In this remarkable four-volume set, *The Praeger International Collection on Addictions,* Angela Browne-Miller, PhD, DSW, MPH, has assembled an all-star and diverse team of leading experts from across the globe to provide a state-of-the-art understanding of the various facets of addiction. Each chapter

is written in a manner that is suitable for professionals working in the field as well as educated lay readers and those who either struggle with addictions or live or work with someone who does. What is especially remarkable about the four-volume set is its emphasis on addiction from around the globe, examining multicultural and international issues in addiction, as well as its coverage of so many multifaceted aspects of diverse addictions. For example, it certainly makes sense to cover fully addiction topics such as alcohol abuse and illegal drug use of, say, cocaine and heroin, yet chapters are also offered that examine addictions to caffeine, Internet pornography, work, television, intimate relationship abuse, and shopping. The chapters highlight biological, psychological, social, spiritual, and public health perspectives, with chapter authors who are psychologists, psychiatrists, other physicians, nurses, social workers, counselors, clergy, and other professionals. Dr. Browne-Miller is uniquely qualified to assemble this project as she is someone who has worked in the field of addiction for many years and has training in a unique blend of both the policy and the clinical sides of psychology, social work, education and public health.

The set is complete, state of the art, and highly informative and engaging. There is something for everyone interested in the field of addiction for professional or personal reasons. It is hoped that professionals and lay readers will greatly benefit from this important work and, in doing so, will find a way to improve the lives of those touched by addiction. It is my hope that both research and practice in the field of addiction will be greatly improved thanks to this set. The lives of those who either struggle with addiction or live with those who do will ultimately be improved thanks in part to this critical series. I am grateful to Dr. Browne-Miller and her assembled contributors for providing us all with such important and high-quality volumes that are now available to the public and professional communities. If only one life is saved or improved thanks to this set, it will be a great success in my view; yet I expect that many lives will ultimately be saved or greatly improved thanks to *The Praeger International Collection on Addictions*.

Preface

Angela Browne-Miller, PhD, DSW, MPH

Welcome to *The Praeger International Collection on Addictions,* addressing the insidious, pervasive, worldwide problem of human addiction. Addiction is clearly a global issue, touching every population, every nation, and every age group, people from all walks of life everywhere, directly or indirectly. Indeed, we are talking about an affliction of epic and epidemic proportions. We cannot look away. This is the health of the human species we are talking about.

The World Health Organization (WHO, 2008, p. 1) reports that "psychoactive substance use poses a significant threat to the health, social and economic fabric of families, communities and nations. The extent of worldwide psychoactive substance use is estimated at 2 billion alcohol users, 1.3 billion smokers and 185 million drug users" (p. 1). The WHO has estimated there to be at least 76.3 million persons with alcohol use disorders worldwide, and at least 15.3 million persons with drug use disorders worldwide. Alcohol use and abuse as well as the use and abuse of other psychoactive substances contributes to substantial individual and public health costs. Alcohol is but one substance playing a major role in this global addiction epidemic, but clearly there are many others, despite efforts to prevent new addictions and addicts, and to contain world drug markets (UN, 2008, p. 7).

For example, cocaine shares the stage with other abused drugs. Its prevalence is estimated to be up to 3 percent of the population in developing countries, with severe medical, psychological, social, and economic consequences including, but not limited to, the spread of infectious diseases (e.g., AIDS, hepatitis, and tuberculosis), plus crime, violence, and neonatal drug exposure.

Amphetamine-type stimulant (ATP) abuse is more widespread than cocaine abuse in at least 20 countries. Methamphetamine is presumed to lead in ATP addiction rates, with massive meth epidemics affecting several whole countries and entire regions of others. Social and public health costs of methamphetamine production and use via smoking, sniffing, inhaling, and injecting are staggering and growing in many regions. Additionally, there has been a global increase in the production, transportation, and use of opioids, especially heroin, with worldwide heroin production doubling or even tripling since the mid-1980s. Global estimates are that 13.5 million persons consume opioids, with 9.5 million of these being heroin users who face health risks including hepatitis, HIV, and death. And cocaine, meth, and heroin are just one piece of the picture.

The hotly debated drug cannabis—or the *Cannabis* family of drugs with the euphoric tetrahydrocannabinols, or THCs, including marijuana and hashish preparations—is said to be the most widely abused drug. Research is now suggesting the risk for acute health effects of long-term, chronic cannabis use, including potential impairment of cognitive development, learning, memory, recall, attention, and coordination. (Certainly the presence and extent of long-term effects of casual, of regular and of chronic use are as yet not entirely ascertained.) Both casual use of marijuana and medical use of forms of what is termed medical marijuana (e.g., dronabinol sold as Marinol, the cannabidiols, or CBDs) are subsets of all forms of cannabis use. There are legitimate therapeutic uses of this substance, and these uses make it all the more difficult to regulate marijuana drugs fairly and effectively.

We have here, and in the use of any psychoactive medication for therapeutic purposes, a gray area in which illicit and licit use overlap and can confuse many adult and youth consumers, researchers, and policy makers, among others. In the emergence (or reemergence in history, some will argue) of cannabis as medicine, we have a model for asking which, if any, abused substances may, and perhaps should, be repurposed for medicinal or treatment purposes, and how this is best done against the backdrop of the global addiction epidemic.

Regarding marijuana, we are confronted with the age-at-first-use issue, which suggests that early onset of regular cannabis use may affect not only the academic and social performance of children and teens, but also their future susceptibility to addictions. It was in the 1960s that the hotly debated label "gateway drug" was applied to marijuana, perhaps to scare off its use, and only in the decades since have we understood better what this might actually mean to us. It may not be that marijuana provides the training wheels for drug addiction, but rather that it may serve as an indicator of future use of the same or other drugs. Of course, today, with so many young people having access, and taking advantage of their access, to the whole range of psychoactive substances,

the question of which drug might be a gateway to which other drug dissolves into the fury of the countless addiction conundrums of our constantly changing times.

There is always a new, or rediscovery of an old, addiction on the horizon. There is also always a new (or rediscovered) psychoactive substance for exploratory, research, and perhaps even treatment purposes emerging (or re-emerging). Labeling all of these substances as addictive right out the gate may or may not serve science or even humanity itself. How can we be certain the approach we take will be a constructive one? With new legal (where licensed for development and experimentation) and illegal (where not being utilized under protection of law) so-called designer drugs emerging at a staggering rate, we must admit that we cannot know what is coming, nor whether the new compound will be addictive, or popular, or of medicinal value, or even accessible. We can only imagine what the brave new world of chemistry will continue to bring and whether any benefits can be made available without accompanying risks and detriments.

Moreover, the desire to explore and achieve various altered states of consciousness in religious, spiritual, ritual, and perhaps even treatment settings, is unfolding into debates about rights (Browne-Miller, 1989, pp. 258–260). When there is no demonstrated risk to self or others, we have to ask ourselves whether this right should be protected, especially in circumstances of traditional uses for religious purposes. Again, this dilemma arises against the backdrop of the global and runaway epidemic of substance addiction. How do we balance pressures from opposite directions (freedom protecting the right to use versus control to stop injury and costs of using), when these pressures are not balancing themselves?

Also against the backdrop of global addiction levels, is the massive level of addiction to legal drugs, many of which are heavily marketed to consumers. The legal drug tobacco is said to be the substance causing the most damage globally, with at least one-third of the global population smoking. While smoking rates may be dropping in some countries, the reverse is true globally. As just one of its effects, smoking accounts for some 90 percent of all lung cancer in men and 70 percent of all lung cancer in women. And yet tobacco use is overwhelmingly viewed as being "the single most avoidable cause of disease, disability and death" in the United States (CDC, 2008, p. 2).

And perhaps nothing here has touched so many lives as the regularly consumed, legal drug caffeine, perhaps because coffee drinking is considered so very normal and acceptable, even necessary, in everyday life. However, we must ask whether there is a level of caffeine use that is abuse—or perhaps self-abuse. Surely we do not want to throw caffeine use onto this list of substance abuses

and addictions. Still, a collection on addiction would not be complete without at least touching on this matter, and therefore we do address caffeine herein.

And then there are also the addictions to prescription drugs (such as Vicodin, Percocet, OxyContin, and Darvon), which we find increasing rapidly and already a worldwide phenomenon, with the most commonly abused prescription drugs being opiates. The U.S. National Institute of Mental Health characterizes prescription drug addiction as the second most common illegal use of drugs in the United States, second only to marijuana.

We must also note that unusual, virtually invisible psychoactive substances are working their way into our everyday lives. Household and workplace products contain many volatile substances, exposure to which can be not only damaging, but also intoxicating, and perhaps addicting. Although this domain of substance use and abuse is not specifically addressed herein, we must acknowledge the severe and perhaps largely unmeasured effects of this domain of even routine, legal substance use as well as unintentional and intentional abuse.

So as not to exclude nonsubstance addictions in this overview of addiction today, the fourth volume in this collection on addiction reminds us that work, television, shopping, food (with its particularly difficult-to-call-addiction nature), intimate partner relationship, gambling, Internet, and even pornography addictions make their marks in our lives, either indirectly or directly. These behavioral, nondrug addictions, which occur alone and co-occur with each other, also do co-occur with substance uses, abuses, and addictions. Every human being is in some way affected by the prevalence of behavioral addictions, either directly or indirectly. The study of behavioral addictions teaches us a great deal about addiction itself.

All this suggests the picture of an addiction-prone and largely chemically dependent human species. And this is just the tip of the iceberg. With this truly incomplete laundry list of human fallibilities—or better stated, perhaps, human *vulnerabilities*—this four-volume collection on addiction is truly that: a collection of perspectives, approaches, and findings. Each chapter is a snapshot of the work and thinking taking place in many fields of addiction. Contributors to this collection work with addiction on the various social, philosophical, psychological, spiritual, policy, political, economic, biological, and even cellular levels, all places where this thing we call "addiction" lives. Certainly this collection would have to comprise hundreds of volumes, rather than the four that it does, to address addiction in all its iterations.

Here we give voice to a diverse cross section of perspectives on addiction. This is in no way an exhaustive cross section (of either perspectives or addictions); rather, this collection suggests the diversity of perspectives, theories, practices, and types of addiction in the field—or better stated, *fields*—of addiction. The four volumes of this collection represent the voices of those who have

graciously and even bravely stepped forward from their numerous countries and arenas of work to contribute their ideas, research, and experiences. Certainly there are many others out there, many other aspects of addiction, and many other drugs and objects of addiction not addressed in these volumes.

This work is divided into four volumes, with the first three addressing addictions to substances and the fourth addressing behaviors that show characteristics of addiction. Volume 1, *Faces of Addiction, Then and Now,* offers a sampling of the depth and breadth of addiction today and in the past; volume 2, *Psychobiological Profiles,* surveys some of the interlinked psychological and biological aspects of addiction; volume 3, *Characteristics and Treatment Perspectives,* samples the range of addiction treatment perspectives and approaches; and volume 4, *Behavioral Addictions from Concept to Compulsion,* gives the reader a glimpse of behavioral addictions other than substance addictions.

Readers will observe that the content of these volumes is indeed diverse and in no way represents any one view or theory of addiction. There are many other voices out there who must also be heard, and only in the interest of time and space are we stopping here, at these volumes. The content of these volumes in no way expresses the opinion of this editor, nor of this publisher, regarding what is right, best proven, or even most en vogue in the addiction world; rather, this *International Collection on Addictions* seeks a display of, a sampling of, the diversity of effort to quell the detrimental effects of addiction on individuals, families, communities, societies, economies, and international relations; on ecologies; and in fact, on the human population of planet Earth.

Introduction to Volume 1: The Many Faces of Addiction

Angela Browne-Miller, PhD, DSW, MPH

This is *Faces of Addiction, Then and Now,* volume 1 of *The Praeger International Collection on Addictions*. Here we bring together a collective understanding of addiction as we know it today. Studying this worldwide epidemic of addiction in all its forms, we see a troubling tide sweeping the planet and hope to turn it back.

We begin part 1 of this volume, "Perspectives," with the public health perspective on addiction as set forth by Elaine R. Feeney, PhD, RN, of the Foundation for Addictions Nursing in Baltimore, Maryland, United States, in chapter 1, "Addiction as a Public Health Issue." Feeney carefully establishes this public health perspective on addiction, one which we cannot deny and cannot afford to ignore. After all, your health is my health, and vice versa. Population and public health and individual health are inextricably linked. While perhaps dauntingly intricate to measure, and seemingly subtle, almost invisible, this linkage is profound. Feeney urges that we press for a strong public health approach to addiction: "By conceptualizing the substance abuse/dependence problem in this country as a public health issue, we might be able to identify possible solutions from the public health perspective as well. Clearly the individual focus has failed, and we cannot afford to continue to allocate resources to initiatives that are unsuccessful. It is my belief that where the problem can be viewed in a population context, the solutions can also be found."

We then turn to chapter 2, "Cross-Cultural Issues in Substance Addiction Research Including Black Americans and Latinos," contributed by Julia F. Hastings, PhD, MSW, from the School of Social Welfare, University of

California Berkeley, in Berkeley, California, United States. Hastings points out that social science researchers are under great pressure to address racial and cultural diversity; however, "culturally informed" research is not easily accomplished. Addressing outcomes according to race or ethnicity does not ensure cultural understanding of addiction. It remains to be seen whether social science research, and research on addiction, will fully recognize and define the differences between race and culture. Hastings notes that, while it is often said that "African Americans, Caribbean Blacks, and Latinos suffer more adverse health conditions from substance addictions than the White population," we must ask what this statement is actually telling us. Hastings comments, "Though identifying many health conditions and their racial differences is important, many other factors associated with substance addiction can impinge on higher substance addiction problems. True, other factors include poverty status, education, unemployment, families in crisis, psychiatric problems, little or no insurance coverage, and public program assistance limitations. Yet the one factor that many researchers and government documents focus on is race and ethnicity. Identifying with a group is important to all people. A group defines who we are and how we envision our place in the world. Above all, we all belong to *many* groups." In working to analyze and treat addiction, we cannot afford to overlook the limitations of a focus on race and ethnicity to the exclusion of an effective operationalization of *culture* itself—its norms, beliefs, and distributions of power and roles.

Next, we look at "Race, Ethnicity, and Early U.S. Drug Policy" in chapter 3, by Sean R. Hogan, PhD, MSW, of the Department of Social Work, California State University Fullerton, in Fullerton, California, United States. Perceptions and definitions of addictions have evolved over time, with dramatic shifts in theories and in biases occurring in the twentieth century (and even now in the early twenty-first century). Hogan provides important examples, one being that opium use was once associated with Chinese immigrants and that this prejudice was actually associated with the first antidrug legislation in the late 1800s. Long after, Hogan writes, "a significant shift in public perception and, consequently, the strategies designed to address substance use occurred when American society began to distinguish 'recreational,' or nonmedical, drug use from that of drug use initiated and prescribed by physicians." Here we see that public perception and public policy regarding substance use can be fueled by prejudice and bias, a tendency which may still to this day be having lasting effects on the formation of drug policy. This report (albeit perhaps inadvertently) brings to the table additional issues and questions: once recreational use is set apart from prescribed use, we are forced to decide whether any recreational use is acceptable, and, if so, what use by whom, and in what amount? Boundaries between categories of use are particularly difficult to establish and maintain. We are also compelled

to note that legal recreational use is perhaps immune to the moral imperative. And here we have it, the slippery matter of moral imperative—what forms this imperative always being the elephant in the room, the presence we hardly see.

In chapter 4, Martha Romero Mendoza, PhD, of the National Institute of Psychiatry, in Mexico D.F., Mexico, contributes her insights into "Gender Inequalities and Inequities among Women with Substance Abuse Problems." Romero Mendoza explains that "health inequalities" are avoidable and unnecessary. Yet, with the majority of addiction research being based on male experience, and based on a gendered society, we are in need of balancing perceptions and understandings of gender differences and similarities. We must be cautious as to the effects of our research paradigms and consequent findings, for, in Romero Mendoza's words, "social inequality and the bias that arises from it at the moment of the research are perpetuated through social hierarchy preservation, that is, power relationships." Here we have the added dimension of gender—the very necessary dimension of addiction research and treatment.

Following this brief look at matters of diversity, we step back in chapter 5 to look at "Ethical Theory and Addiction," by Ann N. Dapice, PhD, of T. K. Wolf Inc., a Native American–focused addiction treatment program in Tulsa, Oklahoma, United States. Dapice emphasizes that the higher levels of moral reasoning must be developed in both addiction treatment professionals and persons who are addicted once into their recoveries. (I emphasize here that Dapice includes professionals.). Dapice also notes that moral development is "hijacked" by addictive substances and behaviors, something we must pay closer attention to in our work. Connecting a few dots here, we might add that if moral development is impaired by addictive substance use, then how responsible is the user from a moral standpoint? Can sound moral judgments be made by an impaired moral function?

Chapter 6, "The Religious and Theological Roots of Alcoholics Anonymous," by Rev. Linda Mercadante, PhD, of the Methodist Theological School in Delaware, Ohio, United States, delves deeply into the theological roots of the Alcoholics Anonymous (AA) 12-Step Recovery Program. Mercadante unearths, via a colorful historical and analytical review, a key dichotomy in the disease versus sin or moral failing views of addiction to alcohol. Mercadante places the 12-Step AA approach in the historical context of the Christian evangelistic Oxford Group, which hit its peak in the 1920s and 1930s; AA founder Bill Wilson was once a member. These roots continue to inform the 12-Step method of addiction recovery, including the focus on sin and conversion in recovery from addiction. Clearly, recognizing what informs any approach to addiction, seeing the evolution of any philosophy of addiction and its recovery, is essential as we move forward in working to respond to addiction.

Casting another light on this matter of addiction, part 1 of this volume concludes through chapter 7 with a report by Jemel P. Aguilar, PhD, MSW, from the School of Social Work, University of Texas at Austin, in Austin, Texas, United States, titled "Adolescent Drug Sellers and Distributors." Aguilar urges us to be aware that, in his words, "with the growing numbers of youth entering into the juvenile justice system because of drug-related crimes, it is important that researchers and practitioners have a better understanding of the dynamics of youth drug selling and distribution so that more effective interventions can be developed to prevent youth from becoming active drug sellers and distributors and/or stem youth involvement once they enter into this economy." Only this awareness can open our eyes to truly understanding what is going on, and our arms to helping to do something about it.

Part 2, "Dimensions," begins with a look at "Historical Aspects of Alcohol Use in India: Role of Culture and Gender," chapter 8, contributed by Meera Vaswani, PhD, Atul Ambekar, MD, and Ramandeep Pattanayak, MD, all from the National Drug Dependence Treatment Centre, Department of Psychiatry, All India Institute of Medical Sciences, in New Delhi, Delhi, India. This chapter looks at the historical and cultural context of alcohol use in India, reaching as far back as 3300 B.C. and building through the eras into present-day alcohol use issues. The authors of this chapter note that alcohol use among women remains understudied in Indian literature; cultural attitudes toward women's alcohol use may be preventing them from reporting alcohol use and abuse. Again, the importance of gender-sensitive addiction research is highlighted.

We then, in chapter 9, turn to "Alcohol and Drug Abuse in Malaysia," contributed by See Ching Mey, PhD, MEd, from the School of Educational Studies, Universiti Sains Malaysia in Pulau Pinang, Malaysia, and Cecilia A. Essau, PhD, MA, HBA, of the School of Human and Life Sciences, Roehampton University, Whitelands College, in London, England. Mey and Essau report that the data they have reviewed indicate that Malaysia is the 10th largest consumer of alcohol in the world. Marketing approaches hard sell alcohol to Malaysians via several means not allowed in many Western nations, including particularly heavy forms of ethnic targeting loaded with health claims, such as the 1980 Guinness Stout campaign including the slogan "Guinness Stout is good for you." Additionally, Malaysia has identified drug use and trafficking as a security problem, one which is increasing, with an overwhelming majority of all drug addicts in Malaysia being in the 20- to 39-year-old age group.

Next, in chapter 10, we look at "Alcohol Use and Binge Drinking in Cyprus," by Xenia Anastassiou-Hadjicharalambous, PhD, of the Department of Psychology, University of Nicosia, in Nicosia, Cyprus, and Cecilia A. Essau, PhD, MA, HBA, and George Georgiou, PhD, both at the School of Human and Life Sciences, Roehampton University, London. Archaeological evidence

suggests that the grapevine has been cultivated and wine has been made in Cyprus for at least 6,000 years. The authors of this chapter report that their ongoing study indicates that today, about one-third of young adults in Cyprus binge drink on a regular basis, with a wide range of social and personal problems attending this behavior. Directions for future research are suggested.

From here, Anna Bokszczanin, PhD, from the University of Opole (Uniwersytet Opolski), in Opole, Poland, and Cecilia A. Essau, PhD, MA, HBA, and Jean O'Callaghan, PhD, from the School of Human and Life Sciences at Roehampton University, London, share with us "Alcohol Use and Abuse in Poland" as chapter 11. In recent decades, alcohol use and abuse have increased in Poland, parallel to the privatization of the market there, after years of markedly low alcohol consumption. Directions for treatment and prevention are reviewed and hope is offered. Questions come into focus—troubling questions. Can we say that the privatization of the market is largely responsible for what has happened in Poland? If yes, is this effect consistent across cultures around the world? If not, what other factors were present and are relevant? For example, do specific characteristics of the regulation of alcohol advertising and distribution make a difference?

Chapter 12, "Alcohol Consumption and Binge Drinking in the United Kingdom," is contributed by Cecilia A. Essau, PhD, MA, HBA, Changiz Mohiyeddini, MD, PhD, and Diane Bray, PhD, of the School of Human and Life Sciences at Roehampton University, London. As in many societies, alcohol use is found to be an acceptable part of social interaction in the United Kingdom. Of great concern is the high cost of prevalent binge drinking in the United Kingdom. The authors of this chapter note that there is a need to balance policies that promote public health with those that promote economic interests. Is this a tension that cannot be worked through to support both sides of this dilemma?

"Alcohol Use and Abuse in Germany," by Changiz Mohiyeddini, MD, PhD, Cecilia A. Essau, PhD, MA, HBA, and Regina Pauli, BSc, PhD, all of the School of Human and Life Sciences at Roehampton University, London, is chapter 13. Here we read more about modern-day alcohol use in developed countries, seeing the great cost of this use and abuse, and at the same time the great investment the alcoholic beverage industry has in the consumption of alcohol. For example, in Germany, where the legal age for alcohol consumption is 16 (typical of many European and other nations, and unlike the United States' general legal age of 21), television advertising aimed at young people utilizes bright colors, youthful music, and high action to attract young people and new consumers of alcohol. This is taking place even though alcohol advertising targeting young people in the European Union (EU) is controlled by means of rules *suggested* in the European Council Recommendation that was adopted on June 5, 2001, by the EU Health Ministry.

We conclude part 2 with chapter 14, "From British India to the Taliban: Lessons from the History of the Heroin Market," by Kathryn Meyer, PhD, from Wright State University's Department of History in Dayton, Ohio, United States. Meyer reports that the plan of Pino Arlacchi (who became head of the United Nations International Drug Control Program in 1997) was to eradicate narcotics worldwide. Arlacchi traveled to Afghanistan as part of a global plan to replace drug crops with alternative industries, yet poppy production continued in Taliban-controlled areas. Meyer weaves the story of a complex political and economic scenario surrounding heroin. Never is the problem of addiction free of politics and economics.

Part 3, "Aspects," includes a collection of chapters sampling aspects of addiction and some of its many faces, beginning with chapter 15, "Youth Tobacco Use: Its Health Effects, Trends in Smoking Rates, and Reasons Why Kids Use Tobacco," by Clete Snell, PhD, at the School of Juvenile Justice and Psychology, Prairie View A&M University in College Station, Texas, United States. Snell reports that the life stage of adolescents is a strong predictor of cigarette and tobacco use, with the transition between elementary and high school being the period of greatest risk for the onset of youth tobacco use. What may drive youth tobacco use is the young person's risk-taking behavior, desire for stress reduction, desire to look older, longing to relieve boredom, and peer pressure.

Next we hear from Va Nee L. Van Vleck, PhD, of the Department of Economics in the College of Social Sciences at California State University Fresno, in Fresno, California, United States, and Thomas K. Greenfield, PhD, at the Alcohol Research Group, in Emeryville California, United States, who report on their study in chapter 16, "Brewing Trouble: Some Employment Implications of Regular Malt Liquor Beer Consumption." Van Vleck and Greenfield examine the association between regular use of malt liquor and poor employment conditions, including unemployment. Van Vleck and Greenfield also note that patterns of alcohol dependence are similar to those of chronic diseases, the latter of which they remind us are "value-neutral." The so-called blame for the physical illness is far less than the blame for the addiction, although addiction can also be a physical illness and surely is a physical—where *physical* includes the brain and other parts of the body—illness.

We then hear, in chapter 17, from David T. Courtwright, PhD, from the University of North Florida, in Jacksonville, Florida, United States, in his chapter titled "The Roads to H: The Emergence of the American Heroin Complex, 1898–1956." Here Courtwright reviews the history of heroin in the United States as a model of the impact of novel psychoactive drugs. A new drug promises a range of therapeutic usages and then is debated per these claims. Eventually, the drug slips out of control and into the hands of the general

population. And then, predictably, government must intervene to control the drug. This is the way heroin emerged into modern times, as a product of Bayer Pharmaceutical Company in the late 1800s. In the decades that followed, a significant underground and underworld interest in heroin developed. By the 1920s, the U.S. federal government had outlawed the manufacture of heroin, listing it as the first official Schedule I drug, meaning that it was totally prohibited, except for research purposes. Having "escaped the realm of healing for that of self-indulgence," heroin has made its way through time and into the veins of far too many, leading the way for other novel drugs.

A consequent, or perhaps parallel, history emerges in the history of the treatment drug for heroin addiction: methadone. Herbert D. Kleber, MD, of the Department of Psychiatry and the Division on Substance Abuse, Columbia University, in New York, New York, United States, reviews "Methadone: The Drug, the Treatment, the Controversy" in chapter 18. Weaving the history and politics of methadone, we see that some things work perfectly but not at all well. Here methadone maintenance as the antidote to heroin addiction is both lauded and revealed for its shortcomings and attending controversies. And of course, here the administration of one drug is done to curb response to another. Is one addiction purposefully replacing another?

Next we consider another addictive drug, methamphetamine, as no sampling of work on addiction can overlook this drug in our times. Chapter 19 considers this drug in "Prevalence of Use and Manufacture of Methamphetamine in the United States: Is the Sky Falling, or Is It Not Really a Problem?" by Herbert C. Covey, PhD, of the Adams County Social Services Department and the College of Continuing Education, University of Colorado at Boulder, Boulder, Colorado, United States. Covey reminds us that unlike other illicit drugs, meth does not have to be imported into the country and can actually be homemade. We have all heard of the meth lab, and this is where it all happens.

Mary F. Holley, MD, of the national organization Mothers against Methamphetamine in Arab, Alabama, and the Alabama State Attorney General's Methamphetamine Task Force, Alabama, United States, adds to this discussion of methamphetamine (also known as "crystal meth" and "ice") use, offering chapter 20, "Interaction between Methamphetamine Use and HIV Infection." Holley points out that methamphetamine use is associated with higher rates of sexually transmitted diseases (STDs), specifically the most deadly STD, HIV. Where we go from here, once we see what meth can do and is doing to many cultures of the world, is perhaps the question of the hour.

The 20 fascinating and illuminating chapters following this introduction open *The Praeger International Collection on Addictions* and compose volume 1, *Faces of Addiction, Then and Now*. These chapters offer a striking and disturbing cross section of addiction today and set the stage for the volumes that follow.

Of great concern is the degree to which human addiction—a condition, an affliction, a malady—is a read on the state of the species. There is hope, however. We are responding as a species, around the globe, on all levels, in all professions, from all religions, world views, from all philosophical standpoints, from all walks of life. We have called ourselves to action and have heard the call. We know that no single theory, policy, philosophy, or religious approach alone can solve this problem, let alone define it.

To this end, the International Substance Abuse and Addiction Coalition (ISAAC) authored its October 2006 *Red Sea Declaration*, which ISAAC has been generous enough to share within this publication. We include this declaration here, in full recognition that there are other statements by numerous other organizations that at some future point we may also have the opportunity to share.

RED SEA DECLARATION

International Substance Abuse & Addiction Coalition (ISAAC)—October 2006

Introduction

The scourge of addiction to alcohol and other drugs is one of the most serious and urgent issues facing humanity today. Tens of millions of men, women and children are either directly or indirectly affected by addiction. The health, social, criminal justice and economic costs of addiction are colossal and well documented. Addiction causes millions of deaths worldwide each year, destroying human potential for millions of others. Drug misuse is one of the main driving factors behind the HIV/AIDS pandemic.

ISAAC's International Network

We represent more than 500 service providers, such as rehabilitation centres, prevention programmes, training providers and street agencies in over 55 countries around the world. Our programmes have been providing help and support to millions of drug addicts and their families over many decades. We have substantial experience in all fields of addiction.

Call to Governments

We call upon the Governments of the world to:

1. **Urgently recognise and address the physical, emotional, social and spiritual roots of addiction.** As faith-based/Christian organisations we recognise the significance of spirituality, in addiction prevention and rehabilitation. This has been demonstrated by scientific studies and we encourage governments to acknowledge this.
2. **Urgently develop, implement and support policies aimed at preventing drug misuse, recognising that demand reduction is more effective than supply reduction.** Communities have the right to be protected from drugs, including the right to information concerning drugs. Prevention goes hand-in-hand with rehabilitation and indeed prevention without rehabilitation is ineffective. Education, life skills development, participatory activities and care and support for young people with the aim of encouraging a drug-free lifestyle are crucial. Criminal justice systems can support, but will never replace, such policies.
3. **Recognise that drug misuse adversely affects all members of the community and vulnerable members, including women and children.** We stress the need for increased access to treatment for women as well as adequate care for their children and to stop all forms of violence and abuse in this context. We also confirm that key populations in the context of drug misuse, including sex workers and street children, should have specially

designated outreach programmes. We emphasise the importance of treating them with compassion and dignity.

4. **Resist all attempts to weaken, or even abolish, the United Nations Conventions on Drugs, which aim to control and prevent drug misuse.** Addicts have the right to rehabilitation and to be treated as patients. However, legalising currently illicit drugs will cause major damage to health, communities and society in general. Legalisation will greatly increase the burden to public health.
5. **Ensure that harm-reduction is never understood as merely reducing the harm to society.** These interventions should put the client at the centre of the care and support systems. It should always offer abstinence as the desirable and realistic option, and provide all means to achieve this for those who choose this option.

Conclusion

- Misuse of alcohol and other drugs is already of epidemic scale in many parts of the world. If we fail to fight the scourge of addiction and the drug trade with all available means, drug misuse will soon be out of control worldwide and the fight against drugs lost. Lack of radical action now will result in devastation for generations to come.
- In our programmes we have seen hope restored, freedom found, and transformation in the lives of addicts, their families and communities worldwide. We want to share this hope with you. Together, we can create societies able to meet the challenges of drug abuse.

Source: This ISAAC Red Sea Declaration is included here with the permission of David Partington, General Secretary, ISAAC. The ISAAC Red Sea Declaration was formulated and unanimously agreed by 160 delegates from over 30 countries at the ISAAC Congress in Egypt, in 2006.

Chapter **1**

Addiction as a Public Health Issue

Elaine R. Feeney, PhD, RN

Addictions and public health: on the surface, they seem only tangentially and linearly related. Certainly if substance dependence is prevalent, one can anticipate consequences for public health such as HIV/AIDS, tuberculosis, sexually transmitted diseases (STDs), other infectious diseases, and so on. However, a much closer parallel and a much stronger relationship exists between addictions and public health. In fact, a case can be made that substance dependence is primarily a public health issue.

For the purposes of this discussion, addictions will be referred to by the *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition (American Psychiatric Association [APA], 2000), category of *substance dependence*, the continued use of substances of abuse (alcohol, tobacco, and other drugs) despite negative physical, mental, or social consequences of such use, accompanied by signs and symptoms of tolerance (progressive increase of the amount of the substance needed to achieve the desired effect) or withdrawal (symptoms of withdrawal are substance-specific). In standard conceptualizations of substance dependence, the individual is the client/patient, and most of the interventions are directed toward that individual. Adjunctive treatment may also be given to the family, usually in response to the disruption caused by the individual client's substance dependence and other behavior. Public health chooses to look at disease state, treatment, and prevention in another way.

WHAT IS PUBLIC HEALTH?

According to the American Public Health Association (2008),

> Public Health is the practice of preventing disease and promoting good health within groups of people, from small communities to entire countries. Public Health professionals rely on policy and research strategies to understand issues such as infant mortality and chronic disease in particular populations. (para. 5)

Public health is a science dedicated to the study and treatment of populations. In public health, interventions are directed toward groups such as neighborhoods, communities, and populations. Therefore the major difference between public health and standard health/medical care is that in public health, the individual client/patient is not the issue of concern. Despite the seeming focus on the individual, as can be seen in public health clinics such as infant immunization clinics, tuberculosis clinics, HIV/AIDS clinics, and so on, it is the general public that is the beneficiary. In these instances, the public good is achieved by ministering to the individual. In immunizing children, or treating people with tuberculosis or HIV/AIDS, the aim is to prevent the spread of the disease and improve the health of the entire community. Therefore public health professionals view the community, not the individual, as the client.

WHAT DOES PUBLIC HEALTH DO?

The activities of public health are best described by the 10 Essential Services of Public Health:

1. Monitor health status to identify community health problems
2. Diagnose and investigate health problems and health hazards in the community
3. Inform, educate, and empower people about health issues
4. Mobilize community partnerships to identify and solve health problems
5. Develop policies and plans that support individual and community health efforts
6. Enforce laws and regulations that protect health and ensure safety
7. Link people to needed personal health services and assure the provision of health care when otherwise unavailable
8. Assure a competent public health and personal health care workforce
9. Evaluate effectiveness, accessibility, and quality of personal and population-based health services
10. Research for new insights and innovative solutions to health problems. (Centers for Disease Control and Prevention [CDC], 2008b, para. 2)

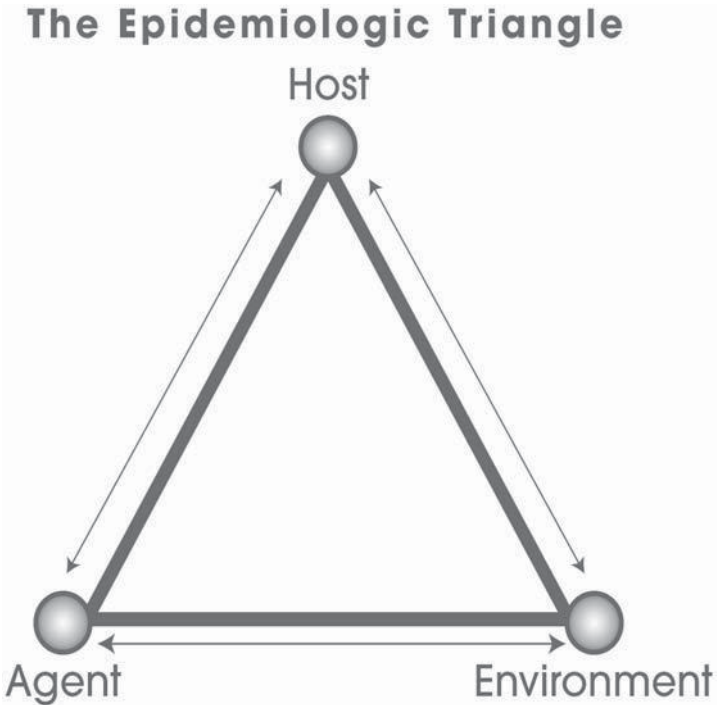

FIGURE 1.1 The Public Health Model prevention diagram. (From Centers for Disease Control and Prevention [2008a].)

As in all of health care, it seems those in need of support, empowerment, and education are those populations that are least informed and least able to advocate for themselves, and those groups that have been underserved by the traditional health care system. These populations are traditionally made up of minority racial and ethnic groups such as Asians, African Americans, Hispanics, and Native Americans. Because of economic and social disadvantages, as a group, these minorities have poorer health status, experience more difficult access to care, comprise a larger proportion of the uninsured, and receive poorer quality of care (Agency for Healthcare Research and Quality, 2005; Institute of Medicine, 2002). These are just the groups targeted by public health initiatives and policies.

THE PUBLIC HEALTH MODEL

The Public Health Model consists of three elements. In this model, all three elements must be present and interacting for disease to occur. The elements of

the Public Health Model (also known as the *epidemiological triangle*; see Figure 1.1) are the host, the agent, and the environment. The original purpose of the epidemiological triangle was to explain the necessary factors for infectious diseases to occur. However, it can also be used to understand noninfectious diseases, including substance dependence.

The Agent

This is the element that causes the disease and is frequently called the *causative factor* or *causative agent*. In the case of substance dependence, the agent refers to the substance (alcohol, cocaine, heroin, etc.). In substance use disorders, some agents facilitate dependence more quickly than others. For example, many people who use nicotine, crack cocaine, or methamphetamine quickly become addicted. Alcohol, on the other hand, is not, in itself, universally addicting. Only 10 percent of the adults in the United States who drink alcohol demonstrate signs of alcohol dependence; 90 percent of the adults in the United States who drink alcohol have no difficulty.

The Host

The host is the individual harboring the disease; in the case of substance dependence, he is the alcoholic or addict. Factors impacting the host include age, sex, gender, marital status, occupation, place in the family, race, genetic predisposition, age of first exposure to substances of abuse, health behaviors (such as sedentary lifestyle), personality factors (which influence the course of illness and tendency to seek care), social status, and educational status.

The Environment

The environment comprises those external factors that cause or allow disease to occur. Environmental factors have been studied more than host or agent factors and are frequently the targets of public health interventions. They include socioeconomic status, educational environment, economic and political organization, social values, customs, receptivity to new ideas, degree of social integration of social classes (mobility, isolation, alienation), natural disasters, presence of substances of abuse in proximity to the individual, ease of obtaining substances, prevalence of substance abuse in the community, law enforcement, and so on.

The host, agent, and environment must have certain factors present to allow for the interaction of the elements and the development of a pathological state.

HOW DO PUBLIC HEALTH PROFESSIONALS DECIDE WHAT NEEDS TO BE DONE?

Since it is the purpose of public health to intervene at the population level, these interventions are conceptualized differently from standard interventions with the individual client/patient. The choice of which of these interventions is conducted depends on the level of risk or impairment of the group in question. The types of interventions are categorized as levels of prevention.

Levels of Prevention

There are three levels of prevention: primary, secondary, and tertiary. These categories are separate and distinct, addressing separate and distinct health concerns with specific interventions.

Primary Prevention

Primary prevention is the lowest, most basic level of prevention in public health. Its aim is the total prevention of disease or health problems in a population that is free from a disease, but at risk for it. This is accomplished by making the individuals or groups less susceptible to disease, or reducing exposure to the disease through health promotion and protective measures. This conceptualization can be used for any disease. For example, clients who do not have measles can benefit from the primary prevention intervention of measles vaccine administration; clients without osteoporosis can benefit from the primary prevention measure of taking calcium and vitamin D supplements and engaging in weight-bearing exercise. Hand washing and prohibition of sharing eating utensils can prevent spread of the influenza virus.

Clients who are not substance-dependent, but are at risk, can benefit from a number of primary prevention measures, including alcohol, tobacco, and other drug education; provision of appropriate health care; job training; counseling; violence prevention; recreational facilities; opportunities to explore cultural arts; adequate child care; after-school/summer programs; community/economic development; employment assistance/job training; family support; mentoring; school-based initiatives; and youth development for disadvantaged children, youth, and families.

Secondary Prevention

This middle level of prevention involves the early detection and prompt treatment of a disease or health problem. The intervention is designed to cure, slow the progression, or prevent serious complications of the disease or

health problem. When infectious diseases are addressed, secondary prevention activities reverse communicability. Examples of secondary prevention include administration of antibiotics for communicable diseases, wearing of orthotics for plantar faciitis, aspirin and exercise for arthritis, ingesting electrolyte drinks for severe diarrhea, and so on. In terms of substance dependence, the choice between secondary and tertiary prevention activities might be a tough call. In some cases, it may be a matter of the difference between substance abuse and dependence (see APA, 2000). Before substance abuse becomes full-blown dependence, it may be possible to disrupt the pattern of substance use to a degree that prevents progression to dependence through educational sessions addressing potential substance dependence and a technique called *screening brief intervention, referral, and treatment* (SBIRT; Babor, Higgins-Biddle, Saunders, & Monteiro, 2001; Fleming & Manwell, 1999; Substance Abuse and Mental Health Services Administration [SAMHSA], 2008c).

Tertiary Prevention

Tertiary prevention refers to activities designed to limit disability and promote rehabilitation by maximizing use of person's residual capacity. This category refers to the most sophisticated, labor-intensive, and individualized interventions: cardiac surgery and rehabilitation for clients with heart disease; chemotherapy for cancer patients; physical medicine and rehabilitation for stroke victims; and drug detoxification, rehabilitation, and use of medication deterrents to alcohol or drug use, and so on, for substance-dependent clients.

Formulation of Policy

Public health professionals have a strong responsibility to help formulate policy that guides primary, secondary, and tertiary prevention. The policies developed and implemented dictate everything from the administration of infant vaccinations to the treatment of drug-resistant tuberculosis and HIV/AIDS. Policies governing substances of abuse fall under this rubric as well. Policy formation usually requires collaborative efforts on the part of a number of community advocacy groups. Public health frequently partners with other groups (Mothers against Drinking and Driving, Gay and Lesbian Alliance, etc.) to achieve common goals.

An example of collaborative efforts working to formulate public health policy is occurring in the state of Maryland. The state legislature has voted to tax fruity alcohol drinks (called *alcopops*) in the same manner in which beer is taxed, as opposed to taxing them as hard liquor. In addition to the tax issue, the controversy seems to center on where the product will be sold.

If the alcopops are taxed like beer, they can be sold in convenience stores, rather than having their sale restricted to liquor stores (like hard liquor). If sold in convenience stores, the alcopops would be more available to underage drinkers, those who prefer the taste of sweet drinks to begin with (Coalition on Alcopops & Youth, 2006). A coalition of advocates consisting of the American Public Health Association, the Maryland Association of County Health Officials, representatives of Advocates for Highway and Auto Safety, and the Maryland Emergency Nurses Association brought pressure on the governor to delay signing the bill (Olson, 2008). While it appeared for a time that the governor would veto the bill, other pressures were brought to bear, resulting in the passage of the bill and allowing alcopops to be taxed (and sold) in a manner similar to beer.

Advocates working in other states have had better success: Utah, Maine, and, most recently, California have passed legislation that will ensure that alcopops are taxed in the same manner as other distilled spirits, thus making them less available to potential underage drinkers (Marin Institute, 2008).

Another example of collaborative efforts working to formulate public health policy is noted in a recent press release from SAMHSA (2008d). It is reported that over 15 percent of people operating a motor vehicle did so under the influence of alcohol at least once in the past year. The report indicated that this prevalence differs from state to state, with the lowest (9.5%) in Utah and the highest (26.4%) in Wisconsin. North Dakota and Minnesota also reported that close to 25 percent of drivers age 18 and up were impaired while driving at least once in the past year. This information may assist public health administrators and legislators to focus primary prevention of impaired driving initiatives on the geographical areas where the problem is most prevalent.

An Exemplar of a Challenge to Public Health Initiatives and Policies: Methamphetamine

The manufacture and use of methamphetamine is a public health problem that challenges every aspect of public health science. In addition to the elements of the epidemiological triangle interacting to cause disease when meth is the agent, the user is the host, and the environment is conducive to such use, the meth has profound detrimental effects on the social, physical, and mental health of the environment in which it is manufactured and used. This threatens the health of the user and others in proximity to the site of the manufacture. Because of the nature of the agent, communities are in very real danger of experiencing serious social and environmental harm.

Meth, also known as crank, crystal, glass, ice, rock, and by other names, is a strong, long-lasting stimulant that is administered by injection, smoking, snorting, or oral preparations. Although the effect of meth lasts longer than that of cocaine, the crash that follows use is as or more uncomfortable for the user. Therefore more meth is ingested, leading to rapid development of tolerance and addiction. The impact of meth on the body is documented in the literature (for thorough treatment, see Society for Public Health Education, 2002).

The aggregate focus of public health is challenged by the use and manufacture of methamphetamine. Because methamphetamine has been relatively easy to manufacture, many small labs have been found in the homes of the users and sellers of this substance. Aside from the detrimental impact on the user, there is an even more serious impact that the manufacturing process has on the environment.

Some of the caustic chemicals required to manufacture meth include pool acid/muratic acid, lye, acetone, brake fluid, brake cleaner, iodine crystals, lithium metal/lithium batteries, lighter fluid, drain cleaners (e.g., Drano or Liquid Fire), cold medicine containing pseudoephedrine or ephedrine, ethyl ether (in engine starting fluid), anhydrous ammonia (stored in propane tanks or coolers), sodium metal, and red phosphorous. When authorities find a meth lab, they often find children who have been neglected and abused. These children have also been exposed to meth, often have detectable meth levels in their blood, and have been exposed to the chemicals required for the drug's manufacture and the toxic substances produced during the manufacture of the drug. In addition, a meth laboratory generates five to six pounds of hazardous waste for each pound of meth produced. Since some so-called superlabs are capable of producing 10 pounds of meth during a single manufacturing cycle (National Drug Intelligence Center [NDIC], 2006), 50 to 60 pounds of hazardous waste are generated as well. Because those who manufacture meth are usually not aware of or concerned with the hazardous nature of the by-products, they frequently discard the toxic substances into the public sewer systems, streams, rivers, backyards, or public places. In addition, the hazardous by-products are frequently released into the immediate environment by the process of manufacture, with fumes permeating furnishings, walls, carpeting, floors, and so forth. Decontamination of the environment is a costly, lengthy, and complicated procedure that may or may not be effective in returning the location of the lab to a safe, inhabitable environment (Illinois Department of Public Health, 2008). Therefore exposure to caustic and toxic chemicals becomes a threat to those living in the home where the substance is made; those entering the home (such as guests, first responders, firefighters, etc.); the environment around the site of manufacture; and the areas in proximity to polluted ground, water, and air.

Reports from 22 geographical areas in the United States deemed by the Department of Justice to be representative of meth use indicate that the overall use of the drug has declined but remains a serious threat to public health across the country (NDIC, 2006). The report indicates that the number of methamphetamine labs west of the Mississippi has decreased sharply, but the number increased dramatically in Florida, Ohio, Michigan, and Pennsylvania. In addition, there is an increase of imported purer methamphetamine from Mexico and a more than expected increase in the use of the drug by youth, women, and Hispanics.

Because of the success of the collaborative relationship between the public health departments, Department of Justice, and other advocates and organizations in decreasing the overall prevalence of meth manufacture and use, there are plans to reduce the federal funding for antimeth activities. This plan is creating fear among officials in the states to be most affected by this decrease in funding. The fear is that as services are no longer available to control manufacture and use of meth, there will be a resurgence of these and related problems such as an increase in the numbers of addicts, children in foster care, prisoners, and crimes (Scharnberg, 2008).

WHAT ABOUT THE MONEY?

Economic Impact of Substance Abuse and Dependence

The Office of National Drug Control Policy (ONDCP; 2006) reports that in 2002, the economic burden to the United States of substance abuse/dependence was $180.8 billion. This figure represents loss in productivity due to industrial and occupational error, absenteeism, criminal justice, health care costs, and so on. In addition, according to the NDIC (2006), a division of the U.S. Department of Justice, the average cost to clean up a methamphetamine production laboratory is $1,900. Since an average of 9,777 methamphetamine laboratory seizures were reported to NCLSS *each year* between and including 2002 and 2004, the economic impact of this activity alone is an additional $37 million (NDIC, 2006).

Problems with all substances of abuse persist to this degree, despite the 2008 national budget of $13.7 billion in support of prevention, treatment, and international economic activities directed toward eradication of the drug problem in this country (ONDCP, 2008). The question is not whether enough money is being spent to correct the problem; rather, one must question whether the funds are being allocated properly. When all the expense is considered, perhaps less individual focus and more aggregate focus is required; the individual focus is not working.

The primary, secondary, and tertiary levels of prevention of disease range from the least expensive to the most costly, with primary prevention being the least expensive. There are funds available in the form of grants to develop programs mostly for underserved populations to increase the level of health for these communities of need. These grants can be categorized as funds available depending on the planned level of prevention.

Grants for Primary Prevention Strategies

There are a number of grants available for community leaders and researchers to conduct primary prevention interventions and study their effectiveness. Some are nonresearch grants that fund implementation of programs that have proven to be effective.

The Harry and Jeanette Weinberg Foundation has made available to organizations that provide direct services to the poor grants of up to $100,000 over two years (Harry & Jeanette Weinberg Foundation, 2008). Some grants have a more specific focus. Safe and Drug-Free Schools and Communities Programs for Native Hawaiians are two grants with specific populations in mind. The Programs for Native Hawaiians consist of two U.S. Department of Education awards totaling $579,518 designed to go to organizations serving and benefiting Native Hawaiians. The funds are to be used for the purpose of creating, developing, and managing interventions geared toward (among other things) primary prevention of use of and dependence on illegal substances by the indigenous Hawaiian population. For the purpose of this grant, a native Hawaiian is defined as any individual whose ancestors were natives, prior to 1778, of the area that now composes the state of Hawaii ("Safe and Drug-Free," 2003). This specificity of target population addresses the important cultural influences that must be considered to achieve the purpose of any specific-population-based intervention.

Grants for Secondary Prevention Strategies

Because 29 percent of those with substance abuse problems will not contact a substance abuse treatment professional directly, perhaps because they do not realize they have a problem, the U.S. Substance Abuse and Mental Health Services Administration (SAMHSA) is providing $3.75 million to medical schools to develop and implement training programs to teach medical residents the techniques of SBIRT. It is hoped that by utilizing the techniques of SBIRT, many of those 29 percent will be identified and treated in time to prevent long-term disability or greater social problems (SAMHSA, 2008b).

Grants for Tertiary Prevention Strategies

In an attempt to limit the long-term disability of alcohol and tobacco use on the fetuses by pregnant women, and make for better outcomes of pregnancy, the Centers for Disease Control and Prevention (CDC/P) has set aside funds to initiate six networks that demonstrate effectiveness and leadership with smoking abstinence and cessation, and abstinence from ingesting alcohol among women of childbearing age (National Networks for Tobacco Control and Prevention, 2006). It is through these interventions directed toward the host that the population of female alcohol consumers of child-bearing age, among others, and their children will benefit.

One population targeted for tertiary prevention interventions has been identified as the underage drinker. The surgeon general of the United States asserted that a comprehensive effort on the part of citizens and the community geared toward prevention of underage drinking will be required to eliminate this problem. A cultural change will be required to realize this goal, and an unusual degree of cooperation and consistency of approach will be needed among community organizations such as local and state government, the criminal justice system, education, business, religious and/or fraternal organizations, civic or volunteer organizations, health care professionals, media, parents, and youth (U.S. Public Health Service, 2007). To this end, the U.S. Public Health Service is awarding 80 grants for up to $50,000 each year as part of the Sober Truth on Preventing Underage Drinking Act Grants (SAMHSA, 2008b). These grants are awarded to communities to strengthen the environmental support of efforts to prevent underage drinking (environment element in the epidemiological triangle). Recipients of these grants are encouraged to solicit funds from other sources for interventions that target the host element in the epidemiological triangle. It is understood that the agent in question here is alcohol.

"Reclaiming Futures: Communities Helping Teens Overcome Drugs, Alcohol and Crime" (Robert Wood Johnson Foundation, 2008) is another grant to be awarded for tertiary prevention activities. These grants will be awarded to communities to help them implement a new program that has proven to be effective in working with substance-abusing or substance-dependent adolescents who have had trouble with the criminal justice system. This program has changed the approach taken when targeting juveniles who are substance abusers or substance-dependent in 10 locations throughout the country. The purpose of this grant is to disseminate the findings of research that has been conducted supporting the effectiveness of these new approaches. It is hoped that the techniques will be utilized in communities in addition to the

10 already engaged in the program. This will be carried out through sharing resources, improving data collection and use, and continuing development and promotion of new standards of practice.

Tertiary prevention is not limited to adolescents. The Center for Substance Abuse Prevention (CSAP) has issued a request for applications for "Grants to Expand Substance Abuse Treatment in Adult Criminal Justice Populations" (SAMHSA, 2008a). Adults who are substance abusers or substance-dependent and involved with the criminal justice system are clearly a specific population with specific needs. Seven grants of up to $400,000 each will be awarded for a period of up to three years to provide treatment for substance-dependent inmates with the hope that recidivism will diminish.

Written documents such as this frequently identify more problems than they solve, but by conceptualizing the substance abuse/dependence problem in this country as a public health issue, we might be able to identify possible solutions from the public health perspective as well. Clearly the individual focus has failed, and we cannot afford to continue to allocate resources to initiatives that are unsuccessful. It is my belief that where the problem can be viewed in a population context, solutions can also be found.

Chapter **2**

Cross-Cultural Issues in Substance Addiction Research Including Black Americans and Latinos

Julia F. Hastings, PhD, MSW

Social science researchers face growing pressure to address racial and cultural diversity issues more explicitly as communities expand in population and clients enter social service agencies with increasingly complex substance addictions. Starting from the position that most researchers want to address the complex issues associated with culturally informed research, outcomes often reflect lists of dos and don'ts based on race or ethnic group. While recording outcomes in this fashion may attend to diversity issues, the practice of identifying issues by racial or ethnic group, unfortunately, rarely enhances the cultural understanding of addictions or advances knowledge. However, understanding the difference between race and culture remains an objective for researchers.

Substance abuse refers to a pattern of substance use leading to significant impairment in functioning (American Psychiatric Association [APA], 1994). The *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition (*DSM-IV*; APA, 1994) further defines *dependence* as a person with a substance use history that includes substance abuse, continuation of use despite related problems, increase in tolerance, and withdrawal symptoms. Obvious, unpleasant physical symptoms are easier to define and recognize than psychological or behavioral manifestations. Under constant debate is the issue of divergent thresholds because a clinical diagnosis of an alcohol and/or drug problem is usually based on moral judgment. Though researchers and clinicians may argue on the definitional accuracy and reliability of the definitions to measure differences in use, abuse, and dependency, neither professional group can ignore that disparities in substance addiction dominate the American public.

The critical issue for contemporary social scientists is to examine whether symptoms can be reliably recognized not only as part of research collaboration to address the World Health Organization's (WHO) focus on universality of psychiatric problems and the reliability of structured diagnostic instruments. The current diagnosis system is far from perfect, yet perhaps, with the development of *DSM-V*, a more useful section dealing with culture will be included. By relegating the cultural component of diagnosis to an appendix, the major aspect of what makes persons different from each other in their presentation of addiction remains omitted from general diagnostic research and arguments. To understand the existing disparities in addiction, researchers must be able to understand more clearly how race, ethnicity, culture, and the meaning attributed to various addictions are valued and recognized among the increasing diverse populations.

It is clear that population growth among racial and ethnic groups in the United States is rapidly increasing. The Census Bureau's Web site extols the significant growth of the population such that by 2050, the majority population is projected to comprise persons from racial and ethnic groups. Research findings, proposed studies, and public health interventions will need to appropriately adjust to the changes naturally occurring. The former director of the National Institute on Drug Abuse (as quoted in Primm, Brown, Primm, & Friedman, 2006) pointed out that "significant gaps in knowledge about the effects of drug abuse and addiction in minority populations" exist (p. 322). These gaps in knowledge will be reflected in this chapter, and many will find frustration with existing data collected on substance abuse where primary efforts are to determine use in the last year, past month, or more recent time periods. For epidemiologists, the information remains quite useful. For social researchers and practitioners, the derived information holds little clinical utility, especially when race and ethnicity, combined with culture and other demographic characteristics, are studied.

The purpose of this chapter is to identify for substance addiction researchers some of the cultural dimensions that may be relevant to understanding cross-cultural patterns of use, misuse, and abstinence for black Americans and Latinos residing in the United States. Both populations are growing due to immigration and birth; however, substance addictions are operationally defined in research—use, misuse, or abstinence—and understanding the manifestation of different patterns, trajectories, and consequences across different cultures and ethnicities remains an important goal (De La Rosa, Holleran, Rugh, & MacMaster, 2005). Researchers need to pay attention to the type of methodology chosen to evaluate the potential impact of culture (for a contemporary discussion of the use of culture, see Johnson, 2007). Though Johnson's

work discusses culture in more international terms, this chapter focuses on the black diaspora (both African American and Caribbean) and Latinos in the United States because these groups traditionally have been researched very little in substance addiction studies and have been portrayed in the literature as having alcohol and drug use patterns that show contradictions. The chapter discusses the black and Latino populations, moves on to the prevalence of substance addictions for both groups, and then covers the dimensions of culture as defined in the literature. Afterward, the chapter examines how research enterprises using a mixed-method approach might improve our understanding of the etiology of substance addiction, and finally, the chapter concludes with understudied research areas related to African Americans and Latinos.

THE U.S. BLACK AMERICAN POPULATION

The 2000 Census reported that of the entire U.S. population, blacks represented 36.4 million, or 12.9 percent. Of this number, 12.3 percent, or 34.7 million people, reported themselves as being black or African American (McKinnon, 2001; U.S. Census Bureau, 2000a); the remaining 1.7 million reported their race as being West Indian. According to the U.S. Census Bureau (2000b), the countries that represent the West Indies are the Bahamas, Barbados, Belize, the British West Indies, the Dutch West Indies, Haiti, Jamaica, Trinidad, and Tobago. In this chapter, the black population includes persons of Caribbean descent. Latinos who reported their race as black, either alone or in combination with one or more other races, are not included in the numbers for African Americans. The 2000 Census reported that an overwhelming majority of the African American population is non-Hispanic, at 98 percent American-born. Those who are foreign-born constitute the remaining percentage of the black population in the United States (McKinnon, 2001; U.S. Census Bureau, 2000a). McKinnon (2001) also reported that between 1990 and 2000, the total African American population increased by 21.5 percent (or 6.4 million).

The majority of African Americans (54%) live in the southern part of the United States, and 19% live in the Midwest, 18% in the Northeast, and 10% in the West. New York City and Chicago are the cities where the largest black populations are located (McKinnon, 2001). One-third (31.3%) of blacks are under 18 years of age, whereas a higher percentage, 38.8 percent, of Caribbean Blacks are under 18 years of age (McKinnon, 2001). Caribbean Blacks have larger family sizes, with four persons, than African Americans, whose families average three persons. Along with the increasing diversity of the black population in the United States, research exploring economic and psychosocial factors

is needed to understand true prevalence rates and how the transitioning population affects substance addiction rates, treatment programs, and prevention strategies.

THE U.S. LATINO POPULATION

Data from the 2000 Census indicate that 35.5 million Latinos, or 12 percent of the U.S. population, live in the United States. The 2000 Census also indicates that during the 1990s, the Latino population increased by 58 percent, from 22.4 million in 1990 to 35.3 million (Therrien & Ramirez, 2000). Guzmán (2001) reports that the Latino population increases at a rate five times faster than any other ethnic group. People of Mexican decent compose the largest Latino population subgroup (Therrien & Ramirez, 2000), followed by persons from South and Central America. Immigrants increased the United States population by 13.2 percent, the majority immigrating from South and Central American countries.

California, Florida, New York, and Texas are states where the majority of all Latinos live (Guzmán, 2001). Almost 39 percent of the Latino population is foreign-born, and 35 percent are under the age of 18 (Guzmán, 2001). Over one-quarter of the Latino population lives below the poverty line (Therrien & Ramirez, 2000). Despite the diversity within the Latino population in the United States, much of the research exploring the economic and psychosocial factors for Latino substance addiction rates has not accounted for inconsistent rates between groups or within ethnic groups. Therefore research findings on Latinos might lead to misunderstandings about the severity of and factors influencing substance addiction among this population.

PREVALENCE OF SUBSTANCE ADDICTION AMONG AFRICAN AMERICANS, CARIBBEAN BLACKS, AND LATINOS

According to the National Comorbidity Survey, from 1992, and the National Comorbidity Survey–Replication (NCS-R), from 2003, few differences in prevalence rates exist for adult alcohol use, tobacco smoking, use of psychoactive drugs outside the prescribed purpose, marijuana, and cocaine (Degenhardt, Chiu, Sampson, Kessler, & Anthony, 2007; Kessler et al., 2004; Kessler et al., 1994). Modest decreases were reported for tobacco smoking, from 76 percent to 74 percent, and for marijuana use, from 46 percent to 43 percent. On the basis of the published work, it is difficult to ascertain racial and ethnic differ-

ences. The national data from the National Survey on Drug Use and Health (NSDUH), however, tell a different story.

Research studies using the NSDUH data document substance addiction problems within various Latino and black populations. In the last decade, rates of dependency on alcohol and illicit drugs increased (Substance Abuse and Mental Health Services Administration, 2007) for Latinos and African Americans. No data were available on Caribbean Blacks or subgroups of the Latino population. Variations within these groups likely exist. To date, the data suggest that African Americans abuse illicit drugs at the same or lower prevalence rates than whites. Illicit drugs refer to marijuana/hashish, cocaine (including crack), inhalants, hallucinogens, heroin, or prescription-type drugs used nonmedically. Marijuana use and nonmedical use of prescription-type drugs are highlighted because these were the most common illicit drug use behaviors reported in the NSDUH for combined data in 2004 and 2005. What is unknown are the methodological issues associated with using samples nonrepresentative to the current population to quantify disparities. Nevertheless, emerging from this research are the findings displayed in Table 2.1.

Overall, respondents 12 or older (an estimated 19.4 million persons) used an illicit drug in the past month, with 6.0 percent (14.6 million persons) using marijuana and 2.6 percent (6.2 million persons) using a prescription-type drug nonmedically. When looking at specific racial groups, African Americans report using illicit drugs and marijuana at higher rates than Caribbean Blacks and Latinos. However, regarding using a prescription-type drug nonmedically, Caribbean Blacks report a higher prevalence rate compared to African Americans and Latinos.

Table 2.1
Prevalence of Past Month Substance Addictions Among African Americans, Caribbean Blacks, and Latinos

Substance Addiction	African American	Caribbean Black[a]	Latino (Mexican)
Illicit drugs	9.2	1.6	7.4
Marijuana	7.3	5.2	5.0
Prescription drugs	1.7	5.5	2.4

Source: Substance Abuse and Mental Health Services Administration (2007).
[a]Alegria, Jackson, Kessler, and Takeuchi (2007).

Overall, research on the drug-using behaviors of Latino populations indicates that Latinos have high prevalence rates for substance abuse, the highest reported symptoms of dependency, and the highest need for alcohol and drug treatment compared to whites. On the basis of the presented prevalence rates, Caribbean Blacks also show a need for focused and culturally appropriate treatment.

Race and Ethnicity Issues in the United States

African American, Caribbean Blacks, and Latinos suffer more adverse health conditions from substance addictions than the white population (Alegría et al., 2006; De La Rosa et al., 2005; Escobar & Vega, 2006; Paniagua, 2000; Primm et al., 2006; Williams, Neighbors, & Jackson, 2003). Though identifying many health conditions and their racial differences is important, many other factors associated with substance addition can create greater substance addiction problems, including poverty status, education, unemployment, families in crisis, psychiatric problems, low or no insurance coverage, and public program assistance limitations. Yet the one factor that many researchers and government documents focus on is race and ethnicity. Identifying with a group is important to all people. A group defines who we are and how we envision our place in the world. Above all, we all belong to *many* groups. We try to identify groups by appearance, culture, nationality, and so on, but the most common (and awkward) means of identification is by a set of categories that often do not capture human variation well.

Researchers in the United States continue their long-standing preoccupation with race and ethnicity issues, particularly the need to categorize groups for descriptive reasons such as accounting for population differences, health disparities, and social problem significance. Interestingly, in 1997, the Office of Management and Budget, the agency that determines the National Institutes of Health's population taxonomy, established standards for the collection of data on race and ethnicity, in which the only recognized ethnic group was "Hispanic" or "Latino" (Escobar & Vega, 2006). Though much research has argued against categorizing people (Fullilove, 1998; Stolley, 1999), and the discussion would extend beyond the purpose of this chapter, five racial groups continue to be recognized, namely, Asian American, American Indian or Alaska Native, native Hawaiian or other Pacific Islander, black or African American, and white. For states that increasingly grow due to immigrant populations, such as California and New York, the ethnic and race categories are increasingly inaccurate and less useful when comparing with other nations. International studies have shown that U.S. ethnic categories hold little meaning in other countries that have their own immigrant sets and minority groups. It is important to allow for a variety of racial and ethnic groups in research *beyond* the standard five

commonly used so that substance addiction research can discover the impact of racial identity on particular substance addictions.

Culture and Its Meaning to Substance Addiction Research

Although the term *culture* is widely used, and most appreciate what the term brings to the research environment, few agree on its meaning or definition, and even less on how we operationalize culture in research. Even fewer use similar operational definitions within the context of addiction research. Part of the problem in gaining a solid grasp on a unifying definition of culture is that its use varies with norms, beliefs, power (including issues of oppression), organizations, and institutions such as *academic culture* or *prison culture*. Culture does not always refer to heritage or ethnicity. Culture, as supported by social science researchers, encompasses all of life's patterns, socialization practices, religious ideals, habits in thinking, and organizations, which groups of persons pass on from one generation to the next. Lum (2003) notes that cultural pluralism significantly affects our current society. *Cultural pluralism* involves the coexistence of many group associations and values that beg to be tolerated and acknowledged in research. Respondent substance addictions can no longer conceptually exist outside of the multiple influences impinging on expressed behavior. The culture in which research on addiction takes place must be carefully identified, and the parts applicable to the specific research project clearly defined.

Effective cross-cultural social science research accurately describes conditions of the research participants' lives by discovering pertinent cultural information about the defined group (Lum, 2004). How might researchers gain a better sense of cultural information when budgets are limited? One way is to develop places throughout the research study to support interactive exchanges of information (data collection between researchers and participants). The exchange of information throughout the research process can assist substance-addicted people in negotiating their environment, finding networks of support, and exploring culturally relevant ways of reducing harm. For addiction researchers, the information exchanges help with interpreting research findings and transform researchers into the *culturally formed*. The exchange of cultural information offers researchers an insider's view of addiction because the position of the researcher is transposed into a position of being an avid learner. Many researchers would agree that publishing research that communicates *new* knowledge would be improved if posed research questions were developed with a cultural consciousness.

Initializing research with an overall definition of *population culture* may be misguided. Instead, starting by identifying a group and then deciphering its

culture would serve as a more effective manner to advance research knowledge. In addition to referring to the addiction literature and exchanging information with other researchers, there are other valuable means of learning about a group's culture. One is through the emic approach of interviewing members of the target population to glean an understanding of the values, behaviors, norms, and symbols of that group that provide coherence for its members. Another means is through ethnographic accounts like those of Philippe Bourgois in his 2003 book *In Search of Respect: Selling Crack in El Barrio,* about the culture of urban Puerto Rican addicts and dealers. Ethnographies provide insight into culture and the intersections of race, ethnicity, and geographic or physical environments. By having the group reveal its culture, researchers can examine the mechanisms in the culture that create or sustain addiction and problems in locating help. Including culture in the research enterprise also includes the realization of situations in which cultural practices both constrain and sanction those who use substances. For example, women of Mexican descent drink alcohol, but where these persons and their social groups follow customs, they are also ridiculed for participating in the alcohol drinking behavior (Vega et al., 1998).

Dimensions of Culture

Culture is a key factor in the helping process. Dawson (1998) offers three reasons why using race to symbolize culture will not advance knowledge: (1) racial or ethnic labeling reinforces notions that racial identity operates as a determining factor in substance addiction and ignores other characteristics known to vary in alcohol use and its associated problems (Collins, 1996); (2) stating racial categories from three racial groups (mainly, African American, Latino, and white) ignores other minority populations, such as the rapidly growing category of Latino immigrants from South America and Mexico and black immigrants from the Caribbean, either by omitting them altogether or lumping them into an "other" category; and (3) listing race ignores heterogeneity within groups, the "other" category included. The task, therefore, charged to contemporary cross-cultural researchers is to conduct research studies that record cultural interpretations of addictive behaviors and treatment practices from both the researcher and research participant perspective.

Beyond the challenges of using race as an organizing category, there is the matter of culture, which is—when it is attended to—treated as a static construct. Culture is organic, dynamic, and fluid. It interacts heavily with the environment and with both race and ethnicity. Along with what Dawson (1998) has pointed out, Bentancourt and Lopez (1993) note that researchers are apt to point to so-called culture when they discover differences among racial and eth-

nic groups. Left out is the fundamental question of what cultural *mechanisms* account for the difference.. To ascribe differences to culture without attention to its operationalization at the individual or group level leaves open a wide gap in our understanding of addictions.

To avoid the traps that Dawson (1998) and Betancourt and Lopez (1993) caution researchers about, this chapter focuses on the research context to advance addiction research. The research context must take into account differences among people, situations, and treatment implementations. This refocusing calls for diversity-inclusive research thinking, planning, and conducting. To begin, a brief argument is presented for utilizing mixed-method research as its tenets may offer a means to generate new knowledge about addiction within racially diverse communities.

Mixed Methodology: An Argument for Addiction Research

Although we know unequivocally that addiction is a disease like any other medical disease and that disparities exist among racial demographic characteristics, the literature is not clear on how to move beyond current findings. This reluctance among researchers is partly due to researchers' adherence to choosing either quantitative or qualitative methods. While addiction in communities of color remains a stigmatized disease, the stigma spills over to all aspects of addiction research, experiences of alcohol consumption, drug use, prevention, and treatment (e.g., obtaining measures of use, safety and legal concerns) and what to do about denial.

To perhaps enjoy greater depth in exploring the new frontier and the dramatic changes in addiction among racially diverse communities (e.g., gambling, prescription drugs, etc.), researchers might want to utilize mixed research methods. Quantitative and qualitative methods are often depicted as dichotomous, separate approaches to conducting research. Each differs in underlying assumptions, purpose, approach, and the appropriate role of the researcher. For example, quantitative methodologies purport that researchers can objectively investigate addictions, while qualitative methodologies suggest that addictions are socially constructed. When quantitative and qualitative methods are viewed as ends of a continuum, one logical argument put forth is that mixing these methods can improve our understanding of addiction. Ercikan and Roth (2006) explain the difficulties to adequately answer any social research questions without both approaches.

Mixed-method research designs, proper notation, terminology, and strengths and weaknesses are still being discussed and fine-tuned within the emerging field of mixed-method research (Creswell & Plano-Clark, 2007). The last 20 years witnessed a growing number of social science and public health research-

ers accepting mixed methods as a legitimate form of research. While some scholars continue to debate the wisdom of mixing methods traditionally associated with the postpositivist or constructivist paradigms, many researchers are beginning to adopt a pragmatic perspective by allowing community-informed research questions to drive the scientific enterprise. It is acknowledged in the addiction research field that racial and ethnic populations are adversely affected by the stigma of addiction; however, unknown are the cultural interpretations of addiction. Also depicted in the literature are the deleterious effects of addiction, which lead to misperceptions about communities in a manner that affects how prevention and treatment programs are delivered. What mixed-method research offers to social scientists is a means with which to produce new knowledge. The contemporary literature points to many areas of disparity for diverse communities, yet available data often lack information on how populations ascribe meaning to addiction. Enhancing data to better depict populations in depth will lead researchers to a greater level of understanding of health service needs. Perhaps a mixed-method approach might provide an avenue to filling in the gaps.

Limited Data

Understanding why addiction disparities exist continues to challenge researchers. It appears that on nearly every index measured, African Americans suffer more severely in relation to white Americans, and often in relation to other racial and ethnic groups. While the causes of and correlations for addiction are immense, researchers are offered a great opportunity to learn more about understudied populations, especially how the concepts of health and disease hold social and cultural meaning. There are deeply entrenched ideologies for all arguments. Though it is clear to many researchers that race is a culturally constructed notion, agreement on the study of racial and ethnic health disparities requires data to illuminate contemporary issues. National data sets are often inadequate to support addiction research because in some cases, the sample is insufficiently diverse, and in other circumstances, the sample includes small numbers of minority respondents compared to whites (LaVeist, 1995). Also, data sets with sufficient sample size frequently lack the range of psychosocial variables that are often of interest in understanding social and behavioral aspects of minority health. For example, most national data sets (such as the National Health Interview Survey, the National Health and Nutrition Examination Survey, or the Behavioral Risk Factor Surveillance System) have limited psychosocial variables. Because these data sets are designed to produce prevalence rates of morbidity and other health-related characteristics of the population, they have broad coverage across a variety of health domains but are

limited in their ability to test novel hypotheses related to the etiology of health disparities.

As one response to the lack of data examining racial and ethnic health disparities, and addiction disparities in particular, the National Institute of Mental Health Collaborative supported the completion of four psychiatric epidemiology surveys that included three national surveys: the National Survey of American Life (NSAL), the NCS-R, and the National Latino and Asian American Study (NLAAS; Pennell et al., 2004). Each of the studies provides a rich opportunity to focus on culture-specific aspects of mental health and substance addiction among U.S. communities of color. Though each study collected data independently, all can be combined with unifying diagnostic interview questions. A slightly modified version of the World Mental Health Composite International Diagnostic Interview was used to ascertain mental disorders as defined by the *DSM-IV*. This instrument was developed for the World Mental Health Project and was also used in the NLAAS and the NCS-R. To explain, a description of the NSAL is provided.

The primary goal of NSAL was to utilize contemporary methodological advancements to gather the best data possible about the physical and mental health as well as the structural and economic conditions of diverse groups of Americans, with a particular focus on African Americans and Caribbean Blacks. The survey instrument included specific assessments of mental disorders, stress, coping, neighborhood characteristics, religion, social support, and work. As background, the NSAL is a national area probability sample based on a race-stratified screening procedure to determine where the sample would be obtained (Jackson et al., 2004). Trained interviewers completed face-to-face interviews with 6,082 adults (3,570 African Americans; 1,621 Caribbean Blacks; 891 non-Hispanic whites) and 1,170 adolescents (810 African Americans; 360 Caribbean Blacks) aged 13–17 years, for a total of 7,252 participants from across the nation.

Barriers to Addressing Differences in Addiction Research

The public health and social work literature in the last 10 years illuminates numerous barriers to addressing diversity in broadening the addiction knowledge base through cross-cultural studies. Recognized barriers vary at the individual, family, systemic, and organizational levels. The barriers challenging researchers infusing diversity issues into their research at the individual level include language, style and content of nonverbal communication, acknowledging the existence of racism and prejudice, stereotypes, and stress. At the systemic level, many of the same barriers exist, and many are reoccurring because nonverbalized norms, policies, procedures, and programs clearly undermine any

efforts to address difference in an effective manner (Loue, 2003). Recruitment may fail because of distrust of the researchers or historical exclusion of specific populations such as women, persons of color, non-English speakers, and persons actively involved in drug or alcohol use. The recruitment issues associated with these populations include increasing costs of translating research materials, liability considerations with women who might be pregnant and using drugs, and unknown health consequences. Other barriers to recruitment are fear of community ostracism or confidentiality in the community regarding substance addiction, poverty status (high transportation costs or in need of monetary incentive), child care, and adverse legal consequences if substance use becomes known. Though a researcher may apply for a certificate of confidentiality to have the research records protected, the mere fact that a participant must return to a community of people who will have knowledge of her substance addiction is an adverse effect that researchers cannot control. Finally, the organization may present barriers to data collection efforts, including a lack of training of staff on recordable service practices; application forms for services that ask lengthy, complex, and indistinguishable diversity questions; service operational hours that do not coincide with the availability of diverse clientele; no stated policies regarding cross-cultural practices; and fiscal constraints toward implementing innovative services. The impact of organizational practices on conducting cross-cultural research is not surprising; however, for addiction researchers to promote and advance cross-cultural knowledge, organizational structure and capacity need to be addressed for addiction populations.

Researchers engaged in building empathy also show a direct path toward moving beyond the barriers listed. Building empathy within the structure of the research process suggests that participants take on a more informed role of community process than the researcher. For example, participants can suggest when it is appropriate and inappropriate to return to communities after participating in research projects. By allowing the participants to share their knowledge of community living, researchers integrate the value of research participants' knowledge into the research process by asking for assistance when needed. This mode of inquiry would allow cross-cultural researchers to shift from understanding racial groups to understanding the experience of diverse people with a cultural identity. Cultural identity plays a central role in one's willingness to participate in research or the ability of so-called treatment to succeed. In the research context, some individuals may be reluctant to volunteer their participation in research due to hearing about adverse problems of past research endeavors or personally experiencing misrepresentation of shared information which led to harm, for example, the Public Health Service–led Tuskegee syphilis study with African American men (Jones, 1981); the use of

alcohol to gain unfair advantage in negotiating Native American homelands (Mancall, 1995); or the Tearoom Trade experiment, identifying the characteristics of men who sought quick and impersonal sexual gratification from other men (Humphreys, 1970).

The tools we use to reach and help people can be culturally appropriate and enhanced. Ultimately, the goal of any research is to create a workable frame of reference for discussion, to advance the knowledge base, and to achieve better understanding of persons in their environments. Rather than focusing solely at the micro level of the individual or solely at the macro level of the neighborhood, breaking down barriers in the future will require a more holistic approach that includes the addiction culture at all levels. To truly address the role social science addiction researchers can play in investigations, the voices of research participants must be heard and understood.

MISSION OF SOCIAL SCIENCE FOR SOCIAL WORK RESEARCHERS IN ADDICTION

Part of what defines a profession is a shared vision, typically referred to as a *mission*. The mission of social work research in addiction is quite similar to the missions of other national professional organizations in that we want "to enhance human well-being and helpmeet the basic human needs of all people, with particular attention to the needs and empowerment of people who are vulnerable, oppressed, and living in poverty" (National Association of Social Workers, 1977, p. 1). The aspects that make the mission of addiction research unique are its focus on the integration of culture, the language used to describe addictive behaviors, and the meaning respondents bring to the research arena from the social context. Social work researchers, not any different from other social scientists, realize that they must pay attention to the environment in which people live and work to change the environment to improve interventions. In doing so, researchers must *listen for meaning*.

Our Mission as Researchers

A culturally informed research agenda focuses on stages, issues, informed findings, and relevant recommendations. The contact phase of research involves establishing a relationship between the researcher and the respondent. As researchers gain a preliminary sense of the populations in their research, such as becoming acquainted with the neighborhoods, leaders, and residents who compose the area in which persons with addictions live, the diverse community, or commonly, the ethnic communities, becomes acquainted with the research

process. The development of the relationship between the community and the researcher fosters rapport and trust. The research process then becomes a working task in which the researcher, the research team, and the respondents collaborate on an accurate description and understanding of the social problem and culturally appropriate responses. The process just described is called *culturally congruent*, which means that no matter the stage of the research process, all participants in the research remain in tune with what is congruent with community, research, and methodological expectations.

Although both researchers and practitioners place high value on informativeness of cross-cultural research, much attention still remains focused on how we conceptualize culture and the role it plays in addiction research. Although many would agree that active listening, translating research materials, using the services of an interpreter, and asking appropriate questions are ways to begin, much more attention needs to focus on the meaning behind words and actions (e.g., Green, 1995; Perlman, 1979). A pathway to discovering new knowledge is attending to word choice and understood meaning. According to Spradley (1979), "language is more than a means of communicating about reality: it is a tool for constructing reality" (p. 17). For all people, and especially for people of color, language serves as more than a tool for transmitting information; it establishes the meanings speakers assign to their experiences. In this regard, a key to understanding differently requires the addition of a question or two about meaning, for example, "Would you share with me what you mean when you use the word *nip*?" By attending to the way that words are used in phrases and terms in ordinary language, greater clarity, understanding, and accurate interpretation are achieved.

The mission of cross-cultural research is to advance knowledge using culturally appropriate methods. In this manner, the goal is to promote social justice and equity, promote a better understanding of what works within the community, enhance researchers' ability to work across systems (micro/mezzo/macro), and translate knowledge into meaningful explanations.

FUTURE RESEARCH AGENDA FOR SOCIAL SCIENTISTS IN CROSS-CULTURAL RESEARCH

What Actions Do We Need to Take?

Though most researchers recognize many pathways to including culture in research, few truly deal with all the issues that contain both subjective and objective content. Advancing social science research requires that researchers use culturally congruent interventions to inform practice. The researcher

must become more involved in the federal funding aspect by participating in the grant proposal review process and demanding that sponsored research delineate the process for diverse subject recruitment. If the research sample is not diverse, challenge the principal investigators to explain how the proposed research could enhance scientific understanding of addiction. All researchers should try to design interventions that practitioners can use and disseminate findings to local interested parties that will enhance practice directly.

Future research also needs to include studies that document what practitioners are doing in service delivery so that researchers know what might represent effective and ineffective practices and also more informed useful practices. Ultimately, practice-oriented researchers need to maintain and develop collaborative relationships with other disciplines and increase connections to communities.

We need to discuss issues that practitioners bring to the research environment in the context of working in the trenches.

Interpersonal Sensitivity

For example, when developing prevention programs for young women of color, researchers should move beyond gaining parental or guardian consent; researchers should include parents or guardians in the data collection process. Not only would this action show researchers to be persons connected to the lives of community members, but also, the potential intervention might be understood as beneficial to the identified group and maintained after the research project is completed. Since the movement among agencies is to use only so-called best practices, or model programs, then attention to cultural concerns will place addiction researchers in the forefront of advancing knowledge.

Assets That Social Science Researchers Bring to Addiction Research

Few careers rival social work in the diversity of opportunities offered; however, all social scientists want to understand social settings that include community centers, courts, prisons, hospitals, nursing homes, and addiction treatment centers, where addiction problems exist at multiple levels—micro (individual), mezzo (community), and macro (policies). The desire to help others and change social conditions represent only two characteristics that allow practitioners and social scientists to show their uniqueness. Social scientists, and social workers, in particular, encompass a large labor force and are located in a wide range of service areas. They possess unique knowledge about diverse populations, skills informed by an interdisciplinary knowledge base, a systems

perspective, community connections, and an unwavering commitment to social justice and equity issues, from a strengths perspective.

CONCLUSIONS

From this chapter, it is clear that complex conceptual and scientific issues need focused attention. A long-term commitment to federal, state, and local funding as well as funding from private foundations is needed to address the multiple gaps in our knowledge. It is important to support new ideas for conducting addiction research so that the next generation of scientists can seek the input of key stakeholders. For instance, the primary stakeholders are the research participants, the social science researchers, and the funders; support from any of these three bodies will help in advancing knowledge. Research studies of the twenty-first century must move forward with the permission of individuals from diverse communities who share their life stories and thoughts. New and provocative questions need to be posed, without social scientists' investment in local and national communities, that allow outsiders to learn something new. Clearly, if the discussion of culture accomplishes little else, advancing the scientific enterprise by better understanding the addictions attributed to African Americans, Caribbean Blacks, and Latinos requires interdependency of all systems to reduce or even eliminate challenges.

ACKNOWLEDGMENTS

Thank you to Dr. Arlene Stiffman and Dr. Luis Zayas of Washington University's George Warren Brown's School of Social Work for the opportunity to develop a conceptual basis for the manuscript. I especially appreciate the guidance and support of the National Survey of American Life principal investigators, namely, Drs. James S. Jackson and Harold W. Neighbors of the University of Michigan Program for Research on Black Americans.

Chapter **3**

Race, Ethnicity, and Early U.S. Drug Policy

Sean R. Hogan, PhD, MSW

Prior to the twentieth century, the perception of drug use and addiction in the United States was very different than it is today. Drug use was not a criminal activity, nor was it regarded as inherently evil. Drug addiction was generally looked on as a bad habit or some type of personal misfortune (Booth, 1996). One reason for the naïveté around substance abuse during this period was simply a lack of information and understanding by the medical establishment as to the consequences of drug use and addiction. For example, early physicians thought morphine could be used as a cure for opium addiction. Ironically, heroin, developed commercially in 1898, was then thought to be a cure for morphine addiction. Cocaine, with its stimulating effects, was first thought to be a cure for alcoholism (Musto, 1999). The American public and its political representatives were equally uninformed. With such a lack of knowledge surrounding drugs, insightful policy making and practices were virtually impossible.

A significant shift in public perception, and, consequently, the strategies designed to address substance use, occurred when American society began to distinguish so-called recreational, or nonmedical, drug use from that of drug use initiated and prescribed by physicians. During the nineteenth century, the typical drug addict was a middle- to upper-class white woman with a dependence on morphine. This dependence was generally satisfied by a prescription from a family physician (Aldrich, 1988) or overindulgence in patent medicines containing opium or morphine (Lindesmith, 1957). The relationship between middle- and upper-class white female opiate addicts, the medical establishment, and a certain social acceptability of opiate use during the nineteenth century

was no coincidence (Courtwright, 1982). As long as drug use and addiction were limited to the dominant and upper-class members of society, addiction was not going to be regarded as a serious social problem; however, once attention for substance use began to shift toward less socially desirable members of society (e.g., minorities and immigrants), the public's perception and reaction to drug use also began to change (Musto, 1999). Drug use and addiction were no longer seen as a consequence of illness or the result of some type of upper-class personal misfortune. Drug use and addiction began to be interpreted as the self-indulgent and irresponsible behavior of lower-class and socially inferior members of an ever diverging American social landscape.

The relationship between race, ethnicity, and early U.S. drug policy is important to U.S. drug policy historians and analysts as it represents the foundation of antidrug legislation in that country. For historians of U.S. drug policy, the years between 1875 and 1937 are significant as it was during this period that antidrug policies specific to narcotics (e.g., opium, morphine, and heroin, cocaine, and marijuana) were first established. Policy analysts, particularly those examining social policy from a constructionist perspective, see social dynamics related to racism and xenophobia as critical to understanding the creation of substance abuse policy in the United States. It is the insidious relationship early U.S. drug policies have with minority and nonnativist groups that defines and contextualizes early antidrug policy making in the United States. Understanding this fundamental characteristic of early U.S. antidrug policy making has helped analysts interpret the construction of substance abuse policy throughout the history of the United States.

In this examination of the relationship between race, ethnicity, and early U.S. drug policy, three examples of race and specific substance associations are provided as models for the genesis of early antidrug legislation. First, the association between the Chinese and opium is examined by looking at some of the details that led to the first antidrug policies in the United States. Despite a more serious social problem with morphine use and dependence, opium became singled out as America's first nonalcoholic substance of abuse. Second, the relationship between African Americans and cocaine is described. Early racist and discriminatory attitudes in the southern United States aided in creating drug-crazed perceptions of an already vilified population, perpetuating the United States' first comprehensive federal antidrug legislation (Musto, 1999). Third, the association between Mexicans and marijuana in the southwestern United States is examined. Economics and the fear of losing jobs to nonnativist laborers would contribute to the passage of America's first antimarijuana policies. Finally, this chapter concludes with a brief discussion of the symbolic association between race, ethnicity, and early U.S. drug policy and its subsequent effects on minority drug users in the United States.

OPIUM AND THE CHINESE

During the 1800s, opium was brought to the United States by Chinese immigrants. In many parts of Asia, opium smoking had become quite commonplace, particularly among the Chinese (Musto, 1999). Consequently, Chinese immigrants who came to the United States during this period also brought with them the custom of smoking opium. Most of these immigrants came to the West Coast of the United States as cheap labor to work in the mining and railroad construction industries. By the late 1800s, it was very common to see opium-smoking establishments, known as *opium dens*, in most cities with any appreciable Chinese population (Lindesmith, 1957). Besides opium, these dens offered other iniquitous activities to their patrons such as gambling and prostitution. Many opium dens were run and organized by secret Chinese criminal societies, known as *tongs* (Booth, 1996). Chinese laborers fell victim not only to the addictive properties of opium, but also to the domination of these oppressive criminal elements. The majority of the Chinese who came to the United States had their transportation paid for and provided by other, more powerful interests (Sandmeyer, 1939). The Chinese laborer would then bind himself to service to repay his debt. Practically all Chinese laborers who came to the United States were single men intent on achieving economic gain (Sandmeyer, 1939). In most cases, the Chinese laborer did not intend to settle permanently in the United States, but to accumulate a sufficient amount of income to enable him to return to China and live in comparative comfort. The dreams and hopes of Chinese immigrants to acquire an economic reserve in America and return home to some type of increased socioeconomic well-being were often compromised by the demands of opium addiction and the opium dens. One author has suggested that some Chinese laborers would spend as much as 50 percent of their daily income in the opium dens (about 50 cents, on average; Booth, 1996). The actual amount of money spent by Chinese immigrants on opium during this period is impossible to determine; however, some insight into the magnitude of the problem may be seen in the importation figures of the time.

Statistics on opium importation during the last half of the nineteenth century are available and are considered by many authors to be accurate and indicative of narcotic use in the United States during that period (Lindesmith, 1957; Terry & Pellens, 1928). According to Lindesmith (1957), between 1860 and 1900, the consumption of opiates increased enormously, far greater than the growth of the population. By the 1890s, the average domestic consumption of crude opium was over 500,000 pounds each year, and that of morphine and its salts over 20,000 ounces annually (Musto, 1999). These figures represent the total consumption of opium and morphine in the United States, includ-

ing opiates used by the medical and patent medicine industries, and are not indicative of opium used solely among the Chinese. While the largest amount of opium ever legally imported into the United States came in 1897 (1,073,999 pounds), opium smoking reached its zenith in 1883 with the importation of 208,152 pounds of smoking opium, mostly through San Francisco, California (Terry & Pellens, 1928); in the 1880s, approximately 20 percent of the entire Chinese population of the United States resided in San Francisco (Helmer, 1975; Sandmeyer, 1939). The relationship between opium and Chinese communities in the western United States during this time period was undoubtedly quite substantial.

Eventually, opium smoking and opium dens would begin to attract individuals from society who were not Chinese. These individuals included gamblers, prostitutes, and underworld figures (Musto, 1999). The isolation of the opium dens within the Chinese communities provided some criminals a safe haven from otherwise inquisitive law enforcement officials. In San Francisco's Chinatown, in 1885, there were 26 opium dens, most of which "catered for twenty-four smokers at a time" (Booth, 1996, p. 195). As opium smoking began to attract members of the non-Asian community, attitudes toward opium smoking also began to change. Although opium smoking was not nearly as widespread as morphine use, opium was the first drug in the United States to receive negative public attention. Many historians of early U.S. drug policy attribute the social opprobrium toward opium and opium smoking to its negative association with the Chinese (Booth, 1996; Helmer, 1975; Lindesmith, 1957). The negativity toward opium and its use had nothing to do with the drug's addictive qualities. According to Booth (1996), public opinion toward opium was primarily based on "racial hatred" (p. 195) by mainstream society toward Chinese immigrants. To support, or validate, this negativity, newspapers of the time carried lurid tales of crime and debauchery in opium dens. All these accounts portrayed the Chinese in a negative light (Musto, 1999). Anti-Chinese sentiments among the general public produced a type of antiopium hysteria. Images of aggressive and depraved opium smokers became indelibly etched in the minds of concerned public officials. A common concern of people was "that many women and young girls, and young men from respectable families, were being induced to visit opium dens, where they were ruined morally and otherwise" (Kane, 1882, p. 1). The issue of interracial smoking was of great concern among prominent members of U.S. society. A San Francisco doctor, Winslow Anderson, expressed his concerns when he claimed to have seen the "sickening sight of young white girls from sixteen to twenty years of age lying half-undressed on the floor or couches, smoking with their lovers. Men and women, Chinese and white people, mix[ing] in Chinatown smoking houses"

(Booth, 1996, p. 195). The antiopium movement was one of the first antidrug movements in which critics used the welfare of young people as a major rationale for social indictment (H. W. Morgan, 1981). It would not be the last.

The hysteria related to the Chinese and opium smoking, the majority of it unfounded, prompted the first antiopium legislation in the United States. It came in the form of a city ordinance. In 1875, the San Francisco municipal authority passed a city ordinance forbidding the smoking of opium (Brecher, 1972). This ordinance also forbade any individual from possessing opium and the paraphernalia necessary to smoke it, and the creation of an opium-smoking establishment (Booth, 1996; Bureau of Justice Statistics, 1992). However, the actual importing and selling of the drug were not included in the ordinance as criminal acts. Significantly, the importers and sellers of opium were usually wealthy San Francisco merchants (Austin, 1978). They did not fall subject to the penalties of the law. This policy never attempted to stop the importation of opium, but merely served to harass and intimidate the Chinese opium den operators and patrons (Helmer, 1975).

Enforcement of the new ordinance was inconsistent. According to Booth (1996), "dens to which whites went were closed down, on racial grounds, but smaller establishments catering primarily for Chinese were ignored" (p. 196). The result of the ordinance was not the cessation of opium smoking, but rather the relocation of non-Chinese (i.e., white) opium smokers from opium dens in Chinatown to "boarding houses owned by Caucasians on the fringes of Chinese residential areas" (Booth, 1996, p. 196). Supplies of opium did not lessen. In 1881, the state of California passed its own statute prohibiting the selling of opium or the visiting of any place for smoking opium (Sandmeyer, 1939). This still did not have much effect on opium smoking. Consequently, in 1882, a bill was passed restricting the immigration of Chinese laborers into the country. While passage of this bill had strong economic underpinnings, opium smoking was also a significant contributing factor to its passage. Regardless of these legislative measures, as noted previously, the greatest amount of smoking opium ever imported into the United States came in 1883, the year after this bill was passed (Terry & Pellens, 1928). The fact that opium importation peaked following the passage of anti-Chinese legislation indicates that the use of opiates in the United States at that period of time was much more than simply a Chinese phenomenon.

Further evidence of the direct relationship between the Chinese race and U.S. drug policy comes from 1887. As the city and state laws enacted against opium smoking between 1875 and 1887 were proving to be rather ineffective, the federal government finally passed its own legislation related to the importation of opium for smoking. The significance of the Opium Import Act (1887)

was in its limitations: the law explicitly stated that "the importation of opium into any of the ports of the United States by any *subject of the Emperor of China* [italics added] is hereby prohibited" (Belenko, 2000, p. 15). This law forbade the importation of opium by Chinese nationals only; Americans were not affected. In 1890, a similar law was passed prohibiting nonnativist Americans from engaging in opium manufacturing, that is, the processing of raw opium into smoking opium. Using antidrug legislation as a device for differentially affecting nonnativist Americans was a relatively new political stratagem at this point in American history. Unfortunately, it would become quite commonplace. In 1904, in an attempt to further discriminate between American nativists and the Chinese Other, and presumably based in part on their negative association with opium use, all Chinese laborers were prohibited from coming into the United States and its territories (Sandmeyer, 1939).

Following the 1904 ban on the immigration of Chinese laborers to the United States, relations between the two countries became very strained. Chinese who had immigrated to the United States prior to the ban had been treated horribly by their American hosts. Chinese travelers visiting the United States for purely recreational reasons were also treated with great disdain. In an attempt to temper Chinese resentment toward America, President Roosevelt proposed a humanitarian act intended to help the Chinese government deal with its own endemic opium problem (Musto, 1999). This proposal came at the bequest of his political and drug advisory representatives in the Far East. The reconciliatory effort would come in the form of an international conference on opium control. On February 1, 1909, the first International Opium Commission convened in Shanghai, China. The conference was initiated by the United States and was attended by 12 countries: Austria-Hungary, China, France, Germany, Great Britain, Italy, Japan, the Netherlands, Persia, Portugal, Russia, and Siam (Terry & Pellens, 1928). Turkey, a prominent opium-producing country of the time, was conspicuous in its absence.

No antiopium policy changes were implemented in any country as a result of this convention. At the request of Great Britain and the Netherlands, the Shanghai conference on international opium control was officially ranked as a commission. This relegated the proceedings to a "fact-finding body which could make only recommendations and not commitments" (Musto, 1999, p. 35). The first universal drug-specific federal narcotic control law in U.S. history, the 1909 Smoking Opium Exclusion Act, was passed as a face-saving measure by the U.S. government. Prior to the convention, the United States did not have any universal federal legislation directed toward the control of opium. Hamilton Wright, the primary U.S. representative for the conference, believed that, as the convening nation of the Shanghai conference, the United States had a respon-

sibility to model its conviction and determination toward antiopium legislation (Musto, 1999). Consequently, on February 9, 1909, in the midst of the conference, the United States proudly announced the passage of the Smoking Opium Exclusion Act. This act banned the importation and use of opium by all members of U.S. society, barring prescription from a physician (Helmer, 1975). The Chinese were no longer singled out with regard to opium prohibition. The circumstance under which this law was borne, however, may call into question its legitimacy. Had the United States not been under such extreme pressure from the international community prior to the Shanghai conference of 1909 to enact some type of national opium control policy, the Smoking Opium Exclusion Act would have been inevitably delayed.

In the final analysis, hostility toward the Chinese and their negative association with opium were predicated more on the economic conditions and market dynamics of the period than the effects opium actually had on American society (Austin, 1978; H. W. Morgan, 1981). Racial and cultural differences, an apparent lack of concern for American political and social institutions, and a perceived clannishness among Chinese immigrants also served to foster intense anti-Chinese sentiment among the American people (Sandmeyer, 1939). However, as many scholars of the subject submit (Austin, 1978; Helmer, 1975; Sandmeyer, 1939), economics was the primary basis for ethnic antagonisms during the last half of the nineteenth century. Hostilities toward Chinese laborers in California began early on their arrival. In the mining communities of the 1850s and 1860s, Chinese laborers were already being regarded as a source of economic trouble by white mine workers. Chinese laborers willing to work for wages deemed unacceptable by white workers were seen as undermining and splitting the early labor market (Helmer, 1975). Rather than direct their economic dissatisfactions toward their employers, white workers attacked the Chinese and drove them from the quickly disintegrating mining industry. Forced from the mines, Chinese laborers relocated to larger urban centers such as San Francisco.

In the 1870s, the economy in California began to suffer from competition with the eastern United States. Access to Californian markets by eastern businesses "had been increased by the completion of the railroads and the resulting drop in freight rates" (Helmer, 1975, p. 21). Severe economic depression ensued, particularly in the city of San Francisco. Chinese laborers were once again identified by white workers as a cause of their own economic hardships. With the increase in unemployment, small manufacturers and white laborers aligned themselves to unfairly identify cheap Chinese competition as the cause of their problem. Cheap Chinese laborers, who were much more tolerable during prosperous times, were now a threat and inconvenience to the

economic well-being of the unemployed nativist workers of the dominant society. According to Austin (1978), it was then that opium became negatively associated with the Chinese. As mentioned previously, a significant result of this negative association was the first antidrug legislation in the nation. Unfortunately, the construction of drug policies in the early United States based on racial and ethnic distinctions would not end with opium and the Chinese.

COCAINE AND AFRICAN AMERICANS

Concurrent with the developing public hysteria over opium use and Chinese immigrants in the West was an even more vicious campaign targeting African Americans and the drug cocaine in the southern United States (Pittman & Staudenmeier, 1994). During the end of the nineteenth century, the United States experienced what some historians refer to as a cocaine explosion (Musto, 1999). The use of cocaine, much like the use of opium and morphine, became very popular. Besides cocaine's euphoric and anesthetic effects, it was well known for its abilities to fend off fatigue and allow its users to be more energetic and productive. As a result, cocaine became popular among some African American laborers in the South (Austin, 1978). Some southern labor bosses were even known to provide their black laborers with cocaine to increase their endurance and productivity (H. W. Morgan, 1981). Cocaine provided by whites to blacks under the pretense of increased economic productivity was seen as forgivable; however, cocaine used by blacks for recreational purposes was an indication of moral depravity. This double standard would ultimately serve to stigmatize southern blacks and cocaine use beyond the already existent racial and social discriminations of the southern United States.

During this historical period in the South, a more energetic and active African American was also perceived as being more aggressive and threatening (Austin, 1978). This perception among the members of the dominant white society only served to perpetuate already existing fears and prejudices. Following the turn of the nineteenth century, increasing reports of cocaine use among African Americans aroused all the malevolent stereotypes and fears of American racism (H. W. Morgan, 1981). As a result, cocaine and African Americans became negatively associated, spurring some fantastic and incredibly lurid tales of cocaine-related offenses committed by African Americans. Anecdotal accounts often told of superhuman strength, violent criminal acts, and ghastly sexual offenses perpetrated by blacks against their white counterparts. Cocaine became associated with aggression, murder, rape, and African American males (Booth, 1996). The myth that cocaine increased the physical

powers of criminals became common knowledge. According to Musto (1999), "one of the most terrifying beliefs about cocaine was that it actually improved pistol marksmanship" (p. 7). Some police departments insisted that ordinary police revolvers lacked the firepower to kill blacks who were under the influence of cocaine. This prompted some police officers to increase the strength of their weapons from .32 to .38 caliber (Musto, 1999).

The fear that cocaine would lessen African American inhibitions and increase their sexual impulses permeated social and political discussions of the time (H. W. Morgan, 1981). Official concerns were expressed by the likes of the aforementioned antiopium crusader Hamilton Wright. Wright (as cited in Austin, 1978) reported that the use of cocaine by southern blacks was "one of the most elusive and troublesome questions which confront the enforcement of the law" and was "often the direct incentive to the crime of rape" (p. 230). Wright went on to emphasize his belief that the misuse of cocaine, particularly by blacks, was the most threatening habit in the country. In a 1914 testimony before Congress, Christopher Koch (as cited in Musto, 1999), a physician with the Pennsylvania State Pharmacy Board, was quoted as saying, "Most of the attacks upon white women of the South are the direct result of a cocaine-crazed Negro brain" (p. 305). In Atlanta, Georgia, the anticocaine discourse was particularly prejudiced. By 1914, the Atlanta chief of police was attributing exorbitant amounts of crime to cocaine use (Musto, 1999). The sensationalizing of cocaine use and crime in Atlanta also led to legal action against the Coca-Cola Company. The Atlanta-based soda fountain drink manufacturer included cocaine in its original formula. After 1903, cocaine was replaced in the soft drink with caffeine (Office of Technology Assessment, 1994).

The imagery and rhetoric of the cocaine-crazed southern black man also spuriously validated an increase in violence against blacks in the South during this period. In the minds of white law enforcers and townspeople, cocaine-related crimes warranted increased physical force and harsher penalties toward African Americans. Unlawful lynching of black men also increased during this period (Helmer, 1975). The relationship between perception and reality, relevant to African Americans and cocaine during this period, appears to be spurious because, although 80 percent of the nation's African American population were concentrated in the South (Timberlake, 1963), it is estimated that fewer than 10 percent of the nation's addict population were African American (Duster, 1970). Additional evidence indicating a lack of support for the relationship between cocaine, African Americans, and crime was provided by E. M. Green, clinical director of the Georgia State Sanitarium. Between 1909 and 1914, Green examined 2,119 blacks admitted to his Georgia institution. In his study, Green found only three cases of narcotic addiction among black patients,

in contrast to 142 drug-related disorders among the white clientele (Helmer, 1975). Furthermore, of the three African American narcotics users, only two used cocaine, while the third was an opium addict (Musto, 1999). Commission reports conducted from 1900 to 1908 of institutionalized inmates and patients in the Washington, D.C., area also failed to indicate any appreciable regard for the use of cocaine among blacks, or otherwise (Helmer, 1975). The reality of the hysteria related to cocaine and African Americans was that it was an invention of white society, a myth created in an environment of fear and prejudice by mainstream society with the intent of maintaining a dominant and oppressive status quo. Depicting African Americans as cocaine-crazed sexual deviants, and a threat to the purity of white women and children, served this end.

Vilifying African Americans in the South was not a new concept at the turn of the twentieth century. Cocaine was just another method for justifying and validating the already existing social disorder in that predominantly racist part of the country. According to Musto (1999), the South has always feared that African Americans "might become oblivious to their prescribed bounds and attack white society" (p. 6). Cocaine use by blacks simply amplified those fears. It was within this context and environment that anticocaine policy was first developed. The fact that the drug was highly addictive, much like opium and morphine, was not a consideration. The synchronicity of the hysteria between opium smoking and the Chinese and cocaine use and African Americans resulted in both drugs being included in the United States' first comprehensive federal antidrug law: the Harrison Narcotic Act of 1914.

MARIJUANA AND MEXICANS

Marijuana smoking, much like opium smoking, was brought to the United States by a foreign population as a norm of their indigenous culture. During the early 1900s, Mexican immigrants, coming to the southwestern United States as cheap laborers, brought with them their native cultural practice of smoking marijuana (Helmer, 1975). It would not be unusual during this period of time to observe a rural Mexican farmworker smoking marijuana at the end of a hard workday, similar to having an alcoholic beverage after work in other cultural settings. Ultimately, the relationship between marijuana and Mexican immigrants during this time period would lead to the construction of America's first antimarijuana laws.

Interestingly, the exact impact that marijuana smoking among Mexican immigrants during the early 1900s had on the United States and the creation of antimarijuana drug policy remains a point of scholarly debate (see Galliher & Walker, 1977, for an early example of this discussion). According

to Musto (1999), during the 1920s, most of the nation had very little concern about marijuana and the individuals who used it. However, Musto goes on to state that "in areas with concentrations of Mexican immigrants, who tended to use marihuana as a drug of entertainment or relaxation, the fear of marihuana was intense" (p. 219). Specifically, these areas were Texas, California, Arizona, and New Mexico; between 1920 and 1930, nearly 90 percent of all the Mexicans in the United States lived in these four states. The peak year of Mexican immigration into the United States during this period was 1924. In this year, 105,000 Mexicans entered the United States, and only 3,572 had reason to leave (Helmer, 1975). However, these figures only reflect the official record; the actual number of Mexicans who entered the country is impossible to determine accurately.

The prohibition of alcohol between 1919 and 1933 increased the popularity of marijuana smoking among drug users. An influx of marijuana smuggling from Mexico and Cuba into the southern United States began to arouse much concern among law enforcement and government officials (Brecher, 1972). The increased popularity in the smoking of marijuana sparked media and government antimarijuana campaigns (Bonnie & Whitebread, 1974). In a remarkably similar course to that of opium and the Chinese, and cocaine and African Americans, marijuana became negatively associated with Mexican immigrants. Public campaigns against the smoking of marijuana began to "center on its use by Mexican laborers and the fears that they would spread the drug to youth and other vulnerable populations" (Brecher, 1972, p. 409). Stereotypical perceptions of disfavored Mexican laborers were created that included marijuana smoking and intoxication (Helmer, 1975). According to Musto (1999), marijuana came to be perceived as the impetus of criminal, sexual, and violent behavior by Mexican immigrants in the southwestern United States. Like opium and cocaine, it was propagandized that marijuana caused Mexican laborers to commit crimes, rape women, and become mentally unstable (Musto, 1999). Both Musto and Brecher (1972) feel that it was this type of discourse that drove the creation of antimarijuana policy.

Evidence to support the validity of these assertions is hard to find. P. A. Morgan (1990) states that "in general, there was simply no basis whatsoever for assuming that Southwestern Anglos were the least bit disturbed about Mexican marijuana use" (p. 235) in the early 1900s. In the principal Californian newspapers of that time, there was very little mention of Mexicans and marijuana (P. A. Morgan, 1990). This obvious lack of media attention seems unlikely for a social problem of such reported repute as drug-crazed Mexicans ravaging women and children in the southwestern United States. Another point that Morgan emphasizes is that "among the Mexican population, low rates

of arrests for marijuana existed during the time of the alleged scare" (p. 236). If the Southwest was so overcome with intense fear, and marijuana-smoking Mexicans were committing so many crimes, arrest records of the time should have been more supportive. A 1930 survey of crime and delinquency among Mexicans in Texas, the state with the greatest Mexican population, concluded that Mexican immigrants "show delinquent tendencies less than their proportion of the population would entitle them to show" (Helmer, 1975, p. 58). The construction of marijuana-smoking immigrants as a menace to society appears to have been more of an invention perpetrated by ulterior social, economic, and political interests of the time, rather than a real social problem.

During the early 1900s, the immigration of Mexican laborers into the southwestern United States was not seen as particularly problematic. World War I had limited labor that would have been provided by European immigrants. Furthermore, according to Helmer (1975), "farmers and planters in the West were unable to compete with the North for black labor" (p. 57). Rather than allowing wage rates to rise, Mexican labor was actually imported by agricultural interests in the West. The surplus of cheap Mexican laborers kept wages low, profits high, and most important, the price of land low for the large agricultural companies (Helmer, 1975). It was not until the beginning of the Great Depression that Mexican labor became a major issue in the United States. As the country became poorer and more frustrated, hostilities toward outsiders and immigrants grew. Rationales to restrict Mexican immigration began to develop among the dominant society. According to Helmer, the actual ostracism of the Mexican laborer "differed from place to place, depending not so much on how prevalent marijuana use was, but on how the economic crisis affected the local population" (p. 57).

Some Americans condemned Mexican immigration for other reasons. According to P. A. Morgan (1990), three primary rationales, based mostly on nativistic and moralistic arguments, were being proffered during this time to keep or restrict Mexicans from coming into the country. First, some American social leaders questioned the civic competence of Mexicans to become proper American citizens. These opponents felt that the Mexican immigrants were not supportive of established American social and political institutions, nor were they capable of contributing to any progressive democratic ideals (P. A. Morgan, 1990). This argument was similar to detractions made about the Chinese during their years of social degradation in the late 1800s. Second, there existed "a strong biological nativist campaign against the growing Mexican population" (P. A. Morgan, 1990, p. 240). This should not be surprising given the United States' history of racism and xenophobia. One prominent member of an apparent eugenic group known as the American Coalition, C. M. Goethe (as cited

in Musto, 1999), was quoted in the *New York Times*, on September 15, 1935, as saying,

> Marijuana, perhaps now the most insidious of our narcotics, is a direct by-product of unrestricted Mexican immigration. Early grown, it has been asserted that it has recently been planted between rows in a California penitentiary garden. Mexican peddlers have been caught distributing sample marijuana cigarets to school children. Bills for our quota against Mexico have been blocked mysteriously in every Congress since the 1924 Quota Act. Our nation has more than enough laborers. (p. 220)

Third, there was a fear that Mexican immigrants would not remain isolated in the rural farming regions of the United States, but would ultimately end up in the populated urban areas (P. A. Morgan, 1990). Urban blight was an ever increasing problem for big cities, and the addition of more poor, nonnative immigrants to the streets of newly developing urban centers, such as Los Angeles, was not a welcome proposition for many Americans. Job competition in the big cities was yet another issue (P. A. Morgan, 1990). It was one thing for Mexicans to work for low wages out on the farm, but to come into the city and compromise the economic saliency of white workers was another matter altogether. It was this perception of the Mexican laborer as a threat to the economic and social welfare of the American nativist, in addition to his negative association with marijuana, that contributed to the passage of the first federal antimarijuana law in U.S. history: the Marijuana Tax Act of 1937.

SYMBOLIC ASSOCIATION

The genesis of the first federal antimarijuana policies in the United States was remarkably similar to that of opium and cocaine policy formation a generation earlier. The relationship between race, ethnicity, and the creation of early U.S. drug policy was quite significant. While other sociopolitical and economic determinants were also instrumental in the construction of these early policies, it appears that the symbolic association between drugs and specific racial and ethnic groups had a significant influence on public opinion and new policy formation. Through the symbolic association of a specific minority group and a negatively recognized drug, powerful groups in society could effectively demonize and vilify less desirable social and economic counterparts (Helmer, 1975). The negatively sanctioned substance simply came to symbolize that specific group. The negative association between a substance and a group proved to be politically and legislatively powerful. In conjunction with the symbolic association of a specific group with a drug came the rationale that these specific

drug-using groups also represented a threat to the welfare of American society (Austin, 1978). Musto (1999) posits that the legal prohibition of certain drugs occurred because these drugs and their use "seemed to undermine essential social restrictions" (p. 294) that were explicitly designed to protect dominant society and maintain a privileged status quo. Musto (1999) further states,

> The occasion for legal prohibition of drugs . . . appears to come at a time of social crisis between the drug-linked group and the rest of American society. Customary use of a certain drug came to symbolize the difference between that group and the rest of society; eliminating the drug might alleviate social disharmony and preserve [the] old order. (p. 295)

A lack of understanding among U.S. society relevant to drugs and drug use made drug use a viable scapegoat for the causes of many social ills (Musto, 1999).

Public response to minority-linked drugs (i.e., opium, cocaine, and marijuana) differed radically from attitudes toward other drugs with similar potential for harm such as morphine or barbiturates. The main differences between opium use and morphine use in the nineteenth century were how and by whom each drug was used. Opium, while available in many patent medicines, was primarily smoked and associated with Chinese immigrants and lower-class opiate users; morphine, on the other hand, was primarily swallowed or injected by middle- and upper-class white women (Courtwright, 1982). Early U.S. antidrug legislation focused primarily on opium used for smoking; morphine was not included. This situation is strikingly parallel to the sociolegal dichotomy that exists between crack cocaine and powder cocaine use in the United States. Crack cocaine is smoked and primarily associated with minority and lower-class users; powdered cocaine is inhaled through the nostrils (i.e., snorted) and primarily associated with white upper-class users. Legislation and policy, while encompassing both variations of the drug, are differentially written and implemented, with more severe and harsher penalties applied to crack dealers and users (Reinarman & Levine, 1997).

Fear and ignorance among mainstream policy makers and the American public played an enormous role in the symbolic associations that contributed to the creation of early U.S. drug policy. The public's fear of addicts and minority-group drug users supplied the powerful motive force behind early antidrug legislation (Musto, 1999). Courtwright (1982) believes that what people think about drug use and addiction depends to a great extent on who is using the substances at any particular time in history. The association between racial groups and drug use served to reinforce the dominant position of white American nativists. Drug-using racial groups became symbolically associated

with backward, premodern, unproductive elements of the ever progressive American ideal (H. W. Morgan, 1981). Groups that represented a threat to, or interfered with, the economic prosperity of the dominant culture became vilified (Helmer, 1975). Drug use was the agent, and symbolic association the device, by which this vilification process took place. Eventually, villains would become criminals, and drugs would continue to be symbolically associated with the less desirable members of society. Law enforcement and the criminal justice system would come to dominate the facilitation of substance abuse policy in the United States. The relationship between race, ethnicity, and early U.S. drug policy formation would provide the foundation for subsequent social and political antidrug responses.

One result of this dynamic has been that many disadvantaged and minority groups in the United States have had to suffer differentially for their drug use. The United States' distinct record of creating substance abuse policy predicated on which individuals in society are using drugs, rather than on the specific characteristics of the drugs or their effects on society, has perpetuated discriminatory social and political responses toward low-income and minority substance abusers. The U.S. predilection for punitive and zero-tolerance substance abuse policies has further compromised the health and welfare of these groups by neglecting their special needs for substance abuse prevention and treatment. Minority groups in the United States that have been historically and unjustly vilified as a result of fear, ignorance, and public misperceptions around substance abuse will continue to suffer inordinate social injustices until drug use and its consequences are more fully understood by U.S. policy makers and the American public.

Chapter 4

Gender Inequalities and Inequities among Women with Substance Abuse Problems

Martha Romero Mendoza, PhD

Gender constitutes a social life–organizing principle, and as with socioeconomic, demographic, and geographic factors, gender is essential to understanding health matters. Evans and Brown (2003) have gathered variables that might define public health policies, resource distribution, power, morbidity, mortality, and development, represented in the acronym PROGRESS. These variables are place of residence (urban/rural), race, occupation, gender, religion, education, socioeconomic status, and social capital/resources. Interaction between these elements could give rise to gender inequalities in well-being.

The significance of gender inequities for women's health has been underscored at two United Nations conferences: at the 1994 International Conference on Population and Development, held in Cairo, and at the 1995 World Conference on Women, carried out in Beijing. These conferences recognized women's physical, emotional, and social well-being as a human right and as an essential element of sustainable development.

Women's health problems related to use, abuse, and dependence on psychoactive substances are not an exception and deserve to be examined from this standpoint.

The aim of this chapter is to discuss, from a gender perspective theoretical framework, the burden of substance abuse disease in women. Inequalities in health with which these women have to cope will be treated here, as will relevant health issues in their treatment and the gaps in policies to deal with their special needs.

WHAT IS A GENDER PERSPECTIVE?

The growing implementation of a gender perspective in the design of interpretations, diagnoses, and public policies has allowed greater visibility of women and their problems. But this has also brought about a certain decline with respect to a reductionist tendency within the realm of this perspective; that is to say, many researchers talk about gender only because they write about women without taking into consideration the theoretical implications, and this constitutes the source of many distortions. Mainly, the theory of gender concerns historical and cultural relationships. It is useful to analyze and understand the female condition and women's situations, but it also serves to analyze the male condition and vital situations of men.

Gender analysis implies a reference to the social and economic contexts in which differences are constructed. Thus a gender perspective is a construction of theoretical, categorical, hypothetical, and interpretative articulations that, once assembled, allow an account of the complexity of decisions, behaviors, and beliefs of social subjects, men and women, as well as of the whole magnitude of social structure and the realm in which each one reproduces itself (Lagarde, 1996).

Gender is the cultural symbolic structure derived from biological sex. It is constructed with the whole of social, cultural, political, psychological, judiciary, and economic characteristics assigned differentially to both sexes. It is also the constitutive element of social relationships based on the differences that characterize sex and is a primary form of significant power relationships (Scott, 1996).

Among the most important gender elements are the following:

1. The available cultural symbols and myths that evoke multiple representations
2. The ruling concepts that express multiple interpretations of the meanings of symbols and behavior; these concepts are expressed in religious, educational, scientific, legal, and political tenets that affirm categorically and in an univocal way the meaning of man and woman
3. The social institutions and organizations of gender relationships: the kinship system, the family, the labor market segregated by gender, and the educational, health, and political institutions
4. Identity

Gender implies a distinct control over material and symbolic resources, and consequently, it is also implied in the concept and structure of power.

Gender structure can become such an overpowering social factor that it may even be thought of as *natural;* this is also true about certain supposed biological

capacities or abilities that are socially and culturally constructed and promoted. It is important to analyze the *articulation* of the biological matter with the social one and to *avoid the denial* of the unquestionable biological difference between men and women (Wilsnack, Vogeltanz, Wilsnack, & Harris, 2000).

HEALTH GENDER INEQUALITIES AND INEQUITIES

There are gender differences in most societies, and as a consequence, there are also health inequalities and inequities that are inherent to social definitions of femininity and masculinity, in terms of resources, opportunities, and problems.

Within this sphere, *equality* and *inequality* are dimensional concepts that refer to measurable quantities.[1] On the other hand, *inequity* and *equity* are political concepts that express a moral commitment to social justice.

In the words of Kawachi, Subramanian, and Almeida-Filho (2008), the difference can be expressed as follows:

> *Health inequality* is the generic term used to designate differences, variations, and disparities in the health achievements of individuals and groups. *Health inequity* refers to those inequalities in health that are deemed to be unfair or stemming from some form of injustice. They are avoidable and unnecessary. (p. 647)

It is more frequent to find research information on health issues linked to men than linked to women's problems (Doyal, 2000). Inequalities have a significant effect on health, and they are not given randomly. Instead, we can state that health troubles are selectively distributed among a population; some people and some sectors do undergo a higher number of troubles than others. This systematic variability is virtually hidden and/or masked in the whole of the population's health, except for some epidemiological data (Starfield, 2006).

Social inequality, and the bias that arose from it at the moment of the research, is perpetuated through social hierarchy preservation, that is, power relationships.

In accordance with Burke and Eichler's (2006) proposal, the existence of social hierarchies gives rise to a problem that has three sides: (1) the problem of preserving them, (2) the problem of failing when examining the generated differences, and (3) the problem of using double standards. What do we mean by this?

1. *Hierarchy preservation*. Every society stratifies people according to gender, abilities, or social classes. These variables are joined to other factors like age, religion, geographic location, sexual preference, or physical appear-

ance. Stratifying people into categories determines their access to all kinds of resources such as power and decision making, education, and income, among other things. There are several mechanisms by which these hierarchies are evident. As an example, we can mention that, in general terms, around the world, women have less social power than their male counterparts, and they have less educational attainment, lower economic income, and limited participation in political decision making.

2. *Failure when examining differences.* The lack of sensitivity when naming differences and when treating as equal people who must be treated in a different way is the prime form by which this problem becomes evident. Treating equally people who are not the same increases inequality, that is, denying social differences, not taking into account biological differences among sexes, or denial of the differences in the expression of multiple health problems.
3. *Using double standards.* Using double standards implies the action of treating groups differently to strengthen their subordinate status. Reputation may be a good example of this. Within the male population, reputation is linked to honesty, so if a man has a bad reputation, he is considered dishonest; in the case of women, reputation is tied to sexuality, so when a woman has a bad reputation, she is regarded as promiscuous. Therefore women's sexuality is subordinated with regard to men's. This constitutes a double social valuation.

Recently, a solid body of working knowledge has been built; this body demonstrates the close relation between gender inequalities and inequities and mental health (Outlook, 1999, Afifi, 2007). Other research has focused on poverty (Medina-Mora & Rojas, 2003; Reidpath & Allotey, 2007), life expectancy, education, employment, reproductive health, access to health services (PAHO, 2007), and other more qualitative dimensions such as well-being.

Results show that health problems suffered by women are not only linked to their specific biological characteristics, such as reproductive health and motherhood (Murphy, 2003); but they also reflect discrimination, and that women are at a disadvantage just by the act of performing their daily activities. This can be shown in cases of substance abuse.

Particularly, when selecting a gender perspective to understand alcohol consumption by men and women, an interpretative aspect is opened that allows one to disclose means of consumption, roles, attitudes, beliefs, restrictions, social consequences, rules, and opportunities.

From a sociocultural perspective, differences in how men and women are allowed or encouraged to drink or use drugs, and to behave when drinking or using drugs, help to define and symbolize the cultural and social structural distinctions between being a man and being a woman. Understanding how and

to what extent women and men drink or use drugs differently should also help to understand better how societies divide both sexes. Gender differences in alcohol use encourage costly biases in how societies try to control or reduce alcohol-related problems (Wilsnack & Wilsnack, 1997). (These differences do vary from country to country and from culture to culture.)

ALCOHOL, DRUGS, AND MENTAL HEALTH

Mental and neurological problems are among the most significant contributors to the worldwide burden of disease. Increasingly sophisticated methods to measure health and its burden, in particular, the *disability-adjusted life year lost* (DALY), have helped to provide a more balanced conception of needs and priorities in the area of health for both developing and developed countries. By 1990, the total percentage of DALY attributed to mental and neurological problems was 10.5 percent, including problems such as unipolar and bipolar affective disorders, psychosis, epilepsy, dementia, Parkinson's disease, multiple sclerosis, drug and alcohol dependence, posttraumatic stress disorder, obsessive compulsive disorder, panic disorder, and other problems (Murray & Lopez, 1996).

Alcohol-related problems account for 288 million cases (World Health Organization [WHO], 1999), and they represent a different DALY for men and for women. Nonetheless, some authors have considered violence, mental health, and substance abuse together to ascertain the burden of disease due to the fact that these factors represent overlapping clusters of problems, especially for women (Wyshak, 2000).

Traditionally, women were excluded from most of the early alcohol and drug research; reasons for this early neglect most likely include: the higher (perceived and actual) prevalence of drinking and drug abuse, and of drinking and drug abuse problems, among men than among women; the fact that men's problems with alcohol (e.g., alcohol-related crime, accidents, or work problems) tended to be more visible than those of women; and finally, the greater accessibility of men with alcohol dependence as research subjects (WHO, 1992). Most of the focus on women's bodies is centered on women's reproductive role in society; as a result, much of the available information about the effects of alcohol on women's bodies is limited to issues related to women's reproductive health.

The greater social stigma of alcohol abuse for women may reflect the common and deep-seated cultural fears that point out that if women drink in excess, this will threaten their successful performance of traditional wife-mother roles and will result in unrestrained sexual activity that will upset the traditional male-dominated sexual balance of power. Whatever its source, the stigmatization of women's drinking has clearly contributed to the greater invisibility of women's

alcohol abuse, by causing both women and their significant others to deny or minimize signs of women's alcohol abuse and by discouraging women abusers from seeking help for alcohol problems they do acknowledge (Wilsnack, 1995). (The degree to which this stigmatization has this effect likely varies from country to country and from culture to culture.)

Biological Gender Differences in Alcohol and Drug Use

Biomedical sciences integrate biological, psychological, and social factors. Hence the distinction between sex differences and gender differences in the biomedical sciences is often arbitrary. The use of the expression *biological gender differences* acknowledges that sex and gender are overlapping, potent, and underrecognized mediators of human health and disease.

Alcohol consumption is not an exception. Inborn differences shape each individual's response to alcohol, including the risk of developing complications from alcohol abuse. Some of these inborn differences may be related to gender: women seem to be more vulnerable than men to alcohol-related liver disease; cardiovascular disease, especially, cardiomyopathy; and brain damage ("Are Women More Vulnerable," 1999; Hommer et al., 1996; National Institute on Alcohol Abuse and Alcoholism [NIAAA], 2000).

An overview of alcohol and women (NIAAA, 2000) concludes that the reasons for this vulnerability are not well understood. Differences in metabolism at a finer level and hormonal and cellular differences may lie behind differences in health consequences. One uniformly observed difference between women and men is that women attain higher peak blood alcohol levels than men when ingesting the same dose per kilogram of body weight. The higher peak blood levels are mainly related to the distribution of alcohol—a water-soluble substance—in the woman's body, with a smaller body water content, as compared to the man's body.

Studies have also differed on whether alcohol elimination rates—a reflection of how quickly the enzyme alcohol dehydrogenase (ADH) in the liver processes alcohol—are different for women and men. No consistent changes in rates of alcohol elimination have been found during the various phases of the menstrual cycle (Gil, 1997); however, higher levels of acetaldehyde—a toxic by-product of alcohol metabolism—were evident after alcohol ingestion in women during high estradiol phases of the menstrual cycle or in women taking oral contraceptives (Erickson, Fukunaga, Sarkola, Lindholm, & Ahola, 1996).

Recent studies indicate that women have larger liver volumes per unit of body weight than men, which could result in higher rates of alcohol elimination in women when expressed per kilogram of body weight (Kwo et al., 1997). The

consequence is that a larger liver will have more ADH available to metabolize alcohol.

In summary, women have a lower body water content than men of similar body weight so that women achieve higher concentrations of alcohol in the blood after drinking equivalent amounts of alcohol. In addition, women appear to eliminate alcohol more quickly from the blood than men. This finding may be explained by women's higher liver volume per unit of lean body mass, because alcohol is metabolized almost entirely in the liver ("Are Women More Vulnerable," 1999). Additional research is needed to clarify the relative alcohol metabolic rates in women and men and the mechanisms behind gender-related differences.

The existence of a genetic vulnerability to alcoholism continues to be debated in the alcoholism research field, in spite of the fact that some studies support the notion that some genetic mediation occurs and that alcoholism is as strongly genetically influenced in women as it is in men. Since alcoholism does not follow the simple rules of Mendelian inheritance in multigeneration pedigrees, it is clear that alcoholism is a genetically complex disorder, influenced by multiple genes that interact in an unknown fashion with each other and with similarly unknown environmental factors to produce the disease (NIAAA, 2000; Svikis, Velez, & Pickens, 1994).

Another example is the effect of combinations of gender differences in drinking styles and gender differences in reactions to stress. For instance, alcohol may play a direct role in cardiovascular disease mortality related to the physiological effects of binge drinking (more common in men) on the cardiovascular system, including the precipitation of sudden death. It may also play an indirect role via the methods that men and women use to cope with stress and depression (Holmila & Raitasalo, 2005).

Regarding reproductive health, alcohol abuse and alcohol dependency are associated with disorders in both men and women. Alcohol-dependent women may have several dysfunctions such as disorders of the menstrual cycle, including amenorrhea, dysfunctional luteal phase, anovulation, and in some cases, early menopause. Most available information about alcohol effects on reproductive function has been derived from clinical studies of alcohol-dependent women during sobriety (Mello, 1988).

Women with alcohol problems are at higher risk of getting sexually transmitted infections such as HIV, leading to AIDS; this is especially important if they or their partners have multiple sexual partners. Furthermore, alcohol suppresses the body's immune system and influences individuals' reasoning and decision-making skills concerning sex. In addition, a woman with an alcohol problems is more likely than other women to be in a violent relationship, and she may be forced to have sex against her will (WHO, 1992).

Pregnancy

Available research information linked to maternal alcohol use is based on data collected in the United States, and there may be a number of biases when such information is applied to other populations, including issues like polydrug use, environmental confounds, and cultural and ethnic facts that affect both alcohol use and drug use and outcomes in mothers and children (Boyd, 1999; Coles, Russell, & Schuetze, 1997); however, in other countries, this information is scarce.

According to Burd, Cotsonas-Hassler, Martsolf, and Kerbeshian (2003), fetal alcohol syndrome (FAS) is a common cause of developmental disability, neuropsychiatric impairment, and birth defects. FAS is identified by the presence of a growth impairment, central nervous system dysfunction, and a characteristic pattern of craniofacial features. The reported prevalence of the disorder varies widely, and recent estimates approach 1 percent of live births. A newborn baby with congenital FAS can develop higher rates of comorbid conditions: attention deficit–hyperactivity disorder (40%), mental retardation (15% to 20%), learning disorders (25%), speech and language disorders (30%), sensory impairment (30%), cerebral palsy (4%), and epilepsy (8% to 10%). Birth defects are common. In the United States alone, the annual birth cohort of persons with FAS could be as high as 39,000 cases yearly.

The overall incidence of FAS in advanced industrial societies is 1 in every 750 children. In South Africa, FAS is thought to be by far the most common cause of mental disability: a 1985 study found that the incidence of FAS in Cape Town is 1 per 281 live births. When examining disadvantaged communities, the incidence of fetal alcohol effects is likely to be much higher (Parry & Bennetts, 1999).

Drug Abuse

Drug abuse research has concluded that there are differences in genetic, physiological, psychosocial, and environmental dimensions of drug abuse and addiction between men and women (Hanson, 2002). The neurobiological basis for drug abuse and addiction is essentially the same, regardless of the drug taken or the person who is taking it. But men and women may differ in their biological and behavioral responses to drugs. Women typically progress to dependence from first use of cocaine, heroin, or marijuana faster than men. Additionally, cocaine-induced cognitive impairments and risk for stroke have been found to be more severe in men than in women. Among the risk factors for using drugs are depression and conduct disorders, which are more pronounced in women than in men.

Women who use illicit drugs also are more likely to experience adverse obstetric and perinatal outcomes than women in the general population. Differences are seen depending on the type of illicit drug used. The most studied case is that of cocaine. Following some recent research, the size of babies born from mothers using cocaine is smaller in all parameters (size, weight, volume), their mothers' pregnancies are likely not to reach full term, the size of the babies is smaller than their gestational ages suggest.

Despite the evident need for adequate care of pregnant alcohol- and drug-abusing women, there is a strong consensus among health professionals concerned with this topic: they affirm that criminalization of alcohol and drug use in pregnancy is misguided and counterproductive (Feinman, 1992).

Adequate prevention requires that obstetrical personnel identify those women who have drinking problems early during their pregnancies or, preferably, before pregnancy (Blume, 1988). The challenge for future policies is to reduce the prevailing punitive and stigmatizing stances concerning pregnant substance-abusing women, while also working to increase the availability of appropriate and sensitive treatment services for this population (Wilsnack, 1995).

SOCIAL ASPECTS OF FEMALE ALCOHOL AND DRUG ABUSE

Attitudes toward drinking and abstention seem to be shaped at an early age by external influences and role models. Especially among women, family influence plays an important role in outlining viewpoints on drinking and abstention, and abstainers are more likely to come from abstaining families. Reasons for abstaining from alcohol are numerous and complex; according to each culture, abstention can be a matter of personal taste, a question of religious faith, or a health issue.

In many societies, the use of alcohol by women is strongly disapproved or prohibited; this tends to restrict alcohol consumption, for example, limiting women's drinking to their homes or forcing them to do it in private. Furthermore, given the differences in drug response between men and women, some authors have emphasized the need to have different measures for male and female patterns of drinking. Though countries vary in their traditions of measuring alcohol patterns, it is unusual to find these different measures.

Gender differences in the use and effects of alcohol may be strongly influenced by sociocultural factors. In the developing countries, these factors can range from traditionalism to more recent social transitions derived from development and the influence of globalization. Although some progress has been

observed in the developed world, full gender equity has not been attained. In developing societies, feminism has reached, at most, middle-class educated women, but other transitions have greatly influenced the situation of poor women, among whom migration is outstanding.

Men's national migration to urban locations and foreign migration have resulted in a familiar reshaping, where women who are left behind must take on some other roles, such as outside-household work, and they must accept the change in their traditional functions (Salgado de Snyder, 1993). The strengthening of women's social and economic positions has increased their ability to cope with problems, but at the same time, it has increased tensions between men and women (Szas, 1998). This acculturation has also created a gender impact on drinking practices for those who migrate.

Caetano and Medina-Mora (1988) describe the way in which, when Mexican men cross the border to the United States, they modify their drinking patterns, and after living in the United States for at least five years, they increase their frequency of consumption and maintain the high quantities of alcohol associated with drinking occasions common in Mexico. In the case of women, length of stay or a woman's generation within the United States has less impact on levels of consumption; rather, the increase in consumption is explained by the degree of acculturation to the American way of life.

Substantial changes in the position of women in society have recently raised the question, known as the *convergence hypothesis*, of whether women, when they become more like men in many respects, will also adopt negative behaviors that used to be more typical for men.

Around the world, men drink more frequently than women, and the latter are subject to more social rejection when they develop drink-related problems. Nevertheless, drinking among women is increasing, and women's share in alcohol-related problems is also growing. Women tend to start abusive drinking much later in life than men, and it is likely that they also develop alcohol-related problems later. However, once alcohol dependence is established in women, the harmful effects tend to progress faster. This phenomenon has been called *telescopic*, and it suggests that when men and women consume the same quantities of alcohol and/or drugs, women will develop health problems earlier, and they will have greater problems related to its consumption.

LIFE CYCLE AND ROLES

The roles people have are historical, and as a consequence of that, they change. They are related to the life cycle of men and women and to their social status and geographical location. *Life cycle* refers to a series of prospects and tasks

that, in an ideal way, women must carry out as they arrive at a certain point of the life cycle; these stages are a construction based on biological changes as well as on social and cultural issues. Roles also vary between rural and urban areas and within generations.

Typically, in all cultures, alcoholic beverages are used more by men than by women and more by young adults than by preadolescents or elderly people. Hence, in any society, the major consumers of alcoholic drinks are more likely to be young men, between their mid-teens and their mid-thirties. Men's drunken comportment usually is more exaggerated and potentially more explosive than that of women, regardless of relative ethanol consumption (Marshall, 1979).

Gender differences in drinking behavior have been observed and explained using the *role theory*, according to which each man and each woman can have at least two types of roles: status and positional.

Status roles involve social expectations based on characteristics that the individual cannot easily influence. From this point of view, gender is considered a status role, along with age, religion, and social class. Status roles determine the appropriate "wetness" of situations. Thus the amount and style of drinking considered appropriate in certain situations may be different for women and men (Knibbe, n.d.).

Positional roles are expectations related to positions in social networks such as work and family. Positional roles structure the everyday life of individuals, and they determine into what kind of situation an individual may enter. From a sociological point of view, the life span can be viewed as a sequence of positional roles. Marked differences in the life courses of men and women may be expected to lead to differences in positional roles and their effects on drinking behavior (Neve, Lemmens, & Drop, 1997).

Traditional Roles

Roles and stereotypes are interconnected. Negative stereotypes about women who drink heavily come from the double standards for women and men that are prevalent in any society, and from social and cultural expectations that state that women are responsible for certain roles within the family.

According to Wilsnack and Wilsnack (1997), Cazes (1994), and Guttman (1997), drinking has often served men as an indication of manliness: by their behavior when drinking heavily, men can or may be forced to demonstrate endurance, self-control, nonconformity, and willingness to take risks. Drinking by male groups, typically in all-male settings, has often been an essential way for men to escape from the control exerted by others, to ignore social differences, to gain social support, and to form strong personal ties between them;

male drinking groups constitute a space of equality. Consumption is socially tolerated and used as a coping strategy to solve problems. Especially among men, employment has a positive influence on alcohol consumption.

Women's drinking is more often discouraged or inhibited because of the fear that it will adversely affect their behavior and their social role of *being for others*. In many cultures, it is often feared that women's intoxication will reduce social control of their sexuality by making women either more sexually disinhibited or more vulnerable to sexual insinuations (Leigh, 1995). Women's drinking has also been restricted or hidden because intoxication was thought to be a signal of a dangerous failure of social control over women's family obligations and public behavior, a fact that threatens the social order. Another reason for condemning women's drinking is motherhood, which is viewed as an overrated and sometimes unique role: "The hand that rocks the cradle shouldn't be tipsy."

A man's sex role is affronted by having an alcoholic wife who has asked for help. How can a man maintain his image of male dominance if his wife is out of control because of alcoholism? The high desertion rate of husbands of alcohol-abusing women may be partly attributable to these common beliefs. Unnecessary or unrestrained drinking, which might be allowed or even encouraged in the case of men, has often led to condemnation, punishment, and ostracism for women, perhaps as a reminder of the social power imbalance between men and women (Wilsnack & Wilsnack, 1997).

Common traditional sex role stereotypes prescribe that women are mostly valued for their nurturing functions and their roles as wives and mothers. Consequently, an alcoholic woman will tenaciously try to hide her alcoholism to keep her status based on those roles (Downing, 1991). As a result of these stereotypes, there is a stigma against women who use alcohol. This makes it more difficult for a woman to admit to herself and to others that she has a problem with alcohol, and she may try to hide her alcohol use or to downplay it. On the other hand, women internalize these negative stereotypes: they are more likely to feel ashamed or guilty about their substance use (they may feel that they are failing in their roles as partners and mothers). The aforementioned has a negative effect on their self-esteem and can lead to increased consumption (Addiction Research Foundation, 1996).

In some cultures, women can also have the role of being producers and distributors of alcohol, but availability of beer and wine does not constitute a stimulus for women to drink heavily or have alcohol problems. Researchers who have occasionally raised the question seem invariably to meet a typical woman's response: "The only trouble we have with alcohol is what some of our men do when drunk" (Heath, 1991, pp. 180–181).

Modern Social Roles

At least since the beginning of the 1970s, a growing number of studies have researched the influence of social roles on alcohol consumption. Research results remain controversial. For example, some of them maintain that multiple roles, such as paid employment, marriage, and having children (*role overload*), can lead to increased alcohol consumption in women. In contrast, another theory proposes that *role deprivation*, the lack of social roles such as marriage, work, and having children, has the effect of leading to less social contact and to isolation, further leading to increased alcohol consumption (Addiction Research Foundation, 1996; Bloomfield, 1999). These results are valuable and interesting but do not necessarily reflect the research needs of other countries.

It is necessary to think in terms of the dual roles many women play in monoparental families, one typical characteristic of many family units living in poverty (Salles, 1994), and, increasingly, above the poverty level as well. Men can be absent for different reasons: migration, extensive labor journeys, abandonment, death, or simply because they have never been present. In these families, women might have both role overload (being single women, earning low salaries in paid employment and domestic work, having children out of school) and role deprivation (fewer social contacts, poverty, and isolation). Insofar as developing countries go, this is the reality of many households. This reality points to the need to rethink words such as *family* and *sex roles*, terms that sometimes tend to be used in an uncritical way, as taken-for-granted concepts. Undoubtedly, historical, geographical, economic, generational, and cultural factors have a profound influence on the roles people play. It is necessary to link these concepts with notions such as the sex-gender system; sexual discrimination; and social inequalities of sex, race, and class (Ettore, 1992). An in-depth reflection on these topics could promote research projects without gender biases.

VIOLENCE

Violence against women is a structural phenomenon that has been deeply rooted—for a thousand years or more—in patriarchal culture. Oppression and inequity have been predominant elements in women's lives for centuries. Power, control, and supremacy have been common features of the relations men have traditionally maintained with women.

Now days, domestic violence is considered a serious problem in most societies, so much so that domestic violence is almost universally ranked as a major public health problem having deep economic and social implications. In recent

years, the international community has acknowledged the urgency of responding to this phenomenon by means of several international mechanisms that regulate and punish violence against women, taking it as an attack on and a violation of their human rights. The Inter-American Convention to Prevent, Sanction, and Eradicate Violence against Women (Convención Interamericana para Prevenir, Sancionar y Erradicar la Violencia contra la Mujer, Belém do Pará, Brazil, 1994) acknowledged domestic violence as a problem of human rights, as a crime that governments must face through multiple actions.

This convention defined violence against women as "an offense to human dignity and an expression of historically unequal power relationships between men and women, which has pervaded to all sectors of society, regardless their class, age and religion, and its eradication constitutes a *sine qua non* for development" (Convecion Interamericana, p. 1)

Violence against women is expressed in several forms, among which intrafamily violence is only one. However, at the social level, it includes values, customs, language, symbols, and behaviors, which are accepted and transmitted from generation to generation, establishing and legitimizing as natural unfair behaviors and actions. Clinical studies have found elevated rates of both physical abuse (domestic violence) and childhood sexual abuse in the histories of alcoholic women in treatment as well as elevated rates of alcohol abuse and dependence in mental health clients with histories of childhood sexual abuse. Long-term effects of child abuse, in addition to substance use disorders, can include self-destructive behavior, anxiety, depression, poor self-esteem, difficulty trusting in others, and hostility (Beitchman et al., 1992; Fox & Gilbert, 1994).

Widom, Ireland, and Glynn (1995) consulted court records to identify cases of childhood physical or sexual abuse. These researchers found that for the case of women, a history of childhood neglect, but not abuse, significantly predicted the number of alcohol-related symptoms experienced, independent of parental alcohol or other drug problems, childhood poverty, race, and age. Wilsnack, Vogeltanz, Klassen, and Harris (1997) found that after controlling for the effects of age, ethnicity, and parental education, women with histories of child sexual abuse were significantly more likely to report recent alcohol use, intoxication, drinking-related problems and alcohol dependence symptoms, depression and anxiety, pain that prevented intercourse, and consensual intercourse before the age of 15 than women without these experiences. Alcoholism cannot be attributed to child sexual abuse or child physical abuse per se without taking into account other possible contributing factors. However, there is a higher likelihood of alcohol problems in women if they were sexually or physically abused as children (Langeland & Hartgers, 1998).

Many studies show a high rate of alcohol abuse among men who batter their female partners. Yet no evidence supports a cause-and-effect relationship between the two problems. Battering is a learned behavior and is not the result of substance abuse or mental illness (Browne-Miller, 2007, pp. 14 and 168). Men who batter frequently tend to use alcohol as an excuse for violence. However, there are many abusive men who do not drink heavily, and conversely, many alcoholics do not beat their partners.

Alcohol is the main drug used by the aggressor/partner at the time of the aggression. The aggressor/partner is often unemployed or has no fixed income, while the woman is often economically dependent on him and fears his threats to kill her if she leaves him. When women are pregnant, aggression is frequent. Women often report men changing because of "aversion" to the "pregnant body," because they are jealous of the future baby, or because they have suspicions about paternity (Monteiro & Oliva, 1993).

DIAGNOSIS

Specific gender-related factors for the diagnostic evaluation of alcohol and drug abuse (or dependence) have not been recommended. There is emerging evidence that the lack of specific gender-related diagnostic criteria may compromise the quality of psychiatric evaluations (Mendelson & Mello, 1998). Women may underreport alcohol consumption while pregnant, and direct questions about drinking may provoke denial (Ernhart, Morrow, & Sokol, 1988). Also, medical biases are established against those women who will never be mothers and who are older, although epidemiological data point out that in some countries, such as Mexico, women begin to drink precisely in their fourth decade of life, when they feel they have moved beyond their period of fertility.

On the other hand, health professionals tend to deny women's alcohol consumption as well as the occurrence of other problems such as violence or HIV. As Morse, Gehshan, and Hutchins (1997) state, "everyone agrees that these problems exist—but not in their practice" (p. 3). As a result, inquiring about drug and alcohol use is often neglected, but especially when providing prenatal care.

Brief instruments, such as the TWEAK (an acronym for *Tolerance* [number of drinks to feel high, number of drinks one can hold], *Worry* about drinking, *Eye-opener* [morning drinking], *Amnesia* [blackouts], and *Cut* down on drinking [K/C]), which incorporates questions about tolerance to alcohol, can be more sensitive than other instruments to a woman's risk of drinking during pregnancy (Russell, 1994).

BARRIERS TO TREATMENT AND TREATMENT MODALITIES

Recovery is a long-term process that involves every aspect of a person's life, including economics, relationships to others, and a redefinition of personhood. Gender is a major element in the way the recovery story develops, the way shame impacts recovery, and how social support materializes and can be—and is—accessed differently by women and men (Davis, 1997). Designing strategies to cope with family, spouses, and/or friends who act as barriers to recovery may be an important skill to develop.

Women face many gender-specific barriers that may limit their access to alcoholism treatment. These barriers can be internal and external. The latter can be further differentiated into interpersonal and structural barriers. In general, there seem to be differences between men and women in how they find their way to treatment. Problems in the workplace often push men to treatment, while in the case of women, family-related issues are often the most prominent (Makela et al., 1996). Also note that alcoholic women are more likely to get divorced when they enter treatment, or to get married to or live with an alcoholic significant other, than men (Gundmundsdottir, 1999; Romero & Durand, 2007). They are more likely than alcoholic men to link the onset of pathological drinking to a particularly stressful event (Blume, 1988).

Women are more likely to have histories both of suicide attempts and of previous psychiatric treatment. Their main reasons for entering treatment and the problems they perceive as related to alcohol are more likely to be health and family problems, whereas in the case of men, job problems and troubles with the law, particularly arrests for driving while intoxicated, are more prevalent.

Various studies have shown that women have histories of other drug dependencies along with their alcoholism—particularly dependence on tranquilizers, sedatives, and amphetamine (Graham & Wilsnack, 2000; Romero, Medina-Mora, Villatoro, & Durand, 2005). Female alcoholics are also more likely to have symptoms of psychological distress, such as anxiety and depression, and to have lower self-esteem than their male counterparts (Gundmundsdottir, 1994), but men are diagnosed more frequently with antisocial personality (Hesselbrock, 1991).

Women used to be underrepresented in alcoholism treatment (Dawson, 1996; Weisner, Greenfield, & Room, 1995; Weisner & Schmidt, 1992). However, according to Green (2006), recent studies suggest that gender either has no effect on treatment initiation or, if it has an effect, women are more likely than men to initiate treatment. Now women appear at least as likely as men to engage in and complete a treatment. On the other hand, men and women are

equally likely to complete treatment, but women who complete are nine times more likely to keep themselves abstinent than women who do not; men who complete treatment are only three times more likely to keep themselves abstinent than men who do not. Current research suggests that women's treatment outcomes are as good as, or better than, men's.

Women in substance abuse treatment are less likely to suffer a relapse than men in treatment. When women relapse, their reasons for going back to substance abuse differ from men's. According to Walitzer and Dearing (2006), relapse rates are similar across genders. Although negative mood, childhood sexual abuse, alcohol-related self-efficacy, and poorer coping strategies predicted alcohol relapse, gender did not moderate these effects. Gender did moderate the association between marriage and alcohol relapse. For women, marriage and marital stress were risk factors for alcohol relapse; among men, marriage lowered this risk. This gender difference in the influence of marriage on relapse may be a result of partner differences in drinking problems.

Alcoholic women are more likely to get married to heavy-drinking partners than alcoholic men (Romero, Mondragón, Cherpitel, Medina-Mora, & Borges, 2001); thus alcoholic women may be put at risk of relapse by marriage, and alcoholic men may be protected by marriage. Few studies document gender differences in substance abuse relapse, and consequently conclusions, are limited and tentative. In contrast to the lack of gender differences in alcohol relapse rates, women appear less likely to experience relapse to substance use compared to men. Women relapsing to substance use appear to be more sensitive to negative affect and interpersonal problems, and they are more likely to relapse when their romantic partners are substance users (Covington, 2002).

Pregnant, Alcohol-Abusing Women

Pregnant, alcohol-abusing women must be provided with comprehensive addictive and obstetrical care and psychosocial counseling. Care must be given in a supportive, proactive, and nonjudgmental way in order that women can know that sharing confidential information with health care providers will not render them liable to criminal prosecution. They should be evaluated in a hospital setting, where a complete history and physical examination should be performed, and target laboratory tests should be carried out to evaluate the woman's overall health status. Maternal-infant attachment should be fostered both prenatally and postpartum; emphasis should be placed on enhancing parenting skills; and the ability of the mother to care for the infant after discharge from the hospital should be assessed by frequent observation at home and in clinical settings (Boyd, 1999; Finkelstein, 1993; Finnegan & Kandall, 1992).

CONCLUSIONS

The majority of addiction research, literature, treatment, and clinical practice is still based on male experience. Unfortunately, stereotypical views of women, lack of acknowledgment of gender differences and gender-based needs, and gender inequalities and inequities are present and based on gendered societies that, with frequency, exclude, or at least downgrade in significance, women's lives and experiences (Covington, 2002). Health staff, legal professionals, and policy makers need to be fully sensitized to a gender framework to have alternative and more realistic points of view of alcohol and drug use among women, and among men as they relate to women.

NOTE

1. The Gender Development Index is a good example; this index is a measure of human development that adjusts the Human Development Index to reflect inequalities between men and women along three different dimensions: a long and healthy life, knowledge, and a decent standard of living (PAHO, 2007).

Chapter **5**

Ethical Theory and Addiction

Ann N. Dapice, PhD

The more we learn, through brain imaging and genetics, about the variety of addictions and the numbers of addicted worldwide, the more we realize the moral and ethical challenges we face. We are presented with an illness that results from nature, nurture, or toxins from the physical environment—or a combination of these factors. The use of moral development, value analysis, psychological type, and ethical theories is critical to address the challenge of addiction, whether to tobacco, alcohol, cocaine or other drugs, food, gambling, online pornography, or shopping. The consequences of addiction vary greatly—from chronic disease to sudden death. The social and financial costs of these addictions eventually affect us all.

The addiction illness appears related to once adaptive responses gone astray (Dapice, 2006; Fisher, 2004; Popkin, 2007). The illness causes people to act in ways that can result in danger to themselves and others. What are the ethical responses? If we cannot, or do not, stop addictive behaviors that are dangerous to us and society, whose responsibility and obligation is it to protect all who are endangered? Our jails are full of the addicted as well as the addicted mentally ill, and our statistics from treatment and interventions remain dismal. When the consequences of addiction lead to child abuse and neglect that result in continuing generations of addiction, the question again arises, Whose responsibility is it to intervene? These questions are at the heart of ethical and moral examination.

Until recently, the so-called medical model has generally not placed blame on individuals who suffer from a disease. In the classical model, there has been

an expectation that individuals who have an illness will attempt to obtain treatment and, whether treatments are successful or not, those who are ill will not be held responsible for the success or failure of the treatments. For example, if individuals are diagnosed with cancers not related to known behaviors, and they undergo treatment for the cancers, relapses of the cancer will be seen to be either the result of ineffective treatment, or no effective treatments yet available. This is especially true in that cancer treatment is mainly carried out by physicians and nurses and is not left to cancer victims to treat by themselves. In recent decades, the use of nicotine has been an exception as research came to show clearly the relationship of cancer as well as other illnesses to tobacco use.

Increasingly, however, it is understood that certain lifestyle activities, such as overeating, lack of exercise, and heavy use of alcohol, lead to disease. People are beginning to be held accountable accordingly. Food cravings and even lack of sleep (University of Bristol, 2004) lead to obesity, type 2 diabetes, and cardiovascular disease. We learn how obesity is linked to cancer, and we are warned by Laura Beil (2008) that "among all preventable cancer risk factors, only smoking claims more lives" than obesity (p. 104). We begin to examine questions of obligation and responsibility. Research tells us that use of tobacco affects not only the user but also others through secondhand smoke, and a study at Duke University (2004) documents that prenatal nicotine causes lasting damage, leaving the infant brain vulnerable to injury and addiction upon later use of the drug.

Using values, moral development, and psychological-type research, along with classical and modern ethical theories, this chapter responds to issues of addiction by examining the challenges we face with an ever growing and increasingly diverse body of knowledge on the nature of addiction. Prevention, intervention, and treatment for addiction as well as punishment for illegal addiction also vary greatly and on an increasing basis. The study of moral development and values among humans is required to begin to respond to this complex, multifaceted dilemma. With that knowledge, ethical theory can then be used to analyze the ethical dilemma of addiction that we find ourselves confronting.

MORAL DEVELOPMENT

Building on the work of Piaget, Kohlberg (1984) developed and researched a six-stage model for moral reasoning. Each stage is seen to be qualitatively better:

Preconventional Level (Egocentric)

Stage 1. Avoidance of punishment and deference to power: "eye for eye and tooth for tooth"
Stage 2. Satisfy self and occasionally others (ethical egoism)

Conventional Level (Ethnocentric)

Stage 3. Behave for approval of others; manners and peer pressure
Stage 4. Orientation toward authority and fixed rules: the 10 Commandments

Postconventional Level (Universalizing)

Stage 5. Right action defined after examination; social contract: the U.S. Constitution
Stage 6. Individual conscience and self-chosen ethical principle: the Golden Rule

The addicted, their families, counselors, researchers, policy makers, and lawmakers can all be seen to be at one of three levels and within one of the six stages of moral development. Kohlberg's research showed most people to be at stage 3 of moral reasoning—behaving for the approval of others—with fewer individuals at the lower stages and fewer still at higher stages. In a sense, stage 3 is an ego-ethnocentric stage since it is the approval of one's family and known groups that is sought, not that of outside groups.

Applied to addiction, a person at stage 1 would be dissuaded from activities of addiction out of avoidance of punishment and deference to power. Family members, counselors, researchers, and policy/lawmakers could all reason at this, the punishment/revenge, stage. At stage 2, people will act just to satisfy themselves. An interesting thing happens, however, at whatever stage the addicted individual *can reason:* acting on the addiction moves the individual to stage 2—in spite of possible punishment (stage 1), in spite of lack of approval from others (stage 3) or laws (stage 4)—and even if the individual can reason at a higher stage 5 or 6. In a similar way, families, counselors, researchers, and policy/lawmakers, depending on their moral development, could make moral decisions based on punishment or revenge (stage 1), to satisfy themselves (stage 2), for approval of others (stage 3), because of fixed rules and laws (stage 4), or by determining what is right based on examination (stage 5). Finally, they could make decisions based on conscience and ethical principle (stage 6). True moral and ethical decision making requires development to stage 5 or 6—least represented in Kohlberg's research.

Not only did Kohlberg utilize Jean Piaget's understanding of cognitive development in his theory and research, but later in his life, Kohlberg related moral behavior to Piaget's theories of socialization for autonomy. In studying the relationship of cognitive judgment to action, Kohlberg and Candee (1981) observed that there are two decisions to be made in moral action: (1) the decision of what is morally right (deontic judgment) and (2) the commitment to act (judgment of responsibility) on one's decision of what is right. Kohlberg and Candee found that people who had been socialized for heteronomy (obedience to authority) would make the deontic choice, but might not follow through on the commitment to act. They would assume that the responsibility to act (or ensure action) lies with those in authority. People who had been socialized for autonomy acted on behavior more similarly to stage 5 individuals, even though they could not reason at that stage. They intuited what they could not consciously reason or understand. In general, people at higher stages of reasoning were more likely to carry through on moral action. From this research, we can say that attempts to respond to the problems of addiction will only be taken by those at higher stages of moral reasoning or those who have been socialized to be autonomous and take responsibility. Others may admit there is a problem with the present, largely ineffective response to addiction, but not feel any obligation to take action.

VALUE RESEARCH

Kohlberg's work was based on conscious reasoning in response to a situational dilemma. Dapice (1997) studied more than 6,000 individuals using the Values Unfolding Instrument (VUI) developed to allow access to less conscious values. These individuals came from a variety of backgrounds and included men and women from 27 countries, all races, and six religions, ranging from 14 to 96 years of age. Continuing results from analyzing responses to the VUI are as follows:

1. Initial values stated by individuals unfold to deeper values only 6 percent of the time. As values unfold in response to the question "why is that important?," quite different values and themes develop. Some of the themes may be in direct conflict with each other.
2. While people's values vary tremendously, nearly all values first listed show concern for others (e.g., love, compassion, fairness, etc.—*ideal* values) but unfold to values that are concerned with self (*real* values).
3. One's gender, race, occupation, geographical region, national origin, and religion make no difference to whether one unfolds values that are concerned with others.

4. While people most often first state values with an orientation toward others, when there is a conflict in values, people's behavior matches their unfolded values focused on self (e.g., feeling good, success, status, feeling loved and appreciated).

Therefore the research shows that the large majority of adults (93%) are self-oriented at the less conscious level but consciously believe themselves to be otherwise. They may act in ways that help others, but only if doing so accomplishes values important to them—feeling good, success, feeling loved, and so on. This knowledge is critical to the understanding of how we respond to the challenge of addiction.

The value unfolding research corresponds to what Paul Tillich (1957), a noted theologian, described as our *god values:* the core or central values that exercise power in our lives. These are the values that we give all our time and energy to. Tillich said a god value could be career, power, or prestige, or it could be a love relationship, one's family, an institution, or a larger cause. In the case of addiction, the substance or behavior can become the god value that exercises enormous power in people's lives, allowing people to behave in ways that otherwise they might not.

PSYCHOLOGICAL TYPE

Four different continua compose the Myers-Briggs Type Inventory (MBTI):

Extroverts (E) focus on the outer world of people and things, while introverts (I) prefer an inner world of ideas and impressions.

Sensing (S) types focus on the present, with a preference for concrete information gained through the senses, while intuitive (N) types prefer the future with a perspective of patterns and possibilities.

Thinking (T) types prefer to base their decisions on logic and objective analysis of cause and effect, while feeling (F) types focus on values and subjective information of person-considered concerns.

Judging (J) types want a planned and organized life with decisions made, while perceiving (P) types like a flexible and spontaneous approach to life and prefer to leave their options open.

These four preferences yield 16 different types, for example, extroverted, sensing, feeling, and perceiving. In many ways, the different types experience quite different worlds and realities. In terms of moral and ethical responses, Myers (1980) wrote that each type has positives and negatives, but different

types are "likely to go wrong from different angles" (p. 25). When an introvert breaks a moral principle, "it may be knowingly and with bitterness"; extroverted intuitives and judging extroverts "may consider that the ends justify the means"; extroverted sensing types are most likely to "drift into wrongdoing" (p. 181).

A comparison of people who completed the VUI, the MBTI, and written journals that described their behaviors (all anonymously coded) yielded the following observations (Dapice, 1997):

1. Extroverts have more difficulty taking moral stands if it means a lone decision. Introverts may not sufficiently attend moral issues in the external environment and may avoid moral actions that require interaction with people.
2. Sensing types have more difficulty going beyond their more concrete and fact-bound reality to take on the role of the Other—an ability necessary for mature moral action. Intuitives may play with moral ideas but not act on them.
3. Thinking types often are insufficiently aware of hurting others and thus may have difficulty with empathy. Feeling types may use insufficient reason to project the consequences of their actions.
4. Judging types too often make moral decisions with inadequate information. Perceiving types often do not make moral commitments (decisions) and have difficulty completing tasks related to commitments of a moral nature.

More specific to the data, scores for intuitives are slightly higher on altruistic values, and intuitives are more likely to be universalizing in perspective (Dapice, 1997). Sensing types, as documented by some of the literature on Myers-Briggs types (Keirsey & Bates, 1978), are more likely to be bound to their known reality of family and group. Carl Jung (1923/1971) wrote that each type needs to develop the less preferred side for wholeness and goodness.

MORAL EPISTEMOLOGY—IS, OUGHT, AND IMPERATIVE

Religions have often referred to addictive behaviors in terms of sin: gluttony, drunkenness, lust, sloth, greed, and so on. Accordingly, religions have prescriptives against many so-called sins. However, on the whole, such age-old lists of sins seem not to have been slowed much by the prescriptives. When viewed as once adaptive behaviors instead of sins, what help do we find from ethical theories that can assist in this complex situation we call addiction?

In moral epistemology, there are three levels of understanding (Dapice, 1997):

1. The *descriptive*, which, while once the territory of philosophy and religion, is now generally seen to be grounded in science. Its tools are description,

correlation, and inference. It can pertain to both a particular group and culture. It can also describe research that applies to a universal or global setting.

2. The *prescriptive*, which is the area of philosophy, religion, and law. It is the language of should and ought. Generally, these shoulds and oughts are particular to a certain group, culture, religion, and nation. Examples of this level are prescriptives such as the following: children ought to obey their parents, elders should be honored, and conditions for taking human life (just versus unjust war, capital punishment, self-defense, conditions for divorce, etc.).
3. The *imperative*, which is the area of philosophy, religion, and international (versus national) law. Examples of this include cross-cultural commands such as the Golden Rule, held as an ideal across religions over thousands of years; its philosophical cousin, the Kant Imperative; and international agreements about treatment of prisoners of war and the Nuremberg Code. Imperatives *must* be capable of being generalized to *all* and reflect the essence of *being* (e.g., dignity, justice, love, treatment of other beings, etc.).

Discussion to this point has involved the descriptive science about moral development, value research, and research related to Myers-Briggs types. It has included worldwide or universal findings. In ethical language, the preceding discussion has been what "is" the case about addiction, not what "should" be the case, or what imperatives require in response to this worldwide challenge. Science can tell what is, and it can point to likely consequences, but it takes another layer of analysis to determine what ought to be.

ETHICAL THEORIES

Three questions require response and are critical to the area of addiction:

1. Do we humans have free will, or are we and our actions determined for us?
2. A related question is, Are we to intervene in the world as we find it; in other words, are we to try to make it different or better, or are we to accept it as it is?
3. Knowing what a situation is, how do we decide what it ought to be?

The answers to all three questions are important to the understanding of ethical reasoning.

What is the impact of understandings of free will and determinism? In scientific terms, addiction appears to be overdetermined by both nature and nurture. For society as well as all individuals directly affected, questions of free will and determinism are not simple or frivolous. These understandings have major implications for everyday life as well as for large-scale social policy. If we believe,

for example, that behavior is genetic and thus determined, we will respond differently than if we believe that a person has chosen to behave badly. Either argument can have a variety of responses. In one case, it may be decided that the behavior is genetic and people with those genetic characteristics should not have children—a decision similar to deciding that people who carry genes for severe physical disease should not bear children because of the potential suffering of the children. Or, as scientific consensus grows that the nature of addiction is not solely based on free will or an individual's conscious choice (Saah, 2005), a different response would be that addiction needs to be perceived and treated as a disease with appropriate intervention and treatment.

If, however, it is believed that the behavior is a choice and not predetermined, the addicted are seen as responsible for their actions, and either incarceration or other compensatory action is required. Psychiatrist Amen (2005), after completing many scans on human brains, came to the conclusion that the amount of free will anyone has is determined by the health of the brain—that people with healthy brains have a great deal of free will, and that those with damaged brains (e.g., obsessive-compulsive disorders or drug and behavioral addictions) have significantly less, and those with Alzheimer's disease have almost none.

Increasing numbers of conditions are being classified as genetic and/or physiological in origin. Conditions once thought to be bad behavior are now termed disease. Decisions about responsibility, about who is responsible—and thus societal policy and law—are changing accordingly. In the field of mental illness, we already have ethical questions about whether people with a mental illness have a right to make free-choice decisions to refuse medication that makes their behaviors more socially acceptable—when such medication often causes uncomfortable side effects. Does someone who is mentally ill have the ability to make such a choice if that is part of the nature of the illness? Freedom and responsibility are therefore issues that are at the center of ethics. They are also at the center of how we respond to people who are addicted—and those who may suffer because of the addictive behaviors of others. For this reason, it is critical to use the best science that exists to address the problem of addiction. At this point, many in the United States, but not all, will say that addiction is a disease, yet still blame relapse on the addicted because "they didn't work their program" or "they weren't spiritual enough." With prisons full of people whose only crime is use of drugs or alcohol, it is clear that at this point in time, it is the individual who is held responsible for the addiction.

In the understanding of *psychological egoism*, all human actions are seen to be motivated by selfish desires. This view agrees that people may do things for others—but only as a means to their own happiness. In the description given

previously, psychological egoism is descriptive, not prescriptive. It not only said that all people are selfish, but that they are incapable of being otherwise (Feinberg, 1987). In the Dapice (1997) research discussed previously, it was demonstrated that at the less conscious level, the large majority is self-oriented, *but not everyone is,* and for nearly all persons, the initial conscious values indicate an orientation to others. In other words, people think that they should be concerned for others, or should at least appear to be, even when they are not.

The theory of *ethical egoism* said that people *should* act according to their own self-interests—thus it is prescriptive, not descriptive. Furthermore, ethical egoism holds that this principle must be universalized to all. People should serve their own interests. The "good" that makes up people's interests may be defined as happiness or pleasure, or it may be of a more "enlightened" nature. For example, one might help others to bring benefit to oneself because not doing so would have negative consequences on long-term self-interest (Frankena, 1973). This is considered to be the business ethic—although not all in business use this ethic. Because professionals are expected to work at a higher level of moral reasoning and action, problems occur when professionals begin working for profit-making institutions. Since professionals in the United States are increasingly employed by for-profit corporations, this has become an area of ethical concern.

According to utilitarian theory, we should choose the alternative that will result in the greatest total good for everyone, regardless of the impact—positive or negative—on those making the decision (Hospers, 1982). As in egoism, the good may be considered happiness or pleasure, or it may be of a higher order, such as helping others (Sher, 1987). John Stuart Mill (1987) stressed that the moral agent is required by utilitarianism to be strictly impartial as a disinterested and benevolent spectator. He gave the examples of the Golden Rule and "loving your neighbor as yourself" as ideal utilitarian morality. A special problem with utilitarianism concerns its use to exclude minorities in a democracy. In the name of maximizing the good for the greatest number of people, theologian George Tinker (1996) has written, "Utilitarianism continues to exert its powerful influence on political practice to such an extent that abject racism can thrive, rationalized as being in the best interests of the state" (p. 167).

Utilitarian theory is the ethic of science. Scientific study often necessarily involves actions that may result in good for many, but not for all. A typical example is a study that involves a research control group. Other variables can affect outcomes. If a control group is used and the method shows positive results, those in the control group will not benefit or will have to wait until a later time to benefit—which, in cases of disease, may cause longer suffering or be too late.

For the scientist, there may be a number of motivations. Research has long been a step toward promotion and tenure in the university setting, so self-oriented motivation cannot be ruled out. For the university, it may bring in grants and money. If the scientist is also a physician, for example, the physician's obligation to the individual patient is different from the obligation of the scientist to research, so there is often a legitimate conflict. In addition to the conflict between the ethic of the physician and that of the researcher, the utilitarian perspective can conflict with that of business. Again, as some research and medical facilities have become for-profit concerns, a conflict may exist between the requirements of quality research and those of the business bottom line. In general, scientific studies must be examined, including those reported previously, for possible conflicts of interest.

Deontological theory is the professional ethic. The Golden Rule and the Kant Imperative are the most common examples of deontology. (Also seen by some philosophers as an example of utilitarian theory.) A frequent misinterpretation of the Golden Rule by less mature individuals is that immature people—and societies—often understand and act on "do unto others as they have done unto you" (Kohlberg stage 1, revenge) or "do unto others so they will do for you" (Kohlberg stage 2). Another difficulty of egocentric individuals is that they make behavioral decisions based on their own preferences, that is, "I like chocolate, so everyone should." In addiction treatment, it would be, "it worked for me, so everyone should have this treatment."

Immanuel Kant (1724–1804) attempted to address this problem. His *Categorical Imperative* stated, "Act as if the maxim of thy action were to become by thy will a Universal Law of Nature" (Hospers, 1982, p. 186). In doing so, he clearly universalized the principle (Hospers, 1982, pp. 186–188). Furthermore, Kant stated that all human beings are to be treated as ends in themselves and never merely as means to ends (Albert, Denise, & Peterfreund, 1988).

The deontological understanding that people are to be treated as ends and not means is the nature of the professional agreement. Patients who assume they are being treated according to their own best interests should not be limited to the interventions of a research project in which their physicians may be engaged—at least not without the consent and desire of the patient. Similar conditions apply to therapists, lawyers, ministers, and professors. It is the interest of the client that is the focus. The frequent vulnerability of clients' situations, especially in relationship to the power of the professionals' status and extensive knowledge, requires a special level of trust and confidentiality and an assumption by clients that advantage will not be taken of them. When people go to physicians due to illness, for example, it is important that they know that their physicians will determine the medication or treatment or surgery that is

best for them and not one that their physicians happen to use based on their own convenience or benefit. In addiction, the goal needs to be what will best help the client's problem with addiction, not the preference of the professional, or a one-size-fits-all treatment, as so often happens in addiction treatment. The needs of clients, not professionals, should be reflected in professional codes of ethical conduct.

How big is "all"? The problem of the size of the universe to be universalized is an old one. In historical Greek times, the universalizing perspective excluded women, non–property owners, and slaves in the same way that earlier in U.S. history, voting in the democracy excluded women, blacks, American Indians, and other groups. Part of the ethnocentric problem is that we may not perceive some people as fully human. Sometimes exclusion is purposeful, but often, others unlike oneself just are not seen.

There is yet another understanding of the inclusivity of "all." Tinker (1996) notes that the "Greek word *cosmos*, translated 'world,' is usually interpreted . . . as referring only to the world of human beings." He continues, "The danger of such privileging of human beings should be obvious. It runs the risk of generating human arrogance, which too easily sees the world in terms of hierarchies of existence, all of which are ultimately subservient to the needs and whims of humans" (p. 156). The Lakota phrase *mitakuoye oyasin*, translated as a "prayer for all my relations," is "inclusive not only of immediate family or even extended family, but of the whole of a tribe or nation; of all the nations of two-leggeds in the world; and particularly of all the nations other than two-leggeds—the four-leggeds, the wingeds, and the living-moving things." Humans in this view are seen as part of a whole, who have particular responsibilities to that whole—as do all the "createds" (p. 158). In this sense of Otherness is a special understanding. Violence cannot be done, even through harvesting and hunting for survival, without an act of reciprocation through prayers and ceremonies to restore the balance of existence. Such a perspective gives the understanding of the "do unto others" of the Golden Rule a much larger interpretation. The way in which animals are used in much of scientific research is important to consider here. Humans, of course, are also used in research, but for four-legggeds and two-leggeds, research requires humane treatment. This has too often not been the case. Since plants are also among the living things that make up the universe, we can say that they should not be used abusively or addictively either.

MODERN ETHICAL THEORIES

Rawls's (1971) *distributive justice* has two principles. The first principle is that each person has an equal right to the most extensive basic liberty com-

patible with the liberty of others. What does this mean, then, regarding the addicted and those who may become their victims? The second principle is that social and economic inequalities are to be arranged so that they are both expected to be to the advantage of all and attached to positions and offices open to all (Albert et al., 1988). What does this mean, again, in relationship to professional and legal responses to those who are addicted and their potential victims? How are inequalities arranged in the situation of addictions—their access to research-based treatment, for example?

Frankena's (1973) *theory of obligation* teaches us that we must do good—the results must be good, not just that we want or intend to do good (Frankena, 1973). We ought to do the following:

1. *Not to inflict evil or harm*. Inflicting harm can be seen to be the case when substitutes are given to addicted clients—such as nicotine gum, methadone, or benzodiazepines (Amen, 2005)—which are in and of themselves known to be addictive and can be toxic to the brain. Inflicting harm can also be prescribing addictive pain medications over a long time.
2. *To prevent harm*. The frequent practice of telling addicts that relapse can be expected, although perhaps well intended, can become self-fulfilling prophecy and does not prevent harm to them, their families, or innocent others.
3. *To remove evil or harm*. It is critical that addicted people not engage in activities that are harmful to themselves and others, for example, driving vehicles or abusing others while under the influence or committing crimes to pay for illegal drugs, gambling debts, and so on.
4. *To do or promote good*. It is critical that professionals update their practice related to ongoing addiction research and related treatment and that professionals not just continue old methods of "doing the same thing, expecting different results" in intervention and treatment.

Firth's (1970) *ideal observer theory* has five characteristics of moral decision making. The first, *disinterestedness or dispassionateness*, means being impartial, *not* that one does not care. It means that one has no egocentric or ethnocentric interests at stake. The second, *omniscience*, means that one obtains all the information one can about a situation. The third, *omniprecipience*, means seeing implications and consequences of actions as if one is experiencing them oneself. The fourth, *consistency*, means reacting in the same manner to the same given act. And the fifth, *normality*, means that we are not sick, hungry, tired, cold, overly stressed, and so on, when making a moral decision. This has major implications in jobs and professions where many errors occur due to regressive conditions. It is also a factor in much family and violent crime.

With regard to the first characteristic, being *disinterested*, it is easy to assume that because we are professionals or researchers, we are, of course, not operating

out of self or group interest. That often requires further examination. Do we counsel using our personal likes or dislikes, what our peers say or think, what the professional norm requires in treatment if not based on recent research—as opposed to what is in the client's best interest? The second characteristic, *omniscience*, requires not that we can be all knowing, but that we obtain all the information and knowledge we can to best serve others—that includes ongoing updating of our scientific knowledge and skills so we can better respond to the problem. While most professionals are required to obtain continuing education credits, there is rarely testing of this knowledge to determine the professional's actual understanding of new research needed to more successfully treat clients. The *omniprecipient* characteristic is often difficult for professionals in dealing with clients. Attempts to accept consequences of actions as if we were experiencing them ourselves is where much burnout occurs. There are few resources to support professionals with the exhausting impact of taking on the role of the suffering Other. Often, in misplaced attempts to "not get too close to the client," we use professional distancing techniques that are both well taught and well learned. These serve to protect us from the often painful reality presented to us. How do we manage our own emotions at the same time we use compassion in serving our clients? Another challenge is the human problem that we too often have difficulty understanding experiences until they happen to us. On the other hand, in addiction treatment, there are many professionals who are in recovery themselves. The temptation here is to believe that their experiences are identical to those of the client or that treatment should be the same as theirs was. The *consistency* question arises especially in how we treat people with differing status and power. Do we react in the same manner with each individual regardless of race, religion, socioeconomic status, and so on? Do we treat the addicted differently if they are in powerful or moneyed positions? Are they placed in jail (punished), as many addicted are, or given a choice to check in to a treatment center that they can afford? It would appear, on the other hand, that when people in power are arrested for drunk driving, they may be more likely to make the news. Regarding *normality*, as professionals and humans, we know that sometimes we are too tired or sick or overly stressed to make an ethical decision or help a client make a decision. Outpatient centers are often understaffed and underfunded. In life experiences, people have often been taught that they are to accomplish the work given to them without question. Most employee handbooks do not give time to think about and consider a client problem. This is a pragmatic, but overlooked, consideration.

Each of these theories shows that practicing in a professionally ethical way is not as simple as following a set of rules set by one's profession. These ethical theories provide practical ethical guidelines to remind us what being an ethical person actually requires. And these principles are not limited to professionals. Most of

us were taught the Golden Rule as a standard. These modern ethical guidelines help us to do the Golden Rule better—to do unto others as we would have them do unto us, not as we have too often been done unto. As we learn more about the science of any problem, we are challenged to develop better responses through treatment, policies, and laws to meet our ethical obligations better.

It becomes clear that conscious choice and free will are markedly reduced. On the basis of scientific research of moral development, most, as described previously, are at an unconscious developmental stage 2—seeking to satisfy themselves and, occasionally, others. Even if the addicted can reason at higher levels of development, addictive substances and behaviors, having hijacked their brains (Amen, 2005), cause their victims to act at stage 2. While most people now call addiction a disease, the most frequent intervention and response to addiction is stage 1 punishment and use of power—either in jails, or programs that tend to shame the addicted—for "not working the program." Since clients operating at stage 2 choose the reward of the substance or behavior over fear of punishment or ill effects, this neither works as intelligent operational policy nor as a way to treat a disease. The number of persons who, at a less conscious level, operate with altruism toward others is about 7 percent, making ethical decision and action dangerously low.

Who are the beneficiaries of addiction? There are, of course, many—whether food, tobacco, alcohol, cocaine, prescription drugs, gambling, video games, or pornography. The expectation of business, and distributors of street drugs, is profit. They are at stage 2 business ethic. Similarly, services, whether treatment facilities or prisons, provide employment.

Who suffers? The obvious victims are the addicted, their families, and the innocents affected by child abuse or death on the highway. Less obvious at first are those who suffer from our two largest and most costly addictions—food and tobacco. This suffering includes type 2 diabetes, cardiovascular disease, and cancer. But it also includes the results of a mother's smoking in pregnancy—children with low birth weight, likelihood to addiction, antisocial behavior, and attention deficit–hyperactivity disorder. In behavioral addictions, we see a range of results, from children victimized by Internet pornography, to loss of families and incomes from gambling, to death, to the victims of stalkers. Clearly the addicted meet the longtime standard of being "dangerous to themselves and others"—whether through chronic disease, secondhand smoke, driving under the influence, suicide, or crime to pay for illegal drugs. Whether from insurance rates, taxes, or low productivity of workers, the financial costs to society are staggering.

While law enforcement will generally use punitive measures with those who drive under the influence and who possess illegal drugs, this is unevenly

enforced with women and minorities, who are more likely to be arrested for similar crimes, while others go to treatment. Yet in stalking, there is a curious reversal where the most lethal and violent of criminals are rarely arrested or convicted, even when protective orders have been put in place by the victims (Meloy, 1998). While stage 1 punishments rarely stop the addicted, there is a need is to stop negative and dangerous behaviors while protecting victims from suffering—and even death. Stalkers, like others who are addicted, will say that they cannot stop. Stopping the behavior becomes important for all those who are addicted—as well as for their victims.

Science gives clear evidence from brain scans that the addicted have limited or little free will. Rawls's (1971) distributive justice says that people should have "extensive basic liberty compatible with the liberty of others" (p. 302). The addicted, especially those who believe that their addictions do not harm others (e.g., food and tobacco), most often claim their rights to eat and smoke as they wish. Obesity is a special problem, for which the argument is often given that weight is a matter of choice and society should not cave in to so-called anorexic norms. However, unlike tobacco, it is necessary to eat to live. People cannot stop eating in the same way that they can stop smoking or drinking alcohol or abusing prescription drugs. Obesity is often a delicate matter because people feel embarrassed when weight is mentioned. Meanwhile, the costs of obesity continue to rise, from health costs that we all share to airline reservations where seats are narrower and people are, literally, wider. Whose rights? Whose responsibilities? Beyond economic realities, do people have a right to cause the suffering of others, whether through disease, abuse, or death? If, due to the nature of the disease, they are unable to meet their responsibilities, then what?

The good news is that in only a few years, we have taken a sharp turn in our consciousness about the problems of obesity. There is new understanding of the kinds of foods and nutrients that are needed by the body and brain. Emphasis on obesity has gone public and is now part of public policy—removing soda machines from schools, adding exercise at school, incentives in the workplace, and so on. Schools and entire cities are changing their diets, led by their elected officials. Perhaps the one addiction that we cannot do totally without will lead the way to success in addressing all of the others.

CONCLUSION

The state of addiction is that we have tremendous numbers of addicted and a larger array of addictions worldwide. Suffering and costs are beyond calculation. Brain scans show the amount of damage in the brains of the addicted. This damage can be clearly seen by all. It does not take an expert to tell which is

a normal brain and which is a damaged brain when the pictures are placed side by side. This is especially important to sensing types for whom seeing is believing. Scans show the functional limits of a damaged brain and thus the limits of free will. If choice is beyond the ability of the addicted to make, whose obligation is it to stop the behavior? With a majority of the population at lower stages of moral development, addicted or not, there is little likelihood that decisions will be made based on higher ethical principles. What are the choices? The ethical question is, What *ought* we to do, or what is it *imperative* that we do?

There are options. There are teaching and learning strategies that can be used to encourage professionals—and the addicted, once they are healthier—to move to higher levels of moral reasoning and responsibility (Dapice, Cobb, Hutchins, & Siegel, 1988). Autonomy as a moral agent can also be taught and learned. Meanwhile, because of the great cost of addiction to us all, it is in the self-interest of all of us to take action. Therefore the concept of enlightened self-interest can be taught and used when people are not able to understand or respond to the suffering of others. Research already tells us much that can be done to help treat the addicted that is generally not being done now. These measures cost far less than most addiction treatment does now. And more is learned about addiction with every new study published. It will be necessary that the conflicts of interest of corporations and organizations be set aside. Knowledge must direct decisions about what treatments are used, not financial benefit, not refusal to change, and certainly not those in the world who gain from the weakness, illness, and death of others.

In addiction, the world's biggest killers interact with each other and are at stake: obesity, type 2 diabetes, cardiovascular disease, cancer, family violence, suicide, so-called accidental death, and murder. It is not a disease about "them." We are all affected. We all pay the price. An addiction deontology is imperative. Ethical theory teaches us that we must do good—the results must be good, not just that we want or intend to do good. We ought not to inflict evil or harm. We ought to prevent and remove evil or harm. We ought to do or promote good. Much work remains to be done, but we are not without a map to guide us.

Chapter **6**

The Religious and Theological Roots of Alcoholics Anonymous

Rev. Linda Mercadante, PhD

Alcoholics Anonymous (AA) prides itself on being "spiritual but not religious." Its ethos asserts that AA takes no position on religion, proclaims no theological doctrine, and promotes no religious adherence. Many members would be surprised to learn, therefore, that the AA 12 Step program is deeply embedded in some quite distinctive religious and theological roots.

Certainly many scholars, and a few AA members, are aware that founder Bill Wilson was for a time involved in the Christian evangelistic Oxford Group. But they assume that because Wilson broke away from it, the Oxford Group had only minimal influence on what would become AA. This chapter claims instead that by examining the beliefs, practices, and assertions of the Oxford Group, one can see direct and long-lasting, yet hidden, theological and practical links between this evangelistic group and AA. This is not to take a stand, pro or con, about this connection, but simply to note how these roots continue to inform the 12 Step method of addiction recovery.

THE OXFORD GROUP HISTORY

The Oxford Group arose in the early 1900s as an independent religious organization meant to revitalize the American church. It hit its peak in the 1920s and 1930s, when it was popular and widely known. It attracted the mighty, the wealthy, and the influential of American society to its program of spiritual revival. The Oxford Group, in many ways, was a throwback to older ideas of sin and conversion. It privatized morality, insisting that private

behavior, rather than negative social conditions, was responsible for human unhappiness and wrongdoing. In fact, the Oxford Group was a reaction against the liberal *social gospel*, which contended that society as a whole needed reform (Mercadante 1996, 189 n. 5).

The Oxford Group was begun by an ordained Lutheran minister, Frank Buchman. From central Pennsylvania, he had received a conservative pietistic German Lutheran upbringing and an education for the ministry. After a formative religious conversion experience in 1908 at a Keswick conference in England, Buchman's charismatic personality began to attract attention. He had tried various forms of ministry—running a settlement house, working as a YMCA evangelist at colleges, serving as an adjunct professor at Hartford Seminary. But in modeling himself after evangelist Dwight L. Moody (Clark 1951, 117–22), eventually, Buchman hit on what would work best for him. Striking out on his own in a ministry of personal evangelism, Buchman soon gathered a group of loyal young people around him. The group was first called "First Century Christian Fellowship" (1908) but soon took the more prestigious name "Oxford Group" (not to be confused with the Oxford movement) since Buchman had tried ministering at that college for a time (Woolverton 1983).

Buchman's message was essentially simple, but in the theological mode of traditional Protestant Christianity mixed with a nineteenth-century revivalist emphasis. Buchman's concise and spare pivotal concepts can be summarized this way: (1) all people are sinners; (2) all sinners can be changed; (3) sincere and thorough confession is essential to any change; (4) once changed, persons can access God directly; (5) miracles are possible; (6) the duty of changed persons is to change others. The group claimed that this was just basic Christianity put into practice. Astute observers of AA should already perceive some similarities between the foundational concepts of the Oxford Group and those of AA's 12 Steps, but this will be elaborated later (Mercadante 1996).

Bill Wilson, who would later go on to found AA, was first exposed to the Oxford Group in 1934 through his friend and former drinking buddy Ebby T. Ebby had become sober through the group and wanted to share his discovery with Wilson. Wilson, in fact, soon became involved in the group when he responded to an altar call at Calvary Episcopal Church and Mission in New York. This was a headquarters of the Oxford Group, led by group leader and Episcopal priest Samuel M. Shoemaker. Shoemaker had a distinct, long-lasting influence on Wilson, and they remained in contact for many years, even after Wilson had moved on to form AA. At AA's twentieth anniversary celebration in 1955, Wilson invited Shoemaker to give one of the major speeches. Also a devoted member of the Oxford Group was Dr. Robert Smith ("Dr. Bob"), who

would go on to cofound AA with Wilson. He had been involved in the group for several years before meeting Wilson. In 1935, Wilson was on a business trip to Ohio when he felt tempted to resume drinking. Through a series of connections, Wilson met Dr. Bob, another struggling alcoholic. The two men found that by helping each other, they helped themselves (Kurtz 1991).

Even though this one-alcoholic-helping-another method would eventually become the heart of AA, it is important to note that the first link between Wilson and Smith was their appreciation and use of conversionist and evangelistic Oxford Group principles. Both men had been committed Oxford Group members for several years. Their breakaway from the group to form what would eventually become AA took place gradually, the final resolution not becoming completely clear until around 1939.

TROUBLESOME CONNECTIONS

Revivalism

Even though many historians of AA are aware of the prior Oxford Group membership of Wilson and Smith, the Oxford Group roots of AA are often played down or only lightly treated when AA history is discussed (Mercadante 1996, 189 n. 3). Before going on to elaborate the connections between the two groups, we should pause to explore some of the reasons this connection is minimized.

The Oxford Group's pietistic Christian roots and revivalist attitude have long been an embarrassment to many people, including those in the church. Even in the group's heyday, revivalism was considered by many to be a nineteenth-century phenomenon, more connected with frontier than with city. It was not seen as a method or emphasis relevant to modern, rapidly industrializing America, with its increasingly apparent and large social problems. Such roots can seem equally problematic today. An organization such as AA, which stoutly insists it is "spiritual but not religious," would not want to be linked to a distinctly religious approach. Instead, it wants to appeal to a more diverse constituency. In a world of increasing heterogeneity, AA would not want to be seen as a derivative Christian program.

Sin and Conversion

Also troublesome to many is the clear-cut Oxford Group stress on sin and conversion. This was a problem from the beginnings of the Oxford Group. As one grouper noted (Grensted 1933, 19), "the very word [sin] is out of date;

it smacks of street-corner salvation meetings; they think only people who are behind the times believe in Sin these days."

Today the concept of sin poses an additional problem for the recovery movement. Science has made us aware of the many unconscious, biological, and inherited factors in human behavior. Addiction has become a scientific concept, linked with theories of genetics, biochemistry, neurobiology, and the like. Although Bill Wilson avoided the term *disease*, he did refer to addiction as a "malady," or illness (Kurtz 1991, 22). Today, this ethos has progressed further, and addiction recovery in general is based on the principle that addiction is a disease, not a sin. In other words, it is a medical, not a moral, problem.

There are some problematic assumptions in this dichotomy, however. The largest is the misperception that sin is primarily about right behavior—that it is moralistic. The Christian doctrine of sin is not about morality, but about relationality. Sin, as a diagnosis of human dysfunction, focuses on alienation first, with behavior following. Thus sin refers to one's orientation toward or away from God, self, and others. Turning away from sin means turning away from destruction and toward human flourishing. The idea of sin also recognizes that humans are in many ways in a bondage they may not always recognize. They need God's grace not only for their release, but even for the true recognition of their plight (Mercadante 1996, 27–39). In many ways, this refined understanding of sin makes it sound much like addiction.

Nevertheless, this refined theological understanding does not change the popular connotation of the word *sin*. When people reject the concept of sin, especially in relationship with addiction, they are most often linking the theological concept with guilt, blame, and free choice. When sin is seen as moralistic, the human will is assumed to be neutral, aware, and fully functional, able not only to clearly distinguish between good and evil, but able to choose one over the other. Yet ever since St. Augustine, this view has been rejected by Christian theology and labeled "Pelagian." Having a Pelagian understanding of sin denies the need for God's grace and credits humans for being totally free and undetermined. Under this mistaken view of sin, alcoholics have chosen their plight and are fully guilty for their condition.

Clearly this Pelagian view presents problems for AA since the program stresses the out-of-control nature of alcoholism. To even suggest that human control over addiction is possible seems to undercut its primary message (Mercadante 1996). We cannot conclude, however, that the Oxford Group held a fully Pelagian view of sin, even though it did emphasize morality. The group did not expect changed behavior until a person changed his or her orientation and turned toward God. Nevertheless, the group was functioning in a

culture that had already begun to distance itself from such Christian concepts as sin, however they might be understood.

Public Perceptions

Another problematic area is the actual history and public perception of the Oxford Group. Over time, this organization fell out of favor with the public (Mercadante 1996, 189–90 n. 7, 8). Not only was it sometimes ridiculed, but important church leaders, such as Reinhold Niebuhr, protested the Oxford Group's methods and principles. This became acute when—before the outbreak of World War II—founder Frank Buchman endorsed Adolph Hitler as a great leader, saying (Niebuhr 1936, p. 1315), "I thank heaven for a man like Adolph Hitler, who built a front line of defense against the anti-Christ of communism. . . . Think what it would mean to the world if Hitler surrendered to the control of God. . . . Through such a man God could control a nation overnight." The Oxford Group tried to shed the bad press by renaming itself Moral Re-Armament in 1938 and by working on issues of political reconciliation (Luttwak 1994). Although this did give it a new lease on life for several decades after the war, many continued to see the Oxford Group as a retrograde organization. AA's departure, right around this time, was just one more aspect of the public distancing.

These and other factors about the Oxford Group–AA connection keep the theological and religious roots of AA buried. Yet the Oxford Group heritage continues to deeply inform the program, principles, and practices of AA. In fact, at least one person who attended Oxford Group meetings with Bill Wilson insists that (Houck 1995, p. 10)

> to leave out the Oxford Group is like saying that the Ford Motor Company began in 1927 with the Model A. . . . The two people who really gave Wilson and Smith their tools were Frank Buchman . . . and . . . Samuel Shoemaker. The latter was Bill Wilson's spiritual mentor, and Bill always referred to him as his chief source. It was from the O.G. that Wilson and Smith discovered the life-changing mechanisms they brilliantly codified into the Twelve Steps and marketed for the benefit of millions.

COMPARISONS OF METHODS AND PRACTICES

Although its message was not new, the Oxford Group prided itself on its contemporary methods and practices. It presented itself as an active group, not mired down in religious controversy. The group stoutly denied that its program

was theological or its practices anything like church. To engage newcomers, they used small groups, personal invitation, one-on-one interviews, interesting entertainment, and "house parties," rather than anything remotely like religious ritual or services. Members' stories of dramatic change were publicized, and members were available to help newcomers and each other at any time. As one scholar notes (Grensted 1933, 5), "'It Works!' was a phrase more frequently heard in the testimonials and endorsements of the Group program and practices." Members grew quite close to each other, doing much more than just meeting together a few times a week. They formed tight social bonds and sometimes even gave up other jobs to join cooperatively in group work.

Unlike traditional evangelism, which often sought out the marginalized or deprived, the Oxford Group focused especially on the well off and well connected. Since they focused on the up and out rather than the down and out, this made some caricature the group as a "Salvation Army for snobs" (Pound 1976/1985). Yet the Oxford Group had this driving force in common with old-time Christian revivalism: they both wanted to awaken a deep sense of individual sin, they both wanted to prompt dramatic conversion, and they both wanted to reform behavior. No matter what a person's background, sin was the common denominator. Whether you "live on Park Avenue or a park bench," they liked to say, the Oxford Group message and practices were relevant.

Group literature assured readers that no one was too far gone to be saved and changed (Grensted 1933, 5):

> Witnesses will go anywhere at any time to help any one whose life has become a burden of Sin, and will stand by until that person has been set free from trouble and brought to a true understanding of Christ and life. No soul has sunk too far, no case for spiritual cure can go beyond their scope. The knowledge that we are in need and have a need for change in our lives is all that is necessary for these life changes to work on.

Those who "changed" through Oxford Group ministrations were expected to remain faithful small group members and then reach out to other hurting people. Volunteers made up the bulk of the helpers, much self-discipline was expected from them, and if they had once harmed others, they were expected to make restitution. Buchman believed that change happened from inside out, starting and ending with individual change. From early on, the Oxford Group took no official stand on social issues. This only changed after 1938, once the Oxford Group reformed to become Moral Re-Armament. Wilson and Smith had split off by that time and were working to create what would become AA.

AA uses many methods similar in spirit to those of the Oxford Group. Meetings are marked by informality, friendliness, and little that seems like reli-

gious ritual (even the traditional AA closing with the Lord's Prayer is, in some places, coming under question). Newcomers are drawn by personal invitation. Testimony is often a core element, and *lead meetings*, where a recovering alcoholic shares his or her story, are both entertaining and interesting. Small group intimacy is a core aspect of the program, and members are encouraged to talk about their problems. Personal support is a primary benefit of commitment, and members are urged to select a sponsor. Members often become friends and form tight social bonds. They are expected to remain loyal attendees of their home group, be ready to help fellow members, take their message to other suffering alcoholics, make restitution, and increasingly exercise self-discipline. AA, like the Oxford Group, keeps its focus on the individual's problem. It takes no organizational stance on social change, but starts and ends with helping alcoholics.

In AA, "working the program" is explained as hard work, but slips and faults are expected. Intense conversation happens before meetings, and members often socialize with each other afterward. Goals, too, are similar to the Oxford Group, including a deep sense of one's plight, conversion to one's Higher Power, and clear-cut behavioral change. AA meetings are often closed with the affirmation "keep coming back; it works!" All three—Christian revivalism, the Oxford Group, and AA—use narratives of dramatic conversion to gain the attention of newcomers and solidify the faith of adherents. And all three see a common problem uniting disparate people (sin for the first two, alcoholism for AA).

Although few writers analyze the theological similarities between the Oxford Group and AA, not everyone plays down the connections. A minority of contemporary writers stress the commonalities as evidence that AA is compatible with traditional Christianity (Mercadante 1996, 188 n. 2). Taking another approach is historian Ernest Kurtz (1991, 49), who insists that early AAs were unaware of the Oxford Group's evangelistic background. Nevertheless, he says, they deliberately borrowed many practices and principles, including submission to God, listening for guidance, checking with others, restitution, confessing one's sins, witnessing to one's conversion, the unpaid status of helpers, and the obligation to help others change.

Is it possible that founders Wilson and Smith could have been unaware of Buchman's Christian orientation? They, and some other early members, had spent formative time in the group when Buchman was dominant, and Wilson kept a close, nearly lifelong connection to Oxford Group principal Reverend Shoemaker. The borrowings that Kurtz mentions are underlaid with many theological assumptions. Therefore it is more likely that the early AAs had a struggle on their hands when they broke with the group. They were disassociating with an organization that had helped them in many ways. They had to

decide how many of the Oxford Group beliefs to explicitly retain, how many to reconfigure, and how many to discard.

It is often thought that Wilson and Smith left the Oxford Group because the group did not make alcoholism a priority or that Wilson's special interest in alcoholics was not appreciated. But a close look at the Oxford Group shows it did not ignore the problem of heavy drinking. Buchman had begun his ministry at Penn State, a hard-drinking school, and he met with much success there. Ever after, he continued to show interest in helping people caught in the snares of alcohol addiction. In fact, the story of the reformed drinker was a favorite one in Oxford Group lore. Ebby T., Wilson, and Dr. Bob, among others, were drawn to the Oxford Group because of members' concern for their alcoholic plight. The Oxford Group expected that miracles and dramatic conversion were possible for anyone. They expected nothing more from a person than a simple desire to change, no matter what his or her particular problems.

COMPARISONS OF BELIEFS

Buchman was generally uninterested in formal theology, and his message was not only simple, but age-old. Groupers refrained from theological argument with prospects, and they insisted they did not care what a person's religious beliefs were. They insisted they "read men, not books" (Clark 1951, 108–10). This anti-intellectual approach is a common American ethos, but observers might note how it is replicated in AA. A similar tendency can be seen in various addiction recovery groups where new members' questions can be dismissed as "intellectualizing." Sometimes recovering persons are told, "Your best thinking got you here," meaning to their addictive plight.

Sin and Disease

Nevertheless, the Oxford Group did focus on several key concepts. Most important was that individual sin was the core problem. Interestingly, especially when compared to the addiction recovery ethos, the Oxford Group often used medical analogies for this. They sometimes referred to new prospects as "patients" (Eisler 1950, 173); spoke about making a "spiritual diagnosis," about confession and conversion as "soul surgery" (Walter 1919); and likened sin to disease. AA carried on this medical terminology from the Oxford Group, but increasingly used it less analogously and more literally over the years as it gained credibility from science. While at first, AA played with the idea that alcoholism was almost like an "allergy" (Alcoholics Anonymous World Services 1976a, xxiv, xxvi, xxviii), later recovery groups began talking about addiction as a potential genetic defect or neurochemical problem.

Yet the content used to define the disease of alcoholism was still very similar to that used for the problem of sin by the Oxford Group. Sin, for Buchman, was anything that stands between the individual and God. It frustrated God's plan for self and other. Sin was primarily against the self and the self's optimum development. Sin would include such problems as hate, greed, fear, and personal shortcomings. Most important, self-centeredness was the heart of sin. They made a big point of showing how "I" stands at the center of the word *sin*. The group's focus on confession and brutal honesty were part of the soul surgery (Mercadante 1996).

AA and modern addiction recovery groups have a very similar understanding. Addiction is primarily a violation of the self. Alcoholics have a large problem with self-centeredness, it is said. The heart of the problem, "an extreme example of self-will run riot" (Alcoholics Anonymous World Services 1976a, 62), blocks alcoholics off from their Higher Power. Not only that, but they are in "denial" about it. Honesty and "deflation at depth" (Wilson 1957, 65) are part of the solution. Defects of character remain after the alcoholic stops drinking and they become part of one's ongoing program.

The Oxford Group, like AA, believed that conversion happens in stages, rather than all at once. Some suggest that the "five Cs" of the Oxford Group—confidence, conviction, confession, conversion, and continuance (Clark 1951, 28)—were enlarged by Wilson to become the famous 12 Steps of AA. In the Oxford Group, all problems got the same treatment. Members were to stay honest, locate their shortcomings, respond to group influence, confess their sins, and continue to submit to "God control." AA is similar, except that Wilson noticed alcoholics could not take group pressure nor perfectionist standards, and he warned against them. In AA, individuals are repeatedly urged to admit their powerlessness and turn their wills and lives over to their Higher Power.

God and Christ

Since the Oxford Group was unashamedly, though generically, Christian, it had views regarding God and Christ. The group believed, for instance, that God can and does communicate with people and desires to guide their every activity. They affirmed that God is loving but does not condone sin. They mentioned the Spirit. Most important, to be changed, they insisted that a person must submit to this guiding God. As for Christ, his place in their theology was conventional. Although there was no worked-out doctrine of the Trinity, they did believe that the finished work of Christ releases humans from sin. This principle undergirds their expectation of miracles and healing. Even with all this Christian doctrine, however, Buchman was not opposed to bracketing the work of Christ if a more generic spirituality would appeal to his listeners.

AA's views echo some of this group theology but pick up Buchman's strategy and move beyond it. The focus is more on a generic spirituality, with no mention of Christ at all. AA is similar to the Oxford Group in expecting a release from human bondage, but unlike its parent organization, AA does not tie this to any once-for-all work of God or Christ. Thus AA retains the diagnosis, expectation of conversion, need for God-control, optimistic hope, and ongoing healing, but loses the theological foundation in Christ's work that secured all this for the Oxford Group.

Church and Religion

Both the Oxford Group and AA are ambivalent regarding church and organized religion. The Oxford Group sometimes cooperated with the church and worked with pastors, but generally, it kept the institution at arm's length. Implicitly there was—as there often is in other para-church organizations—a critique of the church as too rule-bound, mired in controversy, or inactive. Although Buchman was ordained, he did not regularly officiate in any church or submit to the authority of or commit himself to any denominational structure. The church might be used when expedient, but Oxford Group members often had a poorly concealed contempt for conventional religion (Clark 1951, 56).

AA and other recovery groups exhibit a similar attitude toward the church, although officially, they are careful not to criticize religion. Integral to AA is a resistance to organizational ties and an implicit belief that those best equipped to help alcoholics are fellow alcoholics. Although Wilson claimed that AA was only a "spiritual kindergarten" (Alcoholics Anonymous World Services 1976b, 95), AA makes no claim to revitalize church or religion. In fact, many members treat AA as though it is an adequate or superior spiritual replacement for organized religion. And some church leaders have been so impressed by AA's success that they use its principles in their ministries.

Some AA members eventually make their way into organized religion once their recovery is in progress. But for many, the implicit judgment on the church as ineffective in truly helping alcoholics—as well as the sin-versus-disease dichotomy so crucial to the recovery ethos—more often works to keep people away from religion. Instead, members often find themselves tied to the recovery movement as the main way to fulfill their spiritual needs. This is ironic, given the Oxford Group roots of AA. Yet it could also have been predicted, given the trajectory so early set. The irony is enhanced when one realizes how similar are some basic methods and concepts between the Oxford Group and AA. Most striking is that the diagnosis of addiction and the prescription for recovery have so much in common with the Oxford Group's understanding of sin and conversion.

Chapter **7**

Adolescent Drug Sellers and Distributors

Jemel P. Aguilar, PhD, MSW

Young Americans, between the ages of 12 and 18, are actively involved in the selling and distribution of illicit drugs such as marijuana, heroin, crack cocaine, and methamphetamine (E. Anderson, 1999; Black & Ricardo, 1994; Bouchard & Tremblay, 2005; Centers & Weist, 1998; Hohman, Oliver, & Wright, 2004). Although youths are involved in drug selling and distributing, little is known about this population's motivation for and involvement in drug selling and distribution. This chapter offers an overview of the burgeoning literature on youth involvement in drug selling and distribution. Consequently, this chapter includes the current research on young drug sellers and distributors, the outcomes associated with drug selling, and what researchers have identified as a part of the lives of young drug sellers.

As will be discussed, the research on the drug economy encompasses different roles, positions within the overall hierarchy of organizations, and levels of risk to a participant's welfare. Discussing all these structures and roles within the drug economy is beyond the purpose of this chapter; therefore it is important to note that the research included in this chapter focuses on drug selling and distribution. Drug selling refers to the selling of marijuana, heroin, crack cocaine, and methamphetamine in small amounts for another's personal consumption. Distribution describes the activities of individuals that both sell small amounts of illegal drugs and provide other drug sellers with illegal drugs that these sellers can peddle for profit. Although other roles exist, the following section outlines what is known about the selling and distribution of marijuana, heroin, crack cocaine, and methamphetamine.

WHO ARE THE DRUG SELLERS AND DISTRIBUTORS?

Few studies examine the backgrounds of adolescent drug sellers. Of the available studies, it is clear that both young men and women are involved in the selling and distribution of crack, heroin, marijuana, methamphetamine, cocaine, and other illegal substances (Centers & Weist, 1998). Researchers are less clear about the ways in which gender may operate as a factor in a person's decision to enter into drug sales (J. F. Anderson, Brooks, Langsam, & Dyson, 2002). For example, some researchers suggest that young men are more often involved in drug selling and distribution than young women because of the opportunities for young men to garner social and economic prestige. Comparatively, researchers find that young women enter into drug selling and distribution as a result of their sexual relationships.

Regardless of the gender of a drug seller, researchers find that youths become involved in drug sales because they perceive limited opportunities for social and economic advancement through traditional avenues. Some of these findings may be reflective of the populations recruited in that many of the youths surveyed live in low-income and poor neighborhoods in which few economic opportunities exist. For example, in Centers and Weist's (1998) review of drug selling, they report that 1 of the 15 studies the authors reviewed indicated a young population other than low-income youths.

In addition to youths' attempts to garner a positive social standing, youths may enter into drug selling and distribution because they are substance users themselves (Black & Ricardo, 1994). According to this body of research, youths may enter into the drug culture as recreational or episodic users. As users' drug habits evolve and their social relationships become impaired or overwrought by the economic and social costs of drug use, obtaining funds to support a drug habit becomes equally strained. Brunelle, Brochu, and Cousineau (2000) write the following about the youth's drug use to selling evolution:

> To the extent that dependency takes it roots in the lives of some youths, their need for drugs intensifies to the point of becoming their unique and central interest. At this stage of drug dependency, the adolescent consumer does not have the legitimate financial means to meet this compulsive consumption. This therefore leads to involvement in various sorts of money-oriented crimes. This economic-compulsive relation is particularly accentuated among youths who develop a cocaine or heroin dependency, because such ill.icit drugs are more expensive and more addictive than cannabis. (p. 849)

Brunelle and colleagues highlight cocaine and heroin in their economic explanation for the drug-crime connection; however, similar assertions can be made

about other highly addictive substances such as methamphetamine. Overall, researchers examining the user-seller phenomenon report that some drug sellers or distributors will market a portion of their drugs to offset the cost of using illegal drugs.

Aside from drug selling, several options are available for adolescent substance users to obtain drugs or money for drugs: these are prostitution, having a relationship with another drug user that can provide him or her with an adequate supply of drugs, or robbery (Brunelle et al., 2005; Fagan, 1994). For some, drug use is a coping mechanism for dealing with prostituting (Brunelle et al., 2005), while others prostitute and sell drugs to earn enough money for a steady supply of drugs for their own use. For example, in a phenomenological study of drug-using youths, Brunelle and colleagues (2000) write that "drug consumption sometimes turns out to be indispensable for activities such as prostitution, because drugs allow prostitutes to be more at ease in this activity" (p. 844). Alternatively, a youth will have a relationship with another drug user so that he or she may access drugs; however, these relationships are typically short-lived. The last, and more lucrative of the options, is drug selling (Fagan, 1994). Interestingly, the advent of crack and spread of cocaine created avenues for young women to sell drugs with little initial start-up funds, presenting lesser risk than prostitution or relationships with other drug users (Fagan, 1994).

Gossop, Marsden, and Stewart's (2000) study of youth drug sellers, for example, indicates that regular use of benzodiazepines increases the likelihood that a person will engage in drug selling. Similarly, Black and Ricardo (1994) report that some of the youth respondents in their study used drugs and engaged in drug distribution activities as well as other risky behaviors. Some youths will become drug distributors through their participation in drug use, while others may engage in drug selling as a means to increase their social standing.

Most studies of youth drug sellers and distributors indicate that these individuals also engage in criminal behavior to maintain their position within the drug economy or obtain material goods that can be traded or sold. Gossop and colleagues (2000), for example, report that 71 offenders they surveyed were involved in over 900 arrests in the three months before entering into drug treatment. This same group of offenders reported over 39,000 drug offences prior to intake. Consequently, similar to criminological research that posits that a few juvenile offenders engage in a significant number of criminal offenses, this study suggests that a few drug offenders are involved in committing a majority of drug-related crimes.

The research literature on drug selling and distribution reveals another avenue for engaging in drug selling and distribution: through gangs. Valdez and

Sifaneck's (2004) research on Mexican American gang members reveals four drug-related roles that youths engage in that link them to the drug economy. According to these authors, *homeboys* are gang members who are user-sellers and who are a part of street gangs, yet the gangs are not focused on drug selling and distribution. Homeboys will buy drugs for their own consumption and sell a portion of the drugs to support their drug use. Many times, the drug-related activities of homeboys are apart from the activities of the gang. *Hustlers,* on the other hand, are gang members who deal illegal substances from within gang structures, even though the gang is not an organized drug selling and distribution entity. By contrast, hustlers are integrated into the gang network, yet the profits from drug sales are solely for the hustler and do not support the gang. Hustlers may benefit from the protection of the gang and make use of the social connections of the gang members to sell drugs. *Slangers* are a part of gangs that are drug selling and distribution networks, are drug users themselves, and are actively selling and distributing drugs from within the gang. Similar to hustlers, slangers benefit from the protection of the gang, and unlike hustlers, the profits from drug sales go back to benefit the gang enterprise. The final group of gang-related drug sellers are *ballers*. Ballers are members of gang enterprises that sell and distribute illegal drugs, the profits of which are returned to the gang for the benefit of the whole enterprise. Similar to criminal organizations, the purpose of the drug selling and distributing is not for individual profit, but for the profit of the organization. As a result, a gang member's introduction to drug selling and distribution may stem from his or her entrance into a gang network as well as the opportunity for social prestige that leads youths to participate in gang activities and drug selling. The research on youths' entrance into drug selling and distribution provides some ideas about why youths may engage in drug selling and distribution; however, additional questions remain about the interactions of these factors. For example, researchers have yet to examine the dynamic relationship between social prestige and drug use that may encourage a youths to enter into drug selling. Until these relationships are examined, it is clear that social prestige, drug use, and gang affiliation are factors in youths entering into drug selling and distribution.

THE DRUG ECONOMY AND ORGANIZATIONAL ROLES

Current knowledge about the drug economy and organizational roles within that economy primarily comes from research on adult drug sellers and distributors. Thus this section includes research from adult and youth studies of the drug economy. Adler's (1993) ethnographic study is a prominent study in the area of drug selling and distributing. Although Adler's work does not discuss

youth drug selling and distributing, this quintessential work deserves mention because it sets the foundation for studies of drug selling and distributing and highlights the complex nature of social interactions within the adult drug economy that may also apply to studies of youth drug selling. In her study, Adler conducted in-depth observations and interviews with members of a southwest drug distribution cartel that trafficked marijuana and, at times, cocaine from Central American countries into the United States. What her work reveals is the complex nature of the drug-distributing organizations and the tenuous relationships that produce the widespread drug economy. Adler and other researchers (Natarajan & Belanger, 1998; Zaitch, 2005) report that organizations selling drugs are loosely connected, encompass tenuous relationships, and include many isolated individuals. These findings are supported by other research as well as qualitative studies of drug sellers such as Valdez and Sifaneck's (2004) study of drug-selling gang members.

Natarajan and Belanger (1998) conducted a study of drug-distributing organizations and delineate several roles, and associated responsibilities, that individuals occupy within these organizations. These roles include those individuals who trade illicit drugs on the streets, called *retailers*, to those individuals who break down a larger quantity into smaller portions that can be sold on the streets. Moreover, their analysis also revealed that *brokers* are the representatives who link sellers and retailers and/or sellers with other sellers.

Additional research into youths' perceptions of the drug economy and the youth-led drug selling and distribution enterprises is needed to understand the dynamics of these organizations as well as the ways in which youths enter into, operate, and leave drug selling. As previously stated, most of the studies of the drug economy stem from research on adult participants in the drug economy, and research has yet to compare and contrast youth roles within the drug economy against adult participation in the same economy.

DRUGS AND VIOLENCE

Some researchers are examining the relationship between drug selling and violence to determine the best ways to stem the violence that consumes drug-infested communities. In an attempt to understand the theoretical linkages between substance use and violent behavior patterns, Goldstein (1985) developed what he describes as a tripartite model of the drug and violence nexus. In this conceptual framework, Goldstein outlines three models, or avenues, that link violence and drug use. In each of the models, the substance user can be either a victim or offender, and at times, the offender's motives can cross these separate models.

Goldstein (1985) begins his conceptualization with a pharmacological model of substance use and violence. The pharmacological model focuses on biological changes that occur as a result of ingesting substances or during withdrawal from substance use. For example, in Brunelle and colleague's (2005) research on substance-abusing juvenile offenders, the authors apply Goldstein's (1985) model to a sample of 38 juvenile substance abusers between the ages of 16 and 18. Brunelle and colleagues found that a majority of the crimes committed by these youths were classified as serious and violent. Youths in this study described using substances to commit some crimes or avoid negative feelings and enhance other feelings associated with the crimes (Brunelle et al., 2000). In their review of substance abuse and violence literature, Boles and Miotto (2003) confirm Brunelle and colleague's (2005) findings and describe several studies that examined the role of substance use in the commission of crimes. In these studies, 73 percent of state prisoners and 65 percent of federal prisoners confirmed their drug use during the commission of a crime, and 60 percent of arrestees tested positive for illicit drug use at the time of their arrest. An alternative relation between substance use and violence occurs during the withdrawal period. In this scenario, harsh withdrawal symptoms, such as irritability or excitability, may result in aggression and/or violence (Boles & Miotto, 2003; Goldstein, 1985). As Boles and Miotto (2003) note, "intranasal cocaine and crack use have both been found to be associated with pharmacological violence" (p. 167; see also Fagan, 1994). Thus, for many offenders, substance use is a part of their process for committing crimes.

The economic-compulsive model, alluded to earlier, links the economics of drug use with violence (Boles & Miotto, 2003; Goldstein, 1985). Goldstein defines the economic-compulsive model as the quelling of a person's aggressive and violent tendencies as his or her need to obtain money for a supply of drugs increases. Several research studies on the drug economy and substance users support the notion that substance users will commit violent or aggressive acts to obtain the needed money for further drug use. In Fagan's (1994) study of women in the drug economy, he found that sex workers would "vic" (slang for "steal") money from their customers to purchase drugs. Sometimes these robberies would become violent, as the johns would attempt to stop the robbery (Fagan, 1994). In Goldstein's (1985) economic-compulsive model, the victims of these violent crimes are people who have valuables or money such as drug dealers, other drug users going to "cop" (i.e., buy drugs), and strangers. The last model in Goldstein's framework is the systemic model. This model considers the violence embedded within the drug culture that occurs because of a drug user's attempt to obtain drugs or a dealer's management of his or her sellers. Obviously there are other mechanisms leading to violent behavior, but these

two examples are usually presented in the research literature. Fagan's (1994) research on women in the drug economy is again instructive of the dynamics of drug selling and using partnerships. In his study, he found that women selling drugs in groups were more likely to use violence as a means to protect their "turf" from competing dealers, as retribution against users who attempt to steal drugs, and as a means for a managing dealer to discipline her street sellers. The extent of systemic violence is difficult to determine because the victims are less likely to report such incidents to police or hospital personnel. However, respondents continually discuss acts of systemic violence in many qualitative studies of drug dealers (Boles & Miotto, 2003; Fagan, 1994; Feigelman, Stanton, & Ricardo, 1993; Li, Priu, & MacKenzie, 2000). There is additional evidence that youths are entering into drug selling for social prestige instead of the primarily economic motives that are typically attributed to adolescent drug sellers and distributors. For instance, most adolescent drug sellers and distributors act in these roles for short periods of time. Gossop and colleagues (2000) illustrate the short duration of drug selling in their study of adolescent drug sellers.

Drug use and/or selling are also associated with serious and violent crime (Boles & Miotto, 2003; Brunelle et al., 2005; Goldstein, 1985; Okundaye, 2004; Stanton & Galbraith, 1994). Reviews of delinquency and adult crime consistently reveal that drug-using youths and adults are more likely to commit serious and violent crimes to support their drug-using habits and, for sellers, as a customary dispute-resolution mechanism. For example, Fagan's (1994) study of women in the drug trade found that women who sold crack or cocaine in groups were regularly involved in violence that was directed toward regulating interactions between sellers and buyers or other sellers. As Fagan describes, "group sellers have generally higher rates of both nondrug crimes and systemic violence. This association suggests that, as with males, these two dimensions of violence tend to coincide and be a part of a generalized pattern of violence among both male and female drug sellers" (p. 220). Scholars of juvenile delinquency also agree that drug selling is a part of a larger pattern of problematic behaviors among both female and male juvenile offenders (Boles & Miotto, 2003; Brunelle et al., 2005; Huizinga, Loeber, Thornberry, & Cothern, 2000; Lane, 2003).

CONCLUSIONS

The research into youth drug sellers and distributors is just beginning to explain some of the roles and processes that encompass youths' position within the overall drug economy. With the growing numbers of youths entering into the juvenile justice system because of drug-related crimes, it is important that

researchers and practitioners have a better understanding of the dynamics of youth drug selling and distribution so that more effective interventions can be developed to prevent youths from becoming active drug sellers and distributors and/or to stem youth involvement once they enter into this economy.

Chapter **8**

Historical Aspects of Alcohol Use in India: Role of Culture and Gender

Meera Vaswani, PhD, Atul Ambekar, MD,
and Ramandeep Pattanayak, MD

India, as a civilization, has a rich cultural history marked by enormous diversity and deep-rooted traditional value systems. There have been contemporary influences of industrialization and globalization in recent times. The attitudes, belief systems, and patterns of alcohol use have been modified with the changing religious, cultural, and sociopolitical influences. Some of these influences are reflected in alcohol use patterns in contemporary India. Alcohol use has been largely prohibited for women since historical times and was seen as a marker of bad character. A slow but gradual change has been observed in societal attitudes toward women consequent on their social empowerment.

This chapter begins with a review of the history and cultural context pertaining to alcohol use in India. This is followed by a discussion of alcohol use in women and the role of cultural norms in shaping alcohol use in India. A few important statistics regarding India are provided in Table 8.1.

ALCOHOL USE IN INDIA: HISTORY AND CULTURAL CONTEXT

Alcohol use in India can be traced back to antiquity. The degree of cultural permissiveness to alcohol has varied according to the changing historical periods. In this section, perspectives from Indian history and culture will be discussed. The issues pertaining to gender are also highlighted.

Table 8.1
Country Background Information

Total population	1,027,015,247
Adult population (aged 15–59 years; %)	56.9
Sex ratio (no. of women/1,000 men)	933
Population distribution (%)	
Urban	28
Rural	72
Literacy rate (%)	64.8
Life expectancy at birth (years)	
Boys	60.1
Girls	62.0
Gross national income per capita (in USD for year 2006)	820
Percentage below poverty line (less than USD 1 per day)	36
Human Development Index rank	115

Alcohol Use in Antiquity (Bronze Age, 3300–1700 B.C.)

Alcohol distillation possibly originated in the Indus Valley civilization as early as 2000 B.C. Needham (1980) has examined the origins of the distillation of alcohol to India in volume 5(4) of *Science and Civilisation in China*. There have been unearthings of distillation assemblies made of clay at Taxila and at Shaikhan Dheri (now in Pakistan). These were referred to as the Gandhara Stills and were thought to be the origin of all kinds of distillation stills. The alcohol produced from this primitive distillation apparatus might have been only a diluted sort. *Soma* and *sura* were the two earliest beverages, traceable to 2000 B.C. (Chopra & Chopra, 1965). *Soma* came to be identified with the mythical tree of life and immortality (Chand, 1972). The use of beverages derived from the *soma* plant was confined to the nobles and saints, and the rituals of preparation were often kept a secret. Experiences of intoxication on *soma* have been described as transcendentally blissful, enlightening, and tranquilizing, creating euphoric states and stimulating both the mind and body (Chand, 1972). *Sura* was mostly derived from fermented rice, barley, jaggery, or *mahuwa* (flowers of the *madhyaka* tree) and was relatively stronger than *soma*. It was

used by warriors, peasants, and common people. Its effects have been described as invoking moderate euphoria to intoxication (Dikshitar, 1951).

Alcohol Use in the Vedic and Epic Period (Iron Age, 1700–500 B.C.)

In this period, Hinduism was seen not only as a religion, but as a way of life. Drinking was totally prohibited by the *Rig-Veda*.[1] The Sutras,[2] however, mentioned that liquor could be served on special occasions such as on festivals and to guests as they enter a new house (Praskara, 1956). Women, students, and Brahmins were prohibited from using alcohol or any other intoxicant. Members of other castes (Kshatriyas and Vaishyas[3]) were allowed to take milder liquors but were forbidden the spirits distilled from fermented grain (Prakash, 1961). The themes and images associated with alcohol depicted warriors and courtiers. The lowest section of Shudras, the Dalits, were not considered part of mainstream society and therefore were not governed by the religious scriptures. Non-Brahmins were never considered to be able to attain a sense of high religious purity and therefore were allowed alcohol use. The great Indian epic *Ramayana*, in its description of society, generally followed a bad-good or black-white dichotomy. The bad factions were consumers of alcohol and meat, while the good were abstinent vegetarians. Another epic, *Mahabharata*, portrayed the characters in a gray shade and mentioned alcohol consumption by them. It is important to note that in the Vedic and post-Vedic period, alcohol use was never seen as a daily phenomenon, and it was limited mainly to ritual drinking. Alcohol was never considered a part of daily nutrition. Inebriation was severely censured, and abstinence was held in high esteem (Chand, 1972).

Alcohol Use in the Ancient Period (500 B.C. to A.D. 550)

A balanced view of drinking was promoted in this period, and moderation was counseled. The Ayurvedic[4] texts described the beneficial effects of alcoholic beverages and also the consequences of intoxication and alcoholic diseases. Alcohol was thought to increase the mental principle (*pitta*), while diminishing the physical and vitality principles (*kapha* and *vata*). There were prevalent beliefs such as that alcohol mixed with fruit juices could be enjoyed in winter but should be avoided in summer. Kautilya, the prime minister of India's first great emperor, Chandragupta Maurya, in his treatise on statecraft and economic policy, called *Arthashastra*, codified the rules and regulations for alcohol, pointing to its common usage among people in the regime. With the origin of Buddhism, which was spread by Emperor Ashoka (r. ca. 273–232 B.C.) to several neighboring Asian countries, a movement for general abstention

from alcohol was begun. Buddhism prohibited drinking by monks and in monasteries and influenced its followers to stop alcohol use. Alcohol use continued to be forbidden for women. The Laws of Manu,[5] in A.D. 200, mentioned that "a wife who drinks spirituous liquor, is of bad conduct, rebellious, diseased, mischievous, or wasteful, may at any time be superseded (by another wife)" and warned that drinking liquor is one of the major causes of the ruin of women (Doniger, 1992).

Alcohol, however, continued to be used by men belonging to warrior, trader, and peasant classes. Alcoholic beverages were made from fermentation and distillation of grain (barley and rice), flowers (the *mahuwa* flower and jasmine), and fruits (mangos, dates, *kadamba* fruit, and grapes). The sweet exudates from the coconut palm were fermented into a drink called *thari* or *toddy*, and then were distilled to yield *arrack*. The practice remains popular today in southern parts of India. At the height of its trade with Rome in the early Christian era, India also imported amphorae of wine for use by the nobility. But the common drinks were *toddy*, *arrack*, and a variety of highly flavored rice wines.

Alcohol Use in the Medieval (A.D. 550–1500) and Postmedieval (A.D. 1500–1800) Periods

Brewing was practiced all over the country in this period. Alcohol consumption became prevalent in a considerable section of Hindu society, especially home-brewed, low-ethanol beers (Prakash, 1961). Distillation of wine was described in detail in the texts as an art, and a relatively permissive attitude to alcohol consumption continued, especially in the warrior groups. Kshatriyas drank liquor brewed from the grape and sugarcane, Vaishyas preferred strong distilled liquor, and Brahmins drank only fruit juices. Some tribal and low-caste peasants (Shudras) also abstained from drinking in the belief that this would raise their status in society as food is considered an important identity symbol in Indian culture. The anthropologist Srinivas (1997) has defined this process as *Sanskritization*, that is, the process by which a person belonging to a lower Hindu caste changes his customs, rituals, and way of life in the direction of a higher caste, thereby adopting vegetarianism and alcohol abstinence as a marker of higher social class.

The postmedieval period was dominated by the Mughal regime. The Koran prohibited the use of alcohol, referring to it as "great sin and harm." However, there are references to the emperors Babur and Jahangir being regular heavy alcohol users (Rahman, 1984). Alcoholic beverages were consumed by courtesans and nobles alike. Hindu society, in the face of the external Mughal regime,

became somewhat more introverted and rigid in following preexisting codes of behavior and restrictive attitudes toward alcohol.

Alcohol Use in the Colonial Era (A.D. 1800–1947)

The British administration noted the widespread production of *toddy*, *arrack*, and other traditional beverages all over India. In addition, the Portuguese monks in Goa had also developed a distilled liquor called *fenny* from the cashew. Distilled products made from rice and *mahuwa* flowers were also common and mostly were locally produced on a small scale in villages. The Indian rulers of the time neither expected any revenues nor encouraged the commercialization of liquor. The British colonial administration, however, felt the alcoholic beverages to be an excisable commodity (Achaya, 1998). The first distillery in the country was set up for the British army at Cawnpore (now Kanpur) for the manufacture of rum in the year 1805. The British East India Company banned the previously village-based manufacturing system and made strong efforts to increase revenue generation and profits from alcohol. The right to set up distilleries was offered through auction, resulting in an appreciable increase in overall consumption. The production of locally made, low-strength alcoholic beverages was replaced by factory-produced, high-strength spirits.

Voices were raised against drinking as well as against the British educational system, which was seen to be promoting drinking culture. There were national movements promoting temperance in the nineteenth century. Among the nationalist leaders, there were two schools of thought on the subject. One school believed that colonial policy was distorting the existing healthy drinking culture of the people, in particular, causing the mild and harmless drink *toddy* to be replaced by bad spirits, and demanded change in these policies. The other school of nationalist leaders—the predominant school—demanded complete prohibition in India. Many of the political leaders, such as G. K. Gokhale, held the belief that an independent India had to be a pure India, and legal prohibition was a step toward national purity. With the emergence of Gandhi, several attempts were made to encourage temperance among the masses. This also included the "scheduled," or "lower," castes, who traditionally were "permitted" to drink, and women, who otherwise would have been left out from the freedom struggle. Picketing of alcohol sellers was a major activity of women's groups. Sales of drink decreased significantly in many areas, and in the Bombay Presidency alone, liquor consumption fell by approximately 20 percent as a result of picketing during the noncooperation movement (Brown, 1972).

Though this appears to be quite in harmony with the ancient traditions, in fact, it was a significant deviation. The ancient Hindu tradition did not rule out alcohol for everybody in society. In fact, there was a relatively relaxed attitude toward alcohol, barring the elitist Brahmins and the spiritually elevated (Mandelbaum, 1965).

DRINKING CULTURE IN INDIA

India essentially has never accepted alcohol as a part of normal social discourse or eating behavior, and there is a virtual absence of normative patterns of drinking alcohol and attitudes toward it. An exception is seen in the tribal population and a few Hindu religious (*Tantric*) sects. Alcohol is seen by the tribal people of India as a gift of god, as an antidote to witchcraft and sorcery (Rao & Rao, 1976). It has gotten sanction to be consumed on all social occasions from cradle to grave, and as a gesture of friendship and reconciliation after quarrels, though the alcohol used is generally low strength, at 3 to 5 percent alcohol by volume. Tribal people are generally habituated to alcohol, and a tribal man (*chenchu*) may even promise to give away his daughter for marriage in exchange for alcohol (Reddy, 1971). Some Hindu *Tantric* sects also use alcohol rampantly to achieve a different level of consciousness and indulge in casting magic spells under its influence. Such followers are, however, few, and have been generally unsuccessful in having any significant impact on Indian norms and attitudes (Chand, 1972).

In the main, India does not neatly fit into any of the conceptualizations of *abstinent* (condemnation of alcohol use in any form, e.g., by Muslims and some Protestants), *ambivalent* (negative attitudes coexist with attitudes idealizing intoxication, e.g., English and Scandinavian countries), *permissive* (moderate consumption accepted, e.g., Jews and Italians), or *overpermissive* (alcohol use widely accepted and drunkenness permitted in certain contexts, e.g., French and Japanese) cultures, as outlined by Pittman (1964). India displays the culture of purity and abstinence on one hand and permissiveness toward drinking on the other. At best, it can be described as being closest to an *ambivalent* drinking culture, in which prohibitive attitudes coexist with attitudes idealizing intoxication. Drinking is a generally an activity in male-predominated areas away from home. Unlike many other cultures, the aim, while drinking in India, is to get intoxicated. The pattern of drinking in India has undergone a change from occasional and ritualistic use to being a social event with a common purpose to get drunk (Mohan, Chopra, Ray, & Sethi, 2001). The adult per capita per year consumption in India has been found to be 0.8 liters for recorded and 1.7 liters for unrecorded consumption (World Health Organization, 2004), which is on the lower side. However, only around 20 percent of the male popu-

lation have been found to be current drinkers (Ray, Mondal, Gupta, Chatterjee, & Bajaj, 2004); in a nationwide survey, these numbers reflect the fact that those who drink alcohol tend to do so in heavy amounts.

Undersocialized, solitary drinking of spirits, drinking to intoxication, and expectancies of drink-related disinhibition and violence add to the hazardous patterns (Gupta, Saxena, Pednekar, & Maulik, 2003; Saxena, 1999). Despite the appearance of public bars and pubs in some parts of India, pub drinking, as understood in the West, has not yet been institutionalized and norms are only beginning to evolve. These developments have raised concerns about the health and the social consequences of excessive drinking (Saxena, 1999).

ALCOHOL USE IN CONTEMPORARY INDIA

The changes brought by the colonial era are reflected in the Post Independence period and present India. The traditional drinks, such as *toddy* or cottage-made *arrack* (Table 8.2), have been largely replaced by more expensive factory-made alcoholic beverages with greater alcohol content. This, in turn, has led to organized and unorganized production of illicit alcoholic beverages in most parts of the country.

Most authentic figures for prevalence of alcohol use in the general population of India are available from the National Survey on Extent Pattern and Trends of Drug Use in India (Ray et al., 2004). A general population survey (National Household Survey; Ray et al., 2004) was conducted in which a nationally representative sample of over 40,000 males was interviewed. The prevalence of current alcohol use (defined as "use in the preceding 30 days") was

Table 8.2
Traditional Alcoholic Beverages in India

toddy	fermentation of the sap of a coconut palm; alcohol content, 3% to 6%
rice beer	low-strength alcohol beverage used in the tribal belts; alcohol content, 3% to 6%
jack-fruit wine	alcohol content, 7% to 8%
arrack	distillation of fermented molasses, raw brown sugar, palm wine, rice, or palm sugar, common in southern India; alcohol content, 20% to 40%
palm wine	produced from coconut or other palm trees
daru	from the flowers of the *mahuwa* plant, common in northwestern India; alcohol content, 20% to 40%

Source: Global Status Report 2004, World Health Organization (2004).

found to be 21.4 percent. Projecting this figure to the absolute number, it can be safely estimated that there are at least 62.5 million current users of alcohol in the country. The prevalence ranged from 7 percent in the western state of Gujarat (officially under complete prohibition) to 75 percent in the northeastern state of Arunachal Pradesh. Alcohol was found to be the primary drug of abuse in the clinical population (i.e., patients attending drug and substance abuse treatment centers) as well, with as many as 43.9 percent of patients seeking treatment for alcohol-related problems (Drug Abuse Monitoring System; Ray et al., 2004).

The complexity of Indian culture is reflected in the fact that there is a wide variation among various regions, urban-rural settings, socioeconomic statuses, caste groups, and religious beliefs. An earlier study covering both urban and rural areas of eastern, northern, southern, and central India showed that alcohol use was higher among specific groups such as industrial workers, tea plantation workers, and tribals compared to the general population (Mohan, Sharma, Sundaram, & Advani, 1981). A significantly higher use has also been recorded among tribal, rural, and lower socioeconomic urban sections (Ray & Sharma, 1994; Thimmaiah, 1979). Choice of beverages also differed, with home-brewed beverages being more popular among tribal populations and in economically less developed areas. The urban and industrial workers favored factory-made spirits (whiskey, rum, brandy, or locally made liquor). In the rural areas, certain factors, such as age more than 20 years, married, male, Hindu religion, lower educational status, and agriculture as occupation, were found to be significantly associated with alcohol use.

Additional risk factors were having a good harvest, additional farm income, easy availability of local alcoholic beverages, and formation of a subcultural group of friends and relatives (Sundaram, Mohan, Advani, Sharma, & Bajaj, 1984). Caste affiliation was observed to be a major influence on drinking patterns (Mohan et al., 1981), with the Rajputs, ex-rulers and landlords, having a significant effect on the landless laborers and other social groups. Even with affluence as a result of agricultural revolution in the state of Punjab, it was observed that concomitant economic or developmental assets did not emerge; rather, there was a breakdown of the traditional social value systems in the villages, which led to increased alcohol consumption, especially among the young (Deb & Jindal, 1974). The demand for Indian-made foreign-style liquors, local liquors, and the home-distilled illicit liquors has increased dramatically.

Alcohol in contemporary India, thus, reflects the same paradox as in other areas of development of the country, where travel by modern airlines is juxtaposed with the continuing use of the oxcart. Along similar lines, drinking in India also exhibits widely divergent patterns (Mohan & Sharma, 1995).

POLICY AND PUBLIC HEALTH ISSUES IN INDIA

Under the federal structure of India, the country is divided into numerous states, currently 28 in number. Prohibition is a state subject, with alcohol legislation, excise, production, and sale under full state control. The complete prohibition of alcohol was much debated during the framing of the Constitution of India after independence but eventually was not made a mandatory and legally enforceable goal of the state (Government of India, 1996). Article 47 of the Constitution directs that "the State shall endeavor to bring about prohibition of the consumption, of intoxicating drinks and of drugs which are injurious to health." There are three main types of prohibition policies seen in practice: *complete prohibition* of production and consumption (only in the state of Gujarat); *partial prohibition*, where one or more types of liquor (usually *arrack*) are prohibited (in Tamil Nadu, Kerala, and Andhra Pradesh); and *dry days*, where consumption is prohibited only for certain days of the week or month. Regulatory laws pertaining to hours of sale, sale to minors, and drunken driving are in place all over India (Table 8.3).

The alcohol industry, however, continues to grow at a steady pace in India, with an estimated overall growth rate of 7 percent per annum and the cheaper beverages like rum growing at 22 percent per annum, per industrial estimates (Benegal, Gururaj, & Murthy, 2003). The volume of alcoholic beverages sold increased by 44.9 percent from 1,100.3 to 1,594.6 million liters between 1999 and 2004, while the value of alcoholic drinks rose by 75.6 percent from 368,122.2 to 646,528.2 million rupees (Euromonitor, 2005). The recent economic liberalization and relaxation of regulations for multinational companies are benefiting the alcohol industry (Isaac, 1998). The declining trend of alcohol consumption and saturation in many parts of the world, coupled with a huge untargeted potential market in India, could be contributing to this growth.

Table 8.3
Regulatory Measures for Alcohol in India

Prohibition of sales of alcoholic beverages to children below 18 years of age
Restriction of sales at retail shops between 9:00 P.M. and 9:00 A.M.
Prohibition of sales of alcoholic beverages in pubs and hotels between 2:30 P.M and 5:30 P.M. and after 10:00 P.M.
Prohibition of retail outlets within a one-kilometer radius of schools and places of worship
Attempts to regulate sales and consumption of alcohol along the state highways
Restrictions against drinking and driving or operating heavy machinery, including a breath alcohol limit of 30 milligrams %
Advertising of alcoholic beverages and tobacco products is banned

The practical challenges faced in today's India are those of inadequate implementation of policies and lack of political will for restriction of alcohol use. A recent study in Bangalore City across a calendar month found that 40 percent of drivers were over the legal limit (Gururaj & Benegal, 2002). In addition to alcohol-induced physical diseases, alcohol consumption has a disproportionately high association with injuries reported to emergency rooms (Benegal, Gururaj, & Murthy, 2002), domestic violence (Bhatt, 1998), deliberate self-harm and suicide (Gururaj & Isaac, 2001), and high-risk sexual behavior and HIV infection (Chandra, Krishna, Benegal, & Ramakrishna, 2003). Deaths as a result of consumption of adulterated illicit liquor remain by and large underreported. Alcohol use, therefore, inflicts a high cost on society.

Most states derive up to 10 percent of their revenue from taxation on alcohol (Saxena, 1999) and prohibition is seen to be associated with considerable loss of revenues. A little appreciated fact is that the direct and indirect costs attributable to people with alcohol dependence alone far exceed the profits from alcohol taxation (Benegal, Velayudhan, & Jain, 2000). There is an inadequate reappraisal of the tremendous public health impacts of alcohol (Table 8.4). The governmental response remains centered—that, too, in a limited way—on treatment provision to clinical populations instead of on a public health approach directed at communities. Identification of increasing alcohol use in women, as discussed subsequently, has also not attracted any specific intervention from governmental agencies.

Table 8.4
Global Burden of Disease and Disability Attributable to Alcoholic Beverages, by World Bank Region, 1990

Deaths (in thousands)	As percentage of total deaths	YLL(in thousands)	As percentage of total YLL	YLD (in thousands)	As percentage of total YLD	DALY (in thousands)	As percentage of total DALY

Note: Abbreviations are as follows: DALY, disability-adjusted life years; YLD, years of life disabled; YLL, years of life lost.

ALCOHOL USE BY INDIAN WOMEN

Several aspects about alcohol use by women remain understudied in Indian literature. It is only recently that alcohol use in Indian women has begun to generate research interest. In the following section, we provide an overview of the status of women in India, followed by a review of the available literature, and we discuss some pertinent gender issues.

Status of Women in India

The problem of alcohol use among women cannot be separated from other sociocultural aspects (P. Murthy, 2002). The male child is favored over the female in India and is believed to carry the family lineage forward. This is reflected in the adverse sex ratio of the country, with 93 women for every 100 men (Census of India, 2001). With the exception of Kerala, every state has fewer women than men. Only 54 percent of women are literate, as compared to 76 percent of men. The average Indian woman bears her first child before she is 22 years old and has little control over her own fertility and reproductive health. In many states, more than half of women have been found to suffer from anemia (International Institute of Population Sciences and Macro International, 2007). Most women remain at home and do not have autonomy in decision making in their personal lives. Women are generally underrepresented in governance and decision-making positions in the country. The traditional roles and situation have been changing in recent times, and India has had a woman as both prime minister and president. More women are going for higher education and jobs and are economically independent. However, there are wide variations in the progress of women across different regions and settings. Alcohol use in women should be seen in the context of this prevailing social scenario.

Gender Perspectives and Cultural Background

The Indian sociocultural ethos, based largely on Hinduism, has always perceived alcohol use by women as a deviant behavior, and consequently, it has been heavily stigmatized. The tribal populations, sex workers, and low-caste groups living on the fringes of the dominant society were seen as exceptions and not bound by societal rules. The dominant stereotype associated alcohol use with the primitive and/or poor, the immoral, and the privileged (Musgrave & Stern, 1988; Thimmaiah, 1979). There is also a widespread notion that alcohol is limited to the upper crust of the rich and not favored by women from the

middle or upper socioeconomic classes (Kumar & Parthasarathy, 1994; Ray & Sharma, 1994). By and large, until recently, women have been seen as the victims of alcohol-related social and familial problems. The media have highlighted the role of women at the forefront of antialcohol agitations, perpetuating the image of women as champions of temperance (Pande, 2000). The fact that women can be alcohol users has not been adequately recognized and addressed.

In recent times, however, there are indications that the gender gap may be slowly bridging, with an emergence of liberal sociocultural values and increasing economic independence of women. There is identification of alcohol use in women. Cultural attitudes in India, being intensely guilt provoking and discriminatory about the use of alcohol by women, may prevent women from spontaneously reporting alcohol use. The woman who uses alcohol is triply stigmatized (Blume, 1991). First, there is the same stigma as for alcohol-dependent males, which is an attribution of alcohol use to either a moral deficiency or a self-inflicted illness. Second, the woman is held to a higher moral standard than the man, and consequently, the shame involved in her fall from grace is more intense. The third is the sexual stigma related to the myth that alcohol use makes women promiscuous. These stigmatizing beliefs may have implications for the acknowledgment of alcohol use and help seeking by women.

Gender Differences in the Prevalence of Alcohol Use

Gender is a strong and universal predictor of drinking behavior. Research on drinking patterns among women has generally shown that women drink less than men across the developing (Assanangkornchai, Pinkaew, & Apakupakul, 2003; Wei, Derson, Xiao, Li, & Zhang, 1999) and the developed world (Kraus, Bloomfield, Augustin, & Reese, 2000). Reports from India on women's drinking are sparse. The nationwide household survey on drug use (Ray et al., 2004) did not include women and was directed at a representative male population. However, in the same multimodality survey, in a focused thematic study, drug use in women was evaluated qualitatively. Among the surveyed women, alcohol was commonly used in addition to opioids and tranquilizers. The recently concluded National Family Health Survey (NFHS-3; International Institute for Population Sciences and Macro International, 2007) conducted on more than 230,000 men and women, revealed that only two percent of women drink alcohol in contrast to approximately one third of men. Alcohol use was found to be more common among women with no education (4%), in lowest wealth quintile (6%), and belonging to scheduled tribes (14%).Among women who drink alcohol, 40 percent drink alcohol about once a week, and 15 percent

drink alcohol almost every day. Overall, the prevalence of alcohol use among women has been estimated at less than 5 percent by most of the researchers who have included women in their study samples (Isaac, 1998; Mahal, 2000; Mohan et al., 1981; Sundaram et al., 1984). A longitudinal multicentered study among university students (Mohan & Sundaram, 1987) showed drinking in boys to be eight times (21.7%) more common than in girls (2.6%). Mohan et al. (1981), while reporting alcohol use as being at 3.2 percent in women, made an observation that girls had moved from "never use" to "ever use" status. Four large epidemiological studies undertaken in the early 1990s, covering northern, western, southern, and northeastern India, with sample sizes varying from 4,000 to 30,000 (Channabasavanna, Ray, & Kaliaperumal, 1990; Mohan & Desai, 1993; Mohan, Ray, & Sharma, 1993; Singh, Kaul, & Sharma, 1992), indicated that drug and alcohol use was a predominantly male phenomenon, and that 92 to 94 percent of women had never used any psychoactive substance in their lifetimes. The reasons behind this gender gap may be manifold. The physiological differences in acute effects and metabolism (Thomasson, 1995) have been thought to play a role. Certain sociocultural theories have also been put forth to explain the gender differences in the international literature. Drinking is seen as an expression of power dominance and aggression. Alcohol consumption in all-male groups may affirm the privileged status of being a man, rather than a woman (Campbell, 2000), and the ability to consume large amounts of alcohol without apparent impairment may help to demonstrate that the drinker is manly (Neff, Prihoda, & Hoppe, 1991); men have been shown to be more willing or motivated to take risks than women (Weber, Blais, & Betz, 2002); the expectations of enhanced sexual pleasure after alcohol consumption may also be more influential for men than women (Morr & Mongeau, 2004); additionally, greater role responsibilities, particularly at home, may also cause women (more than men) to limit their drinking (Ahlström, Bloomfield, & Knibbe, 2001). Some or all of these social contexts may play a role in India to maintain the gender gaps in drinking behavior.

Recently, there is a suggestion that alcohol use in women has been showing an upward trend. It has been observed in the southern state of Karnataka that 16 percent of women were "ever users," and 5.8 percent of all female respondents reported drinking alcohol in the past year out of a total sample size of 3,000 women (Benegal, Nayak, Murthy, Chandra, & Gururaj, 2005). These findings emerged from a collaborative multinational study called Gender, Alcohol, and Culture: An International Study. It was designed by the International Research Group on Gender and Alcohol using a similar methodology across a number of countries to study gender and cultural differences with regard to alcohol. The results from a state cannot be generalized for the whole of India; neverthe-

less, some useful insights can be gained, as discussed later. A study of drinking habits conducted in Bangalore City (Kumar, 1997) reported that one-fifth of young people who frequented pubs on weekends were girls aged between 13 and 19 years. Changing societal values and liberalization may have formed fertile ground for acceptability of and increased alcohol use in women.

Factors Influencing Initiation of Drug Use by Women

Interviews with female drinkers identified "boredom" and "lack of work at home" as factors for drinking among the high-income group; the low-income group identified "fatigue" and "spousal violence" as triggers for drinking (Kumar, 1997). Women also commonly reported being initiated into alcohol use by family members, and associated alcohol use among key family members was commonly reported. Psychosocial stressors were mentioned as maintaining factors for alcohol use more commonly in women than in their male counterparts (Selvaraj, Prasad, Ashok, & Appaya, 1997). Certain cultural beliefs, such as that alcohol has restorative properties after childbirth, were other common reasons in addition to giving company to husbands (N. V. Murthy, Benegal, & Murthy, 1995). Relief from tension was reported to be a common reason for drug use in less educated, poor, and rural women, while positive expectancies were commonly reported in women from affluent urban and educated backgrounds (Benegal et al., 2005).

Clinical Features of Alcohol Use by Women

The little information that exists about patterns of alcohol use in India indicates that women who drink have patterns of equally heavy alcohol use as men. A study from southern India of a representative sample of 7,445 adult men and 6,919 adult women (Benegal et al., 2003) found that the average consumption on typical drinking occasions, in both men and women, was five standard drinks (12 grams of ethanol per drink). There were no significant differences between male and female current drinkers in terms of age at first drink or the duration of drinking. Eighty percent of male consumers and 65 percent of female consumers drank at hazardous levels (defined as Alcohol Use Disorders Identification Test[6] scores of 8 and above), and a large proportion of drinkers of both genders reported daily or almost daily use. Frequent (weekly or more) heavy drinking (five or more drinks per occasion) was found in 47.6 percent of male drinkers and in 27.9 percent of female drinkers in another large-scale study by Benegal et al. (2005). A significant number of female users (42%) also expressed the opinion that it was really no point having a drink if one did not feel high at the end of it. This supports the fact that the Indian culture of

"drinking to get drunk" among alcohol users is seen among women users as well.

Solitary drinking was commonly seen in female alcohol users seeking treatment (Benegal et al., 2003). Women in urban areas were more likely to drink with meals, at friends' homes, at home, and at parties. The men, on the other hand, were more likely to drink at pubs and bars. The most common reported time of drinking was the weekend after five in the evening, followed by weekday evenings after five (Benegal et al., 2005).

The most commonly used beverages were found to be spirits (Indian-made foreign liquor) for both women (64.3%) and men (70.7%). Wine was drunk by significantly more women than men (Benegal et al., 2005). Data from the alcohol industry also suggest that the sale of hard liquors is much higher in India as compared to beers and wines and that hard liquors constitute more than 95 percent of the market for both men and women. There has been a recent introduction of new products, such as flavored and mild alcoholic products, which is aimed at recruiting nondrinkers and women (Naik, 2002).

Women experience several problems different in nature from men. It was seen that alcohol-using women were less likely to have an intact marriage or stable relationships to provide support, unlike the male alcohol users (N. V. Murthy et al., 1995). Forcible sex after the age of 16 years was reported by significantly more women (10.4%) as compared to men (1.6%), and most abusers were close relatives, spouses, or partners (Benegal et al., 2005). Three hospital-based studies of female alcoholics from southern India (Benegal et al., 2003; N. V. Murthy et al., 1995; Prasad, Murthy, Varma, Mallika, & Gopinath, 1998) reported a high prevalence of medical and psychiatric morbidity along with delayed help seeking until physical health or emotional crises made it inevitable. It was widely believed by both men and women that female users are more likely to experience alcohol-related physical problems compared to men. Overall, half of the total women studied felt that alcohol use in women was acceptable, but these views were expressed by those who had an urban background (Benegal et al., 2005). There was also a strong bias among men against alcohol use in women (even among men who themselves used alcohol).

Emerging Patterns of Alcohol Use by Indian Women

There appear to be two widely divergent patterns of drinking among Indian women based on their socioeconomic status, education, and urban versus rural background (Benegal et al., 2005).

There is a traditional pattern of alcohol use that is confined to less educated, poor, or rural women. Their drinking is marked by binging and drinking to

intoxication, with a high proportion of heavy drinkers (defined as five or more drinks per occasion). They also predominantly use cheaper, high-alcohol beverages: spirits, illicit liquor, and country liquor. Drinking is mostly alone, in undersocialized drinking contexts and at home. Though they drink less frequently, their pattern is close to the male pattern of drinking. Drinking appears to serve the function of tension relief, rather than the enhancement of positive experiences. These women also report more alcohol-related familial, financial, and health-related problems (Benegal et al., 2005).

Benegal et al. (2005) also observed another and recent pattern of alcohol use in educated urban women. They are comparatively younger, educated, with higher spending capacity and a shorter duration of drinking. They drink mostly in socialized circumstances: at restaurants, parties, with spouses, family members, colleagues, and friends. Although spirit drinking is still the most common form, use of low-alcohol beverages like wine and beer is also present. Motivation appears to be equally split between relief of tension and the enhancement of positive experiences. They drink less on a typical drinking occasion and have fewer problems as a result of their drinking. This latter group, with a shorter duration of drinking, reflects the recent change in attitude in a section of society.

Treatment Seeking by Women

Female alcohol users are underrepresented in clinical psychiatric practice in India. Data from treatment centers have shown that female drug users form a minority (3%) of the treatment-seeking population (Ray et al., 2004). A profile of all women treated for alcohol dependence during a 12-year period between 1983 and 1994 revealed a total number of 77, with the majority being from lower socioeconomic backgrounds and having high preceding (33.8%) and concurrent (75.3%) psychiatric and medical (68.7%) morbidity. Only 13 percent of the sample attended follow-up regularly, and the population as a whole showed quite high dropout rates (N. V. Murthy et al., 1995). A retrospective structured chart review of female substance (including alcohol) abusers again indicated low follow-up rates in addition to higher rates of comorbidity and family history (Grover, Irpati, Saluja, Matto, & Basu, 2005). Several factors may be contributing to low treatment seeking: societal disapproval, stigma, presence of a spouse with alcohol use, lack of adequate social support, and lack of separate treatment services for women. There is a need to understand the perspective of female alcohol users and address their barriers to seeking treatment.

Research on Gender Issues Related to Alcohol in India: Future Directions

There is now increasing recognition of alcohol use among women in India, and preliminary information is available regarding clinical and epidemiological aspects of alcohol use. There are several lacunae in the existing research. There is a need to study the (1) course and outcome of alcohol use, (2) measures directed at early identification and prevention of alcohol use, and (3) specific issues, such as reproductive health, in female users. There is also a need to develop effective treatment models catered to female alcohol users. Future studies should be directed to accurately identify the risk and protective factors for alcohol use in both men and women. Changing cultural norms and influences of social factors also should be studied, both quantitatively and qualitatively.

CONCLUSION

India, in several ways, is a unique culture with enormous diversity. Alcohol has been consumed since historical times in India. Traditional religious and cultural beliefs permitted alcohol use in moderation on social occasions and in rituals. Drinking was completely prohibited only for certain sections of society: students, learned men (Brahmins), and those seeking religious purity. Alcohol was never a part of the daily routine in Indian culture. Women were also not permitted to use alcohol, and alcohol was associated with bad character in women. Alcohol use has not been commonly seen in Indian women, and drinking has remained a male phenomenon, with consumption mostly away from home. There has been no normative pattern of alcohol use, and India is closer to an ambivalent drinking culture in many ways. On one hand, abstinence has been held in high regard, and on the other, it has been seen that people who use alcohol "drink to get drunk."

Table 8.5
Changing Patterns of Alcohol Consumption in India

Relatively greater acceptability of drinking as a social norm, especially among the affluent and urban
Wine and beer drinking are gradually emerging
Increase in drinking among women
Heavy drinking is common among male and female drinkers
Alcohol use combined with other high-risk behaviors

Recent times have seen a few changes with increasing liberalization and changing societal values (Table 8.5). Alcohol use has been recognized in women, and generally, the pattern is the same as in men, with most women using in heavy amounts. Women also have higher rates of comorbid physical or psychiatric illnesses. Female alcohol users continue to face stigma from society and even from male alcohol users. There is an emerging segment of urban and affluent women who drink in a socialized context or with family. Drinking appears to be more socially acceptable among them, reflecting the influences of urbanization and globalization. Gender-specific issues by and large remain understudied in India, and there is a need to devote research efforts to them so that effective interventions can be designed aimed at prevention and management.

NOTES

1. The oldest and most revered Indian collection of Vedic Sanskrit hymns dedicated to the gods.
2. A collection of teachings and a guide to proper ritual action.
3. Ancient Indian scriptures divide society into four classes: the Brahmins (teachers, scholars, and priests), the Kshatriyas (kings and warriors), the Vaishyas (traders), and Shudras (agriculturists, service providers, and some artisan groups).
4. The traditional system of Indian medicine attributed to Dhanvantari, the physician to the gods in Hindu mythology.
5. Treatises on the proper righteous way of orderly life for Hindus.
6. Developed by the World Health Organization.

Chapter **9**

Alcohol and Drug Abuse in Malaysia

See Ching Mey, PhD, MEd, and
Cecilia A. Essau, PhD, MA, HBA

The Federation of Malaysia covers a total area of 329,847 square kilometers distributed between two regions, Peninsular Malaysia and East Malaysia on the island of Borneo, which are separated by approximately 640 miles of the South China Sea. There are 11 states and 2 federal territories in Peninsular Malaysia, and 2 states and 1 federal territory in East Malaysia.

The total population is estimated at 26.6 million (2007) and comprises approximately 60 percent Malays, who are constitutionally defined as Muslims; about 26 percent Chinese; and 14 percent Indians and indigenous peoples. The gross national income per capita is USD 5,620 (World Development Indicators Database, 2007).

The Chinese and principally southern Indians came to Malaysia during the British colonial times to work on the plantations, in the tin mines and to provide mercantile and administrative support services. The ethnic groups coexist in harmony, but there is little cultural integration.

ATTITUDES TO AND PATTERNS OF ALCOHOL CONSUMPTION

Before Islamization, the Malay population could be said to follow a largely Hindu/Buddhist faith. Missionaries brought Islam beginning in the thirteenth century with the establishment of several Muslim states in Peninsular Malaysia. Historically, the coming of Islam is identified with the emergence of the Muslim Sultanate of Malacca under Iskander Shah (formerly the Hindu

ruler Parameswara, who converted to Islam on his marriage to a princess from Pasai) at the beginning of the fifteenth century (Freeman, 2003). The Malay Muslim population can thus be described as, by inclination and religion, abstainers.

The same does not hold true for the rest of the population, who brought with them their traditional alcoholic beverages from their home countries or continued to use their traditional fare. These include, among south Indians, *toddy*, a drink made from the fermentation of the sap from the coconut palm, which has an alcohol content of between 4 and 6 percent and which, until recently, was widely available through government- or estate-regulated *toddy* shops (Arasaratnam, 1970). The estate owners used alcohol as a colonizing and proletarianizing force (Van-Onselen, 1982).

The Chinese brought with them *samsu*, a grain-derived alcoholic drink which, if distilled, can reach between 37 and 70 percent alcohol content. *Samsu* production has become an enterprise worth more than RM 180 million annually (Assunta, 2001). A good portion of this is illegally sold through traditional medicine outlets and sundry shops. Often school dropouts are easy targets of this cheap liquor. The price for a 150-milliliter bottle of *samsu* can be as cheap as RM 3.00 (about USD 1.00), hence making it affordable to these children (Consumer Association of Penang, 2008).

A rice wine, *tapai*, is available among the indigenous population in the East Malaysian states of Sabah and Sarawak and is very much a part of their festivals and hospitality. Refusal to drink may be a breach of etiquette.

A survey on urban lifestyles puts alcohol consumption among Malays at 1.4 percent, among Chinese at 27 percent, and among Indians at 23.4 percent (Inoguchi, Baáñez, Tanaka, & Dadabaev, 2005). Another, the Second National Mental Health Survey, suggests that 23 percent of non-Muslims aged 18 years and above admitted to alcoholic beverage consumption (Rugayah et al., 2000). This survey also reported that the rural rate (27.3%) was higher than the rate for the urban population (21.1%). More men (38.3%) drank compared to women (9.8%; Loe & Maimunah, 1997). The pattern of these findings can be ascribed to the culture and social acceptability of alcohol drinking in the Malaysian community among the non-Muslims.

European forms of alcoholic beverages, such as stout, beer, brandy (cognac), and whiskey, were brought by the British. Guinness Stout went from being imported from Dublin to being brewed locally by a Malaysian company, Guinness Anchor Berhad, in a stronger form (8% alcohol content). To avoid the high import duties on beer, Carlsberg A/S of Denmark, the biggest brewer in the world, built a factory and started brewing Carlsberg Green Label locally in 1972. It has viewed Malaysia as a "very important and attractive market"

(Assunta, 2001, pp. 18–21). Currently, Carlsberg is the undisputed beer market leader (Jernigan & Indran, 1997).

The rest of the alcoholic drink market in Malaysia is expected to continue performing positively. It grew at an annual average rate of 1.2 percent between 2000 and 2005 (Guinness Centre, 2005). Traditionally, the most popular European alcoholic beverages have been cognac (brandy), followed by whisky. Wine has become a favorite and a mark of cultural refinement. Some 3.8 million liters of wine are imported. They come from Australia, United States, Chile, South Africa, Argentina, and France.

Malaysia is the tenth largest consumer of alcohol in the world, with an estimated expenditure of over USD 500 million on alcoholic beverages (Assunta, 2001). Although only about one-fourth of the Chinese and Indians admit to drinking, the statistics suggest that they do so heavily. There is no recent record of the number of alcoholics in Malaysia, but it can be foreseen that alcohol abuse may become a social problem in the near future.

Controlling the Drinking Habit

The government, while remaining liberal toward the consumption of alcohol, has taken action to curb the habit. A set of taxes has increased the retail costs of all beverages. For example, the excise duty on beer rose from RM 2.75 in 1991 to RM 7.40 in 2005. The combined import, excise, and sales taxes on a standard 750-milliliter bottle of wine are approximately RM 15.00 (about USD 5.00).

In Malaysia, there has been concern since the late 1990s about aggressive marketing by international companies, using advertisements and promotional tactics in bars and clubs that would not be permitted in many Western countries (Jernigan, 1997). As a result, Malaysia banned direct alcohol advertising over public radio, television, and on billboards, but it is permitted in cinemas, on video cassettes, and in the print media. Sponsorship activities are allowed.

Assunta (2001) has listed the tactics used by the alcoholic beverage industry to attract and keep drinkers. A few of these follow:

Ethnic Targeting

The 1980s Guinness campaign "Guinness is good for you" has been a successful campaign in capturing the poorer working class, especially among the poorer estate workers and laborers. This stout is promoted as a drink that "will put back what the day takes out," and it contains more alcohol than beer for the same price. Even religious occasions, such as Deepavali, the Hindu festival

of lights, are not spared in the advertising campaign. The targets are generally poorer Indians.

Claiming Health Benefits for Alcoholic Beverages

At least two alcoholic concoctions—Yomeishu, which contains 14 percent alcohol, and DOM Benedictine, which contains 40 percent alcohol—have been advertised as restoratives for work-related fatigue and mothers who have just given birth.

Manufacturers of *samsu* have resorted to many misleading health claims. One brand recommends it for anemia, loss of appetite, indigestion, and healing properties (Consumer Association of Penang, 2008).

The growing popularity of red wines may be attributed to claims that they contain substantial amounts of antioxidants to slow down the aging process.

Sponsoring Activities

Alcohol companies used to sponsor music and sports events before the ban on most forms of alcohol advertising. The industry now undertakes indirect advertising or brand stretching. Events in private clubs may be sponsored, and products are offered at substantial discounts to entice drinkers.

Problems Associated with Alcohol

The victims of alcohol abuse are the poor, particularly the rural Indian laborers who work on rubber and oil palm estates, who drink *samsu* and *toddy*. It is a major cause of poverty. Of an estimated 200,000 drinkers, 75 percent are *samsu* drinkers (Assunta, 2001).

Drinking and driving causes about 0.3 percent of total road accidents nationwide and has become enough of a problem for the government to impose roadside monitoring and increased penalties for driving under the influence.

In Malaysia, it is evident that nonbiological factors, especially unemployment, lower educational level, alcohol use, media influence, the presence of gangs, and access to weapons and firearms, are important precursors of violent crime. Alcohol has a strong association with aggressive behavior and violence. Women who live with heavy drinkers are at greater risk of being a victim of partner violence, and men who are under the influence of alcohol tend to commit more serious violence at the time of assault (World Health Organization, 2006).

The reasons for perpetration and victimization in intimate partner violence in Malaysia are not clearly documented. However, based on cases reported to

the Department of Social Welfare, five common causes for violent acts between husbands and wives in 2004 were financial problems, extramarital affairs, conflicts with in-laws, stress at the workplace, and alcohol abuse (Malaysia Department of Social Welfare, 2004).

Legislation Regulating Alcohol

Malaysia has laws related to sales of alcohol. Under Section 32 (1) and 33 (1) of the Excise Act 1976, no person can sell (either wholesale or retail) intoxicating liquor either for use within a premise or outside without a license. The license issued must specify the precise place where sale is allowed. Any sale without a license is an offense under the act. The legal limit for drinking is 80 milligrams of alcohol in 100 milliliters of blood. If a person is caught driving while over the legal limit, he has to pay a penalty of RM 2,000 (about USD 700) or spend a maximum of six months in jail, or both, for the first offense, along with suffering the loss of his driver's license.

In November 2008 several local government councillors from *Parti Islam Se-Malaysia* (Pan-Malaysian Islamic Party—PAS) raised the issue of banning the sale of alcoholic drinks in Selangor, who voiced their concern that alcoholic drinks were easily available for youths (Bernama, 2008). Selangor is one of the states governed by *Pakatan Rakyat* (People's Pact), a new government formed on April 1, 2008. However, according to Chief Minister Selangor, Tan Sri Abdul Khalid Ibrahim, Selangor will not take the drastic action of totally banning the sale of alcoholic drinks as its residents are multiracial and multireligious. He stated that Selangor state government will intensify enforcement to ensure that alcoholic drinks were not sold to Muslims and youths under the age of 18. The state government will hold discussions with traders, local governments, other government agencies, and non-governmental organizations next year to identify the best methods to enhance enforcement on liquor consumption.

DRUG ABUSE IN MALAYSIA

Like other fast-developing countries, Malaysia also faces a plethora of social problems resulting from economic, technological, and societal growth. One of them is drug abuse. Drug abuse in Malaysia is not a recent phenomenon. It has a history that is closely associated with the early development of the country. Drugs were introduced into the country in the early nineteenth century with the importation of migrant labor from China and south India. The Chinese brought the habit of opium smoking, while Indians introduced cannabis or ganja smoking (How, 1999).

The Bureau for International Narcotics and Law Enforcement Affairs (2008) stated that Malaysia is not a significant source country or transit point for U.S.-bound illegal drugs, but regional and domestic drug trafficking remains a problem, and international drug syndicates are still looking to Malaysia as a regional production hub for crystal methamphetamine and ecstasy, or MDMA. The narcotics imported to Malaysia include heroin and marijuana from the nearby Golden Triangle area, while other drugs such as amphetamine-type stimulants (ATS), including crystal methamphetamine, ecstasy, and ketamine are brought from India. Ketamine and crystal methamphetamine are the fastest-growing illicit drugs used in Malaysia.

Malaysian Drug Scenario

Despite strict laws and penalties for drug use and trafficking, the drug problem has been identified as a security problem since 1983, when specific laws were formulated to curb the epidemic. However, the number of drug users identified each year still increases.

Dato' Dr. Chua Soi Lek, then minister of health, in a speech in 2004, stated that the number of drug addicts in Malaysia detected in 2003 was 36,996—a 16 percent jump from the 31,893 cases detected in 2002, vis-à-vis the small 1 percent increase from 2001 to 2002 (Chua, 2004). Chua also said that a total of 20,194 cases were newly detected cases. Malays made up 71.4 percent of the newly detected cases, Chinese 10.6 percent, and Indians 8.2 percent. Among those who gave reasons for their initiation into drug abuse, 52 percent attributed it to peer pressure, 25 percent to curiosity, and 17 percent to a search for pleasure. Of great concern to the Malaysia government is the fact that 70 percent of the drug addicts detected in 2003 were young adults between 20 and 39 years of age—people in their prime of life who ought to be economically and socially most productive. Heroin (36%), morphine (30%), ganja (23%), and methamphetamine, or *syabu* (7%), constituted the most frequently abused drugs (Chua, 2004).

Interestingly, according to UNICEF Malaysia (2007), in 2006, as many as 22,811 drug users were detected, 12,430 of whom were repeat offenders. There was a 34.47 percent reduction in the number of cases detected in 2006 as compared to the 34,813 cases detected in 2005. Pulau Pinang recorded the highest number of detected cases at 5,127, followed by Kedah (2,634), Perak (2,545), Kelantan (2,243), and Johor (2,329). The profile of the drug user is (UNICEF Malaysia, 2007) 97.97 percent male; 69.48 percent Malay; 71.04 percent youth aged between 25 and 29 years old; 78.30 percent minimum secondary Form 3 education (16 years old); 90.69 percent employed (majority laborers); 60.73

percent heroin/morphine users; and 12.56 percent ATS abusers. About 59.78 percent of users said that their use of drugs was influenced by friends.

In its latest bulletin, the National Anti-Drugs Agency (2007) reported that at the end of June 2007, 14,489 drug users were identified, showing another 36.48 percent decrease compared with 2006 (22,811 drug users). The profile of the drug users are 97.60 percent male; 72.62 percent Malay; 70.00 percent youth aged between 19 and 24 years old; 79.17 percent minimum secondary Form 3 education; 92.03 percent employed (majority laborers); 62.56 percent heroin/morphine users; and 10.28 percent ATS abusers. About 55.65 percent of them said that they were influenced by friends to use drugs. Pulau Pinang still recorded having the highest number of drug abusers (3,433), followed by Johor (2,004), Kuala Lumpur (1,756), and Kedah (1,604).

Drug Treatment and Rehabilitation Programs in Malaysia

Drug abuse and related disorders exert a heavy burden on the country's health care and legal systems. Historically, drug abusers were rehabilitated involuntarily in correctional, rather than health care facilities. This primarily criminal treatment approach had limited effectiveness and led to widespread public dissatisfaction until the introduction of medical treatments for addiction. Naltrexone was introduced in 1999, buprenorphine was introduced in 2001 and methadone in 2003. Agonist maintenance programs were embraced rapidly by the medical community in Malaysia. Currently over 30,000 opiate-dependent patients are treated with agonist maintenance treatments by more than 500 medical practitioners in Malaysia (Mazlan, Schottenfeld, & Chawarski, 2006).

The first phase of the Methadone Maintenance Therapy (MMT) program was officially launched at the national level in October 2005. It involved 1,241 clients spread over eight government hospitals, two community health clinics, and seven private health practitioners (UNGASS Country Progress Report, 2008). The program was able to achieve a retention rate of 75 percent after 12 months of implementation. This result is considered a major achievement when measured against World Health Organization (WHO) retention rate standards of 55 to 60 percent as well as against comparable programs in Poland, Lithuania, and Ukraine.

All the clients of the program were closely monitored using the WHO Quality of Life tests combined with appropriate physical, psychological, social relationship, and environmental evaluations over the treatment period.

The expansion of the MMT program (currently in phase 2) will enable an estimated 25,000 clients to be reached by 2010. However, the target deter-

mined by WHO and the Joint United Nations Programme on HIV/AIDS requires that 60 percent of the intravenous drug using population have access to the intervention for it to have an effective impact. This means that the existing program needs to be further expanded. Though this represents a significant challenge, the results thus far from the program have created an argument for long-term commitment of resources by the government and for the continued expansion of coverage.

Drug treatment and rehabilitation in Malaysia are operated either by the National Anti-Drugs Agency, the Prison Department, the Ministry of Home Affairs, or by nongovernmental organizations (NGOs). The National Anti-Drugs Agency operates 29 treatment and rehabilitation centers, also known as Pusat Serenti. These Serenti drug rehabilitation centers provide rehabilitation services for drug users from various categories of addiction ranging from hard-core to new users (Malaysia Ministry of Health, 2002). Until March 2008, there were 7,328 drug users in 29 Serenti drug rehabilitation centers throughout the country. About 646 of them (8.81%) were HIV-positive (Personal Communication, 2008).

The prison system currently operates 12 programs throughout the country. These programs are based on the therapeutic community (TC) model. The programs include a core program philosophy, daily activity schedule, and specific skills, or "tools of the house," that must be learned by each inmate. The programs consist of three phases: (1) induction (pretreatment), (2) core treatment, and (3) reentry (Gerald & Steven, 2003).

The goal of the programs is not punishment. Many activities are consistent across all of the prison TC programs, including (1) different types of group activities (e.g., encounter, peer confrontation, assertiveness training, morning meeting, and house meeting), (2) different types of individual activities (e.g., individual counseling with staff, pull-ups, haircut, and peer confrontation), (3) vocational training, (4) religious education and counseling, and (5) house chores.

The programs use volunteers to assist with religious components, which provide equal emphasis on Muslim, Hindu, Christian, and Buddhist beliefs. However, follow-up and continuing care programming exceed the authority of the Prison Department. As a result, both are not offered formally at present.

The NGOs offer 52 programs nationwide, and these NGO programs are run primarily by small, faith-based organizations (Gerald & Steven, 2003). Persatuan Pengasih (the word *pengasih* means "compassion") was founded in 1991 as a private NGO treatment and rehabilitation institute. It began offering services in 1993. Participation is voluntary. Services include outreach, primary treatment, and hospice care (Gerald & Steven, 2003).

Persatuan Pengasih drug treatment programs also use the TC model of treatment. Persatuan Pengasih's mission is to facilitate the recovery of drug-dependent individuals, help restore families affected by drug abuse, provide compassionate care for people suffering from HIV/AIDS, and provide preventive education programs in the community. All residents agree that the love and support they receive from peers and the sense of family that exists within the community are the most valued aspects of the program. Persatuan Pengasih offers a full continuum of care, including outreach, primary treatment, and hospice services. The organization serves more than 300 persons per month.

There are several challenges faced by the National Anti-Drugs Agency, the Prison Department, the Ministry of Home Affairs, and NGOs in helping drug users. There are increasing numbers of hardcore addicts who use mixed drugs (*dadah campuran*), leading to cross-addiction. The lack of staff experienced in handling these cases creates further challenges.

Drug Abuse and HIV/AIDS

There is a link between intravenous drug abuse and the spread of HIV. The first AIDS case in Malaysia was reported in December 1986; since then, the number of new cases has risen exponentially.

Intravenous drug use has long been seen as being responsible for the spread of HIV in Asia. In Malaysia, the rapid spread of the virus since the 1990s has been attributed to the use and sharing of contaminated intravenous drug equipment. The profile of intravenous drug users continues to be predominantly male, young, of Malay ethnicity, and heterosexual. Women represent a small percentage of Malaysian drug users (around 2%), and their total numbers remain unknown due to the lack of available data and studies of this population (UNGASS Country Progress Report, 2008).

In 2001, cumulative HIV infections were 44,208 cases, 6,024 of which were AIDS cases. Most of the HIV cases were among men (81.5%) and Malays (72.3%), and a staggering 79 percent of reported cases of infection were from intravenous drug use (Malaysia Ministry of Health, 2002). By the end of 2004, 64,000 Malaysians were reported to be infected with HIV, of whom some 9,400 had developed AIDS. The majority of reported AIDS cases and HIV infections were contracted through intravenous drug use (United Nations Development Program, 2007).

As of December 2006, after more than 20 years into the HIV epidemic in Malaysia, the country has recorded a total of 76,389 persons with HIV since the first reported cases in 1986. Most reported infections occur among young heterosexual males between the ages of 20 and 39. About 75 percent of

the cumulative HIV cases were reported among intravenous drug users. The WHO currently continues to classify Malaysia as having a concentrated HIV epidemic (Malaysia Ministry of Health, 2007).

Drug Legislation in Malaysia

Malaysia has five main statutes that cover drug laws. They are as follows:

Dangerous Drugs Act 1952

This is the major legislation relating to Malaysian drug control. This act gives provision for the regulation of the importation, exportation, manufacture, sale, and use of opium and of certain other dangerous drugs and substances. The act has been revised several times in relation to changes in patterns of drug use. This act includes the death penalty for drug trafficking.

Poisons Act 1952

This act is aimed at regulating the importation, possession, manufacture, compounding, storage, transport, sale, and use of poisons. This includes any mixture, preparation, solution, or natural product. It also includes products used in industry, medicine, and agriculture.

Drug Dependents (Treatment and Rehabilitation) Act 1983

This is a comprehensive legislation covering treatment and rehabilitation. The act provides for compulsory treatment and rehabilitation of any person who has been certified as drug-dependent as well as for the establishment and implementation of voluntary treatment programs. The period of compulsory treatment and rehabilitation (i.e., not voluntary) at a rehabilitation center is two years, and thereafter, one must undergo supervision by an officer for two years.

Dangerous Drugs (Special Preventive Measures) Act 1985

This act allows the government to detain anyone suspected of being a trafficker without having to bring the suspect to a court of law. This act is an amendment to the Dangerous Drugs Act 1952 to provide for matters connected therewith.

Dangerous Drugs (Forfeiture of Property) Act 1988

This act allows the government to trace, seize, and forfeit assets of convicted drug traffickers. This act also makes provisions for offenses in relation to prop-

erty, and for the seizure and forfeiture of property, connected with activity related to offenses under this act, or any foreign law corresponding to these acts or to the provisions for offenses under these acts; for assistance to foreign countries in relation to matters connected with dangerous drugs; and for matters connected with the aforesaid provisions.

Actions against Drug Abuse

It is evident that drug addiction is threatening the future of Malaysians, and actions need to be taken to put a stop to it. The responsibility of combating this ominous threat does not rest solely on any one party. Agencies and centers, such as government agencies, NGOs, law enforcement agencies, rehabilitation centers, social and welfare institutions, and the medical fraternity, need to cooperate and collaborate on efforts to develop more effective approaches to combat and manage drug addiction. Total commitment, involvement, and sustained efforts from everyone are crucial. Only then can we hope to make any significant headway in our quest for a drug addiction–free nation.

Family members and the community have a particularly important role to play. Vision 2020 calls for the establishment of a fully moral and ethical society, whose citizens are strong in religious and spiritual values, and a fully caring society and caring culture, where society will come before self and the welfare of the people will revolve around a strong and resilient family system. As such, parents should work hard to instill the right moral values in their children so that they do not fall prey to drugs. And for drug users who have gone astray in the choices that they have made in life, family members and the community should provide the support, encouragement, acceptance, and understanding necessary for them to wean themselves of their habits. They need to be guided back to the right path and be given a second chance at a productive life.

Medical practitioners and other health care providers play an important role in assisting family members and the community in drug prevention and management. Medical practitioners and other health care providers must be prepared to go beyond the call of duty to provide support, counseling, and guidance to the drug users and to help them work through their problem each step of the way. It is also their duty to help change the mind-set of society and erase the stigma and discrimination attached to drug treatment and rehabilitation so that more families will be willing to bring their drug-addicted members in for treatment.

Government agencies like the National Anti-Drugs Agency, the Association for Drug Prevention Malaysia (*Persatuan Mencegah Dadah Malaysia*), the

Ministry of Education, and the Ministry of Health have already taken steps to prevent drug addiction through education. There are dedicated drug prevention programs targeted at the family and community levels; at primary, secondary, and tertiary institutions; and at workplaces to increase public awareness of drugs and their effects, with the hope that people will be better empowered to make the correct choice not to be involved with drugs and to resist negative peer pressure.

According to the Bureau for International Narcotics and Law Enforcement Affairs (2008), in addition to the actions mentioned previously, Malaysia has also made other efforts such as the following:

Policy Initiatives

Malaysia continues a long-term effort launched in 2003 to reduce domestic drug use to negligible levels by 2015, a goal shared by the whole of Association of Southeast Asian Nations (ASEAN). The National Anti-Drugs Agency is the policy arm of Malaysia counternarcotics strategy, coordinating demand reduction efforts with various ministries. Malaysian law stipulates a mandatory death penalty for major drug traffickers, with harsh mandatory sentences also applied for possession and use in smaller quantities. In practice, however, many minor offenders are placed into treatment programs instead of prison or are referred to the Preventive Measures Act, under which they can be held for two years (renewable to eight years).

Law Enforcement Efforts

Malaysian authorities raided three clandestine drug labs in 2007 and had several successful drug seizures, confiscating large quantities of methamphetamine and ecstasy. Police arrested 36,534 people for drug-related offenses between January and August 2007 and held in detention or rehabilitation centers a total of 111,416 drug addicts during the same period. Enforcement officials continued to show successes in ATS-related seizures and have also recorded a higher level of heroin seizures over the same period than last year. The Royal Malaysian Police recorded a 46 percent increase in confiscated property derived from drug-related cases over the first eight months of 2007 (Bureau for International Narcotics and Law Enforcement Affairs, 2008).

Many suspected traffickers continue to be detained under Malaysian special preventive measures, including the Restricted Residence Act and the Emergency Ordinance 1969, which allow for detention without trial of suspects who pose a threat to public order or national security.

Drug Flow/Transit

Drugs transiting from Malaysia do not appear to make a significant impact on the U.S. market. However, Malaysia's proximity to the heroin production areas and methamphetamine labs of the Golden Triangle leads to smuggling across Malaysian borders of drugs destined for Australia and other markets. Ecstasy from Amsterdam is flown into Kuala Lumpur International Airport for domestic use and distribution to Thailand, Singapore, and Australia. Ketamine comes from Tamil Nadu, (southern) India, and is exported to several countries in the region. There is evidence of increased transit of cocaine, although police have not yet thoroughly developed information on this trend (Bureau for International Narcotics and Law Enforcement Affairs, 2008).

Domestic Programs (Demand Reduction)

The National Anti-Drugs Agency continues to target its demand reduction efforts toward youth, parents, students, teachers, and workers, with extensive efforts to engage schools, student leaders, parent-teacher associations, community leaders, religious institutions, and workplaces through prevention and treatment (Global Demand Reduction Efforts on Drugs, 2000). A demand reduction program in Malaysian public schools and a drug-free workplace prevention program began in 1999.

CONCLUSION

The most important implication of this review is that little is known about the prevalence of alcohol use and abuse in Malaysia. However, given the high expenditure being reported for alcoholic beverages, the rates of alcohol consumption and abuse are expected to be relatively high. As with alcohol, we are unaware of any empirical studies that have examined the prevalence of drug use and abuse. However, according to UNICEF Malaysia (2007), a total of 22,811 drug users were detected in 2006, half of whom were reported to be repeat offenders.

To fully understand alcohol and drug use and abuse in Malaysia, there is an urgent need to conduct a large epidemiologic study. Such a study should provide information on the prevalence, comorbidity, risk and protective factors, and course of substance use and abuse in difference age and ethnic groups. This information will be useful from a public health point of view in terms of preventing the occurrence of substance abuse, particularly among young

adults. Given the negative consequences of substance abuse, several prevention programs have been developed for several age and professional groups. The next important step would be to systematically examine the efficacy of these programs.

Chapter **10**

Alcohol Use and Binge Drinking in Cyprus

Xenia Anastassiou-Hadjicharalambous, PhD,
Cecilia A. Essau, PhD, MA, HBA, and George Georgiou, PhD

Cyprus is the third largest island in the Mediterranean, with a population of about 800,000. The island of Cyprus is divided by the so-called Green Line, established following the invasion of Turkey in 1974. About 37 percent of the island is under Turkish occupation. Cyprus joined the European Union in 2004.

Its long Mediterranean summers, mild winters, and gentle winds make Cyprus an ideal place for vine growing. In fact, recent archaeological discoveries show that Cyprus has been a vine-growing and wine-producing country for 6,000 years. Historically, wine production can be divided into four periods: ancient, medieval to 1878, between 1878 and 1980, and 1980 onward (Kythreotou, 2003):

ancient. Archaeological evidence seems to indicate that the cultivation of the grape vine started in Cyprus in the second millennium B.C. For example, the discovery of a shipwreck in 1999 showed that wine was being traded as early as 2300 B.C. Other discoveries include wine containers that belonged to the Bronze Age (2500–2000 B.C.). More recently, the discovery of pottery fragments, dating back to the chalcolithic period (i.e., between 3500 and 3000 B.C.) and containing traces of tartaric acid, gave further proof that this pottery was used for wine. Indeed, these and other recent archaeological discoveries place Cyprus as the first Mediterranean country to produce wine.

medieval to 1878. The island's wine history seems to be closely related to its political and administrative history. For example, during the Lusignan occupation, Commandaria wine was the most popular. Commandaria has

been produced on the island since at least 1000 B.C. and remains the oldest wine still in production. During the Ottoman occupation, wine production declined dramatically due to traditions associated with Islam and the heavy burden of taxation.

1878–1980. The handing over of the island from Ottoman rule to the British Empire in 1878 brought a revival in the wine-making industry. This period also saw changes in taxation rules and the expansion of the local wine industry. An important factor that led to the expansion of the Cypriot wines was related to the phylloxera epidemic, which destroyed the majority of wine-producing vines in mainland Europe in the nineteenth century. Cyprus remained relatively unaffected due to the strict quarantine controls that were in place, which subsequently boosted demand for both Cyprus grapes and wines.

1980 onward. From 1980, three initiatives were launched to overhaul the wine sector to improve the quality of wine. These included the introduction of new varieties of grapes (e.g., Cabernet Sauvignon, Cabernet Franc, and Palomino) and financial support for their cultivation; this initiative was believed to improve quality wine production and so make wines more palatable to overseas markets compared to local grapes. The second incentive was to establish small regional wineries near the vineyards: reducing the distance the grapes had to travel vastly improved the quality of the wine. The third incentive was the launching of the new Appellation of Origin in 2007. Specifically, when Cyprus joined the European Union, it had to classify its wine under the new legislature.

In Cyprus, alcohol is easily available in supermarkets, gas stations, grocery stores, and public facilities.

LAW PARADOX

The Children Law of 1956 states that any person who sells alcohol to a person under the age of 14 years, for his or her own use, is guilty of an offense and will be liable, in the case of a first offense, to a fine not exceeding £25 (€43); for a second offense, to a fine not exceeding £25 (€43); and in the case of a third or subsequent offense, to a fine not exceeding £50 (€85). Furthermore, the police would be authorized to seize alcohol in the possession of any person under the age of 14 years found in any street or public place. This providence law applies only to cases where alcohol is purchased by the child for personal consumption. However, a child is entitled to purchase alcohol on behalf of an adult.

The Children Law of 1956 is in conflict with the Selling of Alcohol Law of 1961, article 83, 1998. The Selling of Alcohol Law of 1961, article 83, 1998,

prohibits the trade or distribution of alcoholic beverages to an individual under the age of 17 years, an offense punishable with imprisonment for up to three months or a pecuniary fine up to £1,000 (€1,709), or both. Proof of age documentation is required when purchasing alcohol. The contradiction between the Children's Law of 1956 and the Selling of Alcohol Law of 1961 is obvious. On one hand, the former allows the selling of alcohol to individuals under the age of 14 when the alcohol purchased is not for personal consumption, while the latter prohibits the distribution and selling of alcohol to individuals up until the age of 17.

A further paradox is observed between the Modified Children's Law of 1999 and the Recreational Centres Law (1985–1999). The Recreational Centres Law (1985–1999) does not foresee any prohibition related to underage drinking. In contrast, the Modified Children's Law of 1999 requires that all drinking establishments ensure that no individual under the age of 16 years is allowed to enter their premises. First-time violators of this law will be subjected to a pecuniary fine up to £500 (€854) or up to three months' imprisonment, or both. The person who violates this law for a second time will incur a pecuniary fine up to £1,000 (€1,709) or up to six months' imprisonment, or both. The establishment may also face losing its liquor license. These contradictory laws are compounded by the lack of law enforcement. Indeed, children and adolescents freely obtain alcohol in bars, clubs, and other establishments and outlets without providing proof of age documentation as the law requires. Currently members of parliament are calling for significant legislative progress and harsher penalties in the fight against underage drinking.

The Cyprus Broadcasting Corporation Law, 300A, 2001, 2002, 2004, requires that the advertisement of alcohol follows the following rules: (1) ads must not be addressed to underage individuals or present underage individuals consuming alcohol; (2) ads must not connect the consumption of alcoholic drinks to improved body performance or to driving a vehicle; (3) ads must not cause the impression that the consumption of alcoholic drinks enhances social or sexual success; (4) ads must not allow the impression that alcoholic drinks have therapeutic attributes or that they act as stimulants, tranquillizers, or analgesics; (5) ads must not encourage overconsumption of alcohol and must not allow a negative image of those individuals who abstain from the consumption of alcohol; and (6) ads must not stress as an advantage of the drink the inclusion of a high amount of alcohol.

The Internal Regulation of the Cyprus Broadcasting Corporation on alcohol advertising states that advertisements for alcoholic drinks will be presented as late as possible in the night and not between programs that are addressed to children or young individuals.

PREVALENCE OF ALCOHOL CONSUMPTION IN CYPRUS

Alcohol Use and Binge Drinking in Adolescents

The only information on the patterns of alcohol consumption in adolescents comes from the European Schools Project on Alcohol and Other Drugs (ESPAD). The ESPAD aimed to examine the frequency of consuming different types of alcoholic beverages (including binge drinking) and other substance use in over 50,000 16-year-olds across Europe (Morgan et al., 1999). Three surveys have been conducted so far: the first one in 1995, the second in 1999, and the third in 2003. A total of 26 and 30 European countries participated in the first and second survey, respectively (Hibbel et al., 2001). In the last survey, 35 countries participated, including Austria, Belgium, Bulgaria, Croatia, Cyprus, the Czech Republic, Denmark, Estonia, the Faroe Islands, Finland, France, Germany, Greece, Greenland, Hungary, Iceland, Ireland, Isle of Man, Italy, Latvia, Lithuania, Malta, the Netherlands, Norway, Poland, Portugal, Romania, Russia (Moscow), the Slovak Republic, Slovenia, Sweden, Switzerland, Turkey, Ukraine, and the United Kingdom. During the 2003 ESPAD survey, 2,152 (999 boys and 1,153 girls) Cypriot adolescents participated.

The results of the most recent ESPAD survey can be summarized as follows (Hibbel et al., 2004):

1. About four-fifths of Cypriot 16-year-olds have tried alcohol sometime in their lives. Specifically, 86 percent of the students reported having consumed alcohol at least once in their lives. Of those who had consumed alcohol, 27 percent reported having consumed alcohol on more than 40 occasions. The 12- and 1-month prevalence of alcohol use was 79 percent and 63 percent, respectively.
2. Beer was the most common alcoholic beverage (53%), followed by wine (36%) and spirits (41%).
3. Alcopops (i.e., the assortment of alcoholic beverages) were consumed by quite a high percentage of adolescents (62%), ranking Cyprus among the highest countries where adolescents drink this beverage.
4. Thirty-four percent of the students had engaged in binge drinking (i.e., having five or more drinks in a row); however, most of them only binged once or twice, and only 2 percent had binged more than 10 times.
5. Boys drink more than girls.
6. The majority of the participants had their first experiences with beer, as opposed to other alcoholic beverages; that is, 68 percent of the participants reported having had beer and first drunkenness at the age of 13 years or

younger, compared to those who had consumed wine (44%) or spirits (27%).

7. Thirty-nine percent of the adolescents reported being drunk sometime in their lives; this figure indicates that Cyprus had among the lowest rate of drunkenness among the ESPAD countries.
8. Forty-eight percent expected positive consequences (mostly related to having lots of fun) of alcohol consumption, compared to 31 percent who expected negative consequences (mostly related to getting a hangover).
9. Perceived easy availability of alcohol beverages was as follows: beer (85%), wine (87%), and spirits (83%).

When comparing the percentage of adolescents who consumed alcohol in the last 12 months across the three surveys, Figure 10.1 shows a decrease from 85 percent in 1995 to 79 percent in 1999 and 2003. Across all the ESPAD countries, the corresponding percentages were 80 percent (in 1995), 82 percent (in 1999), and 81 percent (in 2003; European School Survey Project on Alcohol and Other Drugs, n.d.; Figure 10.1). The rate of drunkenness remained stable, ranging from 27 percent in 1995 to 25 percent in 2003 (Figure 10.2), compared to the respective percentages of 47 percent, 51 percent, and 50 percent for all the ESPAD countries

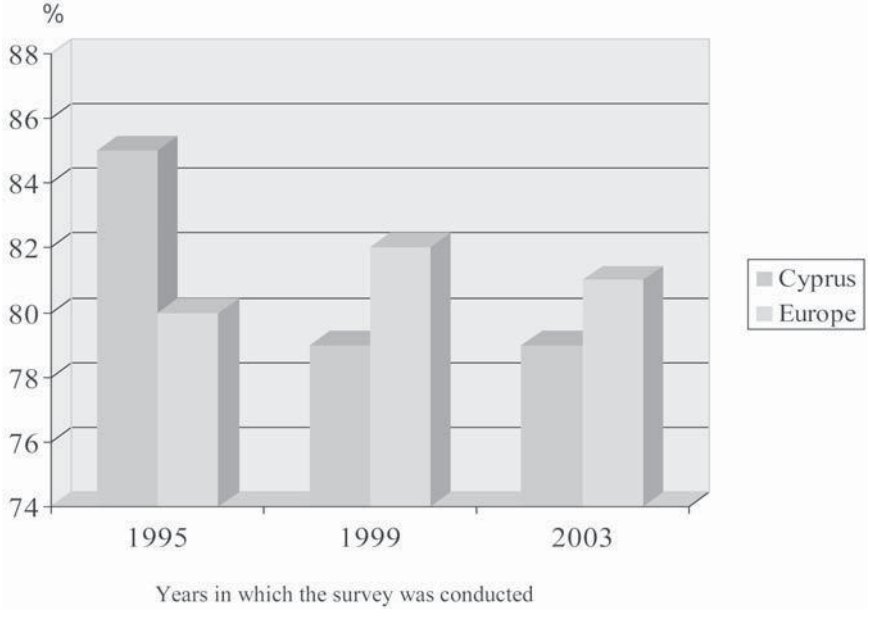

FIGURE 10.1 Percentages of persons drinking any alcoholic drinks in the last 12 months.

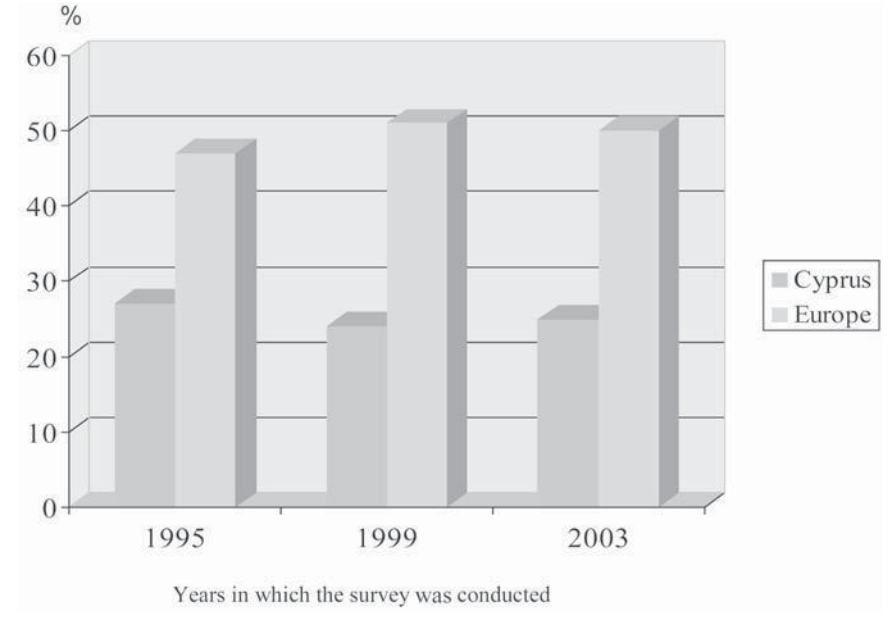

FIGURE 10.2 Percentages of persons experiencing drunkenness in the last 12 months.

Alcohol Use and Binge Drinking in Young Adults

In this section, we describe our recent study (Anastassiou-Hadjicharalambous, Essau, & Georgiou, 2008) on alcohol drinking and binge drinking among young adults in Cyprus.

Participants

A total of 126 students participated in the study (31.5% men and 68.5% women). Their mean age was 23.6 years (*SD* = 5.3). Most of them were still single (84%); 11.9 percent were married and 4 percent were divorced. As for religious affiliation, almost all of the participants reported being a Christian Orthodox (91.9%).

The participants were recruited from various colleges and universities in Nicosia, the capital of Cyprus. They were administered a set of questionnaires that measured frequency, patterns, and motivations for alcohol use.

Instruments

The Alcohol Use Disorders Identification Test (AUDIT; Saunders, Aasland, Babor, de la Fuente, & Grant, 1993) was used to measure recent alcohol use,

alcohol dependence symptoms, and alcohol-related problems. It consisted of 10 questions. The AUDIT was developed by the World Health Organization (WHO) and has been used for screening for excessive drinking in many settings. A cutoff value of 8 points has been identified as an index of problematic drinking. The psychometric proprieties of the AUDIT have been reported in various studies. In this study, Cronbach's was 0.84.

The Self-Regulation Questionnaire (Carey, Neal, & Collins, 2004) was used to measure self-regulation (i.e., the generalized ability to regulate behavior to achieve desired future outcomes). It contains 31 items that can be answered on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). In this study, Cronbach's was 0.88.

The College Alcohol Study (CAS; Weitzman, Nelson, & Wechsler, 2003) was used to measure student alcohol use, patterns of use, reasons for not drinking, and problems associated with alcohol use. In this study, the CAS was slightly modified to adjust to the adults in Cyprus. In this study, a drink was defined as the following: one-half pint of ordinary strength beer, lager, or cider (so a pint is two drinks); a 25-milliliter measure of spirits straight or in a mixed drink; a 125-milliliter (small) glass of wine; and two-thirds pint of beer/alcopop (bottles are one and a half drinks per unit).

A gender-specific definition of binge drinking (i.e., heavy drinking behavior) was used: for men, it was five or more drinks in a row in the past two weeks, and for women, it was four or more drinks in a row in the past two weeks.

The Drinking Motives Questionnaire (DMQ; Cooper, Russell, Skinner, & Windle, 1992) was used to measure the participants' motivation to drink alcohol. The DMQ contains 20 items, which can be rated on a 4-point Likert scale ranging from 1 (almost never/never) to 4 (almost always). The items can be grouped into four different subscales: enhancement, coping, conformity, and social motives. Cronbach's was 0.91.

The Spence-Essau Anxiety Scale (Spence & Essau, 2004) is a 33-item measure of anxiety symptoms in children and adolescents. The items reflect symptoms of the main anxiety disorders from the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (American Psychiatric Association, 1994), including social phobia, obsessive-compulsive disorder, panic/agoraphobia, specific fears, and generalized anxiety disorder. Each item is rated on a 4-point scale in terms of its frequency from 0 (never) to 3 (always). The items are summed to yield a total score, with higher scores reflecting higher levels of anxiety symptoms. Cronbach's was 0.91.

The Comprehensive Effects of Alcohol (Fromme, Stroot, & Kaplan, 1993) was used to measure participants' discrete expectancies about alcohol use. It contains 38 items that can be rated on a 4-point scale ranging from 1 (disagree) to 4 (agree). The items could be grouped into positive and negative factors. The

Table 10.1
Frequency of Binge Drinking by Gender and Age Groups

	Gender		Age group		
	Male (*N* = 40), *n* (%)	Female (*N* = 86), *n* (%)	18–19 (*N* = 60), *n* (%)	20–25 (*N* = 43), *n* (%)	26+ (*N* = 18), *n* (%)
No binge drinking	9 (22.5)	52 (60.5)	21 (35.0)	14 (32.6)	3 (16.7)
Binged 1–2 times in the past 2 weeks	16 (40.0)	29 (33.8)	24 (40.0)	23 (53.5)	13 (72.2)
Binged 3+ times in the past 2 weeks	15 (37.5)	5 (5.8)	15 (25.0)	6 (14.0)	2 (11.1)

positive factors can further be divided into four subscales: sociability, tension reduction, liquid courage, and sexuality. Likewise, the negative factors can be divided into cognitive and behavioral impairment, risk and aggression, and self-perception. In this study, Cronbach's was 0.93.

Results

Significantly more men than women reported binge drinking (2 = 20.65, $p < 0.001$; Table 10.1). Specifically, 77.5 percent of the men reported having binged at least once in the past two weeks. The highest rate of binge drinking was reported by participants in the oldest age group (i.e., 26-year-olds and older).

The most common alcoholic beverages that the participants consumed for *four or more* drinks in a row were spirits (37.1%), followed by beer (22.9%) and alcopops (18.6%). The average time to consume *four or more* drinks in a row was two hours, being reported by 32.8 percent of the participants. Almost all (86.4%) of the participants reported that it was "easy" or "very easy" to obtain alcohol.

The most common problem related to binge drinking was having a hangover. Significant group differences were found in 3 out of 12 problem areas (Table 10.2). Participants who binged at least three times in the past two weeks had significantly more problems with missed classes (2 = 27.35, $p < 0.001$), having unplanned sexual activity (2 = 23.58, $p < 0.01$), and not using protection when having sex (2 = 19.05, $p < 0.05$) than participants who did not binge drink or who had binged only once or twice.

Table 10.2
Problems Related to Binge Drinking

	No binge drinking, *n* (%)	Binged 1–2 times in the past 2 weeks, *n* (%)	Binged 3+ times in the past 2 weeks, *n* (%)
Have a hangover	12 (30)	17 (41.5)	11 (57.9)
Miss a class	2 (5)	13 (31)	6 (31.7)
Get behind in school work	3 (7.5)	13 (31)	7 (36.9)
Do something you later regret	8 (20)	12 (30)	8 (42.2)
Forget where you were or what you did	3 (7.5)	7 (16.6)	5 (26.4)
Argue with friends	2 (5)	8 (19)	4 (27.9)
Engage in unplanned sexual activity	–	9 (22)	9 (45.0)
Not use protection when you have sex	–	8 (19.4)	6 (33.4)
Damage property	1 (2.5)	7 (16.7)	2 (10.0)
Get into trouble with the campus security or local police	1 (2.5)	3 (7.2)	1 (5.6)
Get hurt or injured	3 (7.5)	5 (11.9)	2 (10.0)
Require medical treatment for an alcohol overdose	–	–	1 (5.3)

The participants were also asked their reasons for not drinking or for trying to limit their drinking. As shown in Table 10.3, the most important/very important reasons for not drinking were "going to drive," followed by "not wanting to lose control."

Correlational Analyses

The AUDIT correlated significantly positive with all the four main types of drinking motives, with all the correlations at the $p < 0.001$ level. These findings indicate that high levels of drinking were related to enhancement ($r = 0.41$), coping ($r = 0.31$), conformity ($r = 38$), and social motives ($r = 0.45$).

Table 10.3
Reasons for Not Drinking or Trying to Limit Drinking Alcohol

	Very important to important, *n* (%)	Somewhat to not at all important, *n* (%)
Drinking is against my religion	30 (24.2)	94 (75.8)
Drinking is against my values	44 (35.2)	81 (64.8)
People in my family have had alcohol problems	44 (35.5)	80 (64.6)
I'm not old enough to drink legally	25 (20.5)	97 (79.5)
I'm going to drive	102 (80.9)	24 (19.0)
It costs too much money	29 (23.8)	93 (76.3)
I don't like the taste	42 (33.9)	82 (66.1)
My friends don't drink	22 (18.1)	99 (81.8)
I don't want to disappoint someone I care about	50 (40.3)	74 (59.7)
I'm going on a date	41 (3.8)	80 (66.1)
It is bad for my health	84 (67.2)	41 (32.8)
It interferes with my studying	74 (60.2)	49 (39.8)
It interferes with my athletic activity	66 (53.2)	58 (46.8)
I've decided to cut down	50 (41.3)	71 (58.6)
I don't want to lose control	85 (68.5)	39 (31.4)
I recently drank too much	41 (34.4)	78 (65.5)
I've had problems with alcohol	44 (36.7)	76 (63.3)
It's fattening	49 (40.9)	71 (59.2)
I have a fear of getting caught	22 (20.0)	88 (80.0)

The AUDIT also correlated significantly negative with self-regulatory behavior ($r = -0.24, p < 0.05$). Thus a high level of alcoholic consumption was related to less ability to control one's behavior. Surprisingly, none of the anxiety subscales showed any significant correlations with the AUDIT.

Of all the subscales of the Comprehensive Effects of Alcohol, only cognitive and behavioral impairment correlated with the AUDIT ($r = 0–24, p < 0.01$).

Alcohol Use and Binge Drinking in Adults

Information on the prevalence and patterns of alcohol consumption in Cyprus came from the Attitudes towards Alcohol Survey (European Community, 2007). The survey was conducted at the end of 2006, in 25 member states of the European Union, plus in 2 acceding countries (Bulgaria and Romania) and 1 candidate country (Croatia) and in the Turkish Cypriot Community (TCC). The participants were interviewed face-to-face at their own homes. A total of 604 adults in Cyprus and 372 adults in the TCC participated in the survey. The results of this survey can be summarized as follows:

1. As in most European Union (EU) countries, a high percentage of the Cypriots (74%, compared to 75% across the EU) reported having consumed alcohol beverages during the last 12 months. By contrast, about half (53%) of the participants in the TCC claimed not to have drunk any alcohol in the past 12 months; this high rate of abstinence may be due to religious reasons.
2. About 63 percent and 28 percent of the participants in Cyprus and in the TCC, respectively, reported having drunk alcohol during the last 30 days before the survey. Of the Cypriots who consumed alcohol in the last 30 days, 31 percent of them drank alcohol once a week and 8 percent drank daily; in the TCC, it was 24 percent and 8 percent, respectively.
3. About 46 percent (compared to 31% across Europe) of the Cypriots had not drunk five or more drinks on one occasion. In the TCC, it was 29 percent. Interestingly, of those who had drunk more than five drinks on one occasion, 19 percent of the participants in the TCC reported drinking several times a week; the percentage found for participants in Cyprus who drank five or more drinks on one occasion was 6 percent.
4. A high percentage of the Cypriot (77%) and the TCC (68%) participants reported not knowing the legal blood level that is allowed for car drivers.
5. A majority of the Cypriot (72%) and the TCC (56%) participants did not believe that higher prices of alcohol would discourage young people and heavy drinkers from consuming alcohol.
6. Most participants agree to putting warnings on alcohol bottles and advertisements, particularly for pregnant women and car drivers (Cyprus, 92%; TCC, 91%).
7. A high percentage of the Cypriots (72%) and those in the TCC (89%) approved of banning alcohol advertising that targets young people. Equally high percentages were found for those who supported the idea of banning selling and serving alcohol to the underaged (i.e., under 18 years of age).

CONCLUSION

Information on the frequency, patterns, and correlates of alcohol use and binge drinking in Cyprus is rare. According to some recent European-based surveys, the ESPAD and the Attitudes towards Alcohol Survey (European Community, 2007), Cyprus seems to have the lowest percentages in terms of frequency of drinking compared to other European countries. However, our ongoing study seems to indicate that about one-third of the young adults, especially men, binge drink on a regular basis. Those who binge reported a wide range of personal and social problems. Our study also indicated some common correlates of alcohol use and binge drinking such as lack of self-regulatory control and specific drinking motives (i.e., enhancement, coping, conformity, and social motives). It is hoped that such information will be informative for designing methods of prevention of alcohol abuse among Cypriots (Dadds & McAloon, 2002).

The next stage of research in Cyprus should be (1) to conduct methodologically sound treatment studies, using manually guided interventions with established, empirically validated efficacy; (2) to evaluate treatment outcomes that cover abstinence or relapse status and individuals' psychosocial functioning in various life domains; (3) to evaluate the efficacy of different treatment strategies for different groups of individuals (e.g., with comorbid disorders); and (4) to conduct so-called treatment matching. This chapter suggests that much still needs to be done in Cyprus in terms of alcohol research.

Chapter **11**

Alcohol Use and Abuse in Poland

Anna Bokszczanin, PhD, Cecilia A. Essau, PhD, MA, HBA,
and Jean O'Callaghan, PhD

DRINKING AND POLISH CULTURE

The cultural model of drinking consists of many elements that describe the manner of alcohol consumption in a given country. Single and Leino (1998) consider the following elements to be of greatest importance: the age and gender of drinking people, the place and time of drinking (during meals, meetings, free time), and the kind of alcoholic beverages and the way of drinking (savoring an alcoholic beverage or drinking with the intention of getting drunk).

The customs of drinking alcohol in Poland are deeply rooted and pervasive. Alcohol accompanies the Polish family virtually at every occasion, starting with the birth of a child and finishing with a funeral reception. Alcohol is also drunk to celebrate name day or birthday parties, during meetings with friends, and to evoke different moods—getting emotional, relieving pain, soothing sadness, or cheering up. A typical beverage is vodka (in Polish, *wódka*), which has been produced in Poland since the early Middle Ages, when it was commonly used as a medicine and believed to serve as an aphrodisiac to increase fertility. Large-scale vodka production began in Poland at the end of the sixteenth century, and the end of the eighteenth century saw the beginning of the vodka industry. The production of vodkas became a Polish government monopoly in 1925. Following the Second World War, all vodka distilleries were under the control of the Communist government. During the 1980s, the sale of vodka was rationed, and following the victory of the Solidarity movement, distilleries in Poland were privatized. This privatization has led to an explosion of various brands of vodka and deregulation of rationing.

In terms of gender differences, alcohol drinking is men's domain in Poland. There are many more nondrinking women than men among the adult population of Poland. Traditional alcoholic beverages are high proof, and their consumption usually ends in excess. Statistical data show that more than 50 percent of adult men usually drink vodka in huge amounts (Dolata, n.d.).

One of the most disturbing phenomena in Poland is the high frequency of premature death that is, to a large extent, related to alcohol consumption. The frequency of such death is about 40 percent higher than the European average, especially among men (Piątek, 2003).

GOVERNMENT REGULATION OF DRINKING

Changes in alcohol consumption in Poland need to be considered in the context of political changes and associated economic climates. For example, the generally low rate of alcohol consumption in the 1980s was understood to be associated with depressed consumption of many goods in Poland. This period was marked by increasing inflation and rationing of goods. The political situation was also critical. Specifically, martial law was declared at the end of 1981 to control democratic movements, especially Solidarity. After martial law was lifted, numerous restrictions remained for several years that reduced the civil liberties of people living in Poland. During this period, the Roman Catholic Church played an active role not only in supporting anti-Communist opposition, but also in the promotion of an alcohol-free lifestyle (Wolniewicz-Grzelak, 1990).

Solidarity was again legalized in 1989, which initiated the democratic process. In the early 1990s, the alcohol industry, which was controlled by the state, began to be privatized, leading to less governmental control over alcohol production, distribution, and importation. Prior to 1989, there were no advertisements for any goods on Polish TV or in any other mass media; however, with the first advertisements in the 1990s, a lot of beer ads were addressed at teenagers (Świątkiewicz, 1997). This led to an increased availability of beer and better-quality beer. At the same time, wine prices increased considerably in comparison to beer and vodka. Between 1992 and 1996, alcohol became a dominant aspect of youth culture, being used by 90 percent of 15-year-olds (Sierosławski, 2002). The increase in alcohol consumption among minors was interpreted as being related to a more permissive attitude toward alcohol (Sierosławski, 2002) and to the availability of a wide variety of alcoholic drinks, which stimulated temptations to experiment. At the same time, a revision of Polish state policy toward alcohol drinking in the 1990s involved the process of liberalization, which resulted in less restrictive supply. Thus, while in the 1980s, alcohol policy was based on an abstinence ideology and limitations of availability, in the 1990s, it focused on

promotion of responsible drinking and risk reduction. In this new climate of easy access to alcohol, while selling alcohol to under 18-year-olds is forbidden, nevertheless, social and legal controls on availability for adolescents are not easily enforced (Sprawozdanie, 2006). Furthermore, during the 1990s, many alcoholic beverages became inexpensive (Sprawozdanie, 2000, 2006).

The transformation of the political system in Poland in 1989 from a socialist to a capitalist system also had far-reaching implications with respect to alcohol consumption, as noted previously with regard to the supply and consumption of alcohol (Szymański, Woynarowska, & Mazur, 2001). In comparison with the period before the system's transformation, the consumption of beer and vodka increased considerably among Polish adolescents, whereas among adults, consumption of vodka decreased considerably.

Another important change was Poland's accession to the European Union (EU) in 2004, which is referred to as the second phase of transformation and which brought about changes in practices and customs associated with drinking (Piątek, 2003). It is predicted that Poland will catch up with Europe with respect to addictive practices that are socially degenerative and reinforce alcohol problems for both genders. Positive aspects connected with Poland's accession to the EU must also be considered, especially the possibility of collaborative research. Poland offers considerable potential for research into the prevention and social regulation of alcohol problems (Piątek, 2003).

The legal drinking age is 18. Advertising of alcoholic drinks is prohibited in Poland. An exception is the advertising of beer when it is not (1) addressed to minors; (2) done in such a way that it creates associations with sexual attractiveness, leisure, body fitness, professional activities, job or life success, or health; (3) shown via television, radio, cinema, or theater between 6:00 A.M. and 8:00 P.M.; (4) on videotapes or other data carriers; (5) featured by youth or children's presses; (6) on the front pages of newspapers or magazines; (7) on posters or billboards, except when at least 20 percent of the advertising space is used for information about the adverse effects of alcohol use and the prohibition against selling alcohol to minors; and (8) used with minors. These restrictions do not include advertising that is conducted inside warehouses or in places that sell alcoholic beverages.

PREVALENCE OF ALCOHOL USE AND ABUSE

Alcohol Use in Adolescents

In 1990, Poland joined 32 other countries involved in the Health Behaviour in School-Aged Children surveys (Woynarowska & Mazur, 2000). This study

showed that almost all Polish 15-year-olds had consumed alcohol sometime in their lives (Currie et al., 2000). Specifically, 92 percent and 91 percent of 15-year-old boys and girls, respectively, had drunk alcohol. About 20 percent of the boys and 8 percent of the girls consumed alcohol on a regular basis (i.e., at least once a week). When comparing the frequencies of drinking alcohol from 1994 to 1998 among 15-year-olds, the data showed a decrease. However, the frequency of drunkenness increased by five times in 15-year-old boys and by three times in girls.

Most frequently, alcoholic beverages are drunk at parties, often at all-night ones (Łosik & Chadaj, 2003). The main reason for adolescent drinking was related to the lack of parental control. This tolerant attitude of parents is supported by a recent study that showed that between 25 and 49 percent of adolescents drank alcohol for the first time in the presence of adults; most often, it was in their parents' company (Hryszkiewicz, 2002). Another reason for juvenile drinking is alcohol's availability, despite the law prohibiting the sale of alcoholic beverages to adolescents. The reason for the lack of law enforcement is related to the strong competition in the alcohol market (Łosik & Chadaj, 2003).

Poland has also participated in the European School Survey Project on Alcohol and Other Drugs (ESPAD) since 1995 (Sierosławski, 2005). ESPAD results from the years 1999 and 2003 showed no significant change in levels of alcohol use by 15-year-olds (Sierosławski, 2005). An additional ESPAD survey was conducted in Poland, and the findings showed a decrease (from 93% in 2003 to 85% in 2005) in the lifetime prevalence of alcohol drinking by 15-year-olds. The results showed a decrease in the number of adolescents who consumed alcohol (from 66% in 2003 to 45% in 2005) and who reported being drunk (from 29% in 2003 to 15% in 2005) during the past 30 days. In the mid-1980s, wine was the most popular alcoholic drink, especially among girls. Beer became the alcoholic beverage of choice in 1988 among boys and in 1996 among girls. In 2004, more girls than boys reported drinking (Okulicz-Kozaryn & Borucka, 2006).

One of the most important studies in Poland was the one conducted by Okulicz-Kozaryn and Borucka (2006). This epidemiological study examined changes in patterns of alcohol use from 1988 to 2004 among 15-year-olds in Warsaw. The study started in 1988 and was conducted at an interval of four years thereafter (i.e., 1988, 1992, 1996, 2000, and 2004). This study is of interest because it covers a 20-year period, including significant political, economic, and social changes, which provide a changing context for adolescent alcohol use.

The results can be summarized as follows:

1. The results showed that in the years 1984–1996, the percentage of adolescents who had never drunk alcohol had fallen from 22 to 10 percent. Between 1996 and 2004, the proportion of nondrinking, frequently drink-

ing, and excessively drinking pupils remained stable. This finding was interpreted as a sign of adaptation to the new political, social, and economic conditions of Polish society.

2. A major change between 2000 and 2004 is the increase of vodka abuse by adolescents.

   The most common alcoholic drinks among adolescents who drink with their peers were beer and vodka: 67 percent of the adolescents drank beer with other adolescents in 1988, compared to 81 percent in 2000, while vodka drinking with peers remained stable (72% in 1988 and 80% to 88% in following years). The prevalence of wine drinking with peers was highest in 1992 (60%) but decreased from the mid-1990s to 41 percent in 2004.
3. A small proportion of adolescents drank alcohol alone. The alcoholic beverage most often used with parents was wine (30% in the 1980s and 1990s; 40% in the twenty-first century).
4. Girls drink more. Some possible explanations for this gender difference include (1) a general trend that girls use alcohol, smoke cigarettes, and try illicit drugs at least as frequently as boys, and (2) biological factors, which show a decrease in the age of onset of menstruation in industrialized countries during the twentieth and twenty-first centuries. Biological maturity has a strong impact on alcohol drinking by girls, and the results of some studies provide support for a positive correlation between the age of menarche and girls' tendency to associate with older boys. (3) In terms of spending free time, girls generally spend more time outside of the home than boys, which exposes them to alcohol use. Boys tend to play computer games more than girls (Ostaszewski et al., 2005), which limits the opportunities for drinking alcohol. (4) There seemed to be gender differences in reasons for drinking: girls tend to initiate and continue consuming drugs to cope with negative emotions; boys drink to increase social bonding (Isralovitz & Rawson, 2006). (5) Girls experience high levels of life stressors, and they tend to drink as a way of coping with these stressors.

In interpreting the high rate of alcohol drinking among adolescents, the authors suggested that the following factors may be responsible: a greater availability of alcohol for juveniles, disobedience of rules prohibiting the sale of alcohol to juveniles below the age of 18, and adults' more liberal attitude to juvenile drinking. It can be assumed that the fast political and economic changes in Poland were stressful factors both for parents and for adolescents. Parents' problems with their new professional and social situations, for example, the growth of unemployment, were directly reflected in the behavior of both grown-ups and children (cf. Bokszczanin & Essau, 2007a, 2007b).

A study by Maciorkowska, Buraczewska, and Sacharewicz (2007) examined the frequency of alcoholic beverage use among children and adolescents in Białystok City and examined the influence of familial and environmental fac-

tors on these young people's alcohol consumption. Their first experiences with alcohol occurred when the young people were 5 to 10 years old, with the greatest alcohol initiation (35% of young people) being reported in the 10- to 15-year-old age group. Adolescents' main reason for alcohol consumption was for company (21.6%); they also drank due to a lack of feeling safe (18.4%) and as part of free-time activities (23.4%). More than half of the children (63.4%) had conflict situations at home, and 19.7 percent were unsatisfied with their lives. Despite the ban on selling alcohol to minors, only a very small proportion (5%) of the adolescents reported being asked by a shop assistant for identification. About 18 percent of the adolescents obtained alcohol at parties, 15 percent bought it themselves, and 7 percent asked their older friends to buy it on their behalf. Alcohol was very easily accessible to young people: 21.7 percent of them buy alcohol frequently in the neighborhood shop, and 12.1 percent bought alcohol in a shop where no one knew them. Furthermore, the findings also showed that 70.8 percent of parents talk about bad habits with their children.

A recent study by Makara-Studzińska and Urbańska (2007) examined frequency of drinking, age of alcohol initiation, and preferences toward alcoholic drinks among people from rural areas in Lublin Province between the years 2002 and 2004. They studied 5,000 persons, aged 14–24 years, who had been recruited from various types of schools (i.e., secondary, technical, vocational, and high schools). Participants who attended vocational schools were reported to have started drinking at the earliest age (64% in primary school and 14% before age 10). Among those who attended technical school, 54 percent drank alcohol in primary school and 10 percent drank before the age of 10; 36 percent started drinking after the age of 16. Similar results were obtained among those who attended secondary school (58% and 36%, respectively). Beer was reported to be the most common alcoholic beverage. About half of the adolescents who consumed alcohol on a regular basis described the atmosphere in their homes as unpleasant, and in 25 percent of cases, it was described as very unpleasant. Most of these young adults reported having fathers who abused alcohol, and they described their fathers as aggressive (53%) and quickly aroused to anger (38%).

Alcohol Use among Adults

In 1937, Poland's consumption of alcohol was not greater than 0.7 liters per capita; in the 1950s, it was three to four liters, and in the 1980s, it reached the level of seven liters. In the 1990s, there was another jump to over 10 liters of pure alcohol per capita (Dolata, n.d.). The results of research conducted by the Social Research Laboratory (Jastrun, 2006) indicate that men drink 3.5 times

more alcohol than women, and the greatest consumption of alcohol is observed between the ages of 18 and 29. The unemployed drink the most, whereas pensioners and senior citizens drink the least. The consumption of alcohol among the poorest people increased, while among the wealthiest, it decreased. The most popular alcoholic beverage among young people is beer. Jastrun (2006) presents the latest statistical data concerning drinking, which show an increase in consumption of spirits by one-third, of vodka by 40 percent, and of beer by 10 percent in the years 2002–2005.

The recent survey on Attitudes towards Alcohol (European Community, 2007) in Europe provided information on the prevalence and patterns of alcohol consumption in Poland. The survey was conducted at the end of 2006, in 25 member states of the EU, 2 acceding states (Bulgaria and Romania), and 1 candidate country (Croatia), and in the Turkish Cypriot Community (TCC). The participants were interviewed face-to-face in their homes. One thousand adults in Poland participated in the survey. The results of this survey can be summarized as follows:

1. A high percentage of the participants in Poland (72%, compared to 75% across the EU) reported to have had alcoholic beverages (i.e., beer, wine, spirit, cider, or other local beverages) during the last 12 months. Seventy-five percent of the Poles reported having drunk alcohol during the last 30 days before the survey. Of those who consumed alcohol in the last 30 days, only 1 percent drank alcohol daily, 4 percent had it four to five times a week, 9 percent had it two to three times a week, and 28 percent drank once a week.
2. The percentages of those who had five or more drinks on one occasion in the last 12 months were lower than reported in many EU countries; that is, only 4 percent of the Poles reported drinking such a considerable amount of alcohol several time a week, compared to about 13 percent of respondents across Europe.
3. A high percentage of the participants (61%) have one to two drinks on the days they drink alcohol.
4. A low percentage of the Poles (27%) reported not knowing the legal blood level that is allowed for car drivers. Most participants (78%) agreed that random alcohol checkpoints conducted by police would decrease alcohol consumption before driving.
5. About one-third (36%) of the Poles did not believe that higher prices of alcohol would discourage young people and heavy drinkers from consuming alcohol.
6. Eighty-nine percent of participants agreed with putting warnings on alcohol bottles and advertisements, particularly for warning pregnant women and car drivers.

7. Almost all (93%) of the participants agreed that selling and serving should be banned to under 18-year-olds, and 79 percent agreed with banning alcohol advertising that targets young people.

RISK FACTORS

Research on risk groups (Sierosławski, 2008) shows that among the consumers of alcoholic beverages, 10.6 percent of Poles abuse alcohol, that is, drink above the safety threshold. The smallest number of those drinking at the level of increased risk are the oldest people, whereas the greatest number are people in their forties. Sierosławski's research also proves that marital status does not differentiate people as far as risky drinking is concerned. The size of the place of living differentiates significantly only men: the largest proportion of those included in the risk group live in villages, while towns and cities do not differ in this respect. Individuals with higher education drink less riskily than individuals with secondary or vocational education. The proportion of those drinking riskily is also significantly higher among unemployed people in comparison with those in steady employment. Practicing believers—both men and women—drink riskily much less frequently than others (Sierosławski, 2008).

A recent study by Bobrowski (2007) provided information on adolescents' risky behavior. A factor that reduced juveniles' tendency for reaching for psychoactive substances, including alcohol, by 50 percent was spending at least one hour daily doing homework, reading books for pleasure, or going to the cinema. On the other hand, staying out more than three hours daily increased the risk of abusing psychoactive substances. Interestingly enough, Bobrowski's research also proved that pupils practicing sports intensively have a stronger tendency for abusing psychoactive substances.

Bokszczanin (1998) examined the extent to which belief about the positive influence of alcohol consumption would increase the tendency to be addicted to alcohol. Her results showed that 22 percent of the adolescents from vocational schools (aged 16–17) believed that "those who have strong heads may drink freely." Twenty-one percent of them thought that "beer and wine are not real alcohol," 11 percent claimed that "a driver may drink a little," 15 percent considered the belief that "only primitive people from bad environments have alcoholic problems" to be true, 83 percent of the surveyed juveniles found the opinion that "strong will is the most important thing in dealing with drinking" to be true, and 27.7 percent believed that "alcohol can be a good remedy for different ailments." It seems that these adolescents' opinions, especially about what is and what is not alcohol and about the role of a strong will in drinking, are a reflection of grown-ups' opinions.

TREATMENT AND PREVENTION OPTIONS

The Polish state undertakes many activities to fight drunkenness and alcoholism such as legislative, medical, preventive, and social initiatives. The legal basis for activities connected with the prevention and solution of alcohol problems is the Sobriety Education and Alcoholism Prevention Act of October 26, 1982. According to this law, provincial local governments are obliged to carry out many activities, among others, activities aimed at limiting alcohol consumption, creating social organizations, and cooperating with churches in the field of sobriety education.

According to statistics, there are about 600,000 to 700,000 people addicted to alcohol in Poland (Dolata, n.d.). Alcoholism is treated in state and private clinics and therapeutic centers. In the last 20 years, the treatment of alcoholism in Poland has changed from medical only to psychological and medical. Within the inpatient care system, there are detoxification centers, wards and subwards of psychiatric hospitals, where such forms of aid as detoxification, group therapy, and occupational therapy are used. In outpatient clinics, education in the field of alcohol problems and individual, group, and family therapy are used. The networks of Alcoholics Anonymous support groups and teetotalers' clubs are also popular (Bełza, 2004).

Moskalewicz, Sierosławski, and Dąbrowska (2006) recently evaluated a system that is involved in psychoactive substance addiction treatment in Poland. The following aspects were included in the analysis: resources (personnel, budget), the scope of services, availability, time of treatment, and remaining in therapy. Their results indicated that the dominant aim of therapy was abstinence from alcohol, and subsequently, the improvement of life's quality. The time spent waiting for treatment is relatively short in outpatient clinics (about a week), but it takes a little longer in detoxification wards (20 days on average). Most financial resources for treatment and rehabilitation come from the National Health Fund (a state fund). Treatment programs are completed by fewer than 50 percent of patients.

About 20 years ago, the age of professional preventive activities began in Poland (Szymańska, 2000), and several of the prevention programs have been evaluated (Koczurowska, 2002). Some examples of evaluated prevention programs that have shown some effectiveness are the programs carried out locally in Opole Province, for example, the prevention program for adolescent leaders called the Activation of Juvenile Preventive Initiatives (Łabudziński, 2007), and Peer Help (Raszka, 2007), which aims to educate university students (volunteers), who will later train adolescent leaders in junior secondary schools and secondary schools in the field of preventing addictions. It is hoped that with

many more young people taking part in such programs, the number of those with alcohol problems will decrease.

Chapter **12**

Alcohol Consumption and Binge Drinking in the United Kingdom

Cecilia A. Essau, PhD, MA, HBA,
Changiz Mohiyeddini, MD, PhD, and Diane Bray, PhD

Like in many European and other Western countries, alcohol use is an accepted part of social interaction in the United Kingdom. The majority of adults in the United Kingdom have been reported to drink alcohol regularly. Among young people, drinking is regarded as integral to a night out, and heavy drinking akin to binge drinking is used by some young people to establish and maintain friendships. In fact, it is the group aspect of the binge drinking session that makes getting drunk so much fun.

Binge drinking is nothing new in British society. It has been endemic in British society for centuries, and binge drinking has been embedded in various social and work practices, for example, the Gin Craze that swept over London in the eighteenth century, to illustrate a parallel with the past (Borsay, 2006). The term *Gin Craze* was used to describe a moral panic that characterized concerns related to the impact of rapid urbanization on law and order; the effect of rising levels of wealth on patterns of consumption; the will to work and the fulfillment of domestic responsibilities; and widespread anxiety about family breakdown and government's failure to take effective action to remedy the problems. An increased disapproval of heavy drinking began in British society after industrialization.

ALCOHOL USE

The drinking of alcoholic beverages is both a popular and a generally accepted activity among young people in the United Kingdom. In fact, first experiences

with alcoholic beverages are made together with family members and friends (Essau, Karpinski, Patermann, & Conradt, 1998). Although alcohol is illegal for adolescents in public places, its use is very widespread. According to the European Schools Project on Alcohol and Other Drugs (ESPAD) (ESPAD; Hibell et al., 2001), 91 percent of the adolescents had been drinking alcohol during the last 12 months; this figure is above the average reported for all ESPAD countries (83%). The percentage of adolescents who reported drunkenness during the same period is also higher than the average among ESPAD countries (68% versus 53%). The percentage of those who use alcohol in combination with pills is 7 percent, which is comparable to percentages found in other countries.

The average age for a first experience with alcohol is 11 years among boys and 11.5 years among girls (Leite & Parrish, 1992). An early experience with alcohol is not uncritical. As shown by Holly, Türk, Nelson, Pfister, and Wittchen (1997), alcohol users who first consumed alcohol at the age of 14 years or younger were at higher risk for meeting a diagnosis of dependence and abuse compared to those who initiated alcohol use at 15 years of age or older.

BINGE DRINKING

There is perhaps no other problem in adolescent and young people that has attracted as much media attention as binge drinking. Headlines such as "Binge-Drinking Now the Norm," "Binge-Drinking Has Become a Fashion," and "Teen Binge Drinking: Common and Risky" are common among major British newspapers. The term began to be used in the late 1990s, and between 1998 and 2002, there were 10 to 20 mentions of the term in the print media a year; in 2003, this figure was about double (39 mentions). In 2004, there was a threefold increase in the number of articles that included the term *binge drinking,* most of which were related to the introduction of the Licensing Act of 2003.

Indeed, studies have indicated that young adults between 18 and 24 years of age are more likely than other adults to binge drink (Moore et al., 1994). There is also concern that binge drinking and alcohol consumption are increasing among young people in the United Kingdom (Harnett et al., 2000).

An accumulative number of studies have examined factors associated with binge drinking among young people in the United Kingdom. These include (Murgraff, Parrott, & Bennett, 1999) (1) binge drinking being typically viewed as socially acceptable and normal youth behavior; (2) personal and social motives, such as curiosity and experimentation, group pressure, the desire to

appear grown-up, and positive expectations of alcohol use; (3) availability and affordability—the introduction of alcopop products and specific promotions (e.g., two for the price of one and all you can drink for £10) are thought to have contributed to binge drinking among young people; and (4) advertising of alcoholic drinks through various media, including television, radio, print, point-of-sale promotions, and the Internet.

As shown by several studies, alcohol advertisements have been found to be related to positive attitudes about alcohol among young people.

IMPACT OF BINGE DRINKING

Binge drinking is responsible for various kinds of health care, societal, and personal costs. According to various government reports (Prime Minister's Strategy Unit, The Academy of Medical Sciences, Health Development Agency),

- About 5.9 million adults (23% men and 9% women) engage in binge drinking
- The number of binge drinkers among young British women has increased more than in any other EU country in the last decade
- Death rates as a result of acute intoxication have doubled in the last 20 years among men and women
- Twenty-nine percent of deaths are related to alcohol (mostly as a result of injuries when in a state of intoxication), especially among 16- to 34-year-olds
- The annual cost of crime/antisocial behavior and the cost of productivity lost related to alcohol misuse is £7.3 billion and £6.4 billion, respectively

In economic terms, binge drinking has been estimated to cost Great Britain £20 billion a year. Billions more are spent clearing up alcohol-related crime and social problems. Alcohol-related problems are recorded to be the cause of 22,000 premature deaths each year. Binge drinking and alcohol consumption are also responsible for a wide range of health care costs. Binge drinking is specifically related to accidents and violence, both of which cost the health service billions of pounds each year. Around 40 percent of admissions to the Accidents and Emergency Units are alcohol related, and at peak times (i.e., between midnight and 5:00 a.m.), this figure rises to 70 percent. The cost of alcohol misuse to the health service is about £1.7 billion a year.

People who binge drink report engaging in a range of risk-taking behaviors, particularly while drunk. Some examples of risk behavior reported by young people while drunk include getting in a car with a stranger or going back to a

stranger's house; pranks that put them in physical danger and involvement in disorderly behavior (e.g., fighting, vandalism, and stealing); and unprotected sex or sex with someone they did not know. In fact, Cooper (2002) showed that drinking was strongly associated with decreased protective behaviors among younger individuals and first intercourse experiences. Furthermore, a recent review by Cook and Clark (2005) indicated that problem drinking is associated with an increased risk of sexually transmitted diseases across populations.

Heavy drinking has been identified as a major risk factor for suicide and suicidal behavior among both young people and adults (Beautrais, 1998). Additionally, the risk of alcohol dependence increases with both the volume of alcohol consumption and binge drinking (Caetano et al., 1997). Indeed, alcohol dependence occurs frequently among young adults (Caetano & Cunradi, 2002), particularly among those with frequent drinking at ages 14–15 years and binge drinking at age 16 years.

To cope with these problems, particularly in reducing violence and antisocial behavior, a new licensing law was introduced in 2005. The government's rationale for this licensing law is to enable premises to stagger closing times and for the drinkers not be tempted to try to beat the clock due to the pub's closing time.

THE NEW LICENSING LAW

The new Licensing Act of 2003 came into effect in November 2005. Its introduction has changed the way alcohol and entertainment licensing is administered in England and Wales (Parliamentary Office of Science and Technology, 2005). The new law allows the extension of opening times to 24 hours (seven days a week), the transfer of licensing powers from magistrates to local authorities, and expanded police powers to deal with troublesome premises. It was argued by the Department for Culture, Media, and Sport (DCMS) that extending opening times may reduce the practice of stocking up with alcohol shortly before closing time. The DCMS also suggests that by staggering the closing times, the number of people disgorging on the streets could be reduced. This new law was not without argument. The Royal College of Physicians, for example, suggests that the extended opening hours might actually increase, rather than decrease, overall alcohol consumption.

ALCOHOL AND CRIME

According to the recent results of the British Crime Survey 2006/07 (BCS; Nicholas, Kershaw, & Walker, 2007), in 39 percent of domestic violence cases,

alcohol somehow was involved. In 46 percent of all violent incidents and 58 percent of cases of stranger violence, victims believed offenders were under the influence of alcohol. Furthermore, BCS 2006/07 showed that in 1,087,000 recorded violent incidents, the victims believed that the offender or offenders were under the influence of alcohol. In 58 percent of incidents involving stranger violence, in 47 percent of incidents of acquaintance violence, and in 39 percent of incidents involving domestic violence, the offender was judged to be under the influence of alcohol.

A growing body of literature and empirical results has contributed to the knowledge and understanding that the link between alcohol and crime is multifaceted (Berry & Brain, 1986; Giancola & Zeichner, 1995; Hayes, 1993; Kelly, Cherek, Steinberg, & Robinson, 1988; Room & Collins, 1983). Dehhan (1999) emphasized that alcohol-related crime covers a continuum of offences that involve alcohol as the cause, as a disinhibitor, or as an excuse or that alcohol can result in crime because the individual has a drinking problem. Therefore alcohol can not only be considered as a causal factor in crime, but also, alcohol can contribute to crime and be associated with it.

According to Hayes (1993), alcohol is related to crime through three different pathways: a causal pathway, a contributory pathway, and a coexistence pathway. Causal relationships comprise three groups of offences:

a*lcohol-defined offences*. This group is defined by combining a lawful behavior (being in public places) with consumption of alcohol (drunk in a public place)

alcohol-induced offences. This group includes offences that emerge because the offender has drunk alcohol (e.g. domestic violence)

alcohol-inspired offences. This group comprises offences committed to obtain alcohol (e.g., shoplifting)

Contributory relationships describe alcohol acting as a trigger to gain courage to facilitate an offence (Dutch courage), whereas coexistence relationships refer to criminal behavior alongside (heavy) alcohol consumption.

The Rule of Physical and Social Drinking Environments

Empirical results indicate that a physical and social drinking environment has a significant impact on alcohol-related violence (Roman, 1981). On the basis of an extensive analysis of the information gathered from the academic, health, and policing sources in the United Kingdom, the British Home Office (Deehan, 1999) recommended controlling certain elements of physical and social drinking environments to reduce alcohol-related crime and violence:

- The licensed premises should be attractive and well maintained; such premises have fewer violent incidents
- The licensed premises should avoid offering discounted alcoholic drink promotions and happy hours.
- Alcoholic beverages should be served with food; serving food is associated with lower rates of aggressive behaviors
- The closing times of licensed premises should be staggered; the availability of fast food and transportation should be increased, reducing the number of people on the streets at the same time looking for transport and food
- The intoxication level of drinkers should be considered, and selling alcohol to already intoxicated drinkers should be avoided
- Staff should actively expect customers to behave in a socially acceptable manner and discourage antisocial behavior
- The door staff should be trained to identify potentially aggressive (groups of) customers, refusing them entrance
- Magistrates should make it a condition of a license to use toughened glass on the premises (each year, almost 5,000 injuries occur in the United Kingdom as a result of glass being used as a weapon)

According to Dehhan (1999), a successful initiative for reducing alcohol-related crime and violence will be based on a partnership approach that includes "written agreements, establishment of ownership, adequate funding, active police involvement and an understanding of the need for businesses to make a profit" (p. 1).

Binge Drinking and Crime: The Rule of Age and Gender

Alcohol-related aggression often results in facial injury. According to Magennis, Shepherd, Hutchison, and Brown (1998), about 125,000 people in Britain suffer facial injuries every year in violent circumstances. In 61 percent of cases, either the victim or the assailant had been drinking alcohol. Eighty percent of injured people are men.

The results of BCS 2006/07 (Nicholas et al., 2007) show that in comparison with all other age groups, young adults (18- to 24-year-olds) have the strongest tendency toward binge drinking. Forty-four percent of this age group were identified as binge drinkers, and in this age group, binge drinking was more common among men (49%) than women (39%). Furthermore, compared with regular drinkers (13%), young binge drinkers committed more offences (27%) in the past 12 months. Sixty-three percent of all young adult binge drinkers admitted to criminal and disorderly behavior during or after drinking, compared with 34 percent of other young regular drinkers.

By the same token, the results of BCS show that the relationship between alcohol consumption and crime at a young age is moderated by gender: 25 percent of young male binge drinkers were involved in fights, while only 12 percent of young women got into a fight.

GOVERNMENT INITIATIVES

A number of initiatives have been introduced by the government to tackle binge drinking, particularly among young people, in the United Kingdom, including the following:

1. The Lewisham's Drug and Alcohol Strategy Team recently introduced the "Don't binge and cringe" campaign, which is an innovative approach to tackling binge drinking and its associated harms. During last year's festive season, volunteers gathered in hot spot areas and handed out goody bags that contained (1) a condom; (2) an alcohol leaflet about drunk driving, what is a unit, safe sex, and how to plan a night to ensure how to get home safely; (3) information about alcohol- and drug-related rape and where to get support; (4) spikeys (i.e., the anti-spiking stopper for bottle drinks) to prevent drug-assisted rape; (5) a lollipop; and (6) an overdose card advising what to do if young people are found passed out in the street.
2. Tackling young people's drinking is a pilot scheme to tackle underage drinking. This binge drinking road show aims to educate parents about the dangers of alcohol and drugs.
3. Greater Easterhouse Alcohol Awareness Project has recently launched a new online campaign highlighting the dangers of binge drinking and to promote awareness of the amount of alcohol units in drinks. This project is for young people between 9 and 17. It involves a series of alcohol-related quizzes with four games, and the players compete against each other; the 10 highest scores achieved for each game will go into a top 10.
4. ALCOHOL CONCERN is the national agency on alcohol misuse, working to reduce the level of alcohol misuse and to develop the range and quality of aid services available to problem drinkers and their families.

In addition to these specific initiatives, the National Strategy to Reduce Alcohol Harm was introduced in 2004. This strategy focuses on (1) better education and communication to change attitudes in relation to irresponsible drinking; (2) the introduction of better health and treatment systems so that alcohol problems can be detected and treated early; (3) fighting alcohol-related crime; and (4) working with the alcohol industry both to establish and develop new initiatives. It remains to be seen whether any of these initiatives will prove effective.

CONCLUSION

Binge drinking, particularly among young people, occurs frequently in the United Kingdom and has been estimated to cost Great Britain £20 billion a year. On an individual level, alcohol consumption is associated with a wide range of physical harms. At a societal level, a high level of alcohol consumption will lead to high level of harm and economic disadvantage. Consequently, numerous alcohol policies have been introduced in the United Kingdom that could have an impact on reducing ill health and premature death due to alcohol.

U.K. alcohol policy needs to balance policies to protect and promote public health, on one hand, and on the other hand, to serve the British economic interests. This balance needs to be made correctly to maintain the well-being of British society and its socioeconomic development.

Chapter **13**

Alcohol Use and Abuse in Germany

Changiz Mohiyeddini, MD, PhD,
Cecilia A. Essau, PhD, MA, HBA, and Regina Pauli, BSc, PhD

Germany is a federal parliamentary republic that includes 16 states, and the total area of the country is 357,021 square kilometers. Germany comprises over 82 million inhabitants, the largest population in the European Union (EU). With more than 10 million immigrants (almost 12.4% of the state's population), Germany is home to the third highest number of international migrants worldwide. Germany is the third largest economy by nominal gross domestic product worldwide and was classified in 2007 as the largest exporter of goods internationally. According to the Human Development Index (Human Development Report, 2007–2008), Germany has established a very high standard of living and dispenses a comprehensive system of social welfare and security.

As a consequence of World War II, Germany was divided in 1949 into two separate states along the lines of Allied occupation. After 41 years of division, the two states were reunified in 1990. West Germany was a founding member of the EU and, in 1999, adopted the euro (the common European currency). Germany's gross national income per capita is US$36,810 (World Development Indicators Database, 2007).

The chapter is organized as follows. We begin with a brief review of attitudes to and patterns of alcohol consumption in Germany and discuss the problems associated with alcohol consumption. Afterward, we will explore availability, advertising, and legal restrictions on alcohol consumption and will aim to explain the tactics used by the advertisement industry to attract drinkers. Finally, we will explain the restrictions and controls on alcohol advertisement.

ATTITUDES TO AND PATTERNS OF ALCOHOL CONSUMPTION

In Germany, for several decades now, the parameters of the debate as to whether alcohol is a cultural asset or a drug have been determined on the one hand by social policy and on the other by advertising for alcoholic beverages. In Germany, almost 40,000 to 73,000 people die each year directly or indirectly in connection with alcohol (Bühringer et al., 2000). Approximately 2.5 million people in Germany are addicted to alcohol (Bloomfield, Kraus, & Soyka, 2008).

According to the figures of the German federal police for 2006, more than 30 percent of all violent offences, 40 percent of all murders with robbery, 33 percent of all serious bodily harm, 38.5 percent of bodily harm causing death, and 40.5 percent of homicides happened while the offenders were under the influence of alcohol (Bundeskriminalamt, 2008). The economic damage caused by alcohol-related morbidity and mortality is estimated at between €5 billion and €40 billion (Bergmann & Horch, 2002), with the average estimation being €20 billion. Annually, the German national health system spends €150 million to €200 million treating almost 6,000 babies born with serious health conditions caused by alcohol abuse during pregnancy (Fischer, 1987).

Empirical results indicate that many factors influence alcohol consumption and foster the widespread prevalence of alcohol abuse (Martin et al., 2002). Lindenmeyer (2005) has identified five unwritten laws that affect and regulate alcohol consumption in German-speaking countries (Germany, Switzerland, and Austria): (1) "Regular alcohol consumption is normal," (2) "Alcohol is part of the game" (you can drink alcohol in almost any kind of social situation), (3) "Alcohol is good for you" (alcohol makes you humorous, chatty, easygoing, relaxed, self-confident, and sociable), (4) "Drink as much as your drinking partner" (this rule refers to the pure understanding of risk alcohol consumption and binge drinking among alcohol drinkers), and (5) "Drinking alcohol is a private affair" (nobody can interfere with your drinking behavior and habits).

PROBLEMS ASSOCIATED WITH ALCOHOL IN GERMANY

The long-term development of alcohol consumption shows, for the period from 1973 to 2001, an overall decline in the proportion of 12- to 25-year-olds who regularly drink alcohol. However, alcohol and drug consumption by children and adolescents in Germany is a growing problem. The number of young people who die because of alcohol abuse has significantly increased (Haustein,

Pohlmann, & Schreckenberg, 2004). Additionally, almost 30 percent of car accidents occurring under the influence of alcohol are caused by young people aged between 18 and 24 years. Furthermore, the figures of the German federal office for statistics shows a significant increase of 104 percent from the years 2000 (9,500 adolescents) to 2005 (19,400 adolescents) in the number of children and adolescents who were hospitalized because of alcohol poisoning (Statistische Bundesamt Deutschland, 2008).

The German federal office for health education (Bundeszentrale für gesundheitliche Aufklärung, BzgA) has shown that half of children up until the age of 12 have already had experiences with alcohol consumption. Among 16-year-olds, only 3 percent had never drunk alcohol, while the vast majority (78%) had repeatedly drunk alcohol (Bundeszentrale für gesundheitliche Aufklärung [BzgA], 2001). Fifty percent of young people up to the age of 14 years have already been drunk at least one time. This number rose to 83 percent among 16-year-old boys and to 77 percent among girls (Currie, Hurrelmann, Settertobulte, Smith, & Todd, 2000; Kraus, Heppekausen, Barrera, & Orth, 2004). At the ages of 16 and 17, drinking habits of young people become stabile. As in the subsequent years of life, 37 percent indicated alcohol consumption at least once a week, while 21 percent indicated rarely or never drinking alcohol (BzgA, 2001).

In comparison with other European countries, Germany is in a middle position in terms of experience with alcohol and the regular consumption of alcohol among young people. Recent findings on alcohol consumption among German youths in Europe (the European School Survey on Alcohol and Other Drugs, ESPAD) show that almost all students in Germany had an experience with alcohol during the last 12 months (93%), which is substantially higher than the average for all ESPAD countries (83%). Furthermore, the proportion of students who had been drunk during the last 12 months was higher (61%) than the average (53%). Also 77 percent of students in Germany had smoked in their lifetimes (66% average), and significantly more students in Germany had used marijuana or hashish (27%) than the average for all countries (21%). The use of illicit drugs other than cannabis was also higher than the average (10%, compared to 6%), and use of alcohol in combination with pills is more common in Germany (16%) than the average (7%). One study seemed to indicate the influence of German reunification on the drinking pattern in Germany among adolescents (Silbereisen, Robins, & Rutter, 1995): as a consequence of the open market that followed unification, the East German data showed a twofold increase in alcohol consumption from 1989 to 1990.

Among those who drink alcohol, between 4.3 and 9.7 percent meet the diagnostic requirements for alcohol abuse and dependence. According to the results

of the Early Development Stages of Psychopathology study (Holly, Türk, Nelson, Pfister, & Wittchen, 1997; Holly & Wittchen, 1998), 9.7 percent of 14- to 24-years-olds already have all the criteria for a diagnosis of alcohol abuse, according to the *Diagnostic and Statistical Manual of Mental Disorders*, fourth edition (American Psychiatric Association, 1994), and 6.2 percent for alcohol addiction. Alcohol users who first consumed alcohol at the age of 14 years or younger were at higher risk for meeting a diagnosis of dependence and abuse compared to those who initiated alcohol use at 15 years of age or older. Results of the Bremen Adolescent Study (Essau, Baschta, Koglin, Meyer, & Petermann, 1998; Essau, Karpinski, Petermann, & Conradt, 1998) indicated that 6.7 percent of 12- to 17-year-olds have an abuse diagnosis, and 4.3 percent a dependency diagnosis. A high percentage of those who met the diagnosis for alcohol abuse and dependence also met the diagnosis for other psychiatric disorders. Alcohol use disorders were significantly higher in boys than in girls, and the disorders increased with age.

In addition to being common, alcohol abuse and dependence are frequently associated with a wide variety of problems for the adolescents themselves and their families as well as for society at large. Some examples of problems associated with substance abuse include increased risk for: motor vehicle accidents; consensual sexual behavior resulting in unwanted pregnancy or a high risk of HIV infection; academic underachievement; antisocial behavior; failing to fulfill major role obligations; and, recurrent social or interpersonal problems (Essau, Karpinski, et al., 1998). These results indicate that experiences with alcohol among young people in Germany are very common.

AVAILABILITY, ADVERTISING, AND LEGAL RESTRICTIONS ON ALCOHOL CONSUMPTION IN GERMANY

Converging empirical results show that media and advertisements are crucial predictors of underage drinking behavior, youths' preference for alcohol brands, and current and intended drinking behavior (Gentile, Walsh, Bloomgren, Atti, & Norman, 2001; Martin et al., 2002). By the same token, a considerable body of research during recent years indicates that underage drinking is a main causal factor of many serious problems, for instance, low school performance, early onset of sexual activity, unprotected sex, criminal behavior, sexual victimization, and risk taking (Austin & Knaus, 2000; Cooper, 2002; Fergusson & Lynskey, 1996; Lowry et al., 1994; Mullahy & Sindelar, 1989).

Hence the main targets of the final declaration of the European Ministerial Conference of the World Health Organization on Young People and Alcohol,

2001, were to create a substantial reduction in the number of young people who start consuming alcohol and also delay the onset age of drinking. These targets point to a number of issues and challenges in reducing the pressures on young people to drink that must be considered in national health education and health policy, namely, alcohol promotion, free distribution, advertising, and sponsorship and availability. The charter suggests that each member state should implement strict controls on advertising of alcoholic beverages and ensure that no form of advertising is specifically addressed to young people (e.g., through the linking of alcohol to sports).

According to Kunkel, Wilcox, Cantor, Palmer, and Linn (2004), there is undisputed social agreement that young people need special protection from the unrestrained efforts of the economic marketplace. The issues related to advertising are being increasingly globally recognized. Over the past few years, considerable effort has been made to investigate the impact of advertising and alcohol consumption, which consistently shows a significant correlation between positive evaluations of alcohol advertising and current or intended alcohol consumption (Austin & Nach-Ferguson, 1995; Casswell & Zhang, 1998; Martin et al., 2002; Wyllie, Zhang, & Casswell, 1998). Furthermore, and crucially, the results of the Enforcement of National Laws and Self-Regulation in Advertising and Marketing of Alcohol project indicate that alcohol advertisements are clearly related to positive attitudes and beliefs about alcohol among youths, resulting in an increase in the likelihood that young people will start to drink, the amount they consume, and the amount they drink on any one occasion. By the same token, an enormous body of empirical results indicates that alcohol advertisements increasingly target underage alcohol consumers (Buijzen & Valkenburg, 2002; Grube, 1993; Jones & Donovan, 2001; Waiters, Treno, & Grube, 2001), creating new low-cost products (e.g., designer drinks, alcoholic energy drinks, and premixed cocktails) using packaging designed to be perceived by young people as "in" or "cool."

TACTICS USED BY THE ALCOHOLIC BEVERAGE AND ADVERTISEMENT INDUSTRIES IN GERMANY TO ATTRACT AND KEEP DRINKERS

A substantial body of evidence shows that the drinking behavior of young people is affected by television advertising (Kunkel & Roberts, 1991; Young, 1990). Similar to other countries (Kunkel, 1990), television in Germany is also the predominant medium that the commercial industry has chosen for marketing products to young people. Comparing international advertisement expenditures for alcoholic beverages, Germany occupies third place (behind

the United States and Japan), spending almost €600 million in 2000 for alcohol advertisements (German Advertising Federation, 2006).

Haustein et al. (2004) analyzed the tactics used by the commercial and alcoholic beverage industries to attract and keep consumers. In this study, a sample of TV programs on eight major German TV channels were broadcast over a period of six months and evaluated (174 commercials and product sponsorships in total). The results show that compared to commercials for other alcoholic beverages, advertising spots for alcopops were highly oriented toward young people: they were more strongly characterized by the use of bright colors, youthful music, action, and innovation. On the basis of a content analysis, Haustein et al. concluded that one reason for the increasing popularity of alcopops is the concerted marketing of these products (see also Kraus, Heppekausen, Barrera & Orth, 2004): while in 1998, just 9 percent of 14- to 29-year-olds drank at least once per month (alcopops), the number was already 42 percent in 2002 (BzgA, 2003a), and among 14- to 17-year-olds, it was 48 percent (BzgA, 2003b). The results of Haustein et al. confirm the previous findings in other countries that indicate that young people like the style and image-oriented elements of alcohol television commercials that are delivered with humor and youth-oriented music, colors, and/or characters (Waiters et al., 2001).

Predominant in beer advertising, by far the most frequently advertised alcoholic drink, were images of fun, healthy, pleasure, and socialization with friends and camaraderie, whereas champagne and wine commercials addressed flirtation, love, romance, and a wealthy lifestyle (Aufenanger, Große-Loheide, Hasenbrink, & Lampert, 2002).

A further important result of the study of Haustein et al. pertains to the frequency of alcohol advertisement on Germen television: on average, 1.2 alcohol commercials are shown per hour. Thirty percent of all alcohol commercials are shown on German Sport TV. As previous research indicates, the repetitive character of alcohol advertisements influences the drinking behavior of young consumers (Martin et al., 2002), who believe in information that has been displayed repeatedly without questioning its substance and/or sincerity (Roggeveen & Johar, 2002).

RESTRICTIONS AND CONTROLS ON ALCOHOL ADVERTISING IN GERMANY

As already mentioned, in the EU, alcohol advertising targeting young people is controlled by means of rules suggested in the European Council Recommendation adopted on June 5, 2001, by the Health Ministry. The

members of the EU aimed in this recommendation to take collective action by providing protection for children and adolescents from exposure to alcohol promotion and sponsorship, warranting that alcoholic products do not target children and adolescents, controlling alcohol availability, promoting education through rising awareness of the impact of alcohol, and developing youth-specific health promotion programs. The education programs should support young people to learn and develop a healthy lifestyle, resisting social and the peer group's pressure to consume alcohol (Council of the European Union, 2001; Ugland, 2002). The council recommendation stipulates that national governments, the alcohol and advertisement industries, and retailers are called to ensure, among other things, that advertising does not encourage excessive consumption or disparage abstinence or moderation or link alcohol consumption to driving or create the impression that alcohol enhances physical or mental performance or fosters the sexual attractiveness.

Because of the noncompulsive character of the council recommendation, members of the EU can decide at the national level whether they approach the recommendation through legal, regulatory, or self-regulatory mechanisms (Council of the European Union, 2001). As Ugland (2002) pointed out, this recommendation has no legal character, but rather, it works politically and morally.

In terms of EU-wide legislation, the Television Without Frontiers (TWF) directive has been incorporated into national law. This directive was designed to harmonize regulations so that cross-border transmissions would not contravene national regulations.

In Germany, there is a variety of national restrictions and controls, and mixtures of the statutory and the self-regulatory. The alcohol and advertising industries in Germany argue that Germany's constitution emphasizes the right for everyone to express and disseminate his opinions freely in speech, writing, and pictures—and this includes opinions expressed in the form of advertising (Zentralverband der deutschen Werbewirtschaft, 2006). By voluntary agreement, most spirits are not advertised on TV. On other media, a voluntary code is in operation. The German Advertising Council, which is funded by 41 organizations allied in the German Advertising Federation (ZAW), first issued its Code of Conduct on Commercial Communication for Alcoholic Beverages in 1976. In 1986, the European Commission incorporated the code into the EU TWF directive. The scope of the code was extended by resolution of the ZAW member associations to include teleshopping in 1998 and means of communication in general in 2005. Furthermore, alcohol advertisements and sales are controlled by laws governing fair trade (Gesetz gegen den unlauteren Wettbewerb), food and drink (Lebensmittel- und Bedarfsgegenständegesetz),

and the law for the protection of children and youth (Jugendschutzgesetz and Jugendmedienschutz-Staatsvertrag).

Anyone who feels that advertising violates the German advertising code can complain to the German Advertising Council. The advertising council can also evaluate advertising without a complaint having first been submitted.

Haustein et al. (2004) investigated whether the advertisement industry in Germany considers the guidelines of the European Council Recommendation and the German Advertising Code. According to the results, more than 12 percent of alcohol commercials infringed on the rules of the German Advertising Council by showing excessive alcohol consumption, displaying a dangerous car driving scene, implying that use of alcohol is a coping strategy against social anxiety, and suggesting that alcohol consumption increases social and sexual success.

CONCLUSION

Our review of recent literature on young people in Germany has indicated that a high number of adolescents have had some experience with alcohol. The high rates of alcohol consumption may be related to German law and societal views about the use of alcohol in young people; that is, legal access to alcoholic beverages in Germany begins at age 16 and is accompanied by a widespread acceptance of alcohol use in this age group. This is in contrast to many other countries, where the age for legal access to alcohol is much older. For example, in the United States, the legal age for buying alcoholic beverages is 21 years.

To conclude, numerous studies and government reports have been conducted, which have provided us with information on the trends in alcohol use and abuse in young people. Ideally, such information should be considered in the design of interventions. However, hardly any studies have taken this scientific-based information into consideration in their treatment designs. In this respect, the gap between the practitioner's and the researcher's world is still very wide.

Chapter **14**

From British India to the Taliban: Lessons from the History of the Heroin Market[1]

Kathryn Meyer, PhD

In September 1997, Pino Arlacchi became head of the United Nations International Drug Control Program. He had impressive credentials for an international drug czar: he began his career as a professor of sociology. His excellent books about the Italian Mafia had brought him recognition as a leading expert on organized crime; unlike most scholars, he had put his knowledge into action; he had joined the Italian Parliament and had led an attack against the same criminals whose organization he had researched. By all reports, he was successful in his efforts to bring the Sicilian Mafia under control (see *Financial Times* [London], July 17, 1997; *New York Times*, June 23, 1997).

From his new position Arlacchi announced the beginning of a ten-year plan to eradicate narcotics worldwide. He then opened discussions with the Taliban, the revolutionary Islamic group in control of war-torn Afghanistan, a major poppy-growing area supplying today's heroin market. To his surprise, the Taliban leadership indicated a willingness to work with the United Nations. Thus, in mid-November 1997, Arlacchi went to Afghanistan to discuss concrete plans to provide funds for irrigation projects and a textile factory, all to be built in a key opium-growing area. His trip provided the Taliban with an opportunity to enhance their international image, tarnished by numerous accounts of religious intolerance and poor treatment of women. Because he was criticized in some circles for making compromises with repressive regimes, Arlacchi was careful to point out the positive contributions UN aid would make, including plans for a wool-weaving plant that would employ women (*New York Times*, October 25, 1997, November 14, 1997; Associated Press, November 27, 1997; Lexis/Nexis).

Arlacchi's Afghan trip was the forerunner of a larger global plan to eliminate drug crops through "alternative development." "We would propose an alternative way of life," he told Christopher Wren of the *New York Times*. "They can be rich peasants if they grow opium, but they can die if they don't have roads and hospitals." His plan was not all carrot and no stick, however; it called for enforcement as well. He summarized it as "alternative development, eradication and law enforcement." The program was endorsed by the Clinton administration, and General Barry McCaffrey, the reigning U.S. drug czar, applauded Arlacchi's "focused, high-energy leadership" (*New York Times*, November 25, 1997; December 3, 1997; June 7, 1998).

Yet, in spite of the public professions of compliance by the Taliban, poppy production in Taliban-controlled areas continued. The 1998 harvest was about as large as that of the previous year. In response, Arlacchi told nations contributing aid to Afghanistan that he was prepared to use the earmarked money for border patrols rather than development. Noorullah Zadran, a Taliban spokesman, replied, "God knows we tried. There is a difference in cultures. There is a different perception" (*New York Times*, July 17, 1998). Afghanistan is indeed a place with a distinct culture; however, both Zadran and Arlacchi were wrong if they thought that this made the Afghan situation unique. These two men and their respective organizations fit into a pattern that has been repeated throughout the first hundred years of the illicit heroin market.

Over the course of the twentieth century, the major areas of both poppy production and heroin consumption shifted. Before the Communist revolution of 1949, China was the world's major consumer; since the early 1950s, the United States and Europe have assumed that role. Early in the nineteenth century, heroin made only small inroads into a market dominated by smoking opium; today, it is the most visible illicit opiate available. The opiate market has been defined by the difficulties of delivering a desirable product through an increasing network of international regulations. These laws, rather than ending the traffic, became part of the risk of engaging in a highly profitable trade. Looking at the development of this enterprise may provide some lessons for Mr. Arlacchi.

POPPIES, OPIUM, AND ASIA

The earliest international sanctions against narcotics came in China, only eight years after the invention of heroin. Opium use and cultivation had been legal in that country from 1858 to 1906. Although, at that time, opium smoking was considered to be a Chinese vice, the poppy plant was not native to Asia, nor was the fifty-year-long legality of the drug a policy willingly adopted by

the Chinese government. Legalization was accepted by a weakened Chinese government after China's bold attempts to force British smugglers to withdraw from its shores had enmeshed it in a losing struggle with the British navy. The opium problem was a nagging reminder of a larger attack on the authority of the Chinese state by foreigners.

The best opium came from British India. In 1905, when British diplomats suggested the possibility of opium restriction, the Chinese government responded positively. Statesmen representing the emperor knew they required British participation for any domestic program to prove effective. In 1906 China's opium eradication began with edicts against the cultivation and use of opium in China. This was followed by a British measure restricting exports of opium from India to China. The Qing (Ch'ing or Manchu) dynasty government that began this ambitious project had only five years left in its 270-year reign. On its last legs, it faced general public disorder, economic decline, and increasing foreign encroachment. Yet, as government officials began closing down opium dens and plowing under poppy fields, they were met with public enthusiasm and surprising success (see *North China Herald*, February 8, 1907, April 26, 1907; Hosie 1914, v. 2, 191; and Riens 1991).

In 1911, the Qing dynasty was overthrown, and in 1912, a new republic was declared. Best known in the West for its figurehead leader Sun Yat-sen and his Guomindang, or Nationalist party, the republic was in its early years dominated by the military strongman Yuan Shikai, who immediately began chipping away at the constitution and attacking those who opposed him. Yet, in spite of political conflicts between Sun's democratic ideals and Yuan's authoritarian ambitions, opium reform moved forward after only a short pause. Part of the motivation behind the success was the determination of Chinese patriots to rid their country of a problem that they saw as debilitating to the nation, a plague brought in by foreigners (*North China Herald*, October 12, 1912; Jordan to Grey, March 5, 1912, FO 10168/12644, and Jordan to Grey, January 22, 1913, FO 10481/6308, in Great Britain, Foreign Office 1974).

Narcotics regulation began in this climate of political breakdown, promoted by people with larger political agendas. Suppliers and addicts adapted to the new conditions as best they could. Legitimate opium merchants shifted their business arrangements. Some wealthy addicts bought up the last of the legal supply, while many others tried cures. There were different remedies, however. By 1917, when these first reform campaigns collapsed, "white drugs," including heroin, appeared in China and were advanced as cheaper, more easily transportable alternatives to opium and sometimes as a cure for the opium habit. Thus the introduction of heroin into the Chinese opiate market was dictated by the necessity of circumventing legal barriers. David Courtwright notes that

the same process occurred in America after passage of the Smoking Opium Exclusion Act of 1909 (Courtwright 1982, 83).

THE CHINESE OPIUM BUSINESS TAKES A NEW DIRECTION

The Taliban assured Mr. Arlacchi that the use of intoxicants is contrary to Islam and that, therefore, their own beliefs required them to end Afghan trafficking. At the same time, they obviously relied on opium profits to continue their war efforts, making them appear to be hypocrites of the first order. In fact, the Taliban were responding to a complex political scenario strikingly similar to an episode that occurred in China only ten years after the first opium bans went into effect. The smuggling case associated with the Righteous Yunnan Uprising of 1916 marked the breakdown of the first successful opium reform and demonstrates how illicit delivery systems can become political tools.

One of the most surprising victories during the ten-year opium reform in China came from Yunnan Province. Yunnan shares a border with both Burma and what was then French Indochina, just north of the area known today as the Golden Triangle. Because it had been established as a commercial poppy-growing area during the fifty years in which opium was legal, it came as a surprise to reformers when reports appeared in 1909 that Yunnan was on the road to opium eradication. Local officials were thorough, even giving thought to what we now call crop substitution. Change proceeded despite the obstacle that while opium was moved easily over the rugged Yunnan terrain, rice did not have such an agreeable portability. And when a bumper crop of rice glutted the local market in 1914, officials recommended producing rice wine, to help peasants stave off the temptation to resort to their opium standby (Hosie 1914, v. 2, app. 2; Butler to Grey, February 9, 1910, FO 9392/9773, Great Britain, Foreign Office 1974; *North China Herald,* October 10, 1914).

Then, in 1916, Yunnan became the base of operations for a group of patriotic soldiers who opposed Yuan Shikai. For two years after the 1911 revolution, Chinese politicians had tried to create a constitution and convene a parliament. Yuan, however, dismantled those attempts and became more of a dictator. With each step toward authoritarian rule, Yuan alienated more of his supporters. The last straw came in 1915, when he cast aside all pretense of republicanism and proclaimed himself emperor of China. Yuan's power came from his control of the Chinese army. Many of his officers had supported the revolt against the previous imperial house. The absurdity of Yuan's imperial ambitions made these once-loyal supporters back away from him. Cai E was one of these officers. From his stronghold in Yunnan Province, he formed the Protect the Nation Army and led a revolt against Yuan (Yu 1966 [1917]; Zhang 1986).

Cai E was from a gentry family. He had given up scholarship and trained for a military career because he feared the weakness of China in the modern world. He was ascetic and dedicated to the republican cause. In December 1915, the National Protection Army began an armed revolt, as other officers declared themselves independent of Yuan's erstwhile empire. Yunnan began to attract patriots from all over China, including some members of Sun Yat-sen's Guomindang. In the face of such overwhelming opposition, Yuan Shikai gave up his imperial scheme in May 1916. He died in June 1916 (Ch'en 1972).

This military exercise, though brief, had been expensive. During the struggle with Yuan, the Yunnan patriots remained in contact with sympathetic groups throughout China, including the Guomindang in Shanghai, which sent much needed funds. The Guomindang, in turn, relied on some of the more unsavory characters in Shanghai for fundraising. Shanghai Municipal Police blotters were filled with complaints about the strong-arm tactics used to raise money for the revolt. Also during this period Yunnan opium began flowing once again onto the China market (Shanghai Municipal Police, 1916).

The short revolt and Yuan's subsequent death left a power vacuum in China. Cai E's generals, hailed as heroes, began to plan a greater national role for themselves in the aftermath of victory. In the summer of 1916, the many factions that had united against Yuan came together in Beijing to plan China's political future. Yunnan sent a delegation that left the province on June 23. The generals traveled by train south through French Indochina to Haiphong, where they caught a ship to Shanghai (Figure 14.1).

The Yunnan party hoped to use the visibility they had gained during the war to move into national prominence. To this end, they determined to establish a partisan newspaper and publicity office in Shanghai. They were, however, short on funds, and so they turned to smuggling. Having acquired a supply of opium that had been confiscated by Yunnan police during the earlier poppy eradication campaigns, they loaded it into the trunks that would accompany them on their journey. They felt safe because a prominent member of the old parliament accompanied them, but just to be sure, they packed opium in his trunks as well (Zhang 1986; *Minguo Ribao* [Republican Daily], August 9–23, 1916; *Shi Bao* [Eastern Times], August 9–23, 1916; *North China Herald,* August 9–23, 1916).

Shanghai was the best place from which to move opium onto the Chinese market. As the entrance to the Yangzi (Yangtze) River, it provided access to trade routes running through the country, making it the entrepreneurial center of China. Shanghai also had a significant foreign presence and had been fragmented politically into a French concession; the International Settlement, where British and other foreign nationals lived; and a large, sprawling Chinese city. Each area had its own courts and police jurisdictions, making law enforcement difficult under the best of conditions (Zhang 1985).

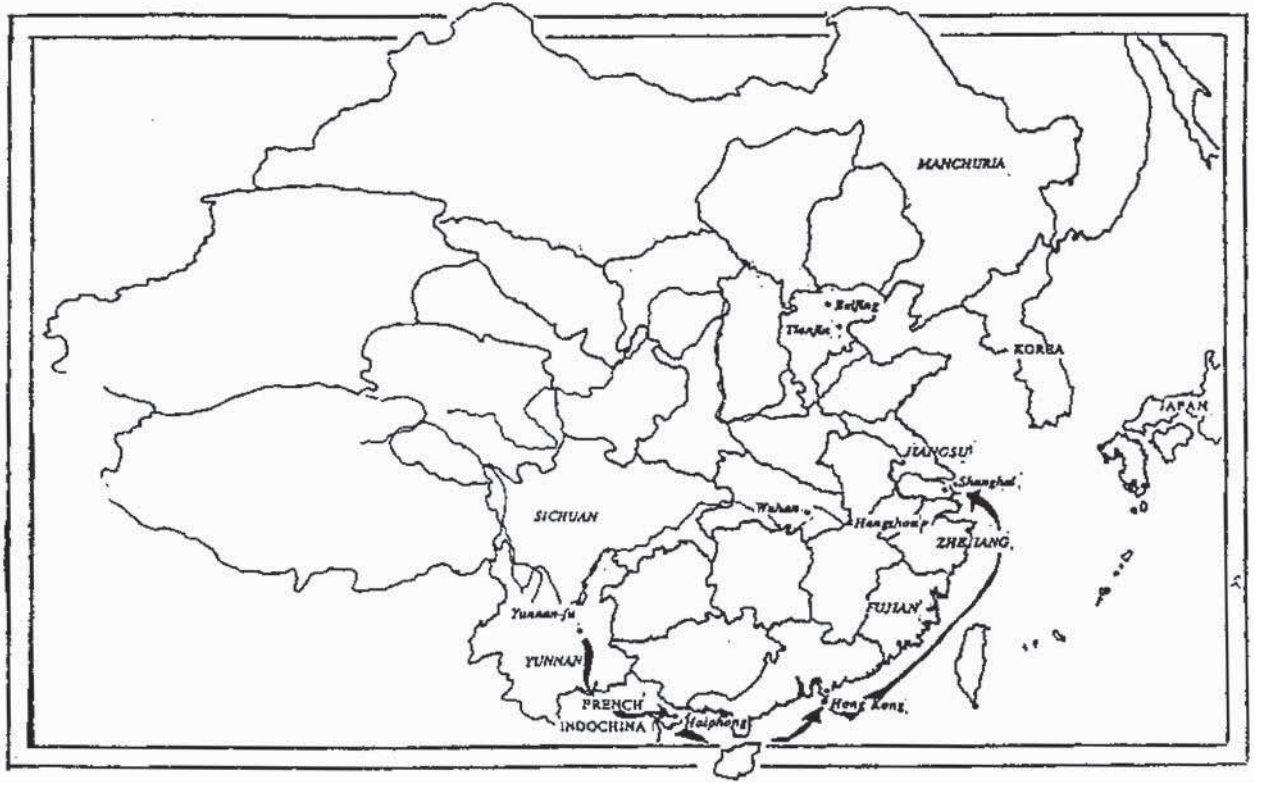

FIGURE 14.1 Route traveled by the Yunnan patriots and their opium-laden baggage.

The opium-laden trunks, sixty in all, easily cleared customs because the Yunnan generals had political connections. The men and their luggage then went to a Chinese inn in Shanghai's International Settlement. But the next evening international police raided the hotel and confiscated four opium-filled trunks. On the following day police traced an additional twenty trunks to the office of a prominent Chinese official, the same man who had signed the customs waiver. When the case reached its conclusion, three members of the Yunnan party were convicted of smuggling, and several Chinese officials were so badly compromised that their careers ended (*Minguo Ribao*, August 22, 1916).

Cai E was never implicated in the scandal, and he probably knew nothing about the opium scheme. During the campaigns he was a busy man, and a sick one. While his subordinates traveled to Shanghai to further their careers, he went there separately, seeking medical attention. Cai's subordinates were more practical and ambitious men than he. Tang Jiyao, the second in command, was very much implicated in the opium scandal. After the fiasco in Shanghai, Tang returned to Yunnan, where he retreated from national politics, making the province into his personal power base. By the 1920s, it was once again a major opium-producing area.

The Yunnan case established a pattern that repeated itself throughout the century, even as heroin replaced opium. The source of opium was in an area with a population poor enough to profit from such labor-intensive endeavors as poppy cultivation and opium manufacture and smuggling. More important, the undertaking was protected by ambitious men willing to make short-term compromises for larger political goals. Putting ideals into practice takes revenue. Many of the Yunnan leaders were against opium because it tarnished the republic, yet the state of civil war made the situation too complex for them to entirely control. Can we call these men simple hypocrites, or was something more complicated going on?

The Yunnan uprising of 1916 solved none of China's problems; Yuan's collapse left a power vacuum that was filled by contending military strongmen, commonly called the warlords, most of whom followed the Yunnan pattern and relied on opium funds. These warlords have such a bad reputation that it is well to recall that the first armed military revolt was filled with promise and is still referred to as the Righteous Yunnan Uprising. In the 1920s and 1930s, this Chinese civil war continued. It changed direction in 1927 when the Guomindang nationalists eclipsed the warlords and fought the Chinese Communists, while facing a serious Japanese threat. Opium, and increasingly, heroin, thrived in this atmosphere.

THE BEGINNINGS OF INTERNATIONAL REGULATION

Pino Arlacchi brought to his career a passionate dedication that transcended the mere filling of a job description. This animated enthusiasm is a requirement for anyone hoping to create successful international reform. Certainly the man who played a pivotal role in the 1920s League of Nations antiopium efforts was equally passionate. Sir Malcolm Delevingne did not invent the international regulatory system, but the force of his personality gave it direction.

International efforts to regulate narcotics traffic began in the first years of the twentieth century. The encouraging signs coming from the Chinese reform effort of 1906 coincided with American legislation to curb narcotics. In the same year that China promulgated its antiopium edicts, the U.S. government passed the Pure Food and Drug Act, the first of its many prohibitionist laws. Americans also were instrumental in calling the first international narcotics conference, convened at Shanghai in 1909, to discuss the issue of opium smoking throughout East Asia. Follow-up conferences at The Hague in 1911–1912, 1913, and 1914 resulted in more substantial agreements that became the basis for League of Nations initiatives (Musto 1973, 24–53; Taylor 1973, 47–122).

The results of these first steps toward international opium control made the Chinese drug market change, rather than disappear. As supplies of both Indian and domestic opium shrank, the skyrocketing price of smoking opium induced many Chinese to satisfy their cravings through heroin. More powerful than opium, it was sometimes injected with a hypodermic syringe but more often was smoked, just as opium had been. Other commodities appeared as well. Red Pills and Gold Pills—capsules containing morphine that had been introduced as cures for opium addiction—soon became popular as cheap opium substitutes. During the ten years of successful opium suppression, a market for refined opiates developed in China. After 1917, when smoking opium became plentiful in China again, heroin use continued, especially among the urban lower classes (Public Record Office, London [hereafter, PRO], "Memorandum Respecting the Opium Problem in the Far East," August 10, 1929, 17–18; "Smuggling Opium into China," *Times* [London], March 27, 1920; Ah Nan 1937).

At first, heroin was not manufactured in China. A few European, American, and Japanese pharmaceutical firms produced the entire world's supply. After World War I, opium control measures expanded to address the additional problem of narcotic substitutes. In 1921 the League of Nations created the Advisory Committee on Traffic in Opium and Other Dangerous Drugs, more commonly known as the Opium Advisory Committee (OAC). Between 1925 and 1936, it produced systems to control narcotics at their source. One such arrangement

was the creation in 1925 of a certificate system to track the international movement of narcotic drugs. The purpose of the agreement was to eliminate the excessive production of narcotic drugs, which resulted in diversion of a substantial quantity into the illicit traffic. In addition to formulating conventions, the OAC did valuable work in less visible ways. It gathered and shared information about the "hot spots" in the drug traffic, and it put political pressure on supply nations, albeit with varying degrees of success (Parssinen 1983, 144, 151; "Foreign Office Minutes 1920," PRO FO 371/ 5307/117–20; "Conference on the Restrictions of Opium," July 19, 1920, PRO FO 371/5307;107–08).

The idea for the OAC came from the British government, and specifically from Malcolm Delevingne, who, as Home Office Undersecretary, had responsibility for the drug traffic. Like Pino Arlacchi, he made elimination of narcotics his life's goal. He became the driving force behind the League's efforts. During the 1920s, information that he received about the sources and movement of narcotics led him to criticize certain European governments and firms for what he considered to be opportunism in finding and using loopholes in international regulations. An instance of this was his censure of the Swiss government's tolerance for the way Hoffmann La Roche slipped around the irregular European laws. This attitude, he said, demonstrated that they "do not take into account the character of the proceedings of the firm from a moral point of view" ("Memorandum Respecting Traffic in Opium," 1920, PRO FO 371/5308/233, 238–41; M. Delevingne to Foreign Office, February 27, 1926, PRO FO 371/11713/156). These efforts had their effect, although not entirely along the lines that Sir Malcolm had envisioned.

A CRISIS IN HEROIN SUPPLY

As a result of the efforts of Delevingne and the OAC, and despite footdragging by certain governments, the situation changed rapidly in Europe by the late 1920s. Enactment of the certificate system, universal enforcement of strictures against trafficking in western Europe by 1930, and the curtailment of production in European factories by 1932 had reduced legitimate opiate production to less than half of what it had been in 1928–1929. This crisis of supply forced a restructuring of the entire industry.

One man whose career demonstrates the changes taking place in Europe is Elie Eliopoulos, a Greek national operating out of Paris. From 1928 to 1931 he sold morphine and heroin to Tianjin, China. He began his career just as it was becoming difficult for illicit traders to make legal purchases of European narcotics. British and American factories were closed to them, and Swiss and German manufacturers were beginning to feel government pressure. However,

a few French factories continued to supply the market. Eliopoulos established connections with two of these—the Comptoir des Alcaloides and the Societe Industrielle de Chimie Organique. In 1930, when the French government passed stronger legislation, restricting narcotics trading licenses to only fifteen or sixteen reputable firms, Eliopoulos adapted. He turned to Istanbul, where his old suppliers opened a factory called ETKIM (Eliopoulos 1932; Moses 1933).

Eliopoulos needed political protection after January 1929, when the French laws took effect. Early in his career, he had struck a bargain with an Inspector Martin of the Paris Prefecture of Police, who supplied protection in return for money. Eliopoulos at first paid Martin 5,000 francs per month; this amount doubled as the business flourished. Eliopoulos could afford even this higher business expense, for morphine and heroin purchased in Europe for £40 or less per kilo could be sold in Tianjin at £70 or more per kilo. Monthly receipts of £21,000 yielded a gross profit of about £9,000 on the Tianjin business alone. From Eliopoulos's perspective, protection was a manageable business expense. Martin protected Eliopoulos until a Surete investigation in 1931 exposed Eliopoulos and made the situation untenable (Eliopoulos 1932).

Eliopoulos's trade with China was not his only narcotics business. Contrary to his profession, "by the memory of my father and all else that is holy," that he never sold drugs to America, he was a regular supplier of Jacob Polakiewitz, also known as Jack Paull, then the largest exporter of narcotics to the United States (Eliopoulos 1932; Moses 1933). Until the 1950s, however, this American market remained secondary to China.

Eliopoulos flourished during a period of crisis and transition in the illicit narcotics industry. At the end of his four-year career, he described important changes taking place in the world market. As restrictive measures in France, Germany, and Turkey made it difficult to divert large quantities of narcotic drugs from European pharmaceutical houses, Asian traffickers had begun to use Chinese opium to manufacture their own narcotic drugs (Eliopoulos 1932, 16–17). It would be Chinese gangsters and Japanese adventurers who would actively develop the heroin market in the 1930s.

BLACK INTO WHITE

After ten years of successful opium reform in China, smoking opium returned to the market, but now it was supplied by smugglers and the price was considerably higher. Poorer addicts, who turned to morphine and heroin, accounted for the demand that Elie Eliopoulos supplied in the 1920s. As Eliopoulos himself observed, however, by the early 1930s, Asian chemists were

learning the secret of turning black (opium) into white (morphine and heroin). And they had developed a better delivery system.

During the years in which Eliopoulos and other Europeans sold heroin to China, the Green Gang of Shanghai rationalized the opium distribution network by perfecting the kind of political connections the Yunnan opium group had tried to create. The Green Gang was well placed to step into the business. It had grown with the port, feeding on protection, gambling, labor racketeering, and prostitution. The gang controlled the wharves of Shanghai, an advantage for smuggling. It was a tip from a Green Gang member to the Shanghai police that had ruined the plans of the Yunnan group, whose biggest mistake was encroaching on someone else's territory (Zhang 1986).

The introduction of opium profits after the breakdown of reform made the 1910s contentious, as Green Gang factions fought over the lucrative trade. Only in the 1920s did three men known as the Three Big Shots—Huang Jinrong, Zhang Xiaolin, and Du Yuesheng—put together what would become in the 1930s a financial empire including both illicit and legitimate enterprises. They would create the kind of syndicate that their American contemporary Al Capone only briefly visualized before his collapse. Huang Jinrong brought with him to this enterprise his Shanghai police connections, and Zhang Xiaolin, his influential friends in the military.

Du Yuesheng, the kingpin of the Green Gang, is as famous to the Chinese as Al Capone is to Americans. Du was able to expand his smuggling empire through building on political connections. His ultimate triumph came in 1927, when the Green Gang helped Chiang Kai-shek purge the Guomindang party of Chinese Communist members in a bloody massacre known as the white terror (Isaacs 1951, 143–85; Marshall 1977, 29–35). After this initial event, Du's opium money contributed to the Nationalist war chest. In return, Du was able to work in Shanghai with relative freedom from police harassment (Xiao 1996).

Du was a diplomat. He ended the violent conflicts that marked the early days of the illicit Chinese opium market through negotiation as much as through force. From 1920 on, he made peace with every military strongman in the Chinese civil war who ventured into or around Shanghai by negotiating agreements that could be mutually profitable. These early deals employed the kind of pure graft exchanged between Eliopoulos and his Inspector Martin. When Du brokered a deal with Chiang Kai-shek, it was made on a pattern already established. Yet Chiang was not an ordinary warlord. He had a vision of national unity that was frustrated by the continuing Communist resistance (Martin 1996, 51–109; Mei and Shao 1987, 50–69).

Scholars have been both kind to and critical of Chiang Kai-shek. He has been praised by some as a nationalist hero and reviled by others as a narrow-minded bully. Those who attack him are quick to point out his alliance with Du; those who honor him respond that Du used his gang to work against the Japanese army during World War II. The truth of the situation is not as simple as either side maintains. Chiang Kai-shek was no friend of the narcotics traffic. He was an abstemious man who thrived under military discipline. But, like the Taliban, he faced a political reality so complex and expensive that his attitudes about drug regulation were easily compromised. In the 1930s, he faced both internal conflict and foreign invasion. He needed money, and he needed information.

One way of appreciating the revenue-generating power of opium at that time is to follow the change in its cost along the Yangzi River from Chongqing, deep in the opium-growing region of Sichuan, to Shanghai, on the coast. In Chongqing the cost of prepared opium was $1.50 per ounce; in Yichang it cost $2.00; in Hankou, $2.80; and in Shanghai, $4.50.[2] These price increases came from taxation. In 1932 the American consul Walter A. Adams conservatively estimated the total revenue produced by the Chinese opium traffic at $300 million per year. Over the decade of the 1930s, the nationalist government initiated opium monopoly schemes, which served to bring the traffic under government control. The profits went into the Agricultural Bank of China, where they funded intelligence operations (Stilwell 1935, 15; Adams 1934; Xiao 1996, v. 20, 609–17).

Du benefited from his alliance with Chiang Kai-shek. Yet there were times when his ambitions clashed with Chiang's sensibilities or with the plans of others also backed by Chiang. One example occurred in 1932, as Du was expanding into morphine and heroin manufacturing. Chiang gave Du a quantity of confiscated opium to make into medical morphine. Du created a processing plant to make the morphine, but he also secretly continued to operate the facility to make illicit heroin from opium that he received from another source. When Chiang learned of the extended operation, he sent police to raid the factory. It took several weeks of negotiation for Du to get himself back in Chiang's good graces.

Why did Chiang decide to raid this factory? There were several explanations at the time. One claimed that Chiang could tolerate opium but would draw the line at morphine and heroin. A second opinion ventured that Dai Li, the head of Guomindang intelligence and a beneficiary of narcotics funds, wanted more direct control of the proceeds of the factory for himself. After this short rupture, Du was able to talk his way back into favor, and he branched into the heroin market as well (Shanghai Municipal Police, November 25, 1933, D 5645; and February 5, 1940, D 9319).

Du clearly was taking advantage of the opportunity presented by the decreasing supply of European opiates. He inherited Eliopoulos's mantle, stepping into the market vacated by European sellers. What Eliopoulos may not have foreseen was that in the 1930s, some Chinese-made morphine and heroin would begin to penetrate into the American market. One exporter who worked this route was Paul Crawley.

Crawley began his career in the California motion picture industry. He first went to Shanghai as a film distributor but later moved into his own variety of the import-export business. Crawley brought pianos and slot machines into China and sent heroin back to his brother in Los Angeles and to a gang of accomplices in San Francisco. Influential friends helped him bring the drug out of China. H. O. Tong, for instance, was one of his Shanghai business associates. A good person for a smuggler to know, Tong worked in the Shanghai Customs Bureau and was a close friend of Chiang Kai-shek's brother-in-law T. V. Soong (Shanghai Municipal Police, November 12, 1931, D 3057).

The relationship between Du and Chiang Kai-shek was mutually beneficial. Chiang continued to make efforts to control opium. In 1935 his government began a six-year plan to eliminate opium use. Du was named to the Shanghai Municipal Opium Suppression Committee. When we consider the pressures Chiang faced in 1935—Communist insurrection, Japanese invasion, opposition from factions within his own party—the appointment seems less a cynical or corrupt calculation than a rational opportunity to increase his control over strong warring forces. If we apply this lesson to the Taliban, we may be able to speculate that they faced a similar situation. Putting questions of revenue aside, the opium producers whom the Taliban were trying to control most likely were factionalized political actors in their own right. This may be part of the meaning of the "cultural differences" to which Noorullah Zadran alluded.

JAPAN CAPTURES THE NARCOTICS MARKET

Although Du Yuesheng ventured into heroin and morphine manufacture, it was his Japanese competitors who became the major producers of opiates for China in the 1930s. From the first, Japanese smugglers had been involved in bringing European pharmaceuticals to China, as can be seen in the statistics. Between 1898 and 1907, Japan imported an annual average of 20,000 ounces of morphine, which represents the standard of morphine consumption for legitimate purposes in the country. Between 1915 and 1920, the average increased to 495,000 ounces of morphine, about twenty-five times the legitimate amount ("Memorandum from the Anti-Opium Association," August 10, 1920, Foreign Office 317/5307/211; "Foreign Office to Board of Trade,

March 23, 1921, Foreign Office 371/6593/162). When European supplies dwindled in the 1930s, Japanese manufacturers picked up the slack.

Until 1895, Japan had little experience with opium. In that year, however, Japan acquired the colony of Taiwan, which had a rich heritage of opium use. Faced with the sudden need for a practical opium policy, Japanese decision makers established a government opium production bureau, issued licenses for existing smokers, and taxed sales, hoping to control and eventually to discourage the use of opium. The architect of this policy was Goto Shimpei, who, in 1895, was the head of the National Board of Health (Ryu 1983, 3–35).

Goto was an unlikely person to become entangled in international narcotics. He was born to a poor samurai family in 1857 and grew up during the excitement of the overthrow of Japan's feudal order. He received a degree in Western medicine, and his articles on public health earned him official recognition and an invitation to help create a modern public health service. Like Sir Malcolm Delevigne and Pino Arlacchi, Goto was a man with a larger social vision. He called his program "biological colonial management" (Tsurumi 1965, v. 1, 872). It included narcotics control.

Through the establishment of the opium monopoly, Taiwan, which initially had been an expensive drain on the Japanese budget, became self-supporting. The policy of gradual withdrawal, along with its monopoly apparatus, became the model used by the Japanese colonial system as it extended through Asia. Goto rose to become a politician of the first rank in early-twentieth-century Japan, serving as minister of foreign affairs, minister of home affairs, and mayor of Tokyo. He was a man of standing and integrity who never thought of himself as encouraging the international opium trade. Yet the system he fashioned leaked at the seams, creating opportunities for traffickers.

As Japan's Asian empire grew, its commercial outposts in and around China also served as staging areas for traffickers. Taiwan became a center of smuggling into south China. Korea, occupied by Japan after 1905 and annexed after 1909, played a similar role in the north. The Japanese presence also penetrated China's sovereign territory, through concession areas and railways. North China became a jurisdictional patchwork in which smugglers could work with ease because, as Japanese subjects, they had special treaty rights that rendered them immune to Chinese law (Minami Manshu Tetsudo Kabushiki Kaisha, Kaisai Chosakai Dai Go Bu 1934).

Periodic scandals exposed this situation. One such drama involved Hoshi Hajime, founder and president of Hoshi Pharmaceuticals. Hoshi came to the narcotics business in 1914, when, through the recommendation of Goto, he received a monopoly license to produce morphine for the Taiwan colonial

administration. By 1921 British authorities suspected that Hoshi's firm was supplying to sources other than the legitimate markets. The British consul in Taiwan estimated that 3,500–4,000 *jin* (4,655–5,320 pounds) of morphine from the Hoshi Pharmaceutical Company reached south China annually (C. Eliot to Lord Curzon, February 26, 1921, PRO, F0371/6594/10-1). These suspicions appeared to have been well founded when, after pressure was put on the Japanese government by the British consular service, a Japanese customs agent discovered Hoshi's opium on a ship headed for Vladivostok without proper papers. Further investigations produced enough evidence that Hoshi had to stand trial for misconduct and was acquitted only on appeal (Hoshi 1971; Hoshi 1926; "Memorandum, Opium Scandal," Japan Chronicle, May 17, 1925, Pro FO 371/12527/108–12; P. Butler to Sir John Tilley, October 16, 1926, PRO FO 371/11714; FO 371/9248/141–47).

White drugs and smoking opium moved between Taiwan and the China coast through the agency of Japanese who had contacts with manufacturers in Japan and dealers in China. One such man was Harry Yamazaki, a sea captain who had learned the smuggler's craft from a Portuguese opium dealer. Yamazaki bought drugs in Taiwan and elsewhere, then sold them in China. In the 1920s and 1930s, his customers were Japanese *ronin*. These adventurers—part samurai, part gangster, part patriot—had gone to China with idealistic intentions of aiding the Chinese in the 1911 revolution. However, as the republic collapsed, many drifted into the service of Chinese warlords, for whom opium and narcotics became a source of income (Nitanosa 1977, 9598; "Note on the Operations of a Syndicate," Shanghai, January 1925, PRO FO 371/10969).

In the early 1920s, narcotics came to Japan from European sources as well as from Hoshi's factory. As the decade came to a close, however, Japanese merchants took advantage of the increasing cost and decreasing availability of European drugs. Japanese alkaloid chemists, trained in Europe, returned to work in factories scattered in concessions on the Chinese mainland. These firms kept costs low, produced close to their market, undercut the prices of their European competitors, and developed a better quality of smoking heroin. The price of morphine plunged from £100–120 per kilo in 1926 to £70 per kilo in 1928 (Yamauchi 1956; Eliopoulos 1932).

One such chemist was Yamauchi Saburo, who worked in Qingdao, Shandong Province, for several years before setting up his own company in Dairen, Manchuria. Producers like Yamauchi sold their product to wholesalers, who in turn distributed it through a system of retail merchants—Korean or Japanese adventurers whose restless lives and political activities in Asia made them familiar with men who could help to distribute the goods. At first there

was much competition among the heroin makers; later, the stronger knocked the weaker out of the market. Those smugglers who survived the competition were the ones who bought protection from the Japanese army.

A 1932 bond issue of 130 million for industrial development was secured by a pledge of anticipated annual revenues of 15 million from the opium monopoly in the Japanese puppet state of Manzhouguo (see Figure 14.2). At this time, Yamauchi tells us, heroin makers donated funds to the military, often receiving decorations in return (Yamauchi 1956).

In 1934 the government of Manzhouguo invited Nitanosa Otozo, a "patriotic agriculturalist of Osaka," to visit and tender some advice. Nitanosa was a peasant with connections to Goto Shimpei. He first became concerned with opium supply in 1895, at the time of the acquisition of Taiwan. He contacted Goto and, with his support, began the experimental planting of opium poppies on his land outside of Osaka. Through the 1910s and 1920s, he used the facilities of the board of health to increase the alkaloid content of his opium plants, clearly a move in preparation for heroin manufacture.

Nitanosa went to Manzhouguo to help make that nation "self-sufficient in opium" and to end its dependence on imports from Persia. Under his guidance, as the Japanese expanded into north China, suitable fields were turned over to poppies. From 1935 to 1936, poppy cultivation increased by 28 percent. In 1937, it increased by another 17 percent. Long after Goto passed from the scene, his legacy remained visible in a colonial structure that aided drug trafficking. Even when there were officials in charge who disapproved of the traffic and wanted the opium monopoly to function as it had originally been intended to do, the potential for abuse was hard to control (Nitanosa 1977, 64, 92).

North China became a haven for heroin supplied by both Japanese and Chinese manufacturers. One reporter paints a vivid description of the "white face houses" where heroin could be purchased in Beijing in the 1930s. Low-class places, located in the eastern and western districts, they were open from sunrise to the middle of the night and supported a continual traffic of pale-faced men and women. Their windows were covered with tattered newspaper. Outside, two or three rickshaws might be parked, each stripped of its cushions and lanterns, which had been pawned to support habits. The better heroin dens could be found in the north of the city. The windows of these houses had glass panes covered with white paper shades. These establishments were run by Koreans, who at that time were Japanese subjects (Ah Nan 1937).

A typical operation involved three people. The manager sat at the counter and acted as both cashier and pawnbroker. At his side sat his wife, who doled out heroin from a bag, using a long-handled brass spoon. She leveled off the powder with a spatula, then emptied the portion onto a square of waxed paper.

FIGURE 14.2 Japanese expansion.

"Pull or stab?" she asked, to find out if the customer intended to smoke the heroin or inject it. If the customer indicated smoking, a pack of matches and a cigarette came with the price. If injection was desired, the heroin was mixed with morphine, because the product from north China was quite pure. Patrons went into a back room to enjoy their purchase. In the darkened room, they lounged on the heated *kong*. Here and there the flair of a match would outline a face in the gloomy room that stank of unwashed bodies and smoke (Ah Nan 1937).

THE FOG OF WAR

In the 1930s, the delivery system for Chinese narcotics became professional, and heroin attracted more of the consumers that system served. Meanwhile, public attention was focused on the dramatic events that would lead the world into war. In north China, reporters followed the Japanese army through a series of low-level conflicts as it expanded its control from Manzhouguo to the outskirts of Beijing (Figure 14.3). Just as today's news junkies are introduced briefly to names and places in the Middle East, only to find them eclipsed by pressing news stories closer to home, average Americans of the Depression years were diverted from following Asian events by their more immediate domestic worries. Once the north China situation escalated into war in 1937, earlier images were recalled, and when Japan became a U.S. enemy, its involvement in narcotics trafficking seemed appropriately sinister.

During World War II, three responses made by the Japanese to their situation made that group of people seem then as cynical as the Taliban seemed half a century later. First, the Japanese armies marching south took over areas previously controlled by the Guomindang opium monopoly and Du Yuesheng's operation. Not only did those commanders need money, but they did not wish to cope with addicts in sudden withdrawal while they were attempting to control a hostile, occupied population. As a solution, they reached for Goto's formula of opium monopoly. In 1939 the Japanese occupation authorities established the Ko-A-In, or Asia Development Board, to facilitate control of the Chinese economy. They attached an opium monopoly bureau to it. Commanders in charge of social control of occupied areas worried about continuing to supply their addicted population. In line with their general war supply problems, the Japanese faced chronic opium shortages for smoking and for opiate production. Manchurian supplies had been adequate to finance local growth during the period of low-level conflict in the north because they had been buttressed

FIGURE 14.3 North China under Japanese control.

by shipments from Persia. The war cut off that supplementary source of supply (Nakamura 1983).

Second, narcotics use in China was a reality that field commanders fighting a total war considered as part of their plans. I have found only one reference to the use of heroin as a way to weaken China, Yamauchi Saburo, a heroin maker who wrote his memoirs in the 1950s. Records from commanders at the front talk instead about undercutting Chinese sources of wealth: they used opium and morphine smuggling schemes to flood the market and drive down the price of Chinese opium. As the war progressed and inflation made currency

all but useless, opium became a form of illegal tender that carried real value. It paid for both strategic materials and information impossible to acquire by using paper money (Yamauchi 1956; Yamamoto 1986; Okada 1980; *Sunday Mainichi*, December 9, 1984).

The Japanese were correct in assessing opium as strategic wealth. Once Shanghai fell to the Japanese, Du Yuesheng left for Hong Kong and, later, Chongqing, where Chiang Kai-shek and the Guomindang had retreated. While Du lived in semiretirement, part of his Green Gang operation worked against the Japanese under the direction of Chiang's chief of espionage, Dai Li, and his Military Statistics Bureau. Du and Dai created at least one company for the purpose of selling opium in Japanese-held territory to pay for much needed supplies. Through this company, exchanges were facilitated by men like the shadowy Xu Caicheng, a double, or perhaps triple, agent whose name appears in police files and memoirs of the time as a Green Gang member, a Japanese espionage asset, a Chinese agent, and an opium merchant with a radio transmitter in his back room (Shen 1961; Zhang 1982).

A third condition the Japanese occupation forces faced was the appearance of antiopium agitation among the Japanese residents of Manzhouguo. Confronted with official propaganda that touted the puppet state as a paradise where five races would live in harmony, many Japanese residents found it difficult to face the corpses of addicts that filled the streets of cities like Harbin and Mukden. In January 1937, a conference of Manchurian governors, who were Japanese, petitioned their government to reduce the number of opium shops and make it harder for addicts to get licenses. "The present conditions might be part of a plan to get rid of the weak," they said, but "it is a disgraceful reflection on the people that they should continue to take poison like candy" (*Shen Ching Shi Bao* 1937, 59–60). This brought a belated effort by the local authorities to curb opium use through the local monopoly.

While the situation improved outwardly, much of the problem retreated to places like the Garden of Grand Contemplation. In spite of its poetic name, this garden was a jerry-built warren of flophouses located in the Chinese slums of Harbin, a city located in the northernmost region of Manchuria. The deserted building had been colonized by a thriving society that included displaced Chinese peasants down on their luck, heroin merchants, prostitutes, and a sprinkling of spies (Hinkosho Chiho Hoankyuko 1941).

The biographies of the residents of the Garden demonstrate the routes people followed into addiction and how heroin use blended in with opium use. Many tenants were peasants who had come north looking for work after floods and war had devastated their fields. Finding no employment, they turned to the slums and the solace available through a Japanese monopoly outlet located

inside the Garden. Most addicts, however, found monopoly opium inferior, so they improved it by adding heroin, a practice called "silver inside gold." The heroin did not come from the monopoly, but it was in plentiful supply through resident smugglers, many of them Korean (Hinkosho Chiho Hoankyuko 1941).

Most of the Garden's residents could afford single rooms in one of the flophouses. Those whose habits brought them to the brink of death rented bunks in dormitories. Skin and bones, these unfortunates often had pawned even their clothes to support their habit. When they became sick and delirious, their fellow tenants tossed them into the bitter winter streets to freeze to death and stole what meager possessions remained. There were programs to help addicts. One resident took a cure, even though he was not an addict, to get the food and new suit of clothes that came with the process. Still, the scope of the problem facing the Japanese in 1941 in places like the Garden was beyond anything they could handle at the same time they fought a war (Hinkosho Chiho Hoankyuko 1941).

Satomi Hajime was a man with an excellent vantage point from which to make sense of the conflicts in Japanese drug policy. Satomi had gone to China in 1913 to study the language. He stayed and became a journalist and a sales agent for the South Manchurian Railway. In 1937 he went to Shanghai, where he ran the city's opium monopoly for the Japanese army. At the end of the war, he was designated a Class A war criminal and served time in Sugamo Prison. When questioned by American prosecutors, he gave them his perspective on the Japanese experience with narcotics. It was not entirely what they wanted to hear.

Satomi felt that the prosecutor wanted him to confirm that the Japanese command had been part of a larger conspiracy to traffic in narcotics. He could not do that, he said. Instead, he told his interrogators that they should stop chasing after the big fish. It was the mid-level officials and officers who were involved in opium. When asked to comment on the Guomindang's supposedly successful campaign against opium in the 1930s, he replied that this assessment was mistaken and cited his own experience in Shanghai. When the Japanese army took over there, he said, they found a healthy opium market in spite of this campaign. He also contradicted the accusation that Japan was flooding China with opium from Manchuria. Satomi said that he had had to scramble for opium supplies because Manchuria could not meet the demand. The frustrated prosecutors asked if he realized that he had been violating international law when he worked in Shanghai. Satomi replied, "Warfare itself is a violation of international law, and the violation of what I call the Opium Treaty was a necessary part of our warfare" (Satomi 1946).

Mr. Arlacchi should consider the words of Satomi Hajime. The good intentions of leaders can indeed be deeply held and sincere. At the same time, if

the leaders also profess an ideology with larger political goals, short-term compromises might be made in order eventually to get those ideals into practice. Today's healthy heroin market continues to thrive on our political passions.

SUPPRESSION OF COUNTERREVOLUTIONARIES

When Pino Arlacchi went to Kandahar in 1997 to meet with the Taliban leadership, he discussed ways to improve their image in the world. He told them that two aspects of their image were in need of change: their opium trafficking and their treatment of women. Should the Taliban leaders indeed decide to undertake poppy eradication and narcotics reform, they could follow the precedent of the programs used by the Chinese Communist Party after its victory in 1949. The Afghan leadership could be influenced to seriously consider such a step by the argument that opium reform programs can be an excellent platform for the advancement of social revolution. Unfortunately, the part of their negative image that involves women is not so amenable to change because the social revolution that the Taliban envision is a regressive one, involving the regulation of ideas and the strict seclusion of women.

On October 1, 1949, the Chinese Communists emerged victorious from the Chinese Revolution, and Chiang Kai-shek's Guomindang troops retreated to Taiwan. Like the other contenders in the struggle to control China, the Communist leadership had trafficked in opium during World War II. Desperate for funds, they had dabbled in the opium trade, though their philosophy decried drug consumption as a weapon of class and imperialist warfare. In February 1950, Zhou Enlai announced stringent opium control laws (Ch'en 1995; Ma 1993).

Satomi Hajime once said, "People who know China know no suppression campaign will work" (Satomi 1946). He had good reason to be cynical. Regulations had been promulgated before the Communist initiative, and no one was in a better position to appreciate how poor the results had been than Satomi. But the new Chinese regime was determined to make a clear distinction between themselves and the past. They looked hard for ways to make the laws work. While they had been holed up in the northern base camp during the war with the Nationalists, they had established a procedure for developing a dedicated Marxist corps of soldiers out of the ragtag volunteers who were drawn to their side. Based on the principle of "unity through criticism," the process involves self-criticism in a public forum. This activity has become familiar to us in the West through reports of the Cultural Revolution of the 1960s. In the early 1950s there was a mass movement called the Three Antis/Five Antis Campaign. Aimed at ridding China of the political corruption that had

plagued the Nationalists, the Chinese Communist leadership included in this larger movement a national campaign against opium use (Ma 1993).

The program included the roundup, trials, and executions of notorious drug dealers. In addition, mass participation in antinarcotics rallies, public confessions by ex-addicts, and neighborhood discussion groups molded popular opinion against drug use. During the time of this movement, China was at war with the United States in Korea. Drug peddlers could be identified with the Guomindang in Taiwan and, by extension, with the United States. This gave the movement a patriotic boost (Ma 1993).

The approach of the Chinese Communists in these campaigns appeared to be harsh but effective. They put forward the message that drug use was not only a degrading habit, but also one that belonged to a decadent capitalist culture. The Taliban could use precisely this kind of propaganda program, substituting their brand of Islam for Chinese Marxism, but the Chinese campaigns, while successful in curbing drug use, also led to suppression of intellectuals and to larger human rights abuses. Considering the repressive social vision of the Taliban, such an antidrug campaign would probably take the same direction. Is this a situation that international regulators would condone?

COLD WAR SOLUTIONS

The Chinese Communist leadership was successful in its antinarcotics campaign because it could link opium and heroin elimination to a larger political program. In the early 1950s, a war-weary Chinese population had been willing to give the new regime the benefit of the doubt, and so it could be inspired by a new vision. In the long run, it became clear that the program of the 1950s had been successful only temporarily. Once Communist China reopened its markets to world trade, it rejoined the world's narcotics users as well. During the thirty years of its isolation, heroin had become the dominant opiate in the United States and Europe. At the end of the twentieth century, China faced a growing heroin epidemic and found that its earlier approach to narcotics control was no longer so effective (Cheng 1993).

It is not surprising that today's heroin problem in China is centered in Yunnan. Not only does Yunnan have a rich legacy as an opium-producing territory, but just across its southern border lies the Golden Triangle, where the heroin trade continued to develop during the years of China's isolation. Because mainland China was perceived as an enemy of the West, American propagandists found it convenient to blame China for the growing heroin traffic flowing into the United States from Burma and Thailand. Harry Anslinger, the longtime head of the Federal Bureau of Narcotics and a dedicated cold

warrior, prominently accused the Communists throughout the 1950s of flooding the United States with heroin (Yates to Narasimhan, June 6, 1962, series 272, box 1, U.N. Archives, New York).

On May 31, 1962, Anslinger repeated this message as he addressed the seventeenth session of the UN Narcotics Commission in Geneva. This created a problem for members of the UN Opium Control Board. Gilbert Yates, the head of that body, privately worried about how to respond to the accusations. According to his information, it was Guomindang irregulars holed up in Burma, on the border with China, who were living off opium. Remnants of Chiang Kai-shek's armies driven out of China at the end of the revolution, in the early 1950s, those soldiers had gone into the Burmese hills, where they staged several attempts to take back the Chinese mainland. After the failure of these efforts, they remained a force in local Burmese politics. It was here that the trafficker Khun Sa later developed his heroin empire (*New York Times*, June 1, 1962; Yates to Narasimhan, June 6, 1962; McCoy 1991, 162– 78).

Yates was observing a shift from the old supply system that had been developed in China during the 1930s. After the Communist revolution in 1949 and the Guomindang retreat, most of the leadership of the defeated forces went to Taiwan, where they nurtured the rhetoric of reconquest of the mainland while building a new society on the island. Some, though, remained around the borders of China in a kind of unholy diaspora. One example is Ke Chaohuang. Ke had been a member of Dai Li's Military Statistics Bureau during the war. As such, he was assigned to infiltrate the secret societies in south China that had already been penetrated by the Japanese secret service. After the success of the revolution, he set up his own organization in Hong Kong, called 14K after the address of its headquarters. Soon 14K began trafficking in heroin from the Golden Triangle (He 1996).

This is the last lesson for Mr. Arlacchi. As the United States lobs missiles into Afghan territory, it is a good time to reflect on the conditions that have nurtured the narcotics trade network during the past century. The raw materials for narcotics production grow in places that not only are poor, but also are strategically located near the conflicts that made that period so violent. Uneven economic development has been the foundation of much of the strife of the last hundred years, but alternative development requires political stability. How should development move forward? Who is to control the resources? Which traditional values and constraints must be sacrificed as the cost of modernization? Each of these questions is difficult to resolve in spite of our modern sophistication. Meanwhile, opium revenues have been too convenient a resource to be forsworn by those caught up in the wars and revolutions that modern tensions have spawned.

Chapter **15**

Youth Tobacco Use: The Health Effects, Trends in Smoking Rates, and Reasons Why Kids Use Tobacco[1]

Clete Snell, PhD

Smoking kills an estimated 434,000 Americans every year. The vast majority of these smokers began smoking in their teen and preteen years. Very few people begin tobacco use as adults. In fact, by the age of eighteen, approximately one in three people in America use tobacco products. Moreover, the earlier adolescents initiate tobacco use, the heavier their tobacco use becomes in adulthood and the longer potential time they have to be users. Long-term chronic health problems, such as cancer, emphysema, and heart disease, are related to the duration and amount of tobacco use. The focus of public health officials for the last couple of decades has been to reduce deaths from tobacco by attempting to prevent young people from taking up the habit.

THE HEALTH EFFECTS OF TOBACCO USE AMONG YOUTH

Tobacco use—especially cigarette smoking—is considered the chief preventable cause of premature death in America. Several reports by the Surgeon General's Office has documented a causal link between cigarette smoking and lung cancer and other fatal cancers, arteriosclerosis and coronary heart disease, chronic obstructive pulmonary disease, and a wide array of other serious health problems.[2] More recently, research has found that passive or environmental tobacco smoke can lead to serious health problems—such as lung cancer—in otherwise healthy nonsmokers. In fact, every three weeks in the United States,

secondhand smoke kills about the same number of nonsmokers as were killed in the September 11th terrorist attacks on the World Trade Center.[3]

Many young people have the false impression that the health effects of smoking and other tobacco use are problems they will have to combat much later in life. Many youth who just start smoking also believe that they can quit at any time. The truth is that smoking has immediate and serious effects on the health of children. Cigarette smoking in adolescence appears to retard the rate of lung growth and the maximum lung function that can be achieved. Young smokers are less likely to be physically fit than young nonsmokers, and more likely to experience shortness of breath, coughing spells, wheezing, and other physical health problems.

Heart disease is the leading cause of death in the United States. Atherosclerosis is a precursor to heart disease and may begin in childhood or young adulthood as a consequence of smoking. Smoking by children and adolescents is related to an increased risk of early atherosclerotic lesions that are a risk factor for heart disease.

Smokeless tobacco (frequently termed snuff or chew) is related to health problems that range from halitosis to severe health problems such as several different forms of oral cancer (cancers of the mouth, tongue, and esophagus). Reports by the Surgeon General have documented that smokeless tobacco use is as addictive for young people as it is for adults. Furthermore, smokeless tobacco users are more likely than nonusers to become cigarette smokers.

Drug use among youth has been a public policy concern for decades, but rarely has cigarette smoking been considered to be among serious drug problems. Nicotine dependence from cigarette smoking is the most common form of drug addiction in the nation. Moreover, to emphasize the seriousness of nicotine addiction, it causes more death and disease than all other addictions combined.[4] The two medical disorders associated with nicotine addiction identified by the American Psychological Association are nicotine addiction and nicotine withdrawal. Symptoms of nicotine withdrawal include "craving for nicotine; irritability, frustration, or anger; anxiety, difficulty concentrating; restlessness; decreased heart rate; and increased appetite or weight gain."[5]

Physical dependence on any type of substance refers to the condition in which withdrawal symptoms are present. Physical dependence makes it much more difficult to achieve and maintain abstinence from a drug and makes it more likely that the user will relapse. Surveys conducted by the National Institute on Drug Abuse (NIDA) have found that severe withdrawal symptoms and the inability to maintain abstinence from use of a drug are more commonly associated with heroin and cigarette smoking than any other forms of addictive drugs, including cocaine and marijuana.

Each year about 20 million Americans attempt to quit smoking, but only about 3% have long-term success.[6] In fact, even among addicted cigarette smokers who have lost a lung due to cancer or have had major heart surgery, only about 50% kick the habit for more than a few weeks.[7]

This startling fact is something I witnessed firsthand while visiting my wife who at the time, worked for MD Anderson Cancer Hospital in Houston. Quite frequently cancer patients, who were obviously receiving chemotherapy evidenced by hair loss, weight loss, and pale skin, could be found outside the hospital connected to IV's and smoking cigarettes.

Nicotine's addictive potential is realized very soon after regular use. Data from the 1985 National Household Survey on Drug Abuse (NHSDA) found that 84% of 12- through 17-year-olds who smoked one pack of cigarettes or more per day felt that they needed or were dependent on cigarettes. The NHSDA research found that young people develop tolerance and dependence for nicotine, increase the amount they smoke over time, and are unable to abstain from cigarettes. This suggests that the addictive processes in adolescents are similar or the same as that for adults.[8]

OVERALL TRENDS IN CIGARETTE USE IN THE PAST CENTURY

It is important to develop an understanding of the magnitude of the problem of tobacco use in the United States and how that has changed over recent years. The National Health Interview Survey (NHIS) has been conducted by the Centers for Disease Control (CDC) since 1965. It uses very large probability samples and interviews are conducted within the home. NHIS respondents are considered current smokers if they have ever smoked at least 100 cigarettes and that they continue to smoke. Former smokers are those who have smoked at least 100 cigarettes and are not current smokers. Those classified as having never smoked have either smoked no cigarettes or less than 100 in their lifetimes. The NHIS also asks questions concerning other types of tobacco use such as cigar, pipe, and chewing tobacco.[9]

Total annual consumption of cigarettes in the United States was 2.5 billion cigarettes in 1900, according to records from the U.S. Department of Agriculture. Consumption increased steadily and dramatically over the years, until reaching a peak of 640 billion cigarettes in 1981. The largest increases occurred in the 1910s, 1920s, and 1940s. For instance, total cigarette consumption was 8.6 billion in 1910 and increased to 44.6 billion in 1920. By 1940, consumption had more than tripled to 181.9 billion cigarettes. Since the peak consumption of cigarettes in 1981, cigarette use has steadily declined to approximately 480 billion cigarettes in 2003.[10]

Because overall cigarette consumption does not take into account the overall population changes over the last century, it is more useful to examine cigarette consumption per capita. The trends are similar to that of overall consumption. Per capita use of cigarettes was 54 in 1900 (54 cigarettes consumed per person), 665 in 1920, 1,976 in 1940, and reached a peak of 4,345 in 1963.[11]

The NHIS first asked questions about cigarette smoking in 1965. At that time an estimated 42% of American adults were current smokers, including 52% of men and 34% of women. By 1991, cigarette smoking prevalence had decreased to 26% overall, 28% for men and 24% for women. Throughout this period of time (1965–1991), blacks were more likely to smoke than whites, and Hispanics were less likely to smoke than non-Hispanics. Prevalence by age was highest among persons aged 25–44 years. During the period studied, smoking decreased dramatically for all sociodemographic groups. From 1965 to 1991, the prevalence of cigarette smoking decreased 46% among men and 31% among women. The decrease in cigarette use was about equal between blacks and whites, and decreased more dramatically among Hispanics. Cigarette smoking prevalence also declined most rapidly among younger adults and among people with more education.[12]

There has also been a large increase in the number of smokers who were able to quit smoking. This is generally referred to as *cessation* in the language of epidemiologists. The number of people who were regular smokers but quit nearly doubled between 1965 and 1991. By 1990, more than half of U.S. men and more than half of American white adults who had ever smoked cigarettes had quit. The prevalence of quitting was higher for men than women, for whites than blacks, and for non-Hispanics than Hispanics. The likelihood of quitting the habit increased with both age and education.[13]

TRENDS IN YOUTH TOBACCO USE

There have been a limited number of research projects that have followed adolescent tobacco use over a long period of time. The Monitoring the Future Project is one that has followed teen smoking since 1976. In one publication, daily cigarette smoking among high school seniors was tracked from 1976 to 1993. Daily cigarette smoking was defined as smoking at least one cigarette per day during the past thirty days. The overall prevalence of daily smoking was approximately 35% lower in 1984 than in 1976. However, from 1976 to 1993 there was a 2% increase in daily smoking. In contrast, smoking prevalence among adults in 1991 was about 20% lower than in 1983. Similarly, daily smoking among white high school seniors increased 14% between 1984 and 1993,

while it decreased 20% among white adults. Male high school seniors increased their daily tobacco use by 21% between 1984 and 1993, while it decreased 20% among adult males. Among female high school seniors, on the other hand, the prevalence of daily smoking was 11% lower in 1993 than in 1984. Among adult women between 1983 and 1991, the decrease in current smoking was even more striking (20% reduction).[14]

The greatest reduction in daily smoking among high school seniors was among blacks. Their self-reported prevalence was 51% lower in 1993 than in 1984. But, in keeping with the overall trends among youth during that time period, the reduction in daily smoking among black high school students was less pronounced (19%).[15]

The National Youth Risk Behavior Survey (YRBS) is another source of information regarding cigarette smoking among high school students. The YRBS measures the prevalence of health risk behaviors among high school students through representative biennial national, state, and local surveys. The samples from this study are representative of students in grades 9–12 in all fifty states and the District of Columbia. A recent publication using this data tracked cigarette consumption between 1991 and 2001. Three types of tobacco behavior were assessed: (1) lifetime smoking, defined as having ever smoked cigarettes; (2) current smoking, defined as smoking at least one day in the last 30 days; and (3) current frequent smoking, defined as smoking on at least twenty of the last thirty days. The report concludes that cigarette smoking rates increased steadily from 1991 to 1997, and since that time they have been declining significantly.[16]

The prevalence of lifetime smoking remained stable throughout the 1990s, but declined significantly from 70.4% in 1999 to 63.9% in 2001. The prevalence of current smoking increased from 27.5% in 1991 to 36.4% in 1997, and then declined significantly to 28.5% in 2001. Current frequent smoking increased from 12.7% in 1991 to 16.7% in 1997 and 16.8% in 1999, and then declined significantly to 13.8% in 2001.[17]

Among female students, the prevalence of current smoking increased steadily from 27.3% in 1991, peaked at 34.9% in 1999, and declined significantly to 27.7% by 2001. Similar trends occurred among white female, black male, Hispanic, Hispanic female, Hispanic male, ninth, and eleventh grade students. In all these cases, smoking prevalence peaked by 1999 and then declined significantly by 2001.

The trend was similar for all males; the prevalence of current smoking increased steadily from 27.6% in 1991, peaked at 37.7% in 1997, and declined significantly to 29.2% in 2001. A similar pattern occurred among white, white male, black, tenth, and twelfth grade students.

CURRENT YOUTH TOBACCO USE

According to the National Youth Tobacco Survey (NYTS) in 2002, about 13.3% of middle school students (grades 6–8) reported current use of any tobacco products. Cigarettes (10.1%) were the most popular tobacco choice among middle school youth, followed by cigars (6%), smokeless tobacco (3.7%), pipes (3.5%), bidis (2.4%), and kreteks (2%). Middle school boys were more likely than girls to use all types of tobacco products except for cigarettes. Middle school boys and girls were about equally likely to smoke cigarettes.[18]

High school students used tobacco products at a rate of about 28.4% in 2002. As with middle school youth, high school students were most likely to smoke cigarettes (22.9%), followed by cigars (11.6%), smokeless tobacco (6.1%), pipes (3.2%), kreteks (2.7%), and bidis (2.6%). Males were significantly more likely to use any tobacco products than females students (32.9% for males compared to 23.9% for females). However, male high school students were only slightly more likely to smoke cigarettes than females (24.6% for males compared to 21.2% for females).[19]

To summarize trends in youth tobacco use, smoking among adolescents declined sharply in the 1970s, but the decline slowed significantly in the 1980s, increased throughout most of the 1990s, then decreased in the late 1990s and continues to drop at the present time. Female adolescent smoking actually exceeded that among males by the mid- to late 1970s, however both sexes are about equally likely to smoke at the present time. Boys are much more likely to experiment with other types of tobacco products than girls. Nationally, white adolescents are more likely to use all forms of tobacco products than are blacks and Hispanics. The decline in the prevalence of cigarette smoking among black adolescents has been dramatic and has occurred over a period of about fifty years.

Why have youth smoking rates dropped in recent years? Experts at the Centers for Disease Control believe that the following factors may have been influential: (1) a 70% increase in the retail price of cigarettes from December 1997 to May 2001; (2) an increase in the number and effectiveness of school-based efforts to prevent tobacco use; and (3) an increase in the exposure of youth to national and state mass-media smoking prevention campaigns. Despite the progress, especially among high school students, over one-quarter (28.5%) of high school youth are current smokers and almost 14% are frequent smokers with probable nicotine dependence.[20]

WHY KIDS START SMOKING

The earliest research concerning how to prevent youth from starting to smoke was the result of the landmark 1964 Surgeon General's report on smok-

ing and health.[21] Early research was not theory-based and did not focus on the question of what motivates young people to smoke. This research viewed cigarette smoking as a health behavior, rather than a social behavior with social causes, functions, and reinforcements. By the mid-1970s, support for theory-based research was provided by the National Clearinghouse for Smoking and Health, the National Institutes of Health (NIH), NIDA, and private health organizations such as the American Lung Association, the American Cancer Society, and the American Heart Association.

The application of psychosocial theories to the area of youth smoking was a major breakthrough in attempts to understand why youth begin to experiment with smoking and what sustains their tobacco use. The early works of Leventhal, Bandura, and McAlister, Perry, and Maccoby were pioneering, but limited in the sense that they tended to rely on simple correlations such as testing for a relationship between parental smoking and children's smoking behavior.[22] The problem with research that examines simple correlations is that it is impossible to come to any conclusions about the actual causes of youth smoking. Subsequent research became much more sophisticated, theory driven, and longitudinal in nature. Longitudinal research tracks the same cohort of youth over a period of time (usually several years) and can provide much more useful information as to why kids initiate tobacco use and why they continue to use tobacco products. Conrad, Flay, and Hill reviewed twenty-seven studies concerning why kids start smoking that had been published since 1980.[23] The fairly large number of rather sophisticated studies allows us to begin to draw some conclusions as to why kids smoke.

Developmental Stages of Smoking

Flay developed a useful model of the five primary stages of smoking initiation among children and adolescents.[24] In the first stage or preparatory stage, general attitudes and beliefs about the value of smoking are formed. Even if an adolescent does not begin to smoke, they come to see smoking as having a useful purpose: to appear mature, cope with stress, fit in with a new peer group, or display independence from the influence of authority figures such as parents.[25] Certain psychosocial risk factors discussed in the next section, such as tobacco advertising and adult or sibling role models who smoke, may provide an influence at this stage.

The second stage is termed "the trying stage" where an adolescent actually experiments for the first time with cigarette smoking, usually smoking two or three times. The psychosocial risk factors involved in this stage include peer reinforcement or encouragement to try smoking, the perception that smoking is normative or socially acceptable behavior, and the availability of cigarettes.

The third stage is the experimental stage where adolescents engage in repeated but irregular smoking. Some of the psychosocial risk factors involved in this stage include social situations such as parties where smoking is often prevalent and important peers such as a best friend who supports smoking; low self-efficacy or the inability to refuse offers to smoke; and the availability of cigarettes. These influences may impact a youth enough to smoke in particular social situations or around certain people, but not become a regular smoker.

The fourth stage is termed "regular use" when adolescents smoke on a regular basis, at least weekly, and increasingly across a variety of situations and personal interactions. The psychosocial influences at this stage include socializing with peers who smoke and reinforce smoking, the perception that smoking has personal utility such as reducing stress or weight loss, and the availability of cigarettes.

The final stage is nicotine dependence and addiction. As discussed earlier, this involves a physiological need for nicotine. This need includes a tolerance for nicotine, withdrawal symptoms if the person attempts to quit, and a high likelihood of relapse if the person quits.

While there is much variation among adolescents in the length of time between an initial attempt at smoking and regular use, on average, it takes only two to three years. In fact, McNeill found that of those youths who experimented with cigarettes, about half were smoking on a daily basis within a year.[26] Thus prevention efforts have focused on delaying or preventing the first attempts at smoking as well as preventing the progression to regular use of cigarettes. Because an adolescent may become a regular smoker in a fairly short period of time (two to three years), a high percentage of adolescents at least try cigarettes, and because adolescents who become regular smokers generally progress to addiction as adults, it is critical to target prevention efforts at middle school, junior high school, and high school youths.[27]

Psychological and Social Risk Factors

In the Surgeon General's report *Preventing Tobacco Use among Young People,* various psychological and sociological (psychosocial) risk factors were identified—through a thorough examination of research—as greatly increasing the chances that adolescents will begin using tobacco products. These risk factors were grouped into the following categories: sociodemographic, environmental, behavioral, and personal. These risk factors are believed to be the first link in the causal chain that leads to tobacco-related health problems. Thus prevention efforts should take these factors into account.

Sociodemographic Factors

Sociodemographic factors such as socioeconomic status or gender do not generally directly impact decisions to start smoking, but rather indirectly impact decisions to start smoking by impacting behavioral and personal factors. Tobacco use may vary according to socioeconomic status, family structure, age, gender, and ethnicity.

Low socioeconomic status (SES) has been found to predict smoking initiation in several longitudinal studies.[28] One German study found that seventh- and eighth-grade students from a school in a low-income area had higher rates of tobacco use and were more likely to start smoking over a six-month period than youth from a higher-income area. Low-income students also had greater expectations of certain positive consequences of smoking, more friends who smoked, and lower scores on a self-image scale. A possible explanation is that lower-income students may start cigarette smoking to cope with the stress that comes with a lack of financial and material resources or with living in a one-parent household. They may find that tobacco use is a quick and easy coping strategy for stress or loneliness.[29] Youth from low-income families may also have more peers or other role models who smoke and less supervision to discourage experimentation than youth from higher-income families.[30] While low socioeconomic status is related to initiating cigarette smoking, it is not a strong predictor of experimenting with smokeless tobacco.

The life stage of adolescence has become a consistent and strong predictor of initiating both cigarette and smokeless tobacco use.[31] In particular, the transition between elementary school and high school seems to be a high-risk period for the adolescent's initiation of tobacco use. In fact, the rate of the onset of smoking and the prevalence of smoking may actually level off during the high school years.[32] There are three major types of developmental challenges that youths face during adolescence. First, youth become physically and sexually mature and begin to establish relationships with the opposite sex. Second, adolescence is a time of responding to cultural pressures to begin making the transition to adult social roles and responsibilities. Third, youth during this developmental period begin to establish a coherent sense of self and a set of values to guide future behavior. Many youth confront these challenges through experimentation and risk-taking behavior.[33] Tobacco use is one of many risky behaviors that many youth believe may make them more attractive to certain peers and may contribute to a positive self-image in many social settings.[34]

Currently the rate of smoking among boys and girls is roughly equal in the United States. However, that has not always been the case. Males were much more likely to smoke and use other tobacco products until the mid-1970s

and mid-1980s. During that time, tobacco use among young men dropped from about 45% to 33% but remained constant at about 34% among young women.[35] Two studies suggest that changing gender roles, or more women are in traditionally male positions of power and authority, may explain why young women have been more resistant to the general trend of lower smoking rates. One review of research on the influence of gender on smoking behavior found that peers and parental models equally influenced both girls and boys. The study did find that girls who smoked were more socially skilled (e.g., at ease with their peers, strangers, and adults) than nonsmoking girls, and more socially skilled than boys who smoked.[36] Girls are also more likely to be concerned with body weight and to believe that smoking may help control weight gain.[37]

Environmental Factors

Environmental factors that may influence the decision to initiate smoking include the availability of cigarettes in the community, the social acceptability of smoking, the influences of peer and parental smoking, and the perceptions youth hold of their environment.

Adolescent smoking behavior has been found to be affected by the acceptability and availability of cigarette use within society or the community. The acceptability of smoking and the availability of tobacco products are affected by the pervasive advertising and promotional activities of the tobacco industry. Multiple role models, including family members, friends, and even television and film actors, also affect the social acceptance of tobacco. Finally, community norms, policies, and ordinances impact the acceptability of smoking by either sending clear signals that tobacco use by youth is tolerated through allowing sales or access to underage buyers, or by enforcing strong ordinances that work to keep tobacco out of the hands of kids.

In a study conducted by the National Adolescent Student Health Survey, 79% of eighth graders and 92% of tenth graders considered it to be "very easy" or "fairly easy" to obtain cigarettes.[38] Similarly, the 1991 Monitoring the Future Project found that 73% of eighth graders and 88% of tenth graders reported that it would be "fairly easy" or "very easy" to get cigarettes. Another study conducted by the Centers for Disease Control found that among a national sample, of the 2.6 million underage smokers, 1.5 million purchase their own cigarettes.[39] Among those who buy their own cigarettes, 84% purchase them from small convenience stores, 50% from large stores such as grocery stores, and 14% obtain them from self-serve vending machines. There have been a number of studies observing cigarette buying behaviors of teens that tend to confirm

these reports. The general availability of cigarettes is important because a number of studies have found that the more available cigarettes are in a community, the earlier the onset of smoking among youth.[40]

My own experience in first trying cigarettes was, in most respects, not unlike other adolescents. I was in a car with three of my peers. We were all juniors in high school. We had just left a party and all three of us had been drinking beer. Someone suggested that we drive up to the local ski resort (I lived in Montana at the time). On the way up, another friend passed around cigarettes. I remember smoking two cigarettes and experiencing a terrible burning sensation in my throat. One of my friends asked if I had ever tried Copenhagen, a brand of smokeless tobacco; I lied and said, "of course." I had tried other forms of smokeless tobacco, which were very popular in Montana. He offered his can and I took as small a pinch as I could. When I awkwardly placed the tobacco between my lip and bottom teeth, he laughed, acknowledging that I was not a very experienced "dipper." Within five minutes I felt a distinct light-headedness and a burning sensation in my stomach (I was swallowing the tobacco juices). We eventually made it to the ski resort after climbing to approximately 6,000 feet in elevation. The combination of beer, cigarettes, smokeless tobacco, and high elevation made me as nauseous and dizzy as I have ever been in my life. We pulled up to the parking lot just in time for me to open the car door and vomit in a snowdrift for several minutes. I remember the humiliation of my friends' laughter and the curious look of strangers walking through the parking lot. My first experience with tobacco use had been decidedly negative and I remember thinking, "Why in the world would anyone decide to do this?" Most adolescents' first experiences using tobacco are not positive in terms of physical sensations. It is the social cues in initial tobacco use that reinforce subsequent use: positive reinforcement from peers and the general feeling of social acceptance and fitting in.

The impact of role models such as parents, siblings, and peers on decisions to start smoking have been carefully examined in research. Role models not only provide the necessary attitudes for the social acceptance of tobacco use, they also provide common social settings, such as parties, in which cigarettes are tried for the first time.[41] These role models and social settings provide the context in which youth come to view smoking as either a positive or negative experience.

The evidence concerning the influence of parents' smoking behavior on their children's cigarette use has been mixed. On the one hand, a number of studies have found a strong and consistent relationship between parental and adolescent smoking.[42] By contrast, parental smoking was a weak predictor of children's smoking in other studies.[43] Conrad, Flay, and Hill examined the findings

of twenty-seven prospective studies concerning the onset of smoking among youth.[44] Fifteen of these studies examined parental influences, and fewer than half (seven) found that parental smoking was a strong predictor of their children's smoking behavior. Chassin and his coauthors believe that parental smoking may influence the decision to try cigarettes, but is far less important in the transition to regular smoking behavior.[45]

Parents are not the only family members who may influence decisions to use tobacco products. I started using smokeless or chew tobacco (for only a short time) after seeing my older brothers use it (and before the beer-tobacco-altitude induced vomit incident). Unlike parents, there is considerable support for the influence of the smoking behavior of older siblings on the smoking behavior of younger siblings. One ten-year longitudinal study of over 6,000 adolescents found that sibling smoking was one of only four factors that predicted risk of regular smoking and also predicted whether or not respondents would still be smoking after ten years.[46] A study by Hunter and colleagues found race and gender differences in the effect of sibling smoking.[47] Sibling smoking was a strong influence for white males, a sister's smoking was an influence for white females, and a brother's smoking influenced both black males and females.

The influence of one's peers (persons of about the same age who feel a social identification with one another) on smoking behavior has been a topic of considerable research. The findings suggest that peers may be the single most important factor in determining when and how youth first try cigarettes. As I described in my own experience, smoking is frequently a behavior designed to achieve social acceptance from peers as well as an effort to experiment with an otherwise adult activity within a familiar and friendly social setting.[48]

Studies of varying sophistication from all over the world have found a strong relationship between smoking initiation and the influence of peers' or friends' smoking.[49] In the stage of first experimentation with tobacco, most youth are in the company of their best friends. Hahn and associates found that 60% of the 11- through 17-year-olds in their study admitted to first smoking with close friends, and 72% reported smoking most recently with close friends.[50] Among a group of 12- through 14-year-olds, those whose best friend smoked were four times more likely to smoke than those whose best friend did not smoke. The influence of best friends' smoking influenced both experimentation with smoking and smoking prevalence. In a review of sixteen well-designed longitudinal studies there was a positive association between peer smoking and the decision to start smoking in all but one study, and peers appear to influence other stages of tobacco use as well.[51] In other words, youth with friends who smoke are much more likely to smoke themselves. The fact that this association was found in 88% of well-designed studies suggests a clear link between friends' smoking

behavior and cigarette use. This link appears to be influenced by other personal factors, such as one's self-confidence, and its greatest influence is on the earliest stages of smoking. Finally, the strength of the bond or attachment to a peer that smokes appears to also have a strong impact on smoking behavior.

Perceptions of the Social Environment

The perceptions or beliefs that youth have about their social environments can influence their behavior, regardless of whether those perceptions are true or not. For example, middle school kids may believe that "lots of kids" their age smoke and thus may be more likely to begin smoking to fit in. The reality is that only a small percentage of children that age are regular smokers. Perceptions that have been examined for their influence on youth smoking include smoking-related norms, social support, expectations, reactions by peers and parents, and barriers that youth believe to be in place within their environment.

Norms can be thought of as what a person within a particular group believes he or she ought to do or what is believed to be acceptable behavior for a given age group, gender, or other type of social group. Gerber and Newman asked adolescents how many of their classmates were smokers.[52] Youth who increased their smoking over the course of the year were much more likely to believe that a high number of their classmates were smokers than kids who had decreased their smoking in the same period. Similarly, Leventhal and colleagues found that all kids in their study greatly overestimated the number of adults and kids who smoke.[53] Adolescents in their research believed that 66% of their peers and 90% of adults were smokers. They overestimated the prevalence of smoking in both groups by a factor of three. One large study of approximately 3,300 junior high students in California found that adolescents who made rather high estimates of regular smoking prevalence were more likely to try smoking, to become smokers, or to increase the amount they smoked over the course of the study.[54]

Social support includes the perceived approval or disapproval of adolescent cigarette smoking by parents, siblings, peers, and other important people in a youth's life such as teachers or employers. One important source of social support is peer pressure. Peer pressure is not always negative. Peers may actually discourage smoking and this has been used successfully in many prevention programs.[55] In the community where I grew up, alcohol use was strongly encouraged, cigarette use was accepted but not strongly encouraged, and other types of drug use, such as marijuana smoking were strongly discouraged by my peers.

Despite the lack of strong encouragement to smoke by my own peers, there is tremendous peer pressure to smoke. Hahn and colleagues found that the urging of one or more acquaintances, especially peers or close friends, prompted over half of the adolescents in their study to try a cigarette for the first time.[56] Another study found that girls who believed that their friends were more supportive than critical about their smoking were more likely than those who saw their friends as less supportive to become regular smokers one year later.[57] Similarly, many adolescents in another study claimed "my friends like me because I smoke." In the same study, nonsmokers were more likely to report "my parents don't want me to smoke."[58]

Social support can also include the general support or approval of others who are important in the adolescent's life. This type of support seems to play an important role in the beginning stages of smoking. One study found that adolescents who claimed that their parents were generally supportive of them were less likely to start smoking than youth who believed their parents were not supportive. In contrast, though, the same adolescents who believed that their friends were supportive of them were *more* likely to start smoking. Similarly, male adolescents who believed they had limited involvement in family decisions were more likely to become regular smokers than male adolescents from families where high involvement in family decisions was reported.[59] Finally, adolescents who believed that parents, siblings, friends, and teachers would not care if they smoked were at much greater risk of taking up smoking than those who believed these role models would care.[60]

Behavioral Factors

There are several behavioral factors such as academic achievement, risk taking and other problem behaviors, health enhancing behaviors, and smoking-related skills that have been examined for their influence on the risk of smoking among adolescents. These behavioral patterns may provide opportunities to look at smoking as something that has a purpose; it is useful or appropriate in certain situations.

Poor academic achievement measured in a variety of ways (grades, truancy rates, and future professional or educational aspirations) has repeatedly been found to be related to the onset of smoking. For example, Borland and Rudolph looked at the relationship between scholastic performance, parental smoking, and socioeconomic status among 1,814 high school students in Pennsylvania.[61] They found that among those variables, scholastic performance was the strongest predictor of smoking. In other words, those with the highest grades were much less likely to smoke than adolescents with lower grades. This result has

been found in a study of urban black male adolescents in Harlem, New York, as well as among Hispanic and Asian adolescents in southern California.[62] Similarly, kids who disliked school and feared school failure were more likely to start smoking in early adolescence than those who liked school and expected to be successful in school.[63] Conrad and colleagues found that of the twenty-seven longitudinal studies they examined concerning the onset of smoking, 80% found a positive relationship between low academic achievement and the onset of smoking.[64] Finally, in a study by Newcomb and colleagues, what they termed "academic lifestyle orientation" (measured by grades, educational aspirations, personal and professional plans, and expectations) was the principal influence on teenage smoking behavior, teenage emotional well-being, social relationships with smokers, and adult smoking behavior.[65] Clearly academic achievement plays an important role in adolescent smoking behavior.

Cigarette use among adolescents has been examined in association with other types of problem behaviors. For example, cigarette smoking has been linked to further illegal drug use. This suggests that smoking may be an entry-level or gateway drug in a sequence of increasingly serious drug use. This line of research is not claiming that smoking causes illegal drug use, but rather that those who use illegal drugs have most likely smoked cigarettes prior to becoming involved in illegal drugs. Studies by Fleming and colleagues and Newcomb and Bentler point to the crucial role of cigarette smoking in the progression to marijuana and harder drug use.[66] These researchers have found that the increased use of cigarettes was associated with the increased use of illegal drugs. For example, one study found that among a group of adolescents tracked for eight years, those who were using illegal drugs in adulthood were roughly twice as likely to have smoked than those who had not smoked.[67]

Risk-taking behavior has been defined as youth having an inclination toward excitement and taking chances and is generally considered an indicator of overall deviance and rebelliousness. Risk taking has been found to be related to trying a cigarette for the first time in several studies.[68] However, among the twenty-seven well-designed studies reviewed by Conrad and colleagues, only five found a strong relationship between rebelliousness, risk taking, and proneness to deviance to the onset of smoking.[69]

Health-enhancing behavior, such as participation in sports, has been suggested as one means of decreasing the likelihood of deviant behavior. Swan and colleagues found that girls who were involved in at least one organized sport were less likely to smoke.[70] However, involvement in sports did not appear to impact boys' rate of smoking in this study. Similarly, McCaul and colleagues did not find a relationship between boys' smoking and participation in extracurricular activities such as sports.[71]

Other behavioral factors that have been examined are those related to the more immediate social situations surrounding smoking. For example, one study found that 42% of smoking experimenters had asked for their first cigarette.[72] Another study found that difficulty in refusing an offer to smoke was a strong predictor of smoking.[73] Furthermore, this difficulty in refusing an offered cigarette seems to be strongly influenced by the offering friend's attitudes and behaviors (e.g., being persistent or critical if refused), particularly for high-risk adolescents.[74] In the review of the onset of smoking conducted by Conrad and associates, three studies found that refusal or resistance skills against smoking were associated with lower rates of the onset of smoking.[75]

Personal Factors

Personal factors, those characteristics inherent within a person, include thought processes, personal values, personality, and overall emotional well-being. Personal risk factors are the filters through which sociodemographic and environmental factors pass as they influence behavior. Personal risk factors also help to explain why youth who are exposed to similar social environments may behave differently. Several personal factors have been examined for their relation to cigarette smoking, including knowledge of the health consequences of smoking, the utility of smoking for youth, self-esteem, self-image, self-efficacy, personality, and general emotional well-being.

Many, if not most, youth tobacco prevention programs have a strong emphasis on teaching kids about the negative long-term health consequences of smoking. They talk about death rates among smokers from cancer, heart disease, and emphysema. However, knowledge of the long-term health consequences of smoking has not been shown to be related to adolescent smoking behavior.[76] Virtually all adolescents—smokers and nonsmokers—are aware of the long-term health effects of smoking, but most youth have a very short-term outlook on life and tend to feel invulnerable. Many also believe, falsely, that they can quit smoking at any time. Belief that smoking has short-term consequences appears to have a much stronger influence on kids.[77] One study found that knowing the health consequences of smoking had a minimal impact on adolescent smoking. However, adolescents in the beginning stages of smoking appear to begin actively denying the health consequences of their cigarette use.

In the search for the reasons why youth start smoking, many have begun to examine tobacco use from the perspective of the adolescent. Many adolescents who begin to smoke perceive several functional purposes of smoking. For instance, adolescent smokers are more likely to view smoking as a way to act mature or more adult; have fun; cope with personal problems, stress, and

boredom; or rebel against authority.[78] Castro and colleagues found that adolescents in their study smoked cigarettes to help cope with stressful and disruptive family events.[79] In one important study by Hahn and colleagues, regular smokers were asked why they first tried cigarettes and why they had most recently smoked.[80] The vast majority (60%) reported first trying cigarettes out of curiosity. Much smaller percentages of youth reported trying cigarettes to fit in (13%) or because of feeling pressured (10%). In the case of most recent use, these adolescents were most likely to claim that they smoked for pleasure (27%), as compared to feeling dependent (20%), out of curiosity (17%), and fitting in with a social group (10%). Similarly, Chassin and colleagues suggest that positive attitudes toward smoking, such as the idea that smoking is fun or pleasurable, are a better predictor of regular tobacco use than they are for initial experimentation.[81]

Adolescence is a period of identity formation and a time where a sense of self develops from interactions with parents, school, and peers. Self-esteem, or the qualitative self-evaluation, emerges from this process. Several studies have found a link between self-esteem and the onset of smoking. For instance, Young and Werch found that young nonsmokers and those with no intention to start smoking had higher levels of self-esteem relative to family, school, and peers than frequent users and those who intended to smoke in the future.[82] Conrad, Flay, and Hill concluded in their review that self-esteem received fairly consistent support and that it was much better than what they had expected from their examination of earlier, less rigorous studies.[83]

It has been suggested that many adolescents may compensate for low self-esteem by attempting to improve their external image. They may want to appear to others as if they are mature or look "cool." One large study found that youth in all racial and ethnic groups viewed smoking as a way to improve their self-image.[84] Chassin and colleagues found that among adolescents in their study, smoking role models were viewed as tough, sociable, and sexually attractive.[85] Thus youth who assume that smoking creates these positive attributes may also believe that it is a powerful mechanism for self-enhancement. Smoking becomes a vehicle that they perceive will create a positive social image and improve the way others view them—particularly peers.

An adolescent's efficacy (or confidence) in performing certain behaviors has been found to significantly counter the influences of peers who smoke. De Vries, Kok, and Dijkstra found that self-efficacy in resisting offers to smoke was the strongest factor in predicting adolescent smoking over a one-year period in the Netherlands.[86] Thus self-efficacy, or personal confidence, appears to act as a strong internal buffer in protecting many adolescents from the tremendous social pressure to smoke.[87]

Several studies have found a relationship between cigarette smoking and symptoms of depression among adolescents. For instance, Covey and Tam found a relationship between depressed mood and smoking, and further, that depression scores correlated with the number of cigarettes smoked.[88] Smoking may act as a short-term self-medicating response to depression by increasing alertness and feelings of euphoria and calm, but these effects would dissipate in the long run as tolerance to nicotine increases.[89]

CONCLUSION

Tobacco use is the most common cause of premature death in the United States, killing over 400,000 Americans each year. Despite being linked to chronic health problems, such as cancer, emphysema, and heart disease, many young people suffer under the illusion that they can quit smoking at any time and that any negative health effects will occur much later in life. The truth is that the nicotine within tobacco products is highly addictive; teens who smoke regularly become dependent on cigarettes and find it as difficult to quit as adults. Also, cigarette smoking has immediate health effects ranging from decreased physical fitness to arteriosclerosis, an early precursor to heart disease. Smokeless tobacco products have even more immediate health effects. They may lead to oral or stomach cancers within a few years of use.

Cigarette use increased steadily and dramatically in the 1900s, reaching their peak in the 1960s when 42% of adults were smokers. Cigarette use has steadily declined after the first Surgeon General's Report on the health effects on smoking was released in 1964. While cigarette smoking decreased steadily among adults in the 1970s, 1980s, and 1990s, cigarette use declined less rapidly among youth, and actually increased throughout most of the 1990s. Currently about 13% of middle school and 28% of high school students use some type of tobacco products.

Youth start smoking in progressive stages. In the first stage, general positive attitudes about smoking are formed. Stage 2 is when a youth actually experiments with tobacco for the first time. Stage 3 involves repeated but irregular tobacco use. In stage 4, regular tobacco use leads to addiction and dependence in stage 5. Throughout each of these stages, a number of psychosocial and personal factors are involved in the decision to start smoking and to persist as a smoker including; the availability of cigarettes, the social acceptance of smoking, peer and parenting influences, perceptions of the social environment, self-esteem, and self-image. One of the reasons that many youth come to believe in the social acceptance of smoking has to do with the pervasiveness of pro-tobacco messages. The tobacco industry spends more than $10 billion a year

to convince consumers that smoking will enhance one's personal image, their social acceptance, and to make it look as though tobacco use is normative and valued in American culture. Despite the tobacco industry's claims, these messages continue to impress youth.

Chapter **16**

Brewing Trouble: Some Employment Implications of Regular Malt Liquor Beer Consumption

Va Nee L. Van Vleck, PhD, and Thomas K. Greenfield, PhD

We examine the association between *regularly* using malt liquor beer products and poorer employment conditions. This study proves that beyond the socioeconomic factors contributing to both choice of alcoholic beverage and employment condition, the choice of high-potency beer products increases the likelihood of nonparticipation and unemployment. Using the 2000 National Alcohol Survey (NAS; including targeted metropolitan oversamples), bivariate probit estimation was used because of the anticipated simultaneity. Regularly drinking malt liquor beer is negatively associated with employment condition even after controlling for endogeneity and sociodemographic characteristics, though the association may not be directly causal. The results suggest that a propensity toward regularly drinking high-potency beer products may exacerbate the likelihood of unemployment and nonparticipation in the labor force.

Alarm over high-potency alcoholic beverages and their disproportionate consumption by racial and ethnic minorities in the United States (National Institute on Alcohol Abuse and Alcoholism, 2000) brings to the fore two related economic problems: first, among those who drink, how much does poor socioeconomic status (SES) increase the likelihood of drinking inexpensive, high-potency alcoholic beverages such as malt liquor? This issue bears on the price sensitivity of specific SES groups. Additionally, how much might high-potency alcohol products adversely affect individual productivity and employability, thereby impairing socioeconomic progress? This second question is the emphasis in the present analysis. There is an urgency to this research question as the demographics of high-potency alcoholic beverage consumers become

more rigorously established (Bluthenthal, Brown Taylor, Guzman-Becerra, & Robinson, 2005; Brown Taylor, 2001). While in the United States beer drinking itself (compared to wine and spirits) is associated with hazardous consumption levels (Rogers & Greenfield, 1999), malt liquor consumption may confer additional risks. For example, in a sample of inner-city, lower-income individuals, predominantly African American, malt liquor use (in contrast to regular beer drinking) was associated with being unemployed, being homeless, or receiving public housing assistance (Bluthenthal et al., 2005). Often costing less than popular beer brands, these products are heavily marketed to and consumed by racial/ethnic younger adults (Allen-Taylor, 1997; Elliott, 2002; Gratz, 1997; Halbfinger, 1997; Herd, 1994, 2005; Powell, 1996)—groups already at increased risk for unemployment, underemployment, and lower wages and earnings in the United States.

Success in the labor market can be elusive for the young and minorities. Obtaining an initial job interview itself can be a significant hurdle. A field experiment by Bertrand and Mullainathan (2004) demonstrated that a comparably qualified résumé submitted under an African American–sounding name (e.g., Lakisha) was significantly less likely to receive a callback compared to a résumé with a white-sounding name (e.g., Emily); this was also true for male names. Even less well understood is *under*employment and work mismatch among the young and racial/ethnic minorities. A greater likelihood of part-time employment, which is less likely to include benefits or offer long-term stability, may put these workers in the lower-income quintiles (Kalleberg, Reskin, & Hudson, 2000; see also Reynolds, 2003).

EMPLOYMENT CIRCUMSTANCES, HEALTH, AND ALCOHOL

The recursive relationship between (long-term) health status and (long-term) economic status is well established and is admittedly complicated. Ill health makes it more difficult to participate (or participate fully) in the labor force or to secure employment, and long and/or repeating spells of unemployment contribute to poorer self-reports of health (Mullahy & Sindelar, 1995; Ross & Mirowsky, 1995; Turner, 1995). Low SES, in addition to race/ethnicity, contributes to health disparities as well as additional vulnerabilities and deficiencies in access to and quality of programs for alcohol problems (Schmidt, Greenfield, & Mulia, 2006; Schmidt, Ye, Greenfield, & Bond, 2007). We have reason to believe that some malt liquor beer drinkers may be unaware of any distinction between malt liquor products and ordinary beer (beyond price); specifically, they may not know that malt liquor beers are higher in ethanol con-

tent (Bluthenthal et al., 2005) than most popular and premium beer brands. (See also Kuo, Wechsler, Greenberg, & Lee, 2003, for a look at the role of prices in the marketing of alcohol to young adults.) Therefore, by choosing the affordable beverage, they may inadvertently consume more alcohol per drinking episode than an otherwise comparable drinker would. Alternatively, some malt liquor beer drinkers for whom the stronger alcohol content is itself a desirable beverage characteristic may be seeking intoxication and feel that the product ensures more bang for the buck. Also, consistent with how the product is advertised, malt liquor drinking may seem associated with celebrity, wealth, and identification with a desirable subculture, as Pampel (2006) has argued for the relationship between SES and smoking. These individuals may have either opted out of the full-time labor market or be willing to risk adverse job and economic consequences in favor of differential sociocultural expression.

Long-term illnesses have been documented as drags on subsequent wages earned, hours worked, and participation in the labor force (Bartel & Taubman, 1979; Bartley & Plewis, 2002; Mullahy & Sindelar, 1995; Pelkowski & Berger, 2004). For example, diabetes has been shown to reduce employment rates, working days, and salaries among men; treatment advances, in turn, have been associated with improved labor force participation (among women) and reduced earnings disparities (Kahn, 1998; see also Brown, Pagan, & Bastida, 2005). Similarly, mental illnesses are associated with reduced employability and lower incomes (Catalano, 1999; Ettner, Frank, & Kessler, 1997; Hamilton, Merrigan, & Dufresne, 1997; see also Marcotte & Wilcox-Gok, 2001). The persistence of these adverse effects may dissipate with time, unless there are recurring episodes of illness (Marcotte, Wilcox-Gok, & Redmon, 2000). Importantly, alcohol dependence (and other chronic substance abuse) shares significant patterns in common with more *values-neutral* chronic diseases (such as diabetes, hypertension, and asthma), including genetic and environmental predictors, physiological impacts, treatment compliance, and relapse rates (McLellan, Lewis, O'Brien, & Kleber, 2000; Weisner, 1997).

ALCOHOL ABUSE AND EMPLOYMENT PROBLEMS

The relationship between alcohol consumption and employment has been addressed most often in the context of problem drinking (variously defined) using cross-sectional data. In a series of articles, Mullahy and Sindelar probed the associations between alcohol abuse and labor market outcomes: schooling, earnings, and occupation (Mullahy & Sindelar, 1989); unemployment (Mullahy & Sindelar, 1991); employment and income levels (Mullahy & Sindelar, 1993); indirect effects via education and marital status (Mullahy & Sindelar, 1994);

employment and unemployment (Mullahy & Sindelar, 1996); and occupational choice (Mullahy & Sindelar, 1998). Mullahy and Sindelar (1989) offered a conjecture of amplified differentials of alcoholism across the life cycle, which now appear to be supported by the findings of Jones and Richmond (2006). Using National Longitudinal Survey of Youth (NLSY) data, Jones and Richmond (2006) quantified significant productivity losses from alcoholism, for both men and women. Recently, *heavy drinking*—episodes characterized by the interaction of quantity, frequency, and temporal pattern, not simply consumption volume—has received some attention in relation to the likelihood of criminal behavior, assessed by arrests (French, Turner, & Greenfield, 2005). However, to date, no economic studies have addressed choice of higher-strength beverages, such as malt liquor, in relation to employment using a suitable national data set.

BEVERAGE CHOICE: REGULAR BEER VERSUS MALT LIQUOR BEER

Beer, wine, and spirits have widely varying alcohol content, conventionally measured by percentage ethanol by volume or alcohol by volume (ABV): a 12-ounce standard drink of beer contains roughly the same volume of alcohol as a 5-ounce glass of wine or 1.5 ounces of hard liquor. But there is a large variance of ethanol content among beer products (Case, Distefano, & Logan, 2000; Kerr & Greenfield, 2003; Kerr, Brown, & Greenfield, 2004; Logan, Case, & Distefano, 1999; Martin & Nirenberg, 1991). The ethanol content of malt liquors in general averages about 6.3 percent ABV, though individual brands contain up to 8 percent ABV (Kerr, Brown, & Greenfield., 2004); in contrast, most mass-market beers have ABV averages of about 5 percent, with the light beer type averaging just over 4 percent. Furthermore, malt liquor is often marketed in large formats, such as 16-ounce cans or 40-ounce bottles with large mouths, in readily accessible coolers found in corner stores in blighted communities, designed to promote immediate, rapid consumption (Greenfield, Brown Taylor, & Bond, 2004 consider also Gruenewald, Millar, & Treno, 1993). Thus the actual consumption of these products may induce higher blood alcohol levels than other beer products (Greenfield, Bond, Korcha, & Kerr, 2003), and greater alcohol-related social and health consequences may be associated with selecting these products in place of regular beer, which holds true even after controlling for overall alcohol intake patterns and other demographic variation (Greenfield et al., 2003. French, Brown Taylor, and Bluthenthal, 2006) show evidence that malt liquor beer consumers are *less* responsive to prices than drinkers of beer or spirits, so that consumption takes on a habitual character.

To the extent that lower-income and underemployed individuals prefer this beverage type, a vicious cycle may become endemic, involving consumption of these less expensive products and experiencing adverse drinking consequences that may affect employment opportunities.

Not surprisingly, malt liquor beer and other fortified alcohol products (wine coolers, fortified wines) have been the target of concern for community groups and public health advocates (Gratz, 1997; Herd, 1994; Mosher, 2005; Powell, 1996) and business ethicists (Brenkert, 1998). A current study from south central Los Angeles already mentioned gives a snapshot of malt liquor beer as the most regular alcoholic beverage choice of inner-city African American men (Bluthenthal et al., 2005). The drinking pattern associated with this subpopulation with multiple economic disadvantages was nearly daily drinking, consuming a higher volume of alcohol per day (than regular beer drinkers), and preferring to drink in outdoor public settings (e.g., a park or parking lot rather than a restaurant or bar). With some differences, U.S. national data have reflected similar profiles. Greenfield et al. (2001) estimated multiple logistic regression models to assess the characteristics associated with use of malt liquor. Self-identified African American non-Hispanic respondents were about 2.8 (CI: 1.9–4.3) times more likely to be regular malt liquor drinkers than whites (2.4 times as likely to report any malt liquor beer use). Younger adults (18–29) and those not completing high school were more likely to drink, and frequently drink, malt liquor, while gender was unimportant. Although lower income was associated with malt liquor use on a bivariate basis, it was not in the multivariate models when controlling for overall drinking pattern; however, in these models, regular malt liquor users compared to beer only drinkers were 1.47 (CI: 1.04–2.07) times more likely to be unemployed, with similarly significant, if weaker, relationships seen for any malt liquor use.

Our principal aim is to probe the influence of regular consumption of malt liquor beer on the probability of *second-best* employment outcomes. We hypothesize that the likelihood of poorer labor outcomes will be positively associated with regularly drinking malt liquor products even after controlling for sociodemographic factors and correcting for possible estimation bias due to endogeneity. Though not the emphasis of the present analysis, we hypothesize that the choice of malt liquor beer may be a response to limited financial resources (reflecting limited income and/or bias against traditional work).[1] Unobservable propensities common to both beverage choice and employment condition (e.g., endogeneity) will result in inconsistent and biased coefficients if either of these outcomes are estimated singly; we use a bivariate probit model to measure the correlation of the error terms and produce unbiased parameter estimates (Ashford & Snowden, 1970; Greene, 1993) of the impact of beverage

choice on employment. Estimates of the error term correlations and their statistical significance supports our hypothesis that endogeneity is present, and so univariate analyses would be biased. (If the error term correlations obtained had been insignificant, then there would have been "no statistical advantages to employing a more sophisticated estimator," Feng, Zhou, Butler, Booth, & French, 2001, p. 515.)

DATA AND METHODS

Data Source

These analyses are based on data from the year 2000 U.S. NAS (N10), which was the first in this series of five-yearly surveys conducted by the Alcohol Research Group to include a sequence of items directly addressing malt liquor beer consumption. Extensively utilized in alcohol epidemiology, previous fieldings of the NAS have been used for labor economic-specific analysis only once (Heien, 1996). Designed for health investigations, it does not have as detailed a set of economic variables as, for example, the NLSY, but on the other hand, it includes a more robust set of alcohol measures and a number of relevant employment questions. The survey's epidemiological design included oversamples of African American and Hispanic individuals and an oversample of 13 low-population states (details of the survey design can be found in Greenfield et al., 2001); Greenfield, Nayak, Bond, and Midanick, 2006; and Kerr, Greenfield, Bond, Ye, and Rehm, 2004).

The national sample for N10, including the designed oversamples, yielded an overall sample totaling 9,044 individuals. The main Random Digit Dial (RDD) sample involved 6,021 individuals including all ethnic groups; oversamples of black and Hispanic respondents added 1,250 cases, and the low-population state oversample added 341 cases (to ensure at least 50 cases in each sate); and finally, oversamples were drawn from five targeted metropolitan areas (Denver, Houston, Kansas City, Philadelphia, and San Francisco), adding 1,432 metropolitan cases. Together, this sample resulted in 1,341 black non-Hispanics (17.9%) and 869 Hispanics (12.8%). There were 5,715 current drinkers overall, but incomplete response reduces our useable sample for analysis to n = 5,509 current (past year) drinkers.

Key Measures

The N10 survey includes item series that allow alcohol use to be measured two ways: (1) a Knupfer Series beverage-specific (beer, wine, or spirits) quantity frequency (QF) measure and (2) the Graduated Frequencies (Greenfield,

2000; Room, 1991). The N10 survey augmented the beer QF questions with the question, "When you drink *beer*, how much of the time do you drink malt liquor?" Here we identify beer drinkers as those respondents who chose to drink beer at some time in the last 12 months. We distinguish beer drinkers (relative to *only* wine and/or spirits), and then we further narrow the focus to examine consumers of malt liquor (among beer drinkers).[2] Respondents who said they had consumed malt liquor beer more than "once in a while" are categorized for this analysis as using malt liquor beer regularly.

The strata of the employment conditions we address are as follows: (1) nonparticipation in the labor force (e.g., due to retirement, school enrollment, or discouragement), (2) unemployment (i.e., available and seeking work), and (3) part-time-only work. Because we are interested in investigating whether or not malt liquor beer is associated with second-best (less remunerative or less secure) outcomes, two of our employment state variables are defined so that an affirmative response is the *poorer* alternative; these are labor force nonparticipation and unemployment. However, we also want to probe whether malt liquor beer decreases the likelihood of even part-time-only employment. For part-time-only employment to serve this litmus test purpose, we have constructed the alternative state as *unemployment* for the estimation analyses. (An affirmative response to part-time only means a person is employed fewer than 35 hours per week; a negative response means being unemployed.) We are assuming part-time only is less desirable than full-time work but more desirable than unemployment. Strictly speaking, part-time work is not always a second-best condition (Barrett & Doiron, 2001; cf. Kalleberg et al., 2000; Reynolds, 2003); yet while recognizing this fact, the N10 data offer us no way to distinguish whether the part-time employment is individually *voluntary* (i.e., first-best) or *involuntary* (i.e., second-best).

Other key measures included in this analysis are variables for religiosity, the age when the respondent began drinking alcohol, regional wetness/dryness, and four count variables of various problems the respondent attributes to his or her drinking. These variables (or variations thereof) are common in this literature. Religiosity can be a protective factor in the development of problem drinking behaviors among adolescents (Brown Taylor, 2001; Mason & Windle, 2002; Wells, Graham, Speechley, & Koval, 2005); this variable is derived from the item, "How important would you say religion is in your life—very important, somewhat important, not really important, or not at all important?" The response "very important" was taken as the positive indicator of religiosity generally found to be related to lower alcohol consumption (Greenfield, 2000). An earlier age of onset is a strong predictor of many later manifesting alcohol problems (e.g., Grant & Dawson, 1998). Regional attitudes toward alcohol were

also considered—broadly speaking, *wet* indicates a relative tolerance of alcohol, whereas *dry* identifies less approval (Hilton, 1988, 1991).[3] Four "alcohol-related problems" variables are components of a larger tangible consequences scale used to assess consequences of alcohol abuse (Hilton, 1991; Midanik & Greenfield, 2000).[4] Current drinker respondents were asked, "Did this happen in the last 12 months?," followed by a series of negative-consequence instances. Problems with the law were assessed by four items, for example, "I had trouble with the law about drinking when driving was not involved," "I have been arrested for driving after drinking," and "a police officer questioned or warned me because of my drinking"; the legal problems variable is the count of affirmative responses. In similar fashion, problems associated with work or employment are positive response counts to the three statements, such as "I have lost a job, or nearly lost one, because of drinking." Consequences affecting health included intoxication lasting several days, concern for physical health, and so on, and were counted from three questions. And the interpersonal consequences of drinking measure covered two questions in which a spouse or coworker expressed concern for the respondent's drinking behavior. In several studies, internal reliabilities of these measures (Cronbach's) ranged from 0.74 to 0.97, excepting health, which was somewhat lower (0.58–0.67), but deemed adequate for brief research measures (Midanik & Greenfield, 2000). Sociodemographic and geographic indicator variables complete the set of independent variables used for these estimations.

Sample means are given in Table 16.1 (including statistics for drinkers who only consumed wine and/or spirits [but not beer] in the interest of comparison). Beer drinkers are unlike drinkers limited to wine and spirits: they are more often male; they are younger; they started drinking alcohol at a younger age; they identify religion as "important" less often; and they report more alcohol-related problems in all four domains (legal, health, work, and interpersonal relationships). Self-identified blacks are *less likely* and Hispanics are *more likely* to drink beer than only wine or spirits. Finally, regular malt liquor beer drinkers have different group characteristics than general beer drinkers. Regular malt liquor beer drinkers tend to be male; have only a high school education or less; are more often unmarried and unemployed; and self-identify more often as black, Hispanic, or other. With the exception of problems related to work, the subgroup who regularly drink malt liquor also report more instances of alcohol-related legal and health problems as well as more interpersonal problems due to drinking than general beer drinkers.

Analytical Framework

Economic modeling of the effects of substance abuse (alcohol, cigarettes, and drugs) on labor market outcomes traces its lineage to human capital (Becker,

1962; Mincer, 1958) and health capital (Grossman, 1972; Grossman, 1989) theories. However, there are few investigations of beverage-specific associations with labor market outcomes and none related to individuals' choices of high-strength alternative beverages like malt liquor; the present analysis begins to fill this gap.

Single-equation probit models of current employment status as a function of beverage choice and other explanatory variables are summarized in the following:

$$\Pr(\text{Employment State}_i = 1) = \Phi(\alpha A\text{Beverage\_Type}_i + \beta \text{AX}_i). \quad (1)$$

In our analysis, there two versions of the binary variable Beverage_Type$_i$: first, current drinkers who chose beer in the last 12 months (yes or no), and second, beer drinkers who chose malt liquor beer products more than infrequently (yes or no). The placeholder variable Employment_State$_i$ in the generic equation (1) describes three distinct employment situations in our analysis: (1) out of the labor force (yes or no); (2) unemployed (yes or no); and (3) underemployed, our construction of part-time-only work versus unemployed. The coefficients α and β are parameters to be estimated; Φ represents the cumulative normal function when estimating a probit model. However, if the Employment_State condition is itself a contributing factor influencing beverage choice (as we expect), estimation of an equation such as equation (1) will produce biased coefficients and inaccurately reflect any association between beverage choice and employment situation.[5]

Our estimation applies a *bivariate* probit model specification in which the variables Beverage_Type$_i$* and Employment_State$_i$* are latent variables that reflect beverage choice(s) and current employment state(s), respectively (following the approaches of Brown et al., 2005; Feng et al., 2001; Hamilton et al., 1997). The multivariate, simultaneous estimation is summarized in the system

$$\begin{bmatrix} \text{Beverage\_Type}_i \\ \text{Employment\_State}_i \end{bmatrix} = \begin{bmatrix} X_i\theta + Z_i\gamma \\ X_i\beta + \text{Beverage\_Type}_i\alpha \end{bmatrix} + \begin{bmatrix} \varepsilon_i \\ \nu_i \end{bmatrix}$$
$$\begin{bmatrix} \varepsilon_i \\ \nu_i \end{bmatrix} \sim NID\left(0, \begin{bmatrix} \sigma^2 & \rho\sigma \\ \rho\sigma & 1 \end{bmatrix}\right) \quad (2)$$

Two versions of Beverage_Type and three versions of Employment_State obtain six bivariate probit systems to be estimated. The independent variables included in $\mathbf{X_i}$ are indicator variables—high school education or below, sex, age, marital status, self-reported race and ethnicity, three Race × Gender (e.g., black women, Hispanic women, and other (non-White) women) interaction terms, and four variables for geographic region—believed relevant both to drinkers' beverage choices (Kerr, Greenfield, Bond, Ye & Rehm, 2004) and

the respondents' employment condition. The matrix $\mathbf{Z}_i$ includes the variables for age started drinking; religiosity; the alcohol-related legal, health, work, and social problems; and wet/dry—these are the instruments for beverage choice.

We assume that ε_i and υ_i are distributed bivariate normal with zero mean and variance-covariance structure described by the parameters σ and ρ. These error terms may be the result of omitted variables that are related to the probabilities of an individual's particular beverage choice and/or employment circumstance but are unspecified either because they are not measurable (e.g., effort or attitude) or because they are not available from the existing N10 questionnaire (e.g., job tenure, length of current unemployment spell, etc.). If ρ is significantly different from zero, there is endogeneity between beverage choice and employment circumstance. Estimates obtained from simply including Beverage_Type directly in a single-equation probit of Employment_State equation(s) will be biased. The sign of ρ reveals the direction of bias: if ρ is positive, a single-equation probit estimate will exaggerate the effect of beverage choice on employment state, and the coefficient will be *overstated;* if ρ is negative, the single-equation estimate will *understate* any impact since the effects of the unobserved factors affect affirmative choice of alcoholic beverage and employment situation in opposite directions, in a diluting effect.

RESULTS

Odds ratios (OR) obtained by a logistic regression (for brevity of exposition results not reported) for the three respective employment states that simply included beer as an independent variable would appear to (very weakly) obtain that choosing beer (rather than wine or spirits) is unrelated to the odds of being out of the labor force (OR = 1.013, *SE* = 0.084, *p<=0.15*) and significantly increases the odds of being unemployed (OR = 1.582, *SE* = 0.358, $p < .05$); furthermore, beer significantly reduced the odds of working part-time-only relative to unemployment (OR = 0.622, *SE* = 0.140, $p < .01$). The same approach, including instead malt liquor beer as the chosen alcoholic beverage, indicates that regularly choosing malt liquor (rather than ordinary beer) looks to be associated with 50 percent greater odds of being out of the labor force (OR = 1.498, *SE* = 0.278, $p < .01$) and almost double the odds of being unemployed (OR = 1.878, *SE* = 0.488, $p < .05$) but would seem to have no significant association with part-time-only work (OR = 0.706, *SE* = 0.200, *NS*).

Bivariate Probit Analysis

The results from estimating the six bivariate probit systems are shown in Table 16.2.[6] The estimates of ρ are statistically significantly nonzero in five of

the six systems (in all three of the malt liquor beer systems but in only two of the beer systems). The estimated ρs are negative in the cases of labor force nonparticipation and unemployment (both second-best outcomes), which means that simple single-equation estimates, such as the logit OR reported earlier, are understated. And in the part-time work systems, endogeneity is also not trivial; the rs are positive and statistically significant.

First, consider that the initial expectation that choosing beer (over wine or spirits) would have no association with labor force participation is now demonstrably inaccurate. Beer is positively associated with an increased likelihood of being out of the labor force and of being unemployed rather than working, *including part-time-only work*, after controlling for human capital and beverage choice covariates. The ubiquity of beer drinking (among those who drink) is visible in the lack of statistical significance for the education and marital status variables, both factors known to be significant to employment condition. Men and younger drinkers prefer beer—contributing to the fact that drinking beer, in contrast to wine or spirits, other things equal, elevates the risks of drinking and driving (Greenfield & Rogers, 1999). Thus it is not surprising to observe the positive association of legal problems in the beer choice equations. Religiosity and an older age of onset appear to have negative effects on choosing beer. Conversely, there is a positive association of health problems related to drinking and the choice of beer.

Beer choice and employment conditions are known to differ by race. This is also reflected in our results. Blacks are significantly less likely to choose beer (versus wine or spirits), which, all else equal, is a plus for avoiding second-best employment outcomes. And still blacks face an increased likelihood of being unemployed. Hispanics and others are as likely to choose beer as are whites, but Hispanic men have a higher probability of being unemployed relative to any employment, and others have higher probabilities of all three second-best employment outcomes.

Given that our main interest was to examine the effects of regular malt liquor beer consumption (not simply alcohol), we now turn to the results for the malt liquor beer and employment systems (the last six columns of Table 16.2). The role of endogeneity is heightened in these three systems: regularly malt liquor beer is significantly positively associated with the second-best outcomes (nonparticipation and unemployment relative to any work). As ubiquitous as the choice of beer was, the choice of regularly drinking malt liquor beer is a relatively enclaved phenomenon associated largely with markers of race and SES. Blacks, Hispanics, and others (though not as strongly for black or Hispanic women) are more likely to choose malt liquor beer. More than occasional choice of malt liquor beer is negatively associated with a later age of drinking onset, education beyond high school, older age, and marriage. Religiosity has

(at best) no inducement and is (at worst) positively associated with the choice of higher alcohol beer among those individuals in the labor force. Among labor force participants, health problems are negatively associated with choosing this higher-strength product. And drinkers of malt liquor beer, more likely to be nonparticipating or to be unemployed, exhibit positive associations with "problems involving negative reactions from others" and "work problems" not observed among drinkers of ordinary beer.

Once controlling for the beverage choice and covariates, self-identifying as black *fails to increase* the probability of any of the second-best employment conditions and also *fails to decrease* the probability of part-time-only work over unemployment. The influence of Hispanic identification is somewhat more mixed: Hispanic men in the labor force are more likely to be unemployed, but Hispanic women are more likely to work part-time-only than to be unemployed. Other things equal, regularly consuming malt liquor beer increases the likelihood of nonparticipation and unemployment, independent of these covariates.

CONCLUDING COMMENTS

The amplified association between regularly drinking malt liquor beer and unemployment highlighted by our analysis gives substance to the niggling unease of community activists and leaders that there is something amiss. Admittedly, it may not be malt liquor beer itself that does the damage; rather, perversely, the individual's choice of malt liquor beer may be an expression of some underlying characteristic that is severely discounted by the labor market. For instance, in the interview callback experiment comparing "Emily" (or "Greg") to "Lakisha" (or "Jamal"), the name itself is not a deterministic signal of ability, yet the outcome illustrates biased assessment of the applicant—*on the basis of the applicant's name*—by the prospective employer. In our analysis, malt liquor beer may be the observable choice that proxies some latent propensity that also increases the likelihood of second-best labor outcomes. The focus for further concern about high-potency beer products is if these contribute to behaviors deleterious to contemporaneous productivity and employability and if they might even be harmful to health (e.g., via an ethanol dose-response mechanism), thereby further limiting future employability and financial security, which themselves feed back to the individual's health status.

There are some limitations of the data and of the analyses that qualify our findings. The NAS analysis assumes the verity of self-report for alcohol consumption, employment, and personal circumstances. As the data are cross-sectional, personal history is only available through respondent recall. A more

robust analysis of the evolution and interaction of specific beverage choices, the several employment-related statuses, and personal income would require a longitudinal panel survey. The results reported here are categorized only in terms of alcoholic beverage chosen (in the last 12 months) and do not incorporate measures of the total volume of alcohol consumed or the frequency of heavy drinking, which is known to have effects on risks of a range of problems (Midanik, Tam, Greenfield, & Caetano, 1996), including nonfatal injuries (Cherpitel, Tam, Midanik, Caetano, & Greenfield, 1995) and even all-cause mortality in men (Rehm, Greenfield, & Rogers, 2001).

Second-best employment outcomes are generally individually and socially costly, affording lower lifetime earnings capacity and/or less employment security and requiring greater social finance, both currently and into the future. We suggest that the ramifications of the popularity during the 1990s of malt liquor beer (and related products), especially among ethnic minority groups, are likely to emerge only gradually. Young racial/ethnic consumers are already at nontrivial risk in terms of health and economic outcomes, without the additional risk identified here.

NOTES

1. For example, young adults across racial/ethnic groups are the marketing audience for rap music; as documented by Herd (2005), the prevalence of references to alcohol use and its association with positive consequences in this genre have increased sharply in the last decade. It is possible, then, that increased consumption of malt liquor beer products by the very populations that are also the audience for rap music is a substitution of relatively inexpensive but high-ABV beverages for an unaffordable (higher ABV) product that has been successfully associated with positive social conditions by admired musical artists.
2. Gill and Michaels (1992) made a distinction between any "drug use" and "hard-drug use" (which was limited to narcotics regarded as more potent or addictive); also, the contrast is implicit in the comparison of marijuana and cocaine in Register and Williams (1992).
3. A more contemporary and potentially more robust/rigorous characterization of regional drinking behaviors has been proposed by William Kerr (2005) of the Alcohol Research Group; ideally, this richer typology will be more informative regarding the drinking attitudes and environments of survey respondents.
4. Our model is a bivariate probit; each of the dependent variables is a binary (0,1). To our knowledge, no a priori endogeneity tests have been developed for this estimation specification.
5. The analysis presented is not an estimation of population parameters; it is an estimation of the relationship between beverage type and employment condi-

tion within individuals. The parameter estimates reported here are obtained from unweighted data (Groves, 1989).

6. We repeated these analyses to consider whether heavy drinking (two characterizations were used) more so than beverage choice was the risk factor. We were surprised to obtain that heavy drinking was only statistically significant in the out of labor force systems, and even so, was small in magnitude.

Chapter **17**

The Roads to H: The Emergence of the American Heroin Complex, 1898–1956[1]

David T. Courtwright, PhD

For some years I have been working on a history of the reception and impact of novel psychoactive drugs. The other day it occurred to me that, at bottom, the story is really a very simple one. It is that of the sorcerer's apprentice. Promising new drugs—aqua vitae, tobacco, morphine, cocaine, barbiturates, amphetamines—are introduced. Therapeutic claims are made and evaluated. Doctors argue among themselves about indications, dosage, and toxicity. The intramural debates seldom attract public notice. But, sooner or later, the new drug slips the bonds of medical discourse and control. It escapes into a larger world of popular pleasure and mischief, prompting official intervention.

The history of heroin in the United States fits neatly into this pattern. In 1898 it was just another promising new product from the Bayer Pharmaceutical Company. In the 1910s it developed a growing underworld following and by the 1920s had become the mainstay of the black market. The federal government outlawed the manufacture of heroin in 1924; as existing stocks dwindled to a few hundred ounces, the drug virtually disappeared from medical practice. The last remaining supplies were swept up by the Narcotic Control Act of 1956, which required the surrender of all remaining pharmaceutical heroin to the federal government. Heroin became, so to speak, America's first Schedule I drug. Its use was totally prohibited, except for restricted research purposes, as cannabis, LSD-25, DMT, and mescaline would be in later years. However, the fact that heroin shared the fate of other potent psychoactive drugs is not an adequate explanation of its prohibition. We need to look more closely at the process of its transformation. We need to understand precisely when, how, and

why heroin became H, the top enforcement priority of the Bureau of Narcotics and the basis of an underworld subculture—predominantly white before World War II, and minority thereafter.

MEDICAL USE AND ADDICTION

Heroin use and addiction were originally medical phenomena. What is not generally understood, however, is that the percentage of medical addicts who used heroin was never large. A retrospective study of fifty mostly medical cases published in 1918 showed only two heroin users, or 4 percent of the total (Scheffel 1918, 853–54). Lawrence Kolb, the government's leading medical authority on addiction, carried out a similar study of 150 medical addicts whose use began between 1898 and 1924, that is, after heroin was introduced and before it was effectively outlawed in the United States. The result: two heroin cases, or just 1.3 percent of the total. "My idea has been that the use of heroin in medical practice seldom resulted in addiction," Kolb wrote, "although when used in the underworld for dissipation only it doubtless has produced numerous addicts."[2]

The infrequency of iatrogenic heroin addiction was due to several factors. Heroin, in contrast to morphine and cocaine, was not touted for virtually every physical and medical affliction. Heroin was discussed in the medical literature primarily as a cough suppressant and means of alleviating respiratory distress. It was "recommended chiefly for the treatment of the air passages attended with cough, difficult breathing and spasm, such as different forms of bronchitis, pneumonia, consumption, asthma, whooping cough, laryngitis, and certain forms of hay fever," summed up a 1906 JAMA literature review ("Heroin Hydrochloride" 1906, 1303). While some authorities also recommended the drug as an analgesic, this idea was controversial and, early on, was challenged by several German and American authorities (for example, Floret 1898, 512; Manges 1898, 770; Wood 1899, 89–90).[3]

Advertising stressed heroin as a specific for respiratory symptoms. This was true even when heroin was combined with other analgesic products such as Antikamnia, a popular medication whose name means "against pain." The promotional literature for Antikamnia and heroin mentioned several possible indications, but concentrated on glowing clinical reports of cases involving cough and respiratory ailments. The medication came in the form of a tablet consisting of 5 grains of Antikamnia (47 parts acetanilide, 50 parts sodium bicarbonate, and 3 parts tartaric acid) and just 1/12 grain (5 mg) of heroin.[4]

This was typical. When heroin was prescribed for cough and respiratory ailments, it was given in small doses in tablets, pills, pastilles, elixirs, or glyc-

erin solutions. Some preparations contained only 1 or 2 mg per dose (see, e.g., "Herotopine" and "Hermonal," n.d., W. H. Schieffelin and Company Collection). The ingestion of small amounts of an opiate was a good deal safer, from the standpoint of addiction, than hypodermic injection, which was how morphine was often administered.

Death was also a good protection against addiction. Pneumonia and tuberculosis had particularly high mortality rates in the period before antibiotics. Patients with these conditions who were treated with heroin presumably would not have lasted long as addicts, assuming they reached the point of physical dependence.

While some early reports gave assurances that heroin was not habit forming, and even recommended it as a treatment for morphine addiction, physicians were quickly disabused of these notions. By early 1900 there were several cautionary statements about heroin's toxic and habit-forming potential; by 1903, if not sooner, there were firm and unambiguous declarations with such titles as "The Heroin Habit: Another Curse" (Pettey 1903; see also Wood 1899, 90; Manges 1900, 82; "Caution Regarding Heroin" 1900, 44).

These warnings about iatrogenic heroin addiction came sooner than comparable warnings about morphine. They were received by physicians who were better educated, more therapeutically conservative, and more mindful of specific treatments for specific diseases than their counterparts of the 1870s and 1880s, when morphine reigned as panacea. In fact, most American (and, ironically, German) doctors in private practice eventually became so wary of heroin that they gave up prescribing it before they were legally required to do so. Government and military physicians had less choice in the matter. The U.S. Public Health Service ceased dispensing heroin in 1916; the army, in 1923; the navy, in 1924 (see "Symposium on The Doctor and the Drug Addict" 1920, 1591; New York State Narcotic Drug Control Commission 1920, 41; Wolff 1932, 2180; Anslinger 1936).

Now contrast the heroin situation with that of aspirin. Introduced commercially in 1899, the year after heroin, aspirin was Bayer's best-selling drug by 1906 and one of the most widely prescribed drugs in the world by 1914 (McTavish 1987, 104).[5] Not only was aspirin useful in treating a wide variety of conditions, but it was relatively safe and not habit forming (in the sense of physical dependence). Indeed, I have long believed that one of the reasons for the decline of all forms of iatrogenic opiate addiction in the early twentieth century was the availability of aspirin and kindred preparations to treat rheumatism, colds and flu, toothaches and headaches, and other common aches and pains.

Going further, I believe that degree of exposure is the single most crucial variable in accounting for the prevalence of heroin or any other type of addic-

tion. Yes, set and setting matter; and yes, personality and genetic makeup play a role; and yes, social integration and cultural norms can militate against abuse; and yes, only a minority of those exposed to a given drug typically end up as full-blown addicts. The simple fact remains, however, that those who are never exposed to a drug will never become addicted, and those who are seldom exposed are at much lower risk than those frequently exposed. Aspirin reduced the odds that millions of people from all walks of life who were suffering from common afflictions would come into contact, through either prescription or self-medication, with powerful opiates like morphine or heroin. The net effect was less opiate addiction.

NONMEDICAL USE AND ADDICTION

How, then, were nonmedical users exposed? No simple answer is possible here. In the underworld, many roads led to H. One story has it that prisoners in a state penitentiary were given heroin for cough. News spread among the inmates that the cough pills were "good dope." Word spread outside the prison, and eventually to tenderloins all over the country (Kane et al. 1917, 503).[6] The story is plausible except in one detail. It seems more likely that word of heroin's psychoactive potency spread from multiple sites, rather than one particular prison.

We know that nonmedical heroin addiction was definitely in play by 1910, the year when Leroy Street, pseudonymous author of *I Was a Drug Addict*, and his teenage friends first started sniffing the drug (Street and Loth 1953, 11).[7] We also know that many of the early nonmedical heroin users—mostly sniffers—had previously used other drugs, notably opium, cocaine, and tobacco cigarettes.

Police pressure and a national import ban (enacted 1909) had made opium smoking riskier and more expensive. Heroin sniffing was cheaper, quicker, and much harder to detect. By 1916 several reports described opium smokers who had expediently switched to heroin (see, e.g., Bailey 1916, 314; McIver and Price 1916, 477, 478). Something similar happened with cocaine. The illicit market for cocaine existed well before passage of the 1914 Harrison Narcotic Act. It was created by a combination of informal professional controls—druggists wouldn't sell cocaine to just anybody—and proliferating legal controls of varying stringency (Spillane 2000). The result was an illicit market and higher prices. Decks of cocaine retailed on the streets of New York City for 25 cents, but contained only 1.3 grains (<85 mg), making the actual price eleven times that of the legitimate wholesale price (Musto 1990, 322–23).

Heroin, by contrast, was cheaper and more readily available from druggists. "Dope users have turned to [heroin]," Boston reformers complained in 1912,

"and as the drug is not so well known we find apothecaries who would not sell cocaine who are selling heroin apparently quite freely" (Chase et al. 1912, 9; see also Towns 1916, 221). Heroin was taken in the accustomed form, sniffing; didn't require injection; and had the added advantage of alleviating unpleasant symptoms, such as depression, that might be experienced when quitting cocaine. In 1923 Lawrence Kolb began a systematic study of 230 cases of narcotic addiction, including 40 heroin addicts. His records show that twenty-six of the forty heroin cases used cocaine prior to or concurrently with their first use of heroin (Kolb Papers, Box 6; Courtwright 1982, 161–62 n. 9; see also Stokes 1918, 756–57; Farr 1915, 893–94).

Not all of the heroin sniffers were veteran opium or cocaine users. Another type was the teenage working-class boy, often of immigrant parents, who lived in a "dirty, noisy, cheap, and tough" neighborhood (Stokes 1918, 757). He began using heroin out of curiosity or peer pressure after he had been introduced by someone in his gang—more like a younger, scruffier version of the Bowery Boys than the Crips or the Bloods. If he took any other drug on a regular basis, it was tobacco. No observation about the first generation of nonmedical heroin addicts is more commonplace than that they were inveterate cigarette smokers (e.g., Blanchard 1913, 142; Stokes 1918, 756).

Is there a connection? The chronology, geography, and sociology are all suggestive. Cigarette use was exploding at the same time nonmedical heroin use was taking off. New York City, the center of heroin use, was also the center of the cigarette revolution. In 1910 the city accounted for 25 percent of all U.S. cigarette sales, despite having only about 5 percent of the U.S. population. Cigarettes were particularly popular with New York's immigrants—and many heroin addicts, though born in the United States, came from immigrant families.[8]

Theories developed. R. M. Blanchard, an army doctor, speculated that inhaling smoke increased the absorption of heroin (Blanchard 1913, 142). Harvey Wiley argued that the boy who acquired the cigarette habit would be "brought into sympathetic association with boys who are going to the bad" and that, among other things, he would "more readily become a victim of alcohol, cocain [*sic*], opium, and other narcotic drugs"—an early version of the gateway theory.[9] The addiction specialist Charles Towns likewise argued that cigarettes to alcohol to opiates was a natural progression, both because smokers developed a need for stimulation and because they ran with bad companions (Towns 1916, 152–53, 167, 172).[10] It is hard to know how much weight to assign cigarettes in the etiology equation, but it is at least plausible that their growing use—even more a symbol of defiance and deviance in 1910 than today—by groups of teenage boys paved the way for heroin experimentation.

HEROIN OUTLAWED

The emerging stereotype of the heroin addict was far more frightening than that of the old-fashioned morphine addict. Heroin addicts were boys and young men who ruined themselves in the prime of life. Morphine addicts were older and sicker and more often female. Heroin addiction was a vice. Morphine addiction had often originated in response to pain or chronic disease. Heroin addicts were dumb, greedy for drugs, visible, and rude, "members of gangs who congregate on street corners particularly at night, and make insulting remarks to people who pass." Morphine addicts were "more intelligent, secretive as to their habit, and usually temperate in the dosage of their drug" (Leahy 1915, 256; Stokes 1918, 757). Heroin addicts came from the lower and "criminal" classes of the big cities. Morphine addicts came from more diverse and, on the whole, better social backgrounds. The data in Figure 17.1, based on Treasury Department questionnaires, show where nearly ten thousand addicts were institutionalized during the period 1916–1918 (U.S. Treasury Department

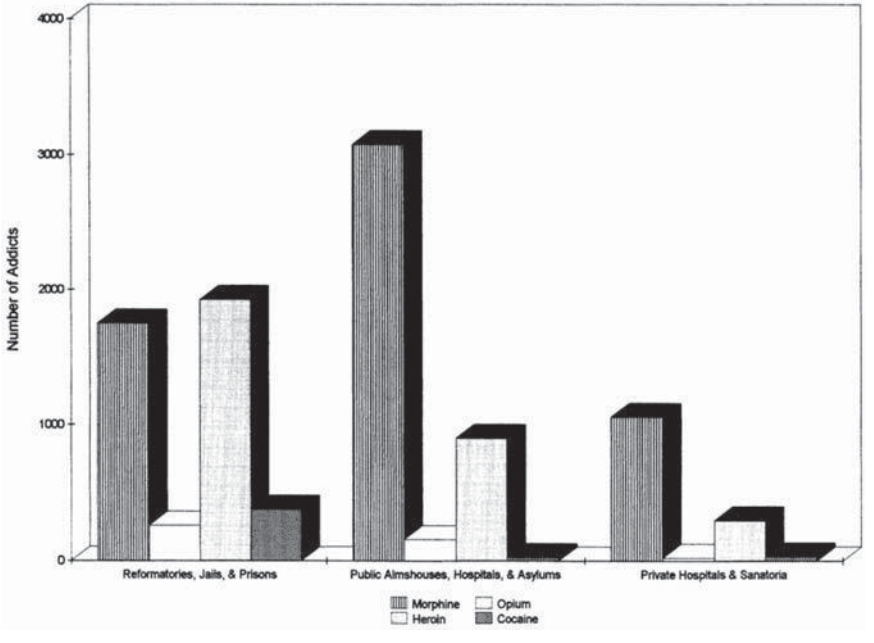

FIGURE 17.1 Institutionalized addicts, 1916–1918 (9,822 cases available to Treasury Department).

1919, 15–19). Heroin addicts were more numerous than morphine addicts in jails and prisons, while morphine addicts were far more numerous than heroin addicts in private hospitals and sanatoria. Unsurprisingly, opium smokers and cocaine addicts were also concentrated in penal or public institutions.

Subsequent studies showed a similar pattern. Of 632 convicted male addicts judged suitable for custodial treatment at New York City's Correction Hospital from March 1927 to June 1928, 588 (93%) used heroin alone or in combination with other drugs. Of 200 female addicts, 168 (84%) did likewise. Though straight morphine addicts were still common in the South in the late 1920s, they were increasingly rare in the North, particularly in correctional settings (Tuttle n.d.).

Why were so many heroin addicts behind bars? In objective terms, the answers are plain enough: because they stole or dealt drugs to support their habits; because they were reared in the slums; because they were single males in their teens and twenties, prime time for crime with or without drugs. But inventive propagandists like Richmond P. Hobson gave another answer: because of the action of heroin itself. It "exalted the ego," he testified, making the addict "suited for daring crimes, holdups, robberies, and such crimes as bandits of old never dared" (U.S. Senate, Committee on Printing 1924, 17).[11] Even if heroin addicts did not commit crimes, they were dangerous because of their tendency to proselytize (Bailey 1916, 315). "He has a mania to see others become addicts," said Hobson, who quoted with approval a comparison between heroin addiction and leprosy (U.S. Senate, Committee on Printing 1924, 16–17). The metaphor stuck.

Those who have lived through the middle to late 1980s do not need to be reminded what happens when the public associates addictive drugs with crime sprees by slum dwellers. In 1920 the American Medical Association's House of Delegates passed a resolution that heroin be eliminated from all medicines and that its importation, manufacture, and sale be banned in the United States. The measure was endorsed by police and penal authorities, and ultimately by Congress, which forbade the importation of opium to manufacture heroin in 1924. Stephen G. Porter, the bill's sponsor, hoped that other nations would emulate America's heroin ban, making it more difficult to divert the drug into the illicit traffic ("History of Heroin" 1953; "Heroin and the International Conferences" 1953, 55–58; Musto 1974, 200–2).[12]

THE HEROIN COMPLEX

Yet within ten years of its prohibition, heroin was the mainstay of the illicit traffic practically everywhere in the United States. In the mid-to-late 1910s most

heroin addicts lived (and died) in the New York–Philadelphia area. That was where most of the large heroin manufacturing and distribution companies were located and where diversion was therefore easiest, as when the American Drug Syndicate Company's Long Island plant was robbed of 150 pounds of heroin tablets in 1920. In other parts of the country, morphine or morphine-and-cocaine addicts were the norm (Courtwright 1982, 101–2; Jonnes 1996, 77).

By the end of 1920 the government had forbidden maintenance and had closed almost all of the municipal narcotic clinics. Some of the displaced patients were able to find doctors willing to write prescriptions. Those who suffered from chronic diseases like advanced tuberculosis, sympathetic figures in the eyes of both physicians and narcotic agents, had the most success in securing a continuous legal supply. But those who were "merely" addicted to narcotics—including virtually all heroin users—generally had to turn to the black market. Most black-market drugs were diverted from legitimate pharmaceutical manufacturers, who were making far more drugs than medically necessary during the 1920s. Enforcement of the Jones-Miller Act (1922) and a series of diplomatic agreements, culminating in the 1931 Limitation Convention to regulate international manufacturing, made diversion more difficult and brought licit production more into line with medical and scientific needs. Supplying the U.S. black market increasingly became a matter of smuggling and then distributing narcotics illicitly manufactured in such distant places as Turkey, the Balkans, and Shanghai.[13]

Heroin was the smuggler's drug par excellence. It was compact and potent, and did not spoil. It could be, and was, adulterated after arrival to increase profits. Even discounting for the adulteration, it was "cheaper for the amount of kick in it" (Helbrant 1941, 30).[14] Neophytes, wary of the needle, could sniff the drug. They could also afford it. Decks of adulterated heroin sold for as little as 50 cents apiece in Harlem during the Depression (Courtwright et al. 1989, 105).[15] These advantages made heroin the primary black-market narcotic throughout the United States, in fact throughout most of the world, by the mid-twentieth century ("History of Heroin" 1953; D'Erlanger 1936, 94).

Not all addicts approved of the trend. American opium smokers, who regarded heroin as dangerous and déclassé, were especially upset. They would have continued as before, but their accustomed drug was becoming progressively scarcer and more expensive. They were victims of what the physician and anthropologist Joseph Westermeyer calls the pro-heroin effects of anti-opium laws. The rigorous enforcement of drug prohibition inevitably drives traffickers and users away from bulkier and more perishable narcotics like opium and toward heroin, with generally evil consequences (Westermeyer 1976, 1135–39).

Let me invoke the work of two other distinguished anthropologists, Vera Rubin and Lambros Comitas. They coined the phrase "ganja complex" to describe a particular pattern of chronic working-class cannabis use in Jamaica and other cultures (Rubin and Comitas 1975, ch. 4; Rubin 1975, 5–6). It seems to me that what had evolved in America by the 1930s was a distinctive "heroin complex." Its attributes can be summarized briefly. Most addicted users were male, poorly educated, irreligious, and engaged in part- or full-time hustling; most lived in cities—about half in New York. Many female addicts were prostitutes. Initiated by sniffing, addicts switched to skin popping and mainlining to maximize the effect of adulterated heroin. They suffered high rates of morbidity, mortality, incarceration, and violence tied to disputes over drugs and money. They were part of a deviant, stratified subculture that revolved around the acquisition and use of heroin, had its own specialized language, and was at once mutually supportive and exploitative. "Never trust a junkie" was more than a prejudice of the straight world.

What happened to the heroin complex? Before World War II, it was mostly white and, as social problems go, of modest significance. Harry Anslinger, longtime head of the Bureau of Narcotics, estimated that there were thirty-five thousand to fifty thousand nonmedical addicts in the country in 1938 (Anslinger 1938). By contrast, Joseph Greenwood, a Drug Enforcement Administration epidemiologist, estimated that there were 504,000 to 578,000 addicts (that is, a 95 percent confidence interval around an estimate of 546,000) in 1975 (Greenwood n.d.). Bearing in mind the critical things I and others have said about official prevalence estimates, there is still no question that the heroin complex of the 1930s was small-time compared with that of the 1970s or, for that matter, of the 1990s.

But before the heroin complex got larger, it got smaller. Addiction hit a record low during World War II. The country was prosperous. There was a sense of national purpose. Jobs were abundant and wages were high. Millions of susceptible youths joined the armed forces. There they might acquire the vices of smoking, drinking, and swearing, but not heroin using, at least not in the 1940s (Burnham 1993, 70–71, 101, 220–21). Back on the streets, prices were high and so was adulteration; black-market heroin was often only 1 percent pure by 1944, when it could be found at all.[16] Addicts had to boil down paregoric, eat *yen-shee* (the residue from smoking opium), bribe physicians, forge prescriptions, rob drugstores, switch to other drugs (such as barbiturates), or just plain quit (see Courtwright et al. 1989, 89, 107–8, 131, 168, 193–94, 268; "What's Cooking?" 1945, 99–100; U.S. Treasury Dept., Bureau of Narcotics 1945, 17; "History of Heroin" 1953; Maisel 1945). Some evidently stayed clean for the duration. Voluntary commitments of drug addicts in New York City,

the nation's erstwhile heroin capital, dipped to almost zero by 1943 (Rosenthal 1951).

Heroin receded from the national consciousness during and immediately after the war. "In 1947 I was as innocent about drugs as I was about sex," William Styron wrote in his quasi-autobiographical *Sophie's Choice* (Styron 1979, 311):

> Our present-day drug culture had not seen, that year, even the glimmerings of dawn, and my notion of addiction (if I had ever really thought of such a thing) was connected with the idea of "dope fiends"—goggle-eyed madmen in straight jackets immured in backwater asylums, slavering molesters of children, zombies stalking the back streets of Chicago, comatose Chinese in their smoky dens, and so on. There was the taint about drugs of the irredeemably depraved, almost as evil as certain images of sexual intercourse—which until I was almost thirteen I visualized as a brutish act committed in secrecy upon dyed blondes by huge drunken unshaven ex-convicts with their shoes on. As for drugs, certainly I knew nothing about the types and subtle gradations of these substances.

But then, in the late 1940s and early 1950s, the narcotic problem became more visible as the flow of smuggled heroin resumed (Jonnes 1996, chs. 8 and 10). The rituals of postwar addicts, the heroin complex, remained much the same. But their background was changing. They were now younger and darker skinned. Just how many teenage addicts there were in the 1950s was much disputed. One of the more comprehensive studies, of newly reported addicts in New York State from 1952 to 1958, showed that about 19 percent were under twenty-one and just 5 percent under eighteen years of age (Schlesinger et al. 1959, 4389). Still, any teenage addiction was alarming, particularly in the apprehensive Cold War climate of the 1950s (see Campbell 2000).

Latino and, especially, black narcotic use was up sharply in the late 1940s and 1950s. From 1935 to 1947 only about 10 percent, on average, of those admitted to the Lexington and Fort Worth hospitals were black. By the mid-1950s the figure had risen to over 40 percent. "I saw a shift in the population," recalled one veteran of Lexington, who was readmitted in 1956. "They came mostly from Chicago and New York, the big cities. They used to say, 'Well, here comes a bunch on the chain from D.C.'—there were a lot of blacks from D.C. If you were arrested and brought there you were hooked up and chained, handcuffed to one another" (Courtwright et al. 1989, 15, quotation at 307).

Explanations for this dramatic development are various and politically sensitive. Some still cling to the "Godfather" conspiracy theory: the Mob decided to dump drugs in black neighborhoods. More plausible is Jill Jonnes's hepster role model theory. When word got out that the coolest of the cool—black

jazzmen like Charlie Parker—used heroin, scores of imitators, "conscientious objectors to the American Dream that never included them," quickly followed (Jonnes 1996, ch. 7, quotation at 121). This began a chain reaction. Older users initiated younger ones, who looked up to them. Dealers became admired figures. Bumpy Johnson, who dealt kilos and drove a Cadillac, was an "idol" to the author Claude Brown's generation, as were "other less well-known, neighborhood racketeers" (Brean 1951, 119; see also Brown 1984, 54). Brown, of course, grew up in Harlem. Underlying all of this was the shift of black population from the rural South, where heroin was practically nonexistent, to the crowded urban slums, where the traffic was well established. Exposure matters.

The postwar revival of the heroin traffic, the involvement of organized crime (and, according to Anslinger, Communist China), the perceived spread of addiction among teenagers, and the very real spread of addiction in the barrios and ghettos contributed to a further hardening of narcotic policy. The outstanding feature of the 1951 Boggs Act, the 1956 Narcotic Control Act, and analogous state legislation ("Little Boggs Laws") was increasingly stiff mandatory minimum sentences. The 1956 statute even permitted juries to recommend the death penalty for those convicted of sales to minors, an indication of the symbolic importance of the endangered-youth issue.[17]

HEROIN AS THE CENTERPIECE OF AMERICA'S DRUG WARS

The events that followed 1956 properly belong to other contributors to this volume. I would, however, like to make one general observation about heroin's first century. Like any psychoactive drug that escapes the realm of healing for that of self-indulgence, heroin provoked a legislative response. What set heroin apart was the strength and persistence of that response.

By my count, there were five, or perhaps four and a half, federal drug wars in the twentieth century. Heroin figured prominently in three of them. The first, longest, and most significant lasted from 1909 to about 1924. Driven by concerns about heroin and other narcotics, it resulted in the de facto criminalization of nonmedical addiction. The postwar expansion of the inner-city heroin complex triggered another major campaign in the 1950s, engineered by the Bureau of Narcotics and its congressional allies. Yet another heroin epidemic in the late 1960s gave rise to Nixon's drug war, a more enlightened and flexible undertaking than either its predecessors or its successor. Heroin was missing in action only in the marijuana skirmish of the mid-1930s and the Reagan-era drug war. The latter grew out of the increased use of marijuana and cocaine, especially in the form of crack. Though crack eclipsed heroin as drug

enemy number one in the late 1980s, heroin made a slow but steady comeback during the 1990s, when increasing supplies and unprecedented levels of street purity provoked new concern. Once again, cocaine users, burned out and jittery, began turning to heroin, just as they had earlier in the century. While it seems unlikely that heroin will again completely supplant cocaine, as it did during the 1920s and 1930s, or will recover the black-market prominence that it enjoyed during the 1950s and 1960s, its suppression remains a critical object of American drug policy.

NOTES

1. From *One Hundred Years of Heroin*/David F. Musto; Chapter 1, pp 3–22, "The Roads to H: The Emergence of the American Heroin Complex, 1898–1956," by David T. Courtwright. Copyright © 2002 by David F. Musto. Reproduced with permission of Greenwood Publishing Group, Inc. Westport, CT.
2. "Questionaire [*sic*] re Drug Habit," Box 6, and Kolb to John Remig, November 14, 1927, Box 4 (Kolb Papers n.d.). This was an almost universal judgment by the 1920s. William White (pers. comm.), an authority on treatment history, adds that early-twentieth-century proprietary drug cures of the mail-order variety almost never mentioned heroin in their advertising.
3. The authoritative *Merck's 1907 Index* refers only to heroin's use as a "cough-sedative" and antispasmodic, recommended in cases of phthisis (tuberculosis), bronchitis, asthma, and so forth. For further discussion of the controversy surrounding heroin's use as an analgesic, see Courtwright (1982, 93). For more on early warnings, see Musto (1974).
4. See the "Heroin" and "Antikamnia" brochures in the Antikamnia Chemical Company Collection (n.d.). Similar items can be found in the Charles L. Mitchell Company Collection (n.d.) and the Lehn and Fink Collection (n.d.). I am grateful to Charles Greifenstein for calling this material to my attention. See also Fiedler (1979) and Haussmann (1891).
5. Another interesting case involves Bromo-Seltzer, an over-the-counter preparation consisting of acetanilide, bromide, caffeine, and citric salts. In the 1930s several deaths were attributed to the product, much to the discomfiture of its manufacturers and advertisers. It turned out, however, that the victims were using Bromo-Seltzer as an analgesic to cope with headaches and other painful symptoms arising from chronic diseases that were the real causes of their demise. Fifty years earlier, they probably would have been using opiates (see J. Walter Thompson Company Archives 1937).
6. Leroy Street tells a version of the story in which the first users were Chinese "hop-heads" arrested sometime during or after 1909 for attempting to secure smoking opium in defiance of the national import ban. "A lot of them had a bad cough; when they were in jail they gave them heroin, which is a *marvelous* cure for a cough.

But aside from that, it's a hell of an addictive drug" (Courtwright, Joseph, and Des Jarlais 1989, 289).

7. The date of the first heroin addiction case admitted to Bellevue also was 1910 (Bloedorn 1917). In 1911 Harlow Brooks and H. R. Mixwell noted that "the habit is by no means infrequent especially on the extreme east and west sides of [New York City]" (Brooks and Mixwell 1911, 386). In short, all available historical evidence suggests that nonmedical heroin use took hold in New York City during or just before 1910 and expanded rapidly thereafter. The number of Bellevue heroin cases went from 1 in 1910 to 649 in 1916 (Bloedorn 1917).
8. For national cigarette production figures, see Brecher et al. (1972, 230). For New York consumption, see Kluger (1996, 62). A study conducted by Sylvester Leahy showed a preponderance of children of immigrants (n = 58) over children of native-born parents (n = 53) among heroin addicts (Leahy 1915).
9. Wiley (1917, 150). I am grateful to H. Wayne Morgan for calling this source to my attention.
10. The idea that tobacco leads to drunkenness and other vices has a long history (see, e.g., Short 1750, 250; Rush 1798, 270; Grimshaw 1853, 27–28).
11. Lawrence Kolb, the man fated to deal with America's narcotic obsessives, thought that these views could not be crazier. He diplomatically said so in his testimony at the same hearings (U.S. Senate, Committee on Printing 1924, 26–27). Nevertheless, the direct heroin-crime link pushed by Hobson and others affected public perception.
12. For a critical account of Porter's subsequent diplomatic maneuverings, see McAllister (2000, chap. 3).
13. Meyer and Parssinen (1998, chaps. 1, 9) offer a comprehensive overview of international developments and how they impacted on the U.S. black market. For more on the 1931 convention as a watershed in international control efforts, see McAllister (2000, chap. 3). Global figures on the declining licit manufacture are found in "History of Heroin" (1953).
14. William S. Burroughs, the "master addict" of his generation, was of the opinion that heroin was eight times as powerful as morphine (from letter to Allen Ginsberg in Burroughs 1993, 215).
15. In the 1920s decks reportedly sold for $1.00, $1.50, $2.00, $3.00, and $5.00 (New York State Commission on Prisons 1924).
16. Well before Pearl Harbor (December 1941), Anslinger had been stockpiling heroin as a strategic material, which drove up the price. The war itself brought tighter border controls, shipping disruptions, and travel restrictions. Seats on the remaining commercial airplanes, for example, were assigned on a priority basis to key government and military personnel. The term *VIP* was born of wartime flight rationing.
17. For more on postwar minority use and the federal laws of the 1950s, see Courtwright Joseph, and Des Jarlais (1989, 14–20) and Musto (1974). The subject is also treated at length in Courtwright (2001).

Chapter **18**

Methadone: The Drug, the Treatment, the Controversy[1]

Herbert D. Kleber, MD

The current methadone controversy is the most recent round in a policy struggle that has been going on since 1964, when the first program began. An appropriate quotation with which to begin a discussion of this rocky history might be the old line "No good deed goes unpunished." Many consider methadone treatment one of the really good deeds, if not great deeds, in the history of the treatment of addiction, yet it clearly is also one of the most assailed.

Methadone was discovered by the Germans during World War II, when they had opiate shortages because of problems with sea routes. After the war it was taken over by Lilly Pharmaceutical and named Dolophine. Some of the anti-methadone groups have claimed the name came from Adolph Hitler and that it is used to weaken the African American community. Actually, Dolophine was named from the Latin *dolor* (pain). Supporters believe that its use can relieve addicts' pain and free them from enslavement to heroin.

After World War II, research on methadone was carried out at the Addiction Research Center in Lexington, Kentucky. The papers from those early days are fascinating. Researchers had little to go on in terms of appropriate dosage. In some studies they put addicts on doses as high as 350 to 400 mg, and then abruptly stopped. The patients would withdraw cold turkey, and the staff would carefully chart what the patients went through. As one of them said, "Man, this stuff never lets you go." Three weeks later, four weeks later, they would still be suffering withdrawal symptoms.

As more became known about the drug, however, unwanted effects were reduced and the benefits became clear. It began to replace morphine or codeine,

the drugs in main use in the late 1940s and early 1950s, as the preferred agent to detoxify individuals from heroin. In 1964 Vincent Dole, an internist, and Marie Nyswander, a psychiatrist, developed the use of methadone as a maintenance drug. Dole had started from the point of view that heroin addiction was really a metabolic disease. Using an insulin model, he had looked for a maintenance drug. Nyswander had written a book based on her experience in treating addicted jazz musicians and the frustrations and difficulties that ensued. She was searching for a medication that would improve outcome. The two, working at Rockefeller University, were trying different maintenance agents; when they got to methadone, they found that their patients behaved very differently. They began to make their beds; they began to talk about wanting to go to work. From that humble beginning, the idea of methadone as a maintenance drug took shape.

There are many key players in this history. Jerry Jaffe, Mary Jean Kreek, Frances Gearing, and Joyce Lowinson have all played major roles in the spread of methadone since the mid-1960s. The controversy about methadone then and now is captured in an anecdote from 1966. At that time I was at the U.S. Public Health Service hospital in Lexington, Kentucky, running one of the addiction treatment units. A program called Daytop Village had just started in New York, and I invited the director to give a talk to the patients at Lexington—although the word "patients" may not be quite accurate: Lexington was a prison. Two-thirds of the thousand residents were serving sentences of from one to ten years. The remaining one-third were voluntary admittees, who signed in because at that time it was the only place to get treatment for narcotic addiction in the United States east of the Mississippi, as its counterpart prison hospital in Fort Worth, Texas, was for west of the Mississippi. The Daytop director talked about therapeutic communities, and, during a question-and-answer period, one of the patients asked about methadone, which they had just heard about. The response was a classic remark: "I think methadone maintenance is a great idea: we should give money to bank robbers, women to rapists, and methadone to addicts."

That was 1966. Five years later the speaker went on to head a methadone program. So life treats us in funny ways. But it is one of my favorite anecdotes because it captures the feeling that a lot of people still have about methadone maintenance—that it constitutes immoral pandering to criminals rather than a scientific treatment of a disease.

In 1968 methadone began to spread out of New York. Jerry Jaffe began his program in Chicago, Bill Weiland started in Philadelphia, and I began in New Haven. All of these programs were supported by NIMH grants. In New Haven we set up a model multimodality treatment program with central intake.

Methadone was just one of the modalities we were using. We also had a therapeutic community, an adolescent program, and narcotic antagonists. In those days, cyclazocine was the antagonist of choice. Also during that era, we learned you didn't need to admit everyone as an inpatient to start, as they did at Rockefeller. Bill Weiland began outpatient induction. We started patients on a day program, which became a fixture in New Haven for many years, to deal with the fact that many of our addicts basically needed resocialization. Anyone who was not working was required to come from 9:00 A.M. to 4:30 P.M. five days a week. During that time they had intensive group therapy, individual therapy, and help with vocational and educational issues. I credit the success of our methadone program in large part to those initial six weeks, which helped to break the code of the streets and to get people involved in wanting to lead not simply a life on methadone, but a whole different life.

As methadone was spreading, so was the controversy. There was continued opposition from therapeutic communities. I was at a number of meetings in those days where, if it was predominantly a TC audience and someone got up to speak about methadone, he would get booed; if it was primarily a methadone audience and someone got up to speak about TCs, *he* would get booed.

There was also a lot of opposition from the black community, some of whom described methadone maintenance as genocidal—an attempt by the white establishment to control young black males by keeping them permanently addicted. I remember vividly one episode during the Black Panther trial in New Haven. Some of the members of that group came to me and said, "If you don't close your methadone program, we're going to burn it down." Their rationale was not that it was not successful, but that it was *too* successful: it helped addicts quit heroin but did not deal with the conditions in the ghetto that they believed *produced* addiction—such as racism, unemployment, and poverty. They viewed it as putting a sort of Band-Aid on the ghetto, an attempt to avoid the total revolution they believed would soon happen.

I believe the thinking was somewhat similar to what the Communists did in the 1930s, trying to kill off the labor unions. The feeling was that labor unions would give the workers half a loaf, and if you did that, they would not rise up and overthrow the whole economic system. These feelings about methadone from some members of minority communities have never totally gone away, although at times they are more prominent than at others. In any event, our clinics neither closed down nor burned down, but instead grew and prospered, because of the help patients were getting.

In retrospect, the 1970s was the golden era of methadone. Bob DuPont in Washington, D.C., showed that you could rapidly develop a large system and bring a great number of the addicts in the city into quality treatment. The fed-

eral government encouraged the spread of methadone maintenance via Bud Krogh, Jerry Jaffe, and SAODAP. By 1973 there were approximately four hundred methadone programs throughout the United States. The National Institute on Drug Abuse (NIDA) was founded, and it was used initially not simply to do research, but also to spread methadone programs.

During that same era, there were a number of studies on methadone safety. There were a lot of myths on the street then about methadone: it got into your bones, it ate away your teeth, it destroyed your vision. In systematically looking at those systems where the street rumors had it that methadone was dangerous—including the kidneys, the eyes, the musculoskeletal system, and the heart—our group at Yale in five-year studies, and Mary Jean Kreek in New York in eight-year studies, found no evidence of any damage due to protracted methadone use. We concluded that addicts could be on methadone for at least five to eight years without adverse physical effects.

Another question began to emerge: Should people be on methadone for life, or, if you rehabilitate them, can they be detoxed and remain abstinent? Dole and Nyswander advocated very strongly, if not the universal lifetime model, then at least keeping patients on methadone for many years—some, perhaps, for their whole life. They believed that being on heroin for many years changed the addict's brain and changed his metabolism, probably permanently.

Our program in New Haven took a different direction. We believed that if you could rehabilitate addicts, you would be able to get them off methadone, especially if you could solve the withdrawal problem. We spent a lot of energy looking at a variety of ways of doing detoxification. From that interest, we demonstrated that clonidine, on the market for hypertension, could markedly decrease withdrawal symptoms, and that combining clonidine and naltrexone could yield a rapid opioid detox with even better results. These methods increased the likelihood that people who had been successfully rehabilitated could get off methadone. While these techniques improved on existing approaches, we still do not have good enough methods by which to end reliance on methadone, and I believe that is one of the major problems. We're not going to know how long people need to be on methadone until we have a much better way of detoxifying them. Buprenorphine is one of the drugs that may help in the future to resolve the controversy as to what percentage of recovering addicts need to remain on methadone versus what percentage can successfully detox from it.

I have a favorite anecdote about the detox controversy. Dole and Nyswander came up to visit our program and give a seminar. One of our counselors, a former methadone patient who had been clean for about six months, asked a lot of pointed questions about the theory that methadone had to be taken for life.

When the seminar was over and we went out for dinner, Marie and Vince said, "Tell us about that guy who was asking all the questions. Has he been on methadone and is now withdrawing?" I replied, "Yes, he's been clean for six months." They then said, "Ah, we thought so. It's that irritability due to the protracted methadone withdrawal that really got him to ask all those questions." Perhaps that was the case, perhaps not, but it reveals the strong feelings of even such wonderful researchers as these two. Parenthetically, the counselor was able to stay off heroin, and methadone, for decades.

While there were other problems in the 1970s, including concerns about methadone overdose among children and nonaddicts who might become exposed to the drug and about methadone diversion, in many ways it was the golden era, a time when, for the most part, methadone was respected and seen as an important part of the treatment system for addicts.

In the 1980s there was a backlash. Early in that decade, the federal block grant replaced direct NIDA grants as a way of funding drug programs. Each state received a certain amount of money that could be used for methadone or for other kinds of treatment, and you began to see a discontinuation of methadone in a number of places. The best study of this natural experiment was the one in Bakersfield County, headed by Bill McLaughlin. What they found when they looked at the patients who were detoxed of necessity, because the clinics were closed, was that, while some stayed clean and some found treatment in other counties, many did not fall into either of those categories. Among this latter group, there were an increased number of deaths and of return to heroin addiction, and an increased amount of criminal activity. Unfortunately, this study did not carry much weight. One of the things I learned in my days in government is that, much as we are reluctant to admit it, science does not drive policy. It may push it a bit—policy makers say they would like to know the science—but, at the end of the day, that is not how they make their decisions.

During the Reagan years, some of the White House drug policy advisers were quite antimethadone. I think of Carlton Turner, for example. That viewpoint peaked in 1988 with the White House Conference for a Drug Free America, which was vehemently antimethadone. They demonized it, as well as NIDA, which they viewed as being "soft on drugs," and they called for a congressional investigation of that agency. This time was probably the lowest point methadone reached, in terms of national policy.

Also during the 1980s, however, evidence was accumulating about the relationship of methadone programs and HIV status. Studies showed that individuals on methadone had a much lower incidence of conversion to HIV-positive status. In England the harm reduction movement was taking hold, driven by the concern over AIDS. The English made a conscious decision in the mid-to-late

1980s that preventing AIDS was more important than dealing optimally with drug abuse, and that, therefore, the main focus of their drug program should be reducing the spread of the HIV virus rather than rehabilitating addicts. The philosophy that flowed from this decision was that no matter how badly a patient is doing on methadone—no matter how much cocaine he is doing, how much alcohol he is drinking, whether he is involved in criminal behavior, and so forth—you keep him on methadone, because if you throw him off, instead of using drugs once a day or once every other day, he will go back to using three or four times a day, and increase the likelihood of HIV conversion.

This attitude took hold in the United States as well, although some of us continued to take the position that the best way to prevent HIV was to offer good-quality treatment with high rather than low expectations. Also during the 1980s, we had the rise of private, for-profit methadone programs. One of the things I am proud of is that during my years in Connecticut I fought to keep for-profit methadone out of the state. Unfortunately, after I left Connecticut in 1989, that Horatio-at-the-bridge position was lost. In other states it was lost a lot earlier. In California, for example, by 1990, 90 percent of their two hundred methadone clinics were privately owned. The major source of funds was patient fees. Between 1980 and 1990, there was an 80 percent increase nationally in reliance on patient fees as the primary source of funding for methadone programs. Along with the rise of the for-profit programs came a curtailment in services.

In the mid-1970s the "slot cost" for a methadone slot was roughly $1,700 a year. In 1990 the Institute of Medicine Committee on Treatment Effectiveness, on which David Courtwright and I, among others, served, showed that from 1976 to about 1986, funding for methadone had increased by only about 9 percent, from $1,700 a slot to $1,850 a slot, while costs went up by at least 35 to 40 percent during those years of high inflation. This disparity eroded the ability of clinics to provide services, and the spread of for-profit programs had a similar effect: if you provided fewer services, you could make more money.

Clinics developed where you would go in, and a drawer like the one on an ATM would come out. You'd put in your credit card, your cash, or your Medicaid card, the drawer would be pulled back, and then it would be pushed forward again, and you'd get your card back, with your dose of methadone. On the wall there typically would be a sign that said, "If you want counseling, please ask one of the staff." Unfortunately, from being the exception in the 1970s, that kind of program has proliferated, and it has had, I believe, a negative impact on public perception. If the methadone patients are basically being maintained but not treated, if the public sees that these patients continue to use cocaine and continue to engage in criminal behavior, they are going to ask, Why should we be paying for this? Why should we permit it?

In the 1990s, when I was Deputy Director for Demand Reduction under Bill Bennett at the Office of National Drug Control Policy, we tried to reverse this movement and to increase respect again for methadone treatment. We put out a White Paper that said very clearly that methadone maintenance was both a legitimate and an important part of the spectrum of drug abuse treatment. We doubled the federal funding for treatment, so that services would be expanded and improved. Unfortunately, the resulting increase in funding accomplished less than we had hoped, because, as we found out later, while we were putting money in the front door via the block grant, the states were pulling out their contributions to program funding through the back door. I tried to get Congress to pass a law that would have made that more difficult, but they were not interested. They said that the Department of Health and Human Services (HHS) already had the power to do that if they wanted to. Unfortunately, HHS was not interested in such a law, nor even in using the power they already had to prevent this supplanting of funds.

The issue of "interim methadone," or "low-threshold methadone," was raised during this period in relation both to the AIDS issue and to the fact that it was very hard to expand methadone treatment. During much of the 1990s, we had about 120,000 methadone slots for somewhere between 750,000 and 850,000 heroin addicts. That's less than one slot for every six potential patients, so there was a push by many people concerned with drug treatment to adopt the so-called Hong Kong model with ten thousand people on methadone and eleven social workers doing therapy. Similarly, in the Netherlands, the dose of methadone was kept low so that patients could continue to use heroin if they wished, and addicts could drop in and out of the program.

I don't like these models. The definitive study, I believe, was Tom McLellan's beautifully designed study, published in *JAMA* in 1984, which randomly assigned addicts to one of three groups: methadone only, methadone as usual (methadone with one counseling session a week), or enhanced methadone (not just drug counselors but also psychologists, psychiatrists, and medical help). At the end of three months, they found that the first group was doing so badly that, for ethical reasons, they felt they had to take two-thirds of them out of the methadone-only protocol and move them into one of the other two types of programs. The enhanced methadone group had markedly lower levels of heroin and cocaine use, needle sharing, and unemployment. Within a few months, the new patients in the groups with counseling were doing just as well as the people who had been there from the beginning. So it clearly was not the patients who accounted for the different results; it was the program. If you have low expectations and minimal services for your patients, they respond appropriately. If you have higher expectations and better services, they respond to that, too.

At the same time these studies were going on, the Dutch were beginning to find out that their methadone policy was flawed. The Amsterdam Health Department published a paper showing that its low-threshold, low-dose methadone approach did not reduce HIV risk. That led to some rethinking of their position. They retained the low-threshold requirement but adopted higher dose levels.

Increasingly, however, states curtailed the length of time patients were allowed to be on methadone maintenance. Oklahoma limited addicts to one year on methadone over a lifetime. Office-based dispensing also aroused disagreements. The central question was, Should people continue indefinitely to have to come to a methadone clinic to obtain the drug, or should they be able to get methadone in a doctor's office? Some people argue for allowing physicians to dispense the drug at the beginning of treatment; others want it only after stabilization and improvement, as one way of increasing the number of methadone slots. I have trouble with the former. I don't have trouble with the latter.

At the same time as these controversies were taking place, the scientific community was confirming the efficacy of methadone treatment. An NIH consensus statement in 1997 asserted the value of methadone. In 1998 General McCaffrey pronounced probably the strongest support I have heard from any director of the Office of National Drug Control Policy: "Methadone is very important to our strategy."

Support of the harm reduction philosophy in the 1990s, however, contributed to decreasing services in methadone programs. At the second national methadone consumers meeting in October 1998, for instance, the argument was the following: "Since methadone doesn't treat cocaine, and that's not why we're in methadone treatment, use of cocaine should never be considered an indication for termination from methadone. Patients should get lower or higher doses as they choose, and they should have the right to have low doses so they can continue to use heroin without the harder override caused by a high dose of methadone."

As is probably evident, I do not agree with much of that harm reduction position. One of the things I've learned in running a methadone program is that drug use is contagious. If you have a program with vigorous support and high expectations, your patients live up to that: you create a program with a relatively low use of other drugs compared to the average clinic. Since many methadone patients want to use other drugs—they are, after all, individuals who enjoy the effects of drugs, whether they be heroin, cocaine, alcohol, or marijuana—once a program permits some patients to use without consequences, the amount of illicit drug use that goes on in the program markedly increases. My experience has been that the more relaxed programs are, and the more tolerant of drug use,

the more they have both drug use and other illicit activities. No one should be surprised by this outcome.

In the summer of 1998, New York City launched its welfare-to-work program. Only about 20 percent of methadone patients were legally employed, and Mayor Giuliani concluded that methadone programs needed to do a better job of getting their patients to work. Unexpectedly, he announced a plan to eliminate methadone maintenance in the city. Of the approximately thirty-six thousand methadone slots in New York City at the time, only about two thousand were controlled by the city. The rest were controlled by New York State, which indicated no interest in cutting methadone. Nonetheless, the plan was highly controversial and generated heated debate.

In the rush to defend methadone and methadone patients that ensued, advocates lost sight of some unpleasant realities. According to the city Health and Hospitals Corporation, for instance, the employment rate in methadone programs in the city ranged, at that time, from a low of 15 percent in the Bronx to a high of 25 to 30 percent in Staten Island and Queens. The reasons are not mysterious. Addicts in many of these programs are on Medicaid, which pays the program over $100 per week. If the patient goes to work and earns perhaps $15,000–$20,000 a year, he may be able to pay the program only $10–$20 per week. If the program accepts that, they are losing up to a hundred dollars. So it is neither in their interest to encourage the patient to go to work, nor in the patient's interest to do so.

I hear from colleagues that the employment rate is a lot higher than 15 to 30 percent, but often it is off the books. Neither the programs nor the patients have an interest in making employment public knowledge when it might result in patients losing welfare and Medicaid—and, perhaps, access to methadone. While this may not be as much an issue in programs less dependent on reimbursement, it certainly is in other methadone programs. A reasonable solution might be to permit people to continue in treatment for a period after they leave welfare—through interim funding, for example.

How was the mayor's statement received? There was no outcry from the majority of people in New York, including the leaders of the black community, many of whom had complained about the mayor in other circumstances. The black community was ambivalent about methadone at best; many of its leaders were hostile toward methadone treatment. Thus they were not unhappy when the mayor attacked methadone clinics. The policy also played very well in conservative upstate New York and other places in the country. While various prestigious scientific organizations, such as the American Psychiatric Association, defended methadone, they were joined by neither key political leaders nor a substantial number of voters.

This should worry treatment specialists more than what a single city official does. Giuliani's order to eliminate methadone and substitute abstinence programs was rescinded after six months. In fact, the mayor decided to add $5 million in new funding to the city-run methadone programs, to improve staffing levels and overall quality of service. I was asked to work with the New York City programs to help achieve this, and spent a year doing so. The programs are now called Narcotic Addiction Treatment Programs. Eventually, they will offer both maintenance and abstinence programs. Some patients will be on methadone maintenance, others on buprenorphine or naltrexone. I see this as a future direction for existing methadone programs in general.

Over the long run, programs that lack political support have trouble competing for resources. Methadone supporters should acknowledge reasonable concerns, such as getting patients to work and preventing Medicaid abuses. High levels of cocaine abuse should be a signal for needed change, not defended as inevitable. On the wall of the therapeutic community that is part of the New Haven program I directed, there is a plaque that says, "You are neither the giant of your dreams nor the pygmy of your fears." Methadone is not the panacea for our heroin problem; it is not the perfect treatment for heroin addiction, but neither is it the demon that some people would like to make it. The truth lies somewhere in the middle.

NOTE

1. This overview of medical practitioners' experience with methadone is adapted from an after-dinner talk, thus the informal tone and absence of scientific citations. Chapter **19**

Prevalence of Use and Manufacture of Methamphetamine in the United States—Is the Sky Falling or Is It Not Really a Problem?[1]

Herbert C. Covey, PhD

Methamphetamine has been available for years; why all of the recent alarm? The answer is easy—many of the indicators of illegal substance use indicate that meth use is spreading throughout much of the United States, and authorities report that meth use has increased to "epidemic" proportions (Rawson, Anglin, & Ling, 2002). This spread has been likened to an epidemic moving from the West and Southwest to the rest of the country.

Is this spread unique to the United States? No. The World Health Organization recently reported that amphetamine and methamphetamine are the second most abused drugs in the world. The World Health Organization estimates that over 35 million people use or abuse amphetamine or meth (Rawson et al., 2002). This compares with 15 million for cocaine and 10 million for heroin. Meth abuse has taken over in some countries as the illegal drug of choice. For example, in Thailand methamphetamine abuse now accounts for almost 70 percent of addictions, and other Asian countries report a similar pattern of increasing abuse (Zickler, 2005c).

THE SPECIAL CHALLENGES OF METH

Does meth pose special challenges for agencies and staff trying to curb its use or address its affects on children and families? Some authorities suggest that meth use and addiction are similar to other stimulants, such as cocaine, and should be addressed using the same approaches. Others conclude that meth use and addiction are unique and require special strategies. Its use does, in fact, pose special challenges.

The drug is relatively abundant compared to illegal substances that have to be imported across national boundaries. It is often locally produced in home laboratories using materials such as household batteries and cold medicines (Bonné, 2001a). Although authorities have made efforts to control the precursor chemicals used to produce meth, it is impossible to eliminate them altogether (Rawson et al., 2002) because they are found in multiple household products.

Meth manufacture has been targeted in rural areas, which are attractive for dealers and manufacturers because the odors and by-products of meth production are more easily concealed from authorities and thus they are less likely to be discovered. Some of the methods of production involve chemicals and substances that are associated with farming and ranching, and their possession is not viewed as extraordinary. For example, anhydrous ammonia and iodine, both chemical precursors for meth manufacture, are commonly used on farms and ranches.

Meth can be produced on a small scale for personal use. Authorities have found labs in car trunks, mobile homes, microwave ovens, and small rooms. For example, one child welfare caseworker found a lab setup in a suitcase she planned to use to pack a child's clothing during the child's removal from a home.

More than a decade ago illicit meth production was restricted to a few "cooks" who kept their recipes relatively secret. Today, instructions for making meth are readily available in publications and over the Internet. Any Internet search engine will generate numerous recipes for producing meth. Internet chat rooms are full of self-proclaimed chemists (cooks) who are willing to provide free advice to aspiring cooks. For example, www.totse.com has a Web site that provides amateur recipes for cooking meth and making other illegal substances. If the Internet is not used, there are books that provide easily accessible recipes on how to produce the drug. The most widely known is Uncle Fester's (2002) *Secrets of Methamphetamine Manufacture: Including Recipes for MDA, Ecstasy, and Other Psychedelic Amphetamines*(6th ed.). Other similar books are available.

Another challenge of meth is that it is intense and powerfully addictive. It affords a strong sense of euphoria from its first use onward and does so for a relatively low cost when compared to other stimulants such as crack cocaine. Because of its effect on the brain and nervous system, heavily involved addicts have difficulty experiencing pleasure that is comparable to being high on the drug.

Users perceive other attractive benefits beyond being high on meth. Initial users and addicts view the drug as effective in reducing fatigue and allowing them to work for prolonged periods of time. For example, over-the-road truck

drivers use meth and amphetamines to stay awake on long road trips. Some students view it as a study aid that allows them to study and stay focused for hours. Other individuals, especially females, view it as an effective way to lose weight.

Treatment approaches must be modified to the special needs of the meth addict. For example, treatment information must be easy to understand (simple) and repeated. This is due partially to the effect meth has on brain functioning. The reasoning portion of the brain is affected by prolonged use. Meth addicts struggle with sequential thinking and instructions. In addition, the depression associated with long-term withdrawal must be addressed.

The distribution of meth is different from other illegal substances. It is not generally a street drug but is sold or provided by family, friends, and associates. This makes law enforcement activities challenging as the drug is less on the street than marijuana, heroin, cocaine, and other street drugs.

TRENDS IN THE UNITED STATES

Many substance abuse authorities believe that meth use and distribution has been a significant problem that is expanding in the United States (Freese, Obert, Dickow, Cohen, & Lord, 2000; Gibson, Leamon, & Flynn, 2002; Herrell, Taylor, Gallagher, & Dawud-Noursi, 2000; Hser, Evans, & Huang, 2005; Huber et al., 1997). Some basic data indicate this growth:

- Meth is showing up in the workplace. Between 1999 and 2003, the percentage of positive workplace drug tests containing amphetamines doubled, from 4.5 percent to 9.3 percent (Center for Substance Abuse Research, 2004).
- There are indications that it is spreading among white, low-income, rural Americans (Bonné, 2001a; Kraman, 2004).
- The National Drug Intelligence Center (2002) reported that crystal meth's availability is expanding in several states. The center reported that 31 percent of all state and local law enforcement agencies considered meth their primary drug threat, and 58 percent considered the availability of the drug in their communities to range from medium to high (National Drug Intelligence Center, 2003).
- The Office of National Drug Control Policy (2003a) reported that federal meth lab seizures increased from 327 in 1995 to 13,092 in 2001. This represents an increase of over 4,000 percent, or a 40-fold increase in the number of labs seized. This number does not reflect all of the undiscovered labs or small and undetected operations.
- The methamphetamine problem is becoming so large nationally that at the 2005 National Association of Counties (NACo) annual meeting, members viewed meth as an "epidemic" and voted to request the president to provide more funding for meth research, treatment, enforcement, education, and

cleanup (Leinwand, 2005; National Association of Counties, 2005). In the same vein, NACo released two surveys on the impact of meth on hospital emergency rooms and the challenges of treating its abuse (National Association of Counties, 2006a, 2006b).

- *National Drug Threat Assessment 2003* data reveal that, nationally, 36.2 percent of state and local law enforcement agencies identified meth as their greatest drug threat, ranking second only to cocaine (37%). State and local law enforcement agencies in the Pacific (90.9%), West Central (80.2%), and Southwest (51.6%) regions were more likely to identify meth as their greatest drug threat than were agencies in the Great Lakes (29.4%), Southeast (28%), and Northeast/Mid-Atlantic regions (2.7%; National Drug Intelligence Center, 2004, p. 1).

MEDIA ATTENTION

In addition to some general indicators, the topic of meth has recently been the subject of television, the press, music, and film. The mass media and pop culture have embraced the topic of meth use and manufacture, which had always been present but were less visible to the general public. As a result of all this attention, increased public awareness of meth, and increased media attention, it seems that the drug is reaching epidemic proportions in many regions of the country.

The Drug Enforcement Administration (DEA; Web site at http://www.usdoj.gov/dea/pubs/pressrel/meth) and the Partnership for a Drug-Free America (http://www.drugfreeamerica.org) contain examples of recent press releases regarding meth, as do other Web sites. There are a number of other examples of recent media titles and press clips regarding meth use:

- "Meth's Deadly Buzz—Sioux City, Iowa" In many ways, this article observes that meth is the crack cocaine of the new millennium. Much like crack, which swept across the nation in the 1980s and 1990s, meth use has hit epidemic proportions in the past several years. Crack plagued inner cities and the black community; methamphetamine is thriving in cities like San Francisco and is sweeping across the Midwest and headed east. It has quietly become America's first major homegrown drug epidemic (Bonné 2001, 2001a).
- "Methamphetamine's Young Victims: Homes Doubling as Drug Labs Pose Serious Dangers to Kids," *Denver Post*, October 20, 2002 (Herdy, 2002).
- "The Meth Epidemic: Inside America's Drug Crisis" ("Meth Epidemic," 2005).
- "Potent Mexican Meth Floods in as States Curb Domestic Variety," *New York Times*, January 23, 2006 (Zernike, 2006).

- "Methamphetamine Use Increasing: Public Health Officials Voice Concerns about Infants Born to Addicted Mothers," *American Medical News,* July 26, 2004 (Elliot, 2004).
- "Children of Ice." A series of articles about methamphetamine addiction in Hawaii noted, "The ice epidemic has touched tens of thousands of lives in Hawaii. It has an impact on our families, our children, our schools, our crime rate, our prisons, our businesses. Our community has never faced a problem quite like this, and we are still searching for the right responses," *Honolulu Advertiser,* September 14, 2003 ("Indicators," 2003).
- "Counties Say Meth Is Top Drug Threat." This article noted that meth is a bigger problem than cocaine, marijuana, or heroin for most communities, according to a survey of law enforcement agencies in 500 counties in 45 states by the National Association of Counties (*USA Today*, July 4, 2005).

Documentaries and films have been produced on meth use and production. For example, a journalistic documentary titled *Crank—Made in America* (2003) shows meth use and the interpersonal relationships among users. The PBS documentary *Frontline* (2006) produced a special titled "The Meth Epidemic."

The music industry has also paid attention to meth. The industry has produced songs about the risks and experiences of meth use. The following songs all refer to meth's use: Eminem, "These Drugs"; Third-Eye Blind, "Semi-Charmed Kind of Life"; Bush, "The People That We Love: Speed Kills"; Eminem, "Purple Pills"; and Green Day, "Brain Stew." The song "Brain Stew" provides typical lyrics that describe meth use.

With all of the attention meth has received in the media in recent years, in an open letter, Dr. David Lewis and Dr. Donald Millar (July 27, 2005) warned that caution should be exercised in drawing unproven conclusions about what meth use means to the unborn and newborns. They and others criticize recent media references to "meth babies" or "ice babies" as being unfounded and damaging. Such labels are detrimental because as they grow up, such children face lower expectations and harmful stereotypes about their abilities. They cite recent media coverage, such as *CBS News,* "Generation of Meth Babies" (April 28, 2005) at CBSNews.com as an example of the misuse of the label "meth baby" in the mass media. They also contend that there is no such thing as a "meth-addicted baby," because babies do not act compulsively in spite of adverse consequences as addicts do.

Lewis and Millar (2005) and other substance abuse experts are concerned that stating that meth use by pregnant women results in severe health consequences for infants has not been established by medical research and may

actually do more harm than good. As was the case for crack babies in the 1980s and 1990s, they argue that there has not been enough scientific research to warrant any medical or addictive conclusions about meth use and infants. With at least two decades of research on the effects of the use of the stimulant cocaine on fetuses and newborns, they observe that the feared epidemic of crack babies never materialized, and the same may be true for meth. Although they do not specifically refer to there being a panic, they do stress that the media has consistently overexaggerated meth at a social cost to infants and new mothers.

WHO USES METH? IS THERE A PROFILE OF METH USERS?

What populations are more likely to use meth? Summarizing the literature, Wermuth (2000, p. 423) wrote, "Low-income and unemployed young white men continue to be the group most likely to use methamphetamine, but by the mid-1990s the drug had increased in popularity in more diverse populations and regions." Numerous studies have found that meth use is predominantly a white phenomenon (Anglin, Burke, Perrochet, Stamper, & Dawud-Noursi, 2000; Yacoubian & Peters, 2004). According to the Substance Abuse and Mental Health Services Administration's (SAMHSA; 2005b) *DASIS Report*, January 7, 2005, treatment admissions for methamphetamine or amphetamine abuse in 1992 were 55 percent male, and that percentage remained stable through 2002. The mean age for treatment admissions increased to 29 years in 2002. In 1992, 62 percent of treatment admissions were white. Whites increased to 66 percent of the admissions in 2002. Of those being admitted for treatment, 25 percent indicated that they had part-time or full-time jobs. A SAMHSA (2005a) report estimated a prevalence of about 0.7 percent for whites.

However, meth users come from a wide variety of socioeconomic profiles. For example, one Sacramento, California, study found that users came from all walks of life, and some users started in their teens (Gibson et al., 2002). The penetration of meth into other demographic circles is occurring. Anglin, Kalechstein, Maglione, Annon, and Fiorentine (1997) reported that other groups such as Latinos, gay-bisexual males, older adult arrestees, and adolescents are increasingly involved. Joe (1996) found and reported on meth abuse among Asian-Pacific women in Honolulu, San Francisco, and San Diego. There are numerous anecdotal reports on the broad spectrum of users, such as those describing high-achieving students who use the drug to perform better in school and college, and others, such as athletes, cheerleaders, beauty pageant participants, and models, who use it to improve performance (Rawson et al., 2002).

While many are at risk of meth addiction, some populations identified in the literature are of special concern:

- Women who have emotional relationships with males who are addicted to meth. The males encourage and often demand that the females in their lives also use meth to "bond" with them. If the male is using, it is likely that the female is also using. Anecdotally, a common pattern is for an older male to introduce the drug and encourage its use of meth by a younger female. Another group to use it is stay-at-home adults, usually females, who begin using meth for its short-term benefits such as its energy boost, to treat depression, or for its related weight loss (Rawson, 2005).
- Workaholics or low-income adults who use it to stay awake and perform in multiple jobs. Working low-income individuals find meth attractive because they must work several jobs or long hours to support themselves or their families. They find that higher energy and alertness (ability to stay awake for prolonged periods) help them cope with the demands of multiple jobs. Probably the best example of this are over-the-road truckers, some of whom use meth (or amphetamine), allowing them to keep driving long distances.
- Gay men who use meth to enhance their sexual experiences and stimulate sexual behavior. According to Freese et al. (2000), urban gay males living along the West Coast of California represent a large segment of the meth-using population. The user's sense of euphoria from using the drug reduces normal inhibitions about sex and multiple partners. Meth use can increase the libido, but long-term use may result in sexual dysfunction. There are reports of gay men using meth to prolong and enhance sexual encounters with several partners without appropriate protection, thus increasing the potential for transmission of HIV among this population. Some suggest that associating the use of meth among this population is important to addressing the spread of HIV (Rawson et al., 2002; Specter, 2005). Aware of the association between meth use and the spread of HIV, some activists have made posters that proclaim, "Buy Crystal. Get HIV for Free," or "Crystal Free and Sexy" (Join Together, 2005). Because of this tie to sexual activity, the gay community poses unique challenges for meth treatment. The problem has grown to such a level in New York City that the gay community has developed Meth Anonymous support groups (New York State Office of Alcoholism and Substance Abuse Services, 2004). Some authorities are also concerned about the spreading of HIV through the sharing of needles, which is common among injectors (Gibson et al., 2002).
- Rural residents who are interested in manufacturing meth for profit and personal use. Meth is particularly attractive in rural areas where farming and the economy are in decline (Wermuth, 2000). North Carolina profiled the typical user as, "young, white, small-town residents with limited education and a blue-collar career" (North Carolina Division of Social Services and

the Family and Children's Resource Program, 2005). One study comparing rural with urban illegal substance use in Nebraska found that while meth use was present in urban Omaha, in rural areas meth use was more common (Herz, 2000). One report found that rural and small-town youth were more likely than their urban counterparts to become substance abusers (National Center on Addiction and Substance Abuse at Columbia University, 2000). The same report found that rural eighth graders were 104 percent more likely than urban eighth graders to use amphetamines. This same group was 59 percent more likely to use methamphetamine than urban eighth graders.

- Heterosexuals drawn to sexual experimentation and sexual experiences who use the drug to alter their sexual pleasure (Wermuth, 2000). Meth is known to lower sexual inhibitions, making it attractive to those interested in sexual activity and seduction.
- Youths and young adults involved with the rave subculture who mix meth with other substances for entertainment and excitement.
- Native Americans, including those living on reservations. Native American meth use is spreading across the reservations. In a special *Newsweek* report, journalist Andrew Murr (2004) found that it was becoming a "scourge" affecting Native Americans living on reservations. SAMHSA (2005a) estimates the prevalence of meth use among American Indians and Alaska Natives at about 1.7 percent. Freese et al. (2000) summarize the literature by noting that new approaches need to be designed to address the meth problem in Native American communities. They noted that Native American communities in Wyoming and Montana are moving forward in addressing the problem at the community level.

Evidence indicates that meth use has the potential to spread to other populations. Rawson et al. (2002) wrote,

> Meth use is expanding from a purely Caucasian, English-speaking clientele to Hispanic and Asian populations. Although the use of methamphetamine appears to be minimal among African Americans, increases among Hispanics and Asians suggest expansion of the methamphetamine problem to new markets. (p. 8)

Whether meth spreads to new ethnic and cultural groups remains to be seen. Some research has found that strong ethnic identification and segregation may offset some drug risks (Zickler, 2005a). For example, meth use has not made serious inroads into the African American population. The Drug Abuse Warning Network (DAWN) is a public health surveillance system that monitors drug-related visits to hospital emergency departments (EDs) and drug-related deaths investigated by medical examiners and coroners. DAWN data reflect less popularity of meth use among African Americans than among

whites and Hispanics (Wermuth, 2000). This pattern may or may not hold steady over time.

What is apparent is that users come from a wide variety of backgrounds. As they continue to use and move on to heavy use, their outward appearances, lifestyle disruptions, thought patterns, and behaviors become more similar. They begin the race at different points and end at the same place, becoming more similar with each dose.

GENDER DIFFERENCES AND METH USE

Research has been conducted on gender and patterns of meth acquisition, initiation, use, motivation, problems, treatment, and manufacture. Before the 1980s, female use of any substance was viewed as dependent on relationships with men. Females were either viewed as "good" citizens with addiction problems, or "bad" ones whose drug use mirrored their roles as deviants (Morgan & Joe, 1996). Since the 1980s, increasing amounts of research have found that women have reasons for drug use outside of their relationships with men.

Today, researchers are exploring gender differences among male and female meth users. For example, Brecht, O'Brien, Mayrhauser, and Anglin (2004) studied 350 people engaged in substance abuse treatment. They found gender differences in selected aspects of meth involvement. Some of the differences found were:

- Females were more likely than males to be introduced to meth and gain access through spouses or boyfriends than were males from girlfriends or spouses. Males were more likely to be introduced and gain access through friends and co-workers.
- Males were more likely to be injectors than were females.
- Males more likely to sell it than were females.
- Females were more likely to report skin and high-blood-pressure problems than were males.
- Females had longer first-time treatment episodes than males did.
- Male polydrug use included a wider variety of drugs than females reported.

Hser et al. (2005) also studied gender differences in meth users in a sample of treatment programs in California. In summary, Hser et al. (2005, p. 84) concluded, "Women in our sample, most of whom were of childbearing age or had children, demonstrated more severe problems than did men." They added, "Many were unemployed, relied on public assistance, and suffered from severe psychiatric problems." Hser et al. (2005) specifically found:

- Women reported meth use at an average earlier age (19.2 years) than males (20.6 years).
- Both genders used meth regularly for about the same number of years (8.7–8.8 years).
- Women reported significantly more numbers of prior treatments for drug use.
- The majority of women in the study had children under 18, but most did not live with their children within the last 30 days. Women were significantly more likely to be living with their children than were men. Though the findings were not statistically significant, more women than men had someone else taking care of their children through court order and had their parental rights terminated.

Research findings support gender differences regarding treatment needs. Hser et al. (2005) summarized the literature and concluded that females in treatment tend to have more psychological symptoms, lower self-esteem, heightened anxiety and depression, and higher rates of childhood sexual abuse than males. Women also had greater issues regarding employment, children, job skills, and incomes than males. Women have additional concerns if they are pregnant because of preliminary research suggesting negative effects of meth use on the fetus. Females are more concerned with child-rearing responsibilities, work, and the other seemingly overwhelming demands on their lives than males. This can affect their willingness to stop using a drug that they believe helps them get it all done. In contrast, males were more likely to be involved in criminal activities and be under criminal system supervision.

MEASURES OF THE EXTENT OF METH USE IN THE UNITED STATES

It is possible to get a sense of the extent of meth use and manufacture in the United States by looking at a number of national statistical indicators. While no measure captures everything, when a number of measures are viewed together, a sense for its use in the United States is possible. The following are some national indicators that give a sense of the extent of meth use, manufacture, and treatment.

A number of national efforts are made to track the extent of drug use, treatment, production, arrests, and other data. These data are useful in identifying trends. One of the most widely known is the Monitoring the Future Survey (MTF). This study is an annual national survey that assesses the beliefs, attitudes, and behaviors of high school students in grades 8, 10, and 12 as well as young adults. The study does not include school dropouts, who could represent a high-risk group for meth use. The MTF study surveys about 50,000 subjects.

Since 1999, meth has been included in the survey. Table 19.1 shows that meth use is not common among high school–aged youths. The numbers are low, which is encouraging. However, before becoming too optimistic, one must realize that the usage reported is at least three years old and does not capture recent regional expansion of the drug. In addition, note the percentage of 12th graders indicating a decline in lifetime use from 1999 to 2005 from 8.2 percent to 4.5 percent, respectively.

Emergency Department Drug Mentions—Drug Abuse Warning Network (DAWN)

Drug-related emergency department (ED) mentions are provided by SAMHSA through its Drug Abuse Warning Network (DAWN), which provides national information on morbidity and mortality related to substance abuse, including meth, collected from short-stay medical and medical examiner offices across the United States. The DAWN study is an annual survey of ED episodes from metropolitan areas. The DAWN data are useful in understanding meth and other substance abuse patterns. The DAWN data show

Table 19.1
Percentage of Methamphetamine Use by Secondary School Students by Grade, 1999–2005

Grade	1999	2000	2001	2002	2003	2004	2005
				Lifetime

Table 19.2
Number of Emergency Department Visits for Methamphetamine Mentions (Drug Abuse Warning Network), 1995–2003

1995	1996	1997	1998	1999	2000	2001	2002	2003
15,933	11,002	17,154	11,486	10,447	13,505	14,923	17,696	25,039

Source: Substance Abuse and Mental Health Services Administration (2004).

that meth-related deaths and ED episodes have increased in many urban areas over recent years. For example, in 2003, according to the DAWN data, meth was involved in 25,039 emergency room visits (SAMHSA, 2004). Table 19.2 shows DAWN data from 1995 to 2003. The data show that ED meth mentions have increased from 1995 to 2003 by 57.1 percent.

Treatment Episode Data Set (TEDS)

The Treatment Episode Data Set (TEDS), once labeled the Client Data System, collects data on clients admitted to substance abuse treatment programs. TEDS is an annual compilation of data on the demographic characteristics and substance abuse problems of those admitted for substance abuse treatment. In 1992–1993, with 42 states and the District of Columbia reporting, admissions due to meth abuse increased in 23 out of 29 reporting states for a net increase of 43 percent (Wermuth, 2000). Meth was the primary substance of abuse in over 116,595 substance abuse treatment admissions in 2003 reported to TEDS (SAMHSA, 2005c). In comparison, the same TEDS data show that the number of meth admissions for 1993 was 20,776, which indicates that admissions increased by 461 percent over this 10-year span. SAMHSA (2005c) reported that from 1992 to 2002, the amphetamine and meth treatment admission rate in the United States increased from 10 to 52 per 100,000. In California, a state at the forefront of meth use and manufacture, publicly funded meth treatment increased 226 percent from 1992 to 1998 (Brecht, 2001). The state of Washington treatment admissions increased more than 1,000 percent from 1992 to the first half of 1998 (Mills, 1999). Nationally, this trend continued, as reported admissions to publicly funded treatment programs for meth abuse grew from 12,122 in 1992 to 55,582 in 2002, representing more than a fourfold increase (Hser et al., 2005). This may be reflective of increased interest by meth addicts in getting treatment and/or of more court-ordered treatment.

SAMHSA's March 15, 2006, *DASIS Report* summarized that meth and amphetamine were identified in more than 136,000 cases as the primary sub-

stance of abuse in treatment admissions. This represented about 7 percent of all treatment admissions. The same report noted that between 1993 and 2003, the meth and/or amphetamine admission rate increased from 13 to 56 admissions per 100,000 population aged 12 or older. This represents a 330 percent increase over the period. The report also noted that 18 states had meth and/or amphetamine treatment rates that were higher than the national average of 56 per 100,000 population 12 or older. In addition, the report found that "the proportion of primary methamphetamine/amphetamine admissions referred to treatment by the criminal justice system increased from 36 percent in 1993 to 51 percent in 2003." This later conclusion indicates that methamphetamine and amphetamine users are being ordered into treatment by the courts more frequently.

Reported Lifetime Use

Another way to measure substance use is to survey a sample of households. The National Household Survey on Drug Abuse (NHSDA) is an annual national survey of drug use by household. During the year 2000, the DEA found that 4 percent of the U.S. population reported trying meth at some time over their lifetime (SAMHSA, 2001). According to its 2004 survey, about 12 million people aged 12 and older reported they had used meth at least once in their lifetime. These people represent about 5.3 percent of the total population. The percentages of reported use from the 2004 household survey broken down by age are shown in Table 19.3.

Quest Diagnostics Data

Quest Diagnostics, a private substance use testing firm, develops an index of use every six months as part of its substance testing operations. Quest

Table 19.3
Percentage of Lifetime Methamphetamine Use among U.S. Population by Age Group, 2004

Age group	Lifetime	Past year	Past month
12 and over	4.9	0.6	0.2
12–17	1.2	0.6	0.2
18–25	5.2	1.6	0.6
26 and older	5.3	0.4	0.2

Source: Substance Abuse and Mental Health Services Administration (2005a)

conducted 7.1 million drug tests in 2003 and has been indexing the results of drug tests since 1988. Quest Diagnostics makes its index of positive results available on its Web site (http://www.questdiagnostics.com). The company reported major increases in positive test results for amphetamines and meth. It recently reported (Quest Diagnostics, 2004),

> Drug tests suggest that greater use of Meth among a large group of general U.S. workforce employees during 2003 may have caused the increase in amphetamines use overall. For this group of workers, the incidence of positive drug tests attributed to methamphetamine increased by more than 68% in 2003 from 2002, reaching 0.32% of all drug tests. During 2002, methamphetamine was 0.19%.)

For the period between January and June 2005, Quest Diagnostics data indicate that of the over 3 million general workforce members who took drug tests between January and June 2005, 0.50 percent tested positive for amphetamine use, which includes meth (Quest Diagnostics, 2005). This percentage was slightly down from the 2004 tests.

Meth Arrests and Seizures

The Drug Enforcement Administration (DEA) tracks the number of drug seizures made each year by reporting law enforcement agencies. The number of seizures only reflects the general amount of drug trafficking known to law enforcement authorities. Law enforcement agencies vary in their effectiveness and efficiency in seizing illegal drugs. Thus these data tend to undercount the amount of true activity. Table 19.4 shows DEA drug seizures for the United States from 1990 to September 2005. For this time span, the number of meth kilograms seized increased by 500 percent. In comparison, seizures for the illegal stimulant cocaine increased by 48.9 percent.

Arrestee Drug Abuse Monitoring Program (ADAM)

The Arrestee Drug Abuse Monitoring Program (ADAM), established in 1987 but no longer in existence, collected urine samples from arrestees in 42 jurisdictions across the United States. It was one of the few national efforts to collect verifiable data on actual drug use by urine specimen. ADAM data for adults are available from 1987 to 2003.

ADAM data from 1991 to 2001 indicate that western states had the highest concentration of positive tests for meth among adult arrestees (Yacoubian & Peters, 2004). ADAM 2002 data reveal that the median percentage of adult male arrestees who tested positive for meth use in 2002 was 5.3 percent. The highest proportions of arrestees testing positive for meth were in the West

Table 19.4
Drug Enforcement Administration Drug Seizures, 1990–September 2005

Calendar year	Cocaine, kg	Heroin, kg	Marijuana, kg	Methamphetamine, kg	Hallucinogens, dosage units
Sept. 2005	84,959	479	222,943	1,817.7	8,425,499
2004	117,622	672	264,714	1,647.5	2,483,663
2003	73,720	789	254,188	1,676.9	2,879,528

Coast, Southwest, and West Central regions. Honolulu led all ADAM reporting cities for the percentage of male arrestees (44.8%) in 2002 who tested positive for methamphetamine. Hawaii has a long history of crystal meth abuse.

Regionalization of Meth

Meth use and manufacture is not evenly distributed across the United States. For years, meth use and production was concentrated in Hawaii, California, and the western United States. Across the border, Mexico is a country noted for meth production, with targeted sales in the United States. Motorcycle gangs often operated clandestine labs in California and western states and for years held the advantage in production. Meth use in other regions, while occurring, remained relatively rare. This regionalization of meth is rapidly changing as the drug is creeping across the United States. For example, midwestern states, such as Missouri, are now major areas of meth production.

In recent years, production has been spreading to other regions of the country. Some states have passed laws that have slowed this progression down but not halted it entirely. There are several reasons why this is occurring. The popularity of the drug, tightening of the borders due to the war on drugs, and the Internet are among the possibilities. The Internet has probably played a critical role in the spread of the manufacture of the drug because of the easily accessible Web site recipes for its manufacture. Virtually anyone who has access to common household chemicals can find a recipe for cooking meth within a few minutes of searching the Internet. The ability to produce small batches of the drug at home has made users throughout the country less dependent on western or Mexican sources of the drug. The trend continues that most users buy the drug rather than manufacture it for personal use.

Figure 19.1 displays three maps that show the percentages of agencies in each state for the years 2003–2005 reporting meth as their greatest threat, broken down by year. States with 0–24.9 percent of agencies reporting meth as the greatest threat are shown in black; 25–49.9 percent in middle gray; 50–74.9 percent in light gray; and 75–100 percent in dark gray. According to the DEA (2006), in 2003, black states were Connecticut, Delaware, Florida, Illinois, Louisiana, Maine, Maryland, Massachusetts, Michigan, New Hampshire, New Jersey, New York, North and South Carolina, Ohio, Pennsylvania, Rhode Island, Vermont, Virginia, West Virginia, and Wisconsin. Middle gray states were Alabama, Alaska, Georgia, Indiana, Kentucky, Mississippi, and Texas. Light gray states were Arkansas, Colorado, Missouri, New Mexico, and Tennessee. The dark gray states of Arizona, California, Hawaii, Idaho, Iowa, Kansas, Minnesota,

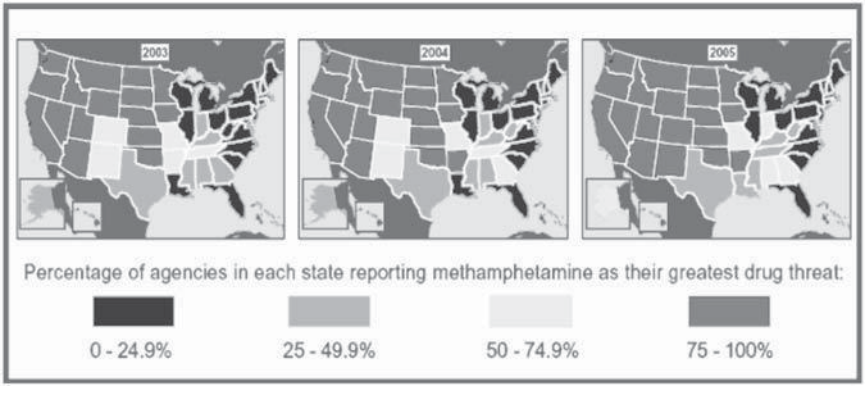

FIGURE 19.1 Methamphetamine threat progression, 2003–2005 (Drug Enforcement Administration, 2006).

Montana, Nebraska, Nevada, North and South Dakota, Oklahoma, Oregon, Utah, Washington, and Wyoming reported meth as their greatest threat. In 2004, West Virginia changed from black to middle gray; Georgia changed from middle gray to light gray; and Arkansas changed from light gray to dark gray. In 2005, Tennessee changed from light gray to middle gray; Louisiana changed from black to middle gray; Alabama, Alaska, and Indiana changed from middle gray to light gray; and New Mexico and Colorado changed from light gray to dark gray. The maps show that meth is marching from the West to the East and South. It has not made serious inroads in the Northeast.

Clandestine Lab Identification

Karen P. Tandy (2004), administrator for the DEA, testified before a congressional hearing that meth was "most frequently produced clandestinely in the United States." These labs can be anywhere. Missouri often shows up as a state with numerous meth labs. It is ideal because of its central location and rural landscape, which helps cooks hide their labs from officials. Leinwand (2003) reported, "In fiscal 2002, local police and U.S. agents shut down 1,039 labs in Missouri, 321 in Illinois, 89 in Florida, and 85 in Georgia." She added for comparison, that "seven years earlier, officials had reported finding 29 labs in Missouri and two each in Illinois, Florida, and Georgia." Other states have reported similar experiences:

- California reported 1,262 meth lab busts from September 30, 2002, to September 30, 2003, more than double the number from seven years earlier (Leinwand, 2003).
- The number of DEA meth lab seizures rose from 8,000 in 1999 to 10,000 in 2003.
- The DEA reported breaking up more than 16,203 clandestine labs in 2002 and 2003 (Ray, 2004).
- The Hazardous Substances Emergency Events Surveillance (HSEES) system reported that meth-related health events increased from 184 in June 2000 to 320 in June 2004. The system reported a total of 1,791 events in 16 states that use the reporting system in 2004. These events resulted in 960 injuries (Edwards, 2005).

The number of lab seizures may undercount the true extent of the lab problem. As states have passed restrictions on the purchase of precursors, illegal meth labs have become fractured. *Fractured* means the production process and acquisition of precursors are spread out over larger geographical areas to avoid detection by authorities. For example, with fracturing, cooks buy precursors from different stores in different towns to avoid detection by law enforcement.

PREVENTION EFFORTS TO CONTROL THE SPREAD OF METH

Prevention is an important component of any community response to meth use and manufacture. Many of the Web sites such as http://www.methresources.gov, http://www.mappsd.org, http://www.stopmeth.org, http://www.preventionpathways.samhsa.gov, and http://www.modelprograms.samhsa.gov provide prevention brochures, ads, video clips, fact sheets, literature, strategies, links, and materials. Some Web sites such as http://www.justthinktwice.com and http://www.montanameth.org provide prevention materials geared toward youth. The Montana Meth Project (http://www.montanameth.org) has films, posters, radio clips, and other excellent prevention resources. SAMHSA can provide prevention documents and materials to any community wanting to prevent meth use. States such as California, Hawaii, Illinois, Indiana, Iowa, Kansas, Michigan, Missouri, Montana, New York, Oregon, South Dakota, Tennessee, and others have launched meth prevention efforts. These are summarized in chapter VII of the SAMHSA-funded *Methamphetamine: A Resource Kit* (Center for Substance Abuse Prevention/National Prevention Network, 2006).

In addition, the Methamphetamine Interagency Task Force (2000a, 2000b) made specific prevention recommendations that are worth noting:

- Address meth issues through broad-based drug prevention and education efforts that target all forms of drug use and that are based on research and established prevention principles.
- Develop science-based prevention program planning and intervention guidelines in communities where meth is already a problem.
- Involve the entire community in prevention efforts, including educators, youths, parents, vendors of materials used in meth manufacture, law enforcement officials, business leaders, members of the faith community, social service providers, and representatives of government agencies and organizations.
- Identify the changing population characteristics of users, their motivations, risk factors, and demographics.
- Involve parents and other adults in prevention and education programs for youths, particularly in the areas of monitoring "latchkey" children, enhancing parent-child communication skills, and providing consistent family/home rules for youth behavior and leisure time activities.
- Ensure that media campaigns proceed with caution, focusing on raising awareness of meth and using messages designed to minimize unintended effects such as arousing curiosity about meth.
- Develop or augment programs aimed at educating those communities in which meth is an emerging or chronic problem.

In an effort to prevent manufacturing of meth, lawmakers in several states and Congress have been active in taking precursors and drugs such as pseudoephedrine off store shelves and restricting access to them. Law enforcement agencies in some jurisdictions have worked with local merchants to monitor suspicious or high-quantity sales of over-the-counter medicines (those containing pseudoephedrine) and chemicals (including fertilizer) that might be used for the purpose of manufacturing meth.

The Comprehensive Methamphetamine Control Act of 1996 identified selected chemicals, such as iodine, as List II chemicals. Using iodine as an example, the DEA requires that detailed records be maintained for sales of iodine crystals that exceed the threshold of 0.4 kilograms (about 14 ounces) to anyone or any entity. The act also requires that distributors and retailers report any suspicious activities to the DEA. Section 21 U.S.C. 841 § (c) (1)–(3) prohibits any person from knowingly possessing or distributing a listed chemical with the intent, knowledge, or belief that the chemical will be used to manufacture a controlled substance such as meth. Section 21 U.S.C. 843 § (a) (7) prohibits the individual from knowingly or intentionally manufacturing, distributing, exporting, or importing any equipment, chemical, or material that may be used to manufacture a controlled substance or listed chemical. Penalties for conviction for each violation are 10 years of imprisonment, a $250,000 fine, or both, and they double with a second or subsequent convictions. States have passed laws to stiffen the penalties. For example, in North Carolina, individuals possessing ingredients in quantities sufficient to make the drug can be punished with up to five years in prison if prosecutors can prove intent to manufacture meth (Eisley, 2004).

Some states have passed laws that hold store owners accountable for large-quantity sales of precursors (ingredients) used to make meth. States that have passed legislation that restricts the sales of precursors are Arkansas, Georgia, Iowa, Illinois, Kentucky, Mississippi, Oklahoma, Oregon, South Dakota, Tennessee, West Virginia, and Wyoming. There are a number of states that have passed laws that restrict the sale of precursors used to manufacture meth:

- Iowa passed legislation that restricts access to over-the-counter cold medicines that can be used to cook meth.
- California, a state with some of the earliest laws restricting the sale of precursors needed to produce meth, believes that it has had positive effects in controlling the spread of meth. After it enacted laws limiting the sale of key chemicals, such as ephedrine and pseudoephedrine, lab busts were cut in half, from 2,090 in 1999 to 1,130 in 2002 (Lacour & Gregory, 2004). California also has strict regulations regarding the sale of iodine crystals. California Code (11107.1) requires all sales to be recorded, limits the quantity, and has other limits.

- Oklahoma passed legislation that requires that pseudoephedrine be kept behind the counter.
- In April 2004, the U.S. Food and Drug Administration (FDA) banned drugs containing the stimulant ephedrine. In 2005, a Utah federal court limited the scope of a FDA rule banning the sale of all ephedrine-alkaloid dietary supplements. The judge ordered the FDA to develop rules for the legal distribution of the drug.

Short of passing restrictions, other efforts have been made to control the distribution of precursors. For example, Illinois issues bulletins to farmers and fertilizer sellers encouraging them to protect their supplies of anhydrous ammonia. In addition, as part of this antimeth campaign, some farmers and suppliers have secured their anhydrous ammonia storage tanks (known in some meth circles as "white buffalos") with fences, motion detectors, and locks.

CLOSING OBSERVATIONS

Meth accounts for a small percentage of the total number of people affected by drug and alcohol problems. However, almost all of the data in this chapter reveal that meth use, manufacturing, and distribution are increasing throughout much of the nation. Some have likened the spread of meth to an epidemic in some regions of the country (Anglin et al., 1997). It is clear that meth has impacted the West, Southwest, and Midwest and is beginning to expand into the Northeast. How extensive this expansion will be is unknown. The other question is whether meth use will grow in prevalence in minority populations. To date Latino, Hispanic, and African American populations have not embraced meth to the extent that Anglos have. If this changes, the negative effects could be substantial. Whether the upward spiral of meth use and manufacture continues remains to be seen. How communities, service agencies, law enforcement, families, elected officials, treatment providers, the courts, and businesses respond to the challenge will influence how, and even whether, this trend can be reversed.

Chapter **20**

Interaction between Methamphetamine Use and HIV Infection

Mary F. Holley, MD

BACKGROUND

Methamphetamine use is associated with higher rates of all types of sexually transmitted diseases. This association is both behavioral and physiological in nature. Methamphetamine use increases sexual behavior in both animals and humans. Methamphetamine stimulates increased sexual desire and promotes prolonged sexual encounters by delaying ejaculation. It greatly increases the dopamine response to sexual stimuli in the nucleus accumbens of rats (Fiorino & Phillips, 1999). Methamphetamine is also disinhibiting, which encourages promiscuous behavior and discourages the use of condoms. Genital ulcers caused by other sexually transmitted diseases also increase the risk of HIV transmission (Dickerson, Johnston, Delea, White, & Andrews, 1996). In addition, methamphetamine is a vasoconstrictor that leads to drying of mucous membranes, both vaginal and rectal, increasing the likelihood of abrasions and the transmission of disease.

The most deadly of the sexually transmitted diseases promoted by meth use is AIDS. Both hetero and homo sexuals are at risk. The incidence of new HIV infections has risen in recent years, particularly in America's coastal cities. Homosexual men from all over the nation relocate to the coastal cities in an effort to find a community. Once there, they may find that the harmonious communities and meaningful relationships they had hoped for do not materialize. They may find themselves even lonelier than they were in the small Midwestern towns they came from. While hoping to connect and make friends, they may be reduced to chance encounters, often at a price. The price is more than just monetary. They often pay with their lives.

The interaction between the methamphetamine epidemic and the recent rise in sexually transmitted diseases, including HIV, is not an accident, and is not confined to the homosexual community. Methamphetamine use increases the transmission of HIV and also promotes its invasion into the immune system and central nervous system. Drug resistance is increased in situations where medication compliance is poor, and co-occurring infections like hepatitis C also accelerate the progression of HIV disease. The mental illnesses associated with methamphetamine are exacerbated in patients who are also HIV-positive, particularly depression and dementia.

The implications for public health in the United States alone are staggering. Our tenuous grip on the HIV epidemic is seriously threatened by the accelerating methamphetamine epidemic. As use of methamphetamine spreads across the nation, more people of all ages are exposed to so-called big-city diseases with potentially devastating consequences for our collective public health.

INCREASED TRANSMISSION OF HIV

Methamphetamine is a powerful aphrodisiac, and many people are using it primarily for its sexual effects. In high doses, especially smoked or injected, it causes a rapid increase in dopamine levels in the midbrain pleasure center, the nucleus accumbens (Fiorino & Phillips, 1999). Methamphetamine stimulates sexual desire, enhances the sexual response, and reduces perception of pain, permitting a wide variety of sexual activities. Methamphetamine users report having more sex partners, more unprotected anal intercourse with casual partners, engaging in sex in more types of venues, and more esoteric sex (Rawstorne, Digiusto, Worth, & Zablotska, 2007). The association between meth and sex is cross cultural, with whites, blacks, and Latinos citing enhanced sexual performance as a primary reason for their methamphetamine use (Diaz, Heckert, & Sanchez, 2005). This is not just a coastal city phenomenon. My personal experience as a practicing gynecologist has shown that methamphetamine use among heterosexual women in rural Alabama skyrocketed between 1991 and 2008, and with it a significant increase in anonymous sex with multiple partners, often as payment to a drug dealer.

Methamphetamine users were also more likely to be taking Viagra than nonusers due to the loss of erectile function seen in more advanced methamphetamine addicts. These men still experience intense sexual desire but are unable to obtain a lasting erection and so take Viagra to maintain an erection or choose to engage in receptive sex predominantly (Mansergh et al., 2006). Both methamphetamine and Viagra use are strongly associated with HIV infection in homosexual men (Drumright et al., 2006).

We are seeing a resurgence of all types of STDs, including syphilis, gonorrhea, and AIDS, particularly in drug-abusing populations. Methamphetamine users are often apathetic about their HIV status and careless about their sexual practices (Taylor, M. M., et al., 2007). Users often engage in unprotected sex, which is further associated with transmission of HIV and other sexually transmitted diseases (STDs). A longitudinal study of men who have sex with men revealed that seroconversions were strongly related to the use of drugs before sex, high numbers of partners, and unprotected anal intercourse (Koblin et al., 2006).

These factors are most obvious and measurable in homosexual communities, which have seen a resurgence of HIV infection since the mid-1990s (Catania et al., 2001). Methamphetamine use is 10–20 times more common in homosexual men than in the population at large (Mimiaga et al., 2008; Shoptaw et al., 2006). Even the occasional use of methamphetamine is associated with increased unprotected and serodiscordant sexual activity—activity with persons of opposite or unknown HIV status across the nation, as documented by Colfax et al. (2005) in San Francisco and Plankey et al., (2007) in Washington, D.C.

In a New York City study, methamphetamine seemed to attract a subset of hypersexual risk-taking gay men who do not take precautions, regardless of HIV serostatus. Equivalent rates of extreme sex acts were reported while high and while sober in this meth-abusing population (Halkitis, Shrem, & Martin, 2005). Failure to disclose HIV positivity is strongly associated with methamphetamine use, and condoms are seen as obstacles to pleasure and reminders of the burden of being HIV-positive (McCready & Halkitis, 2008).

The magnitude of the association between meth and HIV is illustrated by recent data from San Francisco. In a study of people seeking HIV testing at a San Francisco STD clinic, those who admitted to recent methamphetamine use were three times more likely to test HIV-positive The incidence of HIV seroconversion is 6.3 percent per year among homosexual methamphetamine users, three times the 2.1 percent conversion rate among non-meth users Those who used methamphetamine during sexual encounters were four times more likely to test positive with a seroconversion rate of 7.7 percent (Buchacz et al., 2005). These individuals were not predominantly IV users of the drug, but rather recreational users. Among homosexuals who use intravenous (IV) methamphetamine, 68 percent are trading sex for money or drugs, and these people are six times more likely to test HIV-positive than non–meth users (Bacon et al., 2006). In the IV drug-using homosexual population, 70 percent of men reported unprotected anal intercourse (Kral et al., 2005) and 42 percent of the HIV-infected men were not aware of their infection (Bacon et al., 2006).

Methamphetamine abuse contributing to HIV transmission is commonly associated with homosexual communities but is also seen in heterosexuals and adolescents who are also using methamphetamine primarily for its sexual effects (Springer et al., 2007). More than 63 percent of adolescents who are involved with drug abuse have engaged in five or more unsafe sexual practices (Tepline et al., 2005). Juveniles in the justice system are much more likely to engage in unsafe sexual practices, and more than 66 percent of them persist in doing so despite counseling and incarceration (Romero et al., 2007). Heterosexual men are also engaging in unsafe sex under the influence of methamphetamine, even when they know they are HIV-positive (Purcell et al., 2006)

Heterosexual meth-using women have similarly high rates of unsafe sexual activity, including multiple partners, anonymous partners, commercial sex work, and unprotected sex (Semple, Grant, & Patterson, 2004). The prevalence of sexually transmitted disease among homosexual women is comparable to that among heterosexual women, and risk factors are similar, with number of partners and unprotected sex being primary risk factors (McNair, 2005). While exclusively homosexual women have lower rates of STDs, many meth-using lesbians have additional risk factors such as prostitution—both homosexual and heterosexual—and IV drug use. IV drug use is eight times more prevalent in homosexual women, with corresponding increases in hepatitis C and HIV risk factors (Fethers, Marks, Mindle, & Estacourt, 2000).

GENERAL HEALTH EFFECTS OF METHAMPHETAMINE USE

Methamphetamine use is associated with poor hygiene, crowded living conditions, and increased general infection rates. Personal hygiene is often compromised as addicts become homeless or live in poverty. Methamphetamine use frequently causes loss of olfactory function as the nasal mucous membranes are compromised by near-constant exposure to a potent vasoconstrictor. Nasal perforations are seen in addicts who snort the drug frequently. As the sense of smell is compromised, the addict does not realize the severity of his hygiene problem.

Methamphetamine is a powerful anorectic and causes malnutrition in general, and vitamin deficiencies, anemia, and poor wound healing in particular. The immune system is especially vulnerable to poor nutrition, accounting for much morbidity, and even mortality. Generalized weakening of immune function related to vitamin and protein deficiencies predisposes addicts to infection from a variety of sources, in addition to STDs. Increased infection rates with community-acquired methacillin resistant staphylococcus aureus (MRSA) are

noted in methamphetamine addicts, with skin picking behavior so common that it is referred to as meth mites. Addicts also have increased rates of sinusitis and pneumonia among those who smoke the drug, and bacterial endocarditis among those who inject it.

Methamphetamine use is also associated with significant psychiatric comorbidity, as dopamine and serotonin neurotransmission is impaired. Anxiety disorders, major depressive symptoms, and bipolar spectrum are all strongly associated with methamphetamine use. Psychotic symptoms are very common among methamphetamine addicts, including persecutory delusions and frank paranoia (McKetin, 2007). Severe mood and thought disorders increase the likelihood of exposure to infectious diseases, especially STDs, by impairing rational decision making and judgment. Among methamphetamine-dependent gay and bisexual men, the incidence of STDs was increased in those with anxiety disorders, social phobias, bipolar disorder, and major depression (Shoptaw, Pack, Reback, & Rotheram-Fuller, 2003).

METHAMPHETAMINE ACCELERATES HIV PROGRESSION

A single case of a rapidly progressive, multiply resistant form of HIV in a New York man who used methamphetamine lead to speculation of a superinfective form of the disease spread by meth addicts (Centers for Disease Control and Prevention, 2006). And indeed, methamphetamine use is associated with one form of drug resistance in HIV: primary nonnucleoside reverse transcriptase inhibitor resistance (Colfax et al., 2007). Gorbach et al. (2008) reported that methamphetamine users were four times more likely to acquire a drug-resistant form of HIV.[1] Reinfection with a different strain of HIV is a common scenario in situations where HIV-positive individuals are engaging in unprotected intercourse with other HIV-positive partners (seroconcordant sex). But viral loads have not been noted to be higher among methamphetamine users in most studies.[2] The finding of rapid progression to clinical AIDS is also related to immune modulation directly or indirectly caused by methamphetamine. Methamphetamine is also a potent direct immunosuppressant, particularly in relation to HIV and HCV (Hepatitis C virus) infections. Tallóczy et al. (2007) published a series of experiments demonstrating the nature of immunosuppression associated with methamphetamine use, even at low concentrations. Methamphetamine acts biochemically as an adjuvant for HIV infection by reducing the immune response to infection both at the splenic level and in peripheral blood.

Dendritic cells in the spleen serve as the first line of defense against HIV. They recognize and internalize pathogens and subsequently activate T cells.

They are also the initial targets of the HIV virus, adhering to and invading these immune cells as a first step in infection. Methamphetamine interferes with dendritic cell function on several levels. First, it decreases dendritic cell expression of genes associated with chemokine regulation, cytokinesis, apoptosis, and cell cycle regulation (Mahajan et al., 2006). The clarion call for reinforcements is impaired. Methamphetamine also influences expression of two dendritic cell genes coding for adhesion-related proteins (Nair, Mahajan, Sykes, Bapardekar, & Reynolds, 2006), which are important for defense against HIV infection. Methamphetamine thus acts as a cofactor in the invasion of HIV into the dendritic cells of the spleen.

Methamphetamine is also active at the intracellular level in the spleen, inhibiting dendritic cell function by collapsing the Ph gradient these cells use to process antigens in the lysosome. It inhibits autophagosome processing, leading to an accumulation of autophagosomes and halting antigen delivery to immune cells (Tallóczy et al., 2007). Meth decreases T cell profilerative responses to intact antigen, impairing the cells' ability to recognize and repel an invasion. Saito et al. confirmed in 2008 that methamphetamine reduced natural killer cell function in splenic lymphocytes, which did not recover, even with interferon treatment.

Peripherally, methamphetamine also interferes with immune function in peripheral blood. Single and repeated methamphetamine injections acutely reduced peripheral blood leukocyte counts (Saito et al., 2008). Methamphetamine also collapses Ph gradients in peripheral blood macrophages, blocking phagocytosis in these primary immune cells concerned with clearance of bacteria. This is thought to underlie the severity of bacterial infections such as MRSA, periodontal disease, and various forms of pneumonia in methamphetamine addicts. Methamphetamine also inhibits phagocytosis of *Candida* and *Cryptococcus* by macrophages by 40 percent and, in fact, increased proliferation of these pathogenic fungi within macrophages (Tallóczy et al., 2007), even in the absence of HIV infection.

Methamphetamine thus acts synergistically with HIV infection to cause more rapid and severe disease progression to AIDS. Animal models involving retroviruses have elucidated the effects of methamphetamine on HIV infection in humans. Methamphetamine exposure further impaired immune function in mice infected with a murine retrovirus, causing reductions in interleukin 2, interferon, and cytokines in retrovirus-infected mice (Yu et al., 2002) Methamphetamine impaired immune function in the thymus by reducing CD8 and CD4 cells, inhibiting IgM formation, impairing the proliferation of mitogen-stimulated B and T cells, and inhibiting granulocyte-macrophage interactions (In, Son, Rhee, & Pyo, 2005). Similar changes have been noted in

the immune systems of HIV-infected humans who abuse alcohol and cocaine (Chiappelli et al., 2006).

METHAMPHETAMINE ACCELERATES CENTRAL NERVOUS SYSTEM INVOLVEMENT

Methamphetamine produces a massive release of neurotransmitters, including dopamine, serotonin, and nor-epinephrine. As receptors are overloaded and ultimately destroyed, mood regulation is impaired, resulting in symptoms of depression and anxiety, and in manifestations of bipolar disorder. Methamphetamine is a well-known neurotoxin, producing oxygen free radials in many tissues, including the central nervous system (Riddle, Fleckenstein, & Hanson, 2006). These toxic compounds cause direct cellular damage to central areas in the brain that regulate emotion, memory, and perception. The development of psychosis and dementia is especially problematic as both can persist long into recovery and complicate treatment efforts (McCann et al., 2007; Yui, Ikemoto, Ishiguro, & Goto, 2000).

HIV infection also affects the central nervous system with the development of AIDS dementia in up to 60 percent of patients with advanced disease. Cognitive impairment is seen, with loss of memory and concentration, and motor symptoms of clumsiness and abnormal gait. Development of dementia is strongly related to increased viral load in the cerebrospinal fluid (Ellis et al., 2002), decreased CD4+ counts, and poor survival, and the incidence of AIDS dementia has decreased in the HAART (Highly Active Anti Retroviral Therapy) era (Bhaskaran et al., 2008). Progression to AIDS dementia is significantly accelerated in patients who also use methamphetamine.

In Los Angeles, 50 percent of white male homosexuals testing positive for HIV are methamphetamine users (Wohl, Frye, & Johnson, 2007). The more rapid progression of HIV in the presence of methamphetamine abuse has been noted, with more severe deterioration in immune and neurologic function. HIV-infected macrophages invade the central nervous system early in the course of disease, causing inflammatory changes and neurodegeneration. Increased neurotoxicity in these patients is related primarily to increased inflammation independent of viral load (Vitiello et al., 2007).

HIV infection with concurrent methamphetamine abuse results in severe and rapidly progressive HIV-associated dementia, with 58 percent of HIV-positive/meth-positive men showing deterioration versus 38 percent of HIV-positive/meth-negative men showing impairment on neuropsychiatric testing (Rippeth et al., 2004). HIV infection in the brain causes encephalopathy and dementia by releasing a protein called Tat (transactivator of transcription) in

the striatum (motivation and motor control) and frontal cortex (judgment and reasoning, executive function). HIV-infected individuals who also abuse methamphetamine have more severe encephalitis and more neural damage than those who do not abuse meth (Taylor, M. J. et al., 2007). Both Tat and methamphetamine activate glia (neural scar tissue) and induce cytokine production, and cytokine levels are further increased in cell preparations exposed to both. The interaction between meth and HIV resulted in increased destruction of dopaminergic terminals in the striatum of rats (Theodore, Cass, & Maragos, 2006).

Hippocampal (memory storage) neurons exposed to both Tat and meth showed early evidence of neural damage at 6 hours and extensive cell death at 24 hours. These changes were associated with a dysregulated mitochondrial calcium potential (Langford et al., 2004); increased levels of oxidative stress; inflammation; and mitochondrial damage in the frontal cortex, hippocampus, and striatum (Flora et al., 2003). Injury to these areas is strongly associated with memory loss and cognitive impairment in HIV-positive methamphetamine users (Chana et al., 2006).

In human studies, higher viral load was strongly associated with increased cellular damage on Magnetic Resonance Spectroscopy scanning (a measure of cellular metabolic function) in patients who also used methamphetamine, but significantly less in those who did not use meth (Taylor, M. J. et al., 2007). Brain metabolite MRS scanning revealed an additive effect of methamphetamine on the HIV-related brain injury in the frontal lobe and basal ganglia (Chang, Ernst, Speck, & Grob, 2005). On magnetic resonance imaging (a measure of cellular volume and structural integrity), atrophy was seen in the HIV-positive patients, while significant swelling was noted in the cortical areas and striatum of HIV-positive methamphetamine users, and atrophy in the hippocampus (Jernigan et al., 2005). Lower CD4 counts were also associated with more neuropsychiatric impairment in meth-using patients (Carey et al., 2006). When HIV is poorly controlled, methamphetamine exposure results in worsening brain injury.

HIV viral control is markedly impaired in methamphetamine users, related both to the intoxicated state and to the mental health consequences of meth use, including depression and anxiety problems. In a study of new-onset HIV patients, 63 percent had a mental illness (including depression, anxiety, psychosis, or a personality disorder), 45 percent had a substance abuse disorder, and 38 percent had both. Those with untreated mental illness or a substance abuse disorder were in a more advanced disease state—higher viral loads and lower CD4+ counts—than those who did not have these problems (Tegger et al., 2008). Methamphetamine-addicted HIV patients are sicker at presentation, and are also less likely to comply with treatment. A longitudinal study

showed markedly reduced HAART medication compliance in drug-using patients, with a fourfold greater risk of medication errors and noncompliance. Stimulant users were at greatest risk of noncompliance, particularly when they were actively using drugs and thus frequently intoxicated (Hinkin et al., 2007). Active cocaine users had only 27 percent adherence to antiviral medications, versus 68 percent for nonusers. Consequently, only 13 percent of cocaine users maintained viral suppression, versus 46 percent of nonusers (Arnsten et al., 2002). As a result of poor compliance, drug users and patients with mental health problems such as anxiety or depression showed slower rates of virologic suppression and faster rates of virologic failure (Pence, Miller, Gaynes, & Eron, 2007). The risk of developing resistance to HAART is greatly increased in situations of late diagnosis and poor compliance with medical regimens, and these resistant strains are then transmitted to others.

The prevalence of hepatitis C coinfection in HIV-positive patients is around 30 percent over all (Rockstroh et al., 2005) and between 70 and 90 percent among injection drug users (Lauer & Walker, 2001; Sherman et al., 2002). Not surprisingly, persons coinfected with HIV and hepatitis C had poorer response to HAART, higher mortality rates, and were more likely to die from HIV-related causes, even with similar viral loads (Weis et al., 2006) and CD4 counts (Anderson, Guest, & Rimland, 2004). Hepatitis C coinfection makes HIV disease worse. Also not surprisingly, persons coinfected with HIV and hepatitis C had increased rates of HCV persistence (95%) with a lack of CD4 T cell response during acute disease contributing to failure of early disease control (Danta et al., 2008). Coinfected individuals who have cleared HCV spontaneously remain at risk for recurrence of hepatitis C viremia if their CD4 counts fall (Kim et al., 2006). HIV coinfection makes hepatitis C disease worse. Methamphetamine use further impairs the immune response to hepatitis C, resulting in more severe liver disease and poorer response to interferon treatment (Ye et al., 2008). Even co-infected individuals who have cleared their HCV spontaneously remain at risk for recurrence of hepatitis C viremia if their CD4 counts fall (Kim et al., 2006).

HCV is itself associated with cognitive impairment, even in the absence of cirrhosis, in one-third of chronically infected persons (Perry, Hilsabeck, & Hassanein, 2008). Neuropsychological function is further impaired by concurrent hepatitis C infection in HIV-positive patients (Richardson et al., 2005; Aronow, Weston, Pezeshki, & Lazarus, 2008). Hepatitis C infection is associated with higher levels of HIV RNA in the cerebrospinal fluid of HIV-positive patients, reflecting more central nervous system invasion by HIV (Letendre et al., 2005). Both cognitive function and affective symptoms were adversely affected by concurrent hepatitis C infection (Clifford, Evans, Yang, & Gulick, 2005; Ryan, 2004). Patients with concurrent HCV infection, HIV infection,

and methamphetamine use were even more severely impaired, with deficiencies in learning, abstraction, motor skills, information processing, and delayed recall (Cherner et al., 2005). The impact appears to be directly attributable to the viral infections since differences in biochemical measures of liver function did not explain the neuropsychological differences in the hepatitis-infected persons (Morgello et al., 2005).

The cognitive effects of HIV and HCV are not trivial. They can in fact result in frank dementia. Clearly HIV and HCV status must be considered in academic studies of cognitive function in methamphetamine users and in treatment planning for methamphetamine addicts. Treatment involving cognitive behavioral therapy will likely require much more time and attention in cases involving concurrent HIV and/or HCV infection.

INTERVENTIONS

The opportunity for intervention in the progression of HIV-related disease is significant. With the advent of HAART treatments for HIV infection, more infected people are living almost full life spans, and more of them are developing HIV-related dementia. The impact methamphetamine has on HIV-related dementia is substantial, and much morbidity could be prevented by reducing the meth use of HIV-positive patients. Also, many HIV infections could be prevented by reducing the high-risk sexual behaviors of meth users.

Reaching the populations at risk for HIV infection has proven difficult since so many people whose sexual behavior places them at risk do not consider themselves members of the at-risk groups. Youths are increasing identifying with a homosexual lifestyle and yet do not consider themselves at risk for the diseases of the older generation of gays. Adult men who have sex with men often have a wife and kids at home, and though they participate in same-sex adventures frequently, they do not consider themselves gay. Closeted homosexuals or bisexuals also are not likely to participate in HIV risk prevention programs and are unlikely to change their behavior in response to such a program.

Concurrently IV methamphetamine and cocaine addicts often do not consider themselves IV drug abusers because they do not use heroin. IV methamphetamine addicts often do not consider themselves at risk for HIV even though 45 to 50 percent of them are HIV-positive. Public perception of what constitutes a risk factor for HIV is significantly outdated (Bull, Piper, & Reitmeijer, 2002). Safe sex programs aiming only at self-identified homosexuals miss more than half of the at-risk population, including virtually all of the IV drug abusers at risk via needle sharing.

Even among self-identified homosexuals, compliance with safe sex measures is sporadic, especially among meth users. Use of party drugs in relation to sex,

including methamphetamine, increases risk of unprotected sexual encounters with HIV-positive individuals, with reliance on assumptions of seroconcordence (Purcell, Moss, Remien, Woods, & Parsons, 2005). Unprotected serodiscordant sex is considered an act of violence among homosexuals, yet many methamphetamine users regularly engage in it. Risky behavior has escalated in the years since highly active anti-retroviral therapy became available. HIV seroconversion is strongly associated with use of methamphetamine, poppers, and/or Viagra. Methamphetamine use is also associated with unprotected anal insertive or receptive sex, number of partners, and complacency regarding the effectiveness of medical treatments for HIV (Plankey et al., 2007; Schwarcz et al., 2007).

Efforts to reduce unsafe sexual practices among homosexual meth-using men have been disappointing. Cognitive behavioral therapy aimed at reducing unsafe sexual practices in the face of ongoing methamphetamine use improved actual behavior only minimally. Participants engaged in safe sex 25 percent of the time, as opposed to 18 percent of the time for control groups 12 months posttreatment in HIV-positive men (Mausbach, Semple, Stradthdee, Zians, & Patterson, 2007). A similar study with peer-led behavioral intervention reduced unsafe sex among HIV-positive men from 26 percent of encounters to 21 percent at three months' postintervention (Wolitski, Gómez, & Parsons, 2005). The low rates of safe sex among these HIV-positive men suggest that we face a serious challenge in our attempts to control transmission of HIV.

Studies show more success in behavior modification if the drug addiction is addressed directly rather than focusing on the consequent unsafe sexual behaviors. Successful addiction treatment with contingency management, cognitive behavioral therapy, or both was more effective in reducing sexual risk behaviors than counseling directed toward the sexual risk factors themselves (Shoptaw, 2006). Reduced methamphetamine use itself resulted in declining depression scores and reduced sexual risk behavior. This suggests that lowering methamphetamine use has a synergistic effect on reducing unsafe sex among homosexual men (Jaffe, Shoptaw, Stein, Reback, & Rotheram-Fuller, 2007). This beneficial effect on sexual risk behavior was persistent in sustained recovery. Successful drug treatment resulted in reduced sexual risk behaviors at one year follow-up, with fewer anonymous partners, reduced anal intercourse, and an increased sense of responsibility to disclose HIV status (Reback, Larkins, & Shoptaw, 2004).

Unavailability of drug treatment facilities has been a continuing problem in areas hard hit by methamphetamine, particularly in the homosexual communities. A majority of homosexual men who use methamphetamine report concern over the effects meth is having in their lives. Of 174 men surveyed at a San Diego STD clinic, 70 percent had tried to quit their methamphetamine use, and 52 percent were interested in obtaining treatment, but only 12 percent had ever been in drug treatment (Menza et al., 2006). Some men feel that if

they quit using meth, their sex life will be over, and they need a role model of successful recovery to take the first step. The vast majority deal with persistent depression and anxiety and are in need of mental health care (Mimiaga et al., 2008). Greater availability of effective drug treatments offers the best hope for reducing HIV transmission in these populations.

Education programs that reach people where they are, physically and emotionally, are much more effective than programs that require the participant to come to a physical location, or admit something that they do not wish to acknowledge. There is some promise in an Internet-based outreach program that takes advantage of the partner meeting Web sites that abound online. This is the starting point for many crystal methamphetamine–related hookups and offers a potential starting point for interventions and educational efforts (Mimiaga et al., 2008). Specifically, posters and pictures depicting the physical degeneration common in addicts may be effective in communicating with young men who highly value their physical appearance.

Our nation's public health is at significant risk if we fail to address the needs and challenges of our IV drug abusing and our homosexual communities. Diseases that are permitted to flourish in one community will most certainly compromise the health and vitality of the entire nation. Taken solely from an economic point of view, we cannot afford the loss of so many talented young people to a preventable disease. We also cannot afford the large number of liver transplants and expensive medications that will be required in coming years if we refuse to take action.

Drug education and prevention work must be done more effectively, with attention to the needs of our youth, our homosexual communities, recent immigrants, and others who have been marginalized. Tuberculosis control was made possible by raising the standards for health and hygiene over all of the United States. Methamphetamine addiction and HIV control can only be accomplished by raising the standards for drug education all over the nation, including gay America.

NOTES

1. Bushkin et al. (2008) described a cluster of 9 methamphetamine using men with phylogenetically related multiple drug resistant HIV strains with resistance to most anti-retroviral drugs. Only 2 of those men had prior experience with anti-retrovirals. All had had unprotected sex with multiple anonymous partners.
2. A recent study by Carrico et al. (2008) found markedly higher viral loads, higher neopterin levels and lower tryptophan levels (both indicators of immune activiation) in stimulant users, regardless of compliance with antir-retroviral therapy.

About the Editor and Contributors

EDITOR

Angela Browne-Miller, PhD, DSW, MPH, is the Set Editor of the *Praeger International Collection on Addictions* (2009), Director of Metaxis Institute for Personal, Social, and Systems Change, based in northern California, United States; Director of Browne and Associates Violence, Substance Abuse, and Trauma Treatment and Prevention Program, also in northern California; has been a keynote speaker at conferences around the world on addiction, violence, and behavior change; and is the author of numerous books, including *To Have and to Hurt: Seeing, Changing or Escaping Patterns of Abuse in Relationships* (2007) and *Rewiring Your Brain to Change Your Behavior* (2009). Dr. Browne-Miller earned two doctorates and two master's degrees at the University of California, Berkeley, where she lectured in three departments for 14 years, and has served as a National Institute of Mental Health Postdoctoral Fellow, a U.S. Department of Public Health Fellow, the public relations director for Californians for Drug Free Youth, the Research Education and Treatment Director for the Cokenders Alcohol and Drug Program, a member of the board of directors of the Employee Assistance Society of North America, an advisor to addiction treatment programs in the United States and several other countries, and project director on three California Department of Health violence prevention projects.

CONTRIBUTORS

Jemel P. Aguilar, PhD, MSW, is an assistant professor at the University of Texas at Austin School of Social Work and the Center for Women and Gender Studies in Austin, Texas, United States. Dr. Aguilar conducts research on offender populations and educational structures' influences on juvenile offending. His primary research interests include gender studies, criminal and juvenile justice, and theory and model development. Dr. Aguilar has published articles on adolescent experiences in juvenile corrections settings, accountability systems in education and social services, and theoretical articles about the psychosocial risks facing low-income youth in urban areas.

Atul Ambekar, MD, is assistant professor at the National Drug Dependence Treatment Centre and Department of Psychiatry, All India Institute of Medical Sciences in New Delhi, Delhi, India. He earned his MD degree from the All India Institute of Medical Sciences, a prestigious and internationally recognized institute in India. He worked as senior resident and later joined the United Nations Office on Drugs and Crime (UNODC), Regional Office for South Asia, New Delhi, as a research officer. Subsequently, he joined All India Institute of Medical Sciences as an assistant professor. He is a resource person for training and research for various national and international organizations such as UNODC, the Joint United Nations Programme on HIV/AIDS, and the government of India. He has several publications to his credit.

Xenia Anastassiou-Hadjicharalambous, PhD, was born and raised on the Mediterranean island of Cyprus. She obtained her undergraduate degree from Aristotelian University (Thessaloniki, Greece), her MSc in psychology from Essex University (Colchester, United Kingdom), and her PhD from Strathclyde University (Glasgow, United Kingdom). She held a research postdoctoral position at the University of Strathclyde before joining the University of Nicosia in Nicosia, Cyprus in September 2004 as a lecturer of developmental psychopathology. Dr Anastassiou-Hadjicharalambous has received several research grants from various national and international funding bodies. She has four ongoing research projects and has published six articles in peer-reviewed journals.

Anna Bokszczanin, PhD, is an assistant professor at the Institute of Psychology, Opole University, in Opole, Poland. She has published intensively in the areas of the impact of stress on children's and adolescents' well-being and mental health in the context of stressful life events at both individual and community levels (e.g., natural disaster, unemployment). She is the author of the books *Spoleczne i psychiczne reakcje dzieci i mlodziezy na powódz 1997 roku* (Social and

Psychological Response of Children and Adolescents to the 1997 Flood) published by *Warszawa: Wydawnictwo Instytutu Psychologii PAN* (2003); and *Social Change in Solidarity: Community Psychology Perspectives and Approaches* (2007). She is the editor of *Opole: Wydawnictwo Uniwersytetu Opolskiego*.

Diane Bray, PhD, is a principal lecturer and currently head of psychology at Roehampton University in London, England. She obtained her undergraduate degree from Bradford University and doctorate from the North East London Polytechnic (now University of East London). Before joining Roehampton, she held a number of teaching posts and was a research officer at the Centre for Criminological Research (Oxford). Her research interests include risk perception, individual differences, and the relationship between cognition and emotion.

David T. Courtwright, PhD, received his undergraduate degree at the University of Kansas in Kansas City, Kansas, United States and his graduate training in history at Rice University in Houston, Texas, United States. He is the author of *Addicts Who Survived* (1989), *Dark Paradise: A History of Opiate Addiction in America* (rev. ed., 2001), and *Forces of Habit: Drugs and the Making of the Modern World* (2001). He is currently presidential professor at the University of North Florida.

Herbert C. Covey, PhD, is deputy director of Adams County Social Services Department and instructor at the College of Continuing Education, University of Colorado at Boulder in Boulder, Colorado, United States, and has taught juvenile delinquency for over two decades. Dr. Covey received his PhD in sociology from the University of Colorado at Boulder. He has published several articles on a wide array of subjects, including community corrections, disabilities, religion, street gangs, crime measurement, boomtown crime, research methods, determinant sentencing, violent mentally ill offenders, and social gerontology, among other topics. His current research involves substance abuse treatment and the dietary practices of enslaved African Americans. He has also served as an academic journal reviewer for *Criminal Justice Review, Journal of Contemporary Criminal Justice, The Gerontologist, Journal of Applied Sociology,* and *Journal of Crime and Justice.* He has encountered many families and youth who have been involved with meth use and manufacture. He has authored or coauthored nine books and numerous academic articles. He is the editor of *The Meth Crisis* (Praeger, 2006), to which he contributed three chapters. He is a coauthor of the text *Youth Gangs* (2006) and sole author of *African American Slave Medicine: Herbal and Non-Herbal Treatments* (2007). He coordinated four major symposia on methamphetamine for judges, caseworkers, public health officers, law enforcement officers, child protection caseworkers, public administrators, ex-users, and other stakeholders.

Ann N. Dapice, PhD, is director of education and research of T. K. Wolf Inc., a nonprofit American Indian organization in Tulsa, Oklahoma, United States. With PhDs in psychology, sociology, and philosophy from the University of Pennsylvania, she has served as professor and administrator at a number of universities, including the University of Pennsylvania, Widener University, Penn State University, and Goddard College, teaching social sciences and Native American studies. Her cross-cultural research has been reported in professional journals, books, and academic presentations regionally, nationally, and internationally. Speaking engagements include topics related to addiction, stalking, and American Indian issues. She has served on the Elders Council for the American Indian Chamber of Commerce and is a member of the boards of directors of the Mental Health Association in Tulsa and the Tulsa Metropolitan Ministry/Domestic Violence Intervention Services Committee. She consults with the University of Pennsylvania on Native American issues, where she is founder and chair of the Association of Native Alumni.

Cecilia A. Essau, PhD, MA, HBA, obtained her undergraduate and master's degrees in psychology from Lakehead University (Canada), her PhD from the University of Konstanz (Germany), and her postdoctoral degree (professorial qualification in Germany) from the University of Bremen (Germany). She held numerous academic positions in Canadian, Austrian, and German universities before joining Roehampton University in London, England, in 2004 as a professor of developmental psychopathology. With research grants from numerous national and international institutions, her research has focused on understanding the interacting factors that can lead children and adolescents to have serious emotional and behavioral problems, and she has used this research to (1) enhance the assessment of childhood and adolescent psychopathology and (2) design more effective interventions to prevent and treat such problems. She has published more than 150 articles in peer-reviewed journals or edited volumes, and 12 books.

Elaine R. Feeney, PhD, RN, observed that the use of drugs of abuse, including alcohol, caused or exacerbated the health problems for which many of her clients (patients) received medical and nursing care. This awareness spurred her interest in the relationship between drugs of abuse and health status and services. Her doctoral dissertation, "Health Services Utilization by Addicted Women before and after the Initiation of Substance Dependence Treatment," clarified her thinking and guided her view of addictive disease as a public health problem. During her career, she has received numerous awards for scholarship, leadership, advocacy, and teaching. Dr. Feeney has practiced her profession in the role of clinician, manager, researcher, teacher, and consultant to nursing specialty organizations. She is currently serving as the president of the Foundation for Addictions Nursing in Baltimore, Maryland, United States.

George Georgiou, PhD, obtained his BS (honors) and PhD from Goldsmiths College, University of London, England. His PhD focused on the role of clinical and nonclinical anxiety in modulating attention, with particular reference to conscious versus nonconscious processing. After completing his PhD, he worked at a medical health center, where he was actively involved in the treatment of patients diagnosed with various anxiety disorders. He then took up a postdoctoral position at the University of Essex before spending four years as an assistant professor at the University of Nicosia, in Cyprus. George is currently a lecturer at Roehampton University. His current main research interest lies in the information processing biases in affective disorders and implications for therapy, and the role of attentional control in anxiety. He has published several articles in peer-reviewed journals in this area and has recently received two European Union grants primarily aimed at tackling binge drinking and alcohol-related road traffic accidents in Cyprus and the United Kingdom.

Thomas K. Greenfield, PhD, is a senior scientist and the scientific director of the Alcohol Research Group (ARG) in Emeryville, California, United States. He also serves as an adjunct clinical faculty member in the University of California (UC) San Francisco's Department of Psychiatry in San Francisco, California, United States. His research interests include the epidemiology of alcohol use and problems, alcohol policy studies, consumer satisfaction, national alcohol surveys and consumption measurement, drinking patterns and mortality, and services research. His responsibilities include overseeing ARG's national alcohol surveys, which are sponsored by the National Institute on Alcohol Abuse and Alcoholism (NIAAA) and conducted every five years. He has served as vice president and secretary of the Kettil Bruun Society for Social and Epidemiological Study of Alcohol and currently serves on the Extramural Advisory Board of the NIAAA. He grew up in Zimbabwe and lives in Oakland with his wife, a professor at UC, Berkeley's Haas School of Business; they have an adult son.

Julia F. Hastings, PhD, MSW, is assistant professor in the School of Social Welfare at the University of California Berkeley in Berkeley, California. Globally, her research interests cover welfare policy, depression, and health disparities among African Americans. Her research projects focus on the interrelationships between race, mental health outcomes, health conditions, risk and protective factors, and poverty. Furthermore, she conducts research studies on methodological issues associated with understanding how researchers can better diagnose depression among African Americans. She has published on culturally competent research methods within African American communities, welfare participation, depression, and body weight. She received her MSW from the University of Washington and her PhD from the University of California, Los Angeles. Her

postdoctoral training occurred at the University of Michigan in the Program for Research on Black Americans at the Institute for Social Research; the School of Public Policy; and the School of Social Work. She also completed a certification in epidemiology from the Department of Epidemiology at the University of Michigan's School of Public Health.

Sean R. Hogan, PhD, MSW, is assistant professor in the Department of Social Work at California State University Fullerton in Fullerton, California, United States. In 2005, he received his doctorate from the School of Social Welfare at the University of California, Berkeley. Dr. Hogan's teaching interests are in the areas of substance abuse and social welfare policy. He also has an interest in the effectiveness of service learning as a pedagogical method for teaching substance abuse education to social welfare students. Dr. Hogan's research focuses on the effects of welfare reform legislation on marginalized populations, with a specific interest in the effects of eliminating welfare benefits to low-income substance abusers. He also has an interest in the history and construction of substance abuse policy in the United States and its relationship to social inequality.

Mary F. Holley, MD, trained at Baylor College of Medicine in Houston, Texas, United States. She is a licensed physician and a former obstetrician-gynecologist in northern Alabama. She is founder and director of Mothers against Methamphetamine, a national nonprofit drug education organization. Dr. Holley is author of *Crystal Meth: They Call It Ice* and has produced several educational videos for drug education and prevention. She serves on the Alabama Attorney General's Methamphetamine Task Force as chairperson of the Education Committee. Her Web site can be seen at http://www.mamasite.net.

Herbert D. Kleber, MD, is professor of psychiatry and director of the Division on Substance Abuse at the Columbia University College of Physicians and Surgeons and the New York State Psychiatric Institute in New York, United States. Before founding the Division in 1991, he served for two and a half years as the deputy director for Demand Reduction at the Office of National Drug Control Policy in the White House under President George H. W. Bush and director William Bennett. Prior to that, Dr. Kleber was professor of psychiatry at Yale University School of Medicine (1966–1989) where he founded the Substance Abuse Treatment Unit. He currently oversees research on new medications to treat cocaine, heroin, prescription opioids, and marijuana problems. Dr. Kleber is the author or co-author of more than 250 papers, chapters, and books dealing with all aspects of substance abuse, and the co-editor of the *American Psychiatric Press Textbook of Substance Abuse Treatment*. He has received numerous awards, is listed as one of the "Best Doctors in America,"

and was elected in 1996 to be a member of the Institute of Medicine of the National Academy of Science.

Rev. Linda Mercadante, PhD, Straker Professor of theology at the Methodist Theological School in Delaware, Ohio, United States, helps train ministers who understand addiction issues and licensed counselors with a focus on spirituality. She specializes in theology and culture, exploring the theological implications of such issues as addiction, victimization, gender imagery for God, human dysfunction, reproductive loss, film, and memoir. Author of five books and nearly 50 articles, her works include *Victims and Sinners: Spiritual Roots of Addiction and Recovery* (1996), *Bloomfield Avenue: A Jewish- Catholic Jersey Girl's Spiritual Journey* (2006), and *Gender, Doctrine and God: The Shakers and Contemporary Theology* (1990). She lectures internationally on addiction and victimization to therapists, researchers, and recovering persons. She also gives workshops and retreats on these topics as well as on spiritual memoir, faith and film, and other issues in theology and culture.

See Ching Mey, PhD, MEd, is a professor in the School of Educational Studies, Universiti Sains Malaysia in Pulau, Pinang, Malaysia. Her areas of specialization are educational psychology, counseling psychology, counselor education, special education (emphasis on autism), psychological testing, and mental health. She is a registered and licensed counselor. Ching Mey conducts seminars and workshops and is consulted on topics related to motivation, mental health, strategies and techniques in counseling, psychological testing, stress management, grief and bereavement, counseling special populations, screening and diagnosis of special children, teaching and learning of special children, behavior management, and parenting skills. She has published five academic books and about 200 international and national academic journal articles. She has received 16 research grants. In recent years, she has been invited to give keynote addresses, plenary presentations, talks, and workshops by international organizations such as PACERS (Philippines), A WIFI (Philippines), University of San Carlos (Philippines), SAARC (India), Department of Mental Health (Thailand), University of Surabaya (Indonesia), Seoul National University (Korea), iT21-International (Singapore), Charles University (United Kingdom), California State University (United State), Asia Pacific Association of Psychotherapists, and APECA. She has received several awards recognizing her contributions, including several Outstanding Leadership and Service Awards from the Lions Clubs International, the Pingat Jasa Kebaktian (Meritorious Service Award) from the Penang State Government, the Maal Hijrah Excellence Award (for Academic Category) from the University Science Malaysia, and the Sin Chew

Da Ai Award (Sin Chew Kind Heart Award) and Alumni Citizenship Award 2007 from the Ohio State University Alumni Association.

Kathryn Meyer, PhD, is associate professor in the Wright State University Department of History in Dayton, Ohio, United States. Her areas of expertise include Asian narcotics trafficking, Asian crime, and Chinese and Japanese history. She authored the book, *Webs of Smoke: Smugglers, Warlords, Spies and the History of the International Narcotics Traffic*. (1998).She earned her doctorate at Temple University in Philadelphia, Pennsylvania, United States.

Changiz Mohiyeddini, MD, PhD, obtained his undergraduate, MA, and PhD degrees in psychology from Trier University (Germany) and his postdoctoral degree (professorial qualification in Germany) from the University of Tuebingen (Germany). He held numerous academic positions at Luxembourgian, German, and Swiss universities before joining Roehampton University, London, England, in 2006 as a reader in psychology. His research has focused on understanding the process of emotion regulation that can lead children, adolescents, and adults to have serious emotional and behavioral problems (e.g., depression, anxiety, alcohol and drug abuse, rumination).

Jean O'Callaghan, PhD, is a principal lecturer at Roehampton University, London, England, where she coordinates an undergraduate degree program in psychology and counseling. She is an integrative psychotherapist and an academic psychologist with research interests in self-regulation and the psychology of disability. Her therapeutic expertise integrates diverse perspectives of clients' meaning making that variously employ cognitive behavioral and narrative poststructuralist therapeutic techniques to empower clients to reframe a presenting problem such as alcohol addiction.

Ramandeep Pattanayak, MD, is currently working as a senior resident in the Department of Psychiatry, All India Institute of Medical Sciences (AIIMS) in New Delhi, Delhi, India. She obtained her postgraduate degree in psychiatry from the same institute in 2005. During her residency, she has also been trained at the National Drug Dependence Treatment Centre, Department of Psychiatry, AIIMS, and has gained sufficient clinical and research exposure in the field of drug dependence. She has also gained experience as a research officer in a phase 3 drug trial in the Department of Psychiatry, AIIMS. She was awarded a medal in community medicine during her graduation.

Regina Pauli, BSc, PhD, obtained her undergraduate degree in psychology from Royal Holloway, London, and her PhD from the University of Surrey. She has been a lecturer at Roehampton University in London, England, since 1995 and is presently principal lecturer in the School of Human and Life Sciences

there. She has research interests in teamwork, especially in higher education; evaluation of teaching quality; medical image interpretation; and emotion and cognition.

Martha Romero Mendoza, PhD, received her bachelor's degree in clinical psychology at the Universidad Iberoamericana in Mexico City, Mexico, her master's degree in clinical psychology at the National Autonomous University of Mexico, and her doctorate in anthropology at the National Autonomous University of Mexico. Owing to her outstanding studies, she was distinguished with the Medal Alfonso Caso. Since 1985, Romera Mendoza has worked as a researcher of medical sciences and professor at the National Institute of Psychiatry in Mexico City, Mexico, and as professor of qualitative methodology at the Medical School at the National Autonomous University of Mexico. Owing to her interest in gender-related problems as part of the International Research Group on Gender and Alcohol of the Kettil Brunn Society, she has been an advisor of the Word Health Organization in Geneva, Switzerland. Romero Mendoza has participated in different multinational research projects and congresses coordinated by the World Health Organization and the Pan-American Health Organization dealing with addiction problems. She has published more than 70 research articles, 15 book chapters, and 3 research books. Romero Mendoza is presently developing a harm reduction program designed for women who abuse alcohol and drugs and who are situated in high-risk environments. Her main interests are in addictions, gender issues, violence, comorbidity problems, and qualitative research.

Clete Snell, PhD, is assistant professor of criminal justice. He received his PhD in 1999 from Sam Houston State University, in Houston, Texas, United States. Dr. Snell teaches in the master of science in juvenile justice online degree program and is currently chair of the PVAMU Distance Learning Council. His research interests include juvenile delinquency theory and juvenile justice policy. He has an ongoing grant with the Texas Department of Health to evaluate the enforcement of Texas tobacco laws. He recently published a book titled *Neighborhood Structure, Crime, and Fear of Crime: Testing Bursik and Grasmick's Neighborhood Control Theory*. He is currently writing another book titled *Big Tobacco and Youth Smoking*.

Va Nee L. Van Vleck, PhD, received her doctorate in economics from the University of Iowa, in Iowa City, Iowa, United States; she also holds a MA in economics from Columbia University in New York City, United States. Her present research emphases are in applied microeconomics, focusing on issues of labor, health, and the health care sector. She was a postdoctoral fellow in Public Health and Alcohol Studies, funded by the National Institute

on Alcohol Abuse and Alcoholism, at the Prevention Research Center and the Alcohol Research Group in Berkeley, California. During the fellowship, Dr. Van Vleck was mentored in the Drug and Alcohol Research Team in the Division of Research (northern California), Kaiser Permanente, in Oakland. Dr. Van Vleck's most recent research has focused on the adverse effects of alcohol abuse on individuals' incomes and likelihood of employment, positive third-party incentives to combat drunk driving, and the impact of uncompensated care on the financial status of San Joaquin Valley hospitals. Having taught in a wide variety of undergraduate settings, she is now an assistant professor at California State University, Fresno.

Meera Vaswani, PhD, earned her doctorate from Delhi University, a leading university in India. She is a member of the All India Institute of Medical Sciences, a prestigious and internationally recognized institute in India, where she was first a postdoctoral fellow, subsequently became a lecturer, and rose to be a professor in the same institute. She is now at the National Drug Dependence Treatment Centre, department of psychiatry, and at the All India Institute of Medical Sciences, in New Delhi, Delhi, India. During this time, she was elected as a fellow of the Royal Society, London, and as a member of the National Academy of Medical Sciences, India. She was selected for a United Nations fellowship, for which she worked at the University of Glasgow in the United Kingdom. She was one of the three scientists in the world selected for the Distinguished International Scientist Collaborative Award from the National Institute on Drug Abuse, National Institutes of Health, in 2007. She has completed several projects on addiction (alcohol and heroin addiction) and published many papers in both national and international journals. She has been a guest speaker at several national and international forums. She was the only delegate to be invited by Japan to represent India in the Asia Pacific Society of Biological Research in Alcoholism. Subsequently, she was elected to the board of directors of the Asia Pacific Society for Alcohol and Addiction Research.

Series Foreword

Tragically, most people across the globe have either struggled with a health- and relationship-damaging addiction or know someone who has. Addictions, broadly defined, have touched the lives of the majority of people in multiple cultures and locations. For centuries, numerous people have suffered with their addictions to alcohol and drugs as well as with other addictions, with often devastating outcomes. Sadly, important relationships, jobs and careers, and many lives have been lost due to the destructive power of addiction. These tragedies not only occur for those who suffer from addiction, but for their loved ones, coworkers, and community members, and for innocent victims who are perhaps in the wrong place at the wrong time when an addiction-related accident, crime, or violence occurs. The enormous cost of addiction in health care, traffic accidents, crime, violence, loss of workplace productivity, and broken families is too large to quantify. The global spread and success of organizations such as Alcoholics Anonymous (as well as related organizations such as Narcotics Anonymous, Sexoholics Anonymous, and Overeaters Anonymous) is a testament to the numerous people trying to recover from their addictions. Sadly, for every person seeking help for his addiction problem, there are likely to be many more people who never do. Clearly we need help to better understand, evaluate, treat, and cope with those who suffer from addictions.

In this remarkable four-volume set, *The Praeger International Collection on Addictions,* Angela Browne-Miller, PhD, DSW, MPH, has assembled an all-star and diverse team of leading experts from across the globe to provide a state-of-the-art understanding of the various facets of addiction. Each chapter

is written in a manner that is suitable for professionals working in the field as well as educated lay readers and those who either struggle with addictions or live or work with someone who does. What is especially remarkable about the four-volume set is its emphasis on addiction from around the globe, examining multicultural and international issues in addiction, as well as its coverage of so many multifaceted aspects of diverse addictions. For example, it certainly makes sense to cover fully addiction topics such as alcohol abuse and illegal drug use of, say, cocaine and heroin, yet chapters are also offered that examine addictions to caffeine, Internet pornography, work, television, intimate relationship abuse, and shopping. The chapters highlight biological, psychological, social, spiritual, and public health perspectives, with chapter authors who are psychologists, psychiatrists, other physicians, nurses, social workers, counselors, clergy, and other professionals. Dr. Browne-Miller is uniquely qualified to assemble this project as she is someone who has worked in the field of addiction for many years and has training in a unique blend of both the policy and the clinical sides of psychology, social work, education and public health.

The set is complete, state of the art, and highly informative and engaging. There is something for everyone interested in the field of addiction for professional or personal reasons. It is hoped that professionals and lay readers will greatly benefit from this important work and, in doing so, will find a way to improve the lives of those touched by addiction. It is my hope that both research and practice in the field of addiction will be greatly improved thanks to this set. The lives of those who either struggle with addiction or live with those who do will ultimately be improved thanks in part to this critical series. I am grateful to Dr. Browne-Miller and her assembled contributors for providing us all with such important and high-quality volumes that are now available to the public and professional communities. If only one life is saved or improved thanks to this set, it will be a great success in my view; yet I expect that many lives will ultimately be saved or greatly improved thanks to *The Praeger International Collection on Addictions*.

Praeger Series Editor, Abnormal Psychology

Preface

Angela Browne-Miller, PhD, DSW, MPH

Welcome to *The Praeger International Collection on Addictions,* addressing the insidious, pervasive, worldwide problem of human addiction. Addiction is clearly a global issue, touching every population, every nation, and every age group, people from all walks of life everywhere, directly or indirectly. Indeed, we are talking about an affliction of epic and epidemic proportions. We cannot look away. This is the health of the human species we are talking about.

The World Health Organization (WHO, 2008, p. 1) reports that "psychoactive substance use poses a significant threat to the health, social and economic fabric of families, communities and nations. The extent of worldwide psychoactive substance use is estimated at 2 billion alcohol users, 1.3 billion smokers and 185 million drug users" (p. 1). The WHO has estimated there to be at least 76.3 million persons with alcohol use disorders worldwide, and at least 15.3 million persons with drug use disorders worldwide. Alcohol use and abuse as well as the use and abuse of other psychoactive substances contributes to substantial individual and public health costs. Alcohol is but one substance playing a major role in this global addiction epidemic, but clearly there are many others, despite efforts to prevent new addictions and addicts, and to contain world drug markets (UN, 2008, p. 7).

For example, cocaine shares the stage with other abused drugs. Its prevalence is estimated to be up to 3 percent of the population in developing countries, with severe medical, psychological, social, and economic consequences including, but not limited to, the spread of infectious diseases (e.g., AIDS, hepatitis, and tuberculosis), plus crime, violence, and neonatal drug exposure.

Amphetamine-type stimulant (ATP) abuse is more widespread than cocaine abuse in at least 20 countries. Methamphetamine is presumed to lead in ATP addiction rates, with massive meth epidemics affecting several whole countries and entire regions of others. Social and public health costs of methamphetamine production and use via smoking, sniffing, inhaling, and injecting are staggering and growing in many regions. Additionally, there has been a global increase in the production, transportation, and use of opioids, especially heroin, with worldwide heroin production doubling or even tripling since the mid-1980s. Global estimates are that 13.5 million persons consume opioids, with 9.5 million of these being heroin users who face health risks including hepatitis, HIV, and death. And cocaine, meth, and heroin are just one piece of the picture.

The hotly debated drug cannabis—or the *Cannabis* family of drugs with the euphoric tetrahydrocannabinols, or THCs, including marijuana and hashish preparations—is said to be the most widely abused drug. Research is now suggesting the risk for acute health effects of long-term, chronic cannabis use, including potential impairment of cognitive development, learning, memory, recall, attention, and coordination. (Certainly the presence and extent of long-term effects of casual, of regular and of chronic use are as yet not entirely ascertained.) Both casual use of marijuana and medical use of forms of what is termed medical marijuana (e.g., dronabinol sold as Marinol, the cannabidiols, or CBDs) are subsets of all forms of cannabis use. There are legitimate therapeutic uses of this substance, and these uses make it all the more difficult to regulate marijuana drugs fairly and effectively.

We have here, and in the use of any psychoactive medication for therapeutic purposes, a gray area in which illicit and licit use overlap and can confuse many adult and youth consumers, researchers, and policy makers, among others. In the emergence (or reemergence in history, some will argue) of cannabis as medicine, we have a model for asking which, if any, abused substances may, and perhaps should, be repurposed for medicinal or treatment purposes, and how this is best done against the backdrop of the global addiction epidemic.

Regarding marijuana, we are confronted with the age-at-first-use issue, which suggests that early onset of regular cannabis use may affect not only the academic and social performance of children and teens, but also their future susceptibility to addictions. It was in the 1960s that the hotly debated label "gateway drug" was applied to marijuana, perhaps to scare off its use, and only in the decades since have we understood better what this might actually mean to us. It may not be that marijuana provides the training wheels for drug addiction, but rather that it may serve as an indicator of future use of the same or other drugs. Of course, today, with so many young people having access, and taking advantage of their access, to the whole range of psychoactive substances,

the question of which drug might be a gateway to which other drug dissolves into the fury of the countless addiction conundrums of our constantly changing times.

There is always a new, or rediscovery of an old, addiction on the horizon. There is also always a new (or rediscovered) psychoactive substance for exploratory, research, and perhaps even treatment purposes emerging (or re-emerging). Labeling all of these substances as addictive right out the gate may or may not serve science or even humanity itself. How can we be certain the approach we take will be a constructive one? With new legal (where licensed for development and experimentation) and illegal (where not being utilized under protection of law) so-called designer drugs emerging at a staggering rate, we must admit that we cannot know what is coming, nor whether the new compound will be addictive, or popular, or of medicinal value, or even accessible. We can only imagine what the brave new world of chemistry will continue to bring and whether any benefits can be made available without accompanying risks and detriments.

Moreover, the desire to explore and achieve various altered states of consciousness in religious, spiritual, ritual, and perhaps even treatment settings, is unfolding into debates about rights (Browne-Miller, 1989, pp. 258–260). When there is no demonstrated risk to self or others, we have to ask ourselves whether this right should be protected, especially in circumstances of traditional uses for religious purposes. Again, this dilemma arises against the backdrop of the global and runaway epidemic of substance addiction. How do we balance pressures from opposite directions (freedom protecting the right to use versus control to stop injury and costs of using), when these pressures are not balancing themselves?

Also against the backdrop of global addiction levels, is the massive level of addiction to legal drugs, many of which are heavily marketed to consumers. The legal drug tobacco is said to be the substance causing the most damage globally, with at least one-third of the global population smoking. While smoking rates may be dropping in some countries, the reverse is true globally. As just one of its effects, smoking accounts for some 90 percent of all lung cancer in men and 70 percent of all lung cancer in women. And yet tobacco use is overwhelmingly viewed as being "the single most avoidable cause of disease, disability and death" in the United States (CDC, 2008, p. 2).

And perhaps nothing here has touched so many lives as the regularly consumed, legal drug caffeine, perhaps because coffee drinking is considered so very normal and acceptable, even necessary, in everyday life. However, we must ask whether there is a level of caffeine use that is abuse—or perhaps self-abuse. Surely we do not want to throw caffeine use onto this list of substance abuses

and addictions. Still, a collection on addiction would not be complete without at least touching on this matter, and therefore we do address caffeine herein.

And then there are also the addictions to prescription drugs (such as Vicodin, Percocet, OxyContin, and Darvon), which we find increasing rapidly and already a worldwide phenomenon, with the most commonly abused prescription drugs being opiates. The U.S. National Institute of Mental Health characterizes prescription drug addiction as the second most common illegal use of drugs in the United States, second only to marijuana.

We must also note that unusual, virtually invisible psychoactive substances are working their way into our everyday lives. Household and workplace products contain many volatile substances, exposure to which can be not only damaging, but also intoxicating, and perhaps addicting. Although this domain of substance use and abuse is not specifically addressed herein, we must acknowledge the severe and perhaps largely unmeasured effects of this domain of even routine, legal substance use as well as unintentional and intentional abuse.

So as not to exclude nonsubstance addictions in this overview of addiction today, the fourth volume in this collection on addiction reminds us that work, television, shopping, food (with its particularly difficult-to-call-addiction nature), intimate partner relationship, gambling, Internet, and even pornography addictions make their marks in our lives, either indirectly or directly. These behavioral, nondrug addictions, which occur alone and co-occur with each other, also do co-occur with substance uses, abuses, and addictions. Every human being is in some way affected by the prevalence of behavioral addictions, either directly or indirectly. The study of behavioral addictions teaches us a great deal about addiction itself.

All this suggests the picture of an addiction-prone and largely chemically dependent human species. And this is just the tip of the iceberg. With this truly incomplete laundry list of human fallibilities—or better stated, perhaps, human *vulnerabilities*—this four-volume collection on addiction is truly that: a collection of perspectives, approaches, and findings. Each chapter is a snapshot of the work and thinking taking place in many fields of addiction. Contributors to this collection work with addiction on the various social, philosophical, psychological, spiritual, policy, political, economic, biological, and even cellular levels, all places where this thing we call "addiction" lives. Certainly this collection would have to comprise hundreds of volumes, rather than the four that it does, to address addiction in all its iterations.

Here we give voice to a diverse cross section of perspectives on addiction. This is in no way an exhaustive cross section (of either perspectives or addictions); rather, this collection suggests the diversity of perspectives, theories, practices, and types of addiction in the field—or better stated, *fields*—of addiction. The four volumes of this collection represent the voices of those who have

graciously and even bravely stepped forward from their numerous countries and arenas of work to contribute their ideas, research, and experiences. Certainly there are many others out there, many other aspects of addiction, and many other drugs and objects of addiction not addressed in these volumes.

This work is divided into four volumes, with the first three addressing addictions to substances and the fourth addressing behaviors that show characteristics of addiction. Volume 1, *Faces of Addiction, Then and Now,* offers a sampling of the depth and breadth of addiction today and in the past; volume 2, *Psychobiological Profiles,* surveys some of the interlinked psychological and biological aspects of addiction; volume 3, *Characteristics and Treatment Perspectives,* samples the range of addiction treatment perspectives and approaches; and volume 4, *Behavioral Addictions from Concept to Compulsion,* gives the reader a glimpse of behavioral addictions other than substance addictions.

Readers will observe that the content of these volumes is indeed diverse and in no way represents any one view or theory of addiction. There are many other voices out there who must also be heard, and only in the interest of time and space are we stopping here, at these volumes. The content of these volumes in no way expresses the opinion of this editor, nor of this publisher, regarding what is right, best proven, or even most en vogue in the addiction world; rather, this *International Collection on Addictions* seeks a display of, a sampling of, the diversity of effort to quell the detrimental effects of addiction on individuals, families, communities, societies, economies, and international relations; on ecologies; and in fact, on the human population of planet Earth.

Introduction to Volume 2: Where Psychology and Biology Meet

Angela Browne-Miller, PhD, DSW, MPH

This is Volume 2 of *The Praeger International Collection on Addictions: Psychobiological Profiles*. Here we sample the array of understandings of addiction as we know it today. The intent is to share a sampling from a wide range of material, not to hone in on any one drug addiction, or any one mechanism of addiction, but rather to establish the multilevel (social, psychological, biological) omnipresence of addiction, its reality and dangers. As our scientific understanding of the psychological, neuropsychological, molecular, genetic, and related, even inextricably linked, bases of addictions and interacting conditions is rapidly increasing, there is hope that augmented and new approaches to addiction can turn the tide of this mounting global condition.

We begin "Part I: Issues" with chapter 1, "Addiction and Health Promotion," by Kathleen Bradbury-Golas, DNP, RN, APN, of the Richard Stockton College of New Jersey, in Pomona, New Jersey, United States, and also a nurse in private practice in New Jersey. Bradbury-Golas reminds us that substance abuse is harmful both directly and via the negative lifestyle behaviors that accompany it. Relapse prevention therapy and other treatments surely can decrease the conditions which would invite relapse. Primary care practitioners must recognize what is involved here, and collaborate with addiction specialists to achieve positive health outcomes. Clearly, collaborating or at least coordinating to treat and curb addiction is going to be more effective than working in isolation. This collaboration flows in both directions. Bradbury-Golas also notes that what is most hopeful in the primary prevention of addiction—treating it before it occurs—is the addiction vaccine. According to the U.S. National Institute on

Drug Addiction (NIDA), this vaccine is likely to be available within from one to 10 years. One vaccine in this genre is TA-CD, which prevents the cocaine metabolite from ever reaching the user's brain. Like any other vaccine, TA-CD causes the immune system to create antibodies that attach to cocaine molecules, which in turn are broken down by enzymes found in the bloodstream, with the result that both the desire for and the "pleasure" of cocaine use is prevented.

Next, in chapter 2, Ted Goldberg, PhD, at the department of Social Work at Stockholm University, Stockholm, Sweden, and also at the department of Caring Sciences and Sociology at the University of Gävle, in Gävle, Sweden, shares his insights into the process of "Becoming a Problematic Consumer of Narcotics." Based on studies in Stockholm, Sweden over a four-and-a-half-year period, Goldberg presents a four-stage life-history model indicating why drug use begins and continues. Goldberg applies a life development or life-history career model to explain what brought his subjects to, and led them to continue, their drug use. Discussion of the "future problematic consumer" of narcotic drugs includes a review of symptoms that precede first consumption of narcotics. Goldberg notes the "destructive life-project" he has seen in his subjects: "The problematic consumers of illicit substances I studied are extremely self-destructive people who lead lives that slope steeply toward extermination." Those self-destruction and self-extermination tendencies that may be present in drug addiction behavior warrant our direct attention. We must ask what these behaviors may be telling us about ourselves and about our species.

Ann N. Dapice, PhD, of T. K. Wolf, Inc., an American Indian-focused addiction treatment program in Tulsa, Oklahoma, United States, contributes chapter 3, "Adaptation and Addiction." Have we outlived the usefulness of once-essential survival traits? Do we therefore walk around with antiquated brains and nervous systems that are not adapting rapidly enough to our changing environments—or are we more than ever in need of these age old basic functions, such as the fight or flight response? Addiction is nothing new, and in a species scenario in which the environment may change more rapidly than we do, addiction, that enduring and self-exacerbating human behavior, persists. Dapice writes: "Food and tobacco are connected to other addictive substances in important evolutionary and physiological ways. Understanding the co-development of mammalian brains and ancient psychotropic plants, as well as the implications of ancient psychotropic substance abuse in altering mammalian brains, helps assess the causes and effects of addiction in today's world." Dapice also points out that some things can be used addictively by some people while not addictively by others.

Scott E. McClure, PhD, at the University of California San Diego, department of Psychiatry, Center for Criminality and Addiction Research, Training,

and Application (CCARTA) in San Diego, California, United States, authors chapter 4, "Co-occurring Trauma and Substance Use Disorders with Criminal Offenders." McClure points out that individuals who have been abused physically and/or sexually, and those who have "criminally involved" families, have increased chances of being incarcerated and of being traumatized. Hence, post-traumatic stress disorder (PTSD) is common among this group. McClure also notes that the majority of persons in substance abuse treatment programs have experienced traumas, and that there is a significant overlap between "criminogenic" risk factors and those for substance abuse, trauma, and incarceration itself. McClure adds that: "Safety and coping should be the primary focus for individuals in corrections-based treatment. This is especially true for individuals with severe forms of PTSD and other co-occurring disorders who may decompensate upon addressing trauma symptoms. After clients have successfully developed skills to regulate emotions and cope with trauma symptoms without substance use, they may progress to processing the trauma through exposure therapy, and eventually shift their focus on reconnecting to a functional life."

Joan Mathews-Larson, PhD, LADC, and Mark K. Mathews, LADC, BCCR, both of the Health Recovery Center in Minneapolis, Minnesota, United States, add another aspect of addiction, in chapter 5, "The Role of Allergies in Addictions and Mental Illness." Mathews-Larson and Mathews bring together the sciences of human ecology (which says, among other things, that human behavior and mental health can be profoundly affected by substances in our environment) and orthomolecular medicine (which concentrates on particular vitamin and mineral molecules present in the human body to treat particular diseases). Mathews-Larson and Mathews say that both human ecology and orthomolecular medicine must be involved in addressing allergies that affect mental health to reduce inflammatory responses destabilizing the brain, and related tendencies toward addiction. Special attention to "delayed onset allergies" is important, as these allergies can produce numerous symptoms and affect every organ in the body. As Mathews-Larson and Mathews explain: "Unlike the quick response . . . immediate-onset allergy, [delayed onset] symptoms come on slowly—from two hours to several days. Ingesting allergy-provoking foods prompts the gradual formation of immune complexes until finally they overload the immune system's ability to clear them out. That's when symptoms are felt. Unfortunately, the time differential makes symptoms difficult to link to the foods that cause them. And because the initial response to allergy-provoking foods is often a pleasurable, endorphin-like effect, it becomes even more difficult to accept that they are a problem. In the end, a pattern, initiated and sustained by these foods, contributes to an addictive progression of disease." Here we have a model for the pathogenesis of alcoholism, proceeding the way delayed onset

allergic reactions proceed: "Whether responding to alcohol, drugs, or allergy foods, allergic/addictive chemistry follows the same course because the body recognizes all these substances as toxins, and turns to the same system—the immune system—to clear them. It's when the toxic load exceeds the immune system's ability to clear it that inflammation begins its destructive process."

"Part II: Bodies" begins with consideration of something that is oft overlooked in discussions of addiction—the all-too-common effects of caffeine, the world's most popular psychoactive drug. Kyle M. Clayton, MS, and Paula Lundberg-Love, PhD, both of the University of Texas at Tyler (UTT), in Tyler, Texas, United States, address caffeine as addictive in chapter 6, "Caffeine: Pharmacology and Effects of the World's Most Popular Drug." In the United States, about 90 percent of all adults consume caffeine on a daily basis. Caffeine withdrawal brings on a range of symptoms, and caffeine use affects health in a number of ways. Caffeine intoxification, something most of us rarely think about in daily life, is indeed possible when the level of 250 mcgs is consumed, and doses of caffeine over 5 to 10 grams can be lethal.

Dirk Hanson, MA, of the blog, Addiction Inbox, and freelance science writer based in Ely, Minnesota, United States, offers another commonly overlooked aspect of addiction in terms of its potential severity and symptoms in chapter 7, "Marijuana Withdrawal: A Survey of Symptoms." With approximately 14 million Americans smoking marijuana regularly, we cannot avoid noting the presence of withdrawal symptoms among many heavy users. In fact, there is growing evidence that there is a "marijuana withdrawal syndrome" characterized by restlessness, anxiety, hostility, depression, sleeplessness, loss of appetite, and a mental state described as "inner unrest." (Additional withdrawal systems are being detected every day.) Clearly, marijuana withdrawal has gone unnoticed or less noticed as withdrawal from other substances is so much more severe, and better documented.

We then move into three chapters that delve into what is considered a "more serious" addiction, methamphetamine addiction. Mary F. Holley, MD, of Mothers Against Methamphetamine in northern Alabama, United States, and the Alabama State Attorney General's Methamphetamine Task Force, shares her look at "Marijuana Interaction with Methamphetamine Addiction" in chapter 8. Holley informs us that marijuana affects the brain in many of the same areas that methamphetamine does. Injury to the hippocampus and frontal lobes arising in heavy marijuana users can be amplified by use of methamphetamine. Holley refers to the endocannabinoid system here, noting that early use of marijuana can affect adolescent neurodevelopment, as can early meth use. Together, marijuana and meth set the stage for severe effects on development.

Herbert C. Covey, PhD, of the Adams County, Colorado, (United States) Social Services Department, and instructor at the College of Continuing Education, University of Colorado at Boulder, Colorado, United States, asks "What Is Methamphetamine and How and Why Is It Used?" in chapter 9. Covey explains that "Meth abusers typically take the drug early in the morning and in two- to four-hour intervals, similar to being on a medication. In contrast, cocaine abusers typically take the drug in the evening and take it over a period of several hours that resembles a recreational-use pattern. They typically continue using until all of the cocaine is gone." Covey reminds us that a certain amount of meth use, and meth addiction, is hidden while taking place right before our eyes: "Some meth addicts use at levels that allow them to maintain jobs, homes, some money, and at least the appearance of being in control."

In chapter 10, Kathryn M. Wells, MD, at the Kempe Center for the Prevention and Treatment of Child Abuse and Neglect and the Health Sciences Center, both at the University of Colorado at Denver, in Denver, Colorado, United States, reports on "The Short- and Long-Term Medical Effects of Methamphetamine on Children and Adults," which are marked and costly to individual lives and to societies, in fact, to entire nations—with global ramifications. She states, "Meth use and abuse in this country [United States] has far-reaching ramifications for not only the user but for society." Wells calls for "continued collaborative efforts" as these "are critical to advancements in understanding the medical effects of meth on the users and children who are exposed."

In a look at the dangers of "vapors," Jace Waguspack, BS, and Paula K. Lundberg-Love, PhD, at the University of Texas at Tyler (UTT), Tyler, Texas, United States, contribute their research in chapter 11, "Vapors May Be Dangerous If Inhaled: An Overview of Inhalants and Their Abuse." Waguspack and Lundberg-Love tell us that the word *inhalant* is used to describe a "heterogeneous group of chemicals that share a common route of administration," reporting that inhalant use is a "serious problem, particularly among young people. The incomplete knowledge of the mechanisms of action for some of these substances, combined with insufficient resources for the treatment of the abusers and the complexity of the issues surrounding inhalant abuse, make it difficult for these individuals to receive the help that they need."

This is followed by chapter 12, "The Effects and Abuse Potential of GHB: A Pervasive 'Club Drug,'" submitted by Bethany L. Waits, BA, at the University of Texas at Tyler (UTT), Tyler, Texas, United States, and Paula K. Lundberg-Love, PhD, also at UTT. Gamma-hydroxybutyrate (GHB) is a widely used drug—in its purest form, a white powdery substance soluble in water, sometimes found in tablet or a capsule form, sometimes injected into the

bloodstream, and distributed, both legally and illegally, as a colorless, odorless, and tasteless solution. Use of GHB has undergone a marked increase since its discovery in the late 1960s. It affects the brain as Waits and Lundberg-Love explain: "Once ingested, GHB acts by depressing or downregulating the activity of the central nervous system (CNS), including the brain and the spinal cord, and its effects are similar to other CNS depressants such as alcohol and benzodiazepines (BZDs)." GHB offers an example of the novel drug model: "Although GHB was initially synthesized for use as an intravenous anesthetic for surgical procedures, it has since been marketed therapeutically as a dietary supplement, an anabolic agent, and a drug for the treatment of narcolepsy." Additionally, GHB has been studied for its relief of withdrawal symptoms, including those from alcohol. Against the backdrop of treatment uses of GHB is the disturbing undercurrent of illegal GHB abuse by adults and teens, and even children.

In chapter 13, "HIV and Addiction from an African Perspective: Making the Link," we have the work of Mary Theresa Webb, PhD, of the Global Outreach for Addiction Leadership and Learning (GOAL) Project based in Aliquippa, Pennsylvania, United States; also of the International Substance Abuse and Addiction Coalition (ISAAC) based in the UK; and of the OPORA Training Center in Moscow, Russia. ("Opora" is the Russian word for "support." Moscow based nongovernmental OPORA works with the Russian government to fight addiction, has trained over 3,000 people in addiction and Twelve-Step programs, and has implemented 60 recovery groups in 31 cities in Russia.) Webb writes this chapter with Donald Omonge, BA, of the Substance Abuse Recovery and HIV/AIDs (SARAH) Network, a Kenyan faith-based organization. Webb and Omonge advocate that it is essential that special programs be suited specifically to the African cultures and customs in order to effectively combat the spread of HIV/AIDS. They state that "implementing model programs specifically suited to African cultures and customs to combat the spread of HIV/AIDS must include training components that cross both disciplines (HIV/AIDS and alcohol and other drugs) [and] . . . must be geared to those within the culture who are most effective as change agents." Webb and Omonge also note that "unless GBV [gender-based violence] and rape of vulnerable women and children is curtailed through establishing shelters and a legal protection system, very little hope exists for curbing the spread of the HIV virus in Kenya as well as in other African countries." Also note that injected heroin was determined to be the major risk factor for the spread of HIV; however, now alcohol consumption has became a greater risk than injecting heroin.

And, finally, closing Part II of this volume, in chapter 14, "Drug Abuse–Related HIV/AIDS Epidemic in India: Situation and Responses," Atul

Ambekar, MD, and Meera Vaswani, PhD, at the National Drug Dependence Treatment Center, Department of Psychiatry, All India Institute of Medical Sciences, in New Delhi, Delhi, India, insist that we take heed of a serious aspect of HIV/AIDS in India: "The first case of HIV was detected in India in 1986. In the past two decades since then, the HIV epidemic continues to grow unabated in India." Yet, there is "still no generalized epidemic of HIV in India at the national level. . . . The national level data should, however, be interpreted with caution. India, being a vast and heterogeneous country, has a heterogeneous HIV situation. It has often been commented that there is not one, but many, simultaneous HIV epidemics currently spreading in India," Ambekar and Vaswani write. Certainly, there are harm-reduction services in India; however, they are not enough: "There is a visible and obvious gap in terms of the number of services available and the requirements of these services. Without a rapid scale-up in the number and the quality of the services, [it will be] very challenging to realize the goal of halting and reversing the HIV epidemic."

"Part III: Psychobiologies" moves deeper into various psychological and biological aspects of addition, beginning with chapter 15, "Alcohol Abuse: Impact on Vital Brain Functions and Societal Implications" by Mary Theresa Webb, PhD. In this chapter, Webb notes that the European Union countries and the United States have sounded the global alarm that we are destroying our brains as well as our bodies with the high level of alcohol use around the world. Webb reports on the damaging effects of alcohol on vital brain functions, and the related profound effects on the societal level. Webb notes that neuroimaging study data reveal an alarming increase in heavy alcohol use, with related risks in older adults of loss of cognitive abilities, increased risk of cardiovascular incidents, and dementia.

Chapter 16, "Addiction and Cognitive Control," contributed by Vicki W. Chanon, PhD, and Charlotte A. Boettiger, PhD, both at the Behavioral Neuroscience Program at the University of North Carolina at Chapel Hill in Chapel Hill, North Carolina, United States, characterizes substance use disorder as a neurobehavioral disorder, influenced by disruptions in the cognitive control functions of the brain. With the advent of cognitive neuroscience tools, we are now in a position to make great strides in understanding the brain mechanisms of addiction. Chanon and Boettiger detail the functions of cognitive control and explain that "addicts disproportionately direct their attentional resources toward stimuli associated with their abused substance," referring to "abnormalit[ies] in attentional allocation to drug cues in addicts." Further research along these lines can lead to new treatments, and effectiveness in these treatments, of substance abuse disorders. We have just begun to understand the effect of cognitive regulation on addiction etiologies.

Next, Giuseppe Carrà, MD, MSc, PhD, Consultant Psychiatrist and Research Fellow at the University College London, in London, England, and Sonia Johnson, MSc, MRCPsych, DM, Clinical Lecturer at the University College London, share their work on "Schizophrenia and Substance Misuse" in chapter 17. Comorbid substance abuse problems and schizophrenia or other severe psychoses are associated with poor treatment outcomes. The numbers of those affected by this dual condition are significant: U.S. data show that it may be as much as half of persons with schizophrenia who have co-occurring substance abuse disorders. There is a significant overlap between mental illness and substance abuse, one that insists we do not forget it lest we miss a major subpopulation of persons who are addicted.

Mary F. Holley, MD, of northern Alabama, United States, returns in chapter 18, with her look at the "Neural Basis for Methamphetamine Addiction—Rethinking the Definition of Dependence." As indicated by the title, Holley moves for the rethinking of the very definition of dependence. Motivated by her great concern regarding the high usage of methamphetamine and the severe consequences of this, Holley reminds us that low availability of treatment for meth addiction places the burden on the corrections system. Holley writes, "addiction is a brain disease and not merely a moral failure." Rethinking addiction to fully incorporate this perspective, this reality in fact, will shift the entire field of addiction.

This is followed by chapter 19, "Neurobiological Mechanisms and Cognitive Components of Addiction," written by Jorge Juárez, PhD, and Olga Inozemtseva, PhD, both at the Universidad de Guadalajara in Guadalajara, Jalisco, Mexico. Juárez and Inozemtseva note that the boundaries between the concept that addiction is a public health concern and the concept that it is a problem of inadequate social adaptation are blurry. Furthermore, the pleasure center of the brain, the mesolimbic-cortical system, is central in that several potentially addictive substances act upon it. To effectively address addiction, we must take all of this and more into account from a highly interdisciplinary perspective.

And Mary F. Holley, MD, speaks to us again, in chapter 20, with her report on "Fetal, Neonatal, and Early Childhood Effects of Prenatal Methamphetamine Exposure." Methamphetamine, unlike cocaine, is used by women in equal rates to men, and is far more toxic than cocaine, with a far more intense addiction, and a far more rapid disintegration of personal and family life. Children exposed to methamphetamine in utero are highly likely to show learning disabilities and neurologic dysfunction, which is indeed a public health disaster.

Emmanuel S. Onaivi, MSc, PhD, at William Patterson University in Wayne, New Jersey, United States, also of the U.S. National Institute of

Health (NIH), headquartered in Bethesda, Maryland, United States, writes on the "Endocannabinoid Hypothesis of Drug Addiction" in chapter 21. Onaivi argues that pharmacological treatment of drug addiction is disappointing for the most part, and that new approaches are very much needed. Onaivi tells us that, at least to some extent, misconceptions of addiction as a willpower and morality problem have receded, and recognitions that addiction is a brain disease have surfaced. However, misconceptions holding that dopamine is released in the brain's reward system with all drug use linger. Onaivi reports that many substances, or "agents" as they are also called, do not activate midbrain dopamine-mediated transmission and therefore this popularly applied marker (the dopamine marker) is no longer supporting the perception that drugs are merely activating the brain's reward system. Onaivi contends that in the central nervous system the role of marijuana-like substances produced by the human body, endocannabinoids, must be addressed.

Chapter 22, "Regulation of μ-Opioid Receptor Desensitization in Sensory Neurons," is contributed by Cui-Wei Xie, MD, PhD, at the Department of Psychiatry and Biobehavioral Sciences, David Geffen School of Medicine, and the Semel Institute for Neuroscience and Human Behavior, University of California Los Angeles (UCLA), Los Angeles, United States. Here, Xie calls for further study to "identify and characterize interactions between endogenous receptors in native neurons." Such research may reveal to us mechanisms of "control of opioid receptor signaling" facilitating the strength of "treatment of opiate tolerance and dependence." While most studies to date focus on systems where receptors are "overexpressed," Xie writes that "emerging evidence indicates that formation of hetero-oligomers [between receptors] permits cross regulation of receptor signaling and trafficking, which in some cases, leads to the development of cross desensitization." Such research is key to advancing the power and focus of the treatment of addiction on the cellular level.

Each of the contributors to this volume and the other volumes in the *Praeger International Collection on Addictions* is working on one of the many frontiers of modern addiction research and treatment. And all presented herein is surely just the tip of the iceberg, a sampling of what we know and what we think we know about how addictions work as these addictions feed this global epidemic we call *addiction*. The global picture is both one of grim need and one of unwavering hope. If somehow the goal of massive international collaboration to stop both addiction and the conditions it results in can be realized, perhaps hope will triumph.

Chapter **1**

Addiction and Health Promotion

Kathleen Bradbury-Golas, DNP, RN, APN

Substance abuse interferes with a person's life purpose and interpersonal relationships. Health care researchers expect that the overuse of alcohol and illicit medications will impact upon society's health for decades. The impact of substance abuse, addiction, and relapse is far-reaching. Cardiovascular disease, stroke, cancer, human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), hepatitis, and lung disease can all be affected by drug abuse (National Institute on Drug Abuse [NIDA], 2005). Some of these effects occur when drugs are used at high doses or after prolonged use; however, some may occur after just one use.

Substance abuse harms the body not only from the use of the substance itself but from the negative lifestyle behaviors in which the user participates. Poor nutrition, tobacco smoking, insomnia, and lack of exercise all impact on the physical well-being of a person. Pregnant drug users not only have poor self-care, they also bear lower birth weight and addicted babies who must go through withdrawal soon after birth. These negative lifestyle practices create an environment of continued addiction by decreasing the energy level and self-esteem of the abuser (Apovian, 2006). Recovery becomes almost impossible. If an addict manages to achieve a recovered state, he may believe that the other habits don't matter. For example, smokers who are in recovery believe that smoking cessation will threaten the other substance recovery. However, people are more likely to die of tobacco-related diseases than from alcohol-related problems (American Academy of Family Physicians, 2006).

To add to the problem, the 2005 Monitoring the Future and the Centers for Disease Control and Prevention's (CDC) Youth Risk Behavior Surveillance

System (YRBSS) found heroin use beginning as early as 8th grade. The 2005 YRBSS reported 2.4 percent of 8th- to 12th-grade students using heroin at least once in their lifetime. Early-age heroin use will not only complicate the physical and mental health of the individual, but can lead to lost time in the person's most productive years. They are at risk of their educations being interrupted or negatively affected, which in turn, may influence the ability to make necessary lifestyle changes later in life.

The user's obsession with substance use disrupts family life and creates a destructive pattern of a co-dependency within the family; family members supply the user with money to purchase the substance, thereby denying the problem. Families may split apart, either from separation or divorce due to spousal addiction or children being placed in foster care, group homes, or with other relatives due to parental addiction. Employed drug abusers are more likely to have occupational accidents, affecting either themselves or others. These accidents cost their employers two times more in medical and worker compensation claims than their drug-free workers (NIDA, 1999). About 70 percent of crime is drug related and the judicial system in several states has had to resort to drug court (Herbert & Shaw, 2007).

In order to maintain recovery, addicts not only have to resist the use of mood-altering substance(s) but return to a healthy physical state, repair interpersonal relationships, and develop some sense of peace or spirituality. To accomplish this, substance abusers move through a process in which decisions are made to not only initiate the behavior change but to maintain it (Bandura, 1986; Miller & Rollnick, 1991; Ritter, 2002). Many factors, such as increased self-efficacy and educational level, have been identified as important to the recovery process. Other factors, particularly depression, have been shown to increase the likelihood of relapse, preventing recovery from occurring (Compton, Cottler, Jacobs, Ben-Abdallah, & Spitznagel, 2003; Stein, Solomon, Herman, Anderson, & Miller, 2003; Subramaniam, Lewis, Stitzer, & Fishman, 2004). Research has not shown definitive evidence on what triggers relapse or what changes recovering abusers have made in their lives to decrease the incidence of relapse, thereby maintaining a healthy, productive life. Once recovering abusers have not used drugs, do they practice healthy lifestyle behaviors? No studies have focused on substance abusers health behaviors while in recovery.

RESEARCH FINDINGS

Maslow's theory of human motivation (1970) suggests that as persons experience higher levels of need satisfaction, there is less lower-level tension and they are motivated to make better decisions about health promotion. Much of

the early research regarding health and illness used theoretical models that primarily centered on illness prevention, not health promotion. These prevention models include but are not limited to the Health Belief Model (Rosenstock, 1960), Theory of Reasoned Action and Planned Behavior (Ajzen, 1991), and the Relapse Prevention Model (Marlatt & Gordon, 1985).

Drug relapse prevention treatment models have long been based on social cognitive and behavioral theories that transition the addict through the withdrawal phase to identifying and preventing high-risk situations for relapse (Witkiewitz & Marlatt, 2004). All acknowledge self-efficacy as essential in behavior change. Self-efficacy is defined as the degree to which an individual feels confident and capable of performing a certain behavior in a specific situation (Bandura, 1977). Increased self-efficacy is a strong predictor of outcomes in all types of addictive behavior, including gambling (Sylvain, Ladouceur, & Boisvert, 1997), smoking, and drug use (Sklar, Annis, & Turner, 1999). Not only has self-efficacy been a major determinant in relapse prevention, it is also a key factor in maintaining any health-promoting behavior.

Therefore, once substance abusers stop using and have found the motivation to abstain, they not only begin altering their brain chemistry but build new identities (Spriggs, 2003; Wilcox & Erikson, 2004). With improved self-efficacy and relapse prevention skills, the substance abuser reaches a nonusing state, a chosen behavior change. This builds a firm foundation for future health behavior changes. However, presently, health promotion practices of substance users who are maintaining a substance-free lifestyle have not been described in the literature.

Though much of the research on health promotion has described various populations of interest, few studies have been done that utilized an intervention to achieve a behavior change. Nola Pender's revised Health Promotion Model (HPM) combines numerous constructs from expectancy-value and social cognitive theories within a nursing holistic perspective (Pender, Murdaugh, & Parsons, 2006). The model proposes a positive and humanistic definition of health and though disease is present, it is not the most important element. Once a person commits to the behavior change, his affect toward the behavior increases self-efficacy, which in turn, increases the likelihood of enacting the behavior. As the addict attains substance abstinence, his confidence to maintain the behavior increases, which in turn, gives the addict strength to continue the recovery state. Another proposition of the model states that as self-efficacy increases, the number of perceived barriers, such as the loss of a high and withdrawal symptoms, to a specific health behavior decreases. However, in the end, if addicts do not believe that they can succeed at quitting, they will relapse and continue to use. Measuring health promotion can be completed through use of

the Health Promotion Lifestyle Profile II. This reliable and valid instrument includes the six subscales of health promotion: nutrition, physical activity, health responsibility, spirituality, interpersonal relations, and stress management. Much research utilizing this model has centered on adopting improved nutrition and physical activity into a healthy lifestyle.

Many other factors affect the adoption of health-promoting behavior, such as unavailability of primary prevention facilities (Wilson, 2005), obesity (Nies, Buddington, Cowan, & Hepworth, 1998), and internal motivation (Weitzel & Waller, 1990). Internal motivation and recovery engagement have been shown to be major determinants of relapse prevention (Brown, 2003; Zeldman, Ryan, & Fiscella, 2004). Internally motivated study participants had lower relapse rates and higher self-efficacy. Therefore, educational level and increased self-efficacy are the strongest predictors of health promotion in any population (Ahluwalia, Mack, & Mokdad, 2005; Gillis, 1993; Holloway & Watson, 2002; Kawabata, Cross, Nishioka, & Shimai, 1999; Kim, Jeon, Sok, & Kim, 2006; Martinelli, 1999a, 1999b; McCleary-Jones, 1996; Washington, 2001). In one of the few studies using intervention to change health behavior, Sorensen et al. (1998) conducted a WellWorks Study at one of four intervention centers that were participating in the Working Well Cooperative. After assessment for and education regarding weight management and smoking cessation, results showed that those who received ongoing education and assessment reduced their fat consumption significantly. However, smoking cessation was not statistically changed. The researchers found that health promotion programs are most effective among white-collar workers, verifying the previous research findings that education is a strong predictor of lifestyle behavior change.

Much research has been completed on the importance of interpersonal relationships and health. Social support has contributed to physical health by changing diet and exercise regimens, reducing smoking and alcohol use, promoting better sleep and adherence to medical regimens, thereby improving health (Cohen, Underwood, & Gottlieb, 2000). Berkman and Syme (1979) found during a nine-year period that those people who had no social or community ties were more likely to die of all causes than those who maintained family, friend, and community relationships. Allgower, Wardle, and Steptoe (2001) found that low social support was directly related to sedentary lifestyle, poor sleep, and risky behavior such as not wearing seatbelts and not using sunscreen. Numerous other studies have linked poor social support with excessive alcohol consumption, tobacco use, and drug use (Barnes, Reifman, Farrell, & Dintcheff, 2000; Fisher & Feldman, 1998; Shedler & Block, 1990). Other study results demonstrated that intrapersonal determinants accounted for 52 percent of drug use relapses and a person's perception of setting risk for relapse

was the most important element in determining future relapse (Cummings, Gordon, & Marlatt, 1980; Walton, Reischl, & Ramanthan, 1995). Jackson's (2006) study found that depressive symptoms and perceived social support contributed significantly to the prediction of healthy nutritional practices, exercise, substance abuse, and adherence to medical regime in women but not in men.

Lastly, stress management and spirituality are an important part of wellness and are indispensable to maintaining health. Behavioral coping skills have a positive effect to manage work-related stress (Gardner, Rose, Mason, Tyler, & Cushway, 2005). Spirituality, or spiritual growth, is a component of health promoting self-care behavior, or health responsibility. It is a concept that has long been addressed as essential in chronic illness, quality of life and death. A study by Daaleman and Kaufman (2006) found that those participants who reported greater spirituality ($p < 0.01$) were more likely to report less symptoms of depression. Callaghan (2005) investigated the relationship between self-care behaviors and self-care efficacy and found that spiritual growth is significantly related to an adolescent's initiative and health responsibility. This is consistent to existing literature regarding the direction of similar associations with spirituality (National Institute of Mental Health, 2006).

Only one research study has explored health promotion and drug users. Branagan (2006) evaluated a nurse-led education program on preventing overdose among 23 methadone treatment clinics in Ireland. The education program consisted of leaflet and poster education promoting overdose prevention and how to deal with an overdose should it occur. The posters and leaflets were placed in high visual impact locations in 15 clinics in Ireland. A total of 200 questionnaires were distributed and 81 percent of the participants responded positively to reading the poster or leaflet. Of those who responded, 71 percent indicated that they would make changes in their lifestyles based on what they read in the leaflet and recommended that this information be distributed to other agencies that have contact with drug users, such as prisons, and general practice surgeries. Branagan showed positive response to the education; however, the study did not indicate any statistics on overdose knowledge prior to the education program. Being that 16–43 percent of opiate addicts in the United States suffer from multiple overdoses or die from suicide, most frequently the result of overdose, repetition of this educational endeavor may be worthwhile (Hickman et al., 2003; Pfab, Eyer, Jetzinger, & Zilker, 2006).

Regarding addiction, tobacco smoking has been the most extensively studied in relation to health. Smoking increases risks for multiple causes of illness and death, and studies show that 71 percent of those who use illicit drugs also smoke (Ritchie, Ahluwalia, Mosier, Nazir, & Ahluwalia, 1997). Tobacco

smoking has been shown to increase mortality from other health-related illnesses and increase the number of risky lifestyle practices (U.S. Department of Health and Human Services [USDHHS], 2004a; Perkins et al., 1993). Positive relationships between self-efficacy and not initiating smoking, not increasing smoking, and environmental tobacco avoidance was evidenced by Martinelli (1999a, 1999b) and Kawabata et al. (1999). McCleary-Jones (1996) found that age, educational level, and income modified health-promoting practices in smoking and nonsmoking black women. This study found that educational level was the strongest predictor of practicing health promotion, a finding consistent with other studies (Lusk, Kerr, & Ronis, 1995; Foulds et al., 2006).

HEALTH PROMOTION INTERVENTIONS AND SUBSTANCE ABUSE

In January 2000, the U.S. Department of Health and Human Services launched Healthy People 2010, a comprehensive, nationwide health promotion and disease prevention agenda. The National Center for Health Statistics/Centers for Disease Control and Prevention (CDC) quantified the cost of substance abuse (i.e., smoking, illegal drug use, and alcohol) to the United States at more than $484 billion per year, treating such adverse effects as infectious diseases, crime, unintentional injuries, teenage pregnancies, and chronic psychiatric disorders (USDHHS, 2004b). Twenty-five percent of patients seen in primary care clinics have alcohol or drug disorders (Jones, Knutson, & Haines, 2003). Healthy People 2010 has proposed that opioid-dependent patients be able to receive treatment services and opiate antagonist medication (buprenorphine) in outpatient settings, such as primary care offices. In addition, evidence is suggesting that access to primary care will improve not only general health but also drug abuse–related outcomes (Alba, Samet, & Saitz, 2004). The possibility of improved outcomes has created Current Procedural Terminology (CPT) codes for the screening and counseling of alcohol or substance abuse in primary care offices (Hughes, 2008).

Recently, studies have examined common medical problems in patients who are recovering from chemical dependency. Alba et al. (2004) found that chemically dependent individuals without primary care suffered from increased hospitalization, reported chronic medical conditions, and practiced unhealthy lifestyle choices. Friedmann, Zhang, Hendrickson, Stein, and Gerstein (2003) found that the availability of primary care services at onsite substance treatment programs significantly improved addiction severity at follow-up by 14 percent, but did not change the severity of medical outcome. Another alternative is to deliver behavior health services within primary care. In this type of treatment

service, the primary care practitioner addresses the health care issues related to substance abuse whereas the behavioral health and/or addiction specialist services provide management of the substance abuse issues (Ernst, Miller, & Rollnick, 2007).

Substance abuse patients are returning to primary care follow-up sooner than the expected 90 days. With insurance restrictions, patients are often discharged from addiction specialty treatment centers within 7 days and are expected to be monitored for continued use and any other comorbid conditions by primary care providers. The first 90 days postaddictions specialty discharge is the highest risk period for relapse (National Clearinghouse Guidelines, 2005). It requires primary care health providers to be knowledgeable of when to contact the addiction specialist or mental health care provider, assessing the patient for signs of abuse or adherence to the recovery plan, monitoring for adverse effects of addiction-focused pharmacotherapy and consistent motivational support to maintain abstinence. It is imperative that primary care providers work with patients to become more engaged in their own health.

Additional demands are placed on the body while achieving or maintaining recovery. There is a need for more energy, improved psychological well-being, and stabilization of organ function. Proper nutrition supplies the body with the adequate building blocks by which the person can maintain proper health and fight off infection. For cocaine users, the loss of appetite and weight loss from overstimulation can lead to malnutrition; whereas marijuana increases appetite and many long-term users become overweight. Opiate abusers suffer from the constipation effects of the drug class. Diet recommendations include but are not limited to regular mealtimes, portioned low-fat nutritious meals, to prevent overeating and increased vitamins, protein, and fiber. Dehydration is common during recovery, therefore, encouraging adequate fluid intake is essential (Apovian, 2006).

Exercise not only improves mood and reduces mood swings, it adds the internal strength to deal with negative stressful states, which often are triggers that lead to lapses or relapses (Gross, 2006). Stress management techniques assist the substance abusers in preventing lapses and improve their interpersonal communication skills. These interventions create a circle of positive outcomes, thereby leading to a healthier lifestyle, both physiologically and psychosocially. As recovery progresses and the user improves health promotion activities, self-esteem and motivation increase to maintain substance recovery and health. However, the most important element of health promotion is for the person to avoid returning to substance use, before changing diet or quitting smoking.

Pharmacologic agents may assist in achieving recovery. Gamma–vinyl-GABA (Vigabartin) has shown positive effects in blocking the craving for

cocaine. When combined with counseling, 30 percent of patients successfully kept off cocaine during a nine-week study (Interlandi, 2008). Another medication, Acamprosate calcium (Camparal), already on the market for alcoholism, has the potential to reduce cravings and help prevent relapses, though the effect is individual. Naltrexone extended release injectable suspension (Vivitrol) works on blocking the action of the alcohol directly, thereby blocking the feel-good effect. Nothing has been as successful as varenicline (Chantix) for nicotine addiction. Varenicline studies have shown that 44 percent of tobacco addicts were able to quit smoking after 12 weeks. However, none of these medications will work without extensive behavioral-cognitive group therapy and counseling and they are not to be a permanent part of the treatment regimen. These medications remain only tertiary prevention in the early phases of detoxification.

It is the potential of vaccines that is the most hopeful for primary prevention in addiction. Worldwide research is developing vaccines to inoculate people against addictive substances such as cocaine, heroin, and methamphetamine. The National Institute of Drug Abuse states that these vaccines may be available within 1 to 10 years. The most promising vaccine TA-CD, a vaccine for cocaine abuse, prevents the addictive substance from ever reaching the user's brain. It will work like any other vaccine. The immune system is prompted to create antibodies and when an individual takes cocaine the next time, the body mounts an automatic defense. Antibodies attach to the cocaine molecules, which are then broken down by enzymes in the bloodstream. This in turn eliminates the high and desire to have more cocaine (Hylton, 2008). Unfortunately, it has taken almost 10 years to develop this vaccine.

Research on depression as a factor contributing to addiction and relapse has been inconclusive in the literature. The question is not if the depression actually exists since co-occurrence of a mood disorder and substance abuse ranges from 42.6 to 60.3 percent in the United States (Grant, Stinson, & Dawson, 2004; Kessler et al., 1996). However, the question is really "Does depression cause substance abuse?" or "Does substance abuse cause a depressive state?" Depression has a greater impact on overall health than other chronic medical conditions. The underdiagnosis of co-occurring disorders affects clinical interventions, medications, and the psychosocial treatments that can improve patient outcomes, particularly relapse prevention and health promotion behaviors. Without detection and appropriate treatment, the physical and mental health of the individual fails.

Studies have shown that there is a relationship between substance abuse recovery and spirituality. Spirituality in recovery has been limited to the 12 Step–based spiritual practices, whereby a person accepts the existence of a higher power and develops faith, gratitude, and humility that govern the recovery process. Beyond this 12 Step method, however, other spiritual interventions,

such as transcendental mediation and therapeutic touch, have been shown to have a significant positive effect on the recovery process, though not always at a significant level. Unfortunately, many of these studies were limited due to limited funding and allocated resources. Additional research in complementary spiritual practices is needed.

Harm-reduction strategies are presently very controversial in health philosophy, as they are misinterpreted as drug legalization tools. These approaches are to reduce the negative consequences of drug abuse to an individual or harm done to the addict's family or community. Sometimes these strategies ignore the needs of the individual addict as a trade-off for the betterment of the community at large. Needle-exchange programs' primary goal is to reduce the risk of spreading infectious diseases such as HIV/AIDS and hepatitis by taking infected needles out of circulation. Yet, these programs require local funds to operate and are not consistently available throughout the United States. Even the use of agonist medications for heroin addicts is not widely accepted practice, though research has shown that the use of these medications helps in restoring the individual to functionality in the family, at work, and in the community (Kosten, 2005). These strategies have been shown to be helpful in the adolescent age group through behavioral modification, which may eliminate substance use (Canadian Medical Association, 2008).

Patient care is affected by policy. Policy determines who gets what kind of care from whom and when (Mason, Leavitt, & Chaffee, 2007). A major role of the health care providers dealing with substance abusers is to recognize the needs of the client/patient and work toward attaining the resources required to provide high-quality patient care. Caring for the addicted and recovering patient in the outpatient primary care setting is a goal of Healthy People 2010. Discrimination has been shown to have a negative impact on both mental and physical health. Young, Subere, Ahern, and Galea (2005) found that discrimination was significantly associated with poor mental health, depression, and the number of chronic physical health conditions in illicit drug users. Negative emotional states and stress have been shown to have a direct effect on patterns of behavior that affect physical health. Yet, these underserved and misunderstood patients are most often treated negatively and inconsistently when compared to other widely publicized medical conditions, such as cardiovascular and pulmonary disease. Even pharmaceutical companies are reluctant to develop products for drug addicts.

With better health promotion, health care costs in future years could potentially decrease. In addition, earlier initiation of health promotion in the abusing population may assist those individuals in avoiding major disease complications and help in substance abuse recovery. However, the initiation of health promotion education and services is not often covered under insurance or Medicaid

and requires money to enact. Discrimination due to drug use may limit available resources, access to social welfare, and compliance with medications and health care regimens (Young et al., 2005). Obtaining the financial resources for this endeavor would necessitate creating or changing policy at the insurance company, state, or federal level. Primary care and addictions specialty providers are empowered to make these changes occur. Grassroots lobbying efforts from the local to federal level enable these policies to come to fruition.

SUMMARY

Healthy lifestyle practices or behaviors have been defined by many groups, yet perception of health, benefits of a health-promoting behavior, and barriers to the behavior are all individual. The person must have the internal motivation and develop the self-efficacy or confidence to adopt the behavior change and then to maintain it. As addicts attain substance abstinence, their confidence to maintain the behavior increases which in turn gives the addict strength to continue the recovery state. Research has shown internal motivation and self-efficacy as the best predictors of behavior change, including relapse prevention and recovery from drug use. Other factors, such as perceptions of risk and control, also play crucial roles in the recovery process. Barriers to abstinence, such as craving, depression, and withdrawal symptoms, prevent many substance abusers from adopting a permanent lifestyle change. This in turn decreases their chance of life without multiple medical problems. Increasing participation in drug abuse treatment can decrease the spread of these diseases by reducing risky behaviors, such as sharing injection equipment and having unprotected sex.

Relapse prevention therapy, along with other adjunctive treatments, to reduce stress, improve nutrition, decrease depression and physical symptoms, increase the addicted person's emotional and spiritual states, energy level, and overall well-being (Brooks, 2006). With the rise of rapid three-day addiction detoxification programs in health care institutions, addicted individuals will be relying on primary care practitioners to address their addiction and other health needs. To maintain the recovery process, collaboration between primary care and addictions specialists is pivotal in evaluating and treating these patients to ensure positive health outcomes.

Chapter **2**

Becoming a Problematic Consumer of Narcotics

Ted Goldberg, PhD

This chapter is based on participant observation studies of problematic consumers of narcotics in Stockholm, Sweden, over a period of four and a half years. When doing fieldwork, a researcher meets many people with different characteristics, personalities, strengths, and weaknesses. The wealth of data is so great that it is easy to drown in a sea of details. To formulate the theory presented here, it has been necessary to look beyond individual differences and concentrate on what I have come to see as a major underlying pattern common to problematic consumers of narcotics, that is, people who made illicit substances the central element in their lives. I have developed a dynamic developmental model, or a life-history "career model," to illuminate what brought my research subjects to "the drug scene" and why they elect to remain on it.

As narcotics consumption is a complex phenomenon regulated by cultural norms and definitions, place, time, age, gender, and so on, I am unable to determine the extent to which my model can be generalized. It is my hope that readers will be inspired to test its applicability on other populations.

In this chapter the terms *narcotics*, *illicit substances*, and *illicit drugs* will be used as synonyms.

ASSUMPTIONS

All knowledge of humans and society, scientific or otherwise, is based on unproved assumptions. With postulates as a foundation, we build our theoretical understanding (Israel, 1984, p. 16). Differences of opinion in the drug

debate can often be traced to different suppositions. Unfortunately, assumptions in many texts are implicit, leaving it to the reader to unmask them. I shall therefore begin by making explicit the major assumptions upon which my model is based.

Assumptions about Consumers

I assume that the intellectual capacities of those who use narcotics show approximately the same variation as in the population at large, and that those who use illicit drugs understand the consequences of their actions to approximately the same extent that nonconsumers understand their own behavior. Furthermore, I do not agree with those who postulate that it is primarily the chemical effects of the narcotics themselves that determine consumption. Bejerot (1979, p. 90), for instance, writes: "That the individual has become chemically controlled and has serious deficiencies or completely lost self-control vis-à-vis intoxicants is the essential nature of narcotics addiction." Instead, my starting point is that drug consumers should not be seen merely as objects. They are also subjects who actively choose both to use narcotics and to take the consequences thereof.

Assuming that a person is competent to make decisions leads us to ask such questions as: Why does he choose as he does? What alternatives does he believe he has and what alternatives actually are at his disposal? To what extent is he conscious of the motives behind his decisions? The model presented in this chapter will address these kinds of questions.

Nature and Nurture

Certainly, most serious researchers would agree that human behavior is a product of both biochemical and psychosocial processes. However, the relative importance of these two roots in conjunction with drug consumption is the subject of great and ongoing controversy. So even if the term *biopsychosocial* is being used more and more by those who participate in the drug debate, we really aren't in agreement. The question is: How much of human drug behavior should/can be explained by biochemical variables and what is psychosocially determined? This can be illustrated with the help of a continuum. While almost nobody is at either end of the continuum, a person who places himself toward the left side of the continuum is saying something very different from somebody who is near the other end.

Those who assume that human behavior is primarily of biochemical origin see deviance first and foremost as a result of some combination of genetic dispo-

Continuum 1

Behavior	Behavior
biochemically	psychosocially
determined	determined

sition, metabolic disturbance, and/or drug-induced malfunction in vital organs such as the brain or other parts of the central nervous system. For instance, Robinson and Berridge (1993, p. 249) assume that "addictive behavior is due largely to progressive and persistent neuroadaptations caused by repeated drug use." Those who emphasize biochemical determinants are of the opinion that the root of problematic drug consumption lies principally within the individual and/or the narcotics themselves, and that her social experiences are of secondary importance. Solutions are sought by attempting to find substances that will maintain a normal chemical balance within the individual, detoxification, trying to prevent access to illegal psychoactive substances, information, and so on.

By defining the behavior exhibited after drug consumption as a problem lying within the individual and/or the drugs, the biochemical perspective is of major political significance. The implication is that problematic consumption is not an indication of a need for social change.

Researchers emphasizing psychosocial variables analyze either individual characteristics (i.e., personality, life experiences, underlying needs) and/or social structures. On the micro-level, they ask how the individual became such as she is, and look for answers in, for instance, her family and/or other small groups she currently belongs to and/or has belonged to in the past. On the macro-level, they ask what factors in society create problems for parts of the population as a result of their position in the larger social system. Answers are sought in society's social institutions, culture, and history.

The basic assumption among those who place themselves toward the right-hand side of the above continuum is that humans are social beings and their behavior is to a great extent the result of social relationships. Without denying that people differ in their biological make-up, these differences are given subordinate roles. Biology is seen as a framework that sets limits for what we can achieve; social factors are looked upon as determining the extent to which an individual's capabilities will develop. From this point of view, it follows that behavior cannot be analyzed solely in an individual context. We must also look at macro-level processes and political decisions that create possibilities and obstacles both for the individual and the intimate small groups that form her (Mills, 1997).

Complexity and Nonlinear Thinking

Differences of opinion in the drug debate can also be traced to assumptions as to what are causes and what are effects. Some arguments are based on the assumption that biochemical changes induced by illicit drugs produce (undesirable) behavior, such as lack of achievement in school (Nordegren & Tunving, 1984, p. 143), delayed maturation (Dole & Nyswander, 1967, p. 477), and criminality (see Inciardi, 1992, p. 22ff. for some examples of the drastic kinds of statements that have been made and how they have been used politically). Levine (2003, p. 147ff.) uses the term *drug demonization* for the tendency to see illicit drugs as the major cause of just about any behavior we don't approve of in any individual who takes them.

The arguments presented in this chapter will be based on an alternative assumption: neither narcotics nor any other single factor explain human behavior. Instead, we should try to uncover the latticework of multiple factors that increase the probability that some people will choose to take illicit drugs in a problematic way. This implies that rather than principally concentrating on the illicit substances themselves, considerable effort must also be directed toward understanding other factors, such as the consumer's life experiences, her motives, the conditions of her existence, the situations in which illicit drugs are consumed, the society in which her life is being/has been led, and so on.

An assumption upon which the model presented in this chapter is based is that as a result of his social relationships and life experiences, the individual gains knowledge about himself, the society he lives in, and his roles in that society. All of these factors greatly influence the way he will relate to illicit substances, which in turn, has repercussions for his future relationships to others and to society. In other words, there are feedback relationships between the individual, other people, narcotics, and society.

The model presented here is based upon the assumption that narcotics are not the major culprits. While I do not deny that the biochemical effects of psychoactive substances are a part of the equation, human relationships and the societal conditions from which they originate are seen as playing a major role as determinants of both illicit drug consumption and the behavior displayed in conjunction with it.

From this starting point, I ask: What roles do narcotics play in relation to other aspects of the consumer's life? How do illicit substances relate to her past experiences, her present life situation, and her future possibilities? How did she come to contemplate starting to take psychoactive substances? What made her transform these thoughts into action? Once having started taking illicit drugs,

why does she choose to continue? One of my fundamental assumptions is that if drug experiences (both chemical and social) are not relevant for a person's life seen as a whole, she will not make them the major focus of her existence.

Therefore, it is an important task for drug research to uncover and describe the relationships between illicit drug consumption and other life experiences.

Simultaneous and Process Models

Characteristic for simultaneous models is the assumption that all of the factors that operate to produce a phenomenon operate concurrently (Becker, 1963/1973, p. 22–23). In such models, we lose sight of the history of both the individual and the society in which he lives. An example of simultaneous thinking is the desperate parent who says: "My son was a wonderful kid until he fell in with the wrong crowd and was enticed into smoking a joint, which lead to his downfall." In this kind of explanation, all of this adolescent's previous life experiences are deemed irrelevant.

To my way of thinking, it is unreasonable to believe that a single event (how traumatic or euphoric it may have been) could eradicate the effects of all of the experiences a person has had in her life. I therefore attempt to develop a sequential model that analyzes processes that start in the past and continue through the present and into the future. To help develop a sequential model, Becker (1963/1973, p. 24) uses the term *career*. Similar to athletes who begin their careers in a sand lot and work their way up through different leagues before becoming professionals, the "deviant" has a career consisting of different stages, where earlier experiences become a fundament upon which later stages rest. In this chapter, I will briefly present the stages in the deviant career model I developed to explain the data I collected during my fieldwork. (The model is expounded upon in Goldberg, 1999, pp. 79–150.)

DIFFERENT KINDS OF CONSUMERS

It is not difficult to understand why we must use different concepts and variables to comprehend why a connoisseur drinks $500 wines with gourmet dinners than we need for an analysis of the drinking patterns of skid-row alcoholics. Both are using the same psychoactive drug but it is obvious that the underlying meanings and motives are very different. A common way to illuminate this distinction is to differentiate between "users" and "misusers."[1] However, I have found that these two concepts are understood in so many different ways in the literature and in everyday speech that they no longer convey meaning in a precise way. We therefore need other terms.

Continuum 2

Abstainers ..... Recreational consumers ..... Problematic consumers

drugs play ..... drugs first priority
no role .....

My conceptualization is a continuum with those for whom drugs mean nothing at one end and people who make drugs their first priority at the other. As already noted, *problematic consumers* are people who allow psychoactive substances to play a dominant role in their lives, that is, those who approach the far end of my continuum. *Substantial consumer* will be used as a synonym.

Recreational consumers, on the other hand, consider drugs as one aspect among many in their lives. Borrowing an idea from Norman Zinberg, Stanton Peele (1998, p. 8) writes that nonaddicted drug users "subordinate their desire for a drug to other values, activities, and personal relationships, so that the narcotic or other drug does not dominate their lives. When engaged in other pursuits that they value, these users do not crave the drug or manifest withdrawal on discontinuing their drug use." It is in this sense that I use the term *recreational consumers*.

Although frequency of consumption is a significant aspect in my definitions, it isn't a sufficient criterion. Under certain conditions, it is possible to take drugs regularly without allowing them to govern one's activities. In societies where psychoactive substances are readily accessible, socially accepted, and inexpensive, they can be used in this way. In the Netherlands, for instance, cannabis is more or less socially accepted and can be readily and affordably purchased in any number of coffee shops. It is therefore possible to take this drug on a daily basis with a minimum of social and economic cost. Some people smoke cannabis in a manner comparable to those whose alcohol consumption primarily consists of taking a drink after work or before going to bed. To my way of thinking, people who take illicit substances in this manner shouldn't be considered problematic consumers.

Problematic consumers and recreational consumers may well take the same psychoactive substances, but the meanings behind the act and their motives are very different. A central question in conjunction with all drug consumption is: *What is the individual attempting to accomplish when she takes these substances?*

A number of studies based on different populations have found statistical differences in the psychosocial backgrounds of problematic consumers as compared to recreational consumers. For instance, research on more than 50,000 military conscripts in Sweden (Solarz, 1990) shows that the backgrounds of

recreational consumers did not significantly differ from those of nonconsumers. On the other hand, both this and a host of other studies (i.e., Chein, Gerard, Lee, & Rosenfeld, 1964; Puhakka, 2006; Shanks, 2008; Shedler & Block, 1990) clearly indicate that problematic consumers have had unusually negative life experiences predating their initial experience with narcotics. It appears that problematic consumers in postindustrial societies are primarily recruited from those who have many of the following factors in their backgrounds:

- poverty
- at least one parent with a high level of alcohol consumption
- corporal punishment
- serious conflicts in the home
- broken homes
- if the father was physically present, he tended to take little interest in the family
- spoiled or severely frustrated
- subjected to unclear demands
- inconsistent use of punishment
- chronic physical and/or mental illness in the family
- sexual abuse
- overcrowded living conditions
- multiproblem family
- run away from home on multiple occasions
- subjected to discrimination.

These factors play an important role in the development of the individual's self-image, and are major components in the labeling process to be described in this chapter.

The aforementioned studies also indicate that future problematic consumers of illicit substances showed some of the following symptoms prior to their first narcotics consumption:

- depression
- severe headaches
- stomach problems
- low tolerance for stress
- lack of sleep
- anguish
- nervousness
- excessive aggression.

Furthermore, their childhood years were characterized by:

- lack of initiative
- giving up when faced with resistance

- maladjustment in school (i.e., they have felt themselves mistreated, have received poor grades in both academic subjects and conduct, have been left back and/or placed in a remedial class, have been truant)
- extensive consumption of tobacco
- sniffing organic solvents
- frequent hangovers and/or starting to take pick-me-ups at an early age
- criminal offenses such as shoplifting, assault and battery, theft, vandalism
- being registered by the police and/or social authorities
- not participating in organized leisure time activities
- having feelings of inferiority
- a negative self-image.

The prevalence of extremely negative experiences early in the lives of problematic consumers indicates that problematic consumption should not be considered to be primarily an individual predicament. Macro-analysis is necessary for understanding the roots of the problem.

However, people with similar psychosocial backgrounds are not predestined to a given pattern of drug consumption. Individual social experiences and personal characteristics differentiate people from comparable social environments. Therefore, we must also direct our attention to drug consumers as individuals.

Accordingly, explanations for different types of drug consumption should principally be sought:

- on the macro-level, where people are molded by the society in which they live/have lived
- on the micro-level, where individuals are shaped through interaction with other people in intimate small groups
- on the biological level as we differ genetically.

Instead of attempting to cover all of this in one short chapter, I shall concentrate on my fieldwork and the model I developed to explain what I consider to be the most important underlying patterns behind recruitment to the drug scene in Stockholm. Before beginning, I wish to emphasize that the model concerns only problematic consumers and is not relevant for recreational consumers.

THE NEGATIVE SELF-IMAGE AND SELF-DESTRUCTIVE BEHAVIOR

Early in my fieldwork, I was given the following advice by one of my research subjects: "Don't feel sorry for junkies when they're kicking cold turkey. Addicts are masochists who want to suffer and die." At the time, I found this advice absurd, as the people I had previously associated with wanted to make their

lives as satisfactory as possible, and I assumed that everybody had similar aspirations. Furthermore, from the literature I had read about narcotics, I had been given the impression that addicts, if anyone, sought euphoria. At the time, it seemed beyond question that everyone who takes illicit drugs does so because it makes them feel good.

In retrospect, the advice given by this problematic consumer was the key to understanding the essential nature of what I would be observing while in the field. But the idea was so remote from my "preunderstanding" (the ideas I brought with me into the field) that it took a long time before I could accept it.

Few, if any, doubt that problematic consumers of narcotics risk dying young. That they also ruin their health, are disdained by others, can't trust anyone in their surroundings, are obliged to commit crimes or prostitute themselves daily, sometimes "freak out," periodically become "paranoid," and so on is also well known.[2] Why would anybody subject herself to all of this?

A common answer is some variation of the following theme: "Normally both men and animals are steered by the pleasure-pain principle: some degree of effort is required both to obtain pleasure and to avoid discomfort. . . . In drug addiction . . . a 'short circuit' occurs in the biological system and the normal pleasure-pain principle no longer functions" (Bejerot, 1970, pp. 22–23). "When addiction supervenes . . . the drug hunger takes on the strength and character of instinctive drives" (p. 22). "The drug effects take on the strength of libidinal desires and outweigh all mental, physical, social and economic complications arising from the abuse" (p. xvii). In other words, the individual is no longer in control of her actions. All the negative aspects are outweighed by the euphoric effects of drugs that now steer the individual's behavior (see also Bejerot, 1979, p. 28–31, 37–38, 95).

While it is true that some people (but not all) experience moments of euphoria from psychoactive substances, those who start to use drugs on a daily basis quickly discover that there is a flip side to the coin. The proportion between pleasure and pain increasingly tilts toward the latter as the quantity and frequency of narcotics consumption increases.

If one questions them, even those who believe that euphoria is at the root of problematic consumption will usually agree that such is the case. But they argue that the euphoric experiences of the early stages were so powerful that substantial consumers continue in the hope of reexperiencing them, and/or that by the time they discover the negative effects of narcotics it is too late, as they are caught up in a biochemical dependency and can no longer use their own willpower to control their lives.

However, upon closer examination of what the problematic consumers in my study actually did and experienced, I found that "seeking euphoria" does not

explain what was taking place. In fact, quite the opposite was true—they were destroying themselves. In saying this, I am not claiming that everything problematic consumers do is directly or even primarily directed at self-destruction. But the long-term effect of their lifestyle points in this direction.

All of the substantial consumers I observed while in the field were self-destructive—but to different degrees. Some took drastic measures such as "cleansing" one's syringe with water from the toilet bowl in a public restroom when there is a sink right next to it, borrowing other people's "works" in spite of the risk of contamination with HIV and/or hepatitis, asking others to smuggle alcohol into the hospital (instead of a drug that is milder on the liver) while being treated for hepatitis, finding a pill on the street and eating it without having the slightest idea what it contains, and so on.

But acts as drastic as these do not constitute the major part of the self-destructiveness on the scene. We get a better understanding of what is going on by observing less dramatic activities that are repeated as a part of everyday life: that is, improper diet, lack of sleep, unsanitary living conditions, physical and/or sexual abuse, prostitution, not brushing one's teeth, not attending to sores, paranoia, poverty, and so forth. All of these are integral parts of the drug scene. In fact, I find it very unlikely that the word *euphoria* would come into anyone's mind while observing the drug scene. Indeed, it would not be an exaggeration to say that little or nothing in the lives of substantial consumers of illicit substances is as much as pleasant.

Another way to try to get around the obvious self-destructiveness of problematic consumers is to presuppose that they do not understand what they are doing. Some assume that substantial consumers must either be intellectually lacking, or are so influenced by drugs that they cannot think straight, or have an exceptional ability to delude themselves. However, my observations do not lend support to these assumptions. Admittedly, it can be difficult to think clearly while under the influence of psychoactive substances, and just about everybody (including problematic consumers of illicit drugs) engages in a certain amount of self-deception. Many substantial consumers put up a front in their contacts with the "straight world," which can easily reinforce the impression that they are fooling themselves, but if one manages to penetrate behind this facade, as I did during my field research, it becomes obvious that while they might not be conscious of all of the consequences of every particular choice they make, sooner or later just about every problematic consumer comes to understand that in the long run the substances they are taking and the life they are leading will destroy them. While narcotics sometimes (but far from always) give a measure of short-term relief, substantial consumers eventually come to an awareness that their lives are rapidly deteriorating.

Since problematic consumers eventually come to understand that both they themselves and everybody else who remains on the scene are on the road to extinction, yet do not change their way of life, there must be a strong self-destructive side in their personalities. People who aren't extremely self-destructive do not remain on the drug scene very long. That is, there are clear differences between problematic and recreational consumers. Recreational consumers experiment with drugs. They seek certain experiences, such as an alternate state of consciousness, sexuality, new sensations and impressions, relaxation, and so on, and are prepared to make some sacrifices to achieve these ends. But they are not willing to destroy their lives. When economic, social, psychological, and/or physiological costs reach an excessive level, recreational consumers either stop taking drugs altogether or greatly reduce consumption. Few people wish to annihilate themselves and this explains why only a small minority of those who experiment with illicit substances maintain a high level of consumption for long periods of time.

But for people with an extremely self-destructive side to their personalities, the negative effects inherent in the lifestyle on the drug scene become an important reason for continuing with narcotics. At least for my research subjects, *problematic consumption of narcotics is a major component in a self-destructive life project*.

However, it is an oversimplification to divide humanity into two categories: those who are self-destructive and those who aren't. Clearly there are degrees of self-destructiveness. The problematic consumers of illicit substances I studied are extremely self-destructive people who lead lives that slope steeply toward extermination. Not quite as self-destructive people might well follow negative paths, but most likely ones that incline at a lesser angle.

A PROCESS MODEL

The model presented here can be seen as a variation of labeling theory and will identify a series of stages that problematic consumers of illicit substances pass through during their careers. However, before I begin, I must define a few concepts.

The *self-image* is an individual's conception of himself in relation to the ideals of his culture. People do not have a self-image at birth and we are not free to choose our self-image at will. Instead the self-image should be seen as developing through social relationships. Those people whose responses contribute to the formulation of an individual's self-image are his *significant others*. Parents (the people who raise the child) are usually his first and the most important significant others. It is through the parents that the child begins to develop

his self-image. As he grows older and comes into contact with society outside of the home, some of the people he meets will become significant others and they too will influence his self-image. However, the basis of the self-image has already been established by that time.

A person with a *negative self-image* has learned through interaction with significant others that there is a low degree of correspondence between his personal characteristics and/or behavior and cultural ideals as to how one should be.

Labeling is a process, not a few exceptional events. In the sense that the concept is used here, *labeling* is a course of events consisting of a large number of negative reactions from significant others, which taken as a whole, cause the individual to redefine his self-image in a negative direction.[3] Labeling occurs in many different places, such as in the family, in relationships with contemporaries, in school; and it can be evoked by many different things such as the individual's behavior, appearance, beliefs, sexual preferences, and so on. It is important to keep in mind that labeling is an ongoing process during an extended period of time, and even if one can identify dramatic events in the individual's life, these do not constitute a sufficient explanation. The self-image develops from the sum of large numbers of both prominent and seemingly insignificant experiences and reactions during the entire lifetime of the individual. Therefore, the older we get, the more well established it becomes and the longer it takes to change its essential content, even if adjustments can be achieved in a shorter time frame.

Parental Labeling

With the help of the concept *primary deviance*, I can intimate the course of events that have constituted the beginning of the labeling process for my research subjects. *Primary deviance* consists of acts that do not comply with societal norms but that are not committed with malice aforethought. They are not the product of a well-established negative self-image but rather the result of a lack of understanding of the plausible consequences of one's actions. In the words of a famous anthropologist, the newborn child is "a barbarian invader from another planet"; that is, a baby knows nothing of the culture it is born into. In order to learn societal norms (right from wrong), significant others must respond to the child's spontaneous behavior. *Everybody begins their lives with primary deviance. What distinguishes one person from the other are the ways their significant others react*. Somewhat simplified, one can say that some children learn that they themselves are good, even if what they are doing for the moment is unacceptable. Others learn, after a sufficient number of "unsuitable"

reactions, that it is not simply what they are doing for the time being that is unsatisfactory, but rather that there is something basically wrong with them as human beings. This is *parental labeling* and the *first stage* in the deviant careers of my research subjects.

Some parents appear to be unable to help their children develop a positive self-image, and it is reasonable to ask why this is so. Where one seeks answers depends to a large extent upon one's assumptions regarding the relative importance of nature and nurture (see earlier section).

From my point of view, sociological explanations are important as they reveal the societal pressures people in different socioeconomic groups are subjected to, and the increased probability of certain types of behavior. Statistically, such factors as belonging to a minority group, having uneducated parents, living in a slum, and so on, greatly reduce one's choices in life. But societal pressure is only a framework, not an inescapable process that forces people to act (or not act) in a particular way. Indeed, all people in similar social situations do not respond in the same way. Why Smith, but not his neighbor Jones, succumbs to societal pressure and labels his child cannot be explained sociologically. We must therefore also look at psychological and biological variables. However, it is reasonable to assume that if we can reduce societal pressures the number of people who cannot cope should be diminished, thereby decreasing the number of people who label their children.

Societal Labeling

As children grow older, they spend an increasing amount of time out of the home and they come into contact with society, that is, neighbors, day care personnel, elementary school teachers, and so on. During this period, children continue to learn social norms through reactions from others. In their initial contacts with society, the behavior of children is principally characterized by primary deviance, but as they grow older and gain social experience, their actions become increasingly influenced by societal norms. All children exhibit primary deviance in their initial contacts with society. Once again, the most important element is not the behavior but the reactions from significant others. Most children will learn that they are O.K. even if certain things they do are not. But some will learn that the problem lies not in what they are doing, but with them. This is *societal labeling*, the *second stage* in my deviant career model.

However, it is important to keep in mind that not all negative reactions are a part of a labeling process. *Labeling theory does not imply laissez-faire*. People need reactions in order to learn how to function in society. But the reactions must not equate the actions of the moment with the person herself.

Most often, it is not merely a matter of chance if a child is labeled in her contacts with society. Children who have been labeled by their parents run a far greater risk of being subjected to societal labeling. To explain why this is so, I must introduce another concept. *Behavioral incongruity* arises when an individual's behavior isn't in harmony with her self-image. She will react by trying to diminish the incongruity either by changing the behavior or her self-image. Figure 2.1 gives a picture of behavioral incongruity.

However, the picture conveyed by this figure is greatly oversimplified. Firstly, it gives the impression that people are static, when in reality they change. Some of the more important factors influencing changes in my research subjects will be discussed shortly.

Secondly, the self should be regarded as multiple and pluralistic rather than unitary. In, for instance, Robert Ornstein's (1986, 1991) multimind model we have many "small minds." This is because we participate in various social situations and we do not receive the same responses from all of our significant others. This awakens contradictory desires and ambivalent feelings in us. But Ornstein also postulates that there is a "governing self" that decides which of our small minds we are cognizant of at any given time. That is, even if we have

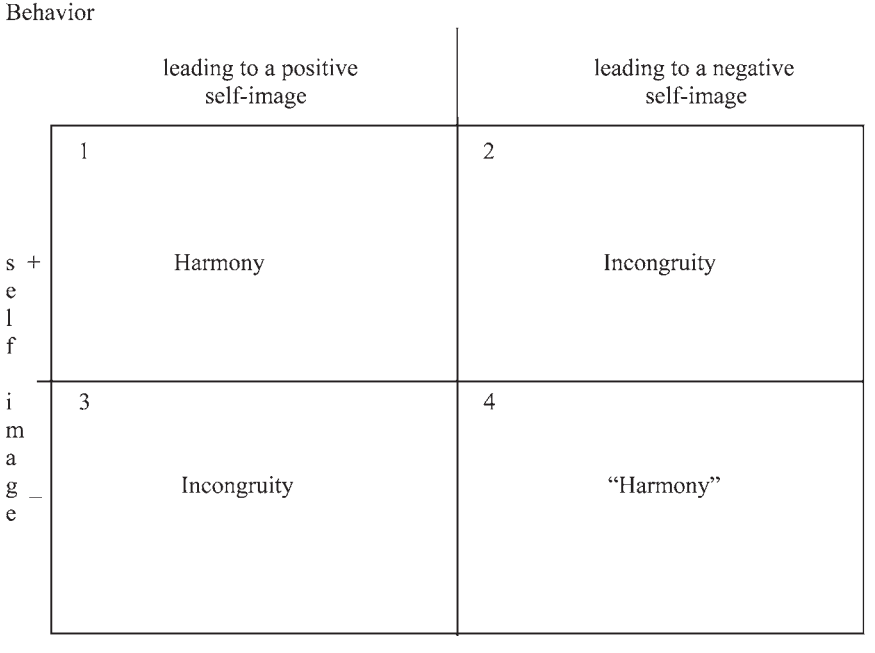

FIGURE 2.1 Behavioral incongruity.

many different "selves" and even if our "identity" changes depending upon the demands of the situation we are in for the moment, all of our identities are not equally important. The *self-image*, as I use the term, can be seen as the *governing self*.

A third complication with the figure is that there are degrees of positive and negative self-images. We can think of the matter as a continuum between those who look upon themselves as a short step under the deity, and those who regard themselves as Satan reincarnated. Depending on where a person stands on this continuum, a certain range of behavior will be acceptable to her; that is, her behavior will not cause incongruity as long as she keeps herself within this domain. However, if she should overstep these boundaries in either direction, that is, either act more positively or more negatively than her self-image will allow for, she will experience incongruity. She must then either discontinue the incongruous activity, place it within the framework of one of her small minds and therefore only be conscious of it in special circumstances, or incorporate it into her governing mind and thereby change her self-image to one that allows for such behavior. Figure 2.2 is a somewhat oversimplified model of these relationships.

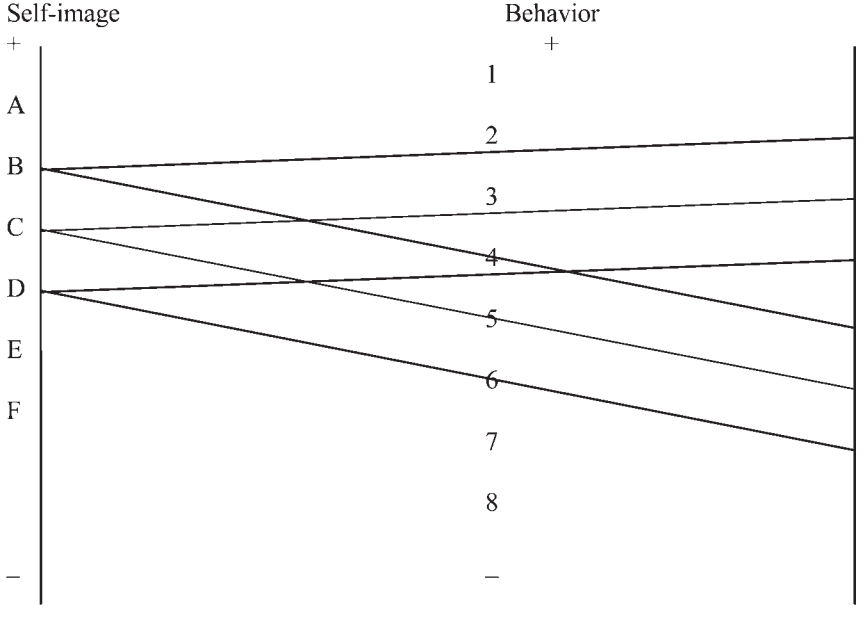

FIGURE 2.2 The relation between self-image and behavior.

An individual with a self-image at position C can behave between points 3 and 6 on the behavior scale without causing incongruity. If he should start acting according to point 2 on the behavior scale, he will either have to change his self-image in a positive direction at least as far as point B, or place the behavior in one of his small minds, or desist from such actions. For instance, upon becoming parents some of my research subjects tried to take care of their children. In doing so, they improved their self-images and this helped to somewhat regulate both their drug consumption and their behavior in general. Indeed, parenthood can be an important factor in getting off the drug scene entirely. But this is certainly not the case for all. Some research subjects who tried to fulfill their roles as parents saw parenthood belonging to a category separate from the rest of their lives. That is, successes in this role were placed in a small mind and not generalized to the self-image. These people tended to limit the amount of time they spent with their children, but when they were with their kids, they exerted themselves. However, it was difficult to see positive effects of this in other situations. And finally, there were those who after a period of time abandoned their children altogether. When I got to know these people well enough for them to confide in me, it became evident that they thought the worse of themselves for having done so. That is, failing to fulfill one's duties as a parent is so important that they didn't merely resume their previous negative self-image, they "devaluated" it further.

Correspondingly, if an individual should start behaving according to point 7 on the behavior scale above, he will either have to change his self-image in a negative direction at least as far as point D, or incorporate the behavior in one of his small minds, or discontinue such activity. Note that the behavior ranges for neighboring points on the self-image scale overlap. This is because people don't change their entire behavioral pattern at once, but rather a little at a time.

An individual with a negative self-image tends to behave so as to provoke others to confirm what he "knows" about himself rather than cause incongruity by acting in a way that would give responses leading to a more positive self-image. For this reason, it is difficult to change an established negative self-image. Negative reactions from significant others tend to modify the behavior of those who basically have a positive self-image, because these reactions are incongruous. For those who already have a negative self-image, admonishments are usually interpreted as a confirmation of what they already believe to be true, and therefore do not lead to behavior more in line with societal norms.

Yet another complication with Figure 2.1 involves the nature of the harmony in cell 1, as compared with the "harmony" in cell 4. In spite of their negative self-images, my research subjects grew up under the influence of mainstream

society and have internalized societal norms. Although some authors refer to the drug scene as a *subculture*, I don't find the concept relevant for my observations in Stockholm.[4] For a deviant subculture to arise and remain in existence, its members would have to neutralize the societal norms they have been bombarded with since birth. Although some researchers have gone so far as to itinerate specific methods for achieving this (e.g., see Sykes & Matza, 1957, p. 667ff.), I was unable to distinguish any significant degree of neutralization in my research subjects. When one merely listens to what problematic consumers say in interviews, it is easy to get the impression that they have different norms from the rest of society. But participation observation allows the researcher to establish relationships based on trust, and once this is achieved, one hears entirely different stories. Neither I nor a host of other researchers who have achieved a deeper contact with their informants report any significant degree of neutralization of societal norms (e.g., see Bourgois, 2003; Jonsson, 1973; Yablonsky, 1962). Not only do problematic consumers accept societal norms, but on the whole they tend to have very traditional values. This can be clearly seen, for instance, in what female problematic consumers have to say about sex roles (Lander, 2003, p. 155ff.) and motherhood (Trulsson, 2003, p. 80, 98).

Among the many tragedies in problematic consumers lives is that every day they break rules they themselves feel they should be following. Consequently, their actions cause self-reproach, which is added to all the negative reactions they get from other people. Therefore, the threat of having to devaluate one's self-image is ever present. Deviance bears within itself a certain degree of incongruence. I have indicated this by placing quotes around the word *harmony* in cell 4 in Figure 2.1. As a result of their inability to neutralize societal norms, problematic consumers experience a definite pull toward society; and almost all of those I met during my fieldwork did in fact take tentative steps in this direction on occasion. An example of this is attempting to find a job. If this tentative step is well received, it can initiate a reevaluation of the self-image. If the endeavor fails, it can be more difficult to try again.

In their early contacts with society, children who have been labeled by their parents exhibit the beginning stages of the provocative behavioral patterns easily recognized by everyone who has worked with marginalized people. Although the child's self-image is not firmly established, he can consciously break rules he is aware of, and in doing so provoke negative reactions that serve as a confirmation of what he believes he knows about what kind of person he is. The more frequently a child receives confirmation of his developing negative self-image, the more strongly established it becomes. It is therefore of primary importance that adults who interact with these children have a clear theoretical and/or emotional understanding of what the child is trying to convey with his

behavior, so that their reactions do not confirm what the child suspects (that there is something wrong with him) or even worse, become a part of the labeling process (that is, teach the child that he is even worse than he previously believed). Once again, the goal is to teach the child norms without labeling him; to react to what he is doing for the moment, but not against the child himself.

In recent years, politicians in practically all industrialized countries have been making budget cuts. To the extent that they decide to "save money" by withdrawing support from institutions and organizations where children and adolescents establish deeper relationships with adults other than their parents, politicians weaken a possible counterbalance to labeling responses in the home. Examples of such measures are increasing the ratio of children to personnel in community-run day care centers, cramming more pupils into school classes, reducing the number of adults working in schools, withdrawing economic support to youth organizations, cultural organizations, recreation centers, athletic clubs, and so on. With reduced resources, it becomes all the more difficult for the personnel to avoid labeling reactions when responding to children with provocative behavioral patterns, and it is therefore reasonable to expect that more of the children who run the risk of proceeding deeper into a deviant career will in fact do so.

Secondary Deviance

When a child has matured to the point where she has a reasonably clear understanding of societal norms, and has established a self-image based on a substantial number of life experiences, she can enter the *third stage* of the deviant career, *secondary deviance*. The age at which this ensues varies depending upon such factors as the amount and the severity of labeling in the earlier stages. For most of my research subjects, this third stage was established within a few years after becoming a teenager, but in extreme cases it occurred earlier.

Secondary deviance is characterized by acts contrary to societal norms that the individual is cognizant of. Secondary deviance is a product of a relatively well-established negative self-image and is a means of attempting to deal with manifest and/or latent problems arising from labeling. The child has become an adolescent. She has a relatively clear comprehension of right and wrong, and her behavior is increasingly influenced by her negative self-image.

Once a person has accepted that she is not accepted by others, normal social control does not function. People with a positive self-image can be brought to desist from certain behavior by negative reactions because these threaten both their view of themselves and their position as members of a group. But

a person with a negative self-image already knows that she is different and an outsider. She doesn't see negative reactions as a guideline to help her gain acceptance because her experiences have taught her that people like her cannot be accepted. So she interprets negative reactions as a further confirmation of how inferior she is. When a person has established a negative self-image, others cannot socially control her by threatening to withdraw love, friendship, or support, since she doesn't feel that she has any of this to begin with. As Bob Dylan succinctly put it: "When you ain't got nothing, you've got nothing to lose."

By defining certain acts as commendable and others as reprehensible, society shows its citizens how to maintain their self-images. For instance, the consumption of certain psychoactive substances is illegal (that is, deplorable). Those who have negative self-images know from their own experiences—the responses they have received from others—that people like them do unacceptable things. They are therefore attracted to illicit drugs. On the other hand, it becomes difficult for people with more positive self-images to consume these substances without experiencing behavioral incongruity. If these people choose to attempt to deal with life's problems by using chemicals, they will go to a doctor to get a prescription for legal drugs. They can do this without causing behavioral incongruity because it is legitimate to take medicine (even if the prescribed drugs should happen to have biochemical effects that are similar to those of narcotics).

If we were to remove current social and legal stigma from illicit substances, the pattern of consumption of these drugs would change. On the one hand, more people would be able to take them as doing so would no longer be experienced as incongruent. On the other hand, those who have a strong negative self-image would either have to take them in an unacceptable manner and/or find new ways to confirm their self-images.

Problematic consumers of narcotics have at least some, and most often all, of the following objectives when they take illegal substances:

1. confirmation of the deeply rooted negative self-image,
2. escape from their own and other people's expectations,
3. self-destruction,
4. revenge.

Due to labeling, problematic consumers of narcotics have drastically negative self-images, initiated prior to their starting to take illicit drugs. Others have deemed them inferior and they have accepted that such is the case. They try to flee, for instance, with the help of psychoactive substances, but they have already internalized the condemnation, and they can't escape from what they bear within. Due to all the negative experiences problematic consumers endure as an integral part of

the life they lead on the drug scene, they confirm for themselves that they deserve to be severely punished. After all, they destroy for others and have devastated their own lives. As time passes and the magnitude of negative life experiences escalates, they become all the more convinced that they are reprehensible and that they do not deserve to exist. Increasingly, their life-pattern becomes a process of ensuring that justice is done. Others have condemned them, they have accepted the verdict, and they become their own executioners. But at the same time, by stealing from them, frightening them, giving them a bad conscience, and so on, problematic consumers wreak revenge on those who have passed judgment.

People establish a self-image through others, and they must have help from others to modify it. If we want an individual to change her behavior, we must be willing to take the role of significant other and not only refuse to confirm the negative self-image but also give responses necessary to help her embark upon and endure the long process that leads to a more positive self-image. But this is easier said than done when the labeling process has gone so far that her experiences have taught her to expect negative responses from others. If she is suddenly given positive reactions, the world becomes incomprehensible to her. If, for instance, a social worker or some other significant other does not react as expected, she is looked upon as either being ignorant or simply not having understood what kind of person she is dealing with. This calls for extremely provocative behavior from the problematic consumer to generate the "correct" responses.

If significant others understand that they are being provoked, and are able to find responses that do not label the individual, this can initiate a reevaluation of the negative self-image. But if the provocations are "successful," which sooner or later they usually are, it leads to more labeling and little by little the individual embarks upon the fourth stage in the deviant career.

The Deviance Spiral

The *fourth stage* is called the *deviance spiral* and consists of the following elements, shown in Figure 2.3.

The problematic life experiences that constitute the labeling process create the negative self-image, which in turn leads to secondary deviance, which constitutes failure according to cultural definitions, which induces more labeling, and so on. Each new failure is partially the result of earlier failings but also contributes to future deviance. In this fourth stage, the individual's behavior is usually secondary deviant in several different areas, that is, consuming drugs, selling drugs, theft, prostitution, unemployment, not providing for one's children, homelessness, and so on. As a result, she is subjected to labeling reactions from many different sources.

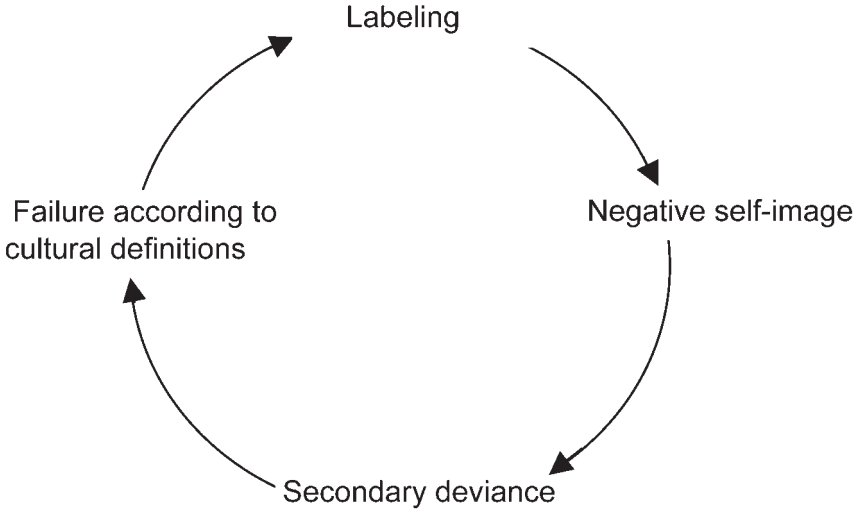

FIGURE 2.3 The deviance spiral.

The deviance spiral is a deterioration of the third stage. As is evident from the name and from Figure 2.3, the problematic consumer of narcotics is now caught in the vortex of a vicious spiral, drawing him downward. This occurs because, when failures and negative reactions accumulate, it becomes all the more difficult to maintain one's self-image at the same (low) level. The individual devalues her self-image still further, which leads to more serious secondary deviance, which other people define as even greater failure and respond to by further labeling, which leads to another devaluation of the self-image, which makes still more serious deviance possible, and so on.

Sooner or later, the deviance spiral leads to everybody who comes into contact with the drug scene getting to the point where they feel that they have had enough. Those who lack self-destructive tendencies usually come to this conclusion quickly and leave the scene shortly after arriving because they don't wish to subject themselves to the rampant negative experiences that surround them. For some people, it takes a little longer before they decide to leave. Only the most self-destructive people stay on the scene so long that they hit rock bottom. That is, they follow the deviance spiral downward to the point where they feel that only two choices remain: either get off drugs, or more directly, commit suicide (e.g., by taking an overdose or by "burning" a pusher who is both willing and able to have them killed). The following example from my fieldwork illustrates the deviance spiral.

When I met R. he was one of the biggest drug dealers in Stockholm. He was unemployed, took narcotics on multiple occasions every day, associated almost exclusively with problematic consumers, and regardless of what the subject of a conversation was initially, it was almost invariably narcotics before the discussion ended. Illicit substances were the hub around which just about everything in his life revolved.

One morning I received a telephone call from him. He was extremely agitated and asked me to come to his apartment. As most problematic consumers do on occasion, he had decided to reappraise his relationship to society. In this particular instance, he was going to try to get a job. When I got to his apartment, he was pacing back and forth nervously, smoking hasch. He told me he had applied for a position as a mailman and that he had an interview at 1:00 P.M. He was certain that nobody would ever employ him, and he was extremely nervous. (In the short run, it was a no-win situation for him. On the one hand, if he was not offered a job, the rejection would have been a blow to his already lacerated self-image. On the other hand, getting a job would have been incongruent to this same self-image.) R. spent several hours smoking one joint after the other and repeating that he wasn't going to get the job. By the time he left for his interview, he was hardly able to communicate. My interpretation of his behavior is that he put himself into a position where if he didn't get the job, he could protect his self-image by claiming that it was because he inadvertently had gotten too stoned.

Amazingly enough, he was given the position, presumably because at the time there was a drastic shortage in the work force in Sweden and the postal authorities were probably desperate.

The most common scenarios when problematic consumers manage to get a job are that they either don't go to it at all, or they show up only sporadically, or they do the job so poorly that they are fired, or they get into conflicts with coworkers and are let go for that reason. Put simply, having a job and doing it well is drastically incongruent to their self-images. With the help of provocation, they get themselves fired and confirm for themselves and others that they are not worthwhile members of society. To illustrate these points I return to R.

On R.'s postal route there were many older four-story walk-ups with only two apartments on each floor (in Sweden the mail is put through a slot in the door of each apartment). One day R. started a conversation with me by saying something to the effect that one of the biggest problems in Sweden is that people are lonely. As he is something of an amateur sociologist, R. presented a long analysis of, among other things, the breakdown of social relationships within the extended family as a result of urbanization. When he finally got to the point, he told me that he had taken it upon himself to do something to help people break their social isolation. In short, he delivered all the mail for each building to just one of the apartments (on the ground floor, of course). That way, he explained,

neighbors would have an excuse to ring each other's doorbells and get to know one another.

On several occasions R. told me that some days he couldn't be bothered delivering the mail at all and just threw it into the bushes. As I never actually saw him at this job, I don't really know to what extent he was exaggerating when he spoke of his way of performing his duties. However, I do know that when he had a large shipment of drugs to sell, he didn't go to work at all. He claimed that he usually just didn't show up without calling in sick.

If some of all this is true, R.'s behavior can be seen as an example of the way problematic consumers use provocation to get others to confirm their negative self-images. Normally, an employee who acts the way R. said he did would be asked to leave. However, R. was not fired.

About six months after he started working as a mailman, R. sold an exceptionally large amount of narcotics and had more cash than he'd ever had before. He became concerned about keeping so much money in his apartment while he was waiting for his suppliers to return to Sweden to collect what he owed them. In his own words, he was getting paranoid about the police being on to him, so he made a deal with a problematic consumer he considered a friend that this person would be paid to keep the cash in his apartment. To make a long story short, two of R.'s "friends" who knew about the money stole almost all of it and went off on a spree in southern Europe. R. was left holding the bag and had to pass on the burn. Luckily for him, his suppliers accepted his explanation, because if they hadn't, he would have been killed, as he could not possibly have gotten hold of so much money. However, his problems were far from over. As R. explained it, he now either had to have the two people who burned him murdered or stop dealing; because if word got around that you could get away with cheating him, R. would be ripped off time and again, and he would have to pass on the burns. Sooner or later (presumably sooner), his suppliers would no longer accept any excuses and they would have him eliminated.

In our conversations during this period, R. repeatedly told me that he was many (bad) things but he wasn't a murderer. However, to maintain his position on the drug scene, he now had to become one. To have somebody killed was drastically incongruent with his self-image and he didn't want to do it, but what would/could he do if he were to leave the scene? R. was tormented and frightened but he could not bring himself to sentence two people to death. Instead he fled to the Far East. He had been out there before but this time it wasn't the same. Even this dream was tarnished, and he returned to Stockholm after about a month.

Before leaving Sweden, R. quit his job as a mailman—but resigning is a very different matter than being fired. He had kept a job for more than half a year and could have continued even longer. Becoming a member of society was evidently not as impossible as it once seemed. At the same time, resuming his position on the scene was not really an option as he would literally have to kill to do so. Upon returning to Sweden, R. quickly found a new job and this was one of the major

steps in the long process of getting off drugs. Instead of continuing downward in the deviance spiral, R. managed to reverse the process. But if he hadn't already established that he could hold a job, his choices may well have been reduced to killing others or himself. To choose the former would be a major step downward in the deviance spiral. The latter is a choice made by all too many problematic consumers.

When he has hit rock bottom, the individual's small mind that wants to join society but that has been held back, is given higher priority. But if he fails now, all that remains is death. It is therefore not advisable to let the deviance spiral go this far. By not confirming the problematic consumer's negative self-image (e.g., by understanding his provocations and finding nonlabeling responses to them), we can help him break the negative spiral much earlier, preferably before it starts to gain momentum.

As it may be difficult to understand how it is practically feasible to do this, an example may be illuminating. A. S. Neill, former headmaster of Summerhill, a school in England that had among its pupils many "problem children" who had been expelled from other schools, and that used very unusual pedagogical methods, writes: "If I should be painting a door and Robert came along and threw mud on my fresh paint, I would swear at him heartily, because he has been one of us for a long time and what I say to him does not matter. But suppose Robert had just come from a hateful school and his mud slinging was his attempt to fight authority, I would join with him in his mud slinging because his salvation is more important than the door. I know that I must stay on his side while he lives out his hate in order for him to become social" (Neill, 1960, p. 119).

We can summarize my career model by comparing *two extreme kinds of careers*. Both begin with primary deviance, but the reactions received make the careers go in diametrically different directions.

Culturally successful career	Deviant career
1 Parental acceptance	1 Parental labeling
2 Societal acceptance	2 Societal labeling
3 Normative behavior	3 Secondary deviance
4 Personality enhancement	4 Deviance spiral

The stages in the careers should not be considered completely separate. They can be in progress concurrently and can either reinforce or counteract each other. For instance, parental labeling begins before societal labeling, but can continue for years after the child has made many societal contacts. It is also not necessarily so that an individual will be subjected to the same kinds of reactions from both parents and society, as is the case in the two extreme careers outlined

above. Labeling reactions from certain significant others can be counteracted by acceptance from others; in which case, the emerging self-image will neither be extremely positive nor extremely negative (see Figure 2.2). In other words, the number of possible careers far exceeds the two mentioned above. In a welfare state such as Sweden, few people experience the kind of extreme deviant career described here, which makes its prevalence among problematic consumers of narcotics all the more noteworthy.

NOTES

1. Obviously, one can choose to nuance even further. For instance, a report from a governmental commission in the United States distinguished between five different patterns of consumption (see Wurmser, 1995, p. 7).
2. *Paranoid*, as it is used on the drug scene, is slang and should not be equated with its scientific namesake. As in all slang, the concept is not clearly defined. Paranoid denotes vague fears, terrifying experiences, and feelings of persecution. The word is frequently used by problematic consumers because being *paranoid* is a prevalent part of their everyday existence.
3. Logically, one could also think of a positive self-image as being the result of a positive labeling process. However, in this chapter, labeling denotes a negative process.
4. *Subculture* may possibly be a relevant term to describe, for instance, people from eastern Africa who continue to chew *khat* while living in Europe, or Iranians who after emigrating, continue to smoke an opiate on special occasions. While this behavior is not accepted in the majority culture, it is within the bounds of the individual's culture of birth. So in the context of the majority culture the individual is now living in, this might be considered a drug subculture. However, these types of culturally regulated consumption have little to do with the behavior of problematic consumers. If a Somali should chew *khat* or an Iranian should smoke heroin at the expense of his other duties, he would no longer be acting within the framework of his culture and his fellow-countrymen would find his behavior unacceptable.

Chapter **3**

Adaptation and Addiction

Ann N. Dapice, PhD

Addiction has been a problem for thousands of years. It involves lasting changes in brain function that may be difficult to reverse. The numbers of "altered brains" include nearly 2 million heroin and cocaine addicts, some 15 million alcoholics, and tens of millions of cigarette smokers in the United States alone (Harvard Mental Health Letter, 2004). Globally, the use of drugs has reached all-time highs (Saah, 2005). As bad as these numbers are, they do not include a far larger array of addictions and numbers of the addicted worldwide.

Research increasingly demonstrates the similarity of, and connections to, a variety of conditions that appear addictive in nature. Some addictions are to external substances (e.g., alcohol, tobacco, cocaine). Some are to external behaviors that stimulate pleasure pathways in the brain (e.g., gambling, online pornography, stalking, and shopping). Some addictions are legal (e.g., food, tobacco, alcohol, prescription drugs, and shopping). Some are not (e.g., cocaine, methamphetamines, stalking). Some substances such as food, alcohol, and prescription painkillers can be used nonaddictively by some people but not by others, and some activities such as gambling, sex, and shopping can be engaged in nonaddictively by some but not others. The consequences of addictions on the addicted and those who are negatively affected by these addictions vary greatly—from chronic disease and slow death, to immediate and sometimes violent death. The social and financial costs of these addictions eventually affect us all. Meanwhile, prevention, intervention, and treatment for addictions, as well as punishment for illegal addictions also vary greatly. Activities such as eating and sexual intercourse are necessary for human survival. In fact, addictions

can be seen as originating in behaviors and substances that were once adaptive for the survival of humankind (Dapice, 2006; Fisher, 2004; Popkin, 2007).

Organisms that develop beneficial adaptations increasing the likelihood of their survival are more likely to pass on adaptive genes. The brain's reward system reinforces important behaviors—eating, drinking, sleeping, engaging in sex, but it is easily misled. Computers, the Internet, slot machines, and money can all activate the same regions of the brain as psychoactive drugs (Breiter, Aharon, Kahneman, Dale, & Shizgal, 2001). A recent brain scan study showed that when men were shown erotic pictures, they were more likely to make a larger financial gamble than if they were shown something frightening like a snake, or something neutral like a stapler. The arousing pictures would light up the same area of the brain that lights up when financial risks are taken. This was described as related to the evolutionary need that men have for both money and women. The study was designed to determine cause and effect. The erotic pictures lit up the area in the brain and risk taking followed. When photos of snakes and spiders were shown to the participants, the portion of the brain that is associated with pain, fear, and anger lit up and people were likely to keep their bets low (Knutson, Wimmer, Kuhnen, & Winkelman, 2008). People have different sets of risk factors: neurobiological, psychological, and social. Regardless of the risks to addiction, it is necessary to have exposure to an object of addiction that stimulates a positive experience in the user—relief of discomfort, or creation of pleasure (Walsh, 2007). What causes relief or pleasure varies greatly with the individual and thus the kinds of addictives vary as well.

Food and tobacco are connected to other addictive substances in important evolutionary and physiological ways. Understanding the co-development of mammalian brains and ancient psychotropic plants, as well as the implications of ancient psychotropic substance abuse in altering mammalian brains, helps assess the causes and effects of addiction in today's world. It allows us to come closer to treating the root of the addiction, not the symptoms alone (Saah, 2005). Processes formerly necessary for our safety, well-being, and survival may now serve to make and keep us ill. These include (1) the so-called "thrifty gene" (Popkin, 2007, p. 91), (2) mechanisms for fight and flight (Dapice, 2006; Dapice, Inkanish, Martin, & Brauchi, 2002), and (3) mechanisms for continuation of the species (Fisher, 2004). Our bodies and brains continue to function according to hunting and gathering needs appropriate thousands of years ago.

THRIFTY GENE

Contrary to expectations, skeletons exhumed from 10,000 years ago on the American continent were seen to be healthier than those found since horti-

culture began (Steckel & Rose, 2002). Early humans stored food substances through the production of insulin in response to the ingestion of carbohydrates. This allowed for fat storage in the body to protect people during winter and times of famine. Similarly, the body and mind sought to limit the amount of energy expanded through physical activity. One ate large amounts when foods were ripe and available, and exercised only as needed for existence (Dapice, 2006, p. 253; Flier & Maratos-Flier, 2007, p. 72; Ozelli, 2007, pp. 84–85).

Food sources became drugs to prevent "decreased fitness" due to starvation and death. Addictive drugs share with "palatable food" the property of increasing extracellular dopamine (Di Chiara & Bassareo, 2007, p. 233). Nicotine, cocaine, and ephedrine sources were first mixed with an alkali substance, most often wood or lime ash, creating a "free base to facilitate diffusion of the drug into the blood stream" (Saah, 2005). Traditionally, American Indians processed corn in a variety of ways using lye or lime ash. Science has since discovered that this process used with corn was required to release complete amino acids and to provide the niacin required to regulate blood sugar. Different tribes had different recipes for treating corn using this method (e.g., Muskogee Creek "softkey," Cherokee "hominy," etc.). Some tribes still have official "corn lyers" (Dapice, Inkanish, Martin, & Montalvo, 2001).

The benefits of civilization have given us mass production and preservation of foods, tobacco, and other substances through agriculture, the industrial revolution, and global transportation. Substances such as tobacco, once rare and localized to a particular geographical area, required first slave labor and then industrialized technologies to produce in amounts sufficient for addiction. Tobacco, once scarce and used for ceremony only, is now plentiful, used in addictive ways, and kills in large numbers worldwide. The World Health Organization estimates that smoking kills more than 4 million people a year. This figure may rise to 10 million per year by 2030 because of rapidly growing tobacco use in developing countries (HealthCentral.com, 2000). As it happens, preservation of tobacco, which includes large amounts of sugar, adds to its addictive qualities by appealing to the brain's natural survival need for carbohydrates (Bennett, Howell, & Doll, 1970).

While tobacco use remains in first place with respect to fatal forms of substance abuse, obesity is rapidly moving ahead as the number-one killer (Tanner, 2004). Research demonstrates that brain circuits involved in drug addiction are also activated by the desire for food. The right orbital-frontal cortex is involved in compulsive behaviors characteristic of addictive states and this same brain region is activated when addicted individuals crave drugs such as cocaine. Food stimulation increases levels of dopamine and when obese individuals were examined, they were found to have fewer dopamine receptors—as has been found

in addiction to other substances (Brookhaven National Laboratory, 2004). It is, of course, important that food be satisfying for the survival of the species. Having fewer receptors increases the level of food intake, when possible, and this was once adaptive during winter and famine (Dapice, 2006; Ozelli, 2007). However, in a new understanding of how people become addicted to food, researchers note that taste and palatability are not the only factors since, when the ability to taste is removed, the same dopamine pathways are stimulated by calories (Andrews & Harvath, 2008; De Araujo et al., 2008). Popkin notes that the rapid globalization of obesity has been encouraged by marketing of unhealthy foods worldwide and the food industry has insisted that governments "should not restrict an individual's dietary choices" (2007, p. 93).

The American Cancer Society notes that while a third of the nation's 50 million smokers attempt to quit each year, not unlike statistics on treatment effectiveness in alcohol and drug addiction (Mathews-Larson, 1991; National Institute on Alcohol Abuse and Alcoholism [NIAAA], 1996; Polick, Aarmor, & Bracker, 1980), fewer than 5 percent succeed (Bartosiewicz, 2004). It has been observed and reported (Morgan, 2003) that smokers who try to stop tobacco use through patches and gum become addicted to these as well (Bartosiewicz, 2004). Research has demonstrated that drinking alcohol improves the enjoyment of tobacco. On the average, more than 85 percent of adults with a history of alcohol abuse smoke, and they may be more addicted to nicotine than are smokers without a history of drinking (Abrams, Monti, Niaura, Rohsenow, & Colby, 1996). Carl Anderson, researcher at Harvard University Medical School, reported in a personal communication (September 2004) that the amino acid, L-Glutamine, is missing in the brains of smokers, but not in the brains of those who can take or leave tobacco products. L-Glutamine also helps regulate blood sugar and related cravings for carbohydrates and alcohol (Mathews-Larson, 1991). Again, the cravings can be seen to be adaptive when it is desirable that one take in more of a substance than is needed at the time.

It is known that EEG brain waves are shaped genetically and researchers have demonstrated that reduced amplitude correlates with alcohol dependence. They have identified the chromosomal region that affects the P300 electrical brain wave, previously correlated with alcohol craving and predisposition to relapse. These EEG abnormalities are true both of alcoholics as well as their "alcohol-naïve" (never used) offspring (Begleiter & Porjesz, 1988; Propping, Kruger, & Mark, 1981; Tabakoff & Hoffman, 1988; Volavka, Pollock, Gabrielli, & Mednick, 1985). Studies at the University of Connecticut by Lance Bauer show that relapse to alcohol, cocaine, and opioid dependence can be predicted by brain waves. The high-frequency activity on EEGs was found to far outweigh clinical and demographic variables as a predictor of relapse (Bauer,

2001). Alcoholic P300 brain waves appear as "jagged mountains" compared to the normal appearance of gentle "foothills."

Alcoholism among some groups is partly related to lack of adaptation to certain foods. Alcoholism is highest among peoples who received grains such as wheat, barley, and oats relatively late—Russians and northern Europeans. American Indians have had even less time to adapt to these foods (Mathews-Larson, 1991). Research also shows that hypoglycemia affects up to 95 percent of alcoholics, causing them to become irritable, angry, depressed, hostile, and crave carbohydrates in the form of food or alcohol. Consuming carbohydrates in various forms serves to relieve symptoms temporarily, but with surges of insulin the cycle continues. In the alcoholic community, this phenomenon is known as "dry drunk" and may be observed whether or not individuals have ever used alcohol. Diabetics often experience these same hypoglycemic symptoms and are taught how to respond appropriately with diet (Bell & Martin, 2002; Mathews-Larson, 1991). The cravings are the key to this once-adaptive behavior.

FIGHT/FLIGHT

The fight/flight physiological process protected our ancestors from predators. The mammalian drive to escape danger is driven by the ability to feel negative emotions (Saah, 2005). However, fight/flight responses become destructive when such actions are inappropriate to the situation or when the stress or danger becomes chronic. Cortisol, produced during these times, becomes toxic to cells in the body and the brain, killing brain cells and leaving depression in its wake (Sapolsky, 1996). Especially important is the relationship of stress, cortisol, and predisposition to self-medication. As noted by the National Institute of Drug Abuse (NIDA) in a special issue on stress and drug abuse (2002), studies in the *Journal Psychoneuroendocrinology* indicate (1) stress and cortisol sensitize animals for drug-seeking behaviors and facilitate self-administration, (2) animals that are underaroused and have low levels of cortisol are more prone to develop drug-seeking behaviors, (3) severe stress early in life induces a series of physiological, neurobiological, and hormonal events that result in dysregulation of biological reward pathways in the central nervous system and in stress response systems; these changes seem to prompt self-administration of drugs and alcohol later in life, (4) prenatal exposure to stress and drugs predispose animals to drug-seeking behaviors in adulthood, (5) posttraumatic stress disorder (PTSD) is a risk factor for substance abuse, and (6) the administration of cocaine to humans causes similar physiological reactions such as secretion of adrenalin and cortisol, and psychological reactions similar to arousal caused

by stress. Researchers at the Scripps Research Institute in California (Koob, 1999) observed that heavy drinking not only depletes the brain's supplies of neurotransmitters necessary for feelings of well-being and pleasure (dopamine, serotonin, GABA, and opioid peptides), but it also promotes the release of cortisol. This release of cortisol causes tension and depression, which in turn causes the individual to drink more, leading to an ongoing vicious cycle.

Child abuse, neglect, sexual abuse, and verbal abuse cause damage to the cerebellar vermis in the brain, causing electrical irritability that the brain attempts to quell physiologically and the individual attempts to alleviate by abuse of alcohol and drugs. This area of the brain is extremely sensitive to stress hormones (Anderson et al., 1999). Brain imaging technology (Teicher, 2002) demonstrates that there are three major changes observed in the brains of adults who were abused as children: (1) limbic irritability with increased incidence of clinically significant EEG abnormalities, (2) deficient development of the left hemisphere of the brain (throughout the cerebral cortex and hippocampus), and (3) deficient integration of the left and right hemispheres of the brain with diminished development of the middle portions of the corpus callosum that serves as a bridge connecting the left and right brain. These lateralization changes in the brain are similar to those found by many other PTSD researchers. Essentially, the right brain takes control with negative affect and related behaviors (Bremner et al., 2000; Dapice et al., 2002; Sapolsky, 2000). However, the cerebellum has the potential architecturally to continue communication between the left and right brain with the administration of electrical stimulation (C. M. Anderson, personal communication, September 2003). Anderson (2001) has also noted a convergence of data suggesting that abnormalities in the cerebellar vermis may be involved in a wide array of psychiatric disorders, including depression, substance abuse, and ADHD. In *Nearness of Grace*, Arnold Mandell writes that exaggerated pruning of unused neural connections as a result of high levels of stress hormones leads to an extremely reduced range of potential behavior, which results in individuals "who lie without reason, get drunk, binge on promiscuity, steal unneeded things, or withdraw into interpersonal isolation" (2005, p. 30).

The relationship between stress and addiction is not limited to humans. Recent research among primates by Michael Nader of Wake Forest University has demonstrated the impact of unequal power on the one with power—and the ones without. Socially dominant male monkeys showed a brain chemistry change that encouraged resistance to using drugs such as cocaine. This alteration actually increased the number of dopamine receptors. Male monkeys at the bottom of the pecking order displayed *no* boost of the dopamine receptors and readily self-administered large amounts of cocaine (2002, p. 53).

CONTINUATION OF THE SPECIES

An example of yet another normal adaptive response gone awry can be seen in the case of romantic love (Fisher, 2004) and stalking behavior. Unlike addictive substances that are taken into the body, it is an example of external events that stimulate internal responses leading to addiction (Fisher, 2004; Meloy & Fisher, 2006). As an addiction, stalking shows all the symptoms—"tolerance, dependency/craving, withdrawal and relapse" (Meloy & Fisher, 2006, p. 364). Because it serves as a paradigm example of addictions that are not substances taken into the body, because more than 1 million women and nearly 400,000 men are stalked every year in the United States alone, and because stalkers are the most lethal of all criminals (Meloy, 2006, p. 172), space will be taken here to discuss how such an addiction works in the brain.

Stalking seems to originate with once-adaptive mechanisms for mating and reproduction—the sex drive or lust (testosterone), attraction or romantic love (dopamine), and attachment or companion love (vasopressin and oxytocin). The sex drive motivates people to consider a variety of possible partners for survival of the species. Attraction causes people to focus their energies on a specific individual. Attachment motivates people to remain in a relationship long enough to raise their offspring. However, these mechanisms in an individual with personality disorders such as narcissism or borderline personality combine in dangerous and often lethal ways. Stalking perpetrators often have attachment problems from early in life that may be the result of parental loss, neglect, abuse, or abandonment, and may also be related in some cases to genetic defect (Meloy, 2006, p. 278).

Brain imaging studies of stalkers demonstrate elevated activity of dopamine in the reward/motivation system. This activity produces focused attention and unwavering motivation and goal-directed behaviors. These are associated with other feelings, including "exhilaration, increased energy, hyperactivity, and sleeplessness." As noted above, this system can be stimulated by a number of phenomena, including money and cocaine. Activation of these pathways is most likely related to several traits of the "spurned or unrequited" stalker. This response includes heightened energy and intense motivation to "pursue the victim" (Meloy & Fisher, 2006, p. 357). Deactivation of other brain responses may be part of the problem. The right amygdala, involved in fear and other negative emotions, is deactivated and this may cause stalkers to be unable to pay attention to the dangers of their actions.

Another shared characteristic of lovers and stalkers is their obsessive thoughts about the loved one. They report that they cannot get the obtrusive thoughts out of their minds. This is linked to the suppressed activity of central

serotonin since research links low serotonin to obsessive thoughts. Low serotonin is also linked to another characteristic of lovers and stalkers—impulsivity. There seems to be a negative feedback loop between dopamine and serotonin. Low serotonin elevates dopamine activity and elevated dopamine suppresses serotonin. As the stalker feels energy, attention, and motivation to pursue the victim, rising levels of dopamine suppress serotonin leading to more obsession and dysphoria. As obsession continues, dopamine further lowers serotonin. Other brain systems combine with these processes to produce the symptoms of "energy, impulsivity, dysphoria, fearlessness, and obsession" (Meloy & Fisher, 2006, p. 359). Observers note that these individuals often appear to be on methamphetamines—even when they are not.

Failed in attachment from childhood, caught in the negative feedback loop of increasing dopamine and decreasing serotonin, along with increasing levels of stress cortisol, continued rejection by the victim, all this sets in motion a frustration-attraction response that may increase and sustain the stalker's ability to stalk. They may also experience abandonment rage, which happens when an expected reward is in doubt or unobtainable, stimulating the amygdala in the brain and triggering rage. Both romantic love and rage have a great deal in common. Both produce obsessive thinking, focused attention, motivation, and goal-directed behaviors desiring union or revenge (Meloy & Fisher, 2006, p. 361). When cortisol has been stimulated over time, the levels become abnormally low and unlike previously thought, it is low cortisol, not testosterone, that is related to violence in bullies in school and prisoners in jails (MacKeen, 2000).

Fisher and Meloy point out that stalkers are in a state of addiction to their own chemicals. They are seen to relapse in the same way as addicts to cues such as people, events, and songs (Meloy & Fisher, 2006, pp. 364–365). One perpetrator said, "She was like a drug . . . that I needed . . . my high was being with her. . . . I felt like dying when not with her." After the victim obtained a protective order, he murdered her. He said he let his obsession ruin his life. "I lost it all because of my obsession. . . . This obsession was bad. . . . It was like being in heaven and in hell at the same time" (Kienlen, Birmingham, Solberg, O'Regan, & Meloy, 2006, p. 140). It is important to notice the narcissism that focuses only on what happened to him—not the woman he killed. In spite of the fact that stalkers may be one of the worst offenders due to their intelligence and violence, they are rarely arrested for their crimes (Meloy, 1998, p. 3; Meloy, Cowet, Parker, Hofland, & Friedland, 2006, p. 143). Stalking behaviors sometimes continue for years, leaving victims in chronic acute traumatic stress where the impact of cortisol damage to victims' brains and other organs is only now beginning to be realized. Stalking behavior needs to be stopped for the sake of both perpetrators and victims.

OTHER BEHAVIORAL ADDICTIONS

Necessary risk taking, mating, and exchange of needed goods are all important to continuation of the species. In "Behavioral Addictions: Do They Exist?," Constance Holden (2001) noted that gamblers get high, show tolerance, have withdrawal symptoms—like drug addicts. Holden gave as example the work of Anna Rose Childress whose brain imaging showed sex addicts to resemble cocaine addicts. Further, Internet abuse is seen as the country's fastest-growing addiction with people addicted online to the same things they are addicted to offline—gambling (including short-term trading), pornography, and shopping, Holden referred to psychiatrist Susan McElroy's statements that the form addictions take has a lot to do with gender. "Men are overwhelmingly represented among sex 'addicts' and outnumber women by about 2 to 1 in gambling and substance abuse." Women are prone to what she calls the "mall disorders"—eating, shopping, and kleptomania—where the ratio of females to males in kleptomania is 2 or 3 to 1 and perhaps 90 percent of compulsive shoppers are women. Bulimia, which is characterized by binging and vomiting, is also seen to be an addiction, unlike anorexia, which involves rigidly controlled behavior and no "high" (Holden, 2001, pp. 980–982). The bulimia-anorexia difference is similar to distinctions between battering and stalking, where stalking is a form of addiction, while brain imaging of batterers demonstrates a misperception of cues causing batterers to mistakenly feel under attack and respond in misplaced attempts to protect themselves (George et al., 2000). Other behaviors such as working and jogging are normally adaptive, but in exaggerated form can take over with the same compulsivity as any other addiction.

A curious example of substance-interaction with addictions thought to be behavioral is the relatively new finding that a prescription drug for "restless leg syndrome" (RLS) can result in a variety of behavioral addictions. Television commercials can be heard regularly listing "side effects" such as pathological gambling, compulsive eating, increased alcohol consumption, and sexual obsession (Mayo Clinic, 2007). What is more interesting is that it is not so widely recognized that over-the-counter diphenhydramine (Benadryl), found in a number of drug combinations for sleep and colds, can elicit RLS (Rye, 2005). The "addictive" behaviors will end with the removal of the RLS medication—and may not begin if diphenhydramine is not taken in the first place.

DISCUSSION

Behaviors once critical to the survival of our species relied on the limits of the environment for regulation. With these limits removed by modern agriculture, transportation, and global trade, we are left with no internal controls

(Saah, 2005) to regulate behaviors where often endless excess is available. In essence, the brain has no brakes. Technology has changed more rapidly than evolutionary adaptations (Walsh, 2007). Drugs of abuse not only stimulate areas of the brain that have evolved to encourage adaptive behaviors, they stimulate these areas more effectively than the survival behaviors themselves (Di Chiara & Bassareo, 2007). In nature, rewards usually come only with effort and after a delay (Harvard Mental Health Letter, 2004). Addictive substances and behaviors provide shortcuts to feeling "fit." Meanwhile, nature and nurture are related in that fight/flight stress makes the brain think famine is coming and so substances are taken in excessively to prepare for the coming "famine." Stress may also exaggerate behaviors that were once adaptive such as sex and risk taking. It is these once-adaptive and interrelated behaviors that now threaten our worldwide health and survival at ever increasing rates.

The understanding of addiction then is complicated and requires both breadth and depth of knowledge from a variety of disciplines if we are to begin to understand its nature. Addiction is no longer about a limited number of substances and people. Many of us, if not most, are addicted to one substance or behavior or another—including the substances and behaviors that are the essence of living itself. The processes that evolved to protect us often do not. It is a new world of addiction—literally and figuratively. Our human "civilization" has made us successful beyond all imagination. First, we learned to gain at least some control of our food supply by planting seeds into the ground so we would not be limited to gathering what Mother Nature provided alone. Instead of hunting untamed animals, we would eventually learn to tend, fence, and breed animals we would depend upon for meat. These actions alone would not prevent hunger from times of famine, but we would also learn to trade with other groups for what we needed but did not have. The movement from hunter-gatherer societies to ones that were pastoral and horticultural required larger families to do the work—as it also provided more food than might once have been available. Larger families would move people from hunter-gatherer egalitarian groups to hierarchical systems where some had more power than others. Eventually, this "civilization," across large societies worldwide, would find slaves helpful in accomplishing even greater amounts of work—allowing others to assume special privilege of class and power. The industrial revolution would come to make slavery no longer necessary, but class and unequal power would generally remain.

Thus the poor may have more abundance than in the past, but it is generally of low quality, full of bad fats and refined carbohydrates that lead to obesity, Type 2 Diabetes, cardiovascular disease, and cancer. Therefore, in what the Food and Agriculture Organization of the United Nations has called the

"double burden" of malnutrition, undernutrition exists side by side with rapid rise in overweight people and obesity and related chronic diseases (Spotlight, 2006). Based on a recent study, Dr. Michele Companion of the University of Colorado describes the same phenomenon occurring with American Indians in the United States—as well as in the developing nations of the world (*Native American Times*, 2008).

Human brains seem not to have evolved much from hunter-gatherer times—they continue to depend on a limiting environment for brakes. For most people worldwide, the environment no longer provides these limits. In the modern world, we use cell phones, e-mail, text messaging, wireless computers, and computer games "24/7." Have our electronics, and their messages, made us more attuned to possible dangers from which we must flee or be ready to fight? There seems to be a constant need to be in touch, to know what is happening, a fear of what will happen if we do not stay continuously "tuned in."

CONCLUSION

Not only do we have "old brains," but with new brain imaging, we are able to understand that the brains of people who are addicted are seriously damaged by the drugs of abuse—and may have been damaged by genetic predisposition, or child abuse, or both, long before self-medication began. Science not only can provide us with new information, it can also tell us of past activities such as the use of lye and lime in treating foods and psychotropic plants for nourishment.

The marketing of tobacco and processed foods worldwide, especially to developing countries, has changed the nature of health problems in the world. Tremendous amounts of money are involved in this global trade. New meaning has been given to "international drug traffic." We have tremendous numbers of addicted and a larger array of addictions worldwide. The material cost and human suffering is beyond imagination. Our "old" brains that are capable of developing the technology that can look inside our brains will need to find new ways to stop the damage.

Chapter **4**

Co-Occurring Trauma and Substance Use Disorders with Criminal Offenders

Scott E. McClure, PhD

It was a moonlit Saturday morning in the slums of London on February 17, 1872, when an event happened that had an indirect yet permanent influence on the English language. Dr. William Chester Minor was a trained physician who served at the Battle of the Wilderness in May 1864 during the American Civil War, a war noted for its gruesomeness and casualties. Dr. Minor's military duties involved the typical medical procedures used to aid the continuous stream of injured soldiers in need of medical treatment. Many of the wounded soldiers needs were far beyond the capabilities of medicine at that time and treatment often resulted in numerous amputations and deaths. In addition to standard medical procedures, Dr. Minor's duties included branding a letter D on the faces of war deserters, many of whom were Irish. These events would later have a profound impact on Dr. Minor's psychological well-being, especially branding Ds on the faces of Irish deserters, a duty he was always reluctant to do. Dr. Minor knew the long-term impact it would have on the Irish, both in the United States and in Ireland where many Irish military veterans planned to return with their newly learned combat skills to fight in the Irish revolts. The branded D would forever label these individuals in the United States as war deserters and would also become an identification mark in Ireland for soldiers of the revolution, thus resulting in rejection by both countries.

Following the Civil War, Dr. Minor's behaviors became impulsive and reckless, often involving alcohol and prostitutes. By 1867 his erratic behavior, accompanied by uncontrolled fits of rage, severe headaches, nightmares, paranoia, and delusions of persecution led to a military discharge and eventually admittance into St. Elizabeth's Lunatic Asylum in Washington, D.C. Upon

release from the asylum, Dr. Minor, still haunted by his paranoid delusions that the Irish were after him, moved to London in an attempt to start a new life. Unfortunately, his symptoms of psychological trauma followed him and eventually precipitated the murder of a complete stranger on this winter morning of February 17, 1872. In an ironic turn of events for history, Dr. Minor's assault resulted in his admittance into the English asylum in 1872 where he spent the majority of his remaining life providing thorough and decisive definitions and literary examples for the first comprehensive English dictionary, the *Oxford English Dictionary*.

In today's modern media, a news report titled "Disgruntled Veteran Murders Innocent Family Man" would be a typical headline for the events that happened on February 17, 1872. If the individual was intoxicated at the time of the event, his fate would fare worse, as society generally lacks empathy for violent crime and substance misuse. But, given the entire background and context, provided by Winchester's (1998) book *The Professor and the Madman*, in which Dr. Minor's offense occurred, it is obvious that he was an outstanding citizen and veteran military doctor, who as a result of psychological trauma triggered by the Civil War acted violently in response to his psychiatric symptoms.

In the 1800s we lacked the scientific knowledge and sophistication to provide adequate treatment for trauma symptoms. In modern psychology and psychiatry, we have made major progress in trauma treatment, yet as with Dr. Minor, we still fail to provide this treatment for many individuals who may need it the most, such as criminal offenders.

INMATE POPULATION PROFILE IN THE UNITED STATES

Violence, sexual victimization, racial segregation, substance abuse, and organized crime are prevalent in jails, state, and federal prisons in the United States. This is concerning as more than half of state and federal inmates are nonviolent offenders (Bureau of Justice Statistics, 2001), many of whom are entering prison for the first time. Hence, in order to reduce the odds of victimization and survive prison culture, inmates face the choice to participate in prison politics, which often involves the cost of witnessing and participating in illegal activities and violent behaviors, or to chance not participating in prison politics, which increases the likelihood of victimization.

The number of incarcerated individuals in the United States has nearly quadrupled since 1980. The deinstitutionalization of mental health care and the criminalization of drug policy ("war on drugs") have substantially increased sentencing for nonviolent offenders. Regardless of a decrease in violent and

property crimes since the 1990s, our state, federal, and jail inmate populations have steadily risen to 2,245,189 in 2006, which constitutes a 2.8 percent increase since 2005 (William, Todd, & Paige, 2007).

Compared to the general population, prisoners disproportionately come from economically and socially disadvantaged environments. According to the 2002 Bureau of Justice Statistics special report on inmate profile statistics, nearly 70 percent of jail inmates reported regular use of alcohol and drugs, 56 percent of jail inmates grew up in a single-parent home, 1 in 9 lived in a foster home, 31 percent grew up with a parent or guardian who abused alcohol or drugs, and 46 percent reported having a family member who had been incarcerated (Bureau of Justice Statistics, 2004). In addition, more than 50 percent of females and 10 percent of incarcerated males reported being either physically or sexually abused in the past. Abuse rates for male inmates may be underreported. This is particularly true for male offenders victimized while in prison, who are often required to play an ultramasculine role to avoid further victimization and to pertain to the prison cultural values of secrecy and loyalty, which are often needed to survive in this hierarchical society (Goff, Rose, Rose, & Purves, 2007).

Individuals who come from past histories of physical and sexual abuse, who have criminally involved families, and participate in substance misuse, have an increased chance of being incarcerated and experiencing traumatic events. Many incarcerated individuals come from neighborhoods inundated with illicit substances and gang activity. As in prison, to survive in economically disadvantaged neighborhoods, individuals often participate in street politics. As a result, it is nearly impossible to avoid witnessing and at times participating in physical violence and various other illegal activities, which often result in increased vigilance, emotional numbing, increased substance use, and other means of coping with those chaotic environments. Many of these coping skills can become symptoms of posttraumatic stress disorder (PTSD), which will be discussed later in this chapter. Even though many individuals will experience traumatic events in their lifetimes, the development of PTSD is the exception and not the norm.

HISTORICAL DEVELOPMENT OF POSTTRAUMATIC STRESS DISORDER (PTSD)

Prior to the Vietnam War, there were few scientific studies that examined the psychological effects of trauma. Though few studies existed, descriptions of the psychological impact of combat trauma are numerous throughout historical literature. The *Iliad* describes the cold and detached nature of Achilles, who fre-

quently partook in reckless acts of courage fighting hundreds of enemy soldiers without regard for his own life. Ernest Hemingway's short story *Soldier's Home*, which is arguably semiautobiographic, describes in great detail the psychological effects of war trauma on the individual and his surrounding life. This story ends with the main character feeling disconnected and emotionally numb to his current life and lacking motivation and excitement about his future.

During the 1800s military doctors began to diagnose soldiers with "exhaustion" due to a mental shutdown following combat trauma. In the late 1800s Dr. Mendez DaCosta described "Soldier's Heart" as a diagnosis for Civil War combat veterans. Psychological symptoms included hypervigilance and increased startle response, and physiological symptoms included fatigue, heart palpitations, sweating, and tremors. During World War I and World War II, the diagnosis "shell shock" and "combat neurosis" labeled the psychological and physiological symptoms associated with war trauma (Herman, 1992). It was not until the Vietnam War that the scientific examination of the psychological effects of trauma in general and during combat began (Friel, White, & Hull, 2008). The post-Vietnam examination of psychological trauma paved the way for our modern-day classification of PTSD, which first appeared as a diagnosis in the *Diagnostic and Statistical Manual of Mental Disorders Version III (DSM–III)* in 1980 (American Psychiatric Association [APA], 1980).

The *DSM–III* required the following criteria for a PTSD diagnosis: The person experienced or witnessed a distressing event that is outside the range of usual human experience such as a serious threat to one's life or physical integrity. In addition to experiencing this event, the individual must also present with the symptom triad of reexperiencing the event, numbing and/or avoidance, and hyperarousal. These symptoms must persist for more than one month following the event (APA, 1980). The *DSM–III* diagnostic definition of trauma was an important step in the evolution of trauma identification and treatment. The new symptomatic PTSD diagnosis allowed researchers to generalize the traumatic experience beyond victims of war and paved the way for new research regarding the traumatic experiences of incest, rape, domestic violence, child abuse, and other trauma-related topics.

Fourteen years after the publication of the *DSM–III*, the *DSM–IV* was published, to be followed shortly by the evidence-based text revision (*DSM–IV–TR*) in 2000 (APA, 2000). Significant advances in PTSD theory and research enabled the *DSM–IV–TR* PTSD committee to change the primary diagnostic criteria to include a response of intense fear, helplessness, or horror in reaction to the traumatic event as well as to improve upon the original symptom triad.

DSM–IV–TR DIAGNOSTIC CRITERIA FOR PTSD

The *DSM–IV–TR* states that for a diagnosis of PTSD an individual must be confronted with, experience, or witness an event or events that involved actual or threatened death or serious injury, or a threat to the physical integrity of others. The person's response to this event must involve intense fear, helplessness, or horror. In addition to the first two criteria, the individual must experience one or more symptoms of *recurrence* (distressing recollections, distressing dreams, flashbacks, distress or physiological reactivity triggered by internal or external cues associated with the event), three or more symptoms of *avoidance/numbing* (avoid thoughts, feelings, or conversation; avoid activities, places, or people that trigger memories of the event; inability to recall important details associated with the event; diminished interest in activities, feeling detached or estranged from others, restricted affect, foreshortened sense of future), and two or more symptoms of *increased arousal* (sleep difficulties, irritability or anger outbursts, difficulty concentrating, hypervigilance, exaggerated startle response). These symptoms must persist for more than one month following the event and cause clinically significant distress or impairment in social, occupational, or other important areas of functioning (APA, 2000).

TRAUMA AND SUBSTANCE USE DISORDERS IN THE GENERAL POPULATION

Nearly all individuals who participate in substance use treatment programs have experienced psychological trauma. Trauma exposure rates for individuals in both inpatient and outpatient, voluntary and mandated drug treatment programs are near 100 percent (Farley, Golding, Young, Mulligan, & Minkoff, 2004). Approximately 40 percent of clients in drug treatment programs meet the diagnostic criteria for PTSD (Brown, Recupero, & Stout, 1995; Dansky, Roitzsch, Brady, & Saladin, 1997; Farley, et al., 2004; Kessler, Sonnega, Bromet, Hughes, & Nelson, 1995; Triffleman, Marmar, Delucchi, & Ronfeldt, 1995). This is exceptionally high considering that the estimated lifetime prevalence of PTSD among adult Americans is 7.8 percent, with women (10.4%) being twice as likely as men (5%) to have PTSD at some point in their lives (National Center for Posttraumatic Stress Disorders, 2005). It is known that PTSD and other trauma-related problems among substance-abusing populations are associated with many physical, emotional, and interpersonal problems. These problems include an increased risk for chronic health problems, use of "harder" drugs, greater consumption of drugs and alcohol, more frequent relapses, poorer retention in treatment, and more inpatient hospitalizations

than having a substance use disorder without trauma exposure (Brown et al., 1995; Jacobson, Southwick, & Kosten, 2001; Cronkite, Henson, Prins, Gima, & Moos, 2004; Ouimette, Finney, & Moos, 1999; Ouimette et. al., 2004). In addition, individuals with PTSD and trauma-related problems are more likely to be unemployed and have less social support than those without (Ouimette et al., 1999).

The physical, emotional, and interpersonal problems associated with individuals who have co-occurring substance use and trauma disorders are alarming. This becomes even more alarming when the overlap between trauma correlates and the criminogenic risk and needs principles used to identify an individual's potential for success in treatment and risk of criminal recidivism are compared.

Marlowe (2007) defines *criminogenic risks* as the characteristics of criminal offenders that increase the likelihood of a relapse to drug misuse and decrease the likelihood for success in treatment, thus increasing the chance of recidivism. The most notable high-risk factors include an earlier onset of substance abuse (especially prior to age 14) or crime (especially prior to age 16), attempting rehabilitation at a younger age (especially before 24 years of age), a recidivist criminal record, previous unsuccessful attempts at rehabilitation, and a co-existing diagnosis of antisocial personality disorder. More strikingly similar are an individual's *psychosocial/criminogenic needs*, which are an individual's areas of dysfunction that, if improved, can considerably reduce the likelihood of continued involvement in substance misuse and criminal behaviors (Marlowe, 2007). Notable high-need factors include compulsive addiction to drugs or alcohol, psychiatric pathology, emotional trauma, brain injury, chronic medical conditions, and illiteracy.

Considering the overlap between criminogenic risk/need factors and those associated with co-occurring trauma and substance use issues, it is fair to assume that many individuals who have not yet participated in the criminal justice system are at substantial risk for incarceration. This is especially true for individuals whose addiction worsens and their need for more and harder substances increase as their tolerance and physiological withdrawal symptoms increase. This progression of addiction usually leads to decreased social functioning and increased criminal behaviors. For example, to achieve the desired level of intoxication needed to numb the emotional pain of past traumas and relieve physical withdrawal symptoms, an individual will likely be in possession of larger amounts of substances and need to participate in other illegal activities such as prostitution, drug sales, theft, and at times violent crimes to financially support his addiction. Hence, for many individuals who go untreated for

co-occurring substance misuse and trauma, it is only a matter of time before they enter the revolving doors of the criminal justice system.

CO-OCCURRING TRAUMA AND SUBSTANCE USE DISORDERS WITH CRIMINAL OFFENDER POPULATIONS

Rates of PTSD for both male and females are higher in prison settings than in the general population (Goff et al., 2007; Kubiak, 2004; Trestman, Ford, Zhang, & Wiesbrock, 2007). The PTSD rates are likely to be higher for incarcerated individuals for several reasons. Most incarcerated individuals have participated in substance use, criminal behavior, and come from areas of extreme poverty, all of which increase the risks of trauma exposure (Hochstetler, Murphy, & Simons, 2004). In addition to being at risk prior to incarceration, prison can be the source of new traumas and a trigger for old ones (Kubiak, 2004). As with individuals who experience traumatic events in war or civilian life, individuals who experience traumatic events in prison will have different reactions and varying degrees of adaptation and/or recovery from the event. The effect of a traumatic event while incarcerated will likely vary dependent upon an inmate's genetics, history prior to incarceration, and resources for overcoming and coping with the experience (Hochstetler et al., 2004).

The assessment and treatment of PTSD and other trauma-related symptoms rarely occurs for criminal offender populations. This is disturbing given the disproportionately high incidence of PTSD in this population, the high comorbidity between PTSD and substance use, and the alarmingly high rates of substance use disorders in criminal offender populations.

Inmates are more likely to have histories of substance abuse, mental health problems, and to have witnessed or been victimized by acts of violence than noninmates (Hochstetler et al., 2004). Prevalence rates for PTSD among incarcerated men have been shown to be over four times greater than those of the general population (Ehlers, Maercker, & Boos, 2000) and two times greater for incarcerated women than in the general population (Jordan, Schlenger, Fairbank, & Cadell, 1996). Even these astonishing rates may be an underestimate. Trestman et al. (2007) examined the lifetime prevalence rates of PTSD in a sample of 2,196 incarcerated male and female inmates not identified as acutely mentally ill at intake in Connecticut jails. In this sample, lifetime PTSD prevalence rates for men reached 20 percent and 41.8 percent for women. These findings are alarming as they suggest that many incarcerated individuals who suffer from PTSD often go undetected and untreated.

In addition, Kubiak (2004) explored the differences in treatment adherence, substance relapse, and criminal recidivism in a sample of 199 incarcerated men (n = 139) and women (n = 60) who volunteered to participate in two residential in-prison substance abuse treatment programs. Fifty-five percent of the treatment population met the criteria for a lifetime prevalence of PTSD with no statistically significant difference in prevalence rates for men (53%) and women (60%). Not surprisingly, due to the aggressive hierarchical nature of men's prisons, men were more likely to report a traumatic experience within the past 12 months while incarcerated than women were. Only one woman reported a traumatic event in the past 12 months compared to 75 percent of men. Most important, statistical analysis identified that both men and women with co-occurring PTSD and a substance use disorder were more likely to recidivate and relapse than those with only a substance use disorder were. This is highly suggestive of the need to address co-occurring substance use and trauma symptoms for incarcerated individuals, as they appear to be highly associated with relapse and criminal recidivism.

Regardless of the high incidence of co-occurring PTSD and substance use with incarcerated individuals, the effects of psychological trauma on substance relapse and criminal recidivism rates are rarely addressed (Kubiak, 2004). This is concerning as several studies have reported high incidence of trauma history among men and women who enter prison (Jordan et al., 1996; Kupers, 1996; Teplin, Abram, & McClelland, 1996), and there is documented evidence of exposure to as well as participation in violence within institutions (Kupers, 1996; Toch, 1998; Websdale & Chesney-Lind, 1998), including sexual victimization for both men and women (Beck & Harrison, 2008; Wolf, Blitz, & Shi, 2007). In fact, an estimated 4.5 percent of state and federal inmates have experienced sexual victimization while incarcerated, with the highest prison rates ranging from 9.3 to 15.7 percent (Beck & Harrison, 2008). This presents a serious problem as 80 percent of federal and state inmate convictions were due to either a drug-related crime, being under the influence during the crime, or having committed a crime to support drug use (Belenko & Peugh, 1998). Approximately 40 percent of clients in drug-treatment programs have PTSD (Brown et al., 1995; Dansky et al., 1997; Farley et al., 2004; Kessler et al., 1995; Triffleman et al., 1995) and up to 50 percent of released inmates who enter community-based treatment programs are thought to have a co-occurring PTSD and substance use disorder and tend to demonstrate poorer long-term treatment outcomes than those without (Ouimette et al., 1999). Hence, in order to reduce recidivism rates with criminal offender populations, the relationship between trauma and substance use disorders needs to be addressed prior to release.

TREATMENT OF CO-OCCURRING SUBSTANCE USE DISORDERS AND TRAUMA

Individuals with PTSD often use substances in an effort to cope with overwhelming emotions, unwanted thoughts and memories, sleep disturbances, anxiety, depression, irritability, and other symptoms associated with trauma. When abstinent from substances, many of these symptoms reoccur with overwhelming intensity and often result in relapse only to further exacerbate PTSD symptoms (Kubiak, 2004). This process makes PTSD different from other mental health issues that co-occur with substance misuse in that trauma symptoms may worsen upon abstinence (Najavits, 2005). Another characteristic that differentiates PTSD from other psychiatric diagnosis is that it is the only mental health diagnosis with a directly identifiable cause that is external from the impacted individual (Najavits, 2005). Fortunately, an identifiable cause makes recovery from PTSD possible. Though recovery is possible, the success of trauma treatment will depend largely on the characteristics of the treated individual (biological vulnerability, genetics, socioeconomic status, single trauma, or chronic exposure), and the selected treatment intervention.

Most addiction treatment programs, whether community- or prison-based, do not assess for trauma history or offer any trauma-related treatment (Dansky et al., 1997). For individuals diagnosed with PTSD, substance use treatment without mental health treatment is less effective than for individuals without PTSD (Kubiak, 2004). For example, studies that have compared individuals in treatment for substance use disorders with and without co-occurring PTSD found higher relapse rates during treatment (Kubiak, 2004), at three-month (Brown, Stout, & Mueller, 1996) and one-year (Ouimette, Ahrens, & Moos, 1997) posttreatment follow-up for individuals with PTSD.

Research has demonstrated better treatment outcomes, for both PTSD symptoms and reduced substance use, when substance use disorders and trauma are addressed simultaneously (Cocozza et al., 2005; Kubiak, 2004; Ouimette et al., 1999). Regardless of this knowledge, most corrections-based addiction treatment programs do not address trauma symptoms. This unfortunate gap between the scientific evidence for effective treatment and its application in frontline treatment delivery may be due to several reasons. For example, trauma assessment rarely occurs in jails or prisons, corrections-based addiction counselors generally lack the knowledge and skills necessary to implement trauma treatment, and most prison-based treatment programs do not utilize clinically licensed supervision to monitor treatment quality.

Currently, there is little empirical research on effective treatment approaches for incarcerated populations. Heckman, Cropsey, and Olds-Davis (2007) con-

ducted an extensive literature review of 156 published empirical articles that addressed trauma treatment in correctional institutions. Only seven articles met the criterion for being empirically oriented and pertaining to PTSD in the criminal justice system. Of those seven, only two studies showed promising results and only one included treatment for co-occurring substance use and trauma disorders (Valentine & Smith, 2001; Zlotnick, Najavits, Rohsenow, & Johnson, 2003). The first study examined an exposure-based approach that utilized repetitive guided imagery of the traumatic event to reduce sensitivity to the event and cognitive restructuring to eliminate irrational beliefs associated with it (Valentine & Smith, 2001). Though the exposure-based treatment had positive results, it did not address substance use and required a trained clinician. This makes it impractical for large substance treatment programs in which the counselors are not clinicians. In addition, exposure-based treatments do not account for the risks associated with doing invasive trauma treatment with substance-abusing individuals whose symptoms may worsen while reliving their traumatic memories.

The second effective treatment intervention utilized *Seeking Safety* (Najavits, 2002), a noninvasive, present-focused, skill-based treatment designed to help individuals cope with both PTSD and substance use disorders (Zlotnick et al., 2003). The strengths of Seeking Safety include a positive current focus, practical coping skills, being manual-based, and noninvasive. Seeking Safety also produced positive outcomes as evidenced by reduced trauma and substance misuse symptoms. Unfortunately, no known empirical studies exist that examine the effectiveness of Seeking Safety treatment with incarcerated men, though it has shown effectiveness with men in the general population (Najavits, 2005).

Presently, there is a substantial need for more research on Seeking Safety's effectiveness with incarcerated individuals, especially for men. Regardless, Seeking Safety appears to be the strongest evidence-based approach to treat co-occurring substance use and trauma disorders with incarcerated individuals. It is present-focused, can be implemented by trained addiction counselors, and is coping skills driven, which makes it a safer intervention for individuals who are at high risk for relapse and may have limited abilities to regulate emotions and impulsivity.

Despite significantly elevated trauma rates and increased exposure to trauma compared to the general population, PTSD treatment for incarcerated individuals is minimal (Heckman et al., 2007). There is limited research on effective treatments for co-occurring PTSD and substance use disorders in the general population (Najavits, 2005) and even fewer for criminal offender populations (Heckman et al., 2007). Hence, there is great need for trauma assessment,

treatment, and empirical research for this underserved population (Goff et al., 2007; Heckman et al., 2007; Kubiak, 2004; Trestman et al., 2007).

IMPLEMENTING CO-OCCURRING TRAUMA AND ADDICTION TREATMENT FOR CRIMINAL OFFENDER POPULATIONS

Clients are best served if both trauma and substance use disorders are treated simultaneously, preferably by the same individual or agency (Najavits, 2005). The time has passed where individuals are required to have a sustained period of abstinence prior to treatment. We now better understand the vicious cycle of substance use and PTSD by which substance use reinforces psychological avoidance, a primary symptom of PTSD, which in turn reinforces substance use. The utilization of an integrated treatment approach to address both substance use and trauma symptoms simultaneously may allow for the improvements in one domain to influence improvements in the other (Najavits, 2005). Thus, as the individual develops improved skills to cope with trauma, the individual will be less inclined to utilize substances as a means of coping, and reduced substance use may in turn reduce the potential for subsequent traumas.

In addition to integrated substance use and trauma treatment, individuals with trauma histories may benefit from stage-based treatment interventions (Herman, 1992; Najavits, 2005). Stage-based trauma interventions generally address safety and coping at the first stage, followed by mourning (processing) the traumatic experience, and finally reconnection, the process by which the individual focuses on functioning in work and relationships (Herman, 1992; Najavits, 2005). Safety and coping should be the primary focus for individuals in corrections-based treatment. This is especially true for individuals with severe forms of PTSD and other co-occurring disorders who may decompensate upon addressing trauma symptoms. After clients have successfully developed skills to regulate emotions and cope with trauma symptoms without substance use, they may progress to processing the trauma through exposure therapy, and eventually shift their focus on reconnecting to a functional life. Corrections-based treatment may be the appropriate place to begin the initial phase of trauma treatment, but referral upon release to individual therapy or advanced group therapy by a licensed clinician trained in trauma treatment is recommended for the advanced stages of trauma treatment that utilize processing and exposure techniques.

Successful treatment implementation will depend upon several factors. First and foremost, the positive benefits of treatment must outweigh any negative

consequences. If trauma treatment elicits negative thoughts and emotions beyond the treated individual's ability to cope and beyond the addiction counselor's skill level, the client's safety will be violated. Safety is fundamental for successful treatment, if violated individuals may relapse into harmful behaviors such as substance use, physical aggression, and even suicide.

In corrections-based addiction treatment, where safety, security, and trust are of the utmost concern, only the safest and most effective trauma treatments should be applied. Regressive-based treatments such as exposure therapy, Eye Movement Desensitization and Processing (EMDR) therapy, and psychoanalytical treatments, though effective if performed by qualified individuals, are not the best modes of treatment for offenders while incarcerated. One point of concern in regard to treating trauma symptoms in corrections-based addiction treatment programs is the lack of qualified clinicians to address the complex issues that arise when clients discuss and/or relive their trauma histories. Most treatment providers are not equipped with the knowledge, skills, or formal education to work with trauma-related issues and can inadvertently induce harm on the inmate client. Unskilled addiction treatment counselors may mistakenly allow clients to disclose specific trauma details. The disclosure of trauma details without a skilled clinician can be harmful during individual therapy, can elicit trauma symptoms for others during group treatment, and can produce vicarious traumatization for both inmates and treatment staff (Baird & Kracen, 2006). Though disclosure can be effective for regressive- and exposure-based treatments, handling trauma disclosure is beyond the skill level of most addiction treatment counselors.

Even if noninvasive skills-based treatment is applied, adequately trained staff should always deliver it. Trained, licensed clinicians are the optimal choice for treatment delivery, but well-trained addiction counselors supervised by a trained licensed clinician may be as effective and more economically practical for corrections-based treatment. In addition to training frontline treatment staff, all staff, including administrative, corrections, and program management can help improve the treatment atmosphere if trained in *trauma-informed* services (Najavits, 2005).

It is very important that addiction treatment programs understand the difference between *trauma-informed* treatment and *trauma-competent* treatment (Najavits, 2006). Trauma-informed treatment includes giving basic trauma education to all staff at all levels. The Substance Abuse and Mental Health Services Administration (SAMHSA) Women, Co-occurring Disorders and Violence Study (WCDVS) has identified 10 principles that define trauma-informed services (Elliot, Bjelajac, Fallot, Markoff, & Reed, 2005). Though the WCDVS study is specific to women, it seems fair to generalize its principles to men.

The 10 principles include:

1. Trauma-informed services (TIS) recognize the impact of violence and victimization on development and coping strategies.
2. TIS identify recovery from trauma as a primary goal.
3. TIS employ an empowerment model.
4. TIS strive to maximize an individual's choices and control over her recovery.
5. TIS are based in a relational collaboration.
6. TIS create an atmosphere that is respectful of survivors' need for safety, respect, and acceptance.
7. TIS emphasize strengths, highlighting adaptations over symptoms and resilience over pathology.
8. The goal of TIS is to minimize the possibilities of retraumatization.
9. TIS strive to be culturally competent and to understand each individual in the context of her life experiences and cultural background.
10. Trauma-informed agencies solicit consumer input and involve consumers in designing and evaluating services.

While trauma-informed services aim to educate the entire workforce in the basic knowledge, skills, and understanding of the needs of individuals with histories of trauma, trauma-competent treatment seeks to train fewer, carefully selected individuals with the skills necessary for trauma treatment (Najavits, 2006). These individuals need to become educated on manual-based interventions for co-occurring substance and trauma disorders, require clinical supervision, and need formal training on trauma-based interventions. In addition, not all addiction treatment counselors are a good fit for delivering trauma-focused treatment (Najavits, 2006). Individuals who have not learned to cope with their own trauma histories, those who have poor boundaries, and those who are particularly confrontational in their treatment approach may jeopardize the quality of treatment, and at times may cause more harm than good. Fortunately, with proper training, the appropriate staff selection, and clinical supervision, it appears that we can begin to address the ever-evolving problem of co-occurring trauma and substance use disorders with criminal offenders.

CONCLUSION

Clearly, there is a need to improve the assessment, treatment, and research on criminal offender populations with co-occurring trauma and substance use disorders (Goff et al., 2007; Heckman et al., 2007; Kubiak, 2004; Trestman et al., 2007).

Treating both substance use and trauma disorders simultaneously can improve the effectiveness of treatment, as both disorders impact one another. To date, there is limited research on effective trauma treatment interventions for criminal offenders, and even less for criminal offenders with co-occurring PTSD and substance use disorders. Even though there is limited empirical research, it appears that present-focused, noninvasive, standardized, skills-based treatment that emphasizes coping and safety, such as the Seeking Safety treatment design (Najavits, 2002), is the best fit for trauma treatment in correctional institutions.

Until there is increased scientific evidence for effective treatment interventions for criminal offenders with co-occurring trauma and substance use disorders, it seems logical to utilize the most efficient and safest interventions possible. It is this author's opinion that corrections-based treatment is not the place to experiment with treatment modalities that are not evidence-based and scientifically driven. The utilization of nonscientifically driven trauma treatment in correctional institutions, especially by staff that are not trained clinicians, may be borderline unethical behavior as criminal recidivism rates continue to fall between 70 and 80 percent, which indicates that treatment as usual is not highly effective. In addition, there is no room for experimentation in this environment where safety and reduced recidivism is the primary concern. Therefore, the benefits of simultaneously treating trauma and addiction is evident and highly needed, and if done correctly, may substantially reduce criminal recidivism and help formally incarcerated individuals become productive members of society.

Chapter **5**

The Role of Allergies in Addictions and Mental Illness

Joan Mathews-Larson, PhD, LADC, and
Mark K. Mathews, LADC, BCCR

Understanding allergies as they pertain to addictions and mental health issues requires an analysis of multiple genetic factors. Most agree allergy symptoms are the result of hypersensitive receptors on mast and basophil cells responding to various antigens by triggering the release of inflammatory mediators—particularly histamine. Standard treatment protocols address this underlying flaw with allergy medications, which block the release of histamine, but do nothing to abolish the underlying problem. The consequence of this approach has fueled a rise in addictive patterns with a progressive decline in the health for many allergy-afflicted people. This chapter will examine a genetic basis for allergies more carefully, and present evidence that the pathogenesis of addictions and many mental health problems are actually manifestations of IgG (immunoglobulin G, a serum protein antibody) delayed-onset allergies progressing toward more serious degenerative diseases.

Although the cause of allergies can be explained as an unregulated degranulation of histamine from mast and basophil cells due to gene malfunction, other complex genetic factors contributing to allergy processes need to also be considered (Akdis & Blaser, 2003, p. 15). More than 30 years ago, scientists suspected a genetic connection involving an immune system disorder existed for many diseases, based on structural anomalies in cells. Researcher Chang (1975) states:

> The view that diseases such as cancer, systemic lupus erythemotosus, and agammaglobulinemia can be successfully treated by unilateral manipulation of the

> humeral or the cell-mediated immune response per se is probably too simplistic. It has become increasingly clear that many of these disorders of the immune system seem to arise from flaws in cell differentiation, resulting in a hyper- or hypofunction of a particular cell type. (p. 82)

Chang's statement suggests gene-influenced diseases might occur in various ways, and even though unique genetic disorders manifest into different diseases, the process is often accompanied by inflammation (i.e., it incorporates an allergy response).

Geneticist Dr. Chris Reading's insightful reasoning expounds on flaws in cell differentiation, as proposed by researcher Chang. He believes maladapted genes causing allergies must be corrected or prevented from being expressed to prevent the progression of disease. Dr. Ravikovich (2003) aptly states Dr. Reading's concerns:

> A slight genetic defect, mostly inherited, occasionally acquired, may remain unnoticed for years. However, time itself and/or cumulative effects of the hazards [allergy provoking substances] may "break the back of the camel." In other words, the initial small defect in the genes may become magnified, and as a result, the operation guided by these genes may cause cells to respond [express] with a pathological reaction to what they would have perceived as harmless before. (p. 7)

Dr. Reading concedes, substances that provoke recurrent allergic responses are especially hazardous for people with underlying genetic defects; but more important, he offers insights into understanding how these structural genetic defects are formed before getting switched on later in life.

Dr. Reading focuses on rogue genes: those present at birth, and distortions that may develop later in life to initiate diseases. Genetic distortions are expressed both structurally and functionally, and with more than 30,000 genes in the nucleus of a single cell, and trillions of cells in the human body, intervening to correct the structural genetic defects causing allergies is impractical, if not impossible (Ravikovich, 2003, p. 8). Instead, Dr. Reading (2002) urges preventative tactics to stop irritating the hypersensitive immune system.

> Hypersensitivity reactions result from repeated exposure to a particular substance or to its chemically related substances. . . . The substance, if it is a large polypeptide, acts as an antigen and stimulates the body to form antibodies. Otherwise the substance acts as a hapten and combines with proteins in the body to form antigens. The reaction between an antigen from a later exposure and the corresponding antibodies results in the release of histamine. (Lu & Kacew, 2002, p. 49)

Like Dr. Ravikovich, Dr. Reading recognizes hypersensitive reactions stem from repeated exposures to allergy-provoking foods. But rather than focusing

on correcting the genetic malfunction causing the exaggerated release of histamine, Dr. Reading recommends avoiding allergy foods (Reading, 2002, p. 143). A delayed allergy response, although clearly tied to the release of histamine, might not respond to histamine corrective protocols; in fact, the classic exaggerated histamine release, used to define an allergic response, may not even be the primary problem in an IgG delayed response. After all, cell degranulation (histamine release) is how healthy tissue should respond when foreign substances (e.g., polypeptides/allergens) come into contact with it (Rocklin, 1982, pp. 49–70; Sirois & Borgeat, 1982, pp. 205–206).

Recognizing substances that provoke allergy responses may compromise the health of the host in more ways than just the release of histamine, Dr. Reading augments previous allergy concepts with a thought-provoking theory that elucidates the pathological progression of diseases, and provides insight into how such great disparities can exist in people's susceptibility to contract them.

To follow his reasoning, Reading (2002) first offers some clinical facts to be reviewed:

1. During pregnancy the mother and fetus interact chemically. Dehydroepiandrosterone (DHEA) secreted from the adrenal cortex of the fetus stimulates estrogen hormones from the mother's placenta to affect the formation (differentiation) of fetal tissues. An adequate supply of vitamins and minerals from the mother is crucial for the process to work.
2. Secondly, the propensity of the most common offending allergy-causing foods (grain, milk, egg, beef, and yeast) to trigger allergies is actually caused by components of the foods called subfractions: proteins such as gluten, a-gliadin, a-casein, and so on.
3. Thirdly, when people consume allergy-provoking foods, they do not properly absorb vitamins and minerals, exacerbating deficiencies in many important nutrients (p. 140).

Dr. Reading reasons when pregnant women consume allergy foods, their allergy-induced vitamin and mineral deficiency has two deleterious effects on the forming fetus: it hinders the release of hormones from the mother's placenta, and it lowers levels of vitamins and minerals supplied to the fetus. This reduces the amount of DHEA being released from the fetus's adrenal cortex, which further interrupts the supply of estrogens from the placenta, resulting in an abnormal balance of hormones, vitamins, and minerals. Additionally, damage caused by the toxic subfractions in the foods to which the mother is allergic may also damage the fetus if the sensitivity to them is passed on genetically. Dr. Reading (2002) states:

> These subfractions, I believe, cross the placenta and can actually take the place of some of the hormones that are [for the reasons outlined above] in short supply.

> In other words, the toxic subfractions may actually have a hormone-like action on the fetus. The net result of the faulty hormone-vitamin-mineral balance, plus the presence and hormone-like action of the toxic food fractions, is that some of the fetus's tissues are laid down abnormally. Formed before the immune system has matured, these tissues have a special metabolism that makes them different from normal cells. They are, in fact, premalignant . . . likely to go wild and proliferate in later life, if exposed again to the toxic food fractions and faulty hormone-vitamin-mineral environment that originally helped to form them. (p. 141)

Biochemists recognize cells have receptors for various hormones, proteins, enzymes, and other substances needed to maintain normal growth and division. Each receptor is specially "tuned" to a specific hormone, protein, or enzyme; however, "Cells forming pre-malignant tissue also have receptors for fractions of toxic foods because they took the place of some natural hormones when fetal tissues were forming in the womb" (Reading, 2002, pp. 141–142). Since genes determine the development and activity of all cellular receptors, it is logical to conclude these problems are structural, not functional (Ravikovich, 2003, p. 2). Therefore, to prevent these genes from being switched on, the food fractions originally present when the anomalous genes first formed must be avoided.

Dr. Reading (2002) notes, when allergy-sensitive people ingest allergy-triggering foods, toxic food fractions cross into their bloodstream and stimulate cells with receptors for them. Additionally, these subfractions suppress the immune system by upsetting the balance of hormones, vitamins, and minerals—basically recreating the anomalous environment that was present when the abnormal tissue first formed.

> [Cells of abnormal] tissue take in toxic food fractions just as they did in the womb. And just as they did in the womb, the fractions stimulate the cells to proliferate and reproduce—only this time the uterus is not present to provide growth-regulating hormones to keep the process in check. So cells proliferate wildly and uncontrollably. And when they do so, cancer has begun. (p. 142)

Whenever someone puts forth a theory to explain the disease of cancer, inevitably eyebrows will rise; however, this time we might not want to dismiss Dr. Reading's theory too quickly. His track record for arresting and reversing cancer using allergy elimination diets is impressive.

Reading (2002) believes cancer and many other diseases are actually congenital disorders: "begun by the effect of food allergies on the developing fetus, and exploding out of control when the faulty pre-birth environment reoccurs." He also notes "such cancers are actually mimicking the rapid proliferation of fetal tissues. Or, if you like, they [cancerous cells] are really abnormal fetal tissues starting to proliferate all over again" (p. 142). What makes his argument

so compelling is that many cancer cells do in fact release fetal proteins, which are normally seen *only* in unborn babies (Akira et al., 1972, pp. 1–7; Reading, 2002, p. 142).

Addicts and alcoholics, unaware of the biochemical damage stemming from allergic subfractions, are often fooled into thinking they will regain their health and start feeling better by simply being abstinent or avoiding their "primary" addictive substances. However, in abstinence they usually feel worse. So, to counter the misery of withdrawal, alcoholics instinctively and unknowingly indulge their allergies by ingesting copious quantities of foods from which their alcohol was fermented—grains, sugars, yeast, and so forth. Consumption of these allergy-provoking foods sustains an ongoing load of toxins, and biochemical imbalances (Randolph & Moss, 1980, p. 23). Until they break away from their allergy foods, addicts and alcoholics will continue to experience physical and psychological pain. Confused, they'll turn to psychological and spiritual treatment, without understanding the source of the problem is their allergy-riddled diet.

Although restoring proper histamine function, as Dr. Ravikovich directed, may be well suited to address functional problems characterizing IgE immediate onset allergies, countering an IgG delayed allergic reaction is a different, more complex allergy problem. We believe it is most effectively dealt with by avoiding subfraction-containing foods that trigger the formation of immune complexes, and the proliferation of disease-causing cells. In other words, these are structural genetic defects that cannot be corrected, but can be controlled by avoiding the triggers (allergy foods) that switch them on. Unfortunately, foods that switch on allergies are the foods people love to eat again and again, their comfort foods—foods with addictive, drug-like qualities. Why do some foods cause drug-like reactions? A survival mechanism allows the body to override pain by releasing "feel-good" chemicals called endorphins (Braly & Holford, 2006, p. 90). Many analgesic drugs are based on similar chemical structures; all of them, including endorphins, are peptides—small groups of bound amino acids (Terenius, 2000, p. 1). When protein is ingested, it is broken down to peptides, and then, if digestion is working well, those peptides get broken down further to individual amino acids. Unfortunately, allergy foods impair digestion and damage the GI tract, impairing the complete digestion of proteins.

> In the laboratory, endorphin-like peptides have been made from wheat, milk, barley, and corn using human digestive enzymes. These peptides have been shown to bind to endorphin receptor sites. Preliminary research shows that certain foods, most commonly wheat and milk, may induce a short-term positive feeling, even if, in the long term, they are causing health problems. (Holford, 2002, p. 73)

Once these peptides reach the bloodstream, they become a problem for the immune system to gather and clear, setting the stage for a classic delayed IgG allergic response.

An IgG delayed-onset food allergy can produce more than 100 allergic symptoms and affect almost every organ or tissue in the body. It is estimated one in three (children and adults), and more than 70 percent of people battling chronic conditions, who are unresponsive to conventional medicine, are also struggling with IgG allergies. In addition, more than 100 medical diseases and conditions have been connected to IgG allergies (Braly & Holford, 2006, p. 16).

> These food allergies occur when your immune system creates an over abundance of IgG antibodies to a particular food allergen. The antibodies, instead of attaching to mast cells like their IgE counterparts, bind directly to the food particles as they enter your bloodstream, creating "immune complexes." The more of these you have floating around the bloodstream, the more on edge your immune system becomes, sending out phagocytes to gobble the complexes up. Basically your immune system gradually goes into red alert. (Braly & Holford, 2006, pp. 15–16)

Unlike the quick response, characteristic of an IgE immediate-onset allergy, IgG symptoms come on slowly—from two hours to several days. Ingesting allergy-provoking foods prompts the gradual formation of immune complexes until finally they overload the immune system's ability to clear them out. That's when symptoms are felt. Unfortunately, the time differential makes symptoms difficult to link to the foods that cause them. And because the initial response to allergy-provoking foods is often a pleasurable, endorphin-like effect, it becomes even more difficult to accept that they are a problem. In the end, a pattern, initiated and sustained by these foods, contributes to an addictive progression of disease.

The starting point of most diseases is in the gut. Allergy foods factor heavily in the etiology of diseases because they damage the GI tract, and impair digestion. In that respect, the deleterious effects from allergies and addictions is the same (Rubin, 2003, pp. 48–55). Furthermore, combining allergy foods with alcohol heaps more stress on the immune system by doing more damage to the gut.

> [For those who drink alcohol], hypersensitivity will continue indefinitely because ethanol greatly increases the permeability of intestinal membranes, making it more likely that macromolecules [polypeptides] will be absorbed into the bloodstream. Alcohol also contributes to immune system hypersensitivity by creating nutritional deficiencies. (Bates, 1987, p. 35)

The problem with alcohol is that it compounds the damage caused by food allergies by increasing permeability in the gut membrane. This destructive effect can be tolerated by the average person, but for the person who already has a food sensitivity problem, just a little bit of alcohol every day will overwhelm the immune system's ability to fight disease and maintain biochemical stability.

> Even a quite moderate use of alcohol will prove to be such an obstacle to healing that the GI tract will never repair itself, and allergies will never cool. Yet these people will turn to alcohol for relief from depression, and it will give a temporary feeling of happiness, giving the impression that it is good medicine. The more you drink, the worse your GI tract will leak allergens into your bloodstream and the more depressed you will become. (Bates, 1987, p. 57)

Bates describes the pathogenesis of alcoholism the same way a food addiction could be described. Whether responding to alcohol, drugs, or allergy foods, allergic/addictive chemistry follows the same course because the body recognizes all these substances as toxins, and turns to the same system—the immune system—to clear them. It's when the toxic load exceeds the immune system's ability to clear it that inflammation begins its destructive process.

Inflammation is a slow progression in some allergic reactions. Unlike quick IgE allergy reactions, where allergens settle directly into tissues to initiate cellular degranulation, many IgG delayed-onset allergies come on slowly. The process begins with antigens clumping to antibodies to form free-floating immune complexes in the blood (Suen & Gordon, 2003, pp. 134–135). Macrophages are then deployed to devour these complexes and take them out of circulation. It's when the immune complexes exceed the immune system's ability to clear them that inflammation occurs—a delayed reaction. Charles Bates (1987) states:

> The body has many ways of dealing with immune complexes. They are large enough to be filtered out of the blood in the liver. Wherever they congregate, they activate the degranulation of mast cells, which release prostaglandins, histamines, leukotrienes, and other inflammatory chemicals called the complement cascade. The result could be heat, pain, or anything from a runny nose to the destruction of healthy tissue. When the immune system destroys healthy tissue in the pancreas, this is called diabetes. Arthritis is the immune system attacking bone and connective tissue. Many diseases of the GI tract follow this pattern. (p. 91)

Recalling the lessons of both Dr. Ravikovich and Dr. Reading, and acknowledging these immune complexes (in delayed-onset food allergies) are clumps of food fractions, the complexity of the biochemical dilemma becomes more

obvious. On the one hand, excessive inflammation will lead to tissue destruction and disease—Ravikovich's concern; on the other hand, clumps of food fractions congregating in healthy tissue will recreate an anomalous environment conducive for the proliferation of premalignant cells—Dr Reading's concern. It is not a choice of one or the other. Under stressful conditions of an IgG allergy, the body must deal with these problems simultaneously. In support of Dr. Reading's advice: the best approach to avert this dilemma is to avoid the foods that put the immune system in such a precarious position.

Clearing allergy-provoking foods can be a challenging task. IgG allergies are perpetuated no differently than any other kind of chemical addiction. If the allergic addictive person is deprived of the offending allergen long enough, he or she will go into withdrawal. Philpott and Kalita (2000a) state:

> Adaptive addiction can be described as a state of relative freedom from symptoms, occasioned when the addictive substance is contacted frequently enough and the biological homeostatic state is in good repair. It is, however, a state of chronic stress, precariously balanced, and paves the way for the emergence of an "illness." (p. 28)

Of course, the stress from an ongoing battle with toxic allergens in foods will weaken the immune system. Then, adding seasonal antigens, environmental stresses, physical stresses, or even emotional stress can finally deplete the body's defenses enough so that illness becomes a frequent state.

The similarities of allergies, alcoholism, and addictions are undeniable (i.e., they are the same problem based on similar molecules, following the same etiology). People with IgG allergies and those with other drug/alcohol addictions are engaged in a similar pattern of use—stimulated by the release of endorphin-like substances, and perpetuated by the need to defer the symptoms of withdrawal. Philpott and Kalita (2000a) state:

> The state of partial and temporary relief by contact with allergens is termed "addiction." Understanding addiction as an extension of a maladaptive allergy state is necessary if one is to understand the seriousness of addiction to frequently eaten foods and commonly met chemicals. (p. 28)

Chemically dependent, allergic addictive people may continually submit their bodies to immune-suppressing, disease-initiating chemicals and toxic food fractions for many years before they finally succumb to the fact that it's robbing them of their health, and taking years off their lives.

The truth about allergies is that they are the foundation of addictions. Correcting the genetic malfunction driving IgE immediate-onset allergies (Dr. Ravikovich's work) does not go far enough to break the hold addictive sub-

stances have on those unfortunate enough to be genetically predetermined or biochemically altered for IgG delayed-reaction allergies and addictions. As Dr. Reading noted, addictions stem from biochemical anomalies shaped by an endless variety of genetic factors—prenatally and later in life. The scope of allergies can also be expanded to elucidate many mental health disorders. Because they too are rooted in biochemical disruptions tied to allergies, preventative interventions can be incorporated before allergies manifest into more serious diseases.

The brain is a very metabolically active organ. Although it composes only 2 percent of the body's weight, it consumes 20 percent of the body's available oxygen and 25 percent of the body's glucose (Atavistik Pictures, 2006). Transporting all that oxygen and glucose to the brain requires a great deal of blood—the same blood that carries allergy-inciting molecules to other organs in the body. You would think this obvious potential for problems would be of great concern to modern medicine.

> Although allergic mental illness is encountered daily in every doctor's office around the world, it is rarely recognized by physicians because they don't realize allergic reactions often appear as depression, anxiety, irritability, confusion, paranoia, hyperactivity, autism, catatonia, or schizophrenia. Unfortunately, most cases of brain allergies are misdiagnosed as doctors search in vain for emotional causes, while allergic brain malfunctions remain unsuspected. (Mandell & Scanlon, 1979, pp. 90–91)

Compounding the problem of medical ignorance, Dr. Russell Blaylock states:

> Whole foods pass through the intestine, get into the bloodstream and bring forth an immune response. . . . The brain's immune system is also activated, releasing toxic components including glutamate, and that causes neurological dysfunction. You can get all kinds of symptoms triggered from immune reactions: lethargy, stupor, disorientation, paranoia, delusions, hallucinations, agitation, rage, panic attacks, criminal behavior, and even seizures. (Atavistik Pictures, 2006)

In spite of various organic risks to stable brain function, conventional medicine and psychiatry mostly refuses to acknowledge and address the brain's vulnerability to allergens and food subfractions ushered in via the vascular transport system.

Along with food fractions from allergens, many viruses also live and thrive in the blood. The body requires a robust immune system to keep them at bay. A key component in that defense system is endothelial-relaxing factor, or nitric oxide, a natural molecule manufactured in healthy blood vessels that works to destroy invading pathogens. "Nitric oxide is used by the immune system to

stave off infectious bacteria, viruses, and parasites, and it even curtails the proliferation of certain types of cancerous cells" (Ignarro, 2005, p. 48). However, as vessels harden over time, or if they are poisoned by toxic heavy metals (lead, mercury, etc.), they lose the ability to manufacture this crucial molecule needed to protect the brain and body from pathogens in the blood. One way of restoring elasticity to the veins and production of nitric acid is through chelation therapy. It is believed that by chelating out heavy metals, blood vessels resume normal production of nitric oxide (Gordon Research Institute, 2000).

But how do viruses contribute to mental illnesses? Philpott and Kalita (2000b) implicate the origin of *all organic brain disorders* to viral infections from the herpes family (i.e., Epstein-Barr, cytomegallo, and human herpes virus #6). If a pregnant mother ingests foods that suppress her immune system (allergy foods), infections flare up, and may get passed on to her developing fetus. In addition, infectious viruses might also invade the brain of a young child, particularly because the blood brain barrier is much more vulnerable in the early years. Then, as that young brain develops, these viruses infect neurons, causing them to swell. Swelling injures the developing brain, including the temporal lobe, and particularly the frontal part of the brain, resulting in damage that impairs perception, judgment, and the ability to concentrate (pp. 148–149).

We believe most mental health disorders can be tied to a symbiotic relationship of allergies (primarily food allergies) and viruses. Unfortunately, viruses do not fade away or die off. Studies reveal Epstein-Barr, cytomegallo, and human herpes #6 viral infections remain in the body and the brain for a lifetime, causing fluctuating symptoms in response to varying levels of stress—and, of course, allergies are great promoters of stress. When stress flares, these viruses become more active, which further stresses the immune system. Philpott and Kalita (2000b) state:

> These are lymphotropic viruses that infect the immune system. B-lymphocytes become disordered from the viral infection, producing antibodies and an autoimmune response inappropriately. As a result, the child's immune system becomes compromised. The child becomes more reactive to chemicals and inhalants in the environment. This additional stress makes the child *much more prone to maladaptively react to specific foods* [authors' emphasis]. (p. 149)

Interestingly, those specific foods are the ones that help viruses to flourish, and disrupt mental stability—allergy foods. In addition, they are the ones that get chosen—even after the infected host has been warned of the gravity of the situation. It is a hallmark of addictive behavior, but it begs the question: Who's in charge—the person, or the pathogens? Perhaps addiction is a struggle for survival between microorganisms that thrive in an acidic, hypoxic environment

and normal cells and tissues that thrive in a more alkaline-hyperoxia environment (Young & Young, 2002, pp. 12–37).

But mental health disorders have been linked to many biochemical abnormalities, not just allergies. Schizophrenia is a branch of mental disorders, in the extreme. Years ago, Dr. Carl Pfeiffer and colleagues (1970) recognized schizophrenia as a syndrome, not a single disease. To his credit, he identified different biochemical deficiencies, which created symptoms interpreted as schizophrenia. For example, he determined many schizophrenics were pyroluric, due to metabolic anomalies, which contributed to a zinc and B6 deficiency (pp. 139–145). Likewise, his contemporary, Dr. Abram Hoffer (2005), saved many "schizophrenics" from wasting away in mental institutions by elucidating the true cause of pellagra—a B3 niacin deficiency (p. 70). Dr. Chris Reading (2002) observed, "While many, or even most, cases of so called schizophrenia are really allergic conditions or hereditary metabolic disorders, a significant minority remains that doesn't appear to fit into either category. These can be called the true schizophrenias" (p. 180). Nevertheless, many symptoms labeled as schizophrenia can be traced back to biochemical deficiencies or excesses altering metabolic processes to create distorted expressions of the brain.

So why do these deficiencies or excesses occur in the first place? If it were just a question of poor nutrition, mental illness would be easy to correct; however, look deeper and you'll find diet is subordinate to the allergies that drive them. Indeed, allergies perpetuate cravings for the very foods that sustain the allergic inflammatory conditions that drive degenerative diseases. Again, let's ask, "Who's in charge, up there in the brain?" Foods that promote inflammation, hypoxia, and acidity—ideal conditions for viruses to thrive in—are the ones schizophrenics and allergic/addictive mentally ill patients want to eat, not diets of nonallergic foods, which cool the inflamed brain, and give support to the immune system (Young & Young, 2002, pp. 12–37). But why should inflammation of the brain (i.e., chronic encephalitis) result for only some who indulge their allergic impulses? Are "nonschizophrenics" only spared a miserable fate of mental anguish because they are not infected with viruses that capitalize on repeated exposures to allergy foods?

Historically, there have been times when schizophrenics were unable to obtain foods that would aggravate their allergies, and intensify their viral infections. During World War II, rations of wheat and rye became scarce in Scandinavian countries. Based on the unavailability of these gluten-containing foods, estimates from Finland figured "the mean annual *decrease* in the number of first admissions [for schizophrenia] from the prewar mean was estimated to be about 19 percent in 1940–1942 and about 45 percent in 1943–1945" (Dohan, 1966). This intriguing study shows a strong relationship between

gluten-containing foods and schizophrenia. Unless steady provisions of allergy foods are ingested, the virus cannot maintain its influence over the brain. Famine for the virus equates to sanity for the host.

Allergies are at the foundation of the problem because they distort the terrain of tissues by forming a more acidic environment conducive for viruses to flourish, and microforms to change into more virulent strains (Young & Young, 2002, pp. 21–23). In other words, allergies work hand-in-hand with disease-causing viruses to suppress the immune system, and influence thought processes of the brain. In their clinical experience, Philpott and Kalita (2000b) note:

> Schizophrenia is a state of disordered brain function in areas of perception, mood, thought, and motor function. Acute mental symptoms can be triggered by maladaptive reactions to foods, chemicals, or inhalants to which the subject is allergic, addicted, or otherwise hypersensitive. Several studies have demonstrated that maladaptive reactions to environmental substances, especially foods, are significant factors in evoking mental illnesses. (p. 149)

These "maladaptive reactions to environmental substances" help to promote, sustain, and expand an internal environment (terrain) that fortifies a viral presence in the tissues of the brain. Viral influence affects the way mood, thought, and personality is expressed; finally, even reason is compromised, resulting in irrational behavior and a demeanor perceived as mentally ill.

Fortunately, there is a way to restore stability and give back control to a "mentally ill" brain. The two branches of medicine best equipped to deal with mental health problems brought on by organic-based infections and allergies are ecology medicine and orthomolecular medicine. Both serve to reduce the inflammatory response from allergies, and stabilize the brain. Ecology medicine works by identifying and abstaining from allergy-causing foods, essentially laying siege to viruses and virulent pathogens by keeping out chemicals and foods fractions that help perpetuate the hypoxic, acidic environment they thrive in. The other approach, orthomolecular medicine, works by providing nutrients in optimum amounts needed to restore proper metabolism and health at a cellular level.

Human ecology acknowledges that substances in our environment can have a profound effect on our mental health and behavior. "Evidence suggests that the basic organic forces behind many chronic physical and mental illnesses are addictive reactions to frequently eaten foods and commonly met chemicals" (Philpott & Kalita, 2000a, p. 57). Identifying and avoiding symptom-inducing substances is fundamental to restoring mental stability. Ecology medicine holds the potential for stopping and reversing the pathology of many mental health diseases.

Orthomolecular medicine strives to treat infectious and degenerative diseases by varying the concentration of "right molecules" (i.e., vitamins, minerals, etc.), which are normally present in the human body (Lawson, 2003). Cells inadequately provided with the nutrients needed for proper metabolism and health create a condition for disease. When a cell becomes deficient in even one nutrient, its entire function will be seriously impaired. Multiply that by millions of cells, and tissues and organs may be affected. The brain is an organ composed of million of cells. When its metabolism becomes disordered due to allergic responses, viral attacks, and nutritional deficiencies, it falls into a state of disease. The brain expresses a diseased state with changes in perceptions and cognitive function, resulting in illusions, hallucinations, and delusions (Philpott & Kalita, 2000a, p. 73).

Orthomolecular psychiatry can repair the nutritional imbalances to restore mental health, but that repair is fragile (i.e., it cannot be sustained if *first-cause* ecological factors are not also stopped). The power of ecological and orthomolecular medicine together gives increased therapeutic value beyond either approach alone. Satisfactory clinical results often cannot be achieved unless both systems are combined. Ongoing research into how nutritional factors and ecology medicine support each other in cooling allergies will improve future treatment of mental health problems.

Chapter **6**

Caffeine: Pharmacology and Effects of the World's Most Popular Drug

Kyle M. Clayton, MS, and Paula K. Lundberg-Love, PhD

Caffeine is the most commonly used psychoactive drug in the world (Julien, 2005). A naturally occurring substance derived from more than 60 plants worldwide, caffeine's availability permeates most cultures. In the United States, it is estimated that up to 90 percent of adults consume caffeine on a daily basis, with an average daily intake of 200 to 400 mg per day (Meyer & Quenzer, 2005). The most common sources for daily caffeine intake include coffee, tea, soft drinks, and chocolate. While various factors, including serving size and method of preparation, affect the amount of caffeine found in particular products, the average cup of coffee contains approximately 100 mg of caffeine, while average servings of tea, soft drinks, and chocolate are slightly lower, 50 mg, 40 mg, and 20 mg, respectively. Caffeine tablets of 50–200 mg are available without a prescription (e.g., Vivarin, Nodoz), and various over-the-counter pain relievers, migraine medications, and antihistamines also contain caffeine. Currently, the Food and Drug Administration lists caffeine as safe for consumption, and its use as an additive is not restricted. However, the pervasiveness of caffeine's use, along with the volume of recent research findings on the subject, facilitates the need for exploring the effects of caffeine on the human body.

HISTORY

People have been consuming caffeine in various forms for thousands of years, with early cultures having discovered that the chewing and ingestion of caffeine-containing plants or seeds caused specific positive mood-altering and stimula-

tory effects. Ancient Chinese legend asserts that Shennong, Emperor of China in approximately 3000 B.C., discovered tea after leaves accidentally fell into boiling water resulting in a fragrant restorative drink (Lu & Yu, 1995). Coffee originated in Africa around A.D. 575, where coffee beans were used for food as well as currency. During the tenth century, coffee was restricted primarily to Ethiopia where its native beans were first cultivated. As Arabic trade expanded, coffee beans moved into other regions including northern Africa, where they were mass-cultivated. Coffee beans eventually entered the European markets where historical sources indicate that coffee initially arrived in Venice as a result of the trade between Europeans and those from North Africa and the Far East.

The appreciation of coffee in Europe was evident in the sixteenth century, and became increasingly popular in the decades to follow. During the seventeenth century, the first "coffee houses" were established, with openings in Britain, Paris, and Venice. Following their inception, coffee houses became popular throughout Western Europe, where they served as a common forum for business and social relations as well as intellectual exchange. Coffee was not widely accepted as the caffeinated drink of choice throughout colonial America until Revolutionary Americans made a nationwide switch from tea to coffee in the eighteenth century. This change occurred as a protest to the Tea Act, in which heavy taxes were levied by the British government on tea imported by Americans. This revolt culminated in the Boston Tea Party, in which large quantities of tea were disposed of in Boston Harbor.

Similar to the coffee bean and tea leaf, the kola nut (cola) also appears to have been rooted in ancient cultural tradition. West African cultures use the kola nut as a euphoric stimulant to restore vitality and ease hunger pangs. Cola was an original additive to many soft drinks, and became the focus of a health scare in 1911 when the U.S. government seized portions of Coca-Cola syrup in Chattanooga, Tennessee, alleging that the product was unsafe due to its caffeine content (Benjamin, Rogers, & Rosenbaum, 1991). Following this seizure, the government initiated litigation (*The United States v. Forty Barrels and Twenty Kegs of Coca-Cola*), in an attempt to force Coca-Cola to remove caffeine from its formula. The public attention brought by the suit led to congressional action, which eventually resulted in the amendment of the Pure Food and Drug Act in 1912, including caffeine on the list of "habit-forming" and "deleterious" substances that must be listed on a product's label.

The earliest evidence of cocoa use comes from residue found inside ancient Mayan pots dated from 600 B.C. to A.D. 250 (Gorman, 2002). Made from the beans of the tropical plant *Theobroma cacao*, cocoa was a favorite drink of ancient Maya and Aztec people in Mesoamerica. Chocolate was consumed in a bitter and spicy beverage called *xocoatl*, often seasoned with vanilla, chile

pepper, and achiote. Xocoatl was believed to fight fatigue, a belief possibly attributable to the theobromine and caffeine content. Chocolate was a valuable commodity during this time as cocoa beans were often used as currency in trade. Chocolate was introduced to Europe in the 1500s, and became popular as a beverage by the late seventeenth century. In the latter part of the eighteenth century, chocolate production began in North America, with the establishment of a cocoa bean grinding mill in Massachusetts.

In 1819, pure caffeine was isolated for the first time by German chemist Friedrich Ferdinand Runge (Weinberg & Bealer, 2001). The structure of caffeine was elucidated near the end of the nineteenth century by Hermann Emil Fischer, who was also the first to achieve its total synthesis (Théel, 1902). During this time, cola products began to appear around the world and became one of the most prominent caffeinated beverages. Along with traditional sources of caffeine, including coffee, tea, and chocolate, the twentieth century saw the rise of caffeine intake through energy drinks, additives, and analgesic and appetite suppressant medications. Today the world population consumes more than 100,000 tons of caffeine annually, the equivalent of one caffeinated beverage per person per day.

PHARMACOKINETICS OF CAFFEINE

Taken orally, which is the typical method of drug administration, caffeine is rapidly and completely absorbed. Significant blood levels of caffeine are reached within 30 to 45 minutes of ingestion, with complete absorption occurring within the next 90 minutes (Julien, 2005). Caffeine's absorption occurs within the gastrointestinal tract, beginning in the stomach but occurring primarily within the small intestine. Following absorption, caffeine is distributed freely throughout the body and the brain. Caffeine is highly lipid-soluble, and higher concentrations are found within the brain as compared to plasma (Paton & Beer, 2001). Specifically, animal studies have demonstrated a significant disparity in brain/plasma concentration, with brain levels of caffeine as high as 80 percent (Kaplan, Greenblatt, Leduc, Thompson, & Shader, 1989).

Caffeine is metabolized to paraxanthine, theobromine, and theophylline, each with distinct effects on the body, including the breaking down of stored fat, blood vessel dilation, increased urine volume, and relaxation of bronchi muscles. These metabolites account for virtually all caffeine excretion, with only a small percentage of the original substance being eliminated as nonmetabolized caffeine.

The half-life of caffeine at modest levels of intake is approximately four to six hours in most adults. This period increases with higher levels of intake and

for the elderly and those with impaired liver function. Caffeine's half-life is extended significantly in women during the late stages of pregnancy, and in instances of long-term use of oral contraceptive steroids (Chawla & Suleman, 2006). Active cigarette smokers experience a shortened half-life for caffeine, but half-life increases following smoking cessation. Research has suggested that increased levels of caffeine in plasma following smoking cessation may contribute to cigarette withdrawal symptoms in heavy coffee drinkers (Feldman, Meyer, & Quenzer, 1997).

MECHANISM OF ACTION OF CAFFEINE

Caffeine acts through multiple mechanisms to exert a variety of effects on the central nervous system. Caffeine's principal mechanism of action is as an adenosine receptor antagonist (Julien, 2005). Caffeine readily crosses the blood brain barrier, and its similarity in structure to adenosine, a naturally occurring substance in the brain, allows the caffeine molecule to bind to adenosine receptors (particularly adenosine A_1 & A_{2a} receptors) on the surface of cells and block the access of adenosine to its receptors. Recent research suggests that the blockade of adenosine receptors and its ensuing reduction in adenosine activity is responsible for the behavioral stimulation associated with caffeine (Fisone, Borgkvist, & Usiello, 2004). Adenosine plays a key role in the transfer of energy within the body, and its inhibitory function promotes sleep and suppressed arousal, while also producing anti-inflammatory effects as well as acting as a cardiac antiarrhythmic agent. Adenosine also serves as a neuromodulator that produces an overall inhibitory effect by reducing the effects of acetylcholine, dopamine, and glutamate within the central nervous system (CNS). In particular, adenosine inhibits ascending acetylcholine projections to the thalamus and cortex, while inhibiting dopamine activity within the hippocampus, striatum, nucleus accumbens, and prefrontal cortex. In addition, adenosine mediates the effects of glutamate release in the hippocampus during excitotoxicity.

In humans, there are four types of adenosine receptors, including A_1, A_{2a}, A_{2b}, and A_3. Each receptor is encoded by a particular gene and has a specific function. The adenosine A_1 receptor is found throughout the entire body, and generally has an inhibitory function. For example, adenosine A1 receptors found in the brain slow metabolic activity. The adenosine A_1 and A_{2a} receptors both act to regulate myocardial oxygen consumption and coronary blood flow, with the A_1 receptor causing a decrease in heart rate, force of contraction, and responsivity to adrenaline, while the A_{2a} receptor increases blood flow through vasodilatation of coronary arteries. Caffeine antagonism of adenosine receptors prohibits adenosine activity within cells, thus altering their function.

Caffeine's blockade of adenosine receptors increases stimulatory activity, producing changes in mood, increased vigilance, and heightened mental acuity. For example, increased release of acetylcholine associated with adenosine inhibition contributes to caffeine's behavioral arousal effects. The positive stimulatory effects of caffeine are primarily due to the blockade of adenosine receptors that stimulate GABAergic neurons, which in turn typically inhibit the release of dopamine in the reward system of the striatum (Mandel, 2002). This inhibition of GABAergic neurons and the resulting increase in dopaminergic activity within certain areas of the brain may explain many of the behavioral effects associated with caffeine use, including heightened alertness, elevated energy, and increased concentration (Garrett & Griffiths, 1997). In particular, elevated dopamine levels in the prefrontal cortex produced by caffeine appear to contribute to an increase in alertness. In contrast, caffeine does not stimulate the release of dopamine in the nucleus accumbens, which is consistent with the mild behavioral reinforcing properties commonly noted (Acquas, Tanda, & Di Chiara, 2002).

In addition to adenosine antagonistic properties, caffeine is a competitive inhibitor of the enzyme cAMP-phosphodiesterase (cAMP-PDE), which converts cyclic AMP (cAMP) in cells to its noncyclic form, allowing cAMP to build up in cells. Cyclic AMP participates in the messaging sequence produced by cells in response to stimulation by epinephrine. Thus, by blocking the removal of cAMP, caffeine intensifies and prolongs the effects of epinephrine and epinephrine-like drugs such as amphetamine, methamphetamine, and methylphenidate.

The metabolites of caffeine also contribute to caffeine's effects. Theobromine is a caffeine metabolite that serves as a vasodilator, increasing the amount of oxygen and nutrient flow to the brain and muscles. Theophylline, the second of the three primary metabolites, acts as a smooth muscle relaxant that increases heart rate and efficiency. The third metabolic derivative, Paraxanthine, is responsible for an increase in the lipolysis process, which releases glycerol and fatty acids into the blood to be used as a source of fuel by the muscles (Dews, 1987).

BEHAVIORAL AND PHYSIOLOGICAL EFFECTS

The effect of caffeine on humans is largely a function of dosage, frequency of use, and individual sensitivity. Effects are often consistent with those reported by users of other CNS stimulants with very different mechanism of action, including cocaine and amphetamines. At low to moderate daily doses (50–300 mg), commonly reported subjective effects include arousal,

increased concentration, elevated mood, increased motivation to work, and decreased sleepiness. The most typical mood-altering effects include increases in energy, alertness, and feelings of well-being (Garrett & Griffiths, 1997). In comparison to the positive effects often reported by respondents consuming low to moderate doses, consumers of higher doses of caffeine increasingly report feelings of anxiety, nervousness, restlessness, and insomnia. The mechanism by which caffeine produces its subjective effects is yet to be determined. Caffeine has not shown to induce dopamine release in the nucleus accumbens of the brain, an action common to drugs with addictive properties, but more likely, exerts effects on mood through indirect stimulation of dopamine in the striatum. Recent research has shown that there is a direct correlation between the experience of positive effects and level of daily use (Attwood, Higgs, & Terry, 2006). Those consuming higher daily doses of caffeine (> 200 mg) were more likely to report positive effects, which may account for their high levels of use. In addition, it was found that while some moderate users did not report significant positive effects, they maintained their schedule of daily consumption, supporting the possibility that low to moderate use may be maintained by other factors, including environmental reinforcement and expectancy. There is controversy regarding the mechanism by which caffeine has shown to elevate mood, as well as performance on tasks utilizing alertness, speed, vigilance, and reaction time. While some have argued that the positive impact of caffeine can be directly attributed to the removal of withdrawal symptoms (James, 2005), more recent research has found improved performance and elevated mood to be a direct result of the stimulatory properties of caffeine, unrelated to effects of withdrawal (Christopher, Sutherland, & Smith, 2005; Hewlett & Smith, 2007; Smith, Sutherland, & Christopher, 2005).

Caffeine-induced anxiety is recognized in the *DSM–IV-TR* as a substance-related disorder characterized by the presentation of prominent anxiety, panic attacks, or obsessions or compulsions directly resulting from the physiological effects of caffeine (American Psychiatric Association [APA], 2000). Moderate daily caffeine consumption (> 200 mg) has been demonstrated to increase anxiety ratings in normal participants (Graham, Schultz, Mayo-Smith, Ries, & Wilford, 2003), while doses of 750 mg have been shown to induce panic attacks (Paton & Beer, 2001). People with a high disposition toward anxiety or those diagnosed with anxiety disorders are often very sensitive to the anxiogenic properties of caffeine, making them particularly vulnerable. Although there is some evidence that those with anxiety disorders tend to limit their exposure to caffeine (Kruger, 1996), it is generally recommended that those with anxiety-related disorders be advised to abstain completely from caffeine use.

Sleep appears to be the physiological process most sensitive to the effects of caffeine. Exposure to caffeine has the ability to produce cerebral stimulatory effects, especially in areas controlling locomotor activity and the sleep-wake cycle, and acute doses exceeding 200 mg are capable of producing significant effects on sleep (Chawla & Suleman, 2006). The *DSM–IV* recognized caffeine-induced sleep disorder as a significant disturbance in sleep brought on by the physiological effects of caffeine (APA, 1994). Caffeine typically disrupts sleep by prolonging sleep latency, shortening total sleep duration, and increasing nocturnal awakenings. Similar to its anxiogenic properties, caffeine's effect on sleep is determined by many factors, including dosage, tolerance, individual sensitivity, and time between ingestion and attempted sleep (Graham et al., 2003). Elevated doses correlate specifically to delays in sleep onset when ingested immediately prior to attempted sleep, and individual differences, such as slower metabolic rate, can increase instances of sleep disruption by extending drug availability. While partial tolerance can decrease caffeine's stimulatory effects, complete tolerance does not occur, leaving even the most habitual users at risk for sleep disturbances. Overall, caffeine's ability to disrupt sleep at high doses is well established, while difficulties at lower to moderate doses appear to be more attributable to individual differences, including sensitivity and schedule of use.

Caffeine also exerts significant effects on cardiovascular function. Research on caffeine's effect on the heart and heart disease is ongoing, and both positive and adverse effects have been demonstrated. Caffeine increases cyclic adenosine monophosphate (cAMP) in heart cells, which simulates the action of epinephrine, causing a slight stimulant effect. This stimulation increases heart rate, cardiac contractility (force of contraction), and cardiac output. Caffeine also has been shown to increase blood pressure, especially in those disposed to hypertension. Repeated blood pressure elevation in habitual users might contribute to an increased risk of heart disease (Lane, Pieper, Phillips-Butte, Bryant, & Kuhn, 2002). In contrast to negative effects, a recent study found that increased caffeine intake provided protection against the risk of heart disease mortality among nonhypertensive elderly participants (Greenberg, Dunbar, Schnoll, Kokolis, & Kassotis, 2007). A conclusive finding regarding the means by which caffeine provides such protection was unavailable; however, Greenberg et al. (2007) suggested that there was evidence to support the hypothesis that caffeine's ability to increase blood pressure counteracts postprandial hypotension. Other possible explanations for caffeine's ability to decrease the risk of heart disease among nonhypertensive elderly patients included commonly demonstrated cardiovascular effects such as increased myocardial contractility (strength of heart contraction), reduced fibrinolysis time (faster clot

breakdown), and inhibition of baroreflex activity (increases blood pressure). Also, caffeine's ability to dilate coronary arteries and increase blood flow to the heart has been demonstrated (Rachima-Moaz, Peleg, & Rosenthal, 1998), which might serve to mitigate negative effects in some individuals. With respect to increased risk for the typical adult population, it is possible that caffeine's ability to increase blood pressure is more prominent in coffee consumption than that of tea, as a recent study has indicated that the amino acid theanine (commonly found in tea) may reduce elevated blood pressure (Rogers, Smith, Heatherley, & Pleydell-Pearce, 2008). While there is not a consensus on the effects of caffeine consumption on heart disease, it is generally recommended that individuals with hypertension or heart disease minimize consumption.

As opposed to caffeine's effect on arteries of the heart, where dilation increases oxygen supply, caffeine has the opposite effect on the blood vessels of the brain; cerebral blood vessels are constricted, which decreases blood flow and reduces pressure within the brain (Julien, 2005). This action can prove beneficial for people suffering from headaches, and more specifically, treatment of migraines. Nonprescription medications containing a combination of acetaminophen, aspirin, and caffeine (e.g., Excedrin Migraine) have demonstrated effectiveness in reducing migraine-related symptoms (Chawla & Suleman, 2006).

Additional physiological effects of caffeine include changes in respiratory, urinary, and gastrointestinal function. Caffeine increases both gastric acid secretion and urine output, while producing antiasthmatic effects on lung function. Caffeine causes bronchial relaxation and is commonly used in the treatment of newborn infants who display apneic episodes (periodic suspension of breathing) or bronchopulmonary dysplasia, which is characterized by inflammation and scarring in the lungs. These conditions often occur in low-weight premature babies, and in such cases, caffeine has shown to be an essential aid in normalizing respiration and preventing death.

TOXICITY

Caffeine intoxication is recognized by both the *ICD–10* (World Health Organization [WHO], 1992) and *DSM–IV–TR* (APA, 2000) as a distinct syndrome associated with excessive caffeine use. Caffeine intoxication is defined by a number of clinical features that emerge in response to recent consumption of caffeine. The *DSM–IV* indicates that the diagnosis of caffeine intoxication is dependent on recent daily consumption, generally exceeding 250 mg (more than 2–3 cups of coffee), along with the presentation of intoxicated related symptoms following caffeine use. Common features of caffeine intoxication in adults are similar to the overdose effects of other central nervous system

stimulants (e.g., cocaine, amphetamine), and include anxiety, restlessness, excitement, insomnia, rambling flow of thought and speech, irritability, tremor, diuresis, flushed face, gastrointestinal disturbance, psychomotor agitation, and irregular or rapid heartbeat. Caffeine intoxication symptoms in infants include rapid heartbeat, rapid breathing, tremors, shock, muscle tension, nausea, and vomiting. In adult cases of highly elevated doses, symptoms such as fever, hallucinations, delusions, and loss of consciousness have occurred (Medline, 2006). Caffeine intoxication, due to its relatively short half-life (4–6 hours), typically resolves rather quickly with cessation of consumption and supportive care. However, individual reactions differ as related to overall health and caffeine sensitivity. Life-threatening complications, generally related to cardiac dysrhythmias, can occur and immediate medical care may be needed to restore cardiovascular stability. Peritoneal dialysis, hemodialysis, or hemofiltration may also be required in cases of severe caffeine overdose. Extreme dose toxicity can result in death, but such instances are very rare. Lethal dosage is dependent on weight and individual sensitivity to caffeine. However, doses exceeding 5 to 10 grams taken within a limited time frame are generally considered a significant risk. Such a sizeable dose is difficult to achieve under conventional methods (e.g., 50 to 100 average cups of coffee), but can be more readily administered with the ingestion of caffeine tablets. In cases of lethal overdose, the typical cause of death is often described as ventricular fibrillation (Holmgren, Nordén-Pettersson, & Ahlner, 2004).

TOLERANCE, DEPENDENCE, AND WITHDRAWAL

Tolerance refers to a decrease in responsiveness to a drug following repeated exposure in which the dose necessary to achieve the initial reinforcing effect is increased. Tolerance can also refer to the decline of aversive effects typically associated with large doses of the drug. Each of these altered responses to drug exposure can promote the use of increased dosage and repeated administration. Partial tolerance has been shown to develop among chronic caffeine users consuming levels as low as 100 mg per day (Evans & Griffiths, 1999). Caffeine tolerance can develop rather quickly among high-dose consumers. Complete tolerance to the sleep disruption effects of caffeine has been reported after consuming 400 mg of caffeine three times a day for seven days, while complete tolerance to subjective effects such as nervousness, tension, jitters, and elevated energy were observed to develop after consuming 300 mg three times per day for 18 days, and it is possible that such tolerance can occur within a shorter period of time (Griffiths & Mumford, 2000). With respect to chronic users, it should be noted that while tolerance has been shown to develop concerning

certain subjective measures (including mood and energy level), tolerance is more prevalent among physiological effects such as respiratory and cardiovascular function, along with sleep disruption.

Substance dependence due to caffeine is recognized as a clinical diagnosis in the *ICD–10* (WHO, 1992). Substance dependence refers to the presentation of cognitive, behavioral, and physiological symptoms related to an individual's continued use of a substance despite significant adverse consequences. Clinical diagnoses of substance dependence can be specified as with or without physiological dependence (evidence of tolerance or withdrawal). While caffeine dependence is not currently recognized as a clinical disorder in the *DSM–IV–TR* (APA, 2000), current research is focusing on whether the diagnosis of caffeine withdrawal or caffeine withdrawal syndrome is warranted for inclusion in future editions of this and other diagnostic texts. Caffeine withdrawal has been documented in numerous empirically validated double-blind experiments (Evans & Griffiths, 1999; Rogers, Martin, Smith, Heatherley, & Smit, 2003; Tinley, Yeomans, & Durlach, 2003). In a recent review of caffeine withdrawal studies, the following symptom categories were indicated as valid: headache, fatigue, decreased energy/activity, decreased alertness, drowsiness, decreased contentment, depressed mood, difficulty concentrating, irritability, and foggy/not clearheaded. It was also noted that additional flu-like symptoms, including nausea/vomiting, tremors, and muscle pain/stiffness are often reported. The most commonly reported symptom in caffeine withdrawal is headache, which occurs in approximately 50 percent of people reporting withdrawal symptoms (Juliano & Griffiths, 2004). Withdrawal symptoms generally begin within 12–24 hours following cessation of caffeine, and reach peak intensity at approximately 20–48 hours with an overall duration of two to seven days. Severity and occurrence of symptoms appear to relate to increases in dosage. However, withdrawal symptoms have been exhibited in those consuming as little as 100 mg/day (approximately one cup of coffee).

REPRODUCTIVE AND PRENATAL CONCERNS

The effect of maternal caffeine consumption on miscarriage and prenatal development remains undetermined, as credible scientific studies have reported a variety of findings. Concerning miscarriage, past studies have shown an increased risk for those consuming high daily doses (> 600 mg) of caffeine, while moderate doses did not increase the risk (Klebanoff, Levine, DerSimonian, Clemens, & Wilkins, 1999). A more recent study found that daily doses exceeding 200 mg were sufficient to increase the risk of miscarriage. In contrast, a recent study by Savitz, Chan, Herring, Howards, and Hartmann

(2008) demonstrated little evidence for risk of miscarriage among women with modest daily caffeine intake. Similar to the issue of miscarriage, caffeine's ability to affect fetal growth is a topic of current debate. A Norwegian study comparing caffeine intake of mothers of small-for-gestational-age (SGA) infants with mothers of non-SGA infants found that high caffeine intake during the third trimester correlated with an increased risk for growth retardation in male fetuses (Vik, Bakketeig, Ulla Trygg, Lund-Larsen, & Jacobsen, 2003). A separate European study reported that caffeine intake was not responsible for increased risk of SGA, and noted that many of the previous studies reporting such an effect had failed to account for other known contributory factors, including smoking and alcohol consumption (Parazzini et al., 2005). In addition to increased risk of SGA, instances of stillbirth also have been studied. In a study by Wisborg, Kesmodel, Hammer Bech, Hedegaard, and Brink Henriksen (2003) containing more than 18,000 pregnant women, those who consumed four to seven cups of coffee a day had an 80 percent increased risk of stillbirth, while women consuming more than eight cups a day had a 300 percent increased risk. While further research is needed to clarify the effects of caffeine on prenatal health and development, current medical recommendations generally advise pregnant women to minimize its consumption.

DRUG INTERACTIONS AND TREATMENT CONSIDERATIONS

Acute administration of high doses of caffeine to individuals diagnosed with panic disorder has been shown to increase cortisol to levels similar to those found in clinically depressed individuals (Paton & Beer, 2001). These elevated levels of cortisol can sometimes mimic the symptoms of depression, leading to false diagnosis. Similarly, caffeine can also interfere with medications prescribed for the treatment of insomnia. Benzodiazepines such as temazepam (Restoril) and triazolam (Halcion) are medications that bind to GABA-A receptors in the brain that enhance the function of GABA and create sedative and hypnotic effects. Caffeine can inhibit the binding of benzodiazepines to their specific receptors on the GABA-A receptor sites, therefore neutralizing the effects of such medications and inhibiting their sedative hypnotic effects (Sawnock, 1995). Such interactions should be considered when evaluating the effectiveness of medications used to treat insomnia. Caffeine screening and monitoring schedules can be an effective tool for proper diagnosis and medication management.

Caffeine also exerts a significant effect on other medications. For example, caffeine additives have demonstrated the ability to increase the effectiveness of

pain relievers in the treatment of headaches by as much as 40 percent while helping the body absorb headache medications more quickly, contributing to faster symptom relief. Thus, augmenting such medications with caffeine allows for dose reduction of the analgesic agent, which can reduce the risk for potential side effects and possible drug addiction (WebMD, 2008). With respect to the treatment of smoking cessation, the effect nicotine has on the metabolism of caffeine should be considered. In regular smokers, nicotine increases the metabolism of caffeine, while smoking cessation often decreases the rate of caffeine metabolism. Slower metabolism leads to increased levels of caffeine in blood plasma, and high levels of caffeine following smoking cessation could contribute to nicotine withdrawal symptoms (Julien, 2005).

Caffeine consumption is very common among patients with schizophrenia (Rihs, Muller, & Bauman, 1996). Heavy caffeine users may require higher doses of antipsychotic medication in treatment. The possible explanations for the elevated therapeutic dose requirements include the following: (1) caffeine may increase the severity of psychotic symptoms due to an increase in catecholamine release, which could result in an increase in medication to treat such symptoms; or (2) caffeine may interfere with the effectiveness of antipsychotic medication. Caffeine's blockade of adenosine receptors can result in increased dopamine binding to dopamine D2 receptors, which competes with the action of many antipsychotic agents that target the blockade of dopamine D2 receptors (Paton & Beer, 2001). Paton and Beer (2001) also suggest that caffeine may decrease the effectiveness of iron, lithium, and zinc, and that increases in caffeine could heighten the possibility of clozapine, olanzapine, and tricyclic antidepressant toxicity.

CONCLUSION

Caffeine is readily available around the world and consumed by most adults in the United States. Caffeine is most often ingested in coffee or tea, but can be found in a wide variety of foods, drinks, supplements, and medications. Taken orally, which is the typical method of drug administration, caffeine is rapidly and completely absorbed within the gastrointestinal tract and then metabolized and excreted with a typical half-life of four to six hours. Caffeine functions primarily as a central nervous system stimulant, with its principal mechanism of action as an adenosine A1 and A2a antagonist. Typical stimulatory effects include elevated arousal and concentration, reduced fatigue, and sleep disturbances. Caffeine also produces significant physiological effects on the cardiovascular, respiratory, and gastrointestinal systems, including increased heart rate and blood pressure, antiasthmatic effects, and increased gastric acid secretion and diuresis.

Caffeine intoxication is generally dependent on recent daily consumption exceeding 250 mg, and presents in adults with symptoms such as anxiety, restlessness, insomnia, tremor, gastrointestinal disturbance, and irregular or rapid heartbeat, with rare instances of hallucinations, delusions, and loss of consciousness following highly elevated doses. Caffeine intoxication symptoms in infants include rapid heartbeat, rapid breathing, tremors, shock, muscle tension, nausea, and vomiting. Extremely high doses of caffeine (5–10 g) can be lethal with the cause of death typically attributed to ventricular fibrillation. Tolerance and withdrawal symptoms have been demonstrated in caffeine users with the most prominent symptoms consisting of headache, fatigue, decreased alertness, and irritability. Withdrawal symptoms generally begin within 24 hours following cessation of caffeine, with an overall duration of two to seven days. Severity of symptoms is often a function of elevated doses or individual sensitivity, but caffeine tolerance has been shown to occur in users consuming as little as 100 mg a day, which is equivalent to one average cup of coffee.

Certain clinical uses for caffeine have been demonstrated, including treatment for migraine headaches, treatment of newborn infants who display apneic episodes (periodic suspension of breathing) or bronchopulmonary dysplasia, and as a possible protection against the risk of heart disease mortality among nonhypertensive elderly participants. Caffeine displays significant drug interactions with medications typically prescribed for anxiety, depression, insomnia, pain relief, and schizophrenia. Such interactions should be considered in the treatment of relevant disorders.

There is debate over caffeine's role in heart disease, prenatal and reproductive function, as well as its classification as an addictive substance. Current research is inconclusive, and further exploration regarding the role of caffeine in these and other conditions is warranted. In general, while caffeine appears safe in moderation, certain individuals, including pregnant women, those with anxiety-related disorders, cardiovascular disorders, or insomnia, are advised to limit its consumption.

Chapter **7**

Marijuana Withdrawal: A Survey of Symptoms

Dirk Hanson, MA

More than 14 million Americans smoke marijuana regularly, making it the most commonly used illicit drug in America. In 2006, marijuana was the only drug used by 52.8 percent of illegal drug users (U.S. Department of Health and Human Services, 2006). Over the past 15 years, as addiction researchers have been busily mapping out the chemical alterations in the human nervous system caused by alcohol, cocaine, nicotine, heroin, and tranquilizers, America's most popular illegal drug has remained largely a scientific mystery. Marijuana, the drug millions of Americans have been using regularly for years, is the least studied drug of all.

Why has cannabis research lagged behind that of other drugs of abuse? For decades, the prevailing belief among users and clinical researchers alike was that marijuana did not produce dependency and therefore could not be responsible for major withdrawal symptoms. This thinking is based, quite understandably, on the widespread observation that most marijuana users do not have difficulty going without marijuana, either by choice or by necessity. However, marijuana withdrawal effects are frequently submerged in the welter of polyaddictions common to active addicts. The withdrawal rigors of, say, alcohol or heroin tend to drown out the subtler manifestations of cannabis withdrawal. As Barbara Mason, director of the Laboratory of Clinical Psychopharmacology at Scripps Research Institute, has explained: "People are deciding every day whether to use or not to use marijuana, for medical purposes or otherwise, and there is little scientific information to advise this decision" (2008, 1).

Marijuana withdrawal, which typically affects only heavy smokers, has not been well characterized by the research community. Until recently, there was scant evidence in animal models for marijuana *tolerance* and *withdrawal*, the classic determinants of addiction. Now, however, several researchers have identified the existence of symptoms brought on by the abrupt discontinuation of regular marijuana use in both animal and human studies (de Fonseca et al., 1997). A growing body of evidence supports the existence of a clinically significant marijuana withdrawal syndrome in a subset of marijuana smokers. The syndrome is marked by irritability, restlessness, generalized anxiety, hostility, depression, difficulty sleeping, excessive sweating, loose stools, loss of appetite, a general "blah" feeling, and a mental state that has been described as "inner unrest."

Recent clinical research, combined with anecdotal field reports collected by the author, demonstrate the existence of marijuana withdrawal and the consistency of the most common symptoms of withdrawal and detoxification.

BACKGROUND

In 1992, molecular biologists identified the elusive brain receptor where tetrahydrocannabinol (THC), the primary active ingredient in marijuana, did its work. Shortly after that discovery, researchers at Hebrew University in Jerusalem identified the body's own form of THC, which uses the same CB1 receptors as THC (CB1 is cannabinoid receptor type 1). They christened the internally manufactured substance *anandamide*, after the Sanskrit *ananda*, or "bliss" (Fackelmann, 1993).

Anandamide has a streamlined three-dimensional structure that THC mimics. Both molecules slip easily through the blood brain barrier. Some of the mystery of marijuana's effects was resolved after researchers demonstrated that marijuana definitely increased dopamine activity in the limbic area of the brain. Tanda, Pontieri, and Di Chiara demonstrated that dopamine levels in the nucleus accumbens doubled when rats received an infusion of THC (1997). It appears that marijuana raises dopamine and serotonin levels through the intermediary activation of opiate and Gamma-aminobutyric acid (GABA) receptors (Wilson & Nicoll, 2001). (GABA is the chief inhibitory neurotransmitter in the mammalian central nervous system. The opiate receptor and other brain receptors are proteins located on the surfaces of nerve cells, or neurons.) THC may perform a signaling function in neurons containing GABA and glutamate.

THC and its organic cousin, anandamide, make an impressive triple play in the brain: They effect movement through receptors in the basal ganglia, they

alter sensory perception through receptors in the cerebral cortex, and they impact memory by means of receptors in the hippocampus. It is clear that some of the effects of cannabis are produced in much the same way as the effects of other addictive drugs—by means of neurotransmitter alterations along the limbic system's reward pathway.

A great deal of the early research was marred by inconsistent findings and differing definitions of addiction and withdrawal. Most recreational marijuana users find that too much pot in one day makes them lethargic and uncomfortable. Self-proclaimed marijuana addicts, on the other hand, report that pot energizes them, calms them down when they are nervous, or otherwise allows them to function normally. Heavy marijuana users claim that tolerance does build. And when they withdraw from use, many report strong cravings.

Work by Jones, Benowitz, and Herning had helped establish certain baseline symptoms—irritability, insomnia, and lack of appetite—as early as 1981. Studies by Budney, Novy, and Hughes in 1999 further outlined the syndrome in heavy daily marijuana smokers. But the abstinence effects were often inconsistent, and frequently hard to measure. Moreover, their clinical relevance was not always evident.

For marijuana withdrawal to be considered a clinical fact, several criteria had to be met. First, the typically transient pattern of withdrawal effects must be distinguishable from rebound effects. (A rebound effect is defined as the reappearance of a preexisting symptom, and is thus not considered a true withdrawal effect.) In addition, the symptoms must occur reliably, as demonstrated by comprehensive prospective studies (Budney, Hughes, Moore, & Vandrey, 2004). The symptoms under consideration must also be considered clinically significant. Finally, there needs to be a clear and repeatable timeline in evidence for the withdrawal effects.

It has been suggested that the reported symptoms of abrupt marijuana cessation do not rise to the level of withdrawal typically associated with drug detox. It is now possible to lay out the neurochemical basis of marijuana withdrawal, and to demonstrate that marijuana acts on the brain in a fashion similar to other addictive drugs.

There is solid experimental evidence that chronic, heavy cannabis users develop tolerance to its subjective and cardiovascular effects. "In summary," Budney et al. write, "cannabis withdrawal effects clearly occur in the majority of heavy, daily users" (2004, p. 1974). As a rough estimate, approximately 10 percent of marijuana users are at risk for dependence and withdrawal, the classic determinants of drug addiction (Joy, Watson, & Benson, 1999). There is clinical and epidemiological evidence that some heavy cannabis users experience problems in controlling their cannabis use, and continue to use the drug despite

experiencing adverse personal consequences of use (Hall, Solowij, & Lemon, 1999). Moreover, there is strong clinical evidence that some users experience a withdrawal syndrome upon the abrupt cessation of cannabis use. The timeline is similar to withdrawal from other addictive drugs.

In 2004, a group at the University of Vermont funded by the US National Institute of Drug Abuse (NIDA), undertook a critical review of all major relevant studies of the validity and clinical significance of marijuana withdrawal (Budney et al., p. 1967). The review of studies demonstrated with certainty that there are people with a propensity for heavy marijuana use who suffer a clearly delineated, verifiable, and frequently vivid set of withdrawal symptoms when they try to quit. One of the most striking pieces of evidence for this is the similarity of symptom sets emerging from the clinical studies to date. The most common "reliable and clinically significant" effects of abrupt withdrawal in heavy pot smokers, according to the University of Vermont research group, included "severity of craving and sleep difficulty, decreased appetite, and increased aggression, anger and irritability" (Budney, et al., p. 1967; Kouri, 2002, p. 30).

As another study author concluded: "Marijuana withdrawal doesn't include dramatic physical symptoms such as the pain, nausea, heavy sweating, and cramps associated with opiate withdrawal. Nevertheless, the symptoms of marijuana withdrawal appear clinically significant" (Zickler, 2002, p. 3). A recent comprehensive outpatient study (Kouri & Pope, 2000, p. 483) with prewithdrawal baselines showed greater levels of anxiety, negative mood, physical discomfort, and decreased appetite during abstinence but not at baseline, compared with two control groups. Moreover, in a "home environment" study, researchers worked with marijuana users who provided self-ratings during marijuana withdrawal; these users smoked an average of 3.6 times daily, did not use other drugs or abuse alcohol, and were free of major psychiatric disorders. The same symptoms predominated, and onset of symptoms occurred reliably within 48 hours of cessation. Moreover, "telephone interviews with collateral observers living with the participants confirmed participants' reports of increased irritability, aggression, and restlessness during abstinence. . . . [T]he validation of symptoms by home-based observers suggested that the effects were of a clinically significant magnitude" (Budney et al., 2004, p. 1971).

Other studies by Budney and colleagues expanded on the list of symptoms that changed significantly from baseline during withdrawal: "anger and aggression, decreased appetite, irritability, nervousness, restlessness, shakiness, sleep difficulty, stomach pain, strange dreams, sweating, and weight loss" (2003, p. 393; 2004, p. 1972). Although most effects were transient, generally lasting no more than two weeks, "strange dreams and sleep difficulties showed significant elevations throughout the study" (2003, p. 394). Budney et al. conclude

that, since most symptoms returned to baseline levels in the former users, "these findings were not rebound effects indicative of symptoms that existed before the use of cannabis" (2004, p. 1972). More recent studies by Haney and others "controlled for potential confounders by using placebo conditions and excluding persons who abused other substances, had an active psychiatric disorder, or were taking psychoactive medication" (Haney et al., 2004, p. 158).

Overall, the research cited above confirms that the most common marijuana withdrawal symptom is low-grade anxiety and dysphoria. Anxiety of this sort has a firm biochemical substrate. A peptide known as corticotrophin-releasing factor (CRF) is primarily responsible. Neurologists at the Scripps Research Institute in La Jolla, California, found that CRF levels in the amygdalas of animals in marijuana withdrawal were as much as three times higher than the levels found in animal control groups (Wickelgren, 1997, p. 1967). Long-term marijuana use alters the function of CRF in the limbic system in a manner similar to other addictive drugs (de Fonseca et al., 1997, p. 2051). (CRF receptors in the amygdala also play a direct role in alcohol withdrawal.)

METHOD

Personal observations and selected case histories of frequent marijuana users were gathered from anonymous, unedited comments posted on a blog site maintained by the author. Punctuation, capitalization, and spelling have been normalized in the excerpts included here. Most of the people who have posted comments thus far (more than 100) arrived at the site by means of the search term *marijuana withdrawal*. This may indicate that a large number of posters are heavy smokers seeking information about abstinence symptoms. The popularity of this search phrase on the Google search engine seems to suggest an interest in, and a need for, scientific information about marijuana withdrawal.

What has surprised many observers is that the idea of treatment for marijuana dependence seems to appeal to such a large and diverse group of people. NIDA has been able to find a cohort of withdrawal-prone smokers with relative ease. According to the principal investigator of one NIDA marijuana study, "We had no difficulty recruiting dozens of people between the ages of 30 and 55 who have smoked marijuana at least 5,000 times. A simple ad in the paper generated hundreds of phone calls from such people" (NIDA, 1999, p. 1). This would be roughly equivalent to 14 years of daily pot smoking.

Comments gathered from anonymous users at an open Web forum created for the discussion of marijuana withdrawal symptoms cannot be controlled for confounding variables such as other addictions or psychological disorders. The comment section of the Web site is open to anyone. What such surveys *can*

accomplish, however, is the demonstration of parallels, or lack of them, between findings in an experimental setting and anecdotal reports from the field. Survey studies cannot offer indisputable proof. Nonetheless, when combined with the results of formal clinical studies, such surveys offer a window into real-world experience, thus complementing the growing scientific data concerning marijuana withdrawal syndrome.

The comments were generated in large part by heavy, regular smokers who either recognized or have begun to recognize in themselves an addictive propensity toward marijuana. As a group, they have great difficulty—and suffer similar symptoms—whenever, and for whatever reason, they choose to abstain. Perhaps, most important, the present survey adds to the growing documentation of the contention that withdrawal symptoms are a frequent cause of relapse in marijuana smokers attempting to achieve abstinence.

RESULTS

All of the following comments can be found at the Web log *Addiction Inbox* (http://addiction-dirkh.blogspot.com/2007/10/marijuana-withdrawal.html). The unnumbered messages on the Web site are dated, and appear in chronological order.

1. Cave. (2008, February 8):
   "Well I just stopped smoking pot after 4 years of everyday use, 5 days ago. I am feeling the withdrawal symptoms ridiculously hard. No appetite, slight nausea, extreme insomnia."
2. Anonymous. (2008, February 26):
   "My boyfriend (of 6 years) has been a smoker for approximately 16 years. He has tried to give up a few times seriously before but has never quite gotten there yet. His behavior is almost unbearable when he does. It really takes a toll on our relationship. I never realized that it could be so bad and that his actions are so exaggerated by withdrawal."
3. Anonymous. (2008, February 26):
   "I'm a 30-year-old man and have been a heavy cannabis user (3 to 4 joints per day, every day) since I was 19. . . . I've been through intense anxiety, depression, restlessness, lack of appetite. I can't sleep for more than a few hours at a time and when I do, I sweat buckets. I have a terrible appetite, I'm cold all the time, like I can't regulate my temperature."
4. Anonymous. (2008, February 27):
   "I thought I was going crazy because all other sites told me that there were no withdrawal symptoms from pot, I can't think or eat and when I do finally get something down my gullet I get the runs straight after. . . . I feel like I have been hit by a truck and it has only been a week since I gave up."

5. Anonymous. (2008, March 1):
"I am 31 and a heavy smoker of 10 years. . . . What is really troubling me, however, is the excessive dreaming. . . . The dreams are vivid and strong, enough to wake me up sometimes."
6. Anonymous. (2008, March 3):
"This idea of 'intense dreaming' is very real and for the first 5 or 6 days after quitting I experienced life-like dreams/nightmares (99% nightmares), which would wake me from my sleep. . . . This idea of breaking out in cold sweat is also very real and quite scary when [it] occurs as [it] got me worried there was something else wrong with me."
7. Scott. (2008, March 3):
"I was blown away when I saw 'excessive sweating' as I have been experiencing that for a few days. . . . If I could cut back drastically, that would be the ideal situation. But I know from experience that I can't just smoke pot 'a little bit.' If I'm going to reduce, it's going to have to be all the way to zero."
8. Anonymous. (2008, March 7):
"I'm on day seven of abstinence and boy, do I feel lousy. Night sweats, anxiety, extreme insomnia, and loads of irritability/anger problems. . . . It's a bit like when you have a bad flu. You plain feel rotten. Anything stress-related is magnified ten-fold."
9. Bob. (2008, March 7):
"I'm 38 years old and have been using weed now daily for almost 21 years. . . . I've been 'clean' now for 4 days and so far it has obviously been difficult, but already I'm showing signs of improvement, the first two days I had no sleep at all. . . . My withdrawal symptoms: Loss of appetite, sweating, irritability, sudden crying fits."
10. Anonymous. (2008, March 8):
"I am a 25-year-old female and I have been smoking pot since I was 13. I have never stopped even a day that I can remember. Not unless I couldn't get it. I have recently started to realize that it is a drug addiction. I was always on the 'it's not addictive' side. I get very anxious if I think I'm not going to have any. . . . It is out of my control I think, and now I'm starting to not feel high. I really wanna stop, but am so scared of the symptoms. I think I need help."
11. Anonymous. (2008, March 18):
"Having read all of these comments and questions I no longer feel so abnormal. I have been experiencing most of these symptoms including vivid dreaming. . . . I have been a smoker since I was 15, every day smoking about 2–3 joints."
12. Anonymous. (2008, March 24):
"I am a 25-year-old female. I started smoking at 18. . . . I quit a few weeks ago. . . . I can't focus on anything. I can't make myself do anything. . . . I snap at everyone, including my boyfriend who has been complaining about my

excessive sweating. I didn't even think of the sweating as a symptom until I read the other posts here."

13. Anonymous. (2008, April 2):
"I just wanted to say I'm glad I found this site because as many people have noted the common wisdom is that there are few, if any, symptoms of withdrawal. . . . I've noticed the irritability and mood swings, which I expected, but didn't make the connection between the vivid and frequent dreams and waking at night until I read all the other comments."
14. Anonymous. (2008, April 8):
"I finally feel sane again after reading these postings. I am a 48-year-old male who has been smoking weed since 1975. Anywhere from 2–6 joints per day of good quality pot for the last four years. Decided to quit about a week ago and my life has been a living hell since. . . . Haven't eaten a full meal in a week, very tired and depressed, stomach in knots."
15. Anonymous. (2008, April 25):
"I quit weed 46 days ago. . . . pretty similar symptoms as everyone else and the most severe anxiety and depression I have ever known. . . . I can't concentrate or focus, I can't seem to forget about what has happened even though I want to, it feels as though my brain keeps reminding me about the 'situation' or some general anxious or negative thought just pops into my consciousness . . . like it's never going to end, like my thoughts are caught in a vicious circle."
16. Richard. (2008, May 3):
"It's not suicidal ideation but it's the feeling that life will just never 'be right'. . . . when you suffer from symptoms that you've been told don't exist, you are left looking for the wrong cause. So, if you're told that marijuana withdrawal does not increase anxiety, anger, or 'hopelessness,' you want to look for a cause of those things. . . . I went through withdrawal periods where I was inappropriately angry at the wrong thing, thinking that specific people were upsetting me when they were not."

DISCUSSION

The U.S. government's essentially unchanged opposition to marijuana research has meant that, until quite recently, precious few dollars were available for research. This official recalcitrance is one of the reasons for the belated recognition and characterization of marijuana's distinct withdrawal syndrome. According to research undertaken as part of the Collaborative Study of the Genetics of Alcoholism, 16 percent of people with a lifetime history of regular marijuana use reported a history of cannabis withdrawal symptoms (Schuckit et al., 1999). In earlier research, Mason discovered that those seeking treatment for

cannabis addiction tended to cluster in two age groups—college age and mid-50s, as reported by Somers (2008).

Budney et al. (2004, p. 1973) write:

> Regarding cross-study reliability, the most consistently reported symptoms are anxiety, decreased appetite/weight loss, irritability, restlessness, sleep problems, and strange dreams. These symptoms were associated with abstinence in at least 70% of the studies in which they were measured. Other clinically important symptoms such as anger/aggression, physical discomfort (usually stomach related), depressed mood, increased craving for marijuana, and increased sweating and shakiness occurred less consistently.

Today, scientists have a much better picture of the tasks performed by anandamide, the body's own form of THC. Among the endogenous tasks performed by anandamide are pain control, memory blocking, appetite enhancement, the suckling reflex, lowering of blood pressure during shock, and the regulation of certain immune responses. This knowledge helps shed light on the wide range of THC withdrawal symptoms, particularly anxiety, chills, sweats, flu-like physical symptoms, and decreased appetite.

Furthermore, we can look to indications for which marijuana is already being prescribed—anxiety relief, appetite enhancement (compounds similar to anandamide have been discovered in dark chocolate), suppression of nausea, relief from the symptoms of glaucoma, and amelioration of certain kinds of pain—for more insight into the common hallmarks of cannabis withdrawal.

What treatment measures can help ameliorate marijuana withdrawal and craving in heavy users who wish to quit? The immediate threat to any decision in favor of abstinence is what might fairly be called the "hair of the dog" effect. Note the findings of a 2004 paper in *Neuropsychopharmacology*: "Oral THC administered during marijuana abstinence decreased ratings of 'anxious,' 'miserable,' 'trouble sleeping,' 'chills,' and marijuana craving, and reversed large decreases in food intake as compared to placebo, while producing no intoxication" (Haney et al., p. 158).

Moreover, "Overall withdrawal severity associated with cannabis alone and tobacco alone was of a similar magnitude. . . . cannabis withdrawal is clinically important and warrants detailed description in the *DSM–V* and *ICD–11*" (Vandrey, Budney, Hughes, & Liguori, 2008, p. 48). It is possible that many more people are trying—and failing—to quit marijuana than researchers have previously suspected. Daily use of marijuana may be driven in part by the desire to avoid or eliminate abstinence symptoms (Haney, Ward, Comer, Foltin, & Fischman, 1999).

To date, there is no effective anticraving medication approved for use against marijuana withdrawal syndrome. More than a decade ago, Ingrid Wickelgren wrote in *Science:* "For instance, chemicals that block the effects of CRF or even relaxation exercises might ameliorate the miserable moods experienced by people in THC withdrawal. In addition, opiate antagonists like naloxone may, by dampening dopamine release, block the reinforcing properties of marijuana in people" (1997, p. 1967). Since stimulation of THC receptors has homologous effects on the endogenous opioid system, various investigators have speculated that naltrexone, the drug used as an adjunct of heroin withdrawal therapy, may find use against symptoms of marijuana withdrawal in people prone to marijuana dependence (Tanda et al., 1997). Further research is needed on the reciprocal relationship between THC and opioid receptor systems.

Serzone (nefazodone), an antidepressant, has been used to decrease some symptoms of marijuana withdrawal in human subjects who regularly smoked six joints per day (Haney et al., 2003). Anxiety and muscular discomfort were reduced, but Serzone had no effect on other symptoms, such as irritability and sleep problems.

Preliminary studies have found that lithium, used to treat bipolar disorder, curbed marijuana withdrawal symptoms in an animal study (Cui, Gu, Hannesson, Yu, & Zhang, 2001). Another drug for mania and epilepsy—Depakote—did not aid significantly in marijuana withdrawal (Haney et al., 2004).

Since difficulty sleeping is one common symptom of withdrawal, common prescription medications might be indicated for short-term use in the case of severe marijuana withdrawal. Some researchers have reported that even brief interventions, in the form of support group sessions, can be useful for dependent pot smokers (Copeland, Swift, & Rees, 2001).

It is also plausible to suggest that the use of marijuana by abstinent substance abusers may heighten the risk of relapse. In a study of 250 patients at a psychiatric/substance abuse hospital in New York, "Postdischarge cannabis use substantially and significantly increased the hazard of first use of any substance and strongly reduced the likelihood of stable remission from use of any substance" (Aharonovich et al., 2005, p. 1507). However, the researchers found that cannabis posed a greater risk to cocaine and alcohol abusers. For heroin, "cannabis use after inpatient treatment did not significantly affect remission and relapse" (Aharonovich, p. 1507).

It is surprising to note the relative paucity of previous clinical data the researchers had to work with in the case of alcohol and marijuana. "The gap in the literature concerning the relationship of cannabis use to the outcome of alcohol dependence was surprising," according to Aharonovich and col-

leagues. "We were unable to find a single study that examined the effects of cannabis use on post-treatment outcome for alcohol dependence, despite the fact that the majority of patients now in treatment for alcoholism dependence also abuse other drugs. Clearly additional studies of this issue are warranted" (2005, p. 1512).

Addiction researcher Barbara Mason of the Scripps Research Institute of La Jolla, California, is, at the time of this writing, overseeing a four-year study of the neurobiology of marijuana dependence under a grant from NIDA. The comprehensive project will involve both animal and human research, and will make use of state-of-the-art functional brain imaging. The federal grant will also be used as seed money for the new Translational Center on the Clinical Neurobiology of Cannabis Addiction at the Scripps Institute ("Scripps Given," 2008).

Above all, it is time to move beyond the common mistake of assuming that if marijuana causes withdrawal in some people, then it must cause withdrawal in everybody. And if it doesn't, it cannot be very addictive. This thinking has been overtaken by the growing understanding that a minority of people suffer a chemical propensity for marijuana addiction that puts them at high risk, compared to casual, recreational drug users. The fact that most people do not become addicted to marijuana and do not suffer from withdrawal is no more revealing than the fact that a majority of drinkers do not become alcoholics.

The idea of marijuana addiction and withdrawal remains controversial in both private and professional circles. For an unlucky few, a well-identified set of symptoms characterizes abstinence from heavy, daily use of pot. In this, marijuana addiction and withdrawal does not differ greatly from alcoholism—the vast majority of recreational users and drinkers will never experience it.

For those that do, however, the withdrawal symptoms of marijuana abstinence can severely impact their quality of life.

Chapter **8**

Marijuana Interaction with Methamphetamine Addiction

Mary F. Holley, MD

The use of marijuana has long been recognized as an antecedent to the use of so-called hard drugs such as methamphetamine. This gateway hypothesis has been roundly debated for many years and attributed to social factors, "peer pressure," and the availability of other drugs in settings in which marijuana is purchased and used. Twin studies have documented the strength of the association between early marijuana use (prior to age 17) and subsequent drug use. In twins discordant for early marijuana use, the marijuana-using twin was more than four times more likely to use and become dependent on stimulants (Lynskey et al., 2003).

The sheer magnitude of marijuana use among adolescents should give us pause to consider the effects of this psychoactive drug on the future of our children. Nearly half of 12th graders have tried marijuana, and 6 percent admit to daily use (Johnston, O'Malley, Bachman, & Schulenberg, 2005), and these are the kids who stayed in school. The rate of marijuana use among high school dropouts is likely to be even higher. The marijuana they are using is also much more potent than the "Iowa Ditch" that grew on the side of the road outside Des Moines in the late 1960s. Marijuana now is grown in high-tech growing labs, with delta-9-tetrahydrocannabinol (TCH) content as high as 15 percent (McLaren, Swift, Dillon, & Allsop, 2008).

This cannabis use is often occurring in adolescence, a time of significant neurologic maturation in areas of executive function, including decision making and impulse control. While multiple predisposing factors predict later drug use, including parental drug use, child abuse, conduct disorder, and novelty

seeking as a personality trait, the use of cannabis in adolescence and early adulthood emerged as the strongest risk factor for later involvement in other illicit drugs (Fergusson, Boden, & Horwood, 2008). Even a small increase in risk of addiction becomes socially significant when 50 percent of high school seniors are trying marijuana.

In addition, marijuana has effects on the brain in many of the same areas that methamphetamine changes, including the hippocampus and many areas of the frontal lobes so that injury to these areas caused by initial use of marijuana may be amplified by subsequent and concurrent use of methamphetamine. While scientists prefer to study isolated drug effects for the intellectual satisfaction of knowing precisely how various systems are affected, human behavior rarely cooperates. We are asked to predict the consequences of drug use based on single drug studies, when single drug use is the exception, rather than the norm.

Medication interactions have often been clinically significant in the context of prescription medications. These interactions are likely to be even more significant in the case of two very popular psychoactive drugs of unknown dose and purity used under conditions of concurrent exposure to alcohol, tobacco, and club drugs in people of variable age and underlying health. This chapter will focus on the interaction between marijuana and methamphetamine on brain function and behavior, with an eye to the development and clinical course of dependence on methamphetamine.

BIOCHEMICAL INTERACTIONS

Recent findings have revealed a vast neurotransmission system dubbed the endocannabinoid system due to its sensitivity to cannabinoid stimulation. The endocannabinoid system has been the subject of vigorous research for many years, not just for its interest as related to a drug of abuse, but also for its importance to understanding neurophysiology in general. The endocannabinoid system is in place not just so that people can get high on pot, but also for numerous neurologic processes of neuromodulation. It influences not only the reward system, but also appetite, learning and memory, and executive functions, including impulse control and decision making. We can expect that use of marijuana, particularly at critical developmental stages, prenatal exposure and adolescent drug use, would exert changes in these functions, perhaps long-lasting changes.

The endocannabinoid system has a complex relationship to the reward system of the brain, changing the sensitivity of the neural structures related to the sensation of pleasure. Interactions between cannabinoid receptors and responsiveness to alcohol (López-Moreno et al., 2008), heroin (Solinas, Yasar,

& Goldberg, 2007), and methamphetamine (Landa, Sulcova, & Slais, 2006) have been delineated, with vast implications for the potential addictiveness of these substances. Since marijuana is often used in the context of concurrent use of other drugs, these interactions must be clearly understood in this time of increasing marijuana use.

Marijuana is also a common drug of abuse in the adolescent age range, from age 10–19, and so its impact on adolescent neurodevelopment must be taken into account as well. Functions such as judgment, impulse control, predicting the future consequences of an action, and delayed gratification, are being established. Such executive functions are processed in the frontal and temporal lobes, in areas that are maturing in adolescence. It is likely the psychoactive drugs have an impact on the maturation of these areas, with profound effects on the mature personality.

IMPACT ON THE REWARD CIRCUIT

Marijuana has, first and foremost, effects on the reward circuit of the brain, resulting in a sensation of euphoria and generalized well-being. Rats treated with a cannabinoid CB1 agonist showed significant increases in dopamine release in the nucleus accumbens as an acute effect (Fadda et al., 2006).

Chronic exposure to TCH has been found to increase the length and number of dendritic branches in the shell of nucleus accumbens and also in the medial prefrontal cortex in rats (Kolb, Gorny, Limebeer, & Parker, 2006). Cannabinoid exposure then seems to increase the sensitivity of the reward circuit to dopamine stimulation at a cellular level. This heightened neural capacity for a dopamine response has its basis in changes in the neuroanatomy of the nucleus accumbens.

Specifically, stimulation of the CB1 cannabinoid receptors primes the reward pathway and sensitizes the system to be more responsive to methamphetamine stimulation (Landa et al., 2006) and to a moderate dose of alcohol (López-Moreno et al., 2008) in a persistent manner. The effect is not just a product of acute intoxication, but is rather a change in the neuroanatomy of the nucleus accumbens. This sensitization could result in a situation in which even low doses of lower-purity methamphetamine would be potently rewarding in individuals who have smoked marijuana prior to, or concurrent with, their first experience with methamphetamine.

This finding alone could help explain the widely differing "addiction rate" among methamphetamine users, depending on the social context of their drug use. Lower addiction rates are often seen in those who use methamphetamine occupationally to enhance their work performance (i.e., military personnel) or

medically (i.e., for obesity) versus those using it recreationally (Eliyahu, Berlin, Hadad, Heled, & Moran, 2007). While still experiencing the alertness, endurance, or anorectic aspects of methamphetamine, these individuals may be much less sensitive to the euphoric effects of the drug in the absence of previous or concurrent marijuana use.

EXECUTIVE FUNCTION

Marijuana has also been found to have significant effects on the functioning of the frontal lobe as it relates to executive function, including decision making and impulse control. This is of concern as methamphetamine also directly impacts many of the same areas. The use of marijuana may set the anatomic stage for the behavioral and personality changes, including the occupational failure and interpersonal strife, so often seen in methamphetamine addiction. These effects would likely be exaggerated in the case of adolescent users who are still in the process of maturing these brain structures. The combined forces of marijuana use and methamphetamine's effects could amplify the frontal lobe injury that so often complicates substance abuse treatment.

Impairment of the frontal lobe areas involved with executive function has been well documented in heavy marijuana users. Bolla, Brown, Eldreth, Tate, and Cadet in 2002 correlated marijuana use to poor performance in problem solving, learning, inhibition, and reaction time in heavy users who were abstinent for 28 days. To delineate the neurologic basis for this finding, Bolla then compared abstinent marijuana users with controls under positron emission tomography (PET) scanning (Bolla, Eldreth, Matochik, & Cadet, 2005) and found that the marijuana users showed less activation in the right lateral orbitofrontal cortex (OFC) and the right dorsolateral prefrontal cortex (DLPFC) than the control group on the Iowa Gambling Task. Heavy marijuana users did not perform as well as nonusers on this measurement of executive function and decision-making skills.

More recent use of marijuana has far more significant effects on the functioning of these executive functions. Pillay et al. (2008) demonstrated anterior cingulate and prefrontal dysfunction in marijuana users at 24 hours' abstinence that partially normalized after 28 days, though anterior cingulate function was still significantly impaired at 28 days' abstinence. Exposure to marijuana, even remotely—after 28 days of abstinence—compromises inhibitory control and executive function. The degree of cognitive impairment is even greater in the presence of acute intoxication, which is the more common context of an individual's first use of methamphetamine.

In tests of inhibition processing, fMRI testing was done at 28 days' abstinence during a Stroop task involving inhibition of the dominant process of reading words to instead give the colors of words printed in incongruent ink. The cortical activation pattern of the heavy marijuana users reflected reduced activation of the anterior cingulate and more widespread dorsolateral prefrontal lobe compensatory activity (Eldreth, Matochik, Cadet, & Bolla, 2004; Gruber & Yurgelun-Todd, 2005). Marijuana users are thus more dependent on dorsolateral prefrontal lobe activity to be successful in inhibitory processing.

Methamphetamine use significantly compromises these "back-up" areas and further impairs decision making and impulse control. The anatomic basis for this reduced impulse control is demonstrated by several fMRI studies involving human methamphetamine users attempting inhibitory control tasks under fMRI monitoring. Anterior cingulate and dorsolateral prefrontal cortex activity has been shown to be essential in response inhibition and impulse control (Garavan, Ross, Murphy, Roche, & Stein, 2002). Studies have demonstrated reduced task-related activation of the anterior cingulate gyrus in methamphetamine users (Hwuang et al., 2006). Paulus et al. (2002) studied methamphetamine addicts in early recovery by fMRI as they did a two-choice prediction task and a two-choice response task. They demonstrated less activation of dorsolateral prefrontal cortex and failure to activate ventromedial prefrontal cortex during this decision-making task.

These changes appear to be more than just a pharmacologic effect of methamphetamine. There appears to be some cellular destruction of a more permanent nature going on as well. The massive releases of neurotransmitter caused by methamphetamine use result in high levels of nitrogen and oxygen free radical formation (Acikgov et al., 2000). These free radicals are formed by the metabolism of methamphetamine, and also by the breakdown of the huge amounts of monoamine neurotransmitters that have been released both intra and extra cellularly. These monoamine neurotransmitters must also be broken down, and MAO, the usual enzyme to do that, is inhibited by methamphetamine. Alternative metabolic routes are used, resulting in the generation of large amounts of hydroxyl free radicals nitric oxide and peroxynitrite, which are extremely toxic to brain cells (Jeng, Ramkissoon, Parman, & Wells, 2006).

Free radical compounds denature proteins, damage DNA, and generally wreak havoc in the areas of the brain in which they are concentrated (Cubells, Rayport, Rajendran, & Sulzer, 1994). Because most of the neurotransmitters are released in the midbrain, nucleus accumbens, and striatum, and in the prefrontal cortex, those areas are disproportionately affected by methamphetamine abuse with progressively worsening cognitive and executive function (Li,

Wang, Qiu, & Luo, 2008). Nordahl et al. (2005) did magnetic resonance spectroscopy (MRS) measures of N-acetylaspartate-creatine and phosphocreatine (NAA/Cr), choline-creatine and phosphocreatine (Cho/Cr), and choline-N-acetylaspartate (Cho/NAA) ratios in the anterior cingulate cortex of abstinent meth users and found evidence of cellular compromise that only partially corrected after prolonged periods (years) of abstinence.

These changes have implications for addiction recovery and relapse as function in crucial frontal lobe areas is compromised. Methamphetamine users had significantly impaired inhibitory control on a Stop Signal Test measuring latency to inhibit a motor response (Monterosso, Aron, Cordova, Xu, & London, 2005). Impulsivity is also related to impaired perception of time intervals, with methamphetamine abusers consistently overestimating time intervals and accelerating fingertaps (Wittmann, Leland, Churan, & Paulus, 2007). This "trigger fingered" impaired capacity for inhibitory processing would reduce the ability to resist impulses, delay gratification, and thus, increase the likelihood of relapse. In a landmark study, Paulus, Tapert, and Schuckit (2005) showed that those addicts who eventually relapsed had markedly reduced activation of the dorsolateral prefrontal cortex and anterior cingulate gyrus compared to addicts who did not subsequently relapse. Subjects were followed for up to three years to observe for relapse, and the predictive power of this functional measure of brain activity in these areas was impressive.

MEMORY AND LEARNING

In addition to its direct effects on the reward circuit and executive function, marijuana has significant effects on the hippocampus and various areas of the frontal lobe that could also affect memory and learning, in a way that could increase the likelihood that a person would use and become dependent on methamphetamine, and increase the neurologic impact of his methamphetamine use. A hippocampus, for instance, that is already compromised by marijuana use might be more vulnerable to the neurotoxic effects of methamphetamine.

Long- and short-term heavy cannabis use leads to impaired verbal memory and fluency, attention, and psychomotor speed at 24 hours after last use (in the absence of intoxication), which has implications for occupational performance and driving safety (Messinis, Kyprianidou, Malefaki, & Papathanasopoulos, 2006). Short-term abstinent cannabis users had deficits in verbal fluency, visual recognition, delayed visual recall, and short- and long-interval prospective memory. There were no differences for immediate visual recall (McHale & Hunt, 2008). Recent users also demonstrated abnormal brain activation pat-

terns during a working memory task, with recruitment of additional regions not typically used for this type of working memory (Kanayama, Rogowska, Pope, Gruber, & Yurgelun-Todd, 2004).

Even after 28 days of abstinence, performance was significantly worse in both long- and short-term memory for heavy users. Nestor, Roberts, Garavan, and Hester (2008) demonstrated that cannabis-using adults had significantly lower activity in the superior temporal gyrus, and several areas of the frontal lobe, compared to controls during learning in a name-face task. Results also showed that cannabis-using adults had significantly lower activity in the frontal and temporal lobes, and higher activity in the right parahippocampal gyrus, during learning. These changes indicate functional deficits and compensatory processes in cannabis users.

Heavy use is defined as daily smoking of at least one joint per day, a condition met by about 6 percent of all high school seniors (Johnston et al., 2005). While moderate recreational users of marijuana had normal performance on tests of working memory and selective attention, cannabis users displayed a significant alteration in brain activity in the left superior parietal cortex after 10 days of abstinence (Jager, Kahn, Van Den Brink, Van Ree, & Ramsey, 2006), indicating that even moderate use has an effect on brain function. But again, those same frontal lobe structures compromised by marijuana use may be more susceptible to the more serious neurotoxic effects of methamphetamine when it is used after or concurrent with marijuana.

The toxicity of methamphetamine is profound, and the cognitive changes seen in methamphetamine addicts are far more pronounced than those associated with marijuana. Methamphetamine abusers have cognitive deficits, abnormal metabolic activity, and structural deficits in frontal, temporal, and para hippocampal cortices, and reduced hippocampal volume. The magnitude of disruption in these areas is correlated with cognitive deficits in attention, memory, and executive function in many domains (London et al., 2005; Thompson et al., 2004). Scott et al. (2007) did a meta-analysis of available data on the neuropsychological effects of methamphetamine abuse/dependence. They revealed deficits in episodic memory, executive functions, information-processing speed, motor skills, language, and visuoconstructional abilities in methamphetamine users that were far more prominent and easily measurable than those found in marijuana users. Primate studies of methamphetamine-exposed animals have demonstrated profound impairment in cognitive function, particularly spatial working memory and long-term associative memory that were related to dopamine deficiencies in the prefrontal cortex, cingulate cortex, and striatum (Castner, Volser, & Goldman-Rakic, 2005). These cognitive deficits greatly impair ability to participate in cognitive behavioral therapy as a com-

ponent of rehabilitation. Memory, attention span, and information processing slowly improve over the course of 12–18 months, requiring prolonged treatment at great cost.

DEVELOPMENTAL CONSIDERATIONS

A large number of the people who are initiating methamphetamine use are in the adolescent age group, with an average age of 19 (Brecht, Greenwell, & Anglin, 2006), and nearly all of them use alcohol, tobacco, and/or marijuana prior to first use of methamphetamine. Adolescents are more likely to smoke or snort meth than to inject it at their first use (Wood et al., 2008) and to do so in the context of marijuana use. Youth and young adults are in a developmental phase in which the rate of maturation and development of the brain is exceeded only by that of infancy and early childhood. In this extremely important developmental window, our teenagers are exposing themselves to neurotoxic drugs that will affect their lives and opportunities significantly.

The vulnerability of the adolescent brain is just beginning to be understood. The endocannabinoid inhibition of synaptic function in the hippocampus was more pronounced in adolescent rats than adults, which may account for the increased sensitivity of adolescent animals to TCH-induced memory impairment (Kang-Park, Wilson, Kuhn, Moore, & Swartzwelder, 2007). Adolescent THC exposure resulted in CB1/G protein uncoupling in the hippocampus that persisted into adulthood (Rubino et al., 2008), suggesting that a cannabinoid-related disconnection can be expressed in adulthood as a developmental deficit. These animal studies support the conclusion that the neurologic changes seen with human marijuana use do not likely precede drug use (as predisposing factors), but are in fact consequences of adolescent marijuana use in normal teens.

Normal adolescent neurodevelopment includes extensive remodeling of the frontal lobes, occurring between the ages of 12 and 21 (Gogtay et al., 2004; Shaw et al., 2008). This process involves myelination of white matter tracts and synaptic pruning in areas of the frontal lobes involved in executive function, including judgment, prediction of future consequences, inhibitory processes, and impulse control. All of these functions are important when resisting peer pressure and controlling alcohol and drug intake.

Tapert et al. (2007) measured brain function by an fMRI technique during a go/no-go task, indicating inhibitory control in adolescent marijuana users compared to controls (controlled for alcohol intake). Marijuana users performed as well as nonusers, but recruited additional cortical areas in the frontal and parietal lobes, in order to perform the task. These changes were noted after 28 days of abstinence and thus reflect a persistent finding. These findings suggest that a key capability of executive function, inhibition of impulses, is

impaired not just when an individual is intoxicated, as classical gateway theories have posited, but for weeks afterward, during a developmental period in which forebrain maturation is taking place.

The effects of marijuana on other cognitive functions have also been found to be more significant in adolescents than in adults. Memory and learning are critical functions for academic and occupational success and have been found to be distorted in adolescent marijuana users. Schweinsburg et al. (2008) showed that marijuana-using adolescents, after one month of abstinence, performed normally on a spatial working memory assessment, but had markedly different cortical activation patterns, reflecting different attention mental strategies used to achieve the same end result. In another fMRI study of marijuana-using adolescents studied in a spatial working memory task, users showed changes in recruitment of the anterior cingulate gyrus, temporal cortex, and hippocampal gyrus, again at 28 days' abstinence (Padula, Schweinsburg, & Tapert, 2007).

Not all of the studies have shown equivalent performance for marijuana-using adolescents. Medina and Tapert's group has done extensive research into the state of the hippocampus in adolescents who use marijuana, alcohol, and both, and found significant differences in hippocampal volumes. They also demonstrated, after a month of monitored abstinence, marijuana users had slower psychomotor speed, poorer complex attention, poorer story memory, and reduced planning and sequencing ability, all correlated with lifetime marijuana exposure and controlling for alcohol use (Medina et al., 2007). Smaller hippocampal volumes in the marijuana-using youth were also associated with more depressive symptoms on the Beck Depression Inventory (Medina, Nagel, Park, McQueeny, & Tapert, 2007).

These studies suggest long-lasting changes in the neuroanatomy of important areas in the frontal lobes related to the acquisition of executive functions. If these areas do not mature properly during adolescence, a developmental window of opportunity is missed. We often find in the course of working with addicted young adults that their emotional maturity matches the chronologic age at which they first began abusing substances. One of the challenges of addiction treatment is encouraging our clients to "grow up." Subsequent maturation can and does occur, but with a great deal more effort on the part of both client and therapist than would be the case with normal adolescence. We must seriously consider such neuroanatomic findings before we blithely accept the fact that 50 percent of our young people are using pot.

PRENATAL EXPOSURE TO POT

Our final concern will be with the issue of prenatal exposure to marijuana and its effects on the unborn child. The young adults and adolescents we have

been describing are predominantly of childbearing age. In Barcelona, Spain, 5.3 percent of newborns had a meconium screen positive for marijuana exposure, while only 1.7 percent of mothers admitted to using it during pregnancy (Lozano et al., 2007). In the United States, 6 percent of newborns in four major cities were positive for marijuana in 2003, an increase from 3 percent in 1993 (Derauf et al., 2007).

Parental substance abuse is a well-known risk factor for the development of substance abuse in children. Children witnessing the substance abuse of a parent are much more likely to view substance abuse as normal and acceptable behavior. They are also likely to have experienced numerous adverse childhood events, including abuse and neglect, which also predispose to addiction as they grow older (Dube et al., 2003).

But there is a little more to it than that. Prenatal exposure to marijuana predicted early use of marijuana by offspring by the age of 14, even after controlling for the child's current alcohol and tobacco use, pubertal stage, sexual activity, delinquency, peer drug use, family history of drug abuse, and characteristics of the home environment, including parental depression, current drug use, and strictness/supervision (Day, Goldschmidt, & Thomas, 2006). Prenatal exposure to marijuana produces changes in the neurologic make-up of the child that independently predispose to later substance abuse.

The endocannabinoid system is key to the early development of the central nervous system, serving as a traffic cop, directing the proliferation, migration, differentiation, and synapse formation of functional neural circuits throughout the developing brain (Harkany et al., 2007). Rats exposed to THC prenatally had increased anxiety scores measure by peeps when removed from the nest, inhibited juvenile social interaction, and play among adolescents, extending into adulthood with impaired elevated maze performance (Trezza et al., 2008). Emotional development has been found to be impaired in humans also. Prenatal marijuana exposure in the first and third trimesters predicted significantly increased levels of depressive symptoms in 10-year-old children (Gray, Day, Leech, & Richardson, 2005).

Prenatal marijuana exposure is also associated with cognitive deficits in children as measured by the Stanford-Binet verbal reasoning and short-term memory scales at ages three, four, and six (Day, Richardson, Goldschmidt, Robles, & Taylor, 1994; Fried & Watkinson, 1990; Goldschmidt, Richardson, Willford, & Day, 2008). Childhood cognitive deficits and learning disabilities represent a nonenvironmental risk factor for subsequent substance abuse. More significantly, prenatal marijuana exposure is associated with impaired executive function and impulse control at age 9–12 (Fried, Watkinson, & Gray, 1998), with poorer Wide Range Achievement Test-Revised (WRAT-R) reading compre-

hension and spelling scores at age 10 (Goldschmidt, Richardson, Cornelius, & Day, 2004), and with impaired higher-order mental function, analysis, and integration at age 13–16 (Fried, Watkinson, & Gray, 2003). These deficits are strong predisposing factors placing children at risk for substance abuse in those vulnerable adolescent years, even if their role models are drug free (Karacostas & Fisher, 1993).

CONCLUSION

Marijuana use is a common antecedent to methamphetamine use, and both drugs affect similar structures in the brain. While methamphetamine is by far the more toxic of the two, causing significant functional disability that may take months or even years of therapy to reverse, marijuana may contribute more to this injury than has been previously acknowledged. Marijuana sensitizes the reward circuit to respond to methamphetamine more robustly, and predisposes to addiction to methamphetamine. Marijuana also appears to aggravate the injury to cognitive structures by impairing the function of the key areas involved in memory and higher-order thinking capacity. These effects are magnified even further when drug use occurs in adolescence, as the brain is going through a major remodeling in preparation for adulthood. When key maturation events fail to occur, there may not be an opportunity for a redo.

Clearly, the scientific findings related to marijuana need to be evaluated whenever the legalization of this drug is considered. The long-term implications of the widespread use of any psychoactive drug should be carefully thought out. If alcohol were up for evaluation by the FDA as a potential addition—and danger—to our society, the data would probably argue for its exclusion. Alcohol causes untold social harm and personal tragedy. Do we really need another intoxicant in our already overly intoxicated society?

Chapter **9**

What Is Methamphetamine and How and Why Is It Used?[1]

Herbert C. Covey, PhD

WHAT IS METHAMPHETAMINE?

Methamphetamine, also known as *speed*, *crystal*, *ice*, *crank*, or *chalk*, is a powerfully addictive stimulant that chemically affects the central nervous system by producing intoxication through the increased stimulation of the dopamine and norepinephrine receptors in the brain. Dopamine is associated with pain suppression, appetite control, and the brain's self-reward center. Norepinephrine activates the body's fight-or-flight response in emergencies. Meth acts on the brain reward pathway by increasing the release of the neurotransmitters noradrenaline, dopamine, and serotonin and reducing the reuptake of dopamine. These neurotransmitters carry messages from one nerve to another and are critical to the individual's sense of pleasure. Meth provides the user, at least initially, with a tremendous sense of pleasure.

Meth is a synthetic stimulant commonly used as a recreational drug. Physicians legally prescribe the drug as a treatment for attention deficit disorder (ADD) under the brand name Desoxyn, for both children and adults. The illegal form of the drug is made easily in clandestine labs with over-the-counter ingredients. For addicts, it is relatively inexpensive to purchase and has desired effects that last for hours. Some users find it appealing because it causes decreased appetite (resulting in weight loss), heightens energy levels, enhances attention, enables people to be physically (sexually) active for long periods, and provides a general sense of well-being and euphoria similar to that of cocaine. The desired effects of meth use can last between six and eight hours, which are then followed by a coming-down period when the user becomes agitated and

potentially violent. It is particularly addictive for females because of the "benefit" of its corresponding weight loss.

Meth is a Schedule II stimulant in the United States, meaning that it is illegal to buy, sell, or possess without a prescription. Outside of the United States, it is legally controlled in most countries and is only available by prescription. The federal government classifies methamphetamine as a controlled substance. The 1970 Controlled Substances Act placed strict limitations on the importing, manufacture, and retail availability of amphetamine-related drugs. The 2000 Methamphetamine Anti-Proliferation Act applied further limits on the sale of precursor ingredients used in other products.

Criminal sentencing for crystal meth is determined by U.S. sentencing guidelines, which are based on the statutory sentences, including quantity-based mandatory minimum sentences, in the Controlled Substances Act. For meth, the statute and guidelines both set forth alternative formulations for determining quantity-based sentences, because "actual" or "pure" meth is distinguished from "a mixture or substance containing" meth. Under federal law, meth trafficking carries a minimum of five years in prison and fines of $2 million for individuals or $4 million for more than one individual for first offenses involving 50 grams or less. Life imprisonment is the maximum penalty for trafficking with two or more prior offenses. U.S. sentencing guidelines should be consulted for specific penalties for trafficking, purity, quantity, forms, and other legal considerations. Unprescribed meth is illegal in every state.

HISTORY OF METHAMPHETAMINE AND ITS USE

Closely related to meth is the drug amphetamine. Amphetamine was first synthesized in 1887 in Germany by a scientist named L. Edeleano, who named it phenylisopropylamine. Initially, amphetamine had no known medical application. During the 1920s, researchers investigated it as a treatment for depression, as a decongestant, and for other medical purposes. By the 1930s, retailers marketed amphetamine as Benzedrine, which was an over-the-counter inhaler used to treat nasal congestion. By the late 1930s, physicians prescribed amphetamine for narcolepsy, attention-deficit/hyperactivity disorder, and depression. During WWII, military organizations used amphetamines (and methamphetamine) to keep soldiers ready and available for duty. As use of amphetamines spread, so did their abuse. To some, amphetamines became a cure-all for such things as weight control and treating mild depression.

In 1919, a Japanese chemist named A. Ogata produced the first meth. In contrast to amphetamine, meth is more powerful and easier to manufacture. Meth's progenitor is ephedrine, which is naturally found in Mahuang, a Chinese

plant whose stimulant properties have been documented for over 5,100 years (Holthouse & Rubin, 1997a, 1997b). During WWII, the Japanese military used meth to improve military performance. It was also sold over the counter in Japan to increase work performance and endurance during the war (Anglin, Burke, Perrochet, Stamper, & Dawud-Noursi, 2000). Following the war, its use, including intravenously, became epidemic in Japan, as supplies were readily available (Wermuth, 2000). It has been suggested that Adolf Hitler may have been a heavy user.

Following the war, Dexedrine (dextroamphetamine) and Methedrine became readily available in the United States. College students, truck drivers, motorcycle gangs, and athletes used the drug to stay awake and to improve concentration and performance.

In the mid-1960s, people were using meth in San Francisco and parts of the West Coast. In 1967, the first meth lab bust occurred in Santa Cruz, California (Holthouse & Rubin, 1997b). By 1970, use of the drug declined following the 1970 Controlled Substances Act, which restricted the production of injectable meth (Wermuth, 2000). However, meth made inroads in the gay community by the late 1970s (Bonné, 2004) and spread in popularity in California during the late 1980s (Leinwand, 2003). Hawaii, California, and Arizona were some of the earliest and hardest impacted states. California was hit particularly hard because of the smuggling of ephedrine, a critical ingredient in the production of meth, across the Mexican border. With tighter federal controls over ephedrine, pseudoephedrine became a replacement ingredient. In 1996, Congress passed the Methamphetamine Control Act of 1996. This Act doubled the maximum penalties for possession of the drug and increased the penalty for the possession of equipment used to manufacture meth from 4 to 10 years. The Act cracked down on large purchases of the ingredients, such as red phosphorous and iodine, and increased civil penalties for companies that sell precursor chemicals to people that manufacture meth. It did not, however, stop the flow of ephedrine into the United States.

By the 1990s, some young adults found methamphetamine to be a popular alternative to cocaine and heroin. White motorcycle gangs controlled production and distribution of meth before the 1990s (Gibson, Leamon, & Flynn, 2002). Small home labs and Mexican-based criminal organizations eventually took over production and distribution of meth. Mexican-based criminal organizations established "superlabs" in California and Mexico that were capable of producing large amounts of highly pure meth. In congressional testimony to the Senate Judiciary Committee, authority Donnie R. Marshall reported that about 85 percent of all methamphetamine used in the United States in 2000 was produced by these superlabs (Marshall, 2000). During the 1990s and up

to the present day, another shift occurred as cooks started to produce meth in small, home-based clandestine labs.

The meth on the streets today is often more powerful than that available in earlier years. Today, meth cooks have refined recipes to the point that some batches have as much as six times the potency of meth cooked in the 1960s (Mills, 1999). This meth is not always sold on the street, but rather cooks circulate (give or sell) it among friends and acquaintances.

Today, meth is a Schedule II drug that is available only through a highly restricted prescription procedure. Physicians have used meth to treat overeating disorders, depression, Parkinson's disease, obesity, attention deficit disorder, and narcolepsy.

STREET AND SLANG TERMS FOR METHAMPHETAMINE

Users and others have developed a set of terms for meth and its related behaviors similar to those used with other street drugs. These terms can be divided into street terms for the drug itself, the behaviors associated with its use, and the types of users. The terms in Table 9.1 are an extensive compilation of words used to refer to meth (Mills, 1999; Office of National Drug Control Policy, 2003), with the most commonly used terms boldfaced.

STREET AND SLANG TERMS FOR METHAMPHETAMINE ADDICTS

Just as there are different terms for meth, there are terms for its addicts. Many street terms have evolved to describe or refer to meth addicts: Basehead, Battery Bender, Cluckers, Chicken-Headed Clucks, Crack Heads, Crackies, Crankster, Cranker, Doorknobbers, Fienda, Fiends, Fiendz, Gacked, Geek(ers), Geekin, Geeter, Go Go Loser, Jibby, Jibby Bear, Jibbhead, Krista, Loker or Lokers, Neck Creature, Shadow People (due to an aversion of users to light), Sketchpad or Schetchers, Skitzers, Sketch Cookie, Sketch Monster, Speed Freak, Spin Doctor, Spinsters, Tweakers, Tweekin/the Go, or Wiggers.

STREET AND SLANG TERMS FOR BEHAVIORS/FEELINGS

Meth addicts have developed a number of terms they use to describe their state of mind when using meth: Ampin, Amped, Awake, Bache Knock 2 Rock, Bachin, "Bob" (as in discombobulated), Buzzed, Cranked Up, Crank

Table 9.1
Slang Terms for Methamphetamine

Albino Poo, Alffy, All Weekend Long, All Tweakend Long, **Amp**, Anny, Anything Going On, Bache Knock, Bache Rock, Bag Chasers, Baggers, Barney Dope, Batak (Philippine), Bato (Philippine), Batu Kilat (Philippine), Batu or Batunas (Hawaii), Batuwhore, Beegokes, Bianca, Bikerdope, Bikers Coffee, Billy (Great Britain) Bitch, Biznack, Blanco, Blizzard, Blue Acid, Blue Belly, Blue Funk, Blue Meth, Bomb, Booger, Boorit-Cebuano (Filipino), Boo-Yah, Brian Ed, Buff Stick, Buggar Sugar, Buggs, Bumps, Buzzard Dust, Caca, Candy, Cankinstien, CC, Chach, Cha Cha Cha, Chalk, Chalk Dust, Chank, Cheebah, Cheese, Chicken Feed, Chicken Flippin, Chikin or Chicken, Chicken Feed, Chingadera, Chittle, Chizel, Chiznad, Choad, Cinnamon, Clavo, Coco, Coffee, Cookies, Crack Whore, **Crank**, Cri Cri (Mexican border), Criddler, Cringe, Crink, Critty, Cristy, Crizzy, Croch Dope, CR (California), Crow, Crunk, Crypto, **Crystal**, **Crystal Meth**, Crystalight, Cube, Debbie, Tina, and Crissy, Desocsins, Devil Dust, Devil's Dandruff, Devil's Drug, Dingles, Dirt, Dirty, Dizzy D, D-monic or D, Do Da, Doody, Doo-My-Lau, Dope, Drano, Dummy Dust, Dyno, Epimethrine, Epod, Ersar Dust, Ethyl-M, Evil Yellow, Fatch, Fedrin, Fil-Layed, Fizz Whizz, Gackle-a Fackle-a, Gak, Gas, Geep, Gemni, Glass, Go Speed, Glass, Go Fast, Go-ey, Go-Go, Go-Go Juice, Gonzales, Goop, Got Anything, Granulated Orange, Grit, Gumption, Gyp, Hawaiian Salt, Hank, Hanyak, High Speed Chicken Feed, Highten, Hillbilly Crack, Hippy Crack, Homework, Hoo, Horse Mumpy, Hot Ice, Hydro, Hypes, **Ice**, Ice Cream, Icee, Ish, Izice, Jab, Jasmine, Jenny Crank Program, Jet Fuel, Jib, Jib Nugget, Jinga, Juddha, Juice, Junk, Kaksonjac, Kibble, Killer, KooLAID, Kryptonite, L.A., L.A. Glass, Lamer, Laundry Detergent, Lemon Drop, Life, Lily, Linda, Lost Weekend, Love, Low, Lucille, M Man, Magic, **Meth**, Meth Monsters, Methaine, Methandfriend, Methandfriendsofmine, Methanfelony, Methatrim, methmood, Method, Motivation (Colorado), Nazi Dope, Ned, Newday, No Doze, Nose Candy, On a Good One, OZs, Patsie, Peaking, Peanut Butter, Peel Dope, Pepsi (means meth), Pepsi One (Crystal meth), Phazers, Phets, Philopon (East Asia), Pieta, Pink, Poison, Poop, Poo'd Out, Poor Man's Cocaine, Pootanany, Powder, Power Monkeys, Powder Point, Project Propellant, Puddle, Pump, Q'd , Quartz, Quick (Canada), Quill, Racket jaw, Rails, Rank, Redneck Heroin, Richie Rich, Rip, Rock, Rocket Fuel, Rocky Mountain High, Rosebud, Rudy's Rumdumb, Running Pizo, Sack, Sam's Sniff, Sarahs, Satan Dust, Scante, Scap, Schlep Rock, Scooby Snax, Scud, Scwadge, Shab, Shabu, Sha-bang, Shabs, Shabu, **Shards**, Shit, Shiznack, Shiznac, Sciznac, Shiznastica, Shiznit, Shiznitty, Shizzo, Shnizzie Snort, Agua, Shwack, Skeech, Sketch, Ski, Skitz, Sky Rocks, Sliggers, Smiley Smile, Smurf Dope, Smzl, Snaps, Sniff, Snow (Colorado), space Food, Spaceman, Spagack, Sparacked, Sparked, Sparkle, Speed, Speed Racer, Spin Spin Spin, Spinack, Spindarella, Spinney Boo, Spinning Spishak Spook, Spoosh, Sprack, Sprizzlefracked, Sprung (Mississippi), Spun Ducky Woo, Squawk, Stallar, Sto-pid, Stove Top, Styels, Sugar, Super Ice, Sweetness, Swerve, Syabu (Asia), Talkie, Tasmanian Devil, Tenna, Tenner, The New Prozac, The White House, Tick Tick, Tical, Tina, Tish, Tobats, Toots, Torqued, Trash, Trippin Trip, Tubbytoast, Tutu (Hawaii), Twack, Twacked Out, Tweak, Tweedle Doo, Tweek, Tweezwasabi, Twiz, Twizacked, 222 (Chicago Area) Ugly Dust, Vanilla Pheromones, Wake, Way, Wash, WE WE We, Whacked, White Bitch, White Cross (after pill form), White Crunk, White Ink, White Junk, White Lady, White Pony, White, Who-Ha, Wigg, **Working Man's Cocaine**, Xaing, Yaba, Yama, Yammer Bammer, Yank, Yankee, Yay, Yead Out, Yellow Barn, Yellow Powder, Zingin, Zip, Zoiks, and Zoom.

It should be noted that some of these terms are used interchangeably with amphetamine, such as "speed."

Whore Jamie, Feelin Shitty, Foiled, Fried, Gakked, Gassing, Gear or Gear-up, Geeked, Geekin, Gurped, Heated, High, Jacked, Lit, Peaking, Pissed, Pumped, Psychosis, Ring Dang Doo, Riped, Rollin or Rollin Hard, Scattered, Schlep Heads, Sketching, Spin-Jo, Speeding, Sparked, Spracked, Spun, Spun Monkey or Spun Turkey, Stoked, Talkie, Trippin, Twacked, Tweaking, Tweeked, Twisted, Wide Open, Wired, Worked, Woop Chicken, Zipper, and Zoomin. When the user is experiencing the initial rush from using meth, he is "amping." Amping refers to the "amplified" euphoria users feel during the rush.

MISCELLANEOUS METH-RELATED TERMS

The meth drug trade has its own set of terms, including those used by meth addicts and distributors for the sales and distribution of the drug. An *eightball* refers to one-eighth of an ounce of meth. A *teenager, Tina*, or *Teena* refers to one-sixteenth of an ounce, and a *paper* is a term for a quarter gram of meth.

Paraphernalia is a general term for medical supplies or equipment used to make or use meth. Addicts refer to needles as *points, rigs*, or *slammers*. They sometimes call a straw or device used to snort meth a *tooter*. Those involved in making it need to shop or otherwise acquire the precursors (materials) needed to make the drug in a manner and in quantities that do not arouse suspicion. This acquisition of supplies is called *smurfing*.

The meth subculture has developed other terms related to use. For example, *crank, craters, crank bugs*, and *spider bites* refer to sores on the face and body resulting from prolonged meth use. *Meth mouth* refers to the terrible dental conditions addicts have from long-term use.

HOW IS METH USED?

Users can inject, smoke, orally ingest, anally insert, or snort meth. The method the user selects influences how the drug is experienced. Meth is a bitter-tasting powder that easily dissolves in beverages. The powder form of the drug is often snorted, which produces a less intense but much longer-lasting high. In 1993, 42 percent of meth and amphetamine treatment admissions reported they used the drug in this manner, according to the Substance Abuse and Mental Health Services Administration (SAMHSA, 2006). By 2003, only 15 percent of the treatment admissions reported they snorted or inhaled the drug. Recent Treatment Episode Data Set (TEDS) data found that in 2003, 56 percent of primary meth and amphetamine admissions reported smoking the drug, which was up from the 15 percent reported in 1993 (SAMHSA, 2006). In 1993, 29 percent indicated that they injected the drug, which compares to 22 percent in

2003. Smoking or injecting the drug produces a short but more intense and pleasurable "rush." In 1993, oral ingestion represented 13 percent and "other" accounted for 1 percent of the routes of administration. By 2003, oral administration declined to 6 percent and other routes of administration remained unchanged at 1 percent (SAMHSA, 2006).

Powdered meth is a hydrochloride salt form that quickly absorbs water from the air. This form of meth is smokable, as is *crystal meth* or *ice*, which refers to meth grown into crystals. Although some people believe that crystal meth is a freebase form of meth, this is not true. Meth that is grown into crystals is simply easier to smoke. Meth in crystal form, rather than powder, also is more likely to be relatively pure because of the difficulty of growing crystals from impure chemicals. According to SAMHSA (2004), in 1992, 12 percent of meth and amphetamine treatment admissions reported they smoked meth. By 2002, 50 percent of the treatment admissions reported they smoked meth in its crystal form. This represents a major shift from inhaling to smoking over this 10-year span.

Another relatively new way of consuming meth is called "booty bumping." This process involves the user heating meth into liquid form and mixing it with water. The user then draws the fluid into a syringe that lacks a needle. The syringe is then inserted in the anus and meth shot into the user's body. Users rely on this technique because the drug is readily absorbed into the bloodstream.

The crystal form of meth is referred to as *crystal, ice*, or *glass*. If heat is introduced, the user can smoke or inject crystal meth. Smoking it is a much faster and intense way to get high than swallowing the drug. The user places a small amount of crystal in a glass pipe (often called a *tooter*), heats it, and inhales the resulting vapors. Crystal meth or ice melts into a liquid when heated and returns to its crystal form when cooled. Boiling crystal turns it into a semiliquid referred to as *snot*, which can be smoked or placed up the nose. Users view smoking meth as ideal because it can be used almost anywhere, since the vapors are odorless and undetectable.

The rush or high felt by the user is the direct result of the release of dopamine into the section of the brain that controls feelings of pleasure. The rush or high associated with its use is relatively long-lasting compared to other drugs. The effects of meth use can last as long as 12 hours. If it is snorted, the user usually experiences effects within about 5 minutes. If it is orally ingested, the user will feel a rush in around 20 minutes. Oral meth use tends to lack rushing, has less euphoric effects, and tends to cause far less of a feeling of wanting to do it again than the other methods.

The fastest rushes occur when the user smokes or injects meth. The user usually experiences an immediate and powerful response. Smoking and inject-

ing are associated with stronger, faster, and more euphoric effects. While injecting results in a faster reward, it also results in a faster crash. Users learn to manage the rapid crashes by trying to attain another rush by taking more of the drug. These effects are more associated with compulsive or addictive user patterns. The general use trend is more toward smoking meth because of this immediacy and the strength of the initial rush. It should be noted that many addicts have an aversion to using needles and never inject the drug.

Standard-shaped light bulbs are easily converted into meth pipes. Meth pipes lack a screen found with pipes used to smoke cocaine or marijuana. The user places the meth inside the bowl of the glass pipe and then heats it until it turns into a liquid and then emits a gas (vapor). Once it turns to a gas, the user inhales it through the stem of the pipe. Over time, a white milky residue builds up on the sides of the bowl. Because the glass bowl gets very hot, users will sometimes have burn marks on their fingertips from holding the hot bowls or closing off the hole at the top of the pipe to keep the gas from escaping (see Figure 9.1).

After being heated, unused crystal meth returns to its crystal state when cooled by ice or a cool wet rag. Users will cool down unused liquid meth to its crystal form because it is easier to transport and use at another time.

Regardless of the method of use, meth addicts will frequently use it with other drugs such as cocaine, marijuana, and alcohol. Because of their poly-drug use, it is sometimes difficult to sort out the effects of the meth from other drugs. Users rely on other drugs or alcohol to either enhance or supplement the meth high or cushion their withdrawal and depression when coming down.

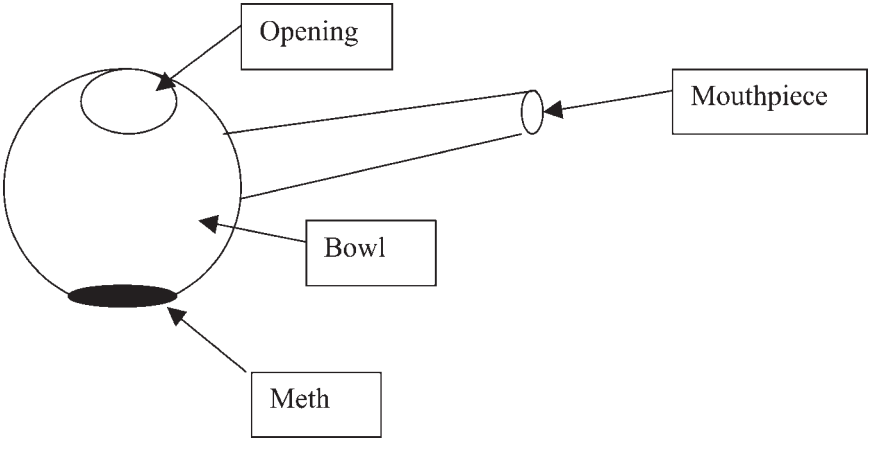

FIGURE 9.1 Typical design of pipe used to smoke methamphetamine.

WHAT DOES METH LOOK LIKE?

Meth is usually found on the street as powder or crystal. Street meth, like many other street drugs, is often diluted or cut with other substances. Powdered meth is cut with a filler or is crushed up with amphetamine or methylphenidate (Ritalin) tablets. Sometimes street meth is not really the drug at all but some other compound. Street meth that is clear and crystal is referred to as *glass* or *crystal*. Meth comes in many colors, including white, yellow, brown, orange, pink, red, or darker colors; it can also be almost transparent. The method of manufacture and chemicals used affects the color meth assumes, but most meth is white. Meth can take such forms as powder, granulated crystals (crystal meth or ice), tablets (pills sometimes called Yaba), or capsules. Crystal meth is made by adding a small molecule group (hydrochloric acid). The Yaba form is a tablet that is often comprised of meth and caffeine and is produced in Asia and Southeast Asia. The tablets are small (they can generally fit through a straw) and most often are reddish orange or green. Yaba tablets sometimes have corporate logos, such as Toyota, MTV, or Calvin Klein, that are popular in the rave scene. Examples of crystal meth can be found in the following photo.

Methamphetamine in crystal ("ice") form. Photo courtesy of the Drug Enforcement Administration.

METH DOSES

When meth is taken in a pill or tablet form, between 0.05 and 0.1 of a gram represents a dose. When it is smoked, the amount needed is smaller—as little as 0.01 of a gram may be all that is needed. The dosage amounts differ based on the purity of the drug, tolerance of the user, frequency of use, and individual reactions that are based on body physiology, metabolism, and method of use. The Erowid (2006) Web site provides some general guidelines for dosage amounts for an infrequent user of pure meth. Caution should be taken with any dosage amount because of the varying individual reactions to the drug. Thus, Table 9.2 lists what some are indicating are dosage estimates and should not be considered a guide for anyone.

The important things to remember about the doses are that a number of factors influence the amount needed to get high—the doses can be very small, and with prolonged use, more of the drug is needed to get the desired results. Erowid (2006) identified vomiting, headaches, dizziness, cold sweats, shaking, and, ultimately, death as possible results from overdosing on meth.

Table 9.2
Approximate Doses by Method of Abuse

	Oral Dosages	Insufflated (Snorted)	Smoked	Injected (IV)
Threshold	5 mg	5 mg	5–10 mg	5 mg
Light Stimulation	5–15 mg	5–15 mg	10–20 mg	5–10 mg
Common	10–30 mg	10–40 mg	10–40 mg	10–40 mg
Strong (some rushing)	20–50 mg	30–60 mg	30–60 mg	30–60 mg
Very Strong (rushing)		501 mg	501 mg	50–100 mg (strong rushing; intense euphoria)
Onset	20–70 minutes (depending on form and stomach contents)	5–10 minutes	0–2 minutes	0–2 minutes
Duration	3–5 hours	2–4 hours	1–3 hours	1–3 hours
Coming Down	2–6 hours	2–6 hours	2–4 hours	2–4 hours
Normal Aftereffects	up to 24 hours	up to 24 hours	up to 24 hours	up to 24 hours

METH USE AND DRUG TESTS

Meth is detectable using standard drug tests of urine from three to five days following use. It is detectable in hair tests for approximately 90 days and in blood samples for one to three days. A number of substances can result in false positives, including ephedrine, pseudoephedrine, and other substances found in such over-the-counter medications as Sudafed, Allerest, Contact, Nyquil, Robitussin, and others. Diet aids, nasal sprays, asthma medications, and several prescription medications may suggest meth use when it has not been used.

WHY DO PEOPLE USE METH?

People use the drug for a number of reasons (Morgan & Beck, 1995). The short-term effects of meth use are desired: the sense of euphoria and pleasure; a high that lasts 8 to 12 hours or more; energy enhancement and alertness; weight loss because of decreased appetite; decreased fatigue; relief from chronic depression; a sense of social bonding with other users; and improved sexual pleasure and drive. Rawson (2005) found that more than 35 percent of the women who used the drug said they did so to lose weight, compared to 10 percent of meth-using men. Rawson also found that about 35 percent of the women used it to relieve depression, compared to about 25 percent of the men. Meth users have reported on what it feels like to use the drug. One indicated, "It made me feel confident, self-assured," then added, "Then it took on a whole new meaning to me. I became a partier" (Bonné, 2004). Another said she felt "this very intense surge of energy through the body." She added, "I felt like I was superhuman because I would think more, I could accomplish more."

Meth users also experience negative short-term effects that are not desired, including increased respiration, higher pulse rate (irregular heartbeat or cardiac arrhythmia), higher blood pressure, increased body temperature (hyperthermia), convulsions, irritability, hyperexcitability, grinding of teeth, nervousness, dilated pupils resulting in an aversion to light, and death, according to the National Institute on Drug Abuse (2002), Anglin et al. (2000), Anglin, Kalechstein, Maglione, Annon, and Fiorentine (1997), and Leshner (2000).

LONG-TERM UNDESIRED EFFECTS OF METH USE

Several agencies, including the Drug Enforcement Administration (DEA) and other authorities (Greenwell & Brecht, 2003; Leshner, 2000; London et al., 2004; National Institutes of Health, 2001, 2004; Volkow et al., 2001a,

2001b) have identified long-term effects of meth use that include severe psychological and physical dependence (addiction); violent behavior that eventually gets coupled with paranoia, making the users even more dangerous; chronic fatigue; talkativeness; overall lifestyle disruption; sleep problems such as insomnia (inability to sleep); cognitive impairments and reduced functioning; confusion; fight-or-flight responses to stimuli; visual and auditory hallucinations; uninhibited sexual functioning with prolonged use; severe depression; picking at the skin and scratching imaginary bugs, which causes open sores and infections. Morals and values are abandoned. The inability to think and act sequentially is impaired and, with heavy, prolonged use, disappears. For example, meth users find it difficult to follow directions or listen to instructions. Heavy use may also lead to homicidal or suicidal thoughts.

Physically, long-term use may result in seizures, chest pain, dry mouth, cardiac valve thickening, death, dramatic weight loss because users lose interest in food and eventually suffer from malnutrition, and brain damage (methamphetamine is neurotoxic). Prolonged use can lead to what is called "amphetamine psychosis," resulting in paranoia, auditory and visual hallucinations, self-absorption, irritability, and aggressive and erratic behavior. Amphetamine psychosis is a disorder similar to paranoid schizophrenia. Individuals with amphetamine psychosis may exhibit bizarre behavior that is sometimes violent.

PATTERNS OF METH USE—LOW INTENSITY, BINGE, AND HIGH INTENSITY

There are three basic patterns of meth use: low intensity, binge, and high intensity. Low intensity is a pattern of use where the user is not psychologically addicted to meth but relies on it for specific perceived benefits, such as a work enhancer or diet-aid drug. Typically, low-intensity users snort or swallow the drug.

Low-Intensity Users

According to Narconon (2002), low-intensity use is characterized by the snorting of powdered meth or ingestion of pills. Users at this level use meth to keep themselves awake and alert for special tasks, or to lose weight. Users at this level are able to hold down jobs, attend school, and otherwise appear to act normal and operate normal lives. Some over-the-road truckers, overtime workers, night-shift workers, stay-at-home parents needing to get several tasks done, and students use it for these purposes. Low-intensity users are unlikely

to come into contact with law enforcement, social service, health, or child welfare caseworkers because of problems resulting from this pattern of use.

Professionals may encounter or be working with low-intensity users and not be aware of their use of meth. It is important to note that chronic low-intensity users often view it as a "functional drug." That is, they see it as helping them get things done, such as lose weight, focus on tasks, or get work done. They believe that they "can stop anytime" or "have it under control." Over the long run, this functionality turns out to be a myth.

Narconon (2002) notes that, while use of meth in this fashion seems to be managed, low-intensity users are a short step away from becoming binge users. Low-intensity users have experienced the rush associated with heavier use and generally only need to smoke or inject to cross over the line into binge-use patterns. When they do so, the problems with their use escalate.

Binge Users

Binge users smoke or inject to experience the euphoria that comes from a more intense use of meth. During a binge, the user will periodically use the drug to maintain the high. It is these strong euphoric experiences that move the user from a low-intensity to a psychologically addicted user. A common and unhealthy use pattern for meth is to re-dose repeatedly for several days in a row. Depending on whether the intention is to stay awake, remain high, or attempt to continue to get "rushing" effects, doses are repeated every 3 to 8 hours to stay awake, or every 30 minutes to 4 hours to remain "high." A user re-dosing often takes the same amount of meth as the first dose. As re-dosing continues beyond 48 hours, the user's dosages tend to increase.

HIGH-INTENSITY USERS

High-intensity users have a goal of never crashing or coming down but maintaining a state of euphoria and the perfect rush. Given the nature of meth and its effects on the body, this becomes an impossible goal. For the chronic user, following the first injection or smoke, each successive rush or high becomes more difficult to obtain, and more of the drug is needed. The user remembers the initial high but can never reach that point again no matter how much of the drug is used.

High-intensity users may start out with a pattern of needing from $20 to $40 a day to support their addiction. This increases several-fold as more and more of the drug is needed to maintain the high they are seeking. The high cost

of heavy use drives many to criminal behavior to support their addiction. For some, crime is the only alternative.

Phases of High-Intensity Use

High-intensity users experience meth use as a series of phases. Depending on how often they use, their history of use, method of use, and dosage amounts, the length and nature of each phase differ but follow a general pattern. In order of occurrence, the general phases follow.

The Rush

The rush is the initial sense of intense euphoria that the user experiences immediately after smoking or injecting meth. Low-intensity users do not experience a rush when snorting or swallowing the drug. During the rush, the user experiences an intense feeling of pleasure and a burning sensation. The initial rush can last between 5 and 30 minutes, which is longer than the rush associated with the stimulant cocaine. Some users, especially injectors, report an initial burning sensation as the meth is introduced into the body. During the rush, the user's metabolic rate increases, blood pressure elevates, and pulse soars. Users compare the experience of the rush as being the equivalent to having multiple sexual orgasms.

The reason for the rush is that meth triggers the adrenal gland to release a hormone called epinephrine (adrenaline), which puts the body in a battle mode—fight or flight. In addition, the physical sensation the rush provides results from the explosive release of dopamine in the pleasure center of the user's brain. Dopamine is released in the brain's pleasure center. Long-term users find that much of their life is devoted to maintaining a constant rush.

The High

The rush is followed by a high that can last between 4 and 16 hours. This is a longer period than that experienced by cocaine users. Some circles refer to being high as the "shoulder." While being high on meth, the user has a sense of being smarter, more focused, argumentative, and aggressive. High users frequently interrupt those around them.

The Binge

When the user continues to use while high, this is known as binging. Binging is an effort by the user to maintain a prolonged high by taking more meth. During the binge the user becomes hyperactive. Because of severe depression

and other negative effects that begin when the drug starts to wear off, users try to avoid crashing or coming down. They may binge to stay high and awake for many days at a time. The law of diminishing returns operates for the user, as the desired effects of meth diminish with each dose. This may cause the user to consume even more to reach the initial rush or stay high. Eventually, there is no rush or high resulting from further consumption, and the user stops.

Tweaking

When the binge ends, a stage of the cycle known as tweaking occurs. The user has a sense of emptiness and dysphoria. Taking more meth will not alleviate the negative feelings experienced by the tweaking user. This stage is not comfortable for the user and some turn to other drugs to self-medicate their feelings. For some, alcohol or other illegal substances are used for self-medications. Tweaking is assumed by many to be the most dangerous stage to professionals, such as law enforcement officers and social workers. Tweakers have not slept for days and as a result are irritable. Think about how moody you get when you don't have enough sleep and then multiply this feeling several times over. Tweakers are unpredictable and short-tempered. Tweakers sometimes are frustrated because they can't find enough of a dose to experience that initial high, and this frustration translates into a sense of unease and aggression. When coupled with the paranoia that results from long-term use, they are loose cannons on the deck able to go off at any time.

Tweakers appear to have rapid and brisk movements. They are overstimulated. Their eyes will rapidly dart around, speech will be rapid, eyes will be clear, and speech concise. A tweaker's eyes may roll back into the head. Tweakers are obsessive about things. For example, they will clean the same thing over and over but ignore other things that need cleaning. The kitchen may be spotless but the house or yard may be full of unfinished projects and filth. In addition, tweakers can become obsessed with dismantling things, such as appliances, with no idea of why they are doing it. They might dismantle a television, washing machine, or any number of objects without a clue about how to put things back together.

Because tweakers hear and see things differently, it can be difficult for law enforcement or caseworkers to predict what, if anything, will set them off. Tweakers have such an altered sense of reality that virtually anybody or anything could set them off into a rage or confrontation. Because many become paranoid, a caseworker, law enforcement officer, family member, or other person could become an unsuspecting target. Because some users fear authorities, they have many weapons around the house. This requires that caseworkers and other professionals be cautious around tweaking individuals.

There is considerable folklore on how long a user can tweak. Reports of 15 to almost 40 days without sleep have been reported to the author. While it is true that addicts do stay awake for very long periods of time, what is likely is they actually take short naps and float in and out of consciousness. They never fall into a deep and replenishing sleep until later in the cycle. While meth is not a hallucinogen or a psychedelic, it is easy to understand how prolonged sleep deprivation would result in bizarre behaviors and thoughts. Sleep deprivation can result in profoundly disturbing hallucinations. For example, many addicts will describe the "shadow people" that seem to appear and be very real to them (Holthouse & Rubin, 1997a).

The Crash

Eventually, because of a lack of sleep and loss of epinephrine, the body becomes exhausted and falls into a deep sleep. This is known as the crash. When high-intensity users stop taking meth they experience depression, anxiety, fatigue, paranoia, aggression, and an intense craving for the drug (London et al., 2004; National Institute on Drug Abuse, 2002). Tweakers sleep like they are dead when the time comes to crash, and they sleep for days afterwards. The crash can last for days, as the body replenishes its supply of epinephrine. Users may try to cushion the crash by using tranquilizers or downer drugs, such as marijuana, heroin, or alcohol (Gibson et al., 2002). Users that are crashing usually pose no real threat to caseworkers, law enforcement officers, or other professionals. However, crashing parents or guardians cannot provide basic care to children and often are neglectful of them and may place them at risk. Protecting, feeding, and overseeing children are not possible for the crashing user, and sometimes their children go without food, sleep, care, and supervision. Some children learn to survive on their own when parents or guardians are crashing. They eat and drink whatever they can find. Crashes may last between one and three days.

Normalcy

Meth addicts eventually return to a state of normalcy for a few days. This stage can last between 2 and 14 days, depending on frequency of use. The high-intensity user never really gets back to complete normalcy because of the physiological damage done to the body, specifically the brain. This is not to say the high-intensity user cannot recover and lead a normal life.

Withdrawal

Users who withdraw from meth experience symptoms of physical distress. Withdrawal from the drug is a prolonged process, and users in withdrawal

experience depression and are initially unable to experience pleasure. They also may experience fatigue, paranoia, and aggression, and have psychotic symptoms that may persist for months or years following use (Office of National Drug Control Policy, 2005). They become lethargic and have no energy. Users, because of poor eating habits, also may experience extreme hunger. If the cravings for meth are strong, some may become suicidal. If more meth is used, their sense of pleasure increases and their depression will temporarily be alleviated. Some suggest that this is a major reason why meth addicts are some of the most difficult to treat and why recidivism rates are high.

Experts agree that meth is a highly addictive stimulant drug (National Institutes of Health, 2001). According to the U.S. Drug Enforcement Administration (2005), "Methamphetamine has a phenomenal rate of addiction, with some experts saying users can get hooked after just one use." Anecdotal accounts and clinical experience suggest that addiction can occur in less than a year. The Center for Substance Abuse Treatment (1999) Tip 33: Treatment for Stimulant Use Disorders notes in chapter 2 that addiction typically occurs after using the drug for two to five years. Prolonged or binge use of meth causes significant tolerance and psychological dependence. Some report addiction after the first use, but this is not typical for most.

THE PHYSICAL APPEARANCE OF METH USERS

It would be inaccurate to stereotype high-intensity meth users as looking a certain way. There is no set appearance for all meth users and addicts. They can assume a variety of appearances depending on a number of factors, including the amount and frequency they are using. Low-intensity meth users can look reasonably normal in appearance. However, if the individual is using meth on a regular basis, obvious physical indications develop over time. It should be noted that as dramatic as the outside appearance may be, there is also physiological damage occurring on the inside of the body. Three excellent Web sites that have examples of the progression of deterioration from meth use are: 2stopmeth.org; www.co.multnomah.or.us/sheriff/faces_of_meth.htm; and www.mappsd.org. The reader can view some examples of the physical deterioration resulting from prolonged meth use on these sites.

Crank Bugs and Meth Mites

Open sores on the skin are the result of the individual scratching imaginary "crank bugs" or "meth mites." Long-term meth users develop the sensation that insects are crawling on their skin, causing them to scratch themselves. The scratching associated with these imaginary insects (known as formication)

eventually leads to lesions in the skin, topical infections, sore areas, and scabs. These open sores are aggravated by the addict continuing to scratch and thus spreading the infection. The user's lack of proper hygiene contributes to the spread of infection. Those who inject frequently develop abscesses, ulcerations, and scars around the injection sites. These injection sites may become infected and also a target of scratching.

"Meth Mouth"

The long-term or heavy use of meth also leads to severe dental problems, which professionals and addicts refer to as "meth mouth." The American Dental Association (ADA, 2005) concluded that "the oral effects of methamphetamine can be devastating." Long-term drug addicts, especially those using meth, do not take good care of their teeth and do not visit their dentists on a regular basis. Meth addicts do not brush their teeth often, have poor diets, and avoid medical and dental professionals to hide their addiction. Meth acts on the gums and teeth as a corrosive. It softens the teeth, and they basically melt away. When a user smokes meth, the chemicals used to make it, such as sulfuric or muriatic acid, are heated and vaporize and spread around the mouth. The user's mouth is irritated and burned by the chemicals, and sores eventually develop that become infected. This infection spreads throughout the mouth and gums. When coupled with the corrosive action of chemicals on tooth enamel, eventually the teeth rot away to well below the gum line. The gums are also affected because meth use causes blood flow to decrease and thus gums to break down and become diseased. For these and other reasons, it is common for the roots to show and the loss of teeth to occur.

The decay occurring can also be attributed to the effect of meth use on saliva production, or what is medically referred to as "dry mouth" (ADA, 2005). Meth dries out the salivary glands and thus the production of saliva. Normally, the body uses saliva to clean the teeth and neutralize acids, and to control harmful bacteria. With less saliva, the user's mouth cannot perform these functions. Consequently, the acids in anything consumed are free to decay the teeth and gums. The sense of a "dry mouth" or "cottonmouth" (xerostomic) causes some users to drink lots of sugary sodas, which also add to tooth decay (ADA, 2005). Damage to the mouth is not limited to those who smoke the drug; it can also be caused by snorting meth, as caustic chemicals flow through the nasal passage to the back of the mouth.

Another fundamental process that destroys the user's teeth is the grinding that occurs during use. Meth use causes the user to feel anxious or nervous, and the unintentional teeth grinding that consequently occurs leads to cracks

and breaks. Meth users often grind their teeth down hard, causing teeth to break and nerve endings to become exposed. The user may also lose fillings because the teeth grinding causes them to fall out. Just breathing through the mouth and having air pass over the teeth and gums can cause some users to feel pain. Whether from smoking or snorting, the user will eventually develop meth mouth, and many users simply use more meth to alleviate the pain.

The best way to visualize and understand meth mouth is to view some of the images of the mouths of long-term users. The color insert section contains examples of meth mouth and the corresponding tooth and gum decay resulting from prolonged meth use. The consequences of meth mouth go beyond pain and disfiguration. Some long-term recovering users with damaged teeth may be reluctant or unable to find dental help. If they do find it, they may lack the money for dental repairs. With poor teeth, they find it difficult to obtain work because potential employers are turned off by unsightly teeth (mouths), and users face social rejection.

THE COMPARATIVE LOW COST OF METH

In addition to the desired effects of meth on the user, one of the reasons for the drug's popularity is its relative low cost. It is relatively inexpensive to produce, but more important, lasts longer than alternative stimulants, such as cocaine. Prices for the drug vary across the United States:

- It costs $20 to $60 for a quarter gram, which is slightly lower than cocaine but lasts significantly longer (Bonné, 2001).
- The National Council of State Governments estimated a $100 batch of methamphetamine would sell on the street for about $1,000 (Kraman, 2004).
- Meth prices range between $5 and $15 a dose (Leinwand, 2003).
- The Drug Enforcement Administration in 2001 provided a price range from $3,500 to $23,000 per pound, $350 to $2,700 per ounce, and $20 to $300 per gram (Drug Policy Information Clearinghouse, 2003).
- The price of crystal meth runs higher because of its purity and additional manufacturing steps. The National Drug Intelligence Center (2005), using Drug Enforcement Administration data, reported the prices for powdered and crystal meth shown in Table 9.3.

Although prices seem high to the nonuser, they represent a good value to the addict. The long-term high of the drug is a good value compared to cocaine or other substances. Likewise, meth quickly becomes expensive as addicts must use increasing amounts of the drug and do so more frequently over time in pursuit of that lasting high and avoidance of the crash. The consequence is that

Table 9.3
National Price Ranges of Methamphetamine, 2003

Quantity	Powder	Crystal
Pound	$1,600–$45,000	$6,000–$70,000
Ounce	$270–$5,000	$500–$3,100
Gram	$20–$300	$60–$700

Source: National Drug Intelligence Center 2005.

the price of meth becomes very high for children as their needs compete with the meth for family resources.

HOW DOES METH COMPARE TO COCAINE?

Because both are powerful psycho stimulants, meth is often compared with cocaine (National Drug Intelligence Center, 2002). Users who have used both drugs report similar experiences, such as a sense of euphoria. Users of both drugs report experiencing an initial rush, and a longer high and sense of euphoria with meth. If the cocaine is in crack form, the rush and high are much shorter. Users can smoke, inject, snort, or swallow either illicit drug. Both drugs may produce anxiety, increased blood pressure, increased temperature, higher pulse rates, and possible death. Short-term effects of both include increased activity, decreased appetite, and respiration. Prolonged use of either drug can lead to psychotic behaviors, hallucinations, mood disturbances, and/or violence. When users of either drug withdraw, they report craving, paranoia, and depression (London et al., 2004).

Differences between the two drugs exist. Cocaine is derived from the refined leaves of the South American coca plant; consequently, almost all cocaine in the United States is imported. The meth found in the United States is also imported from Mexico, Southeast Asia, and other countries. However, unlike cocaine, it can be domestically manufactured in large or small operations. Large spaces, while often desirable, are not required for production. Meth can be produced in small rooms or spaces. The production of meth is relatively easy compared to importing cocaine. All of the necessary chemicals to produce meth are relatively available, thus making law enforcement control of the illicit drug difficult.

Cocaine and meth abusers have different use patterns. For example, meth users report that they use the drug on a more regular basis than that reported by cocaine users. Meth's effects require less-frequent administration than cocaine, because meth leaves the system more slowly and thus has a longer half-life

than cocaine. Meth has a half-life of between 10 and 12 hours, compared with only about one hour for cocaine (Wermuth, 2000). While cocaine is quickly and almost completely metabolized in the body, meth has a longer duration, and a larger percent of the drug remains unchanged in the body (Center for Substance Abuse Prevention/National Prevention Network, 2006; National Institute on Drug Abuse, 2002). Thus, the brain is affected for more prolonged spans of time. Cocaine is not neurotoxic to dopamine and serotonin neurons, but meth is neurotoxic. "Meth has more long-term, serious effects on the brain than cocaine" (National Institute on Drug Abuse, 2002).

Another difference is cost. Meth is cheaper on the street than cocaine. Meth has a longer duration for the initial rush and high. Crack cocaine offers a high of about 15–20 minutes and meth a high of 8–24 hours. The perceived cost-benefit ratio to the user is much greater for the meth addict. Rawson, Anglin, and Ling (2002, p. 7) wrote, "Methamphetamine effects are long lasting and methamphetamine users typically spend about 25 percent as much money for methamphetamine as that spent by cocaine users for cocaine."

According to research by Dr. Sara Simon sponsored by the National Institute on Drug Abuse (NIDA), abuse patterns differ between meth and cocaine abusers (Zickler, 2005). Meth abusers typically take the drug early in the morning and in two- to four-hour intervals, similar to being on a medication. In contrast, cocaine abusers typically take the drug in the evening and take it over a period of several hours that resembles a recreational-use pattern. They typically continue using until all of the cocaine is gone. In addition, another pattern showed that continuous use was more common among meth abusers than among those abusing cocaine. According to other NIDA-sponsored research by Dr. Simon, the effects of meth and cocaine abuse resulted in similar cognitive deficits, but meth abusers had more problems than cocaine abusers at tasks requiring attention and the ability to organize information (Zickler, 2005).

In the 1980s, cocaine use became epidemic, but in recent years, use has declined among the middle class. Crack cocaine remains a serious blight in some inner cities. Cocaine's use, similar to other drugs, is cyclic, with periodic increases and decreases (Rawson et al., 2002). In contrast, meth has the potential of enduring, similar to marijuana and alcohol.

Cocaine addicts typically experience profound life changes in a relatively short time frame because of higher costs of use and use patterns, which involve binging. Cocaine users typically hit bottom sooner than many meth users. Meth addicts experience the same losses and also hit bottom, but in many cases, do so over a longer period. Some meth addicts use at levels that allow them to maintain jobs, homes, some money, and at least, the appearance of being in control.

Chapter **10**

The Short- and Long-Term Medical Effects of Methamphetamine on Children and Adults[1]

Kathryn M. Wells, MD

HISTORY OF MEDICAL USE

Methamphetamine is a drug that has been around and known to the medical community for many years. Chemically, it is a synthetic drug that belongs to the amphetamine class of drugs. Medically, its stimulant effects act on both the central and peripheral nervous systems. Throughout history it has had various medical uses, but it has increasingly been used illicitly.

Meth was first synthesized in 1887 by a German chemist. It was not used therapeutically until the 1930s when it began to be promoted by American pharmaceutical companies for various ailments and was thought to be without risk of addiction. At about the same time, Japan began to produce large quantities of meth in the pill form for domestic consumption. After the war, Japanese pharmaceutical companies launched a large campaign to increase the use of over-the-counter meth pills that were in abundance in former military warehouses. This consequently led to the first large-scale epidemic of meth use and abuse (Kato, 1990). In the United States, a prescription was still needed to legally obtain amphetamines, but by the 1950s, the nonmedical use of amphetamines had spread to the civilian population, most commonly being used by individuals who needed to stay awake for long periods of time or to perform well at monotonous tasks. Additionally, meth was being prescribed for the treatment of hyperactivity, obesity, narcolepsy (a disorder causing spontaneous sleep), and depression (Beebe & Walley, 1995).

The "second wave" of the meth epidemic in the United States occurred in the 1960s when intravenous use of the drug became more popular. These users were the first individuals to take the drug solely for its euphoric effects (Wolkoff, 1997). During this period, users had created a way to manufacture meth on the street called the P2P (phenyl-2-propanone) method. This wave was controlled by law enforcement and public efforts to educate potential abusers and treat users. This method of manufacturing meth used lead acetate as a chemical reagent and, because there were often large quantities of lead in the final product, placing the user at risk for lead poisoning, there was the risk of hepatitis, nephritis, and encephalopathy (Allcott, Barnhart & Mooney, 1987).

The "third wave" of meth use in the United States occurred in the 1980s as a result of the advent of another, faster, and easier method for meth manufacturing called the pseudoephedrine reduction method. This method, further discussed elsewhere in this text, contributed to the rapidly rising accessibility and popularity of the drug on the street in the 1990s and 2000s. It produced a more potent and psychoactive form of the drug with a higher percentage of the dextro-isomer of the drug compared to the P2P method, which produced equal proportions of the dextro- and levo-isomers (Burton, 1991; Center for Substance Abuse Treatment, 1997; Cho, 1990). This is important because dextro-methamphetamine is three to four times more potent to the central nervous system (CNS) than levo-methamphetamine (Sowder & Beschner, 1993). The extent of the potential consequences of the impurities of this manufactured form of meth is unclear (unintended by-products and reagent residuals as well as processing errors), but this is of great concern, as many of these laboratories are operated by uneducated "chemists" who get their recipes from unpublished sources or through the Internet and who are frequently using the drug while processing it.

Additionally, on the street a potent, smokable form of meth, known as *crystal*, *glass*, or *ice*, began to gain popularity, and its use grew rapidly because of the more potent and longer "high." For these reasons, many cocaine users began to be attracted to the use of meth (Wolkoff, 1997). By the 1990s, the use of prescription meth was almost completely discontinued due to the understanding of its potential for addiction. Meth is currently classified as a Schedule II stimulant, meaning that it is known to have a high potential for abuse and is available only by prescription. The only accepted medical indications for use of meth are for the treatment of narcolepsy and attention-deficit/hyperactivity disorder, and the dosages prescribed are much smaller than what is used by the abusers.

HOW IS METH USED?

Meth may be snorted, smoked, orally ingested, injected, or absorbed through any mucous membranes such as sublingually, rectally, or vaginally. It is readily absorbed from the gut, nasopharynx (back of the nose and throat), muscle (when injected), mucosa, and placenta. It alters the mood differently depending on the route of ingestion. When the drug is snorted or taken orally, the user describes a feeling of euphoria or a feeling of extreme well-being called a "high." Smoking or injecting the drug results additionally in a more immediate, brief, intense sensation called a "flash" or a "rush." Users describe this as extremely pleasurable, and it has been characterized by some individuals as being equivalent to multiple orgasms. This is then followed by the euphoria. The "high" and the "rush" are both a result of the release of very high levels of the neurotransmitter dopamine into areas of the brain that regulate feelings of pleasure. Further description of the effect of this drug on the brain will be discussed in a later section.

Different methods of use produce different response within the user's body. The length of time until onset of symptoms is dependent upon the method of use. If the drug is snorted, effects occur within 3–5 minutes due to the rapid uptake of the drug through highly vascular nasal passages. If, however, the drug is ingested orally, it must be taken up through the lining of the digestive system, with effects not occurring for 15–20 minutes. Smoking meth usually allows the drug to reach the brain even more rapidly than injecting it (MacKenzie & Heischober, 1997). This is felt to be related to the small particle size of the drug, allowing it to penetrate deep into the lung tissue, where it rapidly crosses into the pulmonary circulation. In fact, meth is available to the body and brain very rapidly after use as it, unlike cocaine, does not have to be converted to a "free base" in order to be smoked effectively (MacKenzie & Heischober, 1997). The stimulant effects of meth have been reported to last up to 24 hours, most commonly 8–12 hours, compared to cocaine's high of only 20–30 minutes (National Institute on Drug Abuse, 1998). Additionally, the route of administration plays a role in the potential for dangerous and unintended consequences or side effects. Intravenous use is frequently associated with additional illnesses related to the administration of the drug (i.e., sharing of needles) such as hepatitis, HIV infection, tuberculosis, pneumonia, cellulitis (tissue infection), bacterial or viral endocarditis (infection of the lining of the heart), wound abscesses, sepsis (blood infection), thrombosis (blood clot in the blood vessels), thrombophlebitis (infection of lining of the blood vessel), and kidney injury (Šlamberová, Charousová, & Pometlová, 2005; Sowder &

Beschner, 1993). Snorting the drug may be associated with sinusitis (infection of the sinuses), loss of the sense of smell, congestion, atrophy (thinning) of the nasal mucosa, nosebleeds, perforation or damage to the nasal septum, hoarseness, and difficulty with swallowing (Sowder & Beschner, 1993; Gold, 1997).

Meth is commonly used in a "binge and crash" pattern—this means that the user will continue to use the drug ("binge") until they completely "crash." Many users go on a "run," during which time they may forgo food and sleep while binging. This period of use can last for several days. After the heavy binge cycle and before the "crash," the user may experience extreme paranoia, hallucinations, aggression, and agitation. This period of use is called "tweaking" and is felt to be the most physiologically dangerous time for the user as he or she may have a tremendous amount of drug in their body. It is also the time period when the user is potentially the most dangerous, due at least in part to their propensity for violence and feelings of paranoia. The "crash" is believed to occur because the chemical messenger (neurotransmitter) dopamine is depleted from the nerve terminals. It will slowly reaccumulate (at least to some level) while the user is crashing, but during this time the user may sleep for days, not even awakening to take care of regular bodily needs such as eating. Unfortunately, this often leads to increased use of the drug following the crash and eventually to difficulty in feeling any pleasure at all as the nerve terminals become injured. This is further discussed below in the section on central nervous system effects.

Tolerance to meth occurs within minutes, and the pleasurable effects disappear even before the blood concentrations fall. This partially explains the lack of direct correlation between blood level and clinical effects seen with meth. Tolerance means that users often need to take repeatedly higher doses and dose more frequently to get the desired effect. In addition, users often change their method of intake to a method that provides the additional "rush" or "flash" but is also more addictive (injection or smoking). However, there is no tolerance for the negative effects on the user's judgment, impulsivity, aggression, and susceptibility to paranoia, delusions, and hallucinations. In fact, it frequently takes an increasingly smaller amount of the drug to produce these symptoms.

When users discontinue their meth use, they will experience at least some symptoms of withdrawal. The more problematic and prominent withdrawal is the psychological withdrawal, which consists of depression, anxiety and agitation, fatigue, paranoia, aggression, and an intense craving for the drug. Physical withdrawal may also occur and is characterized by excessive hunger (polyphagia) and excessive sleepiness (hypersomnolence). Seizures may occur when the user is withdrawing from this drug. Studies have shown that there are brain abnormalities similar to those seen in people with mood disorders such as anxiety and depression (London et al., 2004) in individuals who have

recently discontinued their meth use. This poses additional challenges for individuals in treatment for this addiction.

CLINICAL EFFECTS OF METH USE

There are many factors that may contribute to how a person's body responds to meth use and abuse. The clinical effects from the use of meth are related to the form of the drug used, the dose, the frequency of use, the route of administration, and the length and amount of use. Additionally, the user may have underlying mental health problems for which he or she is trying to self-medicate with the use of the meth. The user may also be using other drugs in conjunction with meth, which may compound and complicate the effects of the drug. Finally, the methods of manufacturing this drug vary greatly, as does the purity of the final product. Therefore, the chemicals used in the manufacturing process as well as unwanted by-products may remain in the final product. This makes it very difficult to differentiate the effects of the drug alone from the effects of the other chemicals and by-products present. These variables also make it very difficult to predict, with any great certainty, the effects of the drug on each individual user.

Short-Term Effects

Pharmacologically, meth is a strong stimulant and is therefore in a class of drugs that includes cocaine, caffeine, and amphetamines. It is structurally similar to amphetamine as well as some of the body's natural neurotransmitters (chemical messengers) such as dopamine, serotonin, epinephrine (adrenaline), and norepinephrine. Meth has a much greater effect on the central nervous system than other amphetamines. Additionally, it seems to exert fewer peripheral nervous system effects (Beebe & Walley, 1995).

Many users report that they began taking meth to try to increase their alertness and to stay awake for longer periods of time, while others begin taking the drug use to lose weight. Still other users begin using to increase their sexual appetite, using it socially to go dancing or "clubbing."

A large portion of the acute physiological symptoms displayed after the use of meth are related to its peripheral effects on the autonomic nervous system and include dilated pupils, dry mouth, suppressed appetite (and consequent weight loss), elevated blood pressure (hypertension), tachycardia (high heart rate), rapid respiratory rate (tachyon), bruxism (involuntary teeth grinding), insomnia (inability to sleep or decreased need for sleep), tremors, and blurry vision. Additionally, meth is a vasoconstrictor of peripheral blood vessels,

which causes decreased oxygen delivery to the extremities, resulting in poor circulation. This may contribute to the multiple skin lesions that users often have, which are further worsened by the frequent picking behavior that the user demonstrates while perseverating on the lesions. Users also often perseverate on other tasks such as taking electronic items apart but then are unable to focus adequately in order to reassemble them (Center for Substance Abuse Treatment, 1999).

The central nervous system effects of meth ingestion are the result of the structural similarity of meth and the neurotransmitters active in the brain (dopamine, serotonin, epinephrine or adrenaline, and norepinephrine). Meth use can initially create feelings of euphoria (well-being), elevated energy, increased sensory perception, improved attention, excitation, intensification of emotions, perception of elevated self-esteem, increased alertness, agitation, aggression, restlessness, irritability, repetitive stereotyped behaviors, and increased physical activity (Jaffe, 1995). Conversely, it can decrease physical appetite with subsequent often marked and rapid weight loss. Users may have pressured speech and flight of ideas with rapid shifts in thinking, poor concentration, exaggerated self-esteem, hypervigilance, enhanced sensory awareness, fearlessness, suspiciousness, impaired judgment, poor impulse control, aggression, and emotional liability (Center for Substance Abuse Treatment, 1999).

Users have described markedly increased feelings of sexual desire, but despite this increased libido (sex drive), they usually begin to have difficulty in sexual performance. It is believed that the result of meth-stimulated serotonin release in the brain gives an initial antidepressant effect and elevates feelings of empathy. However, it is also responsible for bizarre mood changes, psychotic behavior, aggressiveness, and bruxism (involuntary grinding of the teeth). Some users may also experience feelings of nausea and dizziness.

The central nervous system effects of acute ingestion may include psychotic behaviors such as hallucinations and paranoia, which can lead to bizarre, irrational, and even violent, behavior. These effects may persist for days or weeks after the drug was discontinued (Beebe & Walley, 1995). These individuals may therefore have a great potential for violence, are at risk for homicidal and suicidal behavior (Szuster, 1990), and can be very dangerous to approach in any setting. A condition called methamphetamine psychosis has been described in the literature (Murray, 1998). This illness consists of several features, including extreme paranoia, well-formed delusions, hypersensitivity to environmental stimuli including light and sound, stereotyped "tweaking" behavior, panic, extreme fearfulness, and a high potential for violence. In fact, there is a described "hyperviolence syndrome" where the victim is frequently a part of the perpetrator's delusional belief system. A weapon such as a knife or gun is commonly

used in committing a crime and frequently there are multiple wounds inflicted, sometimes even days after the victim's death (MacKenzie & Heischober, 1997). Additionally, agitated delirium has been described in cases of meth-psychotic states and has also been linked to sudden cardiac death in meth users.

Overdose of the drug may be lethal and can even occur in a first-time user who ingests a single large dose (Jaffe, 1990). Acute symptoms of toxic ingestion may include dizziness, tremor, irritability, confusion, hostility, hallucinations, panic, headache, skin flushing, chest pain, palpitations, increased core body temperature (hyperthermia), irregular heart rhythms (arrhythmias), vomiting, cramps, excessive sweating, and severe high blood pressure (hypertension). This can result in brain hemorrhage or stroke, heart attack (myocardial infarction), and acute pulmonary edema (abnormal accumulation of fluid in the lungs) (Furst, Fallon, Reznik, & Shah, 1990; Nestor, Tamamoto, Kam, & Schultz, 1989a, 1989b). Additionally, the hyperthermia may be exacerbated by increased muscular activity due to agitation and can result in massive muscle breakdown (rhabdomyolysis) and potentially, kidney failure (Beebe & Walley, 1995). The development of a very high fever, rapid heart rate, severe hypertension, convulsions, toxic delirium, and cardiovascular collapse may signal a life-threatening situation (Ellinwood, Sudilovsky, & Nelson, 1973; Rowbotham, 1993; Wetli, 1993).

Medical treatment for overdose of meth consists primarily of supportive care. Other potential causes of presentation must be excluded. There are no specific medications or antidotes for the treatment of meth intoxication.

Sedation and rapid cooling may be used to manage the hyperthermia and agitated movements (Ellinwood et al., 1973; Gold, 1997). Ventilation and oxygenation may need to be provided and medications may need to be used to manage hypertension and seizures. Evaluation for cardiac arrhythmias and injury may need to be undertaken as well.

Long-Term Effects

The long-term effects of meth use can be particularly challenging when dealing with a chronic meth abuser. The use and abuse of this drug commonly leads to progressive social and occupational deterioration. Many who work with meth addicts report that the changes caused by the drug lead to a complete rearrangement of the user's priorities. For this reason, meth causes the heavy user to withdraw from anything and everything that is important to them. The reality is that studies now show that these effects are related to brain changes, many of which may be permanent. Individuals who have used meth for long periods of time demonstrate many features of dependence. It is clear that meth

is highly addictive and may lead to a chronic, relapsing disease. Addiction to meth is characterized by compulsive drug-seeking behavior, which is the result of functional and molecular changes in the brain. There is a stronger potential for addiction when utilizing the more rapid-acting routes of administration such as injection or smoking the drug, since there is stronger positive reinforcement for the use with the extremely pleasurable feelings that immediately follow (National Institute on Drug Abuse, 1998).

Chronic users often exhibit concerning behavioral changes, which consist of paranoia, auditory and visual hallucinations, mood disturbances, and delusions. This may result in homicidal or suicidal thoughts. Chronic users may also demonstrate excessive anxiety, confusion, insomnia, weight loss, and extremely violent behavior. It is important to be aware of this when dealing with someone addicted to the drug as they may exhibit very dangerous, unprovoked rages. Additionally, long-term users may display unusual motor movements that appear very similar to a Parkinsonian tremor. When the drug is discontinued, the user may experience depression, anxiety, fatigue, paranoia, aggression, and an intense craving for the drug. Studies have shown that the behavioral changes may persist for months or years after use of the drug is discontinued (National Institute on Drug Abuse, 1998). Chronic meth abuse may lead to the "kindling" phenomenon or "reverse tolerance" where the user can be pushed into frank psychosis by even very small amounts of any stimulant (methamphetamine, amphetamine, caffeine, or nicotine). This is felt to involve alterations that occur in the brain (Jaffe, 1990). Recent studies have suggested that meth psychosis may also spontaneously be brought on by mild stressors (Yui, Goto, Ikemoto, Ishiguro, & Kamata, 2000). Finally, there is another condition called chronic psychosis or "withdrawal" or "abstinence" psychosis, but it is unclear if this may be related to latent schizophrenia that was uncovered by the meth use (Streltzer & Leigh, 1977; Tomiyama, 1990).

Another feature of long-term meth use and abuse relates to the heightened sexuality linked to the use of this drug. After meth use for any length of time, users frequently describe changes in their sexual behaviors. They report that frequently activities that would previously give them sexual gratification no longer do, which leads many users to turn to increasingly bizarre sexual behaviors to meet their sexual needs. This can lead to predatory sexual behavior, increased promiscuity, and the extensive use of pornography. Frequent, often unprotected, sexual activity results in many unplanned pregnancies as well as the transmission of sexually transmitted and blood-borne infections, including HIV/AIDS and multiple forms of viral hepatitis (particularly hepatitis B and C). These risks are increased further when the users are injecting the drug and sharing the injection equipment. In fact, the use of methamphetamine is

so closely linked to sexual behavior that some studies have shown that sexual photos presented to meth users can trigger desire to use, even after long-term abstinence.

Dental decay has become a hallmark of chronic meth use and abuse. This complication has been termed by many as "meth mouth" and is likely multifactorial. First, meth use markedly reduces the production of saliva, causing a very dry mouth (xerostomia). Since saliva normally serves to bathe the teeth and reduce decay-causing bacteria, its reduction may lead to dental decay. Additionally, users often have a high intake of sugary soft drinks, which, coupled with a lack of oral hygiene as well as poor nutrition, may contribute to dental decay (Shaner, 2002). Finally, the significant vasoconstriction caused by meth use may also decrease blood flow to the teeth through the dental pulp, causing further damage. Another hallmark of chronic meth abuse is skin lesions. This is discussed in detail below in the section on the dermatologic system.

MEDICAL COMPLICATIONS OF METH USE

Meth use can affect any major organ system in the body. It has the most profound effect on the brain and central nervous system, but can also affect other organs.

Central Nervous System

The greatest systemic medical concern about meth use is the serious effect that the drug has on the brain of the user. The effects of meth on the central nervous system are numerous. First, this drug affects the brain at the very cellular level, causing nerve damage and loss.

In order to understand the complex effect that meth has on brain cells, it is important to understand the way that brain cells normally work. Nerve cells pass messages from one cell to another through the assistance of chemicals called neurotransmitters. These chemicals are necessary, because the nerve cells do not actually touch and therefore must pass their messages by the release and uptake of a neurotransmitter. These chemical messengers, such as dopamine, epinephrine, norepinephrine, and serotonin, are stored in structures called vesicles that float around in a fluid called cytoplasm within the presynaptic (sending) nerve cell. They remain there until the cell is given the signal to release the chemical. At that time the vesicle moves to the edge of the presynaptic cell, binds to the cell wall, and releases the neurotransmitter into the synapse (the space between the two nerve cells). The message is then picked up by the postsynaptic (receiving) cell when the neurotransmitter attaches to a receptor

on the cell wall. If there is more neurotransmitter in the synapse than is needed, it will either be destroyed or taken back up into the presynaptic cell for storage until it is needed again. This is done through a mechanism in the cell wall of the presynaptic cell called a transporter.

Dopamine is the neurotransmitter most affected by meth, because the two chemicals are very similar in structure. Dopamine is normally released when something pleasurable occurs, since it acts in the regions of the brain that regulate feelings of pleasure. It also elicits effects in the areas of the brain that regulate movement, emotion, judgment, and motivation. Once meth enters the body, regardless of the manner, it makes its way to the brain cells, among other places, where it causes the cells to release dopamine into the nerve synapse. This is what creates the stimulant effects of the drug that the user desires. Early studies showed that meth decreased the transporter function in dopamine neurons (Brown, Hanson, & Fleckenstein, 2000). However, newer studies have shown that the meth actually enters the presynaptic cell and causes massive release of dopamine from the storage vesicles into the cell cytoplasm as well as an additional massive release of dopamine from the presynaptic cell. This causes flooding of the synapse with the dopamine. There are only a limited number of receptors on the postsynaptic cell, and once they are full of the dopamine, they can no longer take up more of the chemical. Therefore, there is an excess of dopamine left in the synapse. Researchers believe that the excess dopamine is broken down by chemicals in the synapse and is ultimately turned into breakdown products that are toxic to the nerve cells. Additionally, the excess dopamine released into the presynaptic cell's cytoplasm is believed to be damaging to the cell.

Studies using a noninvasive brain imaging technique called magnetic resonance spectroscopy (MRS) have shown that the damage done to nerve cells is long-term and is similar to that caused by strokes or Alzheimer's disease (Ernst, Chang, Leonido-Yee, & Speck, 2000). Another study by Dr. Volkow used positron emission tomography (PET) scans to show that dopamine transporter levels in the striatum of the brain were 24 percent lower in meth users than in control subjects. Additionally, the meth users performed more poorly than nonusers on tests that evaluated brain function associated with the striatum, including fine motor skills, gross motor skills, and memory. The reduction in performance was proportional to the deficits in dopamine transporters. She concluded that compared with the normal 6–7 percent reduction in dopamine transporters found in aging, users saw losses roughly equivalent to 40 years of aging (Volkow et al., 2001).

Damage caused by meth to the dopamine system has been compared to that seen in patients with Parkinson's disease, a brain disease characterized by

the progressive loss of dopamine neurons in the regions of the brain involved in movement. Although damage to the brains of Parkinson's patients is more severe than that in meth users, researchers now believe that long-term meth use may lead to symptoms very similar to Parkinson's disease (Volkow et al., 2001). It is unknown if sustained abstinence from meth use will result in recovery of brain changes. Early studies suggested that abstinence was accompanied by dopamine transporter recovery, but a parallel recovery in cognitive function has been more difficult to identify. It is clear that recovery is related to the individual's baseline prior to use, the length of use, and the length of the abstinence (Volkow et al., 2001). A recent study using proton magnetic resonance spectroscopy suggested that following cessation of meth use, adaptive changes occur in the brain, which was felt to potentially contribute to some improvement in function (Nordahl et al., 2005). However, another recent publication suggests that meth use causes persistent hypometabolism in the frontal white matter of the brain with impairment in frontal executive function (Kim et al., 2005). Many studies are ongoing in this important area.

The release of serotonin is also stimulated by meth ingestion. This neurotransmitter has been implicated in states of consciousness, mood, depression, and anxiety. It is believed that meth has a little bit less serotonin effect than dopamine effect. However, damage to cells responsive to this chemical may explain the problems with depression that recovering addicts face.

As the nerve terminals are injured, the user eventually is unable to feel the pleasure that he began to use the drug for. This can contribute to the cycle of addiction and many of the chronic effects that are seen in long-term users.

Meth use can cause seizure activity, strokes, and spontaneous brain bleeds. It can also lead to chronic psychosis as well as movement disorders.

Cardiovascular System

Because meth is a stimulant, it has multiple effects on the cardiovascular system. These effects appear to be manifest at all dose levels and routes of administration even in otherwise healthy young adults. Virtually any kind of heart disease has been linked to meth use and abuse. First, use of this drug causes an increase in heart rate (tachycardia) as well as elevation of blood pressure (hypertension), both of which can be marked and very dangerous. Additionally, meth use can cause sudden cardiac death as well as the sudden rupture of an aneurysm. Meth is a blood vessel constrictor (vasoconstrictor), and that abnormal constriction of blood vessels of the heart can cause heart damage or a heart attack. This may be worsened or exacerbated by the fact that meth use causes increased platelet aggregation, which may clog cardiac vessels. Primarily because

of the catecholamine (epinephrine and other neurotransmitted) excess, meth abuse may result in cardiotoxicity. This may be manifest as inflammation of the heart muscle (myocarditis) or the heart lining (endocarditis) and abnormalities in the heart muscle itself (cardiomyopathy) (Hong, Matsuyama, & Nur, 1991; Gold, 1997). Finally, chronic meth abuse can cause damage to any vessels throughout the body, further damaging the tissues those vessels supply.

Respiratory System

Respiratory system complications from meth abuse include shortness of breath (dyspnea) and severe chest pain. Coughing spasms following inhalation of the drug may result in pulmonary barotrauma and consequent leakiness of air into the pleural cavity, chest cavity (mediastinum), and soft (subcutaneous) tissues of the chest. Pulmonary edema (excess fluid in the lungs) has been noted in meth fatalities and is felt to be the result of deep inhalation of the drug and subsequent aggravation of preexisting conditions (Nestor et al., 1989a, 1989b). Granulomas may form as a result of chronic irritation from adulterants added to the drugs, and constriction of the blood vessels in the lungs may ultimately affect oxygen exchange, potentially leading to chronic lung disease (Center for Substance Abuse Treatment, 1997).

Dermatologic System

The skin of the chronic user is often in poor condition and may be covered in sores. Poor circulation to the skin, poor nutrition, and tactile hallucinations all contribute to this quickly identifiable problem. Users often report that they believe that there are bugs crawling on their skin (a phenomenon called "formication") and will perseverate on trying to pick at the bugs, often with instruments such as knives. These lesions frequently have difficulty healing well and become readily apparent in chronic users. Some parents will even believe that their children have bugs on their skin and cover the children in insect spray or pick at the child's skin. These lesions may be confused with another skin disorder if the drug use is not identified.

There may be evidence of healed burns if the user participated in manufacturing and was burned—often these individuals do not get medical care for the burns when they occur and attempt to treat the injury themselves. Recent data in the literature suggests that if such a burn patient seeks medical care, he needs to be managed differently from routine burn patients, requiring two to three times the usual amount of fluid resuscitation (Warner, Connolly, Gibran, Heimback, & Engrav, 2003).

Immunologic System

Drug abuse has been linked to increased risk of HIV and Hepatitis B, C, and D infection due to high-risk behaviors of users such as unprotected sexual activity and the sharing of injection paraphernalia. Preliminary animal studies have suggested that meth may also affect HIV disease progression by a more rapid and increased brain HIV viral load. Another study suggested that HIV-positive meth users may be at a greater risk of developing acquired immune deficiency syndrome (AIDS) than non–meth-using HIV-positive patients. Finally, additional studies have suggested that interactions between meth and the HIV virus itself may lead to greater neuronal damage and neuropsychological impairment (Volkow, 2005).

Other Organs

Other organs can be affected by meth use as well. Muscle damage can occur as a result of severely elevated body temperature (rhabdomyolysis). This can lead to major organ system damage, including the kidney, liver, and brain. Giant gastrointestinal ulcers can occur as a result of vasoconstriction decreasing blood supply to the intestines. There have also been reports of acute liver failure following intravenous meth use (Kamijo, Soma, Nishida, Namera, & Ohwada, 2002). One recent study showed significantly decreased calcification in the bone of chronic meth users, suggesting possible chronic effects on bone metabolism (Katsuragawa, 1999).

EFFECTS OF METH USE IN PREGNANCY

Meth use during pregnancy is believed to place the unborn fetus at risk, as does the use of other illicit drugs and alcohol. However, the full extent of maternal use of meth on the fetus and newborn infant is not completely known, and the fact that a mother uses a drug while pregnant does not, in and of itself, ensure that the unborn fetus will be affected. In fact, it is very difficult to differentiate the effects of meth exposure from a multitude of other factors such as maternal nutritional status and health, genetics, socioeconomic status, lack of prenatal care, and concomitant exposure to other drugs, including nicotine and alcohol. Additionally, the effect of any prenatal exposure on the fetus is also related to the gestational period during which the drug was used as well as the amount and form of use (Plessinger, 1998). Exposures in the first and second trimester of pregnancy are more likely to result in systemic abnormalities, while exposures later in pregnancy are linked with growth abnormalities.

There is currently a multicenter study underway to further describe this issue but, preliminarily, the investigators report that the effects appear to be similar to those of cocaine-exposed infants. However, although meth and cocaine are both sympathomimetic agents, it is known that meth has a much longer duration of action, potentially complicating its effects further.

There are several components of the potential risk to the fetus in a pregnancy complicated by maternal meth use. First, the effects of the use of the drug on the mother and father, including fertility, must be considered. Studies have shown that chronic, high-dose stimulant use affects reproductive and sexual functioning in both males and females. Male users report loss of sexual interest, impotence, and difficulty in maintaining an ejaculation, while female users may have abnormalities in their menstrual cycles leading to amenorrhea and infertility, as well as difficulty in achieving an orgasm (Gold, 1997). In the pregnant woman, meth may cause hypertension (high blood pressure), tachycardia, and vasoconstriction. Additionally, the mother's poor nutritional habits, high-risk behaviors, and commonly poor prenatal care may contribute to potential risk to the fetus.

Next, the risks to the placenta and the fetus must be considered. Based on its sympathomimetic function, meth is thought to have direct cardiovascular effects on both the fetus and the placenta, potentially causing fetal hypertension (high blood pressure), tachycardia (high heart rate), and vasoconstriction. These effects may result in premature delivery, intrauterine growth retardation, placental hemorrhage, fetal distress, or spontaneous abortion. Additionally, because the placenta provides the source of nutrition for the fetus, constriction of these blood vessels, as caused by meth, may result in reduced blood flow to the fetus and ultimately reduced oxygen and nutrient supply. These findings are consistent with the pharmacologic properties of meth, as it is known that elevated levels of norepinephrine can cause placental vasoconstriction and increased uterine contractility (Lederman, Lederman, Work, & McCann, 1978; Sherman & Gautieri, 1972). One sheep study released in 1993 showed that methamphetamine readily crosses the placenta and produces significant and long-lasting maternal and fetal cardiovascular effects (Stek et al., 1993). It is also known that meth passes through the placenta to the fetus and can cause elevated fetal blood pressure, potentially leading to prenatal strokes and heart or other major organ damage. The drug can cause an increased or extremely variable heart rate in the fetus and slowing or alteration of fetal growth. Additionally, simultaneous with an increase in maternal blood pressure following meth abuse, there is a decreased blood supply as well as oxygen supply to the placenta and fetus. This impaired oxygen supply can retard fetal development (Stewart & Meeker, 1997). Another study in sheep, released in

1994, showed that maternal administration of meth was found to be associated with a short-term increase in circulating fetal catecholamines, which was followed by hyperglycemia, lacticacidemia, and hyperinsulinism. This began to suggest an alteration of fetal sympathoadrenal activity, which may contribute to the perinatal complications seen with meth use (Dickinson, Andres, & Parisi, 1994). Additionally, it has been shown that the norepinephrine transporter and, to a lesser extent, the serotonin transporter are cellular targets in the human placenta for both amphetamine and meth (Ramamoorthy, Ramamoorthy, Leibach, & Ganapathy, 1995).

Another aspect of prenatal meth exposure that must be considered is any possible direct effect on the fetus. Fetal development abnormalities have been described sporadically in the medical literature, but no true syndrome specifically linked with maternal use of meth in the prenatal period has been described. There are limited numbers of studies in this area, particularly studies focusing on human infants. Additionally, most of the research in this area combines all amphetamines (often including cocaine), and only few studies isolate meth exposures. It is known that because of its low molecular weight and lipid solubility, there is considerable transfer of meth from maternal to fetal blood. This, in addition to the immaturity of fetal metabolic activities, may account for the reason that the drug remains in fetal circulation much longer than it does in maternal blood (Inaba & Cohen, 1993; Stek et al., 1993). Multiple studies looking at human exposures to amphetamines have indicated an association between meth or amphetamine use during pregnancy and cleft lip (Little, Snell, & Gilstrap, 1988; Nelson & Forfar, 1971; Saxen, 1975; Thomas, 1995), cardiac defects (Little et al., 1988; Nelson & Forfar, 1971; Nora, McNamara, & Clarke-Fraser, 1967; Nora, Vargo, Nora, Love, & McNamara, 1970), low birth weight (Little et al., 1988; Oro & Dixon, 1987), growth reduction and reduced head circumference (Eriksson, Larsson, & Zetterström, 1981; Little et al., 1988; Oro & Dixon, 1987), biliary atresia (Golbus, 1980; Levin, 1971), prematurity and stillbirth (Ericksson, Larsson, Windbladh, & Zetterström, 1978), hyperbilirubinemia requiring transfusion (Ericksson et al., 1978), cerebral hemorrhage (Dixon & Bejar, 1989), low body fat, and undescended testes (Little et al., 1988). Although these things have been noted to be associated with meth or amphetamine use prenatally, there is little data to suggest any kind of causative relationship, and the direct link between fetal abnormalities and maternal methamphetamine use is not clearly discernable. One study by Oro and Dixon showed that in utero exposure to cocaine or methamphetamine was adversely, negatively associated with gestational age, birth weight, length, and occipitofrontal circumference. They also showed that "the increased rate of prematurity, intrauterine growth retardation, and perinatal complications

associated with prenatal exposure to cocaine or methamphetamine was greater than that predicted by coexisting risk factors and was consistent with the pharmacologic properties of these drugs" (Oro & Dixon, 1987). Another study by Smith et al. showed an association between decreased growth in infants exposed to meth throughout pregnancy relative to those infants only exposed in the first and second trimesters (Smith et al., 2003). Therefore, it is felt that birth outcomes may improve if the mother stops using the drug in the last one to three months of pregnancy. In addition, this study revealed significantly more small-for-gestational-age infants in the methamphetamine-exposed group than those in the nonexposed group (Smith et al., 2003). There also appeared to be a significant decrease in growth in the meth-exposed infants who were born to mothers who additionally smoked cigarettes compared to those who did not smoke (Smith et al., 2003). Finally, these infants may be at increased risk of blood-borne diseases such as HIV, Hepatitis B, and hepatitis C because of the frequent high-risk behaviors of the mother.

Early studies of amphetamine-exposed infants indicated that many of these infants had difficulties with poor feeding and extreme drowsiness throughout the first several weeks to as long as a year of life (Ericksson et al., 1978, 1981; Ramer, 1974). Some of these infants (like infants with exposures to narcotics) may display an array of behavioral disturbances after birth characterized by tremors, irritability, abnormal sleep patterns, and poor feeding, which may represent direct drug effects rather than withdrawal, as the metabolites were found in the infants' urine for up to seven days after birth (Oro & Dixon, 1987). One study that analyzed 294 mother-infant pairs (134 exposed and 160 unexposed) found that 49 percent of exposed infants displayed evidence of withdrawal symptoms and documented the need for pharmacologic intervention for the treatment of withdrawal symptoms in 4 percent of these infants (Smith et al., 2003). Following this initial hyperirritable phase (usually only displayed in the first several days of life), some meth-exposed infants were so extremely drowsy that they required tube feedings, approximating the prolonged sleep, lethargy, and depression ("crash") seen in adult users (Oro & Dixon, 1987). This period of time through the first four weeks of life is felt to be related to the dopamine depletion syndrome and may be characterized by lethargy in the infant with excessive periods of sleep, poor suck and swallow coordination, sleep apnea, and poor habituation (Shah, 2006). Exposed infants may have irregular sleep patterns, poor feeding, tremors, and increased muscle tone. Their poor ability to habituate or self-regulate, especially under stressful situations, will be further intensified if their environment is noisy and chaotic. They will not tolerate this well, which will likely lead to increased irritability and potential for abuse. In the next four months of life, the infant may display symptoms of CNS immaturity, including effects on motor development; sensory integration problems

including tactile, defensive, and texture issues; and neurobehavioral symptoms affecting their interaction and social development. This period is frequently followed by a symptom-free period or the honeymoon phase from 6 to 18 months. However, from 18 months to 5 years, the children may again begin to exhibit difficulties with sensory integration, poorly focused attention, easy distractibility, poor anger management, and aggressive outbursts (Shah, 2006).

Because of the multitude of confounding variables such as other potential drug exposures, genetic predisposition, and environmental factors, it is difficult to identify postnatal features that are directly related to in utero meth exposure. However, scientists have begun to study infants exposed to meth in utero to attempt to identify potential outcomes. One study by Hansen, Struthers, & Gospe (1993) of infants exposed to meth in utero has identified visual cognitive effects (poorer visual recognition memory—a measure correlated with subsequent IQ) and changes in behavior that appear to be permanent in these infants. Several additional studies in rats have demonstrated similar concerns for spatial learning in adult animals exposed to meth in utero (Crawford, Williams, Newman, McDougall, & Vorhees, 2003; Williams, Vorhees, Boon, Saber, & Cain, 2002; Williams et al., 2003).

Several studies have shown that prenatally meth-exposed infants may go on to exhibit further difficulties in childhood. Children exposed to meth in utero may face difficulties with what is called executive-level functioning. This functioning is related to the brain's ability to absorb information, interpret the information, and make decisions based on it. Difficulties in this level of functioning may help explain the problems that many of these children face with impulsivity, judgment, and connecting behavior with consequence. Although there are mounting studies on the effects of meth on adult brains, studies on the brains of infants exposed to meth in utero are limited but beginning to emerge. One study by Smith et al. attempted to study the possible neurotoxic effects of prenatal meth exposure on the developing brain using brain proton magnetic resonance spectroscopy (Smith et al., 2003). In this study, the researchers found the suggestion of an abnormality in the energy metabolism in the brains of children exposed to meth in utero, but acknowledged the need for more studies and the interpretation of this study with caution due to their small sample size and limited behavioral assessments (Smith et al., 2003). The study, however, may have important clinical implications, since the area found to be affected is the frontal-striatal pathway, which is involved in executive-level functioning.

Studies done in Sweden following the short-term legalization of drugs of abuse in the 1960s looked at populations of children exposed to amphetamines prenatally who were then monitored for their progress and performance (Plessinger, 1998). Several reports indicated difficulties with altered growth

and behavior in the exposed children (Plessinger, 1998). Looking at matched groups of exposed and unexposed children at 8 years and then 14 years of age, a larger number of amphetamine-exposed children did more poorly than unexposed controls in mathematics, language, and physical training (Cernerud, Eriksson, Jonsson, Steneroth, & Zetterström, 1996; Ericksson et al., 1978, 1981). These studies also showed that once these exposed children were past puberty, the boys were taller and heavier and the girls were shorter and lighter than the Swedish standards used for comparison (Cernerud et al., 1996). These findings may suggest an effect of in utero exposure of methamphetamines on normal neural development and maturation of the adenohypophysis, which raises concern that the use of amphetamines during pregnancy may cause a wide variety of effects (Plessinger, 1998).

Additional work is being done in an effort to better define any association there may be between prenatal drug exposures and later drug use and medical complications in young adults and adults. One recent study at the University of Chicago indicated that males who were exposed to meth in utero and then went on to take the drug themselves as teens or adults may have hastened onset of brain disorders such as Parkinson's Disease (Heller, Bubula, Lew, Heller, & Won, 2001).

Finally, there have been reports of deaths in fetuses and infants felt to be related to maternal meth use. Although the actual number of these cases reported in the literature is low, there is concern about the risk of death in infant's exposure to this drug either prenatally or in the postnatal period. One study reviewed the deaths of eight fetuses/infants aged from 20 weeks estimated gestational age to a 1-month-old infant (Stewart & Meeker, 1997). In these cases, it was believed that the maternal use of meth played a role in the deaths of the fetuses/infants, and the authors cited the increased vulnerability of the developing nervous system and potential compromise due to fetal acidosis, hypoxernia, decreased uterine blood flow, changes in fetal blood gases, and an increase in fetal glucose levels (Stewart & Meeker, 1997). There have also been some studies suggesting a possible link between cocaine exposure in utero and sudden infant death syndrome (SIDS), but the nature of this connection is unclear. However, because of this potential link as well as the possibility that the infant may have ingested the drug, California law now requires that all SIDS deaths be tested for certain drugs, including meth.

PARENTING ISSUES IN METH USE

A very important factor that must be considered regarding children that are exposed to meth is the environment in which the child is raised. There are

additional and potentially very dangerous consequences that may occur if a child grows up in an environment where there is active use of methamphetamine. These risks include the actual environment, which may include many hazards including the exposure to the drug itself, as well as the actual quality of parenting that the child receives.

The environment of a meth abuser is one that may contain many risks for growing children. These risks include exposure to the actual drug itself (see the next section), weapons, an unkempt and dirty home, inadequate food, inappropriate sleeping conditions, multiple unsavory visitors, and exposure to violence and sexual content and activity. The child may be neglected while the parents sleep for long periods of time during a "crash." They frequently do not receive adequate medical, dental, emotional, and educational care. Additionally, children living in these homes are at an increased risk of sexual abuse, either from witnessing sexually explicit activity or material or from becoming the actual targets of bizarre sexual activity in the home. They may also be physically abused or even killed when the parent becomes easily frustrated or the child becomes the target of the parent's homicidal ideations.

There are few studies in this area, but one study in which meth was administered to premating, gestational, and lactational rat pups demonstrated that the drug had a negative effect on maternal behavior toward the pups (Šlamberová et al., 2005).

EFFECTS ON CHILDREN

When meth is used in a home where children reside, there are several routes of potential exposure and subsequent danger to the children. First, when there is active use in the home, the drug itself is frequently readily accessible to children, often lying on surfaces within easy reach of a curious child. Children display frequent hand-to-mouth behavior, placing them at risk for picking up the drug itself and ingesting it, resulting in a continuum of possible effects ranging from minor physiologic response to significant intoxication, seizures, and death. Although this is not an uncommon event, there are only a few such cases reported in the literature. In 1998 Kolecki reported 18 cases in which children less than 13 years of age were confirmed to be victims of oral methamphetamine poisoning. In these cases, the drugs had been left out with easy access for the children. The children displayed agitation (9), inconsolability (6), increased heart rate (18), abdominal pain, vomiting (6), seizures, muscle breakdown, fever (1), and ataxia (1). Prior to identification of the cause for the children's illness, multiple tests and treatments were undertaken such as head CTs (5), spinal taps (3), and administration of spider (Centruroides sculptu-

ratus) antivenom (3), since the presentation closely resembled spider envenomation. In fact, one child developed an anaphylactic reaction to the antivenom (Kolecki, 1998). Another case reported in 1995 by Gospe profiled the case of an 11-month-old boy who presented to medical care with irritability and transient cortical blindness and involuntary turning of the head and tested positive for meth. Symptoms resolved after 12 hours of supportive care. Mother reported that she had found the infant chewing on a small plastic bag (Gospe, 1995). An additional case was reported by Narogka, who described a 13-month-old girl whose symptoms of restlessness and roving eye movements were initially felt to be from scorpion evenomation, but when she did not respond to antivenom, a urine drug screen was obtained and found to be positive for meth (Nagorka & Bergeson, 1998).

Effects of exposures to meth through breastfeeding must also be considered. Meth, like most drugs, is transferred to the breast milk when a lactating mother uses the drug. Therefore, the American Academy of Pediatrics does not recommend breastfeeding when the mother is using meth, as it is believed that the infant will receive the drug through breast milk, and this has been reported to cause irritability and poor sleeping patterns (American Academy of Pediatrics, Committee on Drugs, 2001).

At this time, there is not enough scientific data in the literature to fully understand the amount of exposure that a child may receive when living in an environment where meth is actively being smoked or used. There is no information on the potential for intake of the drug through transdermal absorption or passive inhalation. Research in this area is clearly needed.

CONCLUSION

Meth use and abuse in this country has far-reaching ramifications for not only the user but for society. While we currently understand a great deal about the medical effects of this drug on both adults and children, there is far more that needs to be studied. Additionally, the nature and extent of the effects on the user of the by-products and other chemicals that may remain in the meth following the manufacturing process are unknown at this time. The studies that are currently available have only addressed the effect of the actual drug. The National Institute of Drug Abuse (NIDA) is aggressively supporting a comprehensive research program to better understand meth's mechanism of action, physical and behavioral effects, risk and protective factors, treatments, and potential predictors of treatment success (Volkow, 2005). Continued collaborative efforts are critical to advancements in understanding the medical effects of meth on the users and children who are exposed.

Chapter **11**

Vapors May Be Dangerous If Inhaled: An Overview of Inhalants and Their Abuse

Jace Waguspack, BS, and Paula K. Lundberg-Love, PhD

The word *inhalant* is a broad term used to describe a heterogeneous group of chemicals that share a common route of administration. In addition to the drugs identified as "inhalants," there are other drugs that are inhaled, but they are excluded from this group as they fall under other drug classifications (i.e., cigarettes, marijuana, or crack cocaine). Inhalants can be effectively subdivided into three separate groups known as volatile substances, nitrous oxide, and nitrites (Balster, 1998).

The first group, volatile substances, is the most commonly abused of the inhalants, and it includes a wide variety of substances that give off vapors at room temperature (Brouette & Anton, 2001). This group typically includes solvents, adhesives, aerosols, cleaning agents, and gasoline (Sharp & Rosenberg, 1997). There are many different types of chemicals that constitute this group, but some of the more common chemicals include toluene, acetone, butane, trichloroethylene, hexane, propane, fluorocarbons, and others (Sharp & Rosenberg, 1997). These chemicals can be found in a variety of easily acquired products, including some glues, spray paint, dry cleaning agents, paint thinner, nail polish remover, and typewriter correction fluid (Sharp & Rosenberg, 1997). The relative ease with which one can acquire these products is one of the proposed explanations for their widespread abuse, especially among young people (McHugh, 1987).

The chemical that constitutes the second group of inhalants is nitrous oxide. Nitrous oxide is commonly known as laughing gas, and can be acquired by those who have access to medical supplies because it is used in dentistry as a

type of anesthetic. It also is often used as a propellant in whipped cream, which makes it available in grocery stores (Brouette & Anton, 2001).

The final group of inhalants comprises chemicals referred to as nitrites. Nitrites include the chemicals butyl nitrite, amyl nitrite, and isobutyl nitrite, and are commonly found in room odorizers (Brouette & Anton, 2001). Due to the fact that they enhance sexual experiences, they are also often sold in sex shops (Brouette & Anton, 2001).

There are several methods by which these chemicals are inhaled, including "sniffing," "huffing," "spraying," and "bagging." "Sniffing" involves inhaling vapors from an open container (Dinwiddie, 1994). "Huffing" is a practice whereby an individual soaks a rag in the chemical of choice and then holds the rag to his or her face to be inhaled (Brouette & Anton, 2001). Inhalant users sometimes directly spray the desired inhalant into the mouth or nose (Brouette & Anton, 2001). "Bagging," on the other hand, involves filling a bag with the chemical and then breathing from the bag (Brouette & Anton, 2001). The practice of bagging can be quite dangerous, as the drowsiness that inhalants induce coupled with the lack of fresh oxygen received when breathing from the bag may cause the individual to lose consciousness. When adhesives are being used in this manner, the bag may seal to the person's face, causing death by asphyxiation if the individual loses consciousness (Brouette & Anton, 2001).

HISTORY AND EPIDEMIOLOGY

The abuse of inhalant drugs is a relatively recent phenomenon. Inhalant use first began to receive public attention in the 1960s, when sniffing glue became popular (Fredlund, Spence, & Maxwell, 1989). During this time, abuse of nitrites began to emerge as well (Haverkos, Kopstein, Wilson, & Drotman, 1994). Nitrites became particularly popular among homosexual men due to the enhancement of sexual experience from vasodilation (widening of blood vessels) resulting in penile engorgement, combined with relaxation of smooth muscle tissue (Goode & Troiden, 1979), as well as prolonged orgasm (Newell, Spitz, & Wilson, 1988). Chronic use of nitrites has several negative hematological effects, including effects on lymphocyte number and function, reduction of monocyte adherence, and the suppression of natural killer cells. Nitrite abuse also compromises T-dependent antibody induction, cytotoxic T cell induction, and the tumoricidal activity of macrophages (Brouette & Anton, 2001; Dax, Lange, & Jaffe, 1989; Soderberg, Chang, & Barnett, 1996). Due to nitrites' negative hematological effects, as well as a high correlation of nitrite use in AIDS patients, it was once postulated that nitrites were in fact the cause of AIDS (Brouette & Anton, 2001). Because of the discovery of the HIV virus, this

theory was disproved. A positive side effect of the association of nitrites and possible susceptibility to AIDS was that the use of nitrites sharply decreased and has never regained its former popularity (Brouette & Anton, 2001).

However, the use of other inhalant substances remains high, particularly among young people. Some sources even report that inhalants have surpassed marijuana in popularity among 12-year-olds (Meyer & Quenzer, 2005). A recent study found that 17 percent of eighth graders in the United States have used inhalants (Johnston, O'Malley, Bachman, & Schulenberg, 2006). It has been proposed that the magnitude of this number is due to the ease of access to inhalants through a variety of common household substances (Ridenour, Bray, & Cottler, 2007). In fact, because they are so readily available, research indicates that inhalants are the gateway drugs for many children (McHugh, 1987).

While inhalant abuse is most common in young people, prevalence rates vary among different ethnic groups. Use among Hispanic Americans was found to be high, but these data are thought to be confounded by the low socioeconomic status and social dysfunction of the particular group of Hispanics studied (Padilla, Padilla, Morales, Olmedo, & Ramirez, 1979). Prevalence of inhalant use by Native American youths on reservations has been reported to be as high as 34 percent of 8th graders and 20 percent of 12th graders (Beauvais, 1992). Conversely, use of inhalants has been found to be particularly low in African Americans as opposed to other ethnic groups (Compton, Cottler, Dinwiddie, Mager, & Asmus, 1994).

Geographically, while inhalant abuse is seen across the United States, it is most pronounced in Alaska, where as many as 22 percent of high school students report having used inhalants (Meyer & Quenzer, 2005). Appropriately, one of the few inhalant abuse treatment centers in the United States, the Tundra Swan Inhalant Treatment Center, is located in Bethel, Alaska (Meyer & Quenzer, 2005).

COMORBIDITY OF PSYCHIATRIC DISORDERS AND INHALANT USE

Inhalant use has a very high rate of comorbidity with psychological disorders. Research indicates that 70 percent of inhalant users met criteria for a mental disorder at some point during their lifetime and 38 percent met criteria for a mental disorder within a year of the survey (Wu & Howard, 2007). Furthermore, female inhalant users exhibit mental disorders more often than do male inhalant users, and female users exhibit multiple mental disorders more often than do their male counterparts (Wu & Howard, 2007). Major depression was the

most common mental disorder found comorbid with inhalant use (41%), and antisocial personality disorder was the second most common mental disorder (32%) (Wu & Howard, 2007). Of the 70 percent of inhalant users that met the criteria for one lifetime mental disorder, 49 percent met the criteria for three or more disorders. The high rate of comorbidity between inhalant use and psychological disorders has important implications for the treatment of inhalant abuse, which will be discussed later in this chapter. Although, at this time, a causal relationship cannot be inferred between inhalant use and psychiatric disorders, it is interesting to note that in the majority of cases, inhalant use precedes the onset of most mood and anxiety disorders identified in inhalant users, and that the onset of these psychiatric disorders tends to occur earlier in inhalant users versus nonusers (Wu & Howard, 2007).

MECHANISMS OF ACTION

Volatile Substances

The physiological mechanisms of action of the volatile substances are the least understood of all of the inhalants. However, recent research has made some progress in identifying and understanding how these agents affect neurons and brain neurochemistry. Many of the mechanisms of action of these substances are similar to those of ethanol. Moreover, these substances exert specific and nonspecific effects on the brain. With respect to their nonspecific mechanisms, volatile substances interact directly with the cell membranes of neurons, thereby fluidizing them (Brouette & Anton, 2001). Such a process reduces the efficiency of neural processing and results in overall central nervous system (CNS) depression. They also interact with and enhance the activity of gamma-aminobutyric acid (GABA)-A receptors and stimulate glycine receptors. Both GABA and glycine are two different neurotransmitter systems whose activation leads to inhibition of the CNS (Beckstead, Weiner, Eger, Gong, & Mihic, 2000). Chemicals in the volatile substance class of inhalants also appear to inhibit the activity of the N-methyl-D-aspartate (NMDA) glutamate receptors, a neurotransmitter system often responsible for central nervous system excitation (Cruz, Balster, & Woodwar, 2000) and the potentiation of learning and memory. This action further induces inhibition of CNS activity. Some volatile substances (specifically toluene) activate dopamine neurons in the ventral tegmental area, a part of the brain involved in the reinforcing effects of many drugs of abuse (Riegel, Zapata, Shippenberg, & French, 2007). Finally, recent research has shown that volatile solvents enhance the activity of serotonin 3A receptors (5-HT 3A), which are also believed to be involved

in the reinforcement of drug-seeking behavior (Lopreato, Phelan, Borghese, Beckstead, & Mihic, 2003). The mechanisms behind this involvement are not well understood. However, some researchers have demonstrated that activation of 5-HT 3A receptors can stimulate dopamine release in the nucleus accumbens, a structure involved in the reinforcing effects of many drugs of abuse (Chen, van Praag, & Gardner, 1991).

Nitrous Oxide

The mechanisms by which nitrous oxide exerts its effects on human behavior are in dispute. Some argue that nitrous oxide works primarily through the opiate receptor system, and that it modulates the release of beta-endorphins and binds to the three types of opiate receptors: mu, kappa, and delta (Brouette & Anton, 2001; Gillman & Lichtigfeld, 1998). This theory would explain the analgesic effects of nitrous oxide, as activation of opiate receptors is known to produce analgesia (Gillman & Lichtigfeld, 1998). Activation of certain opiate receptors is also known to induce euphoria, which is also observed in nitrous oxide intoxication (Beckman, Zacny, & Walker, 2006). However, other research contradicts the opiate receptor theory of nitrous oxide analgesia and intoxication effects. In one such study, naloxone, a known opiate receptor antagonist, was administered following administration of nitrous oxide (Zacny et al., 1999). If the analgesia and euphoria caused by nitrous oxide were the result of opiate receptor activation, administration of naloxone should have reduced both of these effects. Instead, this study found that there was no significant reduction in analgesia or euphoria following naloxone administration, suggesting a separate mechanism of action for both of these effects (Zacny et al., 1999). Further research is necessary to determine the role of the opiate receptors in the analgesic and intoxicating effects of nitrous oxide, though it would appear that there is more current research that supports some degree of opiate receptor involvement. Less disputed is the theory that nitrous oxide blocks NMDA glutamate receptors (Brouette & Anton, 2001; Yamakura & Harris, 2000). This action is likely to underlie the short-term memory deficits often experienced by those under the influence of nitrous oxide (Brouette & Anton, 2001).

Nitrites

The mechanism of action of the third group of inhalants, nitrites, is quite different from the previous two groups. Instead of binding to specific neurotransmitter receptors, nitrites induce vasodilation, which results in the relaxation of blood vessels, and increased blood flow (Brouette & Anton, 2001).

Vasodilation of cerebral arteries is thought to underlie the psychological effects of nitrite intoxication (Brouette & Anton, 2001), while vasodilation of peripheral blood vessels results in lower blood pressure, flushing, syncope (fainting), throbbing sensations, and feelings of warmth (Balster, 1998). Nitrites also cause relaxation of smooth muscle tissue (Brouette & Anton, 2001).

ACUTE EFFECTS

Intoxication

The symptoms observed in inhalant intoxication vary depending upon the class of the inhalant used. Volatile substances cause drowsiness, diplopia (double vision), dysarthria (slurred speech), ataxia (an inability to walk and balance), and general disorientation (Brouette & Anton, 2001). When inhaled in higher concentrations, visual hallucinations can occur (Brouette & Anton, 2001). Because volatile substances have a similar mechanism of action to that of ethanol, it is not surprising that inhalant intoxication closely resembles that of ethanol. Disinhibition is accompanied by perceptual distortions and incoordination (Dinwiddie, 1994). Furthermore, users often experience nausea and vomiting, headaches, coughing, and excessive salivation (Dinwiddie, 1994). Occasionally, one may develop a rash around the nose and mouth (Dinwiddie, 1994). Some abusers even develop delusions, such as the belief that they can fly, which results in injury if these individuals subsequently jump out of windows or trees (Evans & Raistrick, 1987). There is evidence that tolerance develops with prolonged use of volatile substances (Ron, 1986).

In contrast, the symptoms of nitrous oxide intoxication often mimic those of psychedelic drugs as opposed to alcohol (Atkinson & Green, 1983). Nitrous oxide intoxication is often described as a dissociative experience (Brouette & Anton, 2001). While it does not produce the same reaction in all users, those that abuse it report that it induces euphoria, tingling, numbness, dizziness, hallucinations, and sensations of warmth (Brouette & Anton, 2001). Short-term memory loss has also been observed to occur as a result of nitrous oxide intoxication (Brouette & Anton, 2001).

The final group of inhalant drugs, nitrites, induces euphoria, floating sensations, increased tactile sensitivity, disinhibition, heightened sexual arousal, relaxation of the anus, and prolonged orgasm (Newell et al., 1988).

Sudden Sniffing Death Syndrome

Sudden sniffing death syndrome refers to a phenomenon whereby inhalation of chemicals from the volatile substance class of inhalants sensitizes the heart

to the neurotransmitter epinephrine, which is involved in startle and stress responses (Bass, 1970). When the user is then frightened or stressed, as can happen from being caught inhaling by an adult or a startling visual hallucination, the hypersensitivity of the heart to epinephrine can trigger a fatal cardiac arrhythmia (Committee on Substance Abuse, 1996). Such a fatality can occur at any time, even upon an individual's first use of the substance (Committee on Substance Abuse, 1996). There also may be a higher risk of sudden death associated with fuel gases and aerosols than with adhesives (King, Smialek, & Troutman, 1985).

CHRONIC ORGAN EFFECTS

Chronic abuse of the volatile substance class of inhalants can have deleterious effects on multiple organ systems throughout the body. Hepatotoxicity, or toxicity of the liver, is associated with several of the volatile substances (Brouette & Anton, 2001). However, liver toxicity usually decreases shortly after cessation of inhalant use (Fornazzari, 1988). Pulmonary disease, emphysema, and chemical pneumonitis have also been found in individuals chronically exposed to volatile substances (Dinwiddie, 1994). Furthermore, heart complications, such as those found in sudden sniffing death syndrome, are a serious risk (Brouette & Anton, 2001). Some volatile substances, toluene in particular, can cause renal dysfunction (Brouette & Anton, 2001). Other research has even linked volatile substance abuse to bone marrow suppression (Flanagan, Ruprah, Meredith, & Ramsey, 1990). There are no known long-term complications of nitrous oxide abuse, as the side effects of nitrous oxide subside following abstinence (Brouette & Anton, 2001). Meanwhile, the most common complication resulting from chronic abuse of nitrites is a reduction in the functioning and efficacy of the immune system through various mechanisms, as discussed previously (Brouette & Anton, 2001).

CENTRAL NERVOUS SYSTEM EFFECTS

There are multiple brain structures affected by chronic inhalant abuse. Cell death in the cerebellum, a structure vital for balance and gait, often occurs (Fornazzari, Wilkinson, Kapur, & Carlen, 1983). With prolonged use, this damage may become permanent (Lazar, Ho, Melen, & Daghestani, 1983). Furthermore, destruction of white matter via neuronal demyelination is also observed in many chronic volatile substance abusers (Brouette & Anton, 2001). Myelin is a substance that insulates neurons such that the neural transmission of myelinated neurons is much more rapid than that of nonmyelinated neurons.

Therefore, the destruction of myelin in the central nervous system can produce a wide array of neurobehavioral deficits. In severe cases, this may even produce dementia (Meadows & Verghese, 1996). A recent MRI study confirmed neurological abnormalities in subcortical brain structures and white matter in 44 percent of the solvent abusers studied, as opposed to only 25.5 percent of other drug users studied (Rosenberg, Grigsby, Dreisbach, Busenbark, & Grigsby, 2002). These results imply that volatile solvents are neurotoxic, and that they produce neurological abnormalities more often than do other drugs, such as cocaine, marijuana, alcohol, amphetamines, and opiates.

Neuropsychological Deficits and Organic Solvent Neurotoxicity

Neuropsychological testing of chronic inhalant abusers has revealed a variety of neurobehavioral consequences. These include deficits in auditory discrimination, psychomotor speed, visuo-motor functioning, and memory impairment (Tsushima & Towne, 1977). Furthermore, some research suggests that the length of inhalant use correlates with lower neuropsychological test scores in these areas (Tsushima & Towne, 1977). Impairments in executive function (i.e., impulse control, planning, strategy formation, self-monitoring, and problem solving) have also been observed in chronic volatile substance abusers. These types of impairments may interfere with the effective treatment of these individuals due to the individual's lack of insight into his problems or an inability to follow steps to resolve such problems (Rosenberg et al., 2002).

Some individuals exposed to volatile solvents over a prolonged period of time develop a disorder called organic solvent neurotoxicity (OSN). This disorder is characterized by three levels of severity (Ogden, 1993). Symptoms of Type 1 OSN include fatigue, irritability, depression, and anxiety. This is the mildest form of OSN, and no significant types of neuropsychological impairment have been demonstrated in individuals with this type of OSN (Ogden, 1993). With continued abstinence from solvent ingestion, the symptoms diminish and ultimately disappear (Ogden, 1993). Symptoms of Type 2 OSN include personality and mood disturbances, deficiencies in motivation and impulse control, and deficits in memory, learning, concentration, and psychomotor speed (Ogden, 1993). Symptoms of Type 2 OSN generally improve somewhat, although not completely, after abstinence from exposure to solvents (Ogden, 1993). Type 3 OSN is the most severe form of the disorder, characterized by severe dementia accompanied by progressive deterioration of memory, cognitive abilities, and emotional functioning (Ogden, 1993). This condition is irreversible (Ogden, 1993).

FETAL EFFECTS

Administration of inhalants has been shown to affect the fetus in both animals and humans. Due to their high lipid solubility, most volatile substances rapidly and easily cross the placenta (Brouette & Anton, 2001). In animal studies, prenatal exposure to the solvent toluene resulted in lower birth weight and minor malformations (Bowen, Mohammadi, Batis, & Hannigan, 2007). A condition closely mimicking fetal alcohol syndrome has been identified in human infants born to volatile substance abusers (Toutant & Lippmann, 1979). Symptoms include facial deformities, limb abnormalities, growth retardation, and developmental delays. There is also evidence that the infant can be born with a withdrawal syndrome if the mother had used inhalants a few days before the child's birth (Tenenbein, Casiro, & Seshia, 1996).

INHALANT WITHDRAWAL SYNDROME

Despite the fact that a withdrawal syndrome for inhalants is not classified in the *DSM–IV–TR* (American Psychiatric Association, 2000), research indicates that some individuals do have withdrawal symptoms upon abstinence from inhalants. Symptoms include anhedonia, irritability, sleep disturbances, psychomotor slowing, dry mouth, lacrimation (watery eyes), drug craving, headaches, and heart palpitations (Muralidharan, Rajkumar, Mulla, Kayak, & Benegal, 2008; Shah, Vankar, & Upadhyaya, 1999). Pharmacological treatment of inhalant withdrawal symptoms has not been well established, but some research suggests that the administration of benzodiazepines may be effective (Brouette & Anton, 2001). Some new research indicates that baclofen, a GABA-B agonist may be an effective treatment option (Muralidharan et al., 2008).

TREATMENT OF INHALANT ABUSE

The current approach to the treatment of inhalant abuse in the United States is inadequate (Beauvais, Jumper-Thurman, Plested, & Helm, 2002). There are several factors that limit the effectiveness of the treatment of inhalant abuse, including a need for extended detoxification (Reidel, Hebert, & Bird, 1995), common comorbid psychological disorders (Wu & Howard, 2007), the presence of neurological damage (Beauvais et al., 2002), a lack of treatment centers dedicated to inhalant abuse (Beauvais et al., 2002), and an incomplete understanding of the mechanisms of action of many inhalant drugs (Shen, 2007). Furthermore, as a result of these limitations, treatment centers that do accept

inhalant abusers are often pessimistic about the successful rehabilitation of these individuals (Beauvais et al., 2002).

Despite barriers to effective treatment, some recent progress has been made with respect to the primary prevention of inhalant abuse. Primary prevention focuses on stopping potential users from trying the drug. A recent study examined the response of junior high students to anti-inhalant messages (Crano, Siegel, Alvaro, & Patel, 2007). This study exposed inhalant users, vulnerable nonusers, and resolute nonusers to a variety of different anti-inhalant advertisements. The researchers discovered that indirect messages (i.e., messages not overtly targeting the viewer) were more effective in influencing users and vulnerable nonusers. Furthermore, users responded more negatively to messages that threatened physical harm (as opposed to negative social consequences) as a result of inhalant abuse. Finally, vulnerable nonusers were affected more by messages from someone their age, while users were affected more by messages from an adult doctor. The findings of this study can be used to construct more influential and persuasive anti-inhalant messages based upon the target audience. Anti-inhalant messages that are more effective in overcoming users' resistance have greater potential to influence users to quit before they develop patterns of abuse, dependence, and brain impairment.

Despite the incomplete understanding of the mechanisms of action through which inhalants exert their effects, some preliminary pharmacological treatments for inhalant abuse are under investigation. Some research suggests that inhalants act as 5-HT3-A receptor agonists, similar to one of the known mechanisms of action of alcohol (Lopreato et al., 2003). Based on the success of some 5-HT3 receptor antagonists in decreasing alcohol consumption in rodent models and human test subjects, these researchers suggest that antagonism of 5-HT3 receptors may also decrease inhalant abuse (Lopreato et al., 2003). A single subject case study involving administration of lamotrigine (Lamictal) may support this hypothesis. Lamotrigine blocks voltage gated sodium channels, modulates the release of glutamate and aspartate, inhibits dopamine uptake, blocks 5-HT3-A receptors, and may have some effect on calcium channels (Shen, 2007). In this study, administration of lamotrigine to a chronic inhalant abuser decreased craving symptoms and helped the subject remain abstinent throughout the six-month experimental period (Shen, 2007). While these studies show promise for the future of the pharmacological treatment of inhalant abuse, more research must be conducted to investigate the reliability and efficacy of lamotrigine.

There are other research studies that have examined the pharmacological treatment of withdrawal symptoms of inhalant dependence. In a brief three-

subject case series study, Muralidharan et al. (2008) administered baclofen, a GABA-B agonist, in order to reduce or eliminate the withdrawal symptoms of inhalant dependence. Baclofen's agonism of GABA-B receptors appears to modulate the activity of alcohol (and possibly inhalants) on GABA-A receptors. The three subjects in this study all reported a significant decrease in withdrawal symptoms as well as in inhalant cravings within 48 hours of initiation of baclofen treatment. Furthermore, the symptoms and cravings remained low throughout the course of treatment. The researchers also suggest that baclofen may be useful in relapse prevention.

A large number of drug treatment center directors believe that the treatment of inhalant abusers takes longer than recovery from other types of substance abuse, that it is more difficult, and thus is overall less successful (Beauvais et al., 2002). Furthermore, due to the extended length of detoxification, the high comorbidity of mental disorders with inhalant abuse, and the wide range of social dysfunction seen in many inhalant abusers, many treatment center professionals believe that standard treatment programs, which are highly structured with a brief progress schedule, will not be effective for the treatment of inhalant abusers (Beauvais et al., 2002). Many directors of treatment centers also noted that by the time detoxification of chronic users was complete and effective treatment could begin, the patient had to be discharged, often due to third-party payer restrictions on length of treatment (Beauvais et al., 2002). Moreover, many treatment providers believed that chronic inhalant abusers suffered significant neurological damage, which negatively affected their optimism for a positive outcome for these patients (Beauvais et al., 2002). Therefore, the inclusion of professionals trained in neuropsychological assessment and rehabilitation is important in the treatment of chronic inhalant users. These professionals are essential for detecting whether neurological damage has occurred, how extensive the damage may be, and the development of successful techniques for the neuropsychological rehabilitation of these individuals to help them overcome or compensate for their deficits. Furthermore, with as many as 70 percent of inhalant users meeting the criteria for one or more psychological disorders, therapy and/or pharmacological treatment may be necessary to effectively treat the inhalant abuse. The wide range of social dysfunction present in inhalant users must be addressed as well, and young users typically require significant case management (Beauvais et al., 2002). Education is also an important factor in treatment, as more than 27 percent of drug treatment center directors surveyed indicated that a lack of knowledge by the general public and treatment professionals significantly compromised effective treatment (Beauvais et al., 2002).

CONCLUSION

Inhalants are a diverse group of chemicals that share a common route of administration and are not included in other categories of drugs of abuse that are inhaled (i.e., nicotine, marijuana, or crack cocaine). Inhalants can be divided into three groups of chemicals: volatile substances, nitrous oxide, and nitrites. Common methods of administration include "sniffing," "huffing," "spraying," and "bagging." Inhalant use began to receive public attention in the 1960s, and has since become a significant problem, particularly among young people. Use varies among different ethnic groups. While Hispanics and Native Americans show higher-than-average prevalence rates, African Americans show exceptionally low prevalence rates. Inhalant abuse is also particularly high in Alaska. Furthermore, a high percentage of inhalant users have one or more comorbid mental disorders, with major depression and antisocial personality disorder being the most common.

The mechanisms of action of the volatile substances are not completely understood. However, current research indicates that they fluidize cell membranes, enhance the activity of GABA-A and glycine receptors, inhibit the activity of NMDA glutamate receptors, activate dopamine neurons in the ventral tegmental area, and enhance the action of 5-HT-3A receptors. Nitrous oxide is thought by some to be mediated via the actions on a variety of opiate receptors, although others dispute this hypothesis. It also inhibits the action of NMDA glutamate receptors. Nitrites induce central and peripheral vasodilation and the relaxation of smooth muscle tissue.

The acute effects of inhalant use include intoxication and sudden sniffing death syndrome. In volatile substances, intoxication includes drowsiness, diplopia, dysarthria, ataxia, disorientation, and in higher doses, visual hallucinations and delusions. Nitrous oxide intoxication can induce euphoria, tingling, numbness, dizziness, hallucinations, warmth, and short-term memory loss. Nitrite intoxication results in euphoria, floating sensations, increased tactile sensitivity, disinhibition, heightened sexual arousal, relaxation of the anus, and prolonged orgasm. Sudden sniffing death syndrome occurs when a volatile substance sensitizes the heart to the action of epinephrine and the user is then startled. The subsequent release of epinephrine into the sensitized heart can produce a fatal cardiac arrhythmia. This can potentially happen at any time, even during an individual's first use.

The chronic use of inhalants can have potentially damaging effects on multiple organ systems. In the volatile substance group, these can include hepatotoxicity, pulmonary disease, heart complications, renal dysfunction, and bone marrow suppression. Chronic abuse of nitrites can have negative effects on the

immune system. The effects of prolonged use of inhalants upon the central nervous system include cerebellar atrophy, diffuse destruction of white matter, and the possibility of dementia. Chronic inhalant abuse may also result in deficits in auditory discrimination, psychomotor speed, visuo-motor functioning, and memory. Furthermore, a condition called organic solvent neurotoxicity, which is characterized by a variety of cognitive and mood disturbances may develop. Inhalant use by a mother can also affect an unborn child. There are documented impairments in both animal and human models of the disorder, and in human infants, a condition similar to fetal alcohol syndrome can occur. Moreover, the child can also show withdrawal symptoms upon birth if the mother has recently used inhalants.

Withdrawal of inhalants is not included as a diagnostic entity in the *DSM-IV–TR*, but withdrawal effects have been documented. They include anhedonia, irritability, sleep disturbances, psychomotor slowing, dry mouth, lacrimation, craving, headaches, and heart palpitations. This withdrawal syndrome may be treated with some success by using benzodiazepines or baclofen.

Treatment of inhalant abuse is complicated and may be confounded by many factors. However, important areas to address include primary prevention, pharmacological treatment, neuropsychological evaluation and rehabilitation, treatment of comorbid mental disorders, and education about the disorder. Pharmacological intervention is currently rather limited, but there has been preliminary success in treating an inhalant abuser with lamotrigine.

Inhalant abuse continues to be a serious problem, particularly among young people. The incomplete knowledge of the mechanisms of action for some of these substances, combined with insufficient resources for the treatment of the abusers and the complexity of the issues surrounding inhalant abuse, make it difficult for these individuals to receive the help that they need. Further research into these topics is warranted and necessary, and more resources must be devoted to the study and treatment of inhalant abuse to effectively combat this growing problem.

Chapter **12**

The Effects and Abuse Potential of GHB: A Pervasive "Club Drug"

Bethany L. Waits, BA, and Paula K. Lundberg-Love, PhD

Gamma-hydroxybutyrate, or GHB, is a widely used drug whose popularity has increased dramatically since its discovery in the late 1960s (Miotto et al., 2001). Once ingested, GHB acts by depressing or downregulating the activity of the central nervous system (CNS), including the brain and the spinal cord, and its effects are similar to other CNS depressants such as alcohol and benzodiazepines (BZD). Although GHB was initially synthesized for use as an intravenous anesthetic for surgical procedures, it has since been marketed therapeutically as a dietary supplement, an anabolic agent, and a drug for the treatment of narcolepsy. Moreover, it has been implicated in preclinical trials for the relief of withdrawal symptoms for several addictive substances, particularly alcohol (Julien, 2005; Levinthal, 2006). In its purest form, GHB is a white powdery substance that is soluble in water (Gonzalez & Nutt, 2005). Although GHB can be obtained as a tablet or a capsule, it is usually distributed, both legally and illegally, as a colorless, odorless, and tasteless solution, and it is typically packaged in small bottles, similar in size to those used for shampoo in hotel rooms (Meyer & Quenzer, 2005). Thus, while oral administration is the most common form of ingestion associated with GHB, the drug is sometimes injected directly into the bloodstream (Jones, 2001).

While GHB was initially developed for medicinal purposes, in recent years it primarily has become a drug of abuse, and is frequently referred to as a "club drug" (Britt & McCance-Katz, 2005). According to Levinthal (2006), a *club drug* is a term that describes a group of drugs utilized primarily by young adults at dance parities, or "raves," which occur at night clubs. Other common "club

drugs" include MDMA (ecstasy), ketamine, Rohypnol, methamphetamine, and LSD (Britt & McCance-Katz, 2005, Levinthal, 2006). The club drugs, including GHB, are readily accessible to purchase at raves and are often combined with other substances to heighten their effects. For instance, one study of GHB users found that 53 percent combined GHB with ecstasy, 50 percent with marijuana, 43 percent with cocaine, 40 percent with amphetamines, and 37 percent with alcohol. The same study reported that 40 percent of the participants used GHB intentionally to increase, or extend, the "high" from other drugs. Overall, 71 percent mentioned using GHB with other substances (Miotto et al., 2001).

In addition to raves and night clubs, GHB can be obtained illegally on the street and on the Internet (Britt & McCance-Katz, 2005; Nicholson & Balster, 2001). Common street names include liquid X, liquid E, grievous bodily harm, G, Georgia home boy, G-rrifick, salty water, scoop, somatomac, gamma 10, gamma g, goop, easy lay, cherry meth, blue nitro, nature's quaalude, GH revitalize, revivarant, renew/trient, and fantasy (Britt & McCance-Katz, 2005; Julien, 2005; Levinthal, 2006). At times, it has also been referred to as "liquid ecstasy" due to its ability to produce a state of euphoria similar to MDMA (Jones, 2001). Recently, GHB has become indirectly available on the Internet in the form of "chemistry kits." These kits contain the biological precursors of GHB, gamma-butyrolactone (GBL) and 1, 4,-butanediol (BD), and instructions that describe how to convert GBL or 1, 4,–BD into GHB (Nicholson & Balster, 2001). Furthermore, according to Jones (2001), several Web sites have GHB "recipes" that illustrate ways to produce GHB in a household kitchen.

The increase in the sale and distribution of GHB has been documented in several studies conducted by the U.S. government. The Drug Abuse Warning Network (DAWN) is a national surveillance agency controlled by the U.S. Substance Abuse Mental Health Service Administration that collects data concerning drug-related visits to hospital emergency rooms throughout the United States. DAWN also documents information concerning drug-related fatalities reported by medical examiners and coroners. According to DAWN, in 1994, 683 emergency departments at various hospitals recorded GHB-related visits. By 2000, this number rose to 4,969 documentations of GHB-related incidents, which is approximately seven times the number reported in 1994 (Meyer & Quenzer, 2005; Rosenthal & Solhkhah, 2005). Due to the increase in information concerning GHB misuse, it is important to discuss the hazardous effects and abuse potential associated with this drug. A review of the current research concerning GHB's history, therapeutic indications, and mechanisms of action in the brain will be discussed. Additionally, the behavioral and physiological effects of GHB as well as its toxicity, withdrawal effects, and approaches to treatment considerations will be addressed in the following sections.

HISTORY

The pharmacological properties of GHB were first reported in 1960 by Dr. Henri Laborit, a French scientist well known for his discovery of Thorazine, the first antipsychotic drug (Meyer & Quenzer, 2005). As a surgeon, Laborit was interested in identifying a compound similar to gamma-aminobutyric acid (GABA), a newly discovered inhibitory neurotransmitter that depressed the activity of the CNS. If such a substance could be identified, Laborit speculated, it would produce sedation and might be utilized as an anesthetic in surgical procedures (Gonzalez & Nutt, 2005; Meyer & Quenzer, 2005). After its synthesis was achieved, it was apparent that GHB was a GABA analog that easily crossed the blood brain barrier (a semipermeable membrane that prevents nonlipid soluble substances from entering the brain). Thus, GHB was capable of directly affecting the brain's biochemistry (Carlson, 2007). Early studies on laboratory animals confirmed Laborit's suspicion that GHB produced sedation and anesthesia. Based on this information, GHB was widely used as an anesthetic in Europe, and is still used for this purpose in some European countries (Meyer & Quenzer, 2005). Recently, however, its use has declined as new studies have revealed that its anesthetic effects are not as therapeutic as other drugs that are currently available, due in part to its lack of analgesic (pain-reducing) properties (Gonzalez & Nutt, 2005).

In the United States, GHB received little attention until the 1980s, when health food stores across the nation began to market the drug as a nutritional supplement and as a sleep aid. Due to manufacturers' claims that GHB had the potential to reduce body fat and increase muscle mass, it became a highly sought after drug (Meyer & Quenzer, 2005). Advertisements stated that GHB had a low risk of toxicity and little danger of dependence, and because of these endorsements, GHB soon became popular among many different groups (Miotto et al., 2001). For instance, its use was particularly prevalent among bodybuilders who used GHB as an allegedly safe alternative to anabolic steroids (Jones, 2001). According to researchers, the most frequent users of GHB, other than bodybuilders, included athletes, gym members, models, and habitual travelers across time zones (Gonzalez & Nutt, 2005). Unfortunately, the distribution and sale of GHB was virtually ignored by the medical community and by public health officials for approximately a decade after it was first released in the United States (Nicholson & Balster, 2001). However, by the 1990s, the Food and Drug Administration (FDA) began to receive numerous reports concerning GHB-related illnesses (Meyer & Quenzer, 2005). For instance, seizures and comas were frequently reported by those using supplements containing GHB (Levinthal, 2006). Additionally, the FDA became

concerned about the dramatic increase in GHB use for sedation and growth enhancement. Many agreed that GHB should be prescribed by a medical doctor to minimize the dangers of over-the-counter misuse (Meyer & Quenzer, 2005).

At the same time, GHB began to be used as a date rape drug, often in combination with alcohol, and such reports began to increase public awareness about its dangerous effects (Julien, 2005; Meyer & Quenzer, 2005; Nicholson & Balster, 2001). Because GHB is a colorless, odorless, and virtually tasteless liquid, it can easily be slipped into alcoholic beverages without it being detected by the drinker (Levinthal, 2006). Like other date-rape drugs (i.e., Rohypnol), GHB's ability to produce unconsciousness, especially in combination with alcohol, has been the primary reason for its use in sexual assault. Moreover, because GHB is rapidly absorbed in the body, unconsciousness persists for several hours after ingestion, making it impossible for a victim to resist the attack (Britt & McCance-Katz, 2005). Although little evidence suggests that GHB enhances sexuality, many believe that it disinhibits sexual inhibitions, making sexual assault easier to accomplish. Furthermore, because GHB is excreted from the body in approximately 12 hours, detection of the drug in blood or urine samples is very difficult.

Thus, the victim's attempts to prosecute are often unsuccessful due to lack of medical evidence (Jones, 2001).

Few published cases exist concerning GHB's alleged role in date rape (Gable, 2004). In one study that investigated cases of drug-related sexual assault, GHB was implicated in only 4.1 percent of the total number evaluated (Nicholson & Balster, 2001). According to Gable (2004), this is not necessarily an indication that GHB is rarely used in date rape. Because few laboratories have the capacity to determine the presence of GHB in the body, it is difficult to establish the true prevalence of GHB involved in cases of sexual assault (Gable, 2004).

These types of events led the FDA to designate the drug as a Schedule I controlled substance in March 2000 (Gable, 2004). As a result, GHB could no longer be obtained over the counter, and it became illegal under FDA regulations to possess or manufacture the drug. However, in 2002, the FDA approved GHB for the treatment of narcolepsy under the trade name Xyrem, and it became a Schedule III controlled substance when utilized for this purpose (Meyer & Quenzer, 2005). According to Nicholson and Balster (2001), GHB's current FDA regulation is similar to tetrahydrocanabinol (THC), or marijuana. For example, THC is classified as a Schedule I controlled substance, but the FDA-approved formulation Marinol, which is used to treat nausea associated with chemotherapy, is designated as a Schedule III drug.

THERAPEUTIC INDICATIONS FOR GHB

As previously mentioned, GHB has been utilized as an anesthetic, a growth promoter, a dietary supplement, a treatment for narcolepsy, and a medication to reduce the adverse effects associated with certain types of drug withdrawal (Hernandez, McDaniel, Costanza, & Hernandez, 1998). Even so, the importance of understanding the biological basis concerning GHB's therapeutic indications cannot be disregarded. For instance, GHB's use as a growth promoter and weight loss supplement was largely supported by research demonstrating its ability to enhance the release of human growth hormone. This effect is a result of GHB's ability to increase stages 3 and 4 sleep, also known as slow-wave sleep (SWS), which is a deeper, more restorative sleep state (Carlson, 2007). Since human growth hormone is primarily released during SWS, GHB indirectly increases its release by amplifying the amount of slow-wave sleep an individual experiences through the night (Gonzalez & Nutt, 2005). Thus, by enhancing the level of growth hormone in the body, it was assumed that GHB ingestion would increase overall muscle mass, similar to anabolic steroids (Rosenthal & Solhkhah, 2005). Although manufacturers of GHB-containing products relied on this research to assert its efficacy (Nicholson & Balster, 2001), there is no scientific evidence supporting GHB's capacity to increase muscle development significantly.

While GHB's efficacy as a growth promoter remains equivocal, it appears to be a useful medication for the treatment of narcolepsy. Narcolepsy is a genetic disorder whose symptoms typically appear during adolescence. It is characterized by excessive daytime sleepiness and a disordered sleep stage architecture with rapid eye movement (REM) sleep occurring at sleep onset (Julien, 2005). One of the most frequent daytime symptoms associated with narcolepsy is cataplexy, a complete loss of muscle tone resulting in paralysis. When a cataplexy attack occurs, a fully awake individual will suddenly fall to the ground unable to move (Carlson, 2007). According to Julien (2005), approximately 60–75 percent of patients with narcolepsy experience cataplexy, and it is usually precipitated by strong emotional reactions such as laughter, anger, surprise, or excitement.

When searching for possible substances to treat narcolepsy, researchers speculated that GHB's ability to promote sleep might eliminate certain symptoms of the disorder, namely, cataplexy attacks. For instance, oral doses of approximately 30–50 mg of GHB produce a state of somnolence, which is readily reversible by external events and is virtually indistinguishable from normal sleep (Nicholson & Balster, 2001). Furthermore, the results of sleep studies evaluating participants' behavior and electroencephalogram (EEG)

patterns suggest that GHB-induced sleep mimics physiological sleep by increasing both SWS and REM sleep (Galloway et al., 1997; Rosenthal & Solhkhah, 2005). GHB's ability to produce a normal sleep state underlies its effectiveness in alleviating the symptoms of narcolepsy. Indeed, when GHB is taken at night, it consolidates sleep, restores sleep patterns to normal levels, and reduces hypnagoic hallucinations (i.e., vivid dreams that occur at sleep onset). Also, GHB improves daytime symptoms by reducing cataplexy attacks and daytime sleepiness (Nicholson & Balster, 2001). To date, the only FDA-approved therapeutic indication of GHB is for the treatment of cataplexy attacks associated with narcolepsy. As mentioned earlier, it is distributed under the trade name, Xyrem, and is manufactured by Jazz Pharmaceuticals (Rosenthal & Solhkhah, 2005).

Currently, researchers are investigating GHB's effectiveness in treating the withdrawal symptoms of several addictive substances, specifically alcohol, opiates, and cocaine (Gonzalez & Nutt, 2005). Support for this hypothesis has been provided by Gallimberti, Schifano, Forza, and Miconi (1994), who found GHB reduced alcohol withdrawal symptoms, including tremors and seizures, in laboratory rats. In clinical studies, GHB has been shown to diminish depression, nausea, and anxiety among alcoholics in detoxification programs (Jones, 2001). Furthermore, the long-term usefulness of GHB among alcoholics in detoxification suggests that the drug significantly increases the number of abstinent days experienced by these individuals (Galloway et al., 1997). GHB also has been found to ease the abstinence syndrome produced by opiate withdrawal. Researchers suspect that GHB may stimulate the release of endogenous opiates, thereby relieving the symptoms associated with opiate abstinence (Nicholson & Balster, 2001). Additionally, one preclinical study conducted by Fattore, Martellotta, Cossu, and Fratta (2000) found data to support the use of GHB for the treatment of cocaine addiction. However, no other studies have replicated these findings. While the use of GHB for the treatment of various withdrawal symptoms is promising, it has not yet been approved by the FDA for the treatment of either alcohol or opiate withdrawal. Therefore, more research must be conducted to determine whether the treatment of certain types of drug withdrawal is, indeed, a therapeutic indication of GHB (Addolorato, Caputo, Capristo, Stefanini, & Gasbarrini, 2000).

MECHANISMS OF ACTION

According to Meyer and Quenzer (2005), two competing hypotheses exist concerning GHB's mechanism of action, or sites of action, in the brain. The first theory states that GHB is an agonist at the GABA-B receptor. An agonist is any drug that binds to a specific receptor and either facilitates or enhances

the naturally occurring effects of that particular receptor. As mentioned previously, GABA, or gamma-aminobutryic acid, is an inhibitory neurotransmitter that depresses, or downregulates, the activity of the central nervous system (Meyer & Quenzer, 2005). Thus, a GABA agonist is any substance that activates GABA receptors causing a CNS-depressant effect. There are two types of GABA receptors in the human brain: GABA-A and GABA-B receptors. Many CNS-depressants (i.e., alcohol, benzodiazepines, and barbiturates) stimulate certain subunits on the GABA-A receptor, and cause behavioral effects such as sedation and relief from anxiety. The GABA-B receptor, when activated, leads to similar behavioral effects, and it is hypothesized that GHB acts on this receptor. Evidence supporting this assumption is based on research showing that the behavioral and physiological effects of GHB in animals can be inhibited by GABA-B receptor antagonists. GHB's anesthetic properties and ability to produce sedation may be the result of its GABA-B receptor agonist properties (Miotto et al., 2001; Meyer & Quenzer, 2005).

The second theory concerning GHB's mechanism of action states that its effects are mediated by specific GHB receptors found in the human brain (Kemmel et al., 1998; Meyer & Quenzer, 2005). This hypothesis was first introduced by Roth and Giarman, who demonstrated that GHB was an endogenous substance and, therefore, might act as a neurotransmitter or neuromodulator in various brain regions (Galloway et al., 1997). Current research indicates that GHB fulfills many of the characteristics associated with neurotransmitters or neuromodulators. For instance, it is released in a calcium-dependent manner. It possesses a distinct reuptake system that transports it into synaptic vesicles. It has specific enzymes that remove it from the synaptic cleft after it is released, and, as previously discussed, it has its own particular receptor sites throughout the brain (Meyer & Quenzer, 2005; Nicholson & Balster, 2001). Furthermore, in rats, monkeys, and humans, GHB-binding receptor sites have been identified in the hippocampus, caudate nucleus, cerebral cortex, and cerebellum. In addition, certain substances have been synthesized in laboratories that specifically bind to GHB receptors. One such substance, NCS-382, is a selective antagonist at GHB receptors, blocking GHB's effects in the brain (Meyer & Quenzer, 2005). This research, along with studies supporting GHB's role as a GABA-B receptor agonist, provide a strong scientific foundation in the understanding of GHB's mechanisms of action.

BEHAVIORAL AND PHYSIOLOGICAL EFFECTS

The behavioral and physiological effects associated with GHB are largely dependent on the amount of the drug an individual ingests. When adminis-

tered for therapeutic purposes, typical doses of GHB range from 15 to 30 mg. Unfortunately, GHB is frequently misused as a recreational drug, and regular users have been known to ingest as much as 57 to 71 mg (Nicholson & Balster, 2001). According to Jones (2001), addiction to GHB is highly probable if an individual consumes between 30 and 50 mg on a daily basis. Therefore, like many other substances, GHB's therapeutic effectiveness and potential for abuse is influenced by the dosage of the drug that a person takes.

Although GHB results in many behavioral and physiological effects, it is typically abused for its ability to induce euphoria, or an "out-of-body" high (Levinthal, 2006). Many researchers believe that this "euphoric" effect underlies its potential for abuse (Julien, 2005). Experiments with laboratory animals, using conditioned place preference, have supported the hypothesis that GHB has reinforcing effects. Conditioned place preference, or CPP, is an experimental procedure in which an animal is given a drug, in this case GHB, and is then placed in a specific compartment to create an association between that environment and the effects of the drug. The animal is also given a placebo and placed in a different compartment. After this place-conditioning is established, researchers allow the animal to have access to both compartments at the same time, and measure the amount of time the animal spends in each environment. Thus, if the animal finds the drug rewarding, it spends the majority of its time in the compartment associated with the drug (Meyer & Quenzer, 2005). In a study by Martellotta, Fattore, Cossu, and Fratta (1997), GHB was shown to induce a CPP, meaning that the laboratory animal preferred the compartment paired with GHB administration to the compartment paired with the placebo. However, it took approximately six drug exposures for a CPP to occur, which is significantly more than other addictive drugs, such as cocaine and the opiates, which produce a CPP after two exposures. This finding suggests that while GHB can be classified as a reinforcer, its effects are much weaker than other highly rewarding drugs. Moreover, those that abuse GHB typically believe that it acts as an aphrodisiac, and that it has the ability to increase or enhance sexual experiences (Julien, 2005; Rosenthal & Solhkhah, 2005). While other substances, like alcohol, have been reported to heighten sexuality, there is no evidence that GHB, or other depressants, aid in sexual performance (Julien, 2005).

When a person consumes GHB, it takes approximately 5 to 15 minutes for it to cross the blood brain barrier, and affect behavior. Theses effects can last between four and seven hours. However, in some cases, users report dizziness for up to two weeks after GHB ingestion (Galloway et al., 1997). Small doses of GHB, 10 to 20 mg or less, typically produce muscle relaxation and relief from anxiety. Additionally, disinhibition, sociability, and light inebriation have been

reported. Those using GHB at low doses often describe an alcohol-like experience, with behavioral effects similar to those experienced after drinking two alcoholic beverages (Gable, 2004). Several clinical studies suggest that GHB at low doses has no effect on attention, vigilance, alertness, short-term memory, or psychomotor skills. The only adverse symptoms mentioned by participants included slight dizziness (Nicholson & Balster, 2001). At moderate doses, between 20 and 40 mg, GHB's behavioral and physiological effects are accentuated. For instance, moderate doses of GHB generally induce sleep and produce euphoria (Rosenthal & Solhkhah, 2005). In addition, other common symptoms include physical disequilibrium, grogginess, tactile sensitivity, increased gag reflex, nausea, and vomiting (Gable, 2004; Gonzalez & Nutt, 2005). According to Nicholson and Balster (2001), at 30 to 40 mg, users may experience mild hypothermia, loss of peripheral vision, confusion, agitation, enuresis, myoclonic jerks, tremors, ataxia, aggression, and hallucinations. Furthermore, as doses increase above 40 or 50 mg, users often become unconscious and may experience severe respiratory depression (Levinthal, 2006). Although high doses of GHB are not generally associated with seizures, some users have reported the occurrence of tonic-clonic (i.e., grand mal) seizures after ingestion of 60 to 70 mg of GHB. Furthermore, as doses increase above 70 mg, individuals often experience a state of unarousable sleep or coma, which can last from approximately one to five hours. Researchers speculate that a lethal dose of GHB is approximately 5–15 times higher than a dose producing unconsciousness (Nicholson & Balster, 2001). Finally, in several rare cases, high doses of GHB, over a period of time, have led to Wernicke-Korsakoff syndrome, which is characterized by a deficiency in thiamine and is often observed in alcoholics (Friedman, Westlake, & Furman, 1996; Gonzalez & Nutt, 2005).

In a noteworthy study conducted by Miotto and colleagues (2001), GHB users were interviewed about the subjective effects of the drug. Of the 42 participants in the study, 75–100 percent reported euphoria, feelings of happiness, increased sexuality, increased well-being, heightened sense of touch, relaxation, talkativeness, tranquility, disinhibition, pleasant drowsiness, and optimism after using GHB. Furthermore, 50–74 percent experienced increased intensity of orgasms, increased energy, giddiness, sensitivity to sound, sweatiness, and loss of consciousness. A smaller percentage, 25–49 percent mentioned symptoms of nausea, auditory and visual hallucinations, headaches, frequent urination, and vomiting. Finally, 1–24 percent of those who participated experienced amnesia or seizures. This research suggests that GHB has the potential to cause serious health effects in individuals who consume large quantities of the substance. More information regarding GHB's toxic effects will be discussed in the following section.

TOXICITY

The term *toxicity* refers to a chemical substance's ability to induce functional or anatomical damage to a living organism. While the toxic effects of many drugs have been documented in the medical literature, GHB's toxicity has been more difficult to determine. This is largely due to the fact that certain amounts of GHB naturally occur in the human brain. Also, GHB is rapidly metabolized after ingestion, giving researchers less time to determine its biological effects (Gable, 2004). Because many physicians have little experience with GHB toxicity, the incidence rates of GHB use are difficult to obtain. Only a few laboratories have the capability to detect the presence of GHB in the body, and clinicians can rarely determine actual blood or tissue levels of the drug (Hernandez et al., 1998; Nicholson & Balster, 2001). Moreover, if a laboratory does have the ability to test for GHB, only a specific type of urinalysis, which tests for the presence of one drug, can determine if GHB was ingested by the individual (Gable, 2004). According to Nicholson and Balster (2001), this makes the evaluation of GHB's toxicity very difficult, because the majority of cases involving hospitalization involve the co-ingestion of other substances, such as alcohol.

While only a limited amount of information in the medical literature exists concerning GHB toxicity, evidence obtained from users, clubs, health food stores, gyms, and the street suggest that the prevalence of GHB overdose is much higher than previously suspected (Hernandez et al., 1998). For example, among one sample of first-time GHB users, approximately 53 percent overdosed on the substance (Degenhardt, Darke, & Dillon, 2003). This percentage increased to 75 percent among users who had ingested GHB on more than 15 occasions (Gonzalez & Nutt, 2005). Typically, an overdose from GHB occurs if an individual takes multiple doses over a short period of time, if there is a higher concentration of GHB in the bottle than expected, or if the drug is taken in combination with alcohol or other sedative drugs (Meyer & Quenzer, 2005).

GHB toxicity, or overdose, can lead to a wide variety of medical conditions, which in some cases, may be life-threatening (Hernandez et al., 1998). Since GHB is a depressant, it is not surprising that the most common manifestations of toxicity involve cardiac, respiratory, and central nervous system depression (Gonzalez & Nutt, 2005). Indeed, a nonfatal overdose of GHB is often characterized by respiratory depression and an unarousable coma. According to Gonzalez and Nutt (2005), unconsciousness may be so unexpected that the patient may be injured as a result of the sudden loss of muscle tone. Although individuals typically regain consciousness after five hours, if other sedatives, such as alcohol, have been taken in combination with GHB, an individual may remain in a comatose state for up to eight days (Nicholson & Balster, 2001).

However, it is not uncommon for patients spontaneously to regain consciousness after several hours. As they become more alert, many report feelings of extreme agitation and combativeness (Rosenthal & Solhkhah, 2005). Clearly, respiratory depression and coma are the most common consequences of GHB overdose; other symptoms have been reported by patients. These include stupor, delirium, nausea, vomiting, vertical nystagmus, hypotension, tachycardia, tremor, anxiety, ataxia, jerking movements, bradycardia, disorientation, and muscle stiffening (Gonzalez & Nutt, 2005; Julien, 2005; Miotto et al., 2001). Additionally, seizures have been reported in rare cases (Meyer & Quenzer, 2005).

As mentioned, the toxic effects of GHB are greatly potentiated when combined with other substances, such as alcohol, opiates, barbiturates, and benzodiazepines (Miotto et al., 2001). Unfortunately, many individuals that abuse GHB do so in order to heighten the effects of other abusive drugs. For instance, the euphoric effects produced by alcohol and some stimulants are enhanced when combined with GHB (Nicholson & Balster, 2001). Additionally, when taken with other club drugs such as ketamine and ecstasy, GHB can reduce several of the adverse effects, such as teeth grinding and jaw-clenching, while simultaneously increasing euphoria and disinhibition (Rosenthal & Solhkhah, 2005). Thus, it is not surprising that many users who overdose on GHB are also under the influence of other substances, often exacerbating GHB's toxicity. Indeed, an increase in the adverse reactions to GHB, when combined with other drugs, has been documented in several case reports of overdose victims. One group of researchers evaluated 88 cases of GHB overdose reported by the emergency room of San Francisco General Hospital. Of these cases, approximately 50 percent involved co-ingestion of one or more additional substances other than GHB. Furthermore, the most common substances taken with GHB included alcohol, amphetamine, and MDMA (Chin, Sporer, Cullison, Dyer, & Wu, 1998). While it is rare that an overdose of GHB will lead to death, the majority of GHB-related fatalities have been associated with other drugs of abuse. One death, reported by Ferrara, Tedeschi, Frison, and Rossi (1995), involved ingestion of GHB in combination with heroin. However, according to Gable (2004), GHB toxicity is the most life-threatening when mixed with alcohol.

WITHDRAWAL EFFECTS

Clinical evidence suggests that chronic use of GHB can produce severe withdrawal symptoms among habitual users (McDonough, Kennedy, Glasper, & Bearn, 2004). Those that consume regular doses of GHB at two- to four-hour intervals throughout the day are thought to be the most susceptible to

experiencing a withdrawal syndrome after discontinuation. Furthermore, many of the symptoms associated with GHB withdrawal are similar to the withdrawal symptoms of other CNS depressants (i.e., alcohol, barbiturates, and benzodiazepine). If an individual is also dependent on a substance other than GHB, the withdrawal syndrome associated with GHB may be more complicated (Rosenthal & Solhkhah, 2005). In general, an individual experiences withdrawal symptoms several hours after the last dose of GHB. However, these symptoms tend to worsen and typically last from 3 to 15 days (Julien, 2005). According to McDonough et al. (2004), the mean duration for GHB withdrawal is approximately 9 days, which is very similar to that of alcohol and other sedative-hypnotics. Several reports have characterized the withdrawal syndrome associated with GHB to occur in two phases. In the first phase (2–12 hours after the last dose), milder symptoms such as insomnia, tremor, anxiety, increased heart rate, confusion, and vomiting have been documented (Britt & McCance-Katz, 2005). According to Meyer and Quenzer (2005), the most common withdrawal symptoms initially seen in patients are insomnia, anxiety, and tremors. Additional withdrawal symptoms commonly seen during the first 12 hours include feelings of doom, sweating, craving for the drug, mood lability, abdominal cramping, heart palpitations, diaphoresis, tachycardia, and miosis (Gonzalez & Nutt, 2005; Jones, 2001; Rosenthal & Solhkhah, 2005). The second phase begins 2 to 3 days after the last dose of GHB, when symptoms become more severe (Britt & McCance-Katz, 2005). Disorientation, fever, horizontal nystagmus, severe agitation, confusion, seizures, paranoia, delusional thinking, and auditory or visual hallucinations have been reported among patients (Rosenthal & Solhkhah, 2005). In some severe cases, full-blown psychosis may develop, and it is not uncommon for many patients to experience delirium during withdrawal (Britt & McCance-Katz, 2005; Meyer & Quenzer, 2005). Indeed, patients who were heavy users prior to cessation are more likely to have withdrawal delirium than those who used the drug less frequently (McDonough et al., 2004). In a meta-analysis conducted by McDonough and colleagues (2004), 38 cases of GHB withdrawal were reviewed, and over half of the patients reported sustained delirium after discontinuation of GHB. In another study, withdrawal delirium and agitation were the most long-lasting symptoms and continued for approximately two weeks after the last dose of GHB (Miotto et al., 2001).

TREATMENT CONSIDERATIONS

In cases of GHB overdose, the most common form of treatment involves supportive medical care, often in the form of cardiovascular and respiratory assistance (Julien, 2005). However, according to Gonzalez and Nutt (2005),

for a patient to receive the best possible care, it is important to discover the amount of the drug that was ingested, as well as any other substances currently in the body. As mentioned, GHB toxicity often leads to unconsciousness and sometimes to unarousable coma. Respiratory support is often mandatory, but the majority of patients typically regain consciousness several hours after GHB overdose, and many are well enough to be discharged after waking. In a study conduced by Chin et al. (1998), similar findings were reported with approximately 13 percent of overdose patients requiring intubation. However, the majority of patients recovered within five hours and were discharged from the emergency department.

Although no specific antidote has been identified for the treatment of GHB overdose, several substances have been used in combination with cardiovascular and respiratory support (Julien, 2005). For instance, naloxone, or Narcan, a drug typically used to counter the effects of opiate overdose, has been utilized to reverse the comatose state associated with GHB toxicity (Jones, 2001). Other drugs such as physostigmine or neostigmine, acetylcholinesterase inhibitors, also have been effective in reviving patients. However, evidence suggests that using these drugs may induce more serious side effects (i.e., seizures). The benzodiazepine antagonist, Romazicon, used for the treatment of benzodiazepine toxicity, also has been administered to patients. Unfortunately, this drug has not proven effective in reversing GHB-related coma (Gonzalez & Nutt, 2005). Clearly, more research is required in order to establish an effective treatment for GHB overdose.

As with overdose, the withdrawal syndrome associated with GHB can be difficult to treat (Gonzalez & Nutt, 2005). According to McDonough et al. (2004), GHB detoxification is usually unplanned, and medical assistance is given only after patients are admitted to emergency departments in a state of crisis. Additionally, users who consume large doses of GHB, at short intervals, are often refractory to treatment during withdrawal, making it difficult for medical professionals to stabilize their symptoms. Even after the first two weeks of detoxification, life-threatening withdrawal symptoms may occur. Therefore, it is crucial for individuals to remain in the hospital for several weeks. If patients are allowed to return home too quickly, there is a high risk that they will relapse and recommence GHB use (Gonzalez & Nutt, 2005).

Several drugs have been implicated in the treatment of GHB withdrawal. These typically include benzodiazepines, mood stabilizers, antipsychotics, and at times, GHB substitutes. Usually, a benzodiazepine is the first drug of choice to suppress withdrawal symptoms (Gonzalez & Nutt, 2005). The most common BZDs prescribed to patients include Valium and Ativan (Glasper, McDonough, & Bearn, 2005). During the first few hours after admission, medical professionals monitor the individual and determine the amount of

BZD required to ease her symptoms. Once this dose has been established, it is given to the patient several times a day for approximately one to two weeks. After the second week, daily doses of BZD are reduced and eventually discontinued (Gonzalez & Nutt, 2005). Although BZDs are typically effective in treating symptoms, in extreme cases, an intravenous anesthetic, such as Propofol, may be administered to those that are unresponsive to high doses of benzodiazepines (Gonzalez & Nutt, 2005). Moreover, if a patient experiences withdrawal delirium, a mood stabilizer, such as Neurontin, is often combined with the BZD to decrease agitation (Miotto et al., 2001).

In addition to mood stabilizers, antipsychotics can be used in conjunction with BZDs to reduce the psychotic symptoms associated with GHB withdrawal (i.e., hallucinations, delusions, and paranoia) (Glasper et al., 2005). For instance, low doses of Haldol, an older antipsychotic, have been successful in alleviating several of these symptoms (Jones, 2001). Additional antipsychotics, such as Zyprexa and Clozaril, are effective in treating the hallucinations and paranoia often seen in patients undergoing withdrawal (Rosenthal & Solhkhah, 2005). Finally, a new alternative in the treatment of GHB withdrawal involves the use of Xyrem, a form of GHB used for the treatment of narcolepsy. During inpatient detoxification, the appropriate dose of Xyrem is given instead of benzodiazepines and then is slowly reduced based on the patient's needs. While this new treatment method is rarely used, it is suspected that its popularity may increase in the coming years (Gonzalez & Nutt, 2005).

CONCLUSIONS

GHB is a white powdery substance that is soluble in water, and is usually distributed, both legally and illegally, as a colorless, odorless, and tasteless solution. Although GHB has been used therapeutically as an anesthetic, a growth promoter, a dietary supplement, a treatment for narcolepsy, and a medication to reduce the adverse effects associated with withdrawal, in recent years it has primarily become a drug of abuse and is commonly referred to as a "club drug." Other common club drugs include MDMA (ecstasy), ketamine, Rohypnol, methamphetamine, and LSD. These drugs, along with GHB, are readily accessible for purchase at "raves" (i.e., dance parties) and are often combined with other substances to heighten their effects. Moreover, GHB can be obtained illegally on the street under the following names: liquid X, liquid E, grievous bodily harm, G, Georgia home boy, G-rrifick, salty water, scoop, gamma 10, gamma g, easy lay, and cherry meth. Recently, GHB has become indirectly available on the Internet in the form of "chemistry kits," which contain the biological precursors of GHB with instructions that describe how to convert the

precursors into the drug. These preceding events, along with GHB's alleged use in sexual assault, led the FDA to designate GHB as a Schedule I controlled substance in March 2000.

According to Meyer and Quenzer (2005), two competing hypotheses exist concerning GHB's mechanism of action in the brain. The first theory states that GHB is a GABA-B agonist, meaning that the drug activates GABA receptors causing a CNS-depressant effect. The second theory states that GHB's effects are mediated by specific GHB receptors found in the human brain. Current research indicates that GHB fulfills many of the characteristics associated with neurotransmitters or neuromodulators. These include its release in a calcium-dependent manner, its distinct reuptake system, and its own endogenous receptor system in the brain.

Furthermore, when an individual consumes GHB, it takes approximately 5 to 15 minutes for it to cross the blood brain barrier and affect behavior. Small doses of GHB typically produce muscle relaxation and relief from anxiety. Moderate doses of GHB induce sleep and euphoria, as well as physical disequilibrium, grogginess, tactile sensitivity, increased gag reflex, nausea, and vomiting. When doses increase above 40 or 50 mg, users often become unconscious and may experience severe respiratory depression. At toxic levels, GHB can produce unarousable coma and seizures. Other symptoms involved in GHB overdose include stupor, delirium, nausea, vomiting, vertical nystagmus, hypotension, tachycardia, tremor, anxiety, ataxia, jerking movements, bradycardia, disorientation, and muscle stiffening. Furthermore, when a patient is admitted to the hospital for GHB overdose, the most common form of treatment involves supportive medical care (i.e., cardiovascular and respiratory assistance). Drugs such as naloxone, physostigmine, neostigmine, and Romazicon have been given to patients in combination with supportive medical care to relieve the toxic effects of GHB.

Individuals that consume regular doses of GHB at two- to four-hour intervals throughout the day are thought to be the most susceptible to experiencing withdrawal after discontinuation. The most common withdrawal symptoms initially seen in patients include insomnia, anxiety, and tremors. As the withdrawal syndrome progresses, feelings of doom, sweating, craving for the drug, mood lability, abdominal cramping, heart palpitations, diaphoresis, tachycardia, and miosis occur. The most severe withdrawal symptoms that patients are likely to experience can involve fever, horizontal nystagmus, severe agitation, confusion, seizures, paranoia, delusional thinking, and auditory or visual hallucinations. Several drugs have been implicated in the treatment of GHB withdrawal. These typically consist of benzodiazepines, mood stabilizers, antipsychotics, and GHB substitutes. For instance, Valium and Ativan are the most common

BZDs prescribed to those in withdrawal. If a patient experiences withdrawal delirium, a mood stabilizer, such as Neurontin, is often combined with the BZD to decrease agitation. Additionally, antipsychotics can be used to reduce the psychotic symptoms associated with GHB withdrawal, and GHB substitutes (i.e., Xyrem) may be given instead of BZDs to reduce symptoms.

Chapter **13**

HIV and Addiction from an African Perspective: Making the Link

Mary Theresa Webb, PhD with Donald Omonge, BA

Since U.S. president George W. Bush announced the first AIDS awareness day in 2005, billions of U.S. dollars (President's Emergency Plan for AIDS Relief [PEPFAR]) and euro funds have gone into relieving the suffering of millions of Africans infected by the HIV virus and AIDS. African researchers and leaders came together in a conference in Dar Es Salaam, Tanzania, hosted by USG agencies through PEPFAR on August 29–31, 2005, to discuss alcohol/HIV risk behaviors and transmission in Africa. In a media presentation, Senior Technical Advisor and Prevention Technical Team Leader, Office of U.S. Global AIDS Coordinator Caroline A. Ryan, MD, MPH, stated that only 3 percent of all PEPFAR funding in African countries, notably Botswana and Rwanda, has supported programs that dealt with these alcohol-abusive behaviors that effect the transmission of the HIV virus through sexual contact.

All of the funded programs at that time were engaged in community forums and trainings to raise awareness. In Botswana, the community action forums had three components: the formation of a Citizen's Action Committee on Alcohol, the Botswana Alcohol AIDS Project, and the Botswana Movement against Destructive Decision (BMADD). BMADD held trainings for the health care sector on the issues of family dysfunction, co-dependency, alcohol use and abuse, depression, boundaries, grief, loss and bereavement, and self-worth/self-identity. In Namibia, Health Communication, in partner with Johns Hopkins University, held a series of community action forums in 38 sites across the country. Community leaders in all of the six areas surveyed for feedback noted that alcohol abuse combined with unemployment and poverty were

the main problems contributing to the spread of the HIV virus. Rwanda also held community discussions around the same time period.

In 2006, a year after this conference, the Global Outreach in Addiction Leadership and Learning (GOAL) Project, located in Pittsburgh, Pennsylvania, received the first in three rounds of a New Partner's Initiative in PEPFAR funding for supporting the Kenya-based Substance Abuse Rehabilitation and HIV/AIDS (SARAH) Network of grassroots projects to help in the prevention of the spread of the HIV virus by educating communities, teachers, clergy, probation officers, and others in the disease of addiction and its role in the spread of the virus. The Kenya SARAH Network is highlighted here.

MAKING THE LINK

In the World Health report of 2002, cited in the Resolution of the Fifty-eighth World Health Assembly (2006), the resolution pointed out that 4 percent of disease and 3.2 percent of all deaths are attributed to alcohol, and alcohol is the biggest risk factor in developing countries. The resolution called on member states to recognize the threats to public health and to implement programs to reduce the harmful use of alcohol. Presentations a year earlier at the African Regional Conference (sponsored by USG agencies, 2005), had pointed out the consequences of alcohol consumption for HIV transmission and progression: (1) alcohol consumption is a risk factor; (2) misuse of alcohol affects adherence to HIV medication regimens; and (3) there is increased risk because of the interaction between alcohol, noninjection and injection drug use. In Eastern and Southern Africa, estimated alcohol consumption per person aged 15 years or older is 16.6 liters with 43 percent of the entire population within this age bracket being drinkers (WHO, 2004).

Prior to the resolution from the World Health Report of 2002, injecting heroin was widely known to be a major risk factor in the spread of the HIV virus. Since the rise of independent autonomous African countries and the development of these countries in the twentieth century, alcohol consumption had became a greater risk than injecting heroin because alcohol use and misuse had been on the rise among both young and old (Odejide, 2006). Dr. Flisher at the University in Cape Town in South Africa, clearly defined the causes of harmful use: (1) personal factors, such as low self-esteem, depression, sensation seeking and genetics; (2) interpersonal factors, such as peer pressure, relationship problems, negative responses of health care providers, and other environmental influences; and (3) cultural factors and structural factors, such as poverty (Flisher, 2006). Dr. Kasirye, representing the Uganda Youth Development League, Kampala, Uganda, in the same journal (CRISA, 2006, p. 27) stressed that drinking alcohol increases the risk of being infected with

the HIV virus and that those who are under the influence of alcohol are less likely to be concerned about the use of condoms. Even domestic violence is on the increase in areas with high alcohol consumption.

Africa is second only to Eastern Europe in the level of absolute alcohol consumed, and eastern and southern African countries have the highest consumption per drinker in the world. Burundi, Nigeria, South Africa, Swaziland, and Uganda have the highest recorded per capita consumption (Ashley, Levine, & Needle, 2006, p. 193; Obot, 2006, p. 19). These researchers arrived at the consensus that interventions to lessen the spread of the AIDS virus must also target reducing alcohol consumption. They point out that many studies link alcohol use and sexual arousal, acting on that arousal, as well as condom nonuse increases the risk of HIV infection. Alcohol consumption also reduces adherence to antiviral medications and Tuberculosis medications as well as compliance to treatment (Ashley et al., 2006, p. 193). The same authors raised the issue of gender-based violence (GBV) or violence against women in this journal article (p. 195). The UN Population Fund (UNFPA) Gender Theme Group defines GBV as "violence involving men and women, in which the female is usually the victim; and which is derived from unequal power relationships between men and women. It includes, but is not limited to, physical, sexual and psychological harm" (UNFPA, [defined by United Nations Population Fund Gender Theme Group] 1998; Ashley et al., p. 195). In most African countries, GBV is about 40–60 percent. This explains the alarming rates of the rise of the HIV virus among women and children in Sub-Saharan African countries. This inequality of power was made vivid in a skit put on by a Kenyan team training area clergy in Kakamaga, Kenya, one of the towns in western Kenya. In the skit, a husband and wife were discussing what to do about a son's drinking and drug abuse. The husband sat in a chair while the wife sat on the floor at his feet, as it is the custom for the female to sit lower than the male. A peer-based support group, formed for women whose husbands drink too much in the Kisumu District of Kenya, meets in a mud hut. When this author visited with them, she asked the 15 young mothers and wives present how many had been tested for HIV/AIDS. Three women raised their hands. She asked the others what was keeping them from being tested. "We would be beaten," one member said. The rest nodded their heads in agreement. If any of these women do manage to sneak away to be tested and their tests prove positive, they will probably be shunned by their families and fellow villagers.

RECOMMENDATIONS

According to Ashley et al. (2006), the key step to addressing reducing the spread of HIV/AIDS is to reduce alcohol abuse. They recommend: (1) coalition building, (2) community empowerment, (3) professional capacity building

and evidence-based treatment accessibility, (4) national policies and interventions, and (5) changing alcohol-imbibing cultures and behaviors (p. 196). They advocate for changing socially acceptable African male drinking patterns, training public health officials, and school-based interventions. They recommend cross-training in HIV and addiction and voluntary counseling and testing (VCT) (Ashley et al., 2006).

In addition to Botswana, Nambia, and Rwanda, in Uganda churches partnering with the government and NGOS are encouraging alcohol abstinence as a way forward in reducing the spread of the HIV virus. This chapter will highlight a Kenya prevention model, the SARAH Network, funded by the GOAL Project under President Bush's New Partner's Initiative under PEPFAR, and a treatment model in Egypt that is having an impact in that African country.

THE SARAH NETWORK MODEL (KENYA)

In 2005, the Anglican Bishop for Western Maseno Province in Kenya invited a G.O.A.L. Project team to train Kenyans in addictive disease and its relationship to HIV/AIDS. Margaret Namirembe Oketch, a Kenyan leader, and her colleague, invited 52 potential local leaders, community workers, clergy, teachers, and probation officers to the Brackenhurst Conference Center near Limuru for a two-week training. An American all-volunteer professional team worked with Ms. Oketch to put together an addiction/HIV/AIDS training package that included dramatic skits, PowerPoint presentations, and modeling 12 Step recovery and HIV/AIDS support groups (AA and Al-Anon) during the first week of the training. During the second week, the participants grouped themselves by various interests and worked together to prepare their action plans (mini proposals) that they presented to the whole group and made a commitment to follow through with their plans. Meanwhile, the combined GOAL/Kenya team formed a model structure for supervision and follow-up (Figure 13.1) that gave birth to the SARAH Network.

The SARAH Network can be a model for other African countries faced with the escalating rate of HIV/AIDS due to substance abuse addiction because it meets most of the guidelines recommended by Ashley et al. (2006) for successfully reducing the impact of risky behaviors due to the abuse of alcohol. Two recommendations, coalition building and community empowerment, are listed with examples.

A coalition of grassroots projects make up the SARAH Network. The Aniga Women's Initiative is located in western Kenya, in the Kisumu dis-

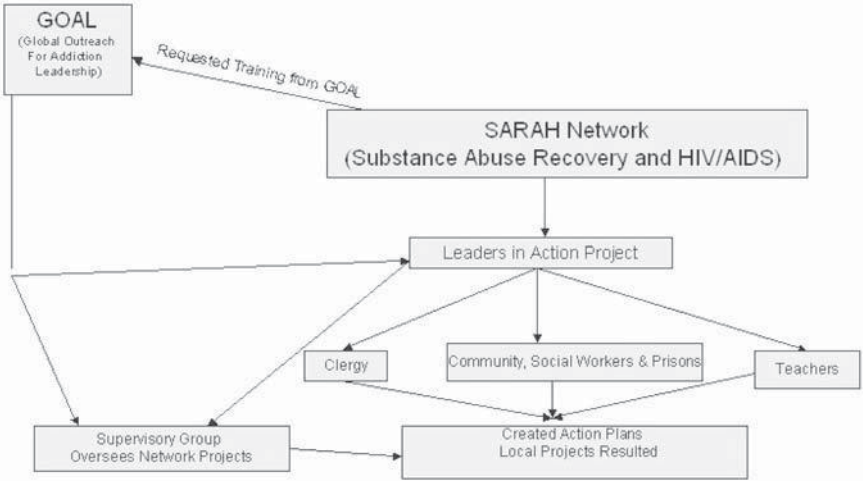

FIGURE 13.1 GOAL/SARAH Network Organizational Chart.

trict, where the statistics for both legal and illegal alcohol abuse and HIV/AIDS among women and children are higher than anywhere else in Kenya. The Kisumu region is also a rural area where village widowed women brew 80 percent proof alcohol called *Chang'aa* and/or are subject to GBV by drunken husbands if they risk going for VCT testing. The women in the Aniga project have been encouraged by their leader to form support groups and to reach out to other village women.

Five new support groups have mushroomed in a two-year period of time. Both men and women in these villages are now planting crops, bee keeping, rearing dairy goats, and raising chickens to bring in sustainable income as alternatives to chang'aa brewing. A mobile unit (van) brings VCT services directly to them.

The Aniga Women Initiative holds community mobilization daylong events in their district. In August, 2007, 2,000 people attended and more than 100 took advantage of VCT located in a tent nearby where the villagers were entertained by skits, poems, and songs that told the HIV and substance abuse prevention message. One reason for the success of this particular project has been the involvement of the local tribal chiefs and community leaders in all of the trainings and that, rather than attempting to change the local customs, such as spousal inheritance, skits are planned around cultural customs to encourage VCT testing by all parties.

Caring Mothers, a group of commercial sex workers in the coastal region of Mombasa, is another rural project. Although commercial sex workers are difficult to work with, the group has grown from 15 to 36 and, with the persistence of their leader; the women are now in peer-based support groups and are learning to protect themselves from acquiring the virus and to stop using alcohol and other drugs. As economic necessity drives many of these women into prostitution, they have begun alternative income-generating activities, such as soap making, growing crops, and hair dressing.

Wholeness Among People Project (WAPIS) is an peri-urban project located in the Banana region, Kiambu District. This project, directed by a member of the Church Army (similar to the Salvation Army), is geared to helping young male drivers of commuting passenger service vehicles called *Matatu*s stop using and dealing in drugs. Drunk-driving traffic accidents have been the major causes of death on Kenyan roads. With the encouragement of their pastor leader and with training in substance abuse prevention and the formation of recovery support groups, about 50 young male drivers now are reaching out to local schools, training peer educators, and doing drug prevention with primary and high school students.

Also, in the Kawangware slums of Nairobi, another pastor has been training peer educators and has started an Alcoholics Anonymous recovery support group at his Upako Center. Under a tin-roofed shack, the young volunteer high school peer educators educate AIDS orphans.

PROFESSIONAL CAPACITY BUILDING

SARAH Network staff conducts weeklong addiction HIV/AIDS training events for clergy, probation officers, and teachers. In a study done in the Kisumu district of Kenya in 1994, the findings indicated that community and church members look up to clergy as trusted community leaders and those impaired seek help (Oketch, 2005). GOAL/SARAH facilitators have trained more than 48 clergy and lay leaders with proven behavior change communication methods and modeling mutual help 12 Step recovery support groups, based on SARAH's motto *Each One Reach One*. These clergy have informed and educated 4,800 persons. SARAH staff collected data and qualitative results using a simple monitoring and evaluation form and followed up with telephone calls, e-mails, and personal visits.

At each workshop, clergy are given a supply of addiction recovery educational books and pamphlets and a list of rehabilitation centers for possible referrals. SARAH also helps affected and infected clergy seek treatment by sponsoring and referring them to a nearby treatment center.

EVIDENCE-BASED TREATMENT ACCESSIBILITY

Although SARAH-trained clergy and teachers refer those persons who request help to existing treatment centers, the majority of Kenyan treatment centers charge a fee and most Kenyans cannot afford to pay those fees. Also, the counselors in these facilities are recovering addicts themselves and have had very little addiction counselor training. Through the SARAH Network, the International Association of Therapeutic Communities, the U.S. Academic Education Development (AED), the Kenya National Campaign Against Drug Abuse Authority (NACADAA), the Support for Addiction Prevention and Treatment in Africa Trust (SAPTA) and the Centre for Addiction Studies and Services in Africa (CASSA), efforts are underway to develop evidence-based interventions, to train addiction counselors, to set up new treatment programs in existing hospitals, and to start a countrywide school and community drug-prevention program.

SARAH Network's motto, *Each One Reach One*, has been successful in spreading the message of hope in healing for both alcohol and other drug abusers and addicts and those infected with HIV/AIDS. Although there are a handful of mutual help 12 Step–based recovery support groups, it will take another 10 years for these to multiply. In Kenya, especially in western Kenya, many more of these peer-based anonymous groups are needed. These recovery support groups have proven successful worldwide for helping addicts stay clean and sober.

CHANGING ALCOHOL-IMBIBING CULTURES AND BEHAVIORS

Alcohol and other drugs have been used and consumed in Kenya as part of the cultural traditions for centuries, but there were certain rules and values of use up until the period just after colonialism and the subsequent breakup of family and tribal cultures. It had been permissible for adults to use alcohol and tobacco, but youth and women were discouraged from using either until after childbearing years. Traditionally, alcohol, including illegal *Bhang'aa* has been used and abused during weddings, birthdays, harvest festivals, funeral ceremonies, and other social events (SINAM/Levi Trust, 1999). However, drunkenness has never been acceptable. In fact, those who exhibit drunkenness as well as those who test positive for the HIV virus become social outcasts. In all their trainings, SARAH staff and project leaders teach the brain disease concept of addiction and the realities of alcohol dependency and the resultant laxity in regard to sexual behaviors.

Khat production and exportation is a booming business among in Kenya. Due to the excessive availability, the abuse of khat is an common activity among long distance truck drivers and others. Among other dangers, excessive use of khat has been blamed for rendering men impotent and hence wives seeking other sexual partners and thus increasing the spread of HIV/AIDS. SARAH staff educates vulnerable individuals on the dangers of the abuse of khat in their HIV prevention activities.

The SARAH staff trainers and project leaders employ dramatic skits, role plays, and dialogues to dispel folklore and myths surrounding alcohol and other drug use. In clergy trainings, clergy also practice methods learned to dispel myths, teach facts, and reduce stigma.

CROSS-TRAINING IN HIV AND ADDICTION AND VCT

Although HIV/AIDS training is now readily available in African countries, thanks to generous funding from the United States, the United Nations, and the European Union, very few programs provide the cross-training in HIV and addiction, as well as modeling both peer-based recovery and HIV+ support groups. SARAH emphasizes a similar mutual help group step for both groups. The basic weeklong training consists of two days of knowledge in drug prevention and treatment, two days in HIV/AIDS prevention and treatment, and one day in implementation planning. SARAH facilitators train people with proven behavior change communication methods. Trainers present topics geared to the specific group to be trained. Participants fill out an action planning sheet provided by the SARAH staff indicating what actions they will undertake and how many persons they anticipate reaching.

The Freedom Center in Egypt, on the continent of Africa and considered a country in the Arab Middle East, an emerging new treatment model that combines the Minnesota Model (i.e., based in peer–based mutual help recovery support group) with a six-week therapeutic community model has been found to be effective. This, combined with a treatment model that includes one-on-one and group counseling as well as attendance at outside recovery support groups, has been accompanied by extensive prevention awareness through television and radio and has taught that treatment for alcohol and other drug addiction is possible.

Three thousand heroin addicts and alcoholics in this Arab African country now wait to get a bed in one of two dozen treatment centers. The Freedom Center, founded by Ehab Elkharrat, MD, former president of the International Substance Abuse and Addiction Coalition (ISAAC) and who now is United Nations Development Programme (UNDP) representative for all Arab coun-

tries, has started other treatment centers in and around Cairo where both heroin and alcohol addiction are huge challenges. Narcotics Anonymous (12 Step) support groups have mushroomed in the past six years. Working on the principle of one addict reaching out to help another and sponsorship, the Egyptian Narcotics Anonymous (NA) support groups have become the lifeline for addicts and are spreading the message of hope in recovery.

CONCLUSIONS

Implementing model programs specifically suited to African cultures and customs to combat the spread of HIV/AIDS must include training components that cross both disciplines, (HIV/AIDS and alcohol and other drugs) that have proven effective for prevention and treatment. They must be geared to those within the culture who are most effective as change agents. The SARAH Network has targeted community opinion-shapers who include clergy, teachers, probation officers, and grassroots community organizers as the most effective as prevention agents.

Difficulties still lie ahead in African countries in meeting the challenges that alcohol and other substance abuse and addiction cause in the spread of HIV/AIDS. Much still needs to be done to assist in the formation of and support for evidence-based treatment facilities, especially for those populations less able to pay. Treatment should embody the establishment and sustaining of mutual help–addiction recovery and HIV+ support groups. Also, unless GBV and rape of vulnerable women and children is curtailed through establishing shelters and a legal protection system, very little hope exists for curbing the spread of the HIV virus in Kenya as well as in other African countries. Limited research has been done to investigate the correlations between HIV and substance abuse issues in Kenya. Despite this fact the SARAH Network's interventions have proven to be effective based on what has worked in other countries. Research-guided interventions would facilitate localized interventions and possibly yield better outcomes. For the existing treatment centers, both public and private, addiction counselor training and certification should be strengthened. More counselor training is needed for family member issues, relapse prevention, therapeutic strategies such as motivational interviewing, and stages of change, as well as a country-wide certification process. These should be put in place in each of the infected African countries.

The Kenya SARAH Network Prevention model and the Egyptian Freedom Center treatment model signal a great new beginning for the African continent in its fight against the spread of the HIV virus.

Chapter **14**

Drug Abuse–Related HIV/AIDS Epidemic in India: Situation and Responses

Atul Ambekar, MD, and Meera Vaswani, PhD

HIV EPIDEMIC IN INDIA: CONTRIBUTION OF INJECTING DRUG USE

The first case of HIV was detected in India in 1986. In the past two decades since then, the HIV epidemic continues to grow unabated in India. As per the latest estimates, there are about 2.5 million people living with HIV in the country. The prevalence of HIV among the general population is estimated to be about 0.36 percent, with a much higher prevalence among men as compared to women (0.43% vs. 0.29%). Prevalence is also high in the young, productive age group with 88.7 percent of all infections occurring in the age group of 15–49 years (National AIDS Control Organization [NACO], 2007a). In other words, there is still no generalized epidemic (defined as more than 1% HIV prevalence in the general population; Joint United Nations Programme on HIV/AIDS and World Health Organization [UNAIDS/WHO], 2004) of HIV in India at the national level.

The national level data, however, should be interpreted with caution. India, being a vast and heterogeneous country, has a heterogeneous HIV situation. It has often been commented that there is not one, but many, simultaneous HIV epidemics currently spreading in India (Monitoring the AIDS Pandemic [MAP], 2004). In three states of the country, the epidemic is generalized, that is, these states have HIV prevalence of more than 1 percent in the general population. These three states are Andhra Pradesh, Manipur, and Nagaland. It must also be remembered that though these states have a higher *proportion* of

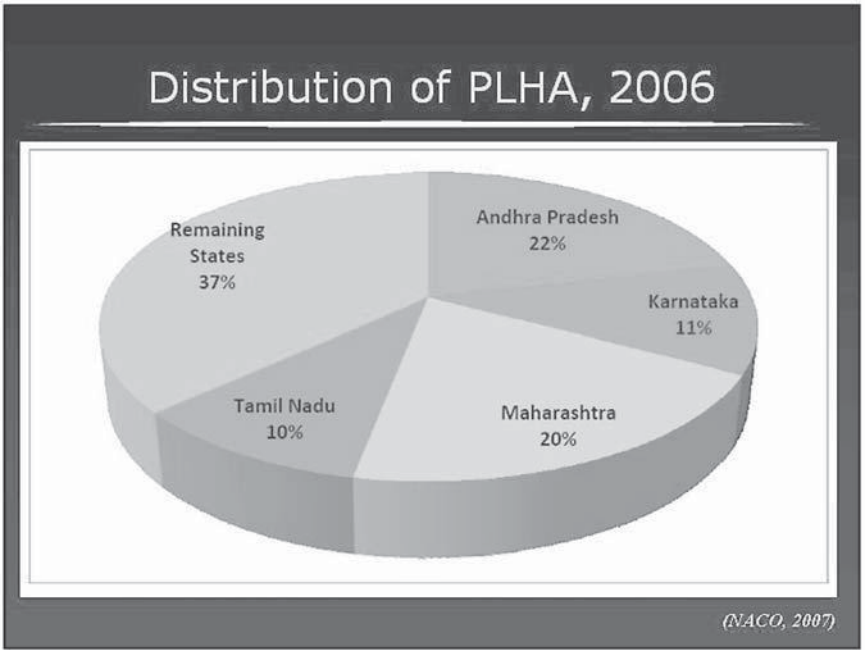

FIGURE 14.1 Distribution of proportion of people living with HIV/AIDS (PLHA) in India, 2006. From *HIV Sentinel Surveillance and HIV Estimation, 2006*, by National AIDS Control Organization, 2007, New Delhi: Ministry of Health and Family Welfare, Government of India.

people living with HIV/AIDS (PLHA), there are other states with far higher *absolute numbers* of people living with HIV (see Figure 14.1).

Besides these three states in the country, there are many other states that are in the "concentrated" stage of the epidemic (UNAIDS/WHO, 2004), in that the prevalence of HIV, though less than 1 percent in the general population, is more than 5 percent in the high-risk groups (HRGs). Certain groups of individuals, based on their enhanced vulnerability to HIV infection, are seen as HRGs. These include female sex workers (FSW), men having sex with men (MSM), and injecting drug users (IDUs). Among these, it is noteworthy that the highest prevalence of HIV at the national level has been found among IDUs (as shown in Figure 14.2).

Since the beginning of the HIV epidemic in India, the major route of transmission has always been heterosexual intercourse, though the proportion of HIV infections attributed to heterosexual intercourse (Correa & Gisselquist,

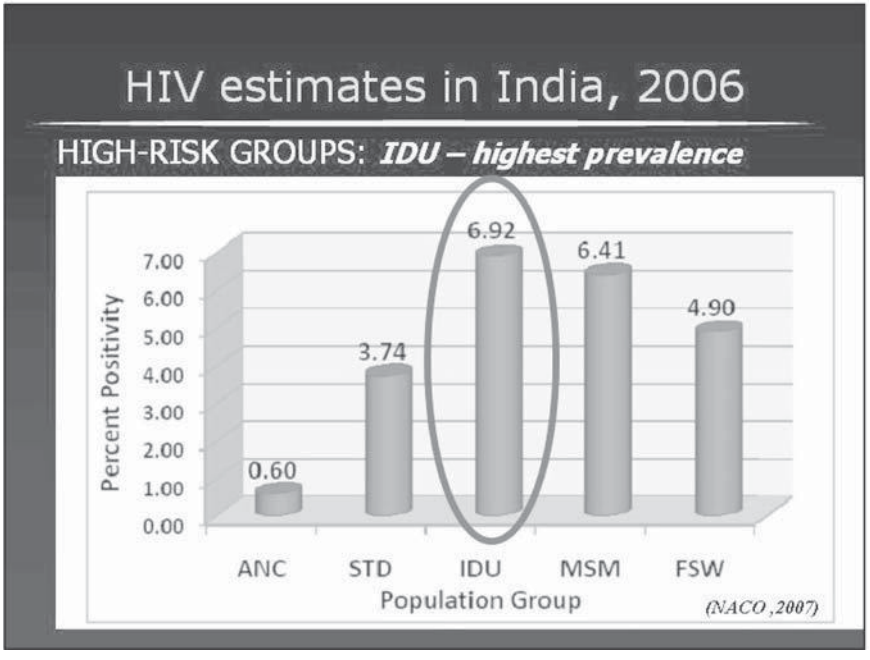

FIGURE 14.2 HIV prevalence among various groups in India, 2006. From *HIV Sentinel Surveillance and HIV Estimation, 2006,* by National AIDS Control Organization, 2007, New Delhi: Ministry of Health and Family Welfare, Government of India.

2006), particularly heterosexual commercial sex (Gisselquist & Correa, 2006), has been debated in the literature. The contribution of injecting drug use (IDU) and consequent sharing of contaminated injection equipment has usually been estimated to be around 2–3 percent of the total HIV infections (Correa & Gisselquist, 2006). Until recently, it has been largely believed that HIV infection among IDUs is concentrated only in the northeastern states (Manipur and Nagaland) and certain large cities of the country (Chennai, Delhi, and Mumbai). Findings from the recent round on sentinel surveillance (conducted annually, at a national level), however, reveal that the HIV infection among IDUs has spread in many states of the country (NACO, 2007a). As seen in Figure 14.3, as many as seven areas of the country have crossed the threshold for a concentrated epidemic among IDUs.

Additionally, many smaller, clinic-based studies have reported high prevalence of HIV infection among injecting drug users in India (Jindal, Arora, &

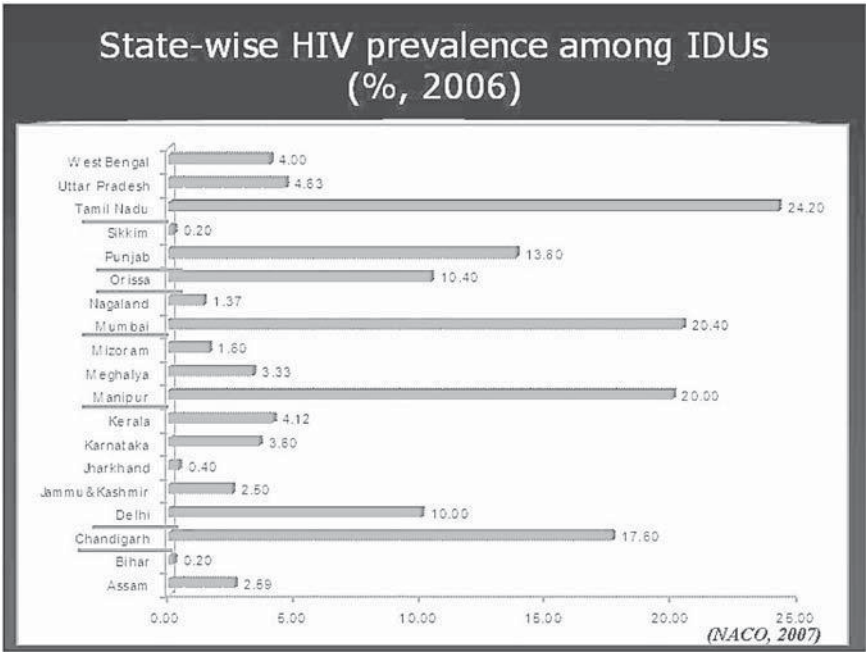

FIGURE 14.3 State-wise HIV prevalence among injecting drug users in India, 2006. From *HIV Sentinel Surveillance and HIV Estimation, 2006*, by National AIDS Control Organization, 2007, New Delhi: Ministry of Health and Family Welfare, Government of India.

Singh, 2008; Saraswathi & Dutta, 2007; Vaswani & Desai, 2004; Vaswani & Rao, 2006). Thus, injecting drug use is a major risk factor for transmission of HIV in India. While, in two of the states (Manipur and Nagaland), it is the primary factor behind a generalized HIV epidemic, the phenomenon may be significantly contributing to the spread of the HIV epidemic elsewhere in the country as well.

INJECTING DRUG USE IN INDIA

Historically, the use of certain intoxicating substances has been prevalent in India for many centuries now. Traditionally, various cannabis derivatives and locally brewed alcohol were the substances of use. There was also a certain degree of social sanction to use of these substances (Dhawan, 1998). Until the early twentieth century, many of the substances of abuse, which are currently illicit, were available through licit channels. Nonmedical or nonprescription

use of psychotropic medications was also observed. Besides opium, cannabis, and alcohol, use of cocaine and even khat was reported in India until 1940. However, many reports up to the late 1960s suggested that most users of these substances used in moderation and only a few did become habitual users or used in excess (Reid & Costigan, 2002).

In the 1980s, however, with the introduction of heroin in India, the situation changed to a great degree. Earlier, opium was available through licensed vendors and a sizable number of registered opium addicts existed in the 1950s (Ray, 1998). Over the years, this practice has been discontinued and new registration of opium addicts has been stopped. In the early 1990s, only a few of the registered opium users were alive and drawing their quota of opium. Consequently, many users of a traditional, plant-based (and relatively less potent) drug like opium were forced to shift to a modern, synthetic (and more potent) drug, that is, heroin (Ambekar, Lewis, Rao, & Sethi, 2005).

Over next few years, many heroin users switched to injecting modes of taking opioid drugs. The phenomenon was first noted in the northeastern states of Manipur and Nagaland, which share their border with Myanmar—the world's second-largest illicit opium-producing country (United Nations Office on Drugs and Crime, Regional Office for South Asia, and Ministry of Social Justice and Empowerment [UNODC/MSJE], 2005). Since taking opioids through an injection route provides a better and quicker high, the injecting route is perceived by the drug users as more cost-effective (UNODC/MSJE, 2004a, 2004b, 2005). The phenomenon was first noted in the northeastern states of Manipur and Nagaland (Sarkar et al., 1991, 1995), which share their border with Myanmar—the world's second-largest illicit opium-producing country (United Nations Office on Drugs and Crime, Regional Office for South Asia, and Ministry of Social Justice and Empowerment [UNODC/MSJE], 2005).

Currently, India figures among the developing and transitional countries with the "largest populations of IDUs," along with Brazil, China, and Russia (Aceijas et al., 2006). However, there are no reliable estimates regarding the number or prevalence of IDUs in the country. The largest of the epidemiological studies in the country—the National Household Survey—found a prevalence of 0.1 percent of IDUs among the adult male population of the country (UNODC/MSJE, 2004a). However, it is widely accepted that household samples are not appropriate to pick up hidden and potentially stigmatizing phenomena such as injecting drug use (Joint United Nations Programme on HIV/AIDS and Family Health International [UNAIDS/FHI], 2003). The same multimodality study (UNODC/MSJE, 2004a) also collected information from patients seeking treatment for substance use problems from more than 200 treatment centers throughout the country through a survey—the

Drug Abuse Monitoring System (DAMS). In this survey, prevalence of injecting drug use ("ever" in lifetime) among treatment seekers was reported to be 14 percent (UNODC/MSJE, 2002a). Yet another component of the same study was the Rapid Assessment Survey (RAS), in which data were collected from drug users contacted at streets in 14 urban locations across the country. Here, the prevalence of injecting drug use was 43 percent (UNODC/MSJE, 2002b). International experts (Aceijas et al., 2004) in a global overview of HIV among IDUs have quoted a rather wide range—from 563,000 to 2,025,000—for the estimated number of IDUs in India.

Like the HIV situation, however, the spread of IDU is also heterogeneous in the country. For a long time now it has been believed that the phenomenon of IDU is a matter of concern only in the northeastern states (Manipur and Nagaland) and the metro cities of the country (Chennai, Mumbai, and Delhi). There have been multiple studies, however, that have produced evidence that IDU is not limited to the aforementioned areas. The 14-city Rapid Assessment Survey (UNODC/MSJE, 2002b) documented the presence of injecting drug use in many other cities of the country other than the northeastern states and metropolitan cities (see Figure 14.4).

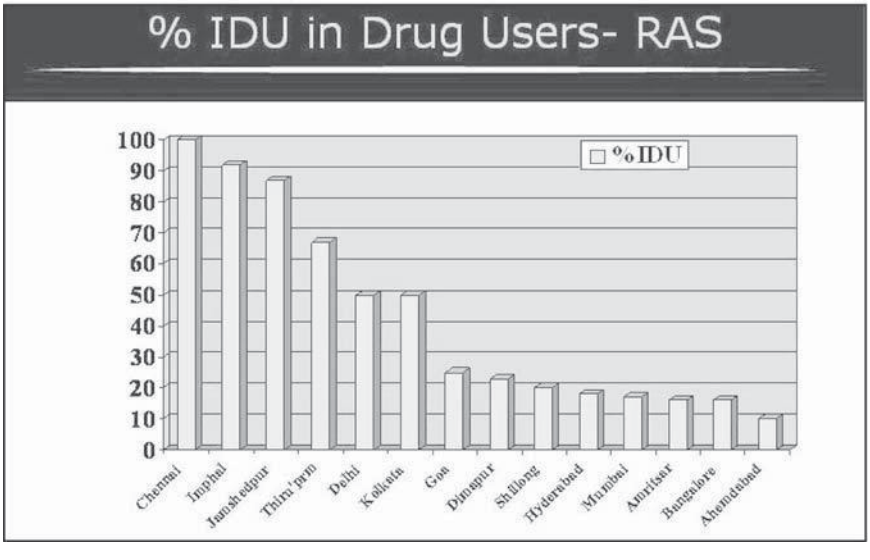

FIGURE 14.4 Proportion of injecting drug users in the total sample of drug users in the Rapid Assessment Survey of Drug Use in India. From *The Extent, Pattern and Trends of Drug Abuse in India: National Survey*, by United Nations Office on Drugs and Crime, Regional Office for South Asia, and Ministry of Social Justice and Empowerment, 2004, New Delhi: UNODC and MSJE.

SHARAN, an NGO working in the area of drugs and HIV, has recently documented the presence of IDU in many parts of the country, including Uttar Pradesh, Maharashtra, Goa, Kerala, and Tamil Nadu (SHARAN, 2007). Similarly, in two of the recent, large-scale studies, presence of IDUs has been documented in many north Indian states, including Punjab, Haryana, Uttar Pradesh, Bihar, Jharkhand, and Orissa (Ambekar & Tripathi, 2006, 2007, 2008).

Thus, there is considerable evidence that IDU is well established in many parts of India. The worrying aspect of this is the presence of IDU in smaller towns and rural areas of the country.

PROFILE OF IDUS IN INDIA

Most of the studies in India have found IDUs to be in their late 20s or early 30s. Notably, most injecting drug users in India are those, who, in the initial phase of their drug-use career, use opioids through a noninjecting route (most commonly, heroin, through smoking or "chasing" routes) and later switch to the injection mode of using opioids. There is usually a time lag—ranging from 2 to 10 years—when people switch from noninjecting to injecting mode of taking drugs (UNODC/MSJE, 2004b). The factors behind initiation of injecting in India have also been studied and are summarized in the accompanying box.

BOX 1

Factors behind Initiation of Injecting Drug Use by Drug Users in India

- Nonavailability of heroin (for smoking or "chasing")
- High cost of heroin (for smoking or "chasing")
- Easy availability of pharmaceutical opiates and other sedatives (injectable) in pharmacies (without prescription)
- Perception that taking drugs through the injecting route produces better and quicker highs and immediate relief from withdrawal symptoms
- Iatrogenic, that is, administration of opioid injections by a health professional
- Curiosity
- Peer pressure

Source: Injecting Drug Use and HIV in India: An Emerging Concern, by United Nations Office on Drugs and Crime, Regional Office for South Asia, and Ministry of Social Justice and Empowerment, 2004, New Delhi: UNODC and MSJE; "My First Time: Initiation into Injecting Drug Use in Manipur and Nagaland, North-East India," by M. Kermode, V. Longleng, B. C. Singh, J. Hocking, B. Langkham, and N. Crofts, 2007, *Harm Reduction Journal, 4*, p. 19.

Most injecting drug users in India prefer to inject either heroin or pharmaceutical preparations. The pharmaceutical preparations include injectable opioids like buprenorphine and pentazocine, which are usually mixed with other sedatives like diazepam, promethazine, and chlorpheniramine. A distinct pattern of using dextropropxyphene capsules for injection has also been observed, particularly from the northeastern states of Manipur, Nagaland, and Mizoram (UNODC/MSJE, 2004b, 2005; Kermode et al., 2007; Ambekar & Tripathi, 2006, 2008).

RISK BEHAVIORS AMONG IDUS: INJECTING RISKS

The risk of transmission of HIV and other blood-borne virus infections due to sharing of contaminated injection equipment is well documented. Injecting serves as an efficient vehicle for transmission of HIV. The injecting route is about three to five times more efficient than the sexual route (0.67% risk for HIV transmission per episode of intravenous needle or syringe exposure as compared to 0.1%–3% risk for HIV transmission per episode of receptive penile-anal sexual exposure and 0.1%–0.2% risk per episode of receptive vaginal exposure; Centers for Disease Control and Prevention [CDC], 1998).

There is ample evidence from the community-based as well as clinic-based studies that a sizable proportion of IDUs in India share their injection equipment and thus are vulnerable to transmission of HIV and other blood-borne virus infections. In the Rapid Assessment Survey of Drug Abuse in India (UNODC/MSJE, 2002b, 2004), injecting drug use was reported to be a group activity. Needle sharing was reported to be "common" among injecting drug users and varied between 52 and 81 percent. Indirect sharing (e.g., sharing of cotton swab, filter, and spoons, etc.) was also common. About half of the IDUs who shared reported that they had shared syringes and needles the last time they injected. Most did not clean the needles and syringes. In the first round of the Behavioral Surveillance Survey (BSS) conducted in India by the National AIDS Control Organization (NACO, 2002a) among 1,355 IDUs, about 44 percent shared injection equipment in the preceding month, while 4 percent reported that they "always" shared injection equipment. In the latest round of BSS also (NACO, 2007b), a large majority of IDUs in Manipur, Delhi, Chennai, and Mumbai reported sharing of injection material. Many of them reported sharing on more than 50 percent of the occasions. In yet another recent study (Ambekar & Tripathi, 2006) conducted at multiple sites nationwide among 5,603 IDUs, 59 percent reported sharing of injections "ever." A large majority of them (77%) shared at the last occasion of injecting. In clinic-based studies, high prevalence of risk behaviors as well as HIV infection has

been reported among IDUs, particularly when compared to non-IDUs (i.e., drug users who take drugs through a noninjecting route). Vaswani and Desai (2004) found a high prevalence of risky injection behavior among IDUs in their sample of 154 consecutive drug users attending a treatment center. Notably, the prevalence of HIV was significantly higher among IDUs (8.2%) as compared to non-IDUs (1.8% in heroin smokers and 0% in alcohol-dependent individuals).

Thus, in this backdrop of widespread injecting drug use and associated practice of sharing contaminated injection equipment, rapid escalation of the prevalence of HIV remains a very likely possibility in India. Some parts of the country have witnessed explosive HIV epidemics among IDUs in the past. For instance, in Manipur in northeast India, the first case of HIV among IDUs was detected in 1989. Six months later, prevalence among IDUs had increased to 50 percent (Sarkar et al., 1993).

RISK BEHAVIORS AMONG DRUG USERS: SEXUAL RISKS

While injecting-related risk for transmission of HIV is well recognized, the contribution of substance use (alcohol as well as illicit drugs like cannabis and opioids) to enhanced transmission of HIV is not recognized so well. There is evidence that substance use (injecting or otherwise) is associated with an enhanced vulnerability to high-risk sexual behavior.

Men who have been drinking alcohol report more contact and noncontact sexual problems as compared to those who do not use alcohol (Verma, Sharma, Singh, Rangaiyan, & Pelto, 2001). In a study on assessment of the risk factors in sexually transmitted diseases (STD), alcohol was one of the risk factors found to be significantly associated with the acquisition of STD (Sharma & Chaubey, 1996). Among studies looking at sexual behavior and its relationship with substance use, in a study from northeast India, among 200 students, sexual behavior was found to be strongly associated with alcohol use (Longkumer, Shrivastava, & Murugesan, 2000). Similarly, in yet another study among adolescents in slums of Mumbai, alcohol use was associated with risky sexual behavior along with the perception that consumption of alcohol before sex heightens sexual pleasure and makes it long-lasting (Singh, Schensul, & Gupta, 2004). Such an association between alcohol and substance use and high-risk sexual behaviors is more evident among groups regarded to be at high risk of HIV such as sex workers and truckers. The number of clients visiting the sex workers decreases during the "dry" (i.e., alcohol-free) periods (Ambwani & Gilada, 1998).

Tripathi, Malhotra, and Sharma (2004) have reported findings of their study carried out in the city of Delhi as a part of a multinational study sponsored by the World Health Organization (WHO). Primary data on alcohol use and sexual risk behavior were obtained from interviews of key informants (KIs), sex workers, truck drivers, and restaurant workers. Among the significant findings, alcohol was found to be a common substance of use among various population subgroups, including sex workers. A clear relationship between use of alcohol and sexual behavior was evident. Though from the general population about 25 percent of respondents reported sexual arousal and enhanced sexual pleasure following consumption of alcohol, among high-risk population groups (sex workers, transport workers, etc.), between 60 and 100 percent reported such feelings. Of more concern was the finding that condom use was uniformly low among all the population subgroups except for sex workers. Consistent condom use was even lower (Tripathi et al., 2004).

Apart from alcohol, other substance use has also been linked to high-risk sexual behaviors. High prevalence of substance use has been found among sex workers and their clients in India. In a nationwide Behavioral Surveillance Survey, among a total of 5,572 female sex workers (FSWs), 22 percent reported that they consumed alcohol every day in the last month (NACO, 2001). Overall, around 15 percent of FSWs reported that they drink regularly before sex. Some (about 6%) had tried other (nonalcohol) addictive drugs, including injections, in the past 12 months. In the same study, among a total of 5,684 clients of FSWs, the proportion of respondents drinking at least once a week was 45 percent and the proportion of those drinking daily was nearly 23 percent. Nearly 13 percent of the respondents regularly consumed alcoholic drinks before having sex with their commercial partners. Around 22 percent reported use of other compounds like cannabis and opium. Some of these respondents (10%) had injected drugs in the last 12 months (NACO, 2001).

In a study from India, comparing the sexual behavior of drug users (excluding alcohol and tobacco) with nondrug users randomly selected from the same community, the average number of sexual partners was found to be significantly higher among drug users (7.4 vs. 4) as compared to nondrug users (Sharma, Aggarwal, & Dubey, 2002). In a recent nationwide study among 12,580 drug users, about 37 percent reported sex with multiple partners. More than a third (35%) reported *never* having used a condom (Ambekar & Tripathi, 2006).

The sexual behaviors of injecting drug users have also been studied. There is evidence that many injecting drug users are sexually active and do visit sex workers (UNODC/MSJE, 2004a, 2004b). In a clinic-based study (Vaswani & Rao, 2006), among 154 consecutive treatment seekers, a significantly higher proportion of IDUs (83.6%) was found to have multiple sex partners as compared to non-IDUs (57.4%). Women IDUs have been found to be engaging in

sex work to sustain their livelihoods (Panda et al., 2001). There is also evidence that HIV infection is being transmitted from injecting drug users to their non-injecting wives and sexual partners (Panda et al., 2000, 2005, 2007).

Thus, in India, a definite association is clearly seen between drug use and high-risk sexual behavior. This association is visible in the general population as well as the known "high-risk" population groups.

RESPONSE TO IDU-RELATED HIV: HARM REDUCTION

While it is well known that drug dependence is a complex, chronic, relapsing condition that is often accompanied by severe health, psychological, economic, legal, and social consequences—or "harms" (McLellan, Lewis, O'Brien, & Kleber, 2000)—with the advent of the HIV epidemic, substance use, in particular, injecting drug use (IDU), is now seen as a major public health issue rather than just a social/legal issue. Injecting drug users are particularly vulnerable to HIV and other blood-borne infections (such as hepatitis C) as a result of sharing contaminated injecting equipment. There is ample evidence from the recent literature that IDUs in India have a high sero-positivity not only for HIV but hepatitis B and C as well (Das, Borkakoty, Mahanta, Medhi, & Chelleng, 2007; Datta et al., 2006; Jindal et al., 2008; Saraswathi & Dutta, 2007; Sarkar et al., 2006). Some of the harms associated with drug use may be attributable to the effects of the drug itself on the body and the mind. More often, drug-related harm is the result of the many social, economic, legal, cultural, and political factors that influence the availability of illicit (illegal) drugs and the conditions under which they are used. Poverty, migration, and social discrimination affect people's vulnerability to the drug-related harm. Stringent laws, unpragmatic policies, and the social stigmatization and discrimination of illicit drug users serve to drive them further toward isolation and away from their social support like family, as well as from various health and social services (Ambekar, Agrawal, & Tripathi, 2008).

Additionally, it should be remembered that "zero tolerance"–based strategies such as legal prohibition of substances and emphasis only on the abstinence-oriented treatment have not been able to eliminate substance use from the society. Despite being illicit and controlled substances, the use of certain drugs like heroin, cocaine, and others is still prevalent in the society and the worldwide illegal trade of these substances is burgeoning (UNODC, 2007). Moreover, making a drug illegal may even increase the harms associated with its use by contributing to the marginalization of a drug user and criminalization of his drug use behavior. There is a growing understanding that the utopian rhetoric, like "a drug-free society" or "a world without drugs," is unrealistic and unachievable. The global community is now realizing that some drug abuse would occur

in any society, despite the best efforts at curbing it. Consequently, a pragmatic response would be to employ strategies that could reduce the harms associated with this drug use. One of the approaches to bring about desirable changes in the behavior of substance-using individuals—and thus reducing the risks of harms—is harm reduction.

While the concept of harm reduction has been used in the context of a variety of risky behaviors, primarily it has been seen as an intervention and management strategy for the individuals using psychoactive substances. Various definitions for the term *harm reduction* (also termed sometimes as *harm minimization*) have been put forward (Lenton & Single, 1998). The International Harm Reduction Association (IHRA) defines harm reduction as "policies and programs, which aim to reduce the health, social and economic harms associated with the use of psychoactive substances" (IHRA, 2006). A defining feature of such policies and programs is their focus on the prevention of drug-related harm rather than the prevention of drug use per se (Hunt, 2003). Instead of viewing drug problems as phenomena caused by individual psychological (or moral) deficiencies, harm reduction views any society's patterns of drug use collectively—holding that many of the most destructive consequences and refractory problems of illicit drug use are not solely attributable to the drugs per se. Rather, many of these problems are more closely linked to the failure of the policies employed to control them (Ambekar & Balhara, 2007; Ambekar et al., 2008).

The adjoining box summarizes some of the key principles of harm reduction (Ritter & Cameron, 2005).

BOX 2

Some Key Features and Principles of Harm Reduction

- The primary goal is reducing harm rather than drug use per se
- Built on evidence-based analysis
- Acceptance that drugs are a part of society and may never be eliminated
- Provides a comprehensive public health framework
- Priority is placed on immediate (and achievable) goals
- Pragmatic—does not seek to pursue policies or strategies that are unachievable or likely to create more harm than good
- Recognizes individual human right—rooted in an acceptance of individual integrity and responsibility

Source: Adapted from *A Systematic Review of Harm Reduction,* by A. Ritter and J. Cameron, 2005, DPMP, Monograph Series No. 06, Fitzroy, Australia: Turning Point Alcohol and Drug Centre.

Though there are many strategies that have been proposed to reduce the harms associated with injecting drug use, in the following section, we limit our discussion to only a few of them. These include (1) needle-syringe exchange programs, (2) agonist maintenance treatment, (3) outreach activities, and (4) legal and policy reforms.

Needle-Syringe Exchange Programs

The programs for needle and syringe exchange are more readily associated with the harm reduction approach than any other type of intervention. At its most basic level, this strategy involves supplying new, clean needles and syringes to IDUs, in exchange for old, used, and potentially contaminated needles and syringes.

As discussed earlier, a sizable number of IDUs in India share their used and potentially contaminated injections with each other, putting themselves and their partners at the risk of acquiring HIV and other blood-borne virus infections. Availability of new, clean injecting equipment, free of cost, would provide these IDUs with an opportunity to protect themselves and their injecting partners from transmission of HIV. Additionally, these programs also provide a point of continuous contact with the drug users that enable these practices and a wide range of other health matters to be discussed. Indeed, most such programs do not limit themselves only to providing sterile injecting equipment but also incorporate a variety of other services such as risk reduction education, condom distribution, bleach distribution, education on needle disinfection, and referrals to substance abuse treatment and other health and social services (Wodak, 2004).

The effectiveness of these programs in preventing the spread of HIV has been a matter of controversy, mainly due to a number of methodological shortcomings in the studies conducted to evaluate their effectiveness. In a review, Gibson, Flynn, & Perales (2001) reported findings from 42 studies, of which 28 found positive effects (reduction in drug-related HIV risk behavior, including self-reported sharing of needles and syringes, unsafe injection and disposal practices, and frequency of injection) and 14 found either no association or a combination of positive and negative effects. Overall, this provides reasonable evidence of the positive impact of needle-syringe exchange programs on HIV risk behavior and HIV infection. Wodak (2004), after his extensive review of 48 studies for the World Health Organization (WHO), has also concluded that not only was there compelling evidence of the effectiveness of needle-syringe exchange programs in reducing HIV infection substantially, there was compelling evidence for their cost-effectiveness as well. Moreover, there was no convincing evidence of any major, unintended negative consequences. However,

and more important, he concluded that these programs on their own are not enough to control HIV infection among IDUs.

Agonist Maintenance Treatment

These programs, known by a variety of names such as "opioid replacement therapy" or "oral substitution treatment" rely on the principle of substituting an illicit, unsafe, short-acting, and more addictive drug with a legal medication of known purity and potency. The origins of opioid replacement therapies can be traced back to the landmark study on the role of methadone maintenance in opioid-dependent subjects (Dole & Nyswander, 1965). Since then, a number of drugs have been used for this purpose such as methadone, LAAM, buprenorphine, slow release oral morphine, and others. However, the search for an ideal agent continues to remain elusive. All of the replacement medications have been shown to be effective in reducing use of illicit drugs, reducing the risk of injecting, reducing the risk of overdose, reducing involvement in illegal activities, and improving socio-occupational functioning (Gowing, Farrell, Bornemann, & Ali, 2004; Mattick, Breen, Kimber, & Davoli, 2003; Mattick, Kimber, Breen, & Davoli, 2003).

For India, these programs are especially relevant because the most favored drugs by the IDUs in India are opioids (Ambekar et al., 2005; Ray & Ambekar, 2005). Though methadone is not available in India as of now, another agent—buprenorphine—is available, and the country has gathered enough experience and expertise in the area of buprenorphine maintenance programs (Dhawan & Sunder, 2008).

Outreach Activities

Several of the drug-using populations may not be accessible through the conventional center-based services. Such populations may remain "hidden" due to a number of factors such as inaccessibility of services, unattractiveness of facilities, distance, stigma, and so forth. Outreach was conceived to overcome these barriers and to reach out to people within their own communities or local milieu, outside of the usual service settings. Community-based outreach involves a number of activities such as establishing contact and rapport with the target populations in their natural environments, providing information about unsafe as well as risk behaviors, and promoting and supporting safe behaviors.

Outreach services have been proved to be effective for reaching hard-to-reach, hidden populations of drug users and provide the means for enabling IDUs to reduce their risk behaviors. According to a WHO review, a significant proportion of IDUs receiving outreach-based interventions reduces their risk

behaviors in drug using, needle, and sexual practices and increases their protective behaviors (Needle et al., 2005).

Outreach services are especially relevant in India, since help seeking among drug users has been found to be low and delayed (UNODC/MSJE, 2004a; Ambekar et al., 2005). Outreach-based activities aimed at identifying and reaching out to hidden IDUs have been employed at many centers in India (Hangzo, Chatterjee, & Sarkar, 1997; Kumar, Mudaliar, & Daniels, 1998). The preliminary evidence from the country suggests that outreach services for IDUs produce significant changes in risk behaviors, especially the injecting-related risk behaviors (Kumar et al., 1998; Kumar, 2008).

Legal and Policy Reforms

The general approach toward drug use in most countries has been "criminalization." This approach may be beneficial in handling drug trafficking but has been shown to be detrimental for an individual drug user, as it promotes marginalization and enhances harm due to increased prices of the prohibited drugs. Such an approach is now under scrutiny and debate. It is now increasingly recognized that by reducing the association of drug use with criminal prosecution, the reform of punitive legal policies can produce clear benefits in the realm of public health and social order.

Since all the harm reduction measures deal basically with illegal drugs and individuals who use these illegal drugs, they are affected by the prevailing legal and policy environment. For instance, there is a possibility that under the existing Indian laws, an agency (or its staff) engaged in providing needle-syringe exchange services in India can be booked under the relevant laws on the grounds of abetment to the crime, that is, facilitating or encouraging drug use by the injecting drug users by providing needle-syringe services to them (Lawyers Collective, 2007).

IDU-RELATED HIV EPIDEMIC IN INDIA: THE INDIAN RESPONSE

The following section will focus upon a critical overview of the response to the IDU-related HIV epidemic in India at the legal, policy, and programmatic level and will attempt to highlight certain existing gaps.

Legal and Policy Issues

In the area of "supply reduction" of drug abuse, India is signatory to all three major international conventions related to drug use, namely, Single Convention

on Narcotic Drugs, 1961, Convention on Psychotropic Substances 1971, and Convention against the Illicit Traffic in Narcotic Drugs and Psychotropic Substances, 1988 (Ambekar et al., 2005). In India, the broad legislative framework on narcotic drugs and psychotropic substances is contained in the three Central Acts: Drugs and Cosmetics Act, 1940, The Narcotics Drugs and Psychotropic Substances Act, 1985 (NDPS Act 1985), and the Prevention of Illicit Traffic in Narcotic Drugs and Psychotropic Substances Act, 1988. The NDPS Act lays down the focus and direction of drug control strategy in the country. Importantly, this Act does attempt to differentiate between a drug user and drug peddler (on the basis of the quantity of the illicit drug found in possession) and also provides for the treatment of drug users (Lawyers Collective, 2007).

India's policy on narcotic drugs and psychotropic substances is based on Article 47 of the Directive Principles of State Policy, Constitution of India, where the "Duty of the State [is] to raise the level of nutrition and the standard of living and to improve public health." However, India does not have a national drug control policy or an apex organization in respect of drug control. The National Health Policy 2002 of India (Ministry of Health and Family Welfare [MOHFW], 2002) does not specifically mention drug use as a component or concern. On HIV/AIDS issues, however, there are explicitly stated and documented policies in the country. The policy document of the National AIDS Control Organization (NACO, 2002b)—National AIDS Prevention and Control Policy (NAPCP)—recognizes various harm reduction measures, as the appropriate strategies to prevent HIV among injecting drug users, although the policy further admits that in India the harm reduction approach is yet to find wider acceptability because of ethical and moral considerations.

As far as the "drug demand reduction" activities are concerned, the nodal agency for drug demand reduction in India is the Ministry of Social Justice and Empowerment (MSJE), and not the Ministry of Health, implying indirectly that drug demand reduction is seen as more of a social justice and welfare issue rather than a health-related issue. The Ministry of Social Justice and Empowerment has developed a three-pronged strategy for drug demand reduction in India. The three components are: (1) building awareness and educating people about ill effects of drug abuse; (2) dealing with addicts through a program of motivation, counseling, treatment, follow-up, and social reintegration; and (3) imparting drug abuse prevention rehabilitation training to service providers. The ministry (MSJE) implements its programs mainly by supporting NGOs all over the country. Currently, the ministry is supporting around 450 drug dependence treatment centers throughout the country, which are being run by NGOs (Ambekar et al., 2005). In addition, the Union Ministry

of Health and Family Welfare and the Health Departments of the States and Union Territories also provide treatment and hospitalization services related to substance use. There are about 122 de-addiction centers, supported at least in part, by the Ministry of Health and Family Welfare (Panda, 2007).

Thus, to summarize, at the policy level, drug use and related issues do not receive a priority status in the health agenda of the government of India. The legal environment in the country, though, is conducive to providing adequate treatment and harm reduction services to injecting drug users.

Programmatic and Service-Delivery Issues

As discussed earlier, treatment services to drug users are delivered through the NGOs (supported by the government, the social welfare sector) as well as the government-run de-addiction centers as part of the health sector. However, it has been repeatedly commented that many of these services remain inadequately utilized (Ambekar et al., 2005; UNODC/MSJE, 2004a). Additionally, the National AIDS Control Organization is also engaged in providing harm reduction services ("Targeted Interventions") to the injecting drug users through NGOs, under the National AIDS Control Programme (NACP), which has just entered its third phase (NACO, 2006).

As of now, there are about 120 targeted interventions in various parts of the country (but concentrated mainly in the northeastern states and the bigger cities), delivering harm reduction (outreach and needle-syringe exchange but *not* agonist maintenance) services to about 90,000 IDUs (Rao & Khumukcham, 2008). This amounts to about 53 percent coverage. As of 2007, there were about 48 intervention sites for buprenorphine substitution also (largely implemented through NGOs, without any direct support from the government), providing services to only a few thousand IDUs (Dhawan & Sunder, 2008). The NACP–III plans, ambitiously, to scale up the existing IDU intervention with various harm reduction services so as to cover about 80 percent of the total number of IDUs in the country (Rao & Khumukcham, 2008). Among the newer initiatives, the NACO proposes to implement oral substitution therapy, in addition to needle-syringe exchange to the IDUs. Clearly, extensive scaling-up of the existing services is required in order to provide adequate coverage to injecting drug users in India to be able to achieve the stated goal of the National AIDS Control Programme—halt and reverse the HIV epidemic (NACO, 2006).

While the effectiveness of the needle-syringe exchange programs in India has not been studied systematically, there is some evidence that these programs may have been successful in bringing IDUs closer to various services, reduction

of risky injection practices, and reducing the prevalence of HIV (Ngully, 2008; Sharma et al., 2003). Similarly, the preliminary evidence regarding the Indian experience with opioid substitution therapy is also encouraging. Dhawan and Sunder (2008), in a brief overview of buprenorphine substitution in India, have concluded that buprenorphine substitution programs have been successful in decreasing the harm associated with drug use, as well as decreasing the drug use per se and improving the quality of life.

To summarize, though various harm-reduction services in India are in place, they remain too few and far in between. There is a visible and obvious gap in terms of the number of services available and the requirements of these services. Without a rapid scale-up in the number and the quality of the services, it would be difficult to provide adequate coverage to the IDU population. This would make it very challenging to realize the goal of halting and reversing the HIV epidemic.

CONCLUSION AND RECOMMENDATIONS

The available evidence indicates that substance use and related HIV is fairly prevalent in almost all parts of India; although, in terms of the HIV prevalence among drug users, different areas within the country are at different stages of the epidemic. However, the presence of risky behaviors—both injecting-related as well as sexual—among drug users would mean continued vulnerability in the country for rapid escalation of the HIV epidemic among drug users and eventually to the general population. Fortunately, among the general population, HIV prevalence is still low in India. The current stage of the HIV epidemic thus should be seen as a window of opportunity for implementing large-scale, evidence-based programs for HIV prevention. Presented below are a few specific measures, which should be urgently adopted by India.

BOX 3

Recommendations for Drug-Related HIV Prevention Programs in India

- Better assessment of epidemiological situation and monitoring/surveillance
- Convergence of abstinence-oriented drug abuse treatment and HIV prevention ("harm reduction") services
- Interventions to address both injecting-related and sexual risk behaviors

Expanding the Knowledge Base

There is an urgent need to expand the knowledge base about drug abuse and vulnerabilities to HIV/AIDS in India. Thus, extensive epidemiological data of adequate quality are urgently required. Additionally, the monitoring and surveillance systems need to be periodically reviewed and, if required, be strengthened and expanded. Behavioral data, wherever possible, should be linked with the biological data. Data collected from clinics by way of "sentinel surveillance" should be supplemented by data collected from the community, that is, the general population. Such an approach has recently been adopted in India for the general population, resulting in a major revision of the HIV estimates in the country (NACO, 2007; UNAIDS, 2007). Finally, a very important research agenda for the country is that of the effectiveness and appropriateness of HIV prevention interventions.

Convergence of "Abstinence" and "Harm-Reduction" Approaches

Services for the treatment for substance use disorders, while available almost everywhere in India, have largely tended to focus upon complete abstinence from drugs. Approaches regarded as "harm reduction" should be urgently scaled up in India. Indeed, both of these—abstinence and harm reduction—should not be seen as two opposite approaches. Rather, emphasis should be on provision of a whole continuum of care, whereby all the services that drug users may require—those aimed at achieving a drug-free life, those aimed at reducing the drug use itself, and those aimed at reducing the consequences of drug use—should be made available to them. Such a comprehensive approach has been recently endorsed by the United Nations as well (UNODC, 2008). Specifically, the country urgently requires oral substitution programs for opioid injectors using agonist agents like methadone and buprenorphine.

Broadening the Scope of the Interventions

Most drug users including IDUs are sexually active and engage in risky sexual behavior. Moreover, a sizable number are married and can potentially transmit the HIV infection to their spouses and regular sexual partners. There is evidence that HIV infection can be transmitted from IDUs to their noninjecting wives leading, ultimately to a generalized epidemic. Thus, it is of utmost importance that interventions aimed at prevention of HIV among IDUs should reach out to their sexual partners as well. Along with the injecting-related risk

behaviors, sexual risk behaviors should also be the targets of various behavior change interventions.

Chapter **15**

Alcohol Abuse: Impact on Vital Brain Functions and Societal Implications

Mary Theresa Webb, PhD

Recent neuroscientific research provides an important scientific and societal basis for raising an international alarm about the risk of binge or heavy alcohol drinking. Heavy alcohol use damages sections of the brain that modulate emotions, controls intellectual functioning, and thus may contribute to an increase in societal violence, family disruption, and diseases, such as HIV/AIDS.

Heavy drinking before the brain is fully matured arrests the development of the frontal lobe, especially the area of executive function, according to neuroscientific research. For adults, heavy drinking over a long period of time risks the loss of cognitive abilities and increases the risk of having cardiovascular incidents and alcoholic dementias, taxing health care systems.

Statistics from a 2006 European Union Study show that countries who have lowered their legal drinking age to 18 or 16 years old show an increase in binge drinking in these age groups at the same time that 100 American college presidents have suggested lowering the drinking age from 21 to 18 years old (Amethyst Initiative, 2008).

ALCOHOL AND BRAIN RESEARCH

The Centers for Disease Control (CDC) has classified alcohol (ethanol), the addictive drug in all alcoholic beverages, as a central nervous system depressant. Alcohol abuse has plagued humankind since people learned to turn barley and corn into mead. Even today, in many rural regions of Africa, villagers brew maise and turn it into 80-proof alcoholic drinks. In America, until the turn of the twentieth century, a bottle of alcohol was kept in the family medicine

cabinet and used as an anesthetic in surgical procedures. Today, in twenty-first-century America, about 7.7 percent of the population are dependent on or abuse alcohol (Lemonick & Park, 2007, p. 44), one-third of all teenagers binge drink (Kann, et.al, 2000), nearly half of all college students binge drink (Leinwand, 2007), and an uncounted number of young, middle-aged, and older adults abuse alcohol. A *binge* is a pattern of drinking alcohol that brings blood alcohol concentration (BAC) to 0.08 gram-percent or above. For a typical adult, this pattern corresponds to consuming five or more drinks (male), or four or more drinks (female), in about two hours. According to estimates by the U.S. Substance Abuse and Mental Health Services Administration (SAMSHA), 3 to 25 percent of older adults are classified as heavy alcohol users and 2.2 to 9.6 percent abuse alcohol (SAMSHA & National Council on Aging, 1998, p. 4).

Alcohol intake in small and infrequent doses can be flushed out of the body through the action of a catalytic enzyme, alcohol dehydrogenese, that metabolizes alcohol into its constituent chemical components to be eliminated from the body, thus reducing the risk of any toxic residual effects. However, when alcohol rushes into the body through excessive drinking, it is like torrential rain causing a river to rise over its banks, saturating the ground and destroying whatever is in its path. In the case of rapid or excessive intake of alcohol, instead of the alcohol being metabolized and flushed out of the body, the excessive alcohol floods the bloodstream and goes into the brain. Although most mature adults can tolerate consuming 58 liters annually or no more than two drinks a day with little or no effect on cognitive abilities (with the exception of women who have a lower amount of the enzyme alcohol dehydrogenese), alcohol is still toxic to neurons if the drug reaches the brain (Lezak, 1995, pp. 250–251). The more alcohol consumed, depending on age and sex, the greater the risk of permanent brain damage. Areas most affected are the frontal lobe or prefrontal cortex and the cerebellum, as shown in Figure 15.1 (Oscar-Berman and Marinkovic, 2004, p. 4).

The frontal area of the brain contains the neurons that regulate emotions as well as executive functioning, or attention, abstract reasoning, organization, mental flexibility, planning, self-monitoring, and the capacity to use external clues to govern behavior. The prefrontal cortex in a human's brain is 120 percent larger than that of other mammals, giving humans higher intellectual functions than any other mammal. However, alcohol abuse impairs and often destroys those intellectual abilities (Phil, 2003).

Synapses and Neurotransmitter Conductivity

Although it has been known for several decades that drugs such as alcohol replace the neurotransmitter, dopamine, that permits the flow of neurons in

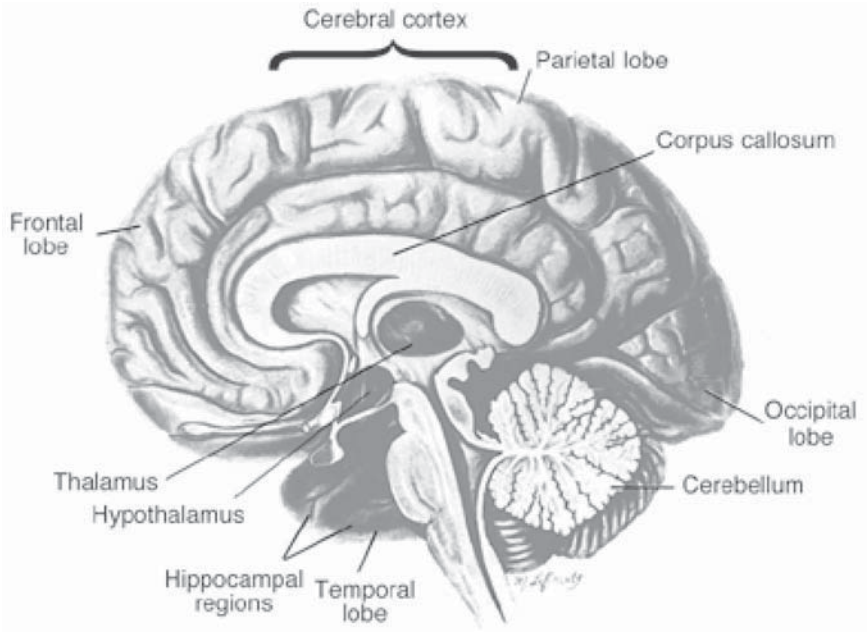

FIGURE 15.1 Alcohol abuse: Impact on the brain. From "Alcoholism and the Brain: An Overview," in *The Neurobiology of Addiction: Introduction to the Brain and the Reward Pathway and Addiction*, by M. Oscar-Berman and K. Marinkovic, 1997, Washington, DC: National Institute on Alcohol Abuse and Alcoholism (NIAAA), p. 4.

the synapse from one nerve ending to another, it has only been in the last 10 years that magnetic resonance imaging (MRI) research studies can show colored pictures of the brain. See Figure 15.2 for how neurotransmitters flow from one synapse to another.

Patterns of brain development and the impact of early onset alcohol use or long-time alcohol abuse and the resultant brain damage have been thus recorded. Through time lapse imaging, researchers at the U.S. National Institute of Mental Health (NIMH) and the University of California showed that the prefrontal cortex doesn't fully develop until young adulthood, for males that is about the age of 25; for females, about the age of 22 (Gogtay, Rapoport, Thompson, Toga, Lusk, and colleagues, 2004). If heavy alcohol use arrests this development, then important executive functions in the prefrontal cortex cannot fully mature.

CONCERNS FOR YOUTH

The 2006 European Union study (Anderson & Baumberg, 2006, p. 76) concludes that almost all 15- to 16-year-old students have drunk alcohol, beginning at 12.5 years of age, and start getting drunk at 14 years. Most countries studied show a rise in binge drinking with the prevalence of heavy drinking greatest among young boys (Grube, 2005, p. 3). The highest prevalence of drunkenness and binging among youth being recorded is in Denmark, the Netherlands, Germany, the Isle of Man, Ireland, and the United Kingdom. In countries that have a more positive view of alcohol and have lower legal drinking ages, youth binge drinking increases (p. 108). In this comprehensive report by the Prevention Research Center of the Pacific Insititute for Research and Evaluation prepared for the U.S. Department of Justice (update on ESPAD and MTF surveys, 2003), drinking rates and alcohol-related problems among teenagers (10th graders) in all EU countries and the United States were compared (see Figure 15.3). With the exception of Turkey, the rate of binge drinking was lowest in the United States. Although this comparative study did not prove that the higher legal drinking age in the United States was a deterrent, the fact that binge drinking among youth was lower than in the EU indicates that the U.S. higher legal drinking age (21) should be considered as one of the factors for this finding. In fact, the author concludes, based on his analysis (Grube , 2005), that the perception that American youth drink more and have more problems than their European counterparts is not true. According to this study there is then no support for changing the minimum drinking age in the United States.

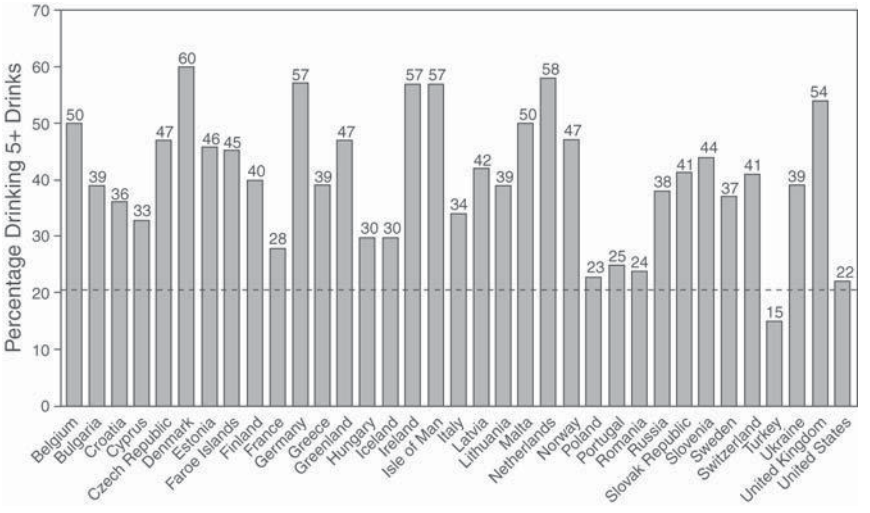

FIGURE 15.3 Prevalence of heavy drinking in the past 30 days: United States and Europe. From Joel Grube of the Prevention Research Center, Pacific Institute for Research and Evaluation, May, 2005 in *Youth Drinking Rates and Problems: A Comparison of European Countries and the United States*, for the U.S. Department of Justice, Office of Juvenile Justice and Delinquency Prevention, Update of 2003 ESPAD and 2003 MTF surveys, Calverton, MD.

The signers of the Amethyst Initiative recognize that binge drinking is a serious problem, with nearly half of America's 5.4 million full-time college students binge drinking once a month, (Leinwand, 2007) many of whom (30% of high school youth) started binge drinking in their high school years (Kann et al., 2000), 2007, p. 1). However, changing the legal age to 18 will not solve this problem. Aggressive measures need to be taken to change the drinking culture on college campuses.

If early alcohol abuse (before the age of 25) damages the brain's intellectual functioning, the ability to think, reason, and make wise decisions, then educating youth to be responsible and intelligent citizens is compromised. Not only might alcohol abuse by adolescents and youth under the age of 25 cause arrested brain development and potential permanent damage, but the resultant brain damage in turn will probably lead to early alcohol and other drug dependency (addiction) and chronic relapse. Improper executive functioning of the prefrontal cortex makes recovery difficult because recovery involves learning to control triggers and cravings. An alcohol-impacted brain also shrinks in size

and has less white matter, leading to cognitive impairment in later life (EU [European Union] Commission, 2006 p. 150).

Occasional or weekend binge drinking, five or six drinks in a row whose purpose is to become intoxicated, popular among teenagers and college students, has long-lasting implications not only for education but for the future of developed and developing countries. As noted in the 2007 U.S. Surgeon General's Report (SAMHSA, 2007), the long-term dangers to America's youth have rung enough alarm bells that the U.S. government has proposed remedial and preventative actions, as has the European Institute of Alcohol Studies in its report to the European Union for implementing public health policies.

CONCERNS FOR OLDER ADULTS

Underdeveloped brains of youth and young adults under the age of 25 are not the only brains affected by chronic heavy alcohol consumption. In a study of male veterans receiving treatment at the Durham Veterans Affairs Medical Center (in the US), researchers Swartzwelder, Zinn, and Stein (2004) administered memory and executive function tests to both alcohol-dependent and age-appropriate primary care outpatients. The alcohol-dependent group scored lower on abstract reasoning, memory, and effectiveness of timed tasks. Although some U.S. National Institute on Alcohol Abuse and Alcoholism (NIAAA) researchers indicate that moderate alcohol use (one drink a day for individuals over 65) reduces the risk of cardiovascular disease and dementia among older adults (Gunzerath, Faden, Zakhari, & Warren, 2004), other researchers (Oscar-Berman & Marinkovic, 2004, p. 5) demonstrated that older adults who had been alcohol users or alcohol abusers as youth had significant brain shrinkage and right hemisphere weakening and were thus more prone to hemorrhagic strokes. Note the shrinkage in cortical grey matter in Figure 15.4.

This condition, known as *alcoholic dementia*, shows cognitive deterioration typically associated with the prefrontal cortex or frontal lobe (Lezak, 1995, p. 255). When years of chronic drinking causes such a stroke in the weakened part of the brain, the frontal lobe in the right brain hemisphere is most often impaired. The affected person can no longer make judgments, use abstract reasoning, or plan and carry out activities without supervision. An estimated 2.3 million older Americans who have or have had problems with alcohol also have this kind of dementia, making it difficult for physicians and caregivers to distinguish between the alcohol-induced dementia and Alzheimer's disease. Two kinds of these dementias, vascular dementia and Wernick-Korsakoff syndrome, are often misdiagnosed as Alzheimer's disease. Korsakoff psychosis (WKS) is a more severe form of alcohol-induced dementia that includes amnesia and

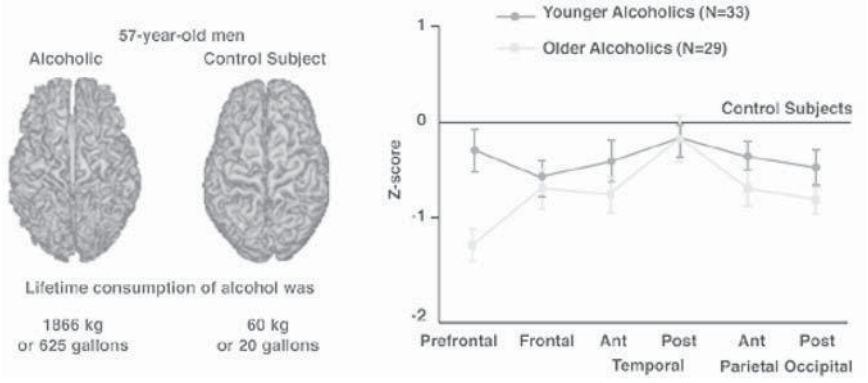

FIGURE 15.4 Cortical gray matter volumes. From "Alcoholism and the Brain: An Overview," in *The Neurobiology of Addiction: Introduction to the Brain and the Reward Pathway and Addiction*, by M. has an accompanying thiamine deficiency with even more pronounced brain shrinkage and damage. Those older adults so affected have very little ability to change self-destructive behaviors.

CONCERN FOR AN INCREASE IN VIOLENCE

According to the most recent studies in the report from the European Union Commission (Anderson & Baumberg, 2006) concerning alcohol and its societal impact, the authors have some evidence that alcohol abuse is linked with crime, especially violent crime. Heavy alcohol use has been associated with about one-quarter of all assaults and harm done through domestic violence and with about 16 percent of child abuse and neglect. Four out of 10 homicides are attributed to alcohol use (p. 211). These statistics do not take into account unintentional drunk-driving accidents, one of the leading causes of traffic fatalities in all countries.

Because alcohol damages the prefrontal lobe area of the brain where emotions are modulated, it naturally follows that this accounts for the lack of anger control, road rage, rage against women and children, that is, spousal and child abuse. Alcohol is also a central nervous system depressant so that heavy alcohol use is a significant factor in intentional deaths, that is, suicides or rage against oneself.

RECOMMENDATIONS FOR ACTION

The 2007 U.S. Surgeon General's Call for Action recognizes the many developmental and environmental influences on youth drinking and recommends that school officials, parents, and community members come together to determine preventative actions to stop early youth use of alcohol, undertake brief interventions to begin treatment early, and change the way the treatment community treats youth who are already impaired. Some of these are already in place in the United States and may be the reason that the United States has a lower rate of heavy drinking among youth than countries in the European Union. However, as evidenced in the July 2008 Amethyst Initiative, college administrations are still struggling to curb the alarming increase in heavy drinking among college students. Both parents and youth should weigh what potential damage alcohol abuse will do to education and career plans and make choices to avoid those institutions of higher learning whose administrations and alumni continue to permit heavy undergraduate drinking behavior and don't undertake aggressive measures to curb such behavior and treat those so affected. Unfortunately, alcoholic beverage companies contribute to the problem as they target underage youth by sponsoring college sporting events.

Health care professionals, clinicians, and social workers need more training in how to utilize alcohol screening instruments with patients and clients, incorporating them into routine health examinations and patient histories. They also need more training in brief interventions to arrest the alcohol abuse prior to further brain shrinkage and alcohol-induced dementias. Newer treatment options that are based on results of neuropsychological testing to determine the extent of executive function impairment are also needed for both older adults and youth who have abused or are addicted to alcohol and may be in recovery to determine appropriate treatment planning.

There is an absence of robust comparable and comprehensive data on the relation between alcohol and crime. More research is needed in this area (Anderson & Baumberg, 2006, p. 200). Although it has long been estimated that 70–90 percent of those incarcerated have committed a crime while under the influence of alcohol or other drugs, these are only estimates. Interviewing prisoners and asking them whether they would have committed the crime if they had not been drunk was one methodology recommended and used in the EU Commission study. Twenty-four percent of those interviewed in a Canadian study acknowledged they had committed crimes when they were drunk at the time of the crime. However, this low figure is probably due to prisoners still in denial, prisoners high on other drugs, and cultural attitudes toward drinking.

Providing facts and dispelling myths is one of the best ways to change public attitudes and cultural practices surrounding alcohol abuse and addiction. Countries around the world can no longer afford to ignore the public health crisis caused by heavy alcohol use. Smoking cigarettes has become unpopular and now has a negative cultural image in many Western countries due to the efforts of alarmed government public health officials. These enlightened officials have acted upon the knowledge of the dangers of passive smoke and have undertaken aggressive intervention and treatment strategies to help people quit. The same aggressive public health campaign can also change the positive image of heavy alcohol use to a negative one and help those who are abusing or addicted to alcohol to abstain. The long-term biological and societal consequences are too great to ignore. Slogans such as this one, *My brain matters, does yours?*, could change the way the public views alcohol use.

Chapter **16**

Addiction and Cognitive Control

Vicki W. Chanon, PhD, and Charlotte A. Boettiger, PhD

Substance use disorder, or addiction, is a neurobehavioral disorder characterized by a compulsion to ingest psychoactive substances (such as alcohol, prescription narcotics, nicotine, opiates, stimulants, and marijuana) despite repeated serious negative consequences. Addiction is a widespread problem, occurring among all ethnic groups and socioeconomic classes. Under normal conditions, our base motivations of hunger, thirst, and healthy fear of death or bodily harm are so powerful that they ensure that our basic needs for food, water, and physical safety are met. The need for emotional companionship, financial security, and sexual gratification also normally motivate our actions. However, for those with substance use disorders, some or all of these drives become secondary to obtaining and consuming their abused substance. This misdirection of motivation can lead to bodily harm, loss of vital relationships, loss of employment, loss of shelter, and even death. Observing addiction from the outside can be extremely frightening and puzzling. Why do addicts risk such harm? Evidence suggests that brain circuits that normally guide goal-directed behavior are malfunctioning in addicts. Recent evidence also suggests that perturbations of cognitive control are hallmarks of addiction. These cognitive aspects of addiction and their neural bases are relatively unexplored, but the advent of cognitive neuroscience tools, which allow exploration of brain activity in humans, may allow us to make quantum leaps in our understanding of the brain mechanisms of substance use disorders in the near future.

HOW DOES ADDICTION RELATE TO COGNITIVE CONTROL?

Cognitive control is a broad term describing processes essential to our survival and well-being, encompassing one's ability to act and react in a situation-specific manner (Miller & Cohen, 2001). Appropriate reactions to a specific stimulus can vary greatly from one time or situation to another. For example, a large cobra behind the glass at the zoo may evoke intrigue and cause you to stop at the exhibit to look closer, while the same snake encountered on a wooded hiking trail may evoke fear and cause you to run away. This flexibility in our cognitive control not only allows us to make key decisions through complex and changing contexts, but also allows us to direct our attention to what we find significant and to create important memories of and associations with those things. Disruptions in this cognitive control, or "dysexecutive" behaviors, are an important and defining characteristic in addictive disorder, as people with this disease are often unable to make situation-appropriate responses to stimuli or events.

Moreover, recent evidence suggests that at least two specific cognitive control faculties are functioning abnormally in addicts: attentional control and decision making. Specifically, addicts disproportionately direct their attentional resources toward stimuli associated with their abused substance. For example, the attention of an alcoholic is biased toward items, images, and words that he or she associates with drinking alcohol. This bias, which is directly related to the likelihood of relapse in abstinent individuals, may be the product of profound associative learning in addicts, whereby drug-related cues and the actions of drug seeking and drug taking are tightly linked within the brain (Robinson & Berridge, 2003). These associations are likely to underlie the intense cravings that present a major barrier to maintaining abstinence from drug use. In addition to attentional abnormalities, clinical evidence suggests that decision-making abnormalities exist among people with substance use disorders as well. For example, a number of laboratory studies consistently find that, across a broad spectrum of addictive disorders, addicts show an immediate reward bias; that is, they are more likely than nonaddict participants to choose a smaller immediate reward over a larger reward for which they would need to wait (Reynolds, 2006). This tendency holds true for various types of rewards, including the addict's drug of choice and monetary rewards. Laboratory-controlled gambling tasks have also linked abnormal decision making with addictive disorders (Bechara, 2005; Clark & Robbins, 2002). These cognitive processes (decision making, attentional control, and reinforcement-based associative learning) are all processes that fall under the general umbrella of execu-

tive function and are associated with frontal circuits within the brain. It is still unclear, though, whether these abnormalities always co-occur, or whether they are separate dysfunctions, each of which occurs in some addicts but not others. Some data suggest that the attentional biases may precede addictive disorders, but comparable data are not available in the decision-making domain. Therefore, it is not yet clear whether decision-making abnormalities contribute to the development of addictive disorders, or are instead a byproduct of addiction or prolonged drug abuse.

ADDICTION AND ATTENTIONAL BIAS

Numerous behavioral studies point to an abnormality in attentional allocation to drug cues in addicts. Attention is quickly captured by and/or held on items associated with an addict's substance of choice (Robbins & Ehrman, 2004). A variety of cognitive tasks have been used to explore and measure this bias, one of the most prevalent being the spatial cuing task. In this task, participants are presented with two visual stimuli (or "cues"), one on each side of the screen. Generally one of the cues, which could be words or images, is a drug-related stimulus while the other is neutral. After the cues disappear, a target item requiring some response by the participant appears in the same location that was occupied by one of the two cues. Addicts respond more quickly to targets when they appear in the location where the drug-related cue had appeared than when they appeared in the location of the neutral cue. This finding suggests that, in addicts, attention is preferentially captured or held by drug-related cues. Another task that has been used to measure drug-related bias is a modified Stroop task (MacLeod, 1991; Stroop, 1935). The original Stroop task presents words (including color names) displayed in different ink (or screen) colors, and tests participants on their speed of naming the font color. For example, if the word *red* was printed in blue ink, the correct response would be *blue*. Participants are generally slower at naming the ink color for color words that do not match the ink than they are at naming neutral, noncolor words, and color words written in a congruent font color. This "Stroop Effect" is thought to occur because attention devoted to reading the word interferes with naming the font color. The task has been modified to study drug-related attentional bias, by presenting drug-related words in varying ink colors, rather than color-related words. Such studies find that, in addicts, drug-related words demand more attentional resources than do neutral words.

While the majority of evidence for drug-related attentional bias comes from spatial cuing and modified Stroop studies, such bias has also been detected using other types of cognitive tasks. For example, change blindness tasks, in

which participants detect slight changes between two rapidly alternating visual scenes, demonstrate that addicts more readily detect drug-related changes in the scene. Another task, the attentional blink paradigm, has also recently been used to measure addiction-related attentional abnormalities. In this task, a stream of visual stimuli is rapidly presented, and participants are instructed to detect two specified target stimuli within the stream. When the first target (T1) and the second target (T2) are separated by about 200–400 milleseconds, participants are more likely to miss the second target because attentional resources are already allocated to processing T1. This phenomenon is referred to as the "attentional blink." If T1 is an addiction-related stimulus, addicts demonstrate a larger and more extended attentional blink. In contrast, when T2 is an addiction-related stimulus, an addict's attentional blink is reduced (Liu, Li, Sun, & Ma, 2008). Together, these studies indicate that, in addicts, words and images associated with their drug use have a heightened capacity to capture and hold attention, and that such stimuli interfere with attention to other things in their environment.

This heightened attention toward drug-related stimuli occurs in a wide variety of addictions, including cannabis, cocaine, opiates, tobacco, alcohol, caffeine, and even gambling. Attention abnormalities have been most thoroughly studied for the most commonly abused substances: tobacco and alcohol. Thus, studies exploring attention in alcohol and nicotine addictions have provided a greater understanding of some complex properties of addiction-related attentional bias. For example, data suggest that attentional bias toward tobacco cues requires the stimuli to be consciously perceived; when the smoking cues are presented too quickly or are masked by another stimulus, they do not affect attentional allocation. Data also show that demographic factors, like age and race, and mood factors, like depression, do not impact attentional bias toward alcohol cues in alcoholics. Studies of alcohol attentional bias have found that heavy social drinkers (but not light drinkers) show attentional bias toward alcohol cues, suggesting that such bias may serve as an early warning sign of alcohol addiction; these findings also bring up another possible explanation for the bias: stimulus familiarity. Previous cognitive psychology studies suggest that familiar or overlearned stimuli can affect attentional allocation (Chanon & Hopfinger, 2007). A contribution of familiarity effects to addiction-related attentional bias is suggested by an alcohol-related bias evident among staff members at a treatment center; however, the magnitude of the attentional bias toward alcohol stimuli was predicted by measures of alcohol dependence among the staff members, suggesting that the root cause of the attention bias goes beyond mere stimulus familiarity.

There is abundant evidence that attention is directed disproportionately to drug-related stimuli in addictive disorders, but do such attention abnormalities really matter? Studies that correlate addiction-related attentional bias with treatment outcomes say "Yes!" Mounting evidence suggests that the magnitude of this attention bias is directly proportional to relapse risk (Munafò & Albery, 2006). Moreover, many studies suggest that the size of the attentional bias is also directly proportional to the level of craving during drug abstinence. This clinical relevance underscores the importance of understanding the neural mechanisms of addiction-related attention bias. As noted above, repeated use of an addictive substance may produce changes in the brain that cause the brain to attribute excessive significance or "salience" to people, places, and things associated with drug use; the development of such hypersensitivity is referred to as "incentive salience" learning (Robinson & Berridge, 2003). Understanding which neural processes are affected and contribute to this increased salience of drug cues could lead to new ideas for better treatments for substance use disorders. Thus far, there has been almost no exploration into these neural correlates; however, studies looking at other aspects of attention and addiction provide some hypotheses about the parts of the brain that are involved.

NEURAL CORRELATES OF ATTENTIONAL CONTROL

While empirical studies of the neural mechanisms of attentional bias toward addictive substances remain incomplete, general studies of attentional allocation provide some clues. For example, neuropsychological studies suggest that patients with damage to the parietal lobes have difficulty disengaging and reorienting their attentional focus (Posner, Walker, Friedrich, & Rafal, 1984). The importance of the posterior parietal cortex (PPC) in attentional orienting also comes from neuroimaging studies, which particularly emphasize the intraparietal sulcus (IPS) (Corbetta & Shulman, 2002). Data from single-cell recording in nonhuman primates and fMRI studies in humans also provide evidence that attention leads to increased perceptual processing. For example, enhanced visual attention leads to increased neural activity in the nonprimary visual cortical areas. Study of the childhood development of attention networks has further enhanced our understanding of the neural mechanisms of attentional control. Explorations into the behavior, brain structure, and brain function related to reorienting and executive control of attention in children versus adults implicate a fronto-parietal network in attentional control. As expected, children showed poorer attentional control behaviorally, and they showed reduced brain activity in right temporo-parietal junction (TPJ)

and dorsolateral prefrontal cortex (DLPFC). These behavioral and functional brain differences between children and adults were associated with structural brain differences; poorer performance and reduced brain activity were associated with less gray matter in the TPJ and DLPFC (Konrad et al., 2005). These studies of typically functioning brains give us a place to begin exploring possible sites of brain dysfunction in addiction, but studies specifically exploring these neural mechanisms in addict populations are in great demand.

While addiction-related attentional bias has not been studied at the neural level, other studies of the addicted brain shed some light on possible mechanisms. Attentional bias toward drug-related cues relies greatly on the fact that these cues have become strongly associated with the use of the drug itself. Based on this deep association, the cues that become associated with drug use can produce an intense craving and relapse both in animals and humans (Robinson & Berridge, 2003). Animal studies that have directly examined the effects of cocaine administration on learned associations suggest that drug administration disrupts orbitofrontal pathways to the striatum, causing impairment in the ability to inhibit previously conditioned responses (Everitt et al., 2007). While it is likely that this cognitive inflexibility plays a role in the attentional bias toward drug-related stimuli, the neural underpinnings of the bias remain a mystery for now. Ongoing studies using emerging neuroimaging and pharmacology techniques to explore the underlying neural mechanisms of addiction-related attentional bias aim to fill this gap in our understanding and to suggest new ways in which to treat addictive disorders.

ADDICTION, DECISION MAKING, AND ACTION SELECTION

Two symptoms used as diagnostic criteria for substance dependence according to the *Diagnostic and Statistical Manual of Mental Disorders* (American Psychiatric Association, 1994) are (1) a persistent desire or unsuccessful efforts to cut down or control substance use, and (2) continued substance use despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by the substance. Research suggests that addiction is related not only to deficits in decision making related to substance use, but also to deficits in more general decision-making processes, and even to deficits in the selection of simple responses to stimuli.

One of the most frequently used tasks to study simple responses selection and inhibition is the "go/no-go" paradigm. This task generally involves presentation of different types of cues that indicate to the participant whether to respond or to refrain from responding on a given trial. Substance-dependent individuals

have difficulty inhibiting planned responses to no-go targets (Lubman, Yucel, & Pantelis, 2004; Verdejo-Garcia, Bechara, Recknor, & Perez-Garcia, 2006). While addicts may demonstrate some generalized inhibitory impairment, one can observe that such impairments appear most evident in the presence of drugs or drug-associated cues. Consistent with this observation, in laboratory go/no-go studies, addicts demonstrate greater inhibitory impairment when drug-related cues are present.

In addition to investigations of simple response selection and inhibition, several neurocognitive studies of addicts have probed higher-level forms of decision making, focusing on two primary forms. The first that we will discuss are known as "gambling tasks," and include the Iowa Gambling Task (IGT) and the Cambridge Gambling Task (CBT) (Bechara, 2005; Clark & Robbins, 2002; Rogers et al., 1999). The IGT requires participants to pick virtual playing cards, one at a time, from one of four decks of cards displayed on a computer screen. Each choice results in either a gain or loss of money. The four decks vary in terms of their riskiness and in their ultimate payoff. Two of the decks have relatively low gains, but even lower losses, while the other two have high gains, and even higher losses; the latter decks also have more frequent losses. Performance on these gambling tasks is assessed by participants' abilities to pick the statistically best decks (i.e., the low-risk decks). One concern with the IGT is that in addition to measuring decision-making behavior, the task is also implicitly measuring learning, as participants learn which decks are best on the basis of their choices. Thus slow learners could be misinterpreted as being poor decision makers. Indeed, some studies have found that performance on the IGT depends on IQ, suggesting an important role for learning in this task. Developed later, the CBT requires participants to guess whether a reward token will randomly appear in a blue box or red box and subsequently place a bet on their decision. There are 10 boxes across the top of the screen and the ratio of red boxes to blue boxes varies from trial to trial (Rogers et al., 1999). Findings with addicts in gambling task studies have been inconsistent; some have found substance abusers to have impairments on the tasks, while others have not. These discrepancies raise the possibility that the type of addiction and/or the duration of abstinence may be important factors affecting performance on the gambling tasks, but greater exploration of these issues is needed before definitive conclusions can be drawn.

The other type of decision-making task most commonly used to study addicts is the so-called delay discounting task. Performance on these tasks has been shown to be IQ independent, and robustly distinguishes between addicts and control subjects. Generally, this type of task requires participants to decide between a reward (e.g., a sum of money) available sooner and a larger reward

available at a later time. The exact implementation of such task varies from lab to lab, but in general, in comparison to control participants, addicts tend to choose the smaller, immediate rewards more often. As with addiction-related attentional bias, delay discounting has been reported for a variety of addictive disorders, including cigarette smokers, alcoholics, amphetamine users, cocaine users, opiate users, and gamblers (Bickel & Marsch, 2001; Reynolds, 2006). While this tendency for addicts to more steeply or more frequently discount delayed monetary rewards is quite consistent, it appears that rewards consisting of the drug of choice are temporally discounted even more severely by addicts (Bickel & Marsch, 2001; Reynolds, 2006). Of clinical and public health significance, heroin-dependent individuals who are willing to participate in risky needle-sharing behavior show greater delay discounting of both heroin and monetary rewards. Together, these findings suggest a generalized mechanism for overvaluing immediate consequences over delayed consequences that may help perpetuate continued drug use in the face of adverse consequences.

NEURAL CORRELATES OF ACTION SELECTION

Numerous studies using various techniques implicate frontal circuits in action selection processes (Duncan & Owen, 2000; Ostlund & Balleine, 2007; Rushworth, Walton, Kennerley, & Bannerman, 2004). For example, studies exploring response selection in nonhuman primates find neuronal activity in prefrontal cortex neurons related to go-no/go responses. Neuropsychological studies of patients with frontal lobe damage have also provided evidence for a role of frontal areas in action selection and response inhibition. In particular, deficits in these functions are frequently observed in frontotemporal dementia (FTD) patients. The term *FTD* is used to describe non-Alzheimer dementias associated with atrophy in the frontal and temporal lobes. Numerous studies indicate that such atrophy, particularly when it involves the orbitofrontal cortex, impairs response selection and the ability to inhibit inappropriate responses (Viskontas, Possin, & Miller, 2007). Similarly, patients with lesions in the right frontal lobe have slower reactions to signals directing them to inhibit their responses than do patients with intact frontal lobes (Aron, Fletcher, Bullmore, Sahakian, & Robbins, 2003). Finally, a large amount of evidence implicating frontal areas in action selection and complex decision making comes from recent neuroimaging data. The frontal lobes, specifically in the right hemisphere, have been implicated in response inhibition tasks when inhibiting responses to external stimuli (Brass, Derrfuss, Forstmann, & von Cramon, 2005; de Wit, Enggasser, & Richards, 2002; McClure, Ericson, Laibson, Loewenstein, & Cohen, 2007; McClure, Laibson, Loewenstein, & Cohen, 2004). Similarly, an

area of the fronto-median cortex plays a role in voluntary response inhibition when the decision to withhold a response is internally rather than externally cued (Brass & Haggard, 2007). Based on accumulated evidence, Michael Frank and colleagues have recently developed models of natural action selection that posit a central role of the basal ganglia (BG) frontal circuits (Frank, Scheres, & Sherman, 2007). These models point to two separate pathways, with each pathway's contribution regulated by dopamine (DA) levels. These pathways, one of which initiates responses and the other of which inhibits them, derive from two separate populations of cells within the striatum, which in turn target divergent pathways through the BG nuclei, thalamus, and cortex.

While many neuroimaging studies have probed the neural correlates of simple response selection, including several studies in addicted populations, investigations into the neural bases of decision making are less numerous. Fewer studies still have assessed the neural signature of behavioral differences between substance-abusing and non–substance-abusing populations (Bickel et al., 2007). Some fMRI evidence suggests that a dysfunction in the orbitofrontal cortex (OFC) is responsible for response selection differences seen in behavioral studies (Goldstein & Volkow, 2002). For example, cocaine addicts and alcoholics both show greater activation in the OFC correlated with poorer performance on a Stroop task, while controls show the opposite pattern, that is, greater OFC activation is related to better performance in controls. These findings suggest the brains of substance abusers are generally working harder to recruit the usual brain areas needed to perform the task, but that some neural inefficiency is impeding effective response inhibition. In terms of more complex decision making, Bechara (2005) describes a neural framework that would account for our ability to make decisions based on future outcomes. Bechara's theory suggests that two interacting brain systems, an impulsive amygdala-driven system and a more reflective prefrontal-driven system, become unbalanced with drug use, resulting in an overactive amygdala driven system. This imbalance between systems is then proposed to impair a drug user's ability to consider distant future outcomes when choosing whether to continue drug use despite probable negative consequences. Neuroimaging data have also explored complex decision making using delay discounting tasks, with results suggesting that activity differences in frontal and amygdala areas are related to differences in choosing smaller, sooner versus larger, later rewards (Boettiger et al., 2007; McClure et al., 2004, 2007).

While neuroimaging studies are one common means for investigating the neural underpinnings of differences in cognitive functions among addict populations, another valuable method is the use of behavioral pharmacology. This tool has been employed most extensively in studies assessing delay discount-

ing behavior. These studies have determined that acutely elevating dopamine levels with amphetamine *decreases* discounting of delayed rewards (de Wit et al., 2002) and that acutely depressing serotonin levels *increases* discounting of delayed rewards (Schweighofer et al., 2008). Two further studies point to the importance of dopamine in regulating discounting behavior. First, blockade of endogenous opioids with naltrexone (NTX; one of the few FDA-approved treatments for some forms of addiction) changed delay discounting behavior in a personality-dependent fashion (Mitchell, Tavares, Fields, D'Esposito, & Boettiger, 2007). The personality measure, the "Locus of Control" score, measures one's tendency to perceive outcomes as under his or her own control or as controlled by external forces (Rotter, 1966), and is theoretically linked to brain dopamine levels (Declerck, Boone, & De Brabander, 2006). This finding that this cognitive effect of NTX is personality-dependent suggests that its therapeutic effects could be as well. The second finding linked a genetic polymorphism that regulates cortical dopamine levels with delay discounting performance (Boettiger et al., 2007). Further investigation is needed, but these data highlight the importance of the modulatory systems targeted by drugs of abuse (Everitt & Robbins, 2005) in influencing decision-making behavior.

CONCLUSION

Animal studies have been undeniably instrumental in furthering our understanding of the neurobiology of addiction. Such studies have determined which circuits in the brain play a role in addictive behavior, how these areas are connected, and how these circuits are regulated by neuromodulators. Important components of these circuits include a brainstem site called the ventral tegmental area (VTA), the prefrontal cortex, and two areas located deep in the brain, the amygdala and the nucleus accumbens. The VTA neurons produce dopamine, which they release into the other three brain areas listed above. Such dopamine release normally occurs in response to natural rewards like food, water, and sex, but it also occurs in response to all drugs of abuse. These circuits are affected by learning, with the result being that cues associated with rewards also come to trigger dopamine release. Chronic intake of drugs of abuse results in an intensified version of such learning, producing extreme hypersensitivity to drug-related cues. This knowledge gathered in animal studies has enabled scientists to take a more educated approach to empirical studies of addiction in humans.

Despite the importance of these animal studies, it is important to recognize that addiction is a human disorder that does not generally occur in animals outside of a laboratory context. With the advent of cognitive neuroscience tools, we

are beginning to understand the neurobiology of addiction in a new way. These tools now allow the investigation of cognitive aspects of addiction, and thus to ask scientific questions that are only addressable by testing human populations. A growing body of research has begun to specifically focus on addiction as a dysfunction of cognitive control. While it is evident that dysfunctions in cognitive control may be central to the disease of addiction, a vast amount remains to be learned about the underlying neural mechanisms of these dysfunctions. A better understanding of the neural mechanisms underlying cognitive control dysfunctions in addiction will lead to a more complete understanding of how cognitive control systems function normally. In addition, this knowledge will stimulate new avenues for treatment development (both behavioral and pharmacological), ultimately increasing the variety and effectiveness of options for treating substance use disorders.

Chapter **17**

Schizophrenia and Substance Misuse

Giuseppe Carrà, MD, MSc, PhD, and
Sonia Johnson, MSc, MRCPsych, DM

Comorbid drug and alcohol problems ("dual diagnosis") are growing concerns among people with schizophrenia and other severe psychoses because of large increases in prevalence and their association with poorer clinical (Margolese, Negrete, Tempier, & Gill, 2006) and psychosocial (Hunt, Bergen, & Bashir, 2002) outcomes. Dual diagnosis clients present more difficulties also from a diagnostic and clinical management perspective than do single diagnosis clients. Substance use has been found to exacerbate positive symptoms (Drake, Osher, & Wallach, 1989; Margolese, Malchy, Negrete, Tempier, & Gill, 2004; Negrete, Knapp, Douglas, & Smith, 1986; Pulver, Wolyniec, Wagner, Moorman, & McGrath, 1989) and to increase aggression and violence (Angermeyer, 2000; Soyka, 2000), as well as medication noncompliance (Bhanji, Chouinard, & Margolese, 2004; Coldham, Addington, & Addington, 2002; Kamali et al., 2001; Margolese et al., 2004; Olfson et al., 2000; Swartz et al., 1998) in people with schizophrenia. Furthermore, time to readmission or community survival is significantly reduced among "dually diagnosed" compared to nonabusing subjects, even when controlling for noncompliance (Hunt et al., 2002).

Improved clinical management of dual diagnosis has been among main concerns of several European National Health Services (Banerjee, Clancy, & Crome, 2002; Carrà & Clerici, 2006; Dervaux et al., 2001; Gouzoulis-Mayfrank, 2004). Options for service development have been widely discussed (Johnson, 1997; Weaver et al., 1999), as models from the United States might perform differently within the context of well-established community mental health services. A variety of treatments exist, but the drive from the United States has been to provide programs integrating treatment of both substance

misuse and severe mental illness. Such programs require additional resources and may require radical redesign of service delivery systems. Actual prevalence rates in European countries and impact on clinical and psychosocial outcomes can inform evidence-based allocation of resources in terms of services and training needed (Johnson, 1997).

THE PREVALENCE OF SUBSTANCE USE IN PEOPLE WITH SCHIZOPHRENIA: STILL AN OPEN QUESTION?

Since the late 1980s, a number of studies have reported that substance use disorders occur at high rates in schizophrenia. U.S. data indicate that approximately 30–50 percent of people with schizophrenia have a lifetime substance use disorder. Nonetheless, whether these rates are generalizable to different countries remains controversial. A number of methodological issues must be considered, which may affect evidence about dual diagnosis prevalence. The first concern is about ascertainment. Most investigations of comorbidity in schizophrenia have been conducted with clinical samples of convenience and this can bias comorbidity rates in an upward direction (Berkson, 1946), and limit generalizability to the general population of individuals with schizophrenia. Studies such as the Epidemiologic Catchment Area (ECA; Regier, Farmer, & Rae, 1990), the National Comorbidity Survey (NCS; Kendler, Gallagher, Abelson, & Kessler, 1996) and the National Psychiatric Morbidity Survey (Jenkins et al., 1997) avoid such sampling problems in that assessments were conducted on both community and institutional populations. Nevertheless, data from these studies are also somewhat limited as the lay interview assessments of psychotic disorders used have been shown to have poor agreement with interviews conducted by clinicians (Kendler et al., 1996). Such poor agreement is indeed common in large-scale surveys and gives rise to expressions of concern among psychiatric epidemiologists (Taub et al., 2005) about validity of evidence. Similarly, the assessment of substance use can also be problematic. Designs often failed to utilize available diagnostic standards of abuse or dependence but instead identify samples based on use, problem use, or combine all levels of severity into one category. Consequently, direct comparisons of rates are limited by the variety of methods of substance use assessment. Reliable multimodal assessment is recommended for dually diagnosed patients (Goldfinger et al., 1996).

The following are the main methods that should be used to assess substance use (Drake, Alterman, & Rosenberg, 1993), with decreasing validity: consensus method (i.e., at least structured diagnosis plus other sources); self-report using formal diagnostic interviews; staff ratings; self-report using screening instrument. A related problem lies in the high prevalence of multiple substance use. This makes it critical to carry out a broad assessment of substance use

and interpretations are limited by the use of more than one substance. Thus, given the frequent occurrence of multiple substance use diagnoses (particularly between alcohol and other drugs), any attempt to attribute observed findings associated with comorbid substance use to a single substance or class of substances is often difficult if not impossible. Finally, a further concern in this research is in relation to the failure to specify time criteria in samples, that is, whether substance diagnoses are based on current, past, or lifetime. Collapsing across current and past use may either obscure or mix up enduring use rates and transient states of intoxication or withdrawal.

WHY AND HOW DO SUBSTANCE-RELATED DISORDERS DEVELOP AMONG PEOPLE WITH SCHIZOPHRENIA?

As mentioned above, comorbidity rates have important implications for nosological issues. The study of comorbidity may enhance the generalizability of research findings. A better understanding both of causal processes underlying comorbidity and of the interplay of individual disorders involved is also needed. Despite the prevalence of substance use disorders in schizophrenia and the worrying effects of dual diagnosis, little is known about its causes. However, attempting to overcome the "chicken and egg" paradox (Meyer, 1986), a number of explanatory models of substance use in schizophrenia have been proposed in the last two decades.

Genetics

There has been accumulating evidence that genetics play a role in schizophrenia (e.g., Sullivan, Kendler, & Neale, 2003), and twin studies have indicated a genetic component to alcohol dependence (Heath et al., 2001; Prescott & Kendler, 1999) and to dependence on other drugs (Kendler, Jacobson, Prescott, & Neale, 2003; Tsuang et al., 1996). Rather more complex is the contribution of genetics to the comorbidity of the two illnesses. Indeed, the available evidence currently suggests little or no genetic relationship between schizophrenia and alcoholism (Kendler & Gardner, 1997), and it may well be that the comorbidity of schizophrenia and substance use disorders reflects the effects of two separate genetic risks in the same individual (Kendler, 1985).

Substance Abuse Leads to Increased Risks of Psychosis

This widely debated association is essentially based on the stress-vulnerability model (Zubin & Spring, 1977), implicating substance use as a stres-

sor precipitating the onset of schizophrenia in vulnerable individuals. Thus, comorbid substance use and schizophrenia may have reciprocal interactions in terms of onset, course, severity, and clinical characteristics (Mueser, Drake, & Wallach, 1998), assuming that the use of substances actually increases the risk of schizophrenia. Indeed, the available evidence supports the hypothesis that cannabis is actually an independent risk factor, both for psychosis and for the development of psychotic symptoms (see Semple, McIntosh, & Lawrie, 2005 for a recent systematic review), with public health concerns (e.g., Fergusson, Poulton, Smith, & Boden, 2006).

Self-Medication Model

An intriguing hypothesis proposes that self-medication by substance abuse is a coping attempt by people with schizophrenia, matching the pharmacological properties of substances with the particular psychiatric symptoms and states experienced (Khantzian, 1985, 1997). However, this should imply diagnostic and symptomatological differences in substance selection (e.g., choice of stimulants and negative symptoms should be associated). Neither prediction is supported by research evidence. Among people suffering from schizophrenia, no replicable patterns of substances chosen and symptoms experienced have been identified (Brunette, Mueser, Xie, & Drake, 1997; Cuffel & Chase, 1994; Hamera, Schneider, & Deviney, 1995), despite preliminary findings supporting the self-medication hypothesis (Schneier & Siris, 1987). As a matter of fact, given the frequent occurrence of multiple substance misuse as discussed above, it is not possible to attribute any observed symptomatological and clinical difference to a single drug class. The only strong evidence is that regarding the association between fewer negative symptoms and dual diagnosis, though it is not still clear whether this may involve lifespan or just current misuse (see Potvin, Sepehry, & Stip, 2006 for a review). Furthermore, the pattern of substance use in schizophrenia is similar to that found in other diagnostic groups (e.g., El-Guebaly & Hodgins, 1992), and reflects a substance use pattern in the general population (Mueser, Yarnold, & Bellack, 1992; Regier et al., 1990) where the sampling took place. However, a less definitive form of the self-medication hypothesis that does have some supporting evidence suggests that substances are used to relieve dysphoria and anxiety and to alleviate tension (Addington & Duchak, 1997; Baigent, Holme, & Hafner, 1995) rather than medicating core psychotic symptoms.

Social and Cross-Cultural Differences

A final framework that may contribute to the model of how substance use and schizophrenia are linked is to assess epidemiological data to determine if

demographic or sociocultural differences in substance use are related to the relative risk for use by people with schizophrenia (Phillips & Johnson, 2001). Availability of substances but also the social context in terms of individual and local or national cultural factors is likely to contribute to the prevalence of dual diagnosis. Internationally, and within a consistent simultaneous sampling framework, the World Mental Health Surveys (WHO World Mental Health Survey Consortium, 2004) reported general population 12-month prevalence for substance disorders ranging between 0.1 and 6.4 percent (IQR, 0.8%–2.6%). This might support the hypothesis about the influence of socioeconomic and cultural factors on dual diagnosis prevalence rates, probably mediated by availability (RachBeisel, Scott, & Dixon, 1999).

THE FIRST WAVE OF EVIDENCE: THE UNITED STATES

Most evidence about the prevalence of this comorbid condition comes from the United States. The largest of these investigations, the Epidemiologic Catchment Area (ECA) study, has shown that the odds of meeting criteria for a substance use disorder are 4.6 times higher for individuals with schizophrenia compared with the rest of the population (Regier et al., 1990). In the National Comorbidity Survey (NCS), roughly half of respondents who met criteria for a substance use disorder at some time in their life also met criteria for one or more lifetime mental disorders (Kessler et al., 1996). Similarly, half of those who met criteria for a mental disorder also met those for a lifetime substance use one. Regarding the general population, the ECA study found that 47 percent of patients with schizophrenia had a comorbid substance abuse disorder, 34 percent related to alcohol, and 28 percent to other drugs (Regier et al., 1990). Further data from the NCS (Kendler et al., 1996) showed that 44.8 percent of individuals with nonaffective psychosis were classified as having a dual diagnosis.

Is Dual Diagnosis Simply Inherent to Psychotic Illness?

Also in the United States, studies in mental health settings suggest variations in dual diagnosis rates, ranging between 20 and 65 percent of persons who have a diagnosis of a severe mental illness (Cuffel, Shumway, Chouljian, & MacDonald, 1994; Drake et al., 1989). For instance, 38 percent of clients of mental health services in a California county reported one or more alcohol dependence symptoms in the previous year, and 21 percent the use of three or more types of illicit drugs (Weisner & Schmidt, 1993), but the prevalence of current substance use in an emergency room among clients with schizophrenia has been reported at 47 percent (Barbee, Clark, Crapanzano, Heintz, & Kehoe,

1989) and among inpatients, it ranges from 12 to 60 percent (Brady, Casto, Lydiard, Malcom, & Arana, 1991; Brady et al., 1990; Dixon, Haas, Weiden, Sweeney, & Frances, 1991; Drake et al., 1989; Havassy & Arns, 1998). On the whole, rates seem higher among patients with psychosis receiving emergency or inpatient treatment (Mueser et al., 1992). The recent Clinical Antipsychotic Trials of Intervention Effectiveness (CATIE) study, recruiting at 57 mixed U.S. clinical sites, found 37 percent with current evidence of substance use disorders (Swartz et al., 2006).

However, some U.S. literature also suggests that dual diagnosis rates might vary between rural or urban areas (Mueser, Essock, Drake, Wolfe, & Frisman, 2001), and different backgrounds (Lambert, Griffith, & Hendrickse, 1996; Mowbray, Ribisl, Solomon, Luke, & Kewson, 1997). These variations may reflect factors such as acute versus nonacute illnesses and differences according to mental health care settings sampled (Drake et al., 1989; Havassy & Arns, 1998) and the availability of illicit drugs in the study location (RachBeisel et al., 1999).

Variations in rates reported from the United States prompt questions about the extent to which comorbidity is a product of local social circumstances rather than vulnerability to substance misuse being an inherent clinical feature of psychosis. A number of such social factors could be studied also in order to implement effective preventive and treatment programs (Jeffery, Ley, McLaren, & Siegfried, 2000) as currently research is focused on assessing whether extra resources, required to deliver substance misuse treatment integrated with mental health care for people with severe mental health problems, will lead to benefit. A number of environmental factors may mediate higher incidence of psychotic illnesses in urban areas (e.g., Allardyce et al., 2001), in its turn potentially mediated by social deprivation or migration into urban areas (Freeman, 1994; Van Os, 2004). Analogous social factors—both at individual level and at local/national level—might mediate incidence of substance abuse in people with schizophrenia, explaining part of the variation in dual diagnosis prevalence rates.

SUGGESTIONS FROM ALCOHOL AND DRUG ABUSE PREVALENCE IN THE GENERAL POPULATION

Evidence about the epidemiology of "pure" drug and alcohol abuse in the general population is particularly useful to explore prevalence variations in different cultural and social contexts. First, in reestimating prevalence values by calibration of case definitions (i.e., imposing methodological constraints to unify case definitions), differences were found between the United States and the UK in prevalence of active drug dependence, which was estimated as 1.4

percent in the United States and 0.5 percent in the UK, just somewhat attenuated when the effect of living in an urban setting was controlled (Furr-Holden & Anthony, 2003). The difference was found despite symptom profiles among active cases being very similar. In both countries, being male, unmarried, of a low socioeconomic status (SES), and living in an urban setting were associated with an increased occurrence of drug dependence. Furthermore within the European Union, differences in lifetime and current prevalence of alcohol and drug abuse have long been assessed by the European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) in its annual reports, and despite the general trend toward increasing rates, variations between countries in prevalence rates of both alcohol and drugs abuse remain wide (EMCDDA, 2005). However, accurate comparisons between countries are still problematic because both strengths and weaknesses of different general population surveys on drug use prevalence vary in conjunction with the survey methodology (EMCDDA, 1997). The EMCDDA 2005 annual report attempted to update figures from recently published national surveys, estimating lifetime dependence prevalence rates in the EU countries ranging from 1.1 to 11.9 percent for alcohol, and between 1.0 and 6.9 percent for any other drug (EMCDDA, 2005). Two recent systematic reviews have provided an overview of prevalence of current alcohol (Rehm, Room, van den Brink, & Jacobi, 2005a) and drug (Rehm, Room, van den Brink, & Jacobi, 2005b) use disorders in EU countries and Norway. Including only studies using the *DSM–III–R* or *DSM–IV,* or *ICD–10,* plus validated instruments to assess alcohol use disorders, prevalence rates for dependence ranged from 0.4 to 7.5 percent for males and 0.1 to 2.1 percent for females. Regarding drug dependence, including cannabis, the 12-month prevalence rates varied between 0.3 and 2.9 percent. Overall, these figures suggest wide variations in the extent of alcohol and drug dependence between different Western countries and support the need to explore whether there are similar variations in the dual diagnosed population.

EUROPEAN EVIDENCE ABOUT PREVALENCE OF DUAL DIAGNOSIS

Until fairly recently, little evidence has been available about the epidemiology of dual diagnosis in other countries and whether prevalence and patterns resemble those found in the United States. The literature on dual diagnosis remains very limited in many European countries (EMCDDA, 2004), but a body of evidence of moderate size has been accumulating in the UK since the beginning of the 1990s (Carrà & Johnson, in press) and, though at a different pace, also in other European countries.

Apart from its importance to service planning and policy making in the European Union, this literature is of general interest in two respects. First, it allows assessment of whether American findings regarding the epidemiology of dual diagnosis generalize to other Western countries or whether, as with general population figures, there are substantial differences between the United States and European countries. Second, unlike the United States, EU mental health services are generally catchment area based, serving the whole population of a specific geographical area. This means that findings from EU studies regarding variations between countries are considerably more likely to be representative of the underlying population than those from the United States, where a variety of factors other than place of residence are likely to influence who uses which service (Mueser, Bond, Drake, & Resnick, 1998; Wang et al., 2005). It also allows exploration of the relationship between comorbidity and the characteristics of the local area and its population.

Most recent UK studies report rates between 20 and 37 percent in mental health settings (Menezes et al., 1996; Weaver et al., 2003), but appear to be especially high in inpatient (Phillips & Johnson, 2003) and crisis team (Johnson et al., 2005a, 2005b) and forensic (Wheatley, 1998) settings. In terms of geography, rates appear highest in inner-city areas (McCreadie et al., 2002). Evidence from France is less homogeneous with reported lifetime use rates from a cross-sectional survey (Launay, Petitjean, Perdereau, & Antoine, 1998) of 50 percent for alcohol and 27 percent for cannabis, and current rates for inpatients of 8 percent (Verdoux, Mury, Besancon, & Bourgeois, 1996). However, inner-city inpatients (Dervaux et al., 2003) reported rates of 43 percent for lifetime and 30 percent for current comorbid disorders. In Germany, schizophrenic inpatients consecutively admitted in the Munich (Soyka et al., 1993) area showed a lifetime prevalence for substance use disorders of 43 percent, while a representative first-episode sample reported a lifetime history of abuse due to alcohol (24%) or other drugs (14%) (Hambrecht & Hafner, 1996). In Italy, recent data based on multistage household probability samples yield a 12-month prevalence of World Mental Health Composite International Diagnostic Interview for alcohol abuse and dependence of 0.1 (0.0–0.2), and for a serious mental disorder of 1.0 (0.4–1.7) (WHO, 2004), although cross-national comparisons are hampered by inconsistencies in diagnostic methods. Nevertheless, some Italian data are available from specific clinical populations, namely, on opiate users in residential treatment (Clerici, Carta, & Cazzullo, 1989), with 30 percent having *DSM–III* Axis I and 59 percent Axis II disorders, and on patients on a methadone maintenance treatment program (Pani, Trogu, Contu, Agus, & Gessa, 1997), with 54 percent having *DSM–III–R* Axis I and 43 percent Axis II disorders. Sampling from community addictions services, it was found that dually diagnosed clients represented 36 percent of

the entire caseload (Carrà, Scioli, Monti, & Marinoni, 2006). Furthermore, one multicenter survey in the Lombardy region (Clerici & Carta, 1996), using standardized diagnostic instruments on 606 opiate users in six outpatient or residential treatment programs, showed that, according to *DSM–III*, 108 (17.8%) suffered only from a substance use disorder, 160 (26.4%) had a further comorbid psychiatric diagnosis (except personality disorders), and 338 (55.8%) had a further Axis II diagnosis. A more nationally representative survey (although it was biased by a large rate of refusals for the CIDI's diagnostic assessment) (Pozzi, Bacigalupi, & Tempesta, 1997) on 11 addicts' outpatient clinics located all over Italy showed an overall lifetime psychiatric comorbidity of 32.3 percent, including psychotic (10%), mood (63%), anxiety (19%), and other mental disorders (8%).

THE CLINICAL IMPACT OF ALCOHOL AND DRUG USE ON THE COURSE OF PSYCHOSIS

Numerous studies report that dual diagnosis is strongly associated with youth and male sex (e.g., DeQuardo, Carpenter, & Tandon, 1994; Mueser et al., 1990; Zammit, Allebeck, Andreasson, Lundberg, & Lewis, 2002). More important, comparing with their nonabusing counterparts, those with a comorbid substance abuse present more difficulties from a clinical management perspective. As a matter of fact, higher rates of mental health services use are reported (Bartels et al., 1993). People with this comorbidity spend significantly more days as inpatients (Menezes et al., 1996; Schofield, Quinn, Haddock, & Barrowclough, 2001; Wright, Gournay, Glorney, & Thornicroft, 2000) and in psychiatric intensive care units (Isaac, Isaac, & Holloway, 2005); and use more Accident and Emergency Departments (A&E) out-of-hours (Todd et al., 2005), assertive outreach (Graham et al., 2001), and community (McCrone et al., 2000) psychiatric services. Such evidence about mental health services use suggests the need to explore clinical and psychosocial characteristics dual diagnosis is associated with. These issues should be the main targets of treatment in terms of clinical management. The topic of the effect of substance abuse on the course and outcome of the psychosis has been extensively studied in the last decade. Several reviews have dealt with the topic, providing useful overviews (Crawford, Crome, & Clancy, 2003; Murray, Grech, Phillips, & Johnson, 2003; Ridgely & Johnson, 2001).

Positive Psychotic Symptoms

Substance use has been found to exacerbate psychiatric symptoms in people with schizophrenia, and it has been especially associated with more prominent

positive psychotic symptoms on various measures (e.g., D'Souza et al., 2005; Green, Zimmet, Strous, & Schildkraut, 1999; Lieberman, Kane, & Alvir, 1987; Lysaker, Bell, Beam-Goulet, & Milstein, 1994; Margolese et al., 2004). A recent meta-analysis (Talamo et al., 2006) reviewed eight studies providing Positive and Negative Syndrome Scale (PANSS) (Kay, Fiszbein & Opler, 1987) ratings in both comorbid and noncomorbid clients suffering from schizophrenia. Studies using different definitions of substance abuse and measuring PANSS ratings and substance misuse simultaneously (Addington & Addington, 1998; Bersani, Orlandi, Kotzalidis, & Pancheri, 2002; Lysaker et al., 1994; Margolese et al., 2004; Scheller-Gilkey, Moynes, Cooper, Kant, & Miller, 2004) or at different times (Compton, Furman, & Kaslow, 2004; Gut-Fayand et al., 2001; Sevy, Kay, Opler, & van Praag, 1990) were pooled. Moreover, scores for individual PANSS items, subscale scores for individual subjects, and many other clinical details were not analyzed, nor were other psychopathological and sociodemographic features, that might covary with dual diagnosis, controlled for. On pooling means among 725 subjects, comorbid patients had very significantly higher PANSS-positive, and lower PANSS-negative, scores (Talamo et al., 2006). Also, the recent U.S. CATIE study (Swartz et al., 2006) that recruited 1,460 subjects (37% comorbid) showed higher positive symptoms as well as lower negative symptoms scores on PANSS in comorbid subjects. The clinical relevance of these findings also derives from evidence that the main aspect of mental state associated with violence is the presence of persecutory delusions (Junginger, 1996). Positive symptoms associated with dual diagnosis may thus lead to the increased aggression and violence rates shown by comorbid clients and probably to their use of acute services and inpatient wards. Dual diagnosis patients are as a matter of fact more likely to commit violent offenses (Angermeyer, 2000), and they seem more likely to be convicted of criminal activity (Soyka, 2000) compared to those who do not abuse substances (40.1% vs. 13.7%).

Negative Psychotic Symptoms

Evidence that dual diagnosis patients experience fewer negative symptoms is relevant to the debate on the self-medication hypothesis. People with schizophrenia might attempt to cope with negative symptoms by stimulant pharmacological properties. In fact, studies testing the self-medication hypothesis in dual diagnosis schizophrenia have not been conclusive, with some studies showing that they experience fewer negative symptoms (e.g., Compton et al., 2004; Goswami, Mattoo, Basu, & Singh, 2004; Serper, Chou, Allen, Czobor, & Cancro, 1999), and others not (e.g., Addington & Addington, 1997; Gut-Fayand et al., 2001).

This topic is probably more complex than that in relation to positive symptoms for several reasons. First, negative symptoms need clear conceptualization and description (Andreasen, 1985). This concept—already implicit in Bleuler's distinction between fundamental and accessory symptoms—was developed particularly by Strauss, Carpenter, and Bartko (1974), explicitly classifying the positive and negative symptoms and differentiating the latter from social dysfunction. Indeed, Bleuler's early descriptions are closely aligned with the current nosological description of negative symptoms as restrictions in the range and intensity of emotional expression (affective flattening), in the fluency and productivity of thought and speech (alogia), and in the initiation of goal-directed behavior (avolition). The loss of the ability to feel pleasure (anhedonia) has also been identified as an associated feature, but controversy remains (American Psychiatric Association, 1994). Andreasen described the first operationalized criteria for positive and negative schizophrenia (Andreasen & Olsen, 1982).

Accordingly, the concept of positive versus negative symptoms in schizophrenia led to the development of several rating scales. Clinical investigations in dual diagnosis have used the Brief Psychiatric Rating Scale (BPRS; Overall & Gorham, 1962), the PANSS (Kay, Fiszbein & Opler, 1987), and the Scale for the Assessment of Negative Symptoms (SANS; Andreasen, 1983), along with numerous other scales. The psychometric properties of some of these scales lead to somewhat heterogeneous results in terms of factor-analytic characteristics of positive and negative symptoms. In SANS three dimensions (i.e., psychosis, disorganization, negative) best represent the scale's factor structure. The PANSS shows five factors—positive, negative, depressive, disorganization, and excitement (Lindenmayer, Bernstein-Hyman, & Grochowsky, 1994). In addition: (1) the SANS is explicitly chosen to measure negative symptoms, whereas other scales assess schizophrenia symptoms in broader terms; (2) it covers cognitive symptoms in a less confusing way than the PANSS; and (3) four out of five SANS fall within the negative factor (Buchanan & Carpenter, 1994). However, the most important difference lies in the lack of an anhedonia item in all scales but SANS because of the controversies over including it among negative features. In practice, the self-medication hypothesis assumes that anhedonia is the main target of substance abuse (Khantzian, 1997). In a recent meta-analysis of studies that used just the SANS (Potvin et al., 2006), people with schizophrenia plus a substance use disorder experienced fewer negative symptoms than abstinent ones, and the largest effect size was observed for the anhedonia subscale. Other important findings from this meta-analysis were that the reduction in negative symptoms was associated with the abuse of cocaine and cannabis, but not alcohol.

A number of other studies using the PANSS were recently pooled in a meta-analysis that showed that comorbid patients had significantly lower PANSS-negative scores (Talamo et al., 2006). Nevertheless, even these findings must be considered in the light of several reservations. The results in relation to substance of choice certainly seem consistent with the self-medication hypothesis. However, in terms of neurobiology, the negative symptoms of schizophrenia have been associated with a dopaminergic deficit in the prefrontal cortex (Finlay, 2001), but it remains unclear why people with schizophrenia should select substances that share the common property of acutely increasing dopamine release in the prefrontal cortex (Devous, Trivedi, & Rush, 2001; Volkow et al., 1996). By taking alcohol and other drugs, people with schizophrenia would be self-medicating their neurotransmitter deficits within the prefrontal system, and eventually, their negative symptoms. In addition, the fact that a difference in negative symptoms was observed only for lifetime dependent people with schizophrenia suggests that this does not depend on the *acute* effects of drugs. However, drugs seem unlikely to have long-term effects on negative symptoms. Moreover, further potential hypotheses remain to be tested. Depression, compliance with medication, or factors not yet identified are candidate variables that could explain this relationship. In terms of reverse explanation, patients with fewer negative symptoms might be simply more prone to substance abuse (Kirkpatrick et al., 1996; Kirkpatrick, Messias, & Tek, 2003). Longitudinal studies are required to resolve this issue as well as to explore whether the exposure to current or lifetime substance abuse is related to negative symptoms. More important, several different patient profiles exist among the dual diagnosis population in terms of social skills (e.g., Salyers & Mueser, 2001). Planning and organization skills are required to obtain substances of abuse and maintain substance use. Therefore, these patients would be able to continue their addiction because they have better cognitive function and fewer negative symptoms (Joyal, Hallé, Lapierre, & Hodgins, 2003).

Quality of Life and Social Functioning

In relation to quality of life (QoL) in severely mentally ill substance abusers, the evidence is still somewhat contradictory. In "pure" alcohol dependent subjects, abstinence, controlled, or minimal drinking are associated with improved QoL and psychiatric comorbidity is an important factor in determining a poor QoL (Foster, Powell, Marshall, & Peters, 1999). A few studies examining the effect of substance abuse on outpatients with established severe mental illness (Brunette, Noordsy, Xie, & Drake, 2003; Lam & Rosenheck, 2000) and

with first-episode psychosis (Addington & Addington, 1997, 1998) found significantly lower quality-of-life scores in those with dual diagnosis compared with patients with schizophrenia with no past history of substance abuse, but these findings were not replicated in a similar later study (Van Mastrigt, Addington, & Addington, 2004). Furthermore, Herman (2004) found that dually diagnosed inpatients express higher levels of satisfaction with their quality of life compared to the non–substance-abusing patients with schizophrenia. However, hypotheses emerge from the literature that might explain differences in findings and which deserve further testing. In dually diagnosed people, quality of life also seems related to medication adherence, with findings from a first-episode psychosis cohort showing poorer quality of life in nonadherent patients (Coldham et al., 2002). Also, social skills and cognition and likewise psychotic negative symptoms are features that might explain part of the variance in quality of life, and they should be controlled for when the influence of dual diagnosis is assessed (Joyal et al., 2003; Salyers & Mueser, 2001). Finally, QoL has been the outcome measure in several trials for the dually diagnosed population, often (Bellack, Bennett, Gearon, Brown, & Yang, 2006; Drake et al., 1998; Schaar & Ojehagen, 2003; Shaner, Eckman, Roberts, & Fuller, 2003), but not always (Lehman, Herron, Schwartz, & Myers, 1993), showing improvements.

Medication Compliance

Approximately 40 percent of patients with schizophrenia stop prescribed medication within one year and 75 percent by two years (Owen, Fischer, Booth, & Cuffel, 1996; Perkins, 1999). As mentioned above, it seems possible that increased symptoms expressed by people with comorbid substance abuse and schizophrenia can be accounted for by medication noncompliance as well as by the direct effect of substances on psychiatric symptoms. Findings from numerous studies (Buchanan, 1992; Drake et al., 1989; Kashner et al., 1991; Kovasznay et al., 1997; Owen et al., 1996; Razali & Yahya, 1995; Swartz et al., 1998) reported lower medication compliance in comorbid patients. Furthermore, a recent history of substance abuse or dependence may more accurately predict future medication compliance than a more remote history of a substance use disorder (Olfson et al., 2000). Poor compliance with neuroleptic regimens in comorbid people seem to be associated with more negative subjective or dysphoric responses, but when comorbid substance misuse and other confounding variables are controlled for, level of insight is a significant factor in determining whether a patient is regularly compliant (Kamali et al., 2001). Thus, a better understanding of reasons for noncompliance might be

helpful also in quantifying the amount of noncompliance mediated by increasing positive symptoms and that attributable just to comorbid substance abuse (Kamali et al., 2001). Indeed, when comorbid patients are adequately treated for their psychiatric illness, there is considerable amelioration in their positive psychotic symptoms (Margolese et al., 2006), even when their substance use remains unchanged.

CONCLUSIONS

Dual diagnosis rates among people with schizophrenia in mental health settings are high. Social factors may be very important in explaining dual diagnosis rates in people with schizophrenia.

People with schizophrenia and dual diagnosis—compared with those without a comorbid disorder—have greater positive and fewer negative symptoms, and report poorer adherence to medication compliance and worse global subjective satisfaction with life. However, the self-medication hypothesis needs further research. Conceptualization and measuring of negative features in dual diagnosis are further candidate areas for research.

The negative impact in dual diagnosis on the symptomatological features and on psychosocial functioning is cause of concern. The high rates of dependence (not simply abuse) on alcohol or other drugs, and their impact on different outcomes deserves attention and cautious consideration also in terms of health service research. Standard treatments provided in community mental health centers might not be appropriate in dealing with dual diagnosis. Results on dual diagnosis prevalence cannot assume to be generalizable from one country to another. Furthermore, for social and cultural reasons, people might not want to admit substance misuse, which could also be more stigmatized in some countries than others.

However, social factors such as area of residence are very important in explaining dual diagnosis rates in people with schizophrenia. Periodic, local, surveys are needed to explore the extent of the comorbidity. Mental health and addiction services should take into account results on local prevalence when planning their treatment programs. Staffing, training, and configuration of health services are all areas to be designed and implemented according to relevant evidence. Better identification and treatment of comorbid dependence in adequate settings should be among treatment priorities. Treatment needs of the comorbid population need to be met in order to guarantee a subjective quality of life at least as high as that of their nondependent counterparts. Further research is also needed to explore whether variations in dual diagnosis rates between centers are the result of different distributions of individual

social characteristics (e.g., poverty, unemployment, single marital status, etc.) or of area-level social characteristics (e.g., drug availability, stigma experienced by the mentally ill, benefits regime, etc.).

Chapter **18**

Neural Basis for Methamphetamine Addiction—Rethinking the Definition of Dependence

Mary F. Holley, MD

Addiction to methamphetamine is a serious disabling condition that affects individuals, families, and communities as end-stage addicts destroy their lives, abuse their children, and lose their jobs. The availability of effective treatment is limited by the economic resources available to treat what many consider an incurable moral failure. Taxpayers and donors are often unwilling to devote large amounts of money to rehabilitate people who voluntarily ingest drugs of abuse. The need for prolonged periods of rehabilitation and extended supervision is even greater for methamphetamine addiction than for addiction to other drugs of abuse. A better understanding of the biologic nature of addiction is needed on all fronts, by addicts, their families, health care policy makers and payers, the legal and judicial fields, and the community at large.

Because of the lack of available treatment, an overwhelming burden is being placed on our corrections system by the sheer volume of inmates sentenced primarily for drug offenses. Corrections facilities are designed to punish and deter antisocial behavior in rational persons. They are now being asked to intervene in the disease of addiction although they are neither funded nor staffed to treat addiction. Addicts do not usually make rational choices but rather are driven by a brain disease that must be treated to prevent the recidivism that plagues our current system.

Even in the field of psychiatry, there is tremendous reluctance to admit that methamphetamine is a neurotoxin and that brain tissue is damaged by it. This in spite of the persuasive animal and human data confirming the serious neurotoxicity, particularly to the frontal lobes, related to methamphetamine use. And

this reluctance is seen in card-carrying Darwinists. Can methamphetamine be a neurotoxin in all known animal models and yet fall harmless to the ground when confronted with the mystical, magical human brain? There is nothing special about human neurons that render them impervious to the oxygen free radical compounds released by methamphetamine.

If we wish to convince the general public and health care policy makers that addiction is a brain disease and not merely a moral failure, we must define it in objective terms, not just in behavioral terms. Our current definition of dependence has as much to do with the tolerance of the patient's employer for poor performance as it does the patient's behavior. We should instead define it in terms of neurochemical, behavioral, and personality changes, which appear early in the clinical course, long before "dependence" is diagnosed under the current paradigm.

NEUROTRANSMISSION

Changes in the neurotransmitter levels of the brain underlie many of the personality changes and mental illnesses associated with methamphetamine. The principal chemicals affected by the use of meth are the monoamines dopamine, serotonin, norepinephrine, and cortisol, a stress hormone.

Methamphetamine stimulates a massive release of monoamines, especially norepinephrine, a 2,000 percent increase (Rothman, Bauman, Dersch, Romero, & Rice, 2001), dopamine, a 500–1,000 percent increase (Gough, Imam, Blough, Slikker, & Ali, 2002; Izawa, Yamanashi, Asakura, Misu, & Goshima, 2006), and serotonin, a 300–500 percent increase (Ago, Nakamura, Baba, & Matsuda, 2008) by both presynaptic and postsynaptic mechanisms. Meth causes the accelerated release of vesicles containing these neurotransmitters, and reverses the presynaptic transporter molecule that normally reabsorbs neurotransmitter once released (Zaczek, Culp, & De Souza, 1991). Methamphetamine changes the conformation of the transporter molecule causing the "vacuum cleaner" to go into reverse and spew neurotransmitter out instead of reabsorbing it (Yudko, Hall, & McPherson, 2003, p. 39). This is in contrast to cocaine, which only blocks the reabsorption of neurotransmitter.

Postsynaptically, meth inhibits the enzyme monoamine oxidase (MAO), which is responsible for metabolizing these neurotransmitters once they are released. This increases the length of time the transmitter is active at the receptor site and thus its effects in the brain (Ramsay & Hunter, 2003). When MAO is inhibited, alternate routes of metabolism are used, resulting in delayed metabolism and hydroxy free radical formation. Methamphetamine stimulation also triggers an increase in gluatamine receptor density in nucleus accum-

bens, acutely increasing its responsiveness to repetitive stimulation (Chao, Ariano, Peterson, & Wolf, 2002).

Methamphetamine also disrupts the hypothalamic pituitary axis, causing a release of cortisol, a stress hormone. Higher cortisol levels are associated with greater dopamine release in the striatum and more positive subjective drug effects (Oswald et al., 2005). Glucocorticoid receptors in the midbrain are affected in the striatum and hippocampus, which is thought to underlie stress-related relapse (Wang et al., 2005).

SENSITIZATION STAGE OF ADDICTION

Methamphetamine addiction progresses through two distinct biochemical stages. Only the later stage is characteristically recognized as *addiction* or *dependence* in the terminology of *DSM–IV.* Those patients still in the initial sensitization stage are considered users, but have not yet had negative sequellae from their drug use and so have not tried to quit or cut down. In sensitization, each dose feels even better than before, lasts longer, and is more intense. Having heard about tolerance, the user understands that only when his drug use accelerates would he be considered an addict, so during this early stage, he assures himself he must be ok. He does not believe his methamphetamine use is having any effect on his brain.

During the sensitization period, neural tracts that are hyperstimulated on an occasional basis by low intensity use become more responsive to methamphetamine. These neural tracts have been shown to increase their sensitivity to repeated doses of methamphetamine, both by increasing numbers of receptors for monoamine neurotransmitters, and also by increasing numbers of glutamate receptors in the brain (Xui, Koeltzow, Cooper, Robertson, & White, 2002). We add more lanes to accommodate increased traffic.

And in the sensitization period, the neurons still have a reserve of intracellular neurotransmitter that can be mobilized by axonal transport, to replenish the terminals with fresh supplies of neurotransmitter, thus enabling the cells to function in the face of massive losses in their neurotransmitter supplies (Yudko et al., 2003). This is why, in the early stage of addiction, function is maintained between "highs" and the "crash" after using is just a mild depression, not even as bad as the hangover after an evening of heavy alcohol intake.

This phase may last for years in the case of oral use of small doses of methamphetamine, and there are medical uses for methamphetamine for treatment of Attention Deficit Hyperactivity Disorder (ADHD), narcolepsy, and weight loss in small closely monitored doses. The military has used methamphetamine in small closely regulated doses for many years with a long record of safety.

Unmonitored use, however, readily lends itself to compulsive and repetitive use with resultant personality changes—what any unbiased observer would call *addiction*.

At this early stage the addict is almost never willing to admit she has a problem. She uses frequently, but perhaps not daily. She feels focused and energetic while on methamphetamine. Her family members notice her personality changes, her short temper and impatience, but she thinks everything is fine. She cannot quit using for any prolonged length of time—what the average person would consider addiction—but she has never really tried to quit, nor does she consider herself impaired in any way, and so a psychiatrist would not diagnose her *dependent*. Psychiatry has rejected the word *addiction* as a diagnostic term. It is used here purely as a functional term referring to the habitual and compulsive use of a substance.

Dependence is diagnosed only when strict criteria are met, including three of the following conditions:

Tolerance
Withdrawal symptoms
Escalation of use
Effort to control use
Occupies time, effort
Replaces other activities
Use despite impairment

Only in the later stage of addiction, when drug use impairs functioning and replaces normal healthy activities, resulting in the loss of relationships or employment, does a psychiatrist consider the individual an addict (dependent). This functional definition has more to do with the reaction of his wife and the demands of his employer than it does with the biochemical effects the drug is having in his brain. He won't make an effort to control his use until threatened with an employee drug test. The level of denial in such a person guarantees that the subjective measures used to define dependence will not apply to him until a set of handcuffs has been applied at least once. The changes in his brain are at an advanced stage by now. By the time dependence is diagnosed, serious mental health problems are often evident, and recovery of normal cognition and personality features will require months, if not years, of intense therapy.

Early diagnosis and intervention are impossible with the current definition of dependence (or addiction) used by psychiatry. In fact, people requesting treatment for their addiction are sometimes turned away by mental health providers because they are "not addicted enough," particularly in the public sector.

LATE-STAGE ADDICTION

In later-stage addiction, neurotransmitter reserves have been depleted as continued massive releases of monoamines have exhausted the cell's capacity to manufacture these complex chemicals de-novo (Vacca, Ahn, & Phillips, 2006). Presynaptic function is also impaired by chronic methamphetamine exposure, with corresponding behavioral changes, an effect that persists at least four months into recovery in an animal model (Melega et al., 2008). Striatal dopamine concentration (reserve) is reduced by 20 percent and presynaptic dopamine transporter density is reduced by 35 percent. Chronic presynaptic depression of function is "renormalized" in cortico-striatal pathways by readministration of methamphetamine, restoring the system to apparent normalcy (Bamford et al., 2008).

At the same time, the postsynaptic side has responded to the massive hyperstimulation by phospohorylating, sequestering, and degrading its receptors (Volkow et al., 2001). While D1 receptors in the striatum are preserved, they are delinked from the adenylyl cyclase that serves as its second messenger in the postsynaptic cell (Tong et al., 2003). The dopamine response is suppressed in response to both psycho stimulants and natural rewards in withdrawal from methamphetamine (Vacca et al., 2006). More and more stimulation is required to trigger a postsynaptic response. The crash becomes more symptomatic and longer lasting as neurotransmitters and receptors are depleted. The addict accelerates his drug dose and interval in an effort to reclaim the high and/or avoid the crash.

As dopamine transmission is impaired in the reward circuit, higher doses of methamphetamine are required to maintain function. The recreational user can't wait until Friday to use again, and the functional user needs higher doses to maintain his current level of productivity. As higher doses are used, side effects, including jitteriness and disorganization, are seen, which impair his occupational adjustment. He is generally oblivious to this change and to the personality changes that are also occurring. His boss and his wife, however, usually are not oblivious to these changes.

His irritability has by now progressed to domestic violence—either verbal or physical. His children are afraid of him. His work performance has become erratic and customers and coworkers are complaining. Personality changes are the hallmark sign of the methamphetamine user. They are much more prominent than those seen in heroin or even cocaine users, and they affect every aspect of life. Some of these personality changes are quite reversible since they are mediated by biochemical changes in brain function, not by structural changes.

But they improve very slowly, over the course of many months of abstinence as neurotransmission is reestablished (Wang et al., 2004).

Other changes seen in later-stage methamphetamine addiction are not as readily reversible. The loss of memory, cognitive ability, motivation, and reality testing are related to structural damage to brain tissue caused by cellular damage to the brain (Thompson et al., 2004). These changes also result in the deepening of the addiction as key structures related to self-control are compromised.

CYTOTOXICITY

The massive release of neurotransmitters caused by high dose and chronic methamphetamine use results in high levels of nitrogen and oxygen free radical formation (Acikgov et al., 2000). These free radicals are formed by the metabolism of methamphetamine, and also by the breakdown of the huge amounts of monoamine neurotransmitters that have been released both intra- and extracellularly. These monoamine neurotransmitters must also be broken down, and MAO, the usual enzyme to do that, is inhibited by methamphetamine. Alternative metabolic routes are used, resulting in the generation of large amounts of hydroxyl free radicals nitric oxide and peroxynitrite, which are extremely toxic to brain cells (Jeng, Ramkissoon, Parman, & Wells, 2006).

Free radical compounds denature proteins, damage DNA, and generally wreak havoc in the areas of the brain in which they are concentrated (Cubbells, Rayport, Rajendran, & Sulzer, 1994). Because most of the neurotransmitters are released in the midbrain, nucleus accumbens, and striatum, and in the prefrontal cortex, those areas are disproportionately affected by methamphetamine abuse with progressively worsening cognitive and executive function (Li, Wang, Qiu, & Luo, 2008).

The power of these free radicals to damage the human brain was demonstrated most vividly by Thompson in 2004 when he and his colleagues demonstrated up to 15 percent loss of brain tissue in large areas of the brain, including both cortical and subcortical tissue in methamphetamine users. These findings were correlated with cognitive and memory defects in the subjects studied. Thompson described it as a "forest fire of brain damage" with real-world consequences in occupational failure, disintegration of relationships, and challenges in treatment.

Methamphetamine use causes persistent hypometabolism in the frontal white matter and impairment in frontal executive function on positron emission tomography (PET) scanning (Kim, Lyoo, Hwang, Sung, & Lee, 2005). Abstinent meth users showed impaired performance on the Wisconsin card-

sorting test associated with reduced metabolism in the right superior frontal lobe. Hypo-frontality in methamphetamine addicts has been thought to contribute to the significant cognitive deficits, memory loss, and poor impulse control that cause significant social failure and complicate treatment participation and success (Homer et al., 2008). A realistic assessment of the nature and extent of these deficits is essential to developing effective treatment programs.

THE PLEASURE CIRCUIT

The pleasure circuit has been well described, and consists of the nucleus accumbens, anterior bed nuclei, anterior lateral hypothalamus, stria terminalis, lateral preoptic area, median forebrain bundle, ventral tegmental area, ventral pallidum, and prefrontal cortex. These areas are profoundly affected by methamphetamine administration, with altered sensitivity and receptor changes in animal models (Brady, Glick, & O'Donnell, 2005; Broom & Yamamoto, 2005; Yong & Kauer, 2003).

Direct stimulation of the nucleus accumbens by dopamine results in euphoria. The ventral tegmental area sends numerous dopaminergic neurons to the nucleus accumbens, contributing to reward and motivation in response to natural pleasures. Methamphetamine increases dopamine in the nucleus accumbens by up to 1,000–1,200 percent, provoking a powerful pleasurable sensation and triggering a powerful motivator. As these dopamine receptors are damaged by overstimulation, natural rewards are not appreciated, and motivation is impaired.

The prefrontal cortex is an integral part of the reward circuit. Pleasures are experienced in all their richness in the prefrontal cortex, and cravings originate in these areas as marked by intense neural activity on exposure to triggers (Kalivas, Volkow, & Seamans, 2005). Prefrontal cortex is hyperresponsive to drug cues, driving the nucleus accumbens, while at the same time, executive function is reduced, diminishing cognitive control. Wilson's analysis of these studies showed the orbitofrontal and dorsolateral orbitofrontal cortex more active in addicts anticipating drug usage, while anterior cingulate cortex was more activated in those trying to resist the urge to drug usage—treatment-seeking individuals (Wilson, Sayette, & Fiez, 2004).

Appeals to the pleasure circuit to explain all aspects of addictive behavior are found wanting in that as addiction proceeds, pleasurable sensations decline, and addicts are often motivated to use substances that no longer give them very much pleasure. Motivation shifts from obtaining pleasure and avoiding the pain and anxiety of withdrawal to compulsive use in the face of serious adverse consequences. The ability of the conscious mind to control behavior is

seriously compromised in addiction, particularly methamphetamine addiction, even when competent cognitive behavioral therapy is received and mastered. This suggests a parallel and separate anatomic basis for behavior control apart from hedonic perception.

THE CONTROL CIRCUIT

The control circuit is less understood, and is not included in most textbooks on the neurophysiology of addiction. The original literature, however, supports the existence of a dedicated set of structures that serve to facilitate control of behavior in the face of desire or craving. This control circuit consists of the prefrontal cortex, anterior cingulate gyrus, the lateral habenula, and fasciculus retroflexus, which exerts inhibitory GABA-A control over the midbrain craving centers in the ventral tegmental area (Ji & Shepard, 2007). There are also direct inhibitory connections between prefrontal cortex and VTA that are also GABA-mediated (Carr & Sesack, 2000).

The influence of this circuit in the modulation of addiction has been delineated in several human studies. Volkow and colleagues in 2001 demonstrated a loss of dopamine receptors in the entire orbitofrontal cortex in abstinent methamphetamine users. More specifically, methamphetamine users showed significantly reduced cerebral blood flow in the anterior cingulate gyrus, with a significant persistent reduction even after six months' abstinence. This suggests a structural change, not just a functional neurotransmitter mediated effect, in the anterior cingulate gyrus, an important area for control of impulses and behavior (Hwang et al., 2006).

Multiple studies have demonstrated reduced task-related activation of the anterior cingulated gyrus in methamphetamine users. Paulus, Tapert, and Schuckit in 2005 showed that those addicts who eventually relapsed had markedly reduced activation of the dorsolateral prefrontal cortex and anterior cingulate gyrus compared to addicts who did not subsequently relapse. Subjects were followed for up to three years to observe for relapse, and the predictive power of this functional measure of brain activity in these areas was impressive.

The cingulum bundle conducts impulses from anterior cingulate gyrus and other prefrontal areas posteriorly, primarily to the hippocampus, but also to multiple other midbrain structures, including the lateral habenula. The cells in this transmission line are exquisitely sensitive to methamphetamine, with destruction of more than 90 percent of the cingulum bundle demonstrated after just a single intoxicating dose of methamphetamine in animal models (Zhou & Bledsoe, 1996). This is not just a change in the sensitivity of the

neurons, but the destruction of a key pathway between the cingulate gyrus and midbrain structures, including hippocampus and lateral habenula.

The lateral habenula itself is sensitive to the effects of methamphetamine with specific degeneration of large areas of lateral habenula with continuous exposure to meth as would be seen in a binge pattern of self-administration (Ellison, 1992). In 2000, Carlson and colleagues reported that many drugs of abuse impair function in the habenula and fasciculus retroflexus, dubbing it "the weak link in addiction." This line of research was then almost completely neglected for many years until recent studies have further delineated the significance of Ellison's and Carlson's findings.

The lateral habenula is a significant processing center conveying information from cognitive cortical areas to subcortical areas. Habenular lesions result in learning deficits, and reductions in memory and attention consistent with its central role in cognition (Lecourtier & Kelly, 2007). In humans, the lateral habenula is especially responsive to feedback about errors, exerting inhibitory impulses when errors are detected and response patterns need to be changed (Ullsperger & Cramon, 2003).

Lateral habenula neurons in the primate are activated in a no-reward condition, exerting inhibitory control over dopamine release from the ventral tegmental area (Matsumoto & Hikosaka, 2007). In this study even weak stimulation of lateral habenula elicited strong inhibition of dopamine release. Dopamine levels are thus decreased when predicted rewards do not occur, a biological basis for disappointment (Pagnoni, Zink, Montague, & Berns, 2002).

Specifically, lateral habenula in turn exerts a powerful inhibitory effect on dopamine transmission by the ventral tegmental area via the fasciculus retroflexus, a GABAergic pathway. Ji and Shepard (2007) did the definitive study of this tract, demonstrating that single-pulse stimulation of the lateral habenula effectively shut down the activity of 97 percent of the dopaminergic neurons in the substantia nigra and ventral tegmental area. Stimulation of the lateral habenula resulted in a complete cessation of spontaneous firing in nearly all dopamine neurons in the substantia nigra and ventral tegmental areas. Lesions of the fasciculus retroflexus completely blocked this strongly inhibitory effect on dopamine neurons.

These ventral tegmental dopaminergic signals are responsible for recurrent drug-taking behaviors even in the absence of an external trigger for the hedonic reward pathway (Nakajima et al., 2004). Uncontrolled ventral tegmental stimulation of the nucleus accumbens produces dopamine signals that are experienced in the frontal cortex as cravings and the desire to get high. If sufficient inhibitory control in the frontal cortex is not present to suppress these signals, behavior is likewise uncontrolled.

PROPOSED TREATMENTS

Since a number of interrelated adaptations to drug use occur in multiple areas of the brain, it would be expected that intervention would also have to occur at multiple levels for successful rehabilitation. There are adaptations in the reward areas, motivation and drive, memory and conditioning, and inhibitory control areas that result in long-lasting changes in a person's responsiveness to natural rewards, cognitive ability, and inhibitory control. While acute drug intake increases dopamine release, chronic use impairs it not only in the reward centers but also in the frontal lobes (cognitive ability) and cingulate gyrus (inhibitory control) (Volkow, Fowler, & Wang, 2004).

GABA-mediated inhibitory control is a target for many of the newly proposed treatments for addiction, including baclofen, gabapentin, and vigabatrin. These drugs are GABA A agonists (baclofen), or GABA transaminase inhibitors (gabapentin and vigabatrin), essentially amplifying the inhibitory signals and thus improving impulse control and reducing craving. Animal studies were very promising (Barrett, Negus, Mello, & Caine, 2005; Di Ciano & Everitt, 2004; Filip et al., 2007), as were open-label studies using baclofen and gabapentin (Urschell, Hanselka, Gromov, White, & Baron, 2007) and vigabatrin (Brodie, Fiqueroa, Laska, & Dewey, 2005; Fechtner, Khouri, Figueroa, Ramirez, & Federico, 2006). However, double-blind studies of baclofen and gabapentin showed no effect (Heinzerling et al., 2006; Shoptaw et al., 2003). A randomized controlled trial of vigabatrin is needed. Though vigabatrin has been linked to visual field defects with long-term use, its safety in short-term use is suggested by the open-label studies completed (Brodie et al., 2005).

Reducing the reward value of methamphetamine is another biochemical target area that is open to intervention. As in the case of heroin addiction and its partial agonist buprenorphine, there is a partial agonist for stimulant drugs in the form of modafinil. In animal studies, modafinil substituted partially for both cocaine and amphetamine in rats trained to discriminate these stimulants from saline, but was much less potent (Dopheide, Morgan, Rodvelt, Schachtman, & Miller, 2007). While it is not a dopamine receptor agonist, it has a similar clinical profile to stimulants with alertness and cognitive improvement and does increase dopamine release in the nucleus accumbens (Murillo-Rodríguez, Haro, Palomero-Rivero, Millán-Aldaco, & Drucker-Colín, 2007). A double-blind controlled trial of modafinil showed it is effective in reducing cocaine dependence with few adverse effects (Dackis, Kampman, Lynch, Pettinati, & O'Brien, 2005). It is especially beneficial in improving cognitive performance and thus participation with cognitive behavioral therapy (Makris,

2007; Minzenberg & Carter, 2008). Buproprion, a dopamine and norepinephrine reuptake blocker, has also been shown effective in a subset of men using low doses of methamphetamine, but was not effective for the population at large (Elkashef et al., 2008; Shoptaw et al., 2008).

Alternatively, dopamine blockade has been evaluated for effectiveness in reducing stimulant relapse. Selective D3 receptor antagonists reduced cocaine seeking behavior in rats (Xi et al., 2006; Cervo, Cocco, Petrella, & Heidbreder, 2006). Available D2 blockers including arapiprozole (Beresford et al., 2005) and olanzapine (Smelson et al., 2006) relieve cravings in comorbid schizophrenic stimulant addicts, but with the usual anhedonic side effects characteristic of these medications.

NONPHARMACOLOGIC APPROACHES

But there are nonpharmacologic ways of influencing the self-control tract of the brain and enhancing its function, some of which the rehabilitation industry has used for years without really understanding the neurobiology behind them. One of them is the "boot camp" approach. All rehabilitation programs include at least a component of this approach, and some are almost exclusively a boot-camp experience. Chores and schedules and responsibilities are expected and are recognized as important to recovery from addiction.

The value of these interventions consists of the conditioning, and in some cases, regeneration, of damaged tissue, restoring function in the areas of the brain mediating self-control. Classical rehabilitation techniques are used from the physical therapy paradigms and applied to behavioral rehabilitation with good success. When a neural tract is impaired, for instance, after a stroke, rehabilitation consists of forcing the relevant area of the brain to work, thus facilitating the recruitment of surrounding surviving cells to take over the function of the diseased tissue, a process called activity-dependent plastic change, or neuroplasticity (Ward, 2005).

In the same way, when the self-control pathway is compromised, rehabilitation consists of imposing conditions that force the patient to exert inhibitory control over her behavior, facilitating recruitment of surviving cells to take over the function of the diseased tissue. This is particularly effective at the cortical level in retraining the anterior cingulate cortex to control behavior. Addicts are "forced" to get up at a given time, do chores, and keep a schedule, so that impulse inhibiting areas are stimulated to function on a regular basis. The principles of neuroplasticity ensure that such "exercise" will stimulate recovery of function by increases in brain-derived neurotrophic factor (BDNF), dendritic arborization, and synaptic plasticity.

Contingency management capitalizes on these same principles, as an external motivator is used to improve compliance and modify behavior. Coupled with cognitive behavioral therapy and the social support found in the group therapy setting, success in treatment of methamphetamine addiction is comparable to treatment of other addictions. Cognitive and attentional problems limit the application of cognitive behavioral techniques in early abstinence, but as the brain heals and remodels, retention and insight improve and treatment outcomes are comparable to those obtained with treatment of cocaine and other drug addictions (Rawson et al., 2000).

FUTURE DIRECTIONS

Until now, most neuropharmacology research has been devoted to understanding the reward system of brain physiology with an eye toward blocking the rewards associated with drug abuse with dopamine blockers of various types. Atypical antipsychotic medications have been used and found effective, but anhedonia is a frequent side effect. Clinical usefulness is limited to those patients who are willing to forgo all rewards for an indefinite period of time. Compliance with such therapy is usually confined to the court-ordered population. Substitution therapy with modafinil is more likely to be effective and acceptable to patients, but carries its own risks of exacerbating mental illnesses such as bipolar disorder and psychosis, and also cardiovascular complications (Kampman, 2008).

More attention should be directed toward the self-control system to develop new treatments based on enhancing the addict's control over her own behavior. GABAergic medications offer the potential to amplify normal inhibitory neural tracts to improve impulse control at the midbrain level, while behavioral modification and cognitive behavioral therapy addresses the cortical components of the self-control circuit. This could lead to improvements in the effectiveness of our current contingency management and motivational enhancement techniques, both of which are components of effective cognitive behavioral treatment. A greater understanding of the neurologic components and functional biochemistry of the self-control factor would extend pharmacologic and nonpharmacologic support to empower addicts to control their own lives instead of being controlled by drugs of abuse.

Our enhanced biological understanding of addiction would also permit a more objective definition of drug dependence itself, thus avoiding the denial and deception that complicates the accurate diagnosis of addiction. We are in dire need of an accessible biochemical or radiological marker for drug dependence that does not rely on subjective discomfort, third-party report, or personal desire for change, all of which can be missing in a person who is

shooting up daily and sustaining serious neurologic damage. The level of denial and deception among drug users is legendary. A scan documenting the loss of dopamine activity in the midbrain might be fairly motivating to a patient considering rehabilitation for her drug problem. Earlier intervention would be possible if addiction could be diagnosed at an earlier stage before significant frontal lobe damage has occurred.

Much work needs to be done to identify dopamine, serotonin, or norepinephrine metabolites in peripheral blood, develop scanning techniques to identify brain cell dysfunction, or cognitive testing, or scales of personality parameters that could inform users of the effect drug use is having on their brains before their condition worsens to the point of serious disability. We are close to having the capability of doing just that. Morris, Normandin, and Schiffer (2008) have validated a PET-based technique that accurately measures microdialysis confirmed dopamine levels noninvasively. Our reliance on the recognition of late behavioral changes diagnostic of addiction under *DSM IV* is keeping us behind the curve when assessing the impact methamphetamine is having on individual lives and on society as a whole.

Addiction must be defined and diagnosed in neurologic terms if it is to be recognized as a "brain disease" deserving of comprehensive and compassionate treatment and not a "moral failure" subject to incarceration. A better public understanding of addiction as a brain disease would move it out of the court system and into the therapist's office, with corresponding improvements in public perception, patient self-image, relegation of public resources, and insurance coverage.

Chapter **19**

Neurobiological Mechanisms and Cognitive Components of Addiction

Jorge Juárez, PhD, and Olga Inozemtseva, PhD

Addictive behavior can be seen as either a public health concern or as a problem of inadequate social adaptation. The boundaries between these two concepts become rather unclear once we consider that such disturbances may be determined by an altered genetic condition or by acquisition in any stage of development due to external agents, including the aforementioned social adaptation factor. Several studies support the position that addictive behavior has a genetic substratum, a condition that may lead individuals to seek contact with drugs and to become dependent on them even after only one or a few exposures. Other hypotheses argue that any healthy subject can become addicted if he or she is exposed to a drug with some frequency. A third point of view holds that repeated exposure to a drug by a subject with a certain genetic charge that confers specific biological or personality characteristics may be more prone to acquiring an addiction than another individual with distinct characteristics. The problem is that we have not yet identified with precision just what those characteristics are that may predispose a person to more easily acquire an addiction. What is more, if such traits do exist, they would not necessarily be the same for all potentially addictive substances. Beyond looking at causes, other studies are focusing on analyses of the mechanisms of action of the different substances that can produce addictive behavior in the organism, in an effort to provide information that may lead to possible forms of treatment. The integrated analysis of causes, mechanisms of action, and treatment is an ideal condition for studying addictions, but analyzing each one of these components apart from the others also constitutes an important task for scientists, one

that requires a great deal of research that will contribute data and information to each objective of study on a daily basis. This chapter focuses primarily on describing the mechanisms of action in the brain of several substances of abuse and analyzing some of the cognitive components that have been associated with addictive behavior by cause and effect.

Generally speaking, addictive behavior is associated with the consumption of one or more of a variety of illicit substances, though it can also be related to the compulsive consumption of completely licit substances, such as certain foods, or to practicing a broad range of social and physical activities that can go from obsessive physical exercise to the behavior of the compulsive gambler. It is clear that addictions can be exemplified by a wide variety of behaviors, but for the purposes of this chapter, discussion is limited to those substances better known as drugs of abuse, the consumption of which is widespread in the population, generally in a form called *recreational* use. The chemical characteristics of such drugs vary greatly and are responsible for each one's particular properties of diffusion and distribution in the body, as well as for the specific mechanisms of action that affect different tissues in the organism. Despite the heterogeneity in the characteristics of the different drugs of abuse, it is clear that they may act on the same sites in the brain and that their activity may produce similar neurophysiologic responses.

THE MESOLIMBIC-CORTICAL SYSTEM

This system is also known as the pleasure circuit. It is intimately associated with reinforcing mechanisms and is of particular importance here because several potentially addictive substances act upon it in one way or another. For this reason, it is necessary to describe in broad terms its composition, both anatomical and neurochemical. From the anatomical perspective, the mesolimbic-cortical system is made up of the ventral tegmental area (VTA), the accumbens nucleus (Acc), the prefrontal cortex (pfC), and the amygdala (Am). Most of these structures have reciprocal connections in which diverse neurotransmitters intervene; the most important of which in terms of its reinforcing action linked to addictive conduct is dopamine (DA). The main dopaminergic projections of this circuit are those that project from VTA to Acc, pfC, and Am (Ford, Mark, & Williams, 2006). The pfC, in turn, sends glutamatergic projections to the VTA and to the Acc, while the basolateral Am sends this same type of projections to pfC. The opioid system also plays an important role in this system's functioning, as the beta-endorphins liberated in the hypothalamus are able to facilitate the liberation of dopamine indirectly. Moreover, the activation of kappa receptors has an inhibiting effect on the dopaminergic neu-

rons of the VTA (Margolis, Hjelmstad, Bonci, & Fields, 2005). Other neurotransmitters and modulators of neuronal activity are involved in the function of the mesolimbic-cortical system, but as it is not the purpose of this chapter to present an exhaustive description of them, they will be mentioned only to the degree in which they are pertinent to the description of the mechanisms of action of the drugs examined.

NICOTINE (C10H14N2)

Nicotine is a natural alkaloid, a nitrogenated compound that acts as a base in relation to acids. It was first isolated from tobacco leaves by Posselt and Reiman in 1828, and is found in concentrations as high as 5 percent. The nicotine content of a cigarette is normally from 1 to 2 percent. Nicotine is a tertiary amine that penetrates membranes easily and is absorbed through the mucosa, skin, and lungs. From there, it spreads through the bloodstream in just a few seconds. Like many other molecules, nicotine requires receptors to produce its biological action. Receptors are proteins that can be found in the membrane, the cytosol, or the cell nucleus. The nicotine receptors, called nicotinic, are found in the cell membrane joined to ionic channels and may be activated by acetylcholine or nicotine. Once the ligand, in this case nicotine, binds to the receptor, it generally produces excitability in the cell. At the peripheral level, it stimulates the autonomous ganglions and the suprarenal medulla, thus increasing blood pressure and cardiac frequency. Its action on the neuromuscular union increases muscle tone. In the central nervous system, it acts on several regions where there are nicotinic receptors, while in terms of its effects related to the acquisition of addiction, it acts upon nicotinic receptors in the mesolimbic-cortical system that, as mentioned above, is related to reinforcing mechanisms.

The neurons in the ventral tegmental area synthesize DA, which is released by specific stimuli. It is precisely in those neurons that we find nicotinic receptors that upon being stimulated by nicotine produce the release of DA by these neurons (Keath, Iacoviello, Barrett, Mansvelder, & McGehee, 2007). This action is associated with the euphoric effects, the increased state of alertness and, probably, nicotine's addictive potential. The activation of other neurotransmission systems also seems to play an important role in the effects of nicotine, as this drug has the ability to inhibit monoaminoxidase (MAO), an enzyme that in addition to degrading DA also degrades norepinephrine (NE) and serotonin (5-HT). In this way, the inhibiting of this enzyme by nicotine provides a greater availability of these three neurotransmitters and thus increases their activity in neuronal communication. Nicotine's action has a specific characteristic

in that during chronic exposure it produces a desensitization of the receptors and their inactivation (Corringer et al., 1998), an effect that may be associated with satiating the desire to smoke; however, in the short term, this inactivation produces an increase in the number of receptors as a compensating phenomenon, a mechanism known as receptor up-regulation that, it has been suggested, may be associated with the abstinence syndrome and the compulsive urge to smoke. Hence, this alternation between the deactivation of the receptors and their up-regulation may generate dependence and, therefore, the cyclical desire to smoke.

ALCOHOL (ETHANOL)

Alcohol is another substance the consumption of which is legal, though we know that it is by no means exempt from abuse and can cause a behavioral state of dependence. Ethanol is an alcohol produced through fermentation, whose molecular formula is CH3CH2OH. Its high degree of solubility in water allows it to penetrate practically all of the organism's tissues, including the brain. Additionally, it has a certain degree of liposolubility that allows it to interact with the lipid bilayer of the cell membrane in such a way that it modifies some of its properties. Alcohol is classified as a substance that depresses the central nervous system, a property intimately related to its affinity for the type-A receptors of gamma aminobutyric acid (GABA), which are widely distributed in the central nervous system. These receptors are inserted in the cell membrane and have different subunits that surround an ionic canal that permits the flow of chlorine (Cl^-). The activation of these GABA receptors makes the chlorine—a negatively charged ion—flow toward the interior of the cell, producing an even higher negative potential there, a phenomenon known as *hyperpolarization* that raises the threshold of cell activation that, in turn, produces an inhibiting action upon it. The activity of these GABA receptors is potentialized by alcohol, thus increasing its inhibiting action. The ansiolitic properties of alcohol, amply described in the literature, seem also to be associated with alcohol's action on the GABA receptors.

In addition, alcohol produces an increase in the liberation of beta-endorphin (an endogenous opioid) by the hypothalamus that, as already described, may be associated with the gratifying and analgesic properties of alcohol. Moreover, some authors have postulated that one of the causes of alcoholism may be associated with a compensatory action on the part of the opioid system that acts through the consumption of alcohol; this, because it has been found that alcoholic subjects present a deficiency of beta-endorphins (Genazzani et al., 1982). Hence, the release of beta-endorphins by alcohol would generate a more

pleasant effect in subjects who have this endogenous opioid deficiency than in normal subjects. Though the direct effect of the release of beta-endorphins by alcohol may be reinforcing per se, there is another mechanism that affects the mesolimbic-cortical system and that seems to potentialize or complement the gratifying properties of alcohol. This mechanism operates as follows: the activity of certain GABAergic type neurons in the VTA exercises an inhibiting effect on the dopaminergic neurons of the VTA and their role is to modulate the dopaminergic discharge toward the accumbens nucleus (Olson & Nestler, 2007). These GABA neurons contain opioid receptors whose activity has an inhibiting effect on the secretion of these same neurons; that is, on the secretion of GABA (Steffensen et al., 2006), such that when beta-endorphins are liberated through alcohol consumption, they bind to the opioid receptors at the GABA terminals and inhibit them (Xiao & Ye, 2008). Given that these receptors then exercise an inhibiting action on the dopaminergic cells of the VTA, the final result is an inhibiting of the inhibition that produces the release of dopamine toward the Acc and the pfC. As mentioned above, this produces a gratifying effect. It is well known that alcohol interacts with other neurotransmission systems; however, as far as its addictive properties are concerned, the action on the opioid and dopaminergic system plays a preponderant role. Alcohol consumption also depends on the functional state of the organism, and that is where the endocrine system seems to play an important role, as studies have described that estrogens can affect alcohol consumption in two ways (Juárez, Vázquez-Cortés & Barrios De Tomasi, 2005); that is, there is evidence that estrogen treatment initially decreases alcohol consumption, but if the subjects are exposed to alcohol after several days of estrogen treatment, consumption increases significantly, a result that seems to depend on the action of the estrogens on the greater or lesser availability of opioid receptors. These data are relevant from the clinical perspective, as estrogens play a very important role in the development of both men and women, and are especially significant in the case of the latter due to their dynamic presence during the reproductive life of women and their subsequent declination during the postmenopausal period.

DRUGS THAT ACT ON THE OPIOID SYSTEM

As is well known, the organism produces its own opioids, molecules derived from amino acids called peptides. These substances are derived from different precursor molecules, and in some cases, are joined to common receptors, though this union presents different degrees of affinity. The principal endogenous opioid peptides are beta-endorphins—enkephalins and dinorphins—that are found widely distributed at both the peripheral and central levels.

Their mu (μ), delta (δ), and kappa (κ) receptors are also widely distributed in the organism, and their activation has been related to multiple functions, some of the most important of which are analgesia, the hedonistic aspects of behavior, and the modulation of nervous activity in the brain (Barrios De Tomasi & Juárez, 2007). It may seem paradoxical that the same type of opioid peptide is secreted in conditions characterized by pain and by pleasure, but it is not really so once we consider that reducing or eliminating pain can be just as pleasant as the presence of an agreeable stimulus. The most common drugs of abuse that act on the opioid system are morphine and heroin, the first of which is often used in clinical medicine because of its powerful analgesic properties, while the second is preponderant in recreational use. Both have a significant addictive potential and produce an intense abstinence syndrome that can be described in two phases: the early phase is generally marked by sweating, rhinorrhea, irritability, dysphoria, trembling, agitation, anorexia, tearing, gooseflesh, and drug craving; the later phase may be characterized by an increase in the signs and symptoms of the early phase, plus nausea, vomiting, diarrhea, increased blood pressure and heart rate, depression, generalized muscle spasms, dehydration, and a low threshold for convulsive crises (Carvey, 1998, chap. 4).

One point of discussion has been whether the dependence on these substances results from the individual seeking the drug intensely in order to eliminate the signs and symptoms of the abstinence syndrome, or if the euphoric effects and reinforcement of such drugs suffice to maintain dependence on them. These hypotheses may, in fact, be complementary rather than mutually exclusive because, as mentioned above, eliminating a harmful stimulus can be just as pleasing as positive reinforcement. Either way, the results would sustain the substance-seeking behavior of the addict. We know that blocking the m opioid receptors in the caudal region of the accumbens nucleus decreases the self-administration of heroin in rats (Martin, Kim, Lyupina, & Smith, 2002), which suggests that in this structure opioid activity on its own produces reinforcing effects that lead the addict to continue consuming the drug. However, the opioids have other mechanisms of action, produced indirectly through the activation or inhibition of other neurotransmission systems that may play an even more important part in the acquisition and continuance of addictions to these drugs. One of the most important of these is precisely the effect on the dopaminergic mesolimbic-cortical system. In this action, the agonistic opioid, which could be morphine or heroin, would act in a way similar to that described for the beta-endorphins liberated by alcohol. In this scenario, these drugs would bind preferentially to the m receptors of the GABA neurons in the ventral tegmental area, and thus inhibit them. This inhibition would, in turn, facilitate the liberation of dopamine. The different opioid receptors may

seem to have different functions in the release of dopamine toward the VTA, as it has been reported that the activation of the kappa receptors inhibits the release of dopamine toward the prefrontal cortex, but not toward the accumbens (Margolis et al., 2006). This finding supports the notion of the different functionality of the DA in the Acc and pfC, and suggests that the release of DA from the VTA toward these structures may take place independently.

PSYCHOSTIMULANTS

Drugs that stimulate the central nervous system (CNS) include substances with diverse structural characteristics that share the common effect of raising a person's state of alertness and level of motor activity. They are also known as sympathomimetic substances, as they increase or imitate the activity of the autonomous sympathetic nervous system. The best-known stimulant drugs are amphetamines, methamphetamines, and cocaine in all of its forms.

Amphetamine and Methamphetamine

Amphetamines are aromatic amines (C9H13N) that exercise a powerful stimulant action on the CNS. Their most common effects are raising the state of alertness, improving concentration, increasing motor activity, producing a sensation of well-being or euphoria, inhibiting sleep, anorexia, and stimulating respiration, among others. In clinical medicine, they have been prescribed to treat obesity, narcolepsy, attention-deficit hyperactivity disorder, and depression, as well as for problems of asthma, as they also have a bronchodilator effect. Because of their euphoric effects and the increased state of alertness they produce, plus their induction of an emotional state of well-being, they are used and abused recreationally. Methamphetamines (C10H15N) are the methylated form of amphetamines; that is, they are differentiated from the latter by the presence of a methyl group in the amine group, a small structural change that reduces their peripheral effects and results, it would appear, in lessening the undesirable effects associated with the activation of the sympathetic nervous system. At the central level, however, the effects of methamphetamines are quite similar to those described for amphetamines, though they tend to be preferred for recreational use because of their lesser undesirable effects. Moreover, methamphetamines are pyrolized more easily and commonly inhaled, which favors their distribution through the lungs, quickly generates higher levels in the brain and, therefore, generates a more intense "high."

Chemical-structural variations between amphetamines and methamphetamines may give them a greater or lesser degree of activity on each neurotrans-

mitter involved; however, given that their mechanisms of action at the cerebral level are practically the same, this activity will be described indistinctly for both substances. Consuming amphetamines or methamphetamines generates a greater availability of dopamine and noradrenaline in the synaptic space and, at least in the olfactory bulb, amphetamines are more efficient in liberating DA than NE (Mesfioui et al., 1998). The action on serotonin seems to be less when compared to that on the other two neurotransmitters, though it has been reported that some amphetamine analogues may present a greater effect on serotonin traffic.

There are basically three mechanisms of action at the cellular level that produce a greater availability of the neurotransmitter: (1) these drugs facilitate the non–calcium-dependent release of the neurotransmitter; there is evidence that amphetamines act on the recently synthesized neurotransmitter and on the contents of the vesicles, given that the previous administration of reserpine, a substance that depletes the neurotransmitter from the vesicles that contain it, attenuates the effect of amphetamines on the release of dopamine (Sabol & Seiden, 1998); (2) they act on the mechanisms that recapture the neurotransmitter and compete with it in its transportation toward the interior of the cell, a competition that makes the neurotransmitter remain available to be utilized by the postsynaptic receptors and thus exercise its effects for a longer period of time (Jayanthi & Ramamoorthy, 2005); and (3) they inhibit the degradation of the DA, NE, or 5-HT by acting competitively on the mononaminoxidase enzyme (MAO), which is in charge, precisely, of deactivating these neurotransmitters. As can be seen, the common result of these mechanisms is a greater availability of the neurotransmitter and, therefore, an increase in its activity. The fact that amphetamines compete with the neurotransmitter in its transportation toward the interior of the cell at the same time as it competes with it to be externalized by that same transporter prevents a dopaminergic overstimulation from occurring with increased doses of amphetamines, because of the greater quantity of amphetamines inside the cell, competition for the transporter favors the amphetamine, while the externalization of dopamine is attenuated. This permits a wider safety margin from harm due to overdoses, compared to that of other drugs whose blocking of the transporter is noncompetitive.

Cocaine (C17H21NO4)

This is an alkaloid obtained from the leaf of the coca plant, which contains approximately 0.5 to 0.7 percent of the active substance. Its most common version is cocaine hydrochloride in powder form that is administered intra-

nasally (snorted) or intravenously (Schuckit, 2000, chap. 5). Another often used form is called *crack*, which is obtained by adding a base—usually ammonia or sodium bicarbonate—to cocaine hydrochloride previously dissolved in water and then filtered. This form of cocaine has a lower point of fusion than cocaine hydrochloride, which allows it to be inhaled (smoked by itself or in combination) at the moment it is pyrolized, and thus take effect more quickly than when it is aspirated. The name *crack* is onomatopoeic of the sound "crack" makes when pyrolized (Carvey, 1998, chap. 12; Schuckit, 2000, chap. 5). Many of cocaine's effects on behavior and the individual's state of mind are similar to those obtained through the consumption of amphetamines or methamphetamines, though there are important differences in the intensity and duration of its effects. Cocaine produces an intense state of euphoria that may be related to the size of the dose taken. It also increases the state of alertness and mental sharpness, creates a sensation of energy, self-confidence, and egocentricity, and apparently augments sensorial sensitivity, while decreasing appetite, the need to sleep, and the signs and symptoms of the activation of the sympathetic nervous system (Gold & Jacobs, 2005, chap. 13). Its mechanism of cellular action consists in blocking the recapture proteins in the presynaptic terminal, where dopamine is primarily released, but it also acts in a similar way in the recapture of noradrenaline and serotonin. However, unlike amphetamines, cocaine does not establish a competitive action with the neurotransmitter through its entry into the cell's cytosol, but simply blocks its entry by producing a greater availability of it in the synaptic cleft, which in turn produces an increase in the dopaminergic, noradrenergic, or serotonergic activity, according to the type of neurotransmitter that is compromised.

As can be appreciated, the common denominator in the action of the drugs described above is their effect on dopaminergic transmission in the mesolimbic-cortical system, which has been related, as discussed above, to the motivational and reinforcing mechanisms in different species of mammals, including humans. Although there can be no question, given the evidence described in the literature, that all of these drugs exercise a common action on the brain, we know that they also affect other systems of neurotransmission that, acting in concert, produce the effects characteristic of each different, potentially addictive substance. The effects of these drugs have varying degrees of severity on the functional state of the organism in general and of the brain in particular. During the acute phase of a drug's action, a series of neuroadaptive changes takes place. In some cases, these changes are reversible, such that once the effect of the drug passes, the organism returns to homeostasis. In other cases, however, the brain may suffer irreversible damage due to the acute or chronic consumption of the substance. In some cases, the magnitude of the damage is so great that it can be

perceived both anatomically and behaviorally, while in others, the harm may be functional and thus more difficult to detect. Nonetheless, it may manifest itself and be detected through testing of the individual's cognitive capacities, and this is precisely the objective of the analysis described in the following section of this chapter.

NEUROPSYCHOLOGICAL COMPONENTS IN ADDICTED SUBJECTS

The main objective of the neuropsychological analysis of addictions is to search for the relationship between the use of substances and the neuropsychological impairments that may become manifest at the behavioral, cognitive, emotional, and personality levels. These neuropsychological impairments have been studied primarily in patients with different degrees of dependency or addiction to one particular substance or among polyabusers. Koob et al. (2004) conceptualize the addictive state as a disorder that progresses from impulsivity to compulsivity through a cycle; that is, in order for the patients to reach the addictive state they must follow a path that leads from the occasional, controlled use of a drug to a point at which they lose behavioral control over the search for, and consumption of, that substance; a situation defined as chronic addiction. The *Diagnostic and Statistical Manual of Mental Disorders* (*DSM–IV–TR*; American Psychiatric Association, 2002) defines substance dependency as "a cluster of cognitive, behavioural, and physiologic symptoms that indicate that the person has impaired control of psychoactive substance use and continues use of the substance despite adverse consequences (p. 218)." Substance abuse and its chronic use may result in the individual presenting the adverse neuropsychological deficits examined below, based on studies carried out with patients addicted to two of the most widely used and easily accessible kinds of psychostimulants: cocaine and methamphetamines.

As mentioned previously, cocaine is a potent psychostimulant that acts upon the monoaminergic neurotransmission systems, especially the dopaminergic system. The most frequently reported cognitive deficits in cocaine-addicted patients in abstinence indicate problems related to memory, attention, abstract reasoning, and the executive functions. Several researchers have reported deterioration of verbal and visual memory, in the phase of immediate and delayed recall, as well as in verbal learning (Beatty, Katzung, Moreland, & Nixon, 1995; Gillen et al., 1998; Horner, 1997; Rosselli & Ardila, 1996; Serper et al., 2000). The deficit in attention and concentration processes has been evidenced in both visuoperceptual and verbal tasks (Rosselli & Ardila, 1996; Strickland et al., 1993; Toomey et al., 2003). Finally, the decrease in the capacity for abstract rea-

soning has been observed in problem-solving tasks (Beatty et al., 1995; Rosselli & Ardila, 1996). In addition to a deficit in specific cognitive abilities (memory, attention, abstract reasoning), studies have reported a more general decrease in intellectual levels (Rosselli & Ardila, 1996), and in global neuropsychological functioning (Robinson, Heaton, & O'Malley, 1999). Given that cocaine acts primarily on the dopaminergic system, several studies have also revealed some deterioration in motor functions (Robinson et al., 1999; Toomey et al., 2003).

Addiction to cocaine is often associated with addictions to other substances, most often alcohol. Findings in the literature on the comorbid effect of chronic cocaine and alcohol abuse are contradictory, as some studies report no effect of the comorbidity of cocaine and alcohol on cognitive functions, while in others the consumption of "pure" cocaine is associated with more marked deficiencies in certain functions. Thus, Beatty et al. (1995) compared a group of "pure" cocaine addicts and a group of "pure" alcohol addicts to a third group made up of healthy participants. They reported that both groups of addicts presented a significantly poorer execution than the control group in most of the measurements of learning, memory, problem solving, executive functions, and perceptual motor-speed. Furthermore, they considered that the general pattern of neuropsychological impairment was similar in the two addict groups. In contrast, Robinson et al. (1999) compared cocaine addicts, cocaine-alcohol addicts, and healthy persons using the Halstead-Reitan neuropsychological test battery. There, the cocaine addicts presented a significantly lower execution than the cocaine-alcohol co-abusers in both complex and simple motor functioning, as well as on a measure of global neuropsychological functioning. However, the results attained by the cocaine-alcohol co-abusers did not differ significantly from those of the control group in most of the applied tasks. Brown, Seraganian, and Tremblay (1994) found no differences in the execution of a variety of neuropsychological tests between a group of cocaine- and alcohol-dependent patients and individuals addicted only to alcohol.

The complex nature of cocaine addiction includes changes at different levels of the functioning of the organism (including modifications at the level of genetic expression) that may be long-lasting or even permanent (Nestler, 2005). In this vein, Juárez (2004) has suggested that the repeated and prolonged exposure to a variety of drugs, such as cocaine, is capable of producing homeorretic modifications in the organism, which are understood as adaptive changes in different systems within the organism that may be permanent or transitory. Therefore, it is logical to ask: Is the neuropsychological deterioration in addicted patients transitory or permanent? The most natural way of responding to this question would be through studies of patients in long-term abstinence, or through longitudinal studies. In this area, Strickland et al. (1993) reported the

presence of attention and concentration deficit, learning difficulties, and a deterioration of visual and verbal memory in patients addicted to crack cocaine after six months of abstinence. These researchers came to the conclusion that prolonged exposure to cocaine produces a persistent neuropsychological deficit. Di Sclafani, Tolou-Shams, Price, and Fein (2002) examined cognitive functions in abstinent crack-dependent and crack- and alcohol-dependent individuals after six weeks and six months of abstinence. Both groups of addicted patients presented deficits in attention, executive functions, spatial processing, memory (immediate and delayed), and in the global clinical impairment store after six weeks of abstinence. The substance-dependent groups were still significantly impaired at six months of abstinence. Bolla, Funderbuk, and Cadet (2000) detected an association between the dose of both cocaine and alcohol and performance on neuropsychological tasks among patients addicted to cocaine with and without alcohol use at 1–3 days of abstinence. The same effect observed in the first evaluation persisted in the second procedure, carried out with the same patients after four weeks of abstinence.

Cocaine addiction produces a deterioration of the CNS and then proceeds to exercise a negative effect on general neuropsychological functioning and specific cognitive functions, which appears to persist even after the person ceases to consume the drug for a prolonged period of time.

Methamphetamines are another, relatively recent, powerful psychostimulant that have become very popular among the addict population in the past couple of decades. Similar to cocaine, methamphetamines or deoxyephedrine, commonly known as *ice* or *crystal*, act primarily on the dopaminergic system, though their mechanism of action is somewhat different from that of cocaine, as described above. The difference in the mechanism of action at the cellular level between these two psychostimulants may be determinant for the profile of the neuropsychological deficits in persons addicted to one or another of these two substances. We have not found any studies in the literature that report a comparative analysis of the cognitive characteristics of addicts to these two drugs, though numerous works have focused on one or the other of the two. The most frequently reported deficits in methamphetamine addicts are related to learning processes and immediate and delayed verbal memory (Kalechstein, Newton, & Green, 2003; Rippeth et al., 2004; Simon et al., 2000), working memory (Rippeth et al., 2004), attention (Kalechstein et al., 2003; Nordahl, Salo, & Leamon, 2003; Rippeth et al., 2004), psycho-motor speed (Kalechstein et al., 2003), executive functions (Kalechstein et al., 2003; Salo et al., 2005; Simon et al., 2000), motor abilities (Rippeth et al., 2004; Volkow et al., 2001), and abstract reasoning (Simon et al., 2000). No reduction in the premorbid intellectual level, as measured by the Shipley-Hartford Vocabulary test (Simon

et al., 2000), has been reported for methamphetamine addicts. The studies reviewed here in regard to this group of patients point to a profile of neuropsychological impairments similar to that of cocaine addicts. However, additional work is necessary to answer the question whether the neurotoxic effects of cocaine and methamphetamine produce conspicuous differences in the neuropsychological profile of these patients.

The neuropsychological impairments in the area of addictions frequently accompany findings on the functioning of the CNS. The most commonly used techniques in this field are positron emission tomography (PET), functional magnetic resonance imaging (fMRI), and single photon emission computed tomography (SPECT), among others, all of which make it possible to detect changes in patterns of brain blood fluid (CBF) and the metabolism of brain glucose. In relation to cocaine addicts, studies with neuroimaging techniques report a reduction in CBF, both globally and regionally, because, as it turns out, cocaine is a powerful vasoconstrictor. Regional hypoperfusion appears to be more prominent in zones rich in dopamine. Many studies conducted with patients addicted to cocaine report a marked reduction in CBF in the regions of the prefrontal cortex, particularly in the anterior cingulate (Bolla et al., 2004; Volkow et al., 1993) and the orbitofrontal cortex (Adinoff et al., 2003; Volkow et al., 2005). In addition, the activity of the SNC in these patients has been negatively correlated with the consumption dose of the drug (Bolla et al., 2004; Johnson et al., 2005). Moreover, studies of these patients have revealed changes in the pattern of the activation of the limbic system, which is traditionally associated with motivation and the compulsive drug intake (Lu et al., 2005). In contrast, Childress et al. (1999) demonstrated an increased blood flow in the amygdala and anterior cingulate in addicts as compared to healthy individuals when all were shown a video on the consumption of cocaine.

In methamphetamine addicts, neuroimaging studies have been widely used to detect the availability of dopamine transporters (DAT) in the neuronal terminals. It has been shown that methamphetamine addicts present DAT loss in the orbitofrontal and dorsolateral regions of the prefrontal cortex, the amygdala, and other subcortical regions (Ernst, Chang, Leonido-Yee, & Speck, 2000; Sekine et al., 2003; Volkow et al., 2001). Furthermore, in several studies, the density of the DAT correlated negatively with the years of use of the substance (Sekine et al., 2003; Volkow et al., 2001). Sekine et al. related the low density of DAT in the orbitofrontal and dorsolateral cortex to the severity of patients' psychiatric symptoms. Volkow et al. observed DAT loss in the striatum (caudate 27.8% and putamen 21.1%) in methamphetamine addicts, compared to control subjects, associated with a persistent motor deficit. Other alterations of the SNC have also been reported for this type of addict. For

example, Ernst et al., using the proton magnetic resonance spectroscopy (MRS) technique, found a significant reduction in the frontal white matter and basal ganglia. Nordahl et al. (2005) reported a reduction in the metabolism of the anterior cingulate and in the insular cortex (London et al., 2005). Furthermore, Thompson et al. (2004) demonstrated a cortical and hyppocampal structural deficit in patients addicted to methamphetamines.

The prefrontal cortex has been associated with cognitive executive functions (Luria, 1982, p. 185), which Lezak (1995, p. 650) referred to as dimensions of human behavior that are related to the way in which behavior is expressed. They are abilities related to forming objectives, planning, carrying out goal-directed behavior, and the effectiveness of production. Lezak added that these abilities are necessary for appropriate, socially responsible, self-sufficient behavior.

In a review study, Verdejo-García, López-Torrecillas, Giménez, & Pérez-García (2004) referred to the executive functions as those that permit anticipation and the establishment of objectives; the designing of plans and programs; self-regulation and task-monitoring; an appropriate selection, organization, and sequencing of behavior in space and time; monitoring of behavior with respect to affective and motivational states; adaptive decision making; efficiency of execution; and feedback.

In those addicted to several types of substances, including psychostimulants, studies have described impairments in the executive functions that find expression in a lack of cognitive flexibility, verbal fluency (Kalechstein et al., 2003; Simon et al., 2000; Verdejo-García & Pérez-García, 2007), inhibition (Ardila, Rosselli, & Strumwasser, 1991; Kalechstein et al., 2003; Nordahl et al., 2003; Rosselli, Ardila, Lubomski, Murray, & King, 2001), abstract reasoning (Ardila et al., 1991; Rosselli et al., 2001; Simon et al., 2000), and planning and organization (Bechara, 2005). Bechara et al. (2001) and Damasio (1994) consider that substance addicts present a deterioration of the executive functions related mainly to motivational aspects and decision making linked to the orbitofrontal cortex.

At the clinical level, detecting the deficit in executive functions and developing possible treatments have important implications. The problems that addicted patients experience in the area of executive functions are often cited to explain their failure to remain in rehabilitation programs, and their frequent relapse and desertion from treatment. On the other hand, various authors mention that deficiencies in the executive functions prior to addiction may create a predisposition to addiction among these patients through such mechanisms as excessive sensibility to reinforcers, or their inability to control their impulsivity (Rogers & Robbins, 2001; Verheul, 2001). However, to date we have no answer to the question: Is the executive deficit in addicted patients premorbid, or is it

the consequence of the use of substances? It is still difficult to find a response to this question given the methodological complications involved, but advances in scientific knowledge in the area of neuroscience will allow us to posit new research strategies designed to search for answers to questions such as these that may have repercussions for the rehabilitation and treatment of addicts.

Chapter **20**

Fetal, Neonatal, and Early Childhood Effects of Prenatal Methamphetamine Exposure

Mary F. Holley, MD

Drugs of abuse have a long legacy of causing significant impairment in the development of the human brain. Alcohol abuse during pregnancy results in significant changes that include facial dysmorphisms, neurobehavioral problems such as Attention Deficit Hyperactivity Disorder (ADHD), and mental retardation. The full complex of alcohol-related dysfunction is known as fetal alcohol syndrome. Methamphetamine exposure has not been identified with a syndrome or an identifiable pattern of malformation or dysfunction, but clusters of symptoms have been associated with neurologic deficits identified on sophisticated brain scanning of children exposed to methamphetamine (Chang et al., 2004). These findings require our attention and reasonable changes in our patterns of practice in the prenatal clinic and the nursery.

There are a number of developmental risk factors that are common to all drugs of abuse and that may overlap with the effects of lower socioeconomic status. These include genetic influences, nutrition status of the mother, poverty and associated stressors, mental illness either as a predisposing factor to addiction or as a consequence of drug use, infectious diseases, and lack of prenatal care. Each of these factors contributes to the environmental stressors impacting the development of the child born into a family affected by drug abuse. We will also consider the risk factors specific to methamphetamine use, including placental insufficiency, preterm labor, congenital malformations, and the neurotoxic effects of methamphetamine on the developing brain.

Early identification of drug-exposed infants and children is crucial to our efforts to intervene in the lives of these children. Early childhood development

is strongly affected by the drug use of parents, particularly mothers. Proactive intervention, however, demands that we know at the infancy or preschool stage that a child is at risk for drug- or alcohol-related developmental challenges. In order to effectively intervene in these children's lives, we have to know who they are, and be willing to take action to protect them. The consequences of our failure to do so will be made manifest in the juvenile detention centers of the next decade.

INTRODUCTION

In the United States, methamphetamine use among pregnant women doubled over the six-year span from 1998 to 2004 (Cox, Posner, Kourtis, & Jamieson, 2008), as methamphetamine has gradually replaced cocaine as the drug of choice in many areas of the nation among Americans in general and women of childbearing age in particular. Unlike cocaine, methamphetamine is used by women at rates equal to men (Cohen, Greenberg, Uri, Halpin, & Zweben, 2007), primarily for weight loss and increased energy. Methamphetamine is a much more toxic drug than cocaine, causing more rapid and intense addiction (Gonzalez, Castro, Barrington, Walton, & Rawson, 2000), more symptoms of mental illness (McKetin, McLaren, Lubman, & Hides, 2006), and more rapid personal and family disintegration. For all these reasons, methamphetamine has exacted a higher toll on the family, higher even than cocaine, which has already destroyed countless families across this nation.

Both cocaine and methamphetamine produce sexual arousal and promote promiscuous sexual behavior, but methamphetamine produces this effect for far longer than cocaine, and is commonly used by addicts to enhance their sexual experience. As the people using methamphetamine are predominantly of childbearing age, this drug poses greater risks to their unborn children than other comparable drugs of abuse. Increased risk of disease transmission, including sexually transmitted diseases (STD), hepatitis C, and HIV, higher risk of obstetric complications, prematurity and growth restriction, are of particular concern as methamphetamine use increases in the mothers of our children (Smith, LaGasse, Derauf, Grant, & Shah, 2006).

Of major concern are the numerous anecdotal reports of significant neurologic dysfunction in children exposed to methamphetamine in utero. Caretakers of these children have reported cases of severe ADHD, conduct disorders, learning disabilities, and developmental delays in the children of methamphetamine users. These reports have been of great concern to the family members, adoptive and foster parents who are taking responsibility for these children. Scientifically valid information regarding their prognosis and effective interventions is greatly needed.

Education professionals are concerned about the impact of methamphetamine abuse on the special education demands placed on their schools as large numbers of children with learning disabilities and attention deficits are enrolled in the nation's public school system. And since children with learning disabilities and academic failure have higher rates of delinquency (Aseltine, Gore, & Gordon, 2000), methamphetamine-exposed children are more likely to grow up to be wards of the juvenile justice system, further straining our criminal justice system. Early identification of the drug-affected child would permit intervention and training opportunities before entry into the school system, at a time when such interventions are most likely to be effective. But early identification requires drug testing of neonates at or shortly after birth.

True primary prevention would require identification of the drug-using mother in the first trimester of pregnancy, a time when many mothers are amenable to interventions to help their children. Drug testing in the prenatal clinic, however, is generally not done because of fears such testing would deter women from seeking prenatal care. Lacking reliable prenatal information, we are left with secondary prevention, limiting the effects of a disease by controlling its complications—damage control. This we seek to do by neonatal drug testing to detect exposure early and offer remedial assistance to the child and rehabilitation to the mother after prenatal exposure has already occurred.

There is a great deal of controversy over the utility and validity of drug testing of neonates. There are concerns over the accuracy of the tests, false positive results, interactions with prescribed medications, and possible lawsuits by mothers alleging breaches of their privacy rights. There are also concerns over possible legal prosecution against the mothers of these children, actions taken by child protective services workers, including termination of parental rights, custody battles, and the lack of rehabilitation facilities accepting mothers with their young children.

An accurate understanding of and response to the epidemic of drug use in this nation (and around the world) is essential to prevent a public health disaster of epic proportions as today's children become tomorrow's parents. In view of the significant neurotoxicty of methamphetamine, the anecdotal reports of neurologic dysfunction and learning disability in methamphetamine-affected children cannot be dismissed altogether as unreliable. These reports instead must be investigated and fully understood in order to institute preventative measures and offer meaningful intervention to affected children and their families.

NONSPECIFIC RISK FACTORS

Nutrition is a strong variable associated with poor outcomes in drug-using pregnancies (Knight et al., 1994). Some drugs of abuse, such as alcohol, replace

normal food intake and compete with nutrients for entry into the mother. Other drugs are potent anorectics, among them cocaine and methamphetamine. These drugs can cause profound nutritional deficiencies in chronic users, to the point of starvation. Vitamin deficiencies, anemia, and protein calorie malnutrition are significant risks to a pregnancy already complicated by substance abuse.

Poverty is also strongly associated with drug abuse, as addicts are unable to hold down a job or manage their finances appropriately. Some methamphetamine addicts are employed and hold middle-income jobs, but all of their resources go to procure drugs and alcohol, and adequate housing and nutrition are not priorities for these people. Uninsured mothers living in poverty are less likely to attend prenatal clinics and more likely to have untreated infections and poor nutrition regardless of their drug abuse status.

Chronic stress is often a characteristic of the lifestyle of drug-abusing mothers (Derauf et al., 2007). Homelessness is common, and many addicts move from place to place with no permanent address. Addicts sometimes live in cars or abandoned buildings without utilities or a stable food supply, conditions not conducive to a healthy pregnancy. Legal problems are common with multiple arrests, bonds, and fines. Criminal activity and domestic violence are especially common in methamphetamine-affected households. Methamphetamine addicts are irritable and impatient, and with the onset of psychotic symptoms, sometimes become violent. This violence is often directed at family members.

Mental illness is very common in substance abusers, especially methamphetamine abusers. Addicts sometimes have preexisting major illnesses such as bipolar disorder or schizophrenia, but more often, they develop methamphetamine-induced symptoms of mental illness, which may or may not clear after a period of detoxification (Mahoney, Kalechstein, De La Garza, & Newton, 2008). Addicts may become paranoid, suspicious, and hypervigilant. Real and apparent threats are ubiquitous. Addicts feel threatened by other addicts, aggressive dealers, "snitches," and the authorities and often develop delusions surrounding these and other threats. Their mental problems lead directly to severe distress, and indirectly to occupational failure, economic distress, noncompliance with prenatal care, and poor parental adjustment. Long-term methamphetamine use can cause a form of dementia with memory loss and frontal lobe dysfunction, leading to severe impairment in some users (McCann et al., 2007).

Infectious disease is common in drug-abusing populations regardless of the substance used. Sexually transmitted diseases flourish in the climate of promiscuity, the sex-for-dope economy, and reduced precautions characteristic of methamphetamine abuse. Methamphetamine increases sexual desire and drive much more than other drugs of abuse, and so is associated with extremely

high rates of infection with STDs. Methamphetamine users experience drying of mucous membranes due to the vasoconstrictive effects of the drug. Methamphetamine addicts engage in higher rates of unprotected sex and larger numbers of anonymous partners. They are less likely to present for medical care and less compliant with treatment for STDs.

Increased risks of hepatitis B and C and HIV are well known, particularly in IV drug users and sexually promiscuous users. Methamphetamine appears to act as an adjuvant, increasing the risk of infection when exposed to either hepatitis C (Ye et al., 2008) or HIV (Mahajan et al., 2006; Nair et al., 2006; Talloczy et al., 2008). These infections are transmitted vertically to the neonate at birth. While measures can be taken to protect the developing fetus from HIV, there are currently no prophylactic treatments available to prevent hepatitis C from transmitting to the newborn.

Substance abusers are also less likely to present for prenatal care and so are less likely to have been tested and treated for their infectious diseases. Methamphetamine abusers often first present to the hospital in advanced labor having no prior relationship with any health care provider. Fearing involvement with the legal system, they frequently deny illegal drug exposure. Their drug use can only be detected by drug testing in the presence of high-risk behavioral indicators.

METHAMPHETAMINE SPECIFIC RISK FACTORS

Aside from the general risk factors associated with abuse of any drug, there are also a host of risk factors specific to methamphetamine abuse. These include obstetric complications, poor neonatal growth, increased risk of congenital malformations, and neurologic injury to the neonatal brain related to exposure to a potent neurotoxin. The human fetus and placenta lack enzymes that could metabolize methamphetamine as it crosses the placental barrier (Dixon, 1989). Since methamphetamine crosses the placenta very efficiently, blood and tissue levels in the fetus are comparable to maternal blood and tissue levels (Stek et al., 1993; Won, Bubula, & Heller, 2001). Methamphetamine has a much longer half-life than cocaine, particularly in the human fetus. These factors can result in the accumulation of active drug in the fetus, and higher blood levels of the drug have been seen in the developing fetus than seen in the mother under conditions of chronic administration (Stewart & Meeker, 1997).

The immature organ systems of the fetus are therefore exposed to "big people" doses of a potent stimulant drug with all of its vasoconstrictor and cellular toxic properties. The picture is further complicated by the fact that more than 80 percent of methamphetamine-using mothers also use one or more addi-

tional drugs of abuse, most commonly alcohol (Brecht, Greenwell, & Anglin, 2007). The impact on the developing fetus is thus increased exponentially in its clinical presentation.

Obstetric complications are significantly increased in methamphetamine-abusing pregnant mothers. Because of its prolonged half-life in humans—12 to 20 hours—chronic vascular disruption is seen, leading to long-term complications. Placental insufficiency is often seen, leading to intrauterine growth restriction in the fetus (Smith et al., 2006). Some congenital malformations may also be associated with the intense vasoconstriction associated with methamphetamine use (Hoyme et al., 1990). Maternal hypertension associated with methamphetamine is of much longer duration than similar findings in cocaine abusers and can lead to obstetric catastrophe with abruption and fetal distress or fetal demise (Stewart & Meeker, 1997).

Maternal hypertension is often mistaken for preeclampsia or co-occurs with preeclampsia (Elliott & Rees, 1990). Accurate diagnosis is essential since the treatment differs for methamphetamine abusers. Treatment with beta blockers such as Labetolol can have untoward results in methamphetamine abusers as these drugs do not block the alpha adrenergic effect of methamphetamine and can lead to rapidly progressive heart failure in methamphetamine-abusing gravidas (Samuels, Maze, & Albright, 1979 and author's personal experience). Older antihypertensives are preferred, such as appressoline or nipride, which block alpha receptors and control the hypertension seen in methamphetamine abuse. These drugs must be dosed carefully and slowly to prevent overshoot hypotension and resulting fetal distress.

Preterm labor, premature rupture of membranes, and chorioamnionitis are all increased in methamphetamine-affected pregnancies (Eriksson, Larsson, & Zetterström, 1981). The result is often a low birth weight newborn with signs of drug withdrawal, including tremors, lethargy, poor feeding, excess irritability, and other neurobehavioral abnormalities (Smith et al., 2003). Physical signs of withdrawal in the neonate include tachycardia, hypertension, hyper-reflexia, often mixed with symptoms related to the concurrent use of narcotics such as heroin. The Neonatal Abstinence Scoring system is validated for neonates exposed to all drugs of abuse, although the findings can be widely different for infants withdrawing from heroin versus those exposed to stimulants (Oro & Dixon, 1987). Many of these children are exposed to multiple drugs with conflicting effects, leading to confusing findings and missed detection of exposed children.

The incidence of congenital malformations has been studied in chart review studies (Forrester & Merz, 2006, 2007), or retrospective studies of affected children (Torfs, Velie, Oechsli, Bateson, & Curry, 1994), but these studies did not

include a routine neonatal drug-testing protocol and instead relied on patient report and sporadic drug testing in response to risk factors over the course of normal obstetric care. Both methods of detection are fraught with difficulty as only 25 percent of drug-abusing mothers admit to drug use when questioned (Ostrea, Brady, Gause, Raymundo, & Stevens, 1992), and drug testing is often done based on stereotype, missing many drug-using mothers who do not fit the profile of the "drug addict." As a result, we do not know the true incidence of congenital malformations in the infants of methamphetamine-abusing mothers. Anecdotal reports have linked methamphetamine abuse with gastroschisis, eye and ear malformations, cardiac defects, renal anomalies, and limb reduction defects, all of which are exceedingly rare (Bays, 1991).

Effects of methamphetamine exposure on the developing brain have been extensively studied, particularly in light of the overwhelming evidence that methamphetamine is a neurotoxin in the adult brain (for a review, see Yamamoto & Bankson, 2005). Most of these studies have been done on rodent species. Very few human studies have been done to assess human brain development in methamphetamine-exposed children, but those that have been done suggest a significant effect, and a long-lasting effect, with behavioral changes and increased social problems extending into adolescence.

METHAMPHETAMINE'S EFFECT ON BRAIN DEVELOPMENT

Theoretically, methamphetamine should have a significant impact on brain development. It is a potent vasoconstrictor, reducing blood supply to the placenta and thus delivery of oxygen and nutrients to the developing fetus. It is also a potent neurotoxin, releasing free radical compounds that cause neural cell death (Yamamoto & Bankson, 2005). And indeed stimulants do impact embryogenesis of the developing central nervous system. Cell proliferation and migration are impacted and synaptogenesis is impaired (Weissman & Caldecott-Hazard, 1995). There is reduction in neural growth factor and a marked increase in reactive oxygen species and free radicals (Jeng, Wong, Ting-A-Kee, & Wells, 2005; Wells et al., 2005). These toxic chemicals are known neurotoxins and have been implicated in the progression of cellular damage to the brain in adult methamphetamine users (Acikgoz et al., 2000).

Animal models, rats, mice, and gerbils, have been used to study the fetal effects of many drugs, including methamphetamine. Rodents metabolize methamphetamine differently from humans; the half-life of methamphetamine in rodents is only around 1 hour, compared with 12 hours in humans (Cho, Melega, Kuczenski, & Segal, 2001). Rodents also mature their central nervous

system in the first month postnatally while humans do so in the third trimester of pregnancy (Gomez-DeSilva, Silva, & Tavares, 1998). Rodents are born at an earlier gestational maturity than humans, and so are usually dosed 10 to 20 days after birth to simulate third-trimester human exposure. Neonatal rodents have been found to be relatively resistant to the effects of methamphetamine compared to adults. These factors explain the significant differences in dosing of animals compared to typical human use patterns. These differences often cloud interpretation of animal data by clinicians who accuse animal researchers of vastly overdosing the animals. Because of the markedly reduced half-life of methamphetamine in rodents, these studies more likely underestimate the impact of fetal methamphetamine exposure, rather than overestimating it. Overall, methamphetamine appears to be a much more neurotoxic drug than cocaine, as might be expected based on its metabolic profile.

A summary of the most recent research in the field of methamphetamine effect on brain development reveals some disturbing trends. Acevedo, de Esch, and Raber (2006) studying mice found significant disruption of hippocampus dependent cognitive function in adult animals exposed to methamphetamine in the neonatal stage. Cognitive functions affected included spatial learning, memory, and object recognition. Vorhees, Skelton, and Williams (2007) looked at rats and also found spatial learning and memory deficits that persisted into adulthood, suggesting a permanent structural change in brain development. In an older but well-done study, Hildebrandt, Teuchert-Noodt, and Dawirs (1999) localized the site of methamphetamine-induced injury to the dentate gyrus of the hippocampus, specifically to impaired granule cell proliferation (a 34 percent deficit). Even low-dose methamphetamine exposure caused significant spatial learning deficits in rats, suggesting that there is no safe level of exposure during pregnancy (Williams, Moran, & Vorhees, 2004).

Gomez-DeSilva and colleagues (2004) demonstrated increased catecholamines in neonatal rat brains exposed to methamphetamine, particularly in the substantia nigra, caudate putamen, and nucleus accumbens. Williams, Brown, and Vorhees (2004) demonstrated injury to the hippocampus, nucleus accumbens, and parietal lobes in rats exposed to methamphetamine. These findings have been replicated repeatedly by numerous researchers, demonstrating a significant neurotoxic effect of methamphetamine in brain development with functional loss of memory and coordination.

The mechanism of this damage was elucidated by Jeng et al. (2005), who investigated the metabolic pathways by which methamphetamine damages developing neural tissue. They found that methamphetamine causes oxidative cell injury in the brains of mice exposed to neonatal methamphetamine. Oxygen free radicals are produced by the metabolism of both methamphetamine and

the monoamine neurotransmitters released in response to methamphetamine. These free radicals are potent neurotoxins. The fetal brain lacks key alternate enzymes needed to metabolize monoamines and methamphetamine, leading to the build-up of high levels of oxygen free radicals and consequent long-term impairment of brain development (Wells et al., 2005).

These neurotoxic changes persist into adulthood and sensitize the adult brain to the effects of adult exposure to methamphetamine, particularly in males. Neurotoxicity to the dopaminergic projections in response to methamphetamine challenge in adulthood was significantly increased in animals that had been exposed to methamphetamine prenatally, suggesting a persistent sensitivity (Heller, Bubula, Lew, Heller, & Won, 2001). This finding has significant implications for meth-exposed children growing up in meth-abusing homes who learn early in life how to solve their problems with a pipe.

HUMAN STUDIES OF METHAMPHETAMINE IMPACT

Clearly, methamphetamine should not be given to neonatal rats, mice, or gerbils. It damages their little brains. But what about humans? Do the animal studies apply to the human infant? Most human methamphetamine users are polydrug users and have multiple other risk factors in addition to their drug use, including poverty, stress, nutritional deficiencies, and infections, to name a few. For these reasons, the rodent studies more likely *underestimate* the impact of the total prenatal environment on the human fetus and its development.

The earliest studies on human response to fetal methamphetamine exposure were grim indeed. Tests of visual recognition in human infants exposed to methamphetamine showed significant decreases (Hansen, Struthers, & Gospe, 1993) and corresponding differences in attention, distractibility, and activity level (Struthers & Hansen, 1992). Changes in visual recognition in the infant are strongly associated with cognitive function later in life, and lack of eye contact can also impair maternal–infant bonding in the first days of life. Dixon and Bejar at UCSD (1989) found that 35 percent of neonates exposed to cocaine and/or methamphetamine in utero had abnormalities in brain structure at birth, including intraventricular hemorrhage, necrotic echodensities, and cavitary lesions. These lesions were thought to be due to the severe vasoconstrictive effects of stimulant drugs of abuse. A significant number of stimulant-exposed infants (10%) had ventricular dilation, reflecting diffuse atrophy of cortical tissue.

But the human brain is not the same as a rodent brain. Cortical areas are much more richly developed in humans, and the human cortex continues postnatal development over the first 21 years of life, especially in the first 3 years of life. The developmental window that extends from birth to age three is a time of

explosive growth in cognitive, emotional, verbal, and social development. Given adequate interaction, stimulation, and nutrition, the human cortex increases in size significantly. If the meth-exposed child is sent home with responsible parents, much (though perhaps not all) of the brain injury sustained before birth could be compensated for and its impact diminished. Early intervention in methamphetamine-exposed children could be extremely important to the long-term prognosis for human cognitive and social development.

And indeed that is what the studies demonstrate. When methamphetamine-exposed children are studied at age 8 to 10 years, the cavitary lesions and ventricular dilation are no longer seen (Smith et al., 2001). All of the children in this study had been exposed to methamphetamine with very low levels of exposure to other drugs of abuse, including alcohol. Children with diagnosed developmental delay, impaired growth, seizure disorders, or ADHD were excluded. Only those children who looked perfectly normal were studied. Although these children did have signs of metabolic changes in the basal ganglia, no cavitary lesions were found.

In a follow-up study by the same group, Chang et al. in 2004 investigated further the changes seen in the basal ganglia of methamphetamine-exposed children. Using some of the same subjects, again excluding children with obvious developmental delays or ADHD, significant subcortical changes were seen. Methamphetamine-exposed children had significantly smaller hippocampus, globus palidus, putamen, and caudate (17%–26% smaller), the same areas that are impaired in the animal studies.

A corresponding decrement in neuropsychological testing was also observed in these methamphetamine-exposed children. They scored lower on measures of visual-motor integration, attention, verbal memory, and long-term spatial memory, all essential functions in efficient learning. Again, these were children who had not been identified as having a developmental delay or ADHD by teachers or caregivers. These children looked perfectly normal and were performing normally in school, but they were challenged by the effects of their prenatal methamphetamine exposure.

Long-term follow-up of methamphetamine-exposed children over a period of up to 15 years shows the impact of these challenges. Billings, Eriksson, Jonsson, Steneroth, and Zetterström (1994) demonstrated increased aggressive behavior and poor adjustment in children 8 to 10 years old exposed to methamphetamine prenatally. The same children followed up to 15 years of age (Cernarud, Eriksson, Jonsson, Steneroth, & Zetterström, 1996; Eriksson, Jonsson, Steneroth, & Zetterström, 2000) showed higher rates of academic failure and poor social adjustment. These methamphetamine-exposed children were three times more likely to be behind in school (15% were one year or more behind) and had lower grades than nonexposed peers.

These long-term studies did not attempt to control for alcohol exposure. Indeed, 81 percent of these children were also exposed to alcohol prenatally. Fetal alcohol syndrome has clearly been linked to significant neurobehavioral abnormalities, including ADHD, learning disability, verbal memory deficits, and mental retardation (Pie, Rinaldi, Rasmussen, Massey, & Massey, 2008). Most of these children (80%) were also exposed to nicotine, which has been linked to abnormalities of the auditory association area (Dwyer, Broide, & Leslie, 2008) and dysregulation of emotion and attention (Shea & Steiner, 2008). The majority (78%) of these children did not live with their birth mothers throughout childhood. Many were wards of the state and had moved from foster home to foster home, a condition that is strongly linked to academic failure and delinquency (National Center on Addiction and Substance Abuse at Columbia University, 2004).

We do not know the true incidence or severity of psychomotor or neurocognitive disability in children exposed to methamphetamine because routine drug testing is not being done, and so the majority of affected children are not identified at birth or assessed as they mature. Human studies will always be complicated by concurrent alcohol and other drug abuse, since most meth addicts use other drugs as well. We do not yet have the necessary data to assess the true incidence and risk of methamphetamine exposure to the development of the human brain.

EARLY DETECTION AND INTERVENTION

Primary prevention of drug-related disability in the infant requires that the drug-abusing mother be identified and counseled early in the prenatal course so that disease and impairment is prevented. Screening of obstetric patients for drug and alcohol abuse is required by the laws of most states, yet is inconsistently done by most providers and even more seldom reported or acted upon during the pregnancy. This is in spite of the fact that a poor obstetric outcome is likely in the event of drug abuse during pregnancy, and that the poor outcome is likely to be attributed to substandard obstetric care if the existence of drug abuse has not been documented.

Prenatal screening is fraught with difficulty because of the fear that the drug-abusing gravida will simply avoid prenatal care if serious attention is directed to her drug or alcohol abuse, especially in the form of drug testing. Screening is thus limited to verbal questioning with its attendant underestimation of the extent of the problem at hand.

For verbal screening to be effective, questioning should be incorporated into the routine intake interview so that a rapport is established with the health care provider and suspicion as to the intentions of the provider is minimized.

Questioning should begin with an inquiry into family history of substance abuse, ideally in the context of a general family history review. This line of questioning is less threatening to the patient and less likely to raise resistance than a direct assault on her fitness to be a mother. If the family history of addiction is then recorded as an illness, not a moral failure, the patient may be more likely to admit to her own "addictive illness" than she would be to admit to her "illegal drug use" with its criminal intonations.

Early prenatal identification of a drug or alcohol problem permits primary prevention of the neonatal complications—the ideal situation—rather than just the damage containment obtainable with neonatal drug testing. Prenatal identification requires an informed, concerned, and honest patient, who has been apprised of the risks drug abuse poses to her and her baby's health, a nonjudgmental attitude on the part of the medical provider, and the availability of appropriate inpatient or outpatient treatment facilities.

Since primary prevention is often not accomplished, we are left with damage containment measures that focus on identification of the affected newborns and rehabilitation of their mothers after delivery. But even postdelivery "damage control" interventions are often not carried out because of poor detection of drug and alcohol abuse in the neonatal stage. The period of hospitalization presents our best opportunity to detect and intervene in the addiction process because of the prolonged period of intense observation by skilled professionals in the labor and delivery suite. Professionals trained in recognition of the signs of addiction can identify mothers and infants with risk factors for addiction, and in most states, can order a neonatal drug test at the slightest hint of a problem. The most seriously affected children are likely to be identified in this way; however, not all drug addicts look, act, and smell like drug addicts. Not all labor and delivery professionals are alert to the signs and symptoms of addiction, and not all doctors and hospitals permit drug testing on their favored (insured) patients. Some doctors and hospitals, wishing to avoid all the hassle associated with drug testing, do testing on only the most egregious cases, missing many affected children. The extremely short hospitalizations for delivery that are now common also limit the ability of trained professionals to observe mothers over an extended time and recognize abnormal patterns of behavior and failures in bonding.

Most children exposed to drugs of abuse are not identified at birth, and most of them go home with their drug-abusing parents without any intervention. These children, who have already been exposed to a potent neurotoxin, are then exposed to poor nutrition, domestic violence and child abuse, infectious diseases, and a host of environmental problems associated with poverty and addiction. They are at significant risk for academic and social failure if their

problems are not addressed in a proactive manner. Proactive intervention, however, demands that we know at the infancy or preschool stage that a child is at risk for drug- or alcohol-related developmental challenges. Early identification offers us the opportunity to intervene in the development of a child and reduce the likelihood of a poor outcome.

Despite a long history of neonatal testing for medical problems and inborn errors of metabolism in our newborns (e.g., PKU [phenylketonuria] and hypothyroid), the United States has no systematic program for testing all neonates for exposure to neurotoxic drugs of abuse. This is in spite of the large numbers of children thought to suffer from these exposures and the ease of testing by meconium or hair analysis (Garcia-Bournissen, Rokach, Karaskov, & Koren, 2007). Testing is instead based on stereotypes and behavioral indications that may unfairly stigmatize some segments of the population, and at the same time, fail to detect the majority of cases. Basic public health science tells us that this is a totally inadequate system of detection of a major public health risk.

In a large study of meconium drug testing, 44 percent of all neonates in an inner-city hospital tested positive for illicit drug exposure. The majority of children with prenatal exposure to illegal drugs appeared normal at birth, and so would not have been tested under most protocols. Only one in four drug-abusing mothers admitted to her drug use on questioning in the perinatal setting (Ostrea et al., 1992). Of those who admitted to drug use at any time during pregnancy, around 90 percent of their infants had a positive meconium drug screen at birth.

Current neonatal indications for drug testing include obvious withdrawal symptoms, low birth weight, neurobehavioral abnormalities, seizures, stroke, cardiac problems, and necrotizing enterocolitis in a term baby. Only severely affected infants will display symptoms this severe—around 4 percent of methamphetamine-positive neonates (Smith et al., 2003). Most methamphetamine-affected children (> 50%) do not have any significant withdrawal symptoms, yet are still at risk for developmental delay or learning disability. Identification of these children is essential for effective intervention to prevent social and academic failure.

Current maternal indications for neonatal drug testing include a known history of drug abuse, lack of prenatal care, home delivery or precipitous delivery, preterm labor, poor weight gain in pregnancy, hypertension without proteinuria, abruption, fetal distress, sexually transmitted disease, and obvious intoxication. Poor, single, or homeless mothers are much more likely to be tested for drug abuse than mothers who are employed and have stable family relationships.

The currently practiced methods for drug testing of neonates rely heavily on stereotypes of how drug-abusing mothers typically behave. This approach

is dangerous and misleading for two reasons. First, women from disadvantaged backgrounds may fit the "profile" of the drug-abusing mother and may be selected for testing at a higher rate. This risk factor–based testing leads to a stigmatized feeling of reproach, being held under suspicion merely for being poor or unmarried or homeless.

Second, stereotype-based drug testing misses many infants whose mothers do not fit the profile but who are abusing illegal drugs, especially methamphetamine. Methamphetamine differs from other major drugs of abuse in that many low-dose users do not consider themselves "drug users." Methamphetamine abusers are often well educated, highly functioning individuals, working two jobs, highly driven and successful. They use methamphetamine to work harder and longer, get more focus and enhance attention, or to lose weight and/or prevent weight gain. They consider methamphetamine a "medication," not a "drug," and so will deny "drug use." Methamphetamine users frequently do not fit the stereotype of the "addict." Drug testing based on stereotypes misses this sizable population of mothers, and so their methamphetamine-exposed newborns are not detected.

Universal drug testing offers a major improvement to our current protocols based on perceived risk factors. The currently high cost of meconium drug testing would be greatly reduced if all newborns were tested with resulting economies of scale, just as the cost of the PKU test was reduced when it became part of standard care. State laws to provide for testing of all newborns for exposure to drugs of abuse, just as we currently test all neonates for PKU and thyroid dysfunction, would permit detection of the vast majority of drug-affected newborns. The basis for testing for PKU and thyroid dysfunction is that early intervention is life saving and prevents severe disability in affected children. This rationale also applies to the drug-exposed newborn. Identified mothers could be offered treatment and counseling, and a major cause of child abuse would be prevented. Children could be screened for learning disabilities and receive the special attention they need to develop normally.

We currently screen children for learning disabilities in early elementary school, long after the best window of opportunity for intervention—birth to age three—has passed. Universal neonatal testing for drug exposure would permit earlier intervention in the child's cognitive and social development, and would also permit earlier intervention for the mothers of drug-exposed children, allowing more of them to obtain the treatment they need to preserve the family. None of these interventions can happen if we do not know a newborn has been exposed to substance abuse.

If all newborns were tested, no mother would feel singled out or stigmatized, and no drug-affected children would be missed. Counseling and follow-up

could be offered to mothers and their children, and early detection of learning difficulties could be facilitated. Early detection could lead to better outcomes for children and their families as addictions are identified in earlier stages when treatment outcomes are more favorable. Earlier detection of the subtle learning disabilities associated with methamphetamine exposure permits educational intervention to mitigate the long-term impact of these challenges.

The major limitation of universal neonatal meconium drug testing is that it would only detect late second- and third-trimester use, and would miss those children whose mothers didn't like the hyperemesis treatment offered by their obstetrician, and elected to use their college friend's hangover treatment instead. These women are extremely unlikely to admit to drug use, and if their children exhibit learning difficulties or neurologic injury, they will find someone else to blame.

Another limitation is the incidence of false positive results even with the use of gas chromatography or mass spectrometry confirmation testing. Meconium screens are not reliable for PCP (Phencyclidine) exposure—the use of dextromethorphine (Robitussin) cough medicine is enough to make the PCP screen positive. The meconium screen would also be positive for amphetamines in the case of prescription use of stimulants such as Adderall and Desoxyn. These drugs are not recommended for use in pregnancy (Category C) as alternative treatments are readily available for their indications.

But the most common reason for failure to obtain a drug test is denial, usually based on stereotyping of the mother and fear of offending the favored (insured) patient. Patients are in denial, their families are in denial, and often health care workers join them in the assurance that everything must be just fine. A good girl like her couldn't possibly be using illegal drugs. Denial is generally discouraged in the medical field, since lives are at risk if a serious diagnosis is missed.

DENIAL DOESN'T WORK

Denial on a societal scale is just as dangerous as denial on an individual level. Our reluctance to "label" drug-affected children results in a complete inability to assist them since we do not know who they are. Universal drug testing of neonates would break down barriers to treatment and intervention for children and their families. Family drug courts could assure compliance with treatment on the part of parents and assemble the wide range of services and programs that could prevent the disintegration of these fragile families.

When affected children are missed, opportunities for intervention are missed.

We lose opportunities to impact the child and family with drug-treatment options, prevent child abuse and neglect, improve cognitive performance, and prevent academic failure. We miss the opportunity to prevent second-generation drug abuse in these children as they grow up with poor self-esteem and fall into delinquency. Universal drug testing offers us an inroad to identify and assist families and children at risk. We would be remiss if we fail to take action.

Chapter **21**

Endocannabinoid Hypothesis of Drug Addiction

Emmanuel S. Onaivi, MSc, PhD

In reviewing the history of human drug addictions, one finds previous misconceptions that people addicted to drugs lacked willpower and were morally weak. But we now know that drug addiction is a chronic relapsing brain disease characterized by the compulsive use of addictive substances despite adverse consequences to the individual and society. For more than 50 years, it has been assumed that all drugs of abuse release dopamine in the brain's reward system to produce pleasure and euphoria and, consequently, lead to addiction in vulnerable individuals (Salamone, Correa, Mingote, & Weber, 2005; Spanagel & Weiss, 1999). However, many agents, such as inhalants, barbiturates, or benzodiazepines, do not activate midbrain dopamine-mediated transmission consistently, despite the fact that these drugs have rewarding properties and are heavily abused (Spanagel & Weiss, 1999). Therefore, dopamine is not a simple marker of reward or hedonia, and it might no longer be tenable to suggest that drugs of abuse are simply activating the brain's "natural reward system" (Salamone et al., 2005). In this chapter, I propose that the dopamine hypothesis of drug abuse and reward is another misconception. The dopamine projections in the brain do not convey a specific "reward" signal because dopamine release occurs not only to all drugs of abuse but also to stress, foot shock, aversive and salient stimuli (Horvitz, 2000; Roll, 2005). Mice that cannot make dopamine (DD mice) have been used to test the hypothesis that dopamine is necessary for reward. The results show that dopamine is not required for natural reward (Cannon & Palmiter, 2003) and morphine-induced reward (Hnasko, Sotak, & Palmiter, 2005). Thus, there are numerous problems associated with

Table 21.1
Problems Associated with Dopamine Hypothesis of Reward

Beyond the nucleus accumbens and dopamine hypothesis of reward
• Not all studies point to a unitary role for dopamine in one brain circuitry as the most relevant system in drug abuse.
• Dopamine may not be involved in brain reward mechanisms as previously thought.
• Reward centers in the brain consist of multiple systems and neuroanatomical sites other than the mesoaccumbens dopamine circuitry.
• Dopamine-independent mechanisms involving other neurotransmitters like glutamate, GABA, serotonin, endocannabinoids, stress hormones, and dynorphin are potential substrates for the rewarding effects of abused substances.
• In schizophrenics, dopamine excess in mesoaccumbens causes heightened state of arousal and not pleasure.
• Smokers and cocaine addicts continue to take hits long after the cigarettes become distasteful or after the effects of cocaine have worn off.
• Addictions arise from a complex pattern of pathogenetic and environmental situations.
• Differential effects of abused substances on the complex network of genes, hormones, neurotransmitters, and modulators do not support the concept of a single reward transmitter.
• Manipulation of dopamine circuitry as a pharmacology target should provide medication for substance abuse.
• There is no causal relationship for dopamine as a pleasure or reward transmitter triggered by abused substances.
• Activation of dopamine pathways is not involved in brain-stimulation reward of all brain sites relevant to addiction.
• Electrolytic lesions and 6-OH dopamine lesion studies of dopamine cell bodies in the ventral tegmental area and other brain sites did not attenuate brain-stimulation reward.

dopamine hypothesis of reward (Table 21.1). For example, self-administration of opiates and alcohol occurs even when the mesolimbic dopamine system is lesioned (Koob & Le Moal, 1997) and interference with accumbens dopamine transmission does not substantially blunt the primary motivation for natural rewards (Salamone et al., 2005). Although we cannot underestimate the role of dopamine in the central nervous system, recent studies in schizophrenia, where dopamine hypothesis had dominated the treatment approaches, now show that glutamate receptor offers promise for a new class of antipsychotic agents (Patil et al., 2007).

It appears that the strong and long-held belief of dopamine hypothesis as a basis for drug reward and addiction will not change overnight. However, the recent evidence indicating that the endocannabinoid system plays a pivotal role in reward processes (Solinas, Goldberg, & Piomelli, 2008) suggests that the endocannabinoid system may be a target for the treatment of addictive behaviors. So the activation of the "natural reward system," supposedly mediated by the accumbens dopamine, cannot reasonably be used as a general explanation for drug abuse and addiction (Salamone et al., 2005). Furthermore, the discov-

ery that dopamine neurons fail to respond when animals receive anticipated reward contradicts the neurobiological model of acute drug reward and reinforcement associated with the mesolimbic dopamine system (Sullivan et al., 2008). Most of the addictive substances are plant-derived, including cocaine, caffeine, morphine, ephedrine, nicotine, and so on, and from an evolutionary perspective, the natural function of these plant alkaloids evolved to deter consumption, which is incompatible with the mesolimbic dopamine hypothesis of drug reward and reinforcement—an incompatibility that has been termed "the paradox of drug reward" (Sullivan et al., 2008).

A number of observations have led to renewed questions of the dopamine hypothesis. For example, first-time users of cannabis, or tobacco and other recreational drugs, usually have unpleasant responses with nausea and vomiting. It is also now recognized that these abused substances selectively activate specific pathways, so that while nicotine binds with cholinergic receptors, cannabinoids and opiates bind to cannabinoid and opioid receptors, respectively, and not dopaminergic receptors. It is therefore timely that there is accumulating evidence indicating a central role for the endocannabinoid system (ECS) in the regulation of the rewarding effects of abused substances. Such recent studies have shown that this endocannabinoid system is involved in the common neurobiological mechanism underlying drug addiction (De Vries & Schoffelmeer, 2005; Fattore et al., 2007; Maldonado, Valverde, & Berrendero, 2006; Parolaro, Vigano, & Rubino, 2005), and see Table 21.2. Thus, an endocannabinoid hypothesis of drug reward is postulated from data from our studies and those of others. Endocannabinoids mediate retrograde signaling in neuronal tissues and are involved in the regulation of synaptic transmission, to suppress neurotransmitter release by the presynaptic cannabinoid receptors (CB-Rs). This powerful modulatory action on synaptic transmission has significant functional implications and interactions with the effects of abused substances. Additional support for the endocannabinoid hypothesis of drug reward is derived from the action of cannabinoids or marijuana use on brain reward pathways that is similar to other abused substances. Furthermore, administration of cannabinoids or the use of marijuana exerts numerous pharmacological effects through their interactions with various neurotransmitters and neuromodulators (Table 21.2).

In our preliminary studies to test the endocannabinoid hypothesis of drug reward, we investigated the interaction between vanilloid and cannabinoid agonists and antagonists in the mouse model of aversion using the elevated plus-maze test. The vanilloid agonist used is a natural product, capsaicin, the active ingredient in hot chili peppers that is known to be habit forming. In a follow-up study, we determined the effect of the CB1 antagonist, rimonabant, on withdrawal aversions from chronic treatment with abused drugs. Our

Table 21.2
Framework for an Endocannabinoid Hypothesis of Drug Reward

- The existence of an endocannabinoid physiological control system (EPCS) with a central role in the regulation of the rewarding effects of abused substances.
- The EPCS is intricately involved in almost all the biological processes of the human body and brain.
- The EPCS appears to exert a powerful modulatory action on retrograde signaling associated with cannabinoid inhibition of synaptic transmission.
- The retrograde signaling appears to be involved in the modulation of neurotransmitter release by cannabinoids and endocannabinoids.
- The abundant distribution of the cannabinoid receptors in the brain provides the EPCS limitless signaling capabilities of cross-talk within, and possibly between, receptor families.
- A missense mutation in human fatty acid amide hydrolase may be associated with problem drug use in vulnerable individuals.
- Cannabinoids induce alterations in brain disposition and pharmacological actions of drugs of abuse.
- Changes in endocannabinoid contents in the brain of rats chronically exposed to nicotine, ethanol, or cocaine.
- "Runners high," the sense of euphoric well-being that comes with vigorous exercise such as running, stimulates the release and elevated levels of endocannabinoids.
- The mechanisms of dependence to different substances appear to be different in terms of their impact on the EPCS.
- The endocannabinoid transmission is a component of the brain reward system and appears to play a role in dependence/withdrawal to abused substances.
- Reduced sensitivity to reward in CB1 knockout mice. But mice that cannot make dopamine (mice lacking tyrosine hydroxylase) respond to rewarding stimuli, indicating reward without dopamine.
- Overeating, alcohol and sucrose consumption is decreased in CB1 receptor deleted mice.
- Involvement of endocannabinoid system in the neural circuitry regulating alcohol consumption and motivation to consume alcohol.
- Evidence for the existence of a functional link between the cannabinoid and opioid receptor systems in the control of alcohol intake and motivation to consume alcohol.
- Decreased alcohol self-administration and increased alcohol sensitivity and withdrawal in CB1 receptor knockout mice.
- Endocannabinoid system modulates opioid rewarding and addictive effects by cross-talk between endogenous opioid and endocannabinoid systems in drug reward.
- Involvement of endocannabinoid and glutamate neurotransmission in brain circuits linked to reward and mnemonic processes. Abolition of LTP in mice lacking mGluR5 receptors and enhanced LTP and memory in mice lacking cannabinoid CB1 receptors.
- Endocannabinoid system in memory-related plasticity may be a common mechanism in the control of conditioned drug seeking by cannabinoids.

results suggest that the endocannabinoid physiological control system may be important natural regulatory mechanisms for reward.

ENDOCANNABINOID PHYSIOLOGICAL CONTROL SYSTEM (EPCS) AND REWARD, DRUG ABUSE, AND ADDICTIONS

Cannabinoids are the constituents of the cannabis plant, and endocannabinoids are the marijuana-like substances produced on demand by the human body (Onaivi, Sugiura, & Di Marzo, 2006). Currently, there are two well-characterized CB-Rs with known splice variants, CB1-Rs and CB2-Rs (Onaivi et al., 2006), that are known to mediate the effects of marijuana use and those of the endocannabinoids. 2-Arachidonyl glycerol has emerged as one of the endocannabinoids that acts as a full agonist at CB-Rs. Anandamide, the first endocannabinoid isolated, is a partial agonist at CB-Rs and a full agonist at the vanilloid receptor. CB1-Rs are known to be expressed in the brain and in peripheral tissues. Although CB2-Rs was once believed to be restricted to immune cells, we and others have demonstrated that it is also functionally expressed in neurons, albeit at lower levels than CB1-Rs (Onaivi, Ishiguro, et al., 2006; Van Sickle et al., 2005). These cannabinoid receptors are G-protein coupled receptors with seven transmembrane domains.

Many studies now show that the endocannabinoid system is involved as the major player, and most likely, the common neurobiological mechanism underlying drug reward. There is substantial evidence supporting a role for the endocannabinoid system as a modulator of dopaminergic activity in the basal ganglia (Giuffrida & Piomelli, 2000). The endocannabinoid system therefore participates in the primary rewarding effects of alcohol, opioids, nicotine, cocaine, amphetamine, cannabinoids, and benzodiazepines through the release of endocannabinoids that act as retrograde messengers to inhibit classical transmitters, including dopamine, serotonin, GABA, glutamate, acetylcholine, and norepinephrine (Onaivi, Sugiura, et al., 2006). Furthermore, the endocannabinoid system is intricately involved in the common mechanisms underlying relapse to drug-seeking behavior by mediating the motivational effects of drug-related environmental stimuli and drug reexposure (Maldonado et al., 2006). Therefore, substantial data now point to a role of the endocannabinoid system in triggering and/or preventing reinstatement of drug-seeking behavior (Fattore et al., 2007). It appears that the effects of perturbation of the endocannabinoid system by drugs of abuse can be ameliorated by restoring the perturbed system using cannabinoid ligands.

It is not surprising that preliminary studies with cannabinoid antagonists are showing promise in the reduction of drug use, in smoking cessation,

and reduction in alcohol consumption and, of course, rimonabant has been approved in Europe for treating obesity. It is hoped that these encouraging positive results will lead to new therapeutic agents in the treatment of drug dependency. The promiscuous action and distribution of cannabinoid receptors in most relevant biological systems provides the EPCS limitless signaling capabilities of cross-talk within, and possible between, receptor families that may explain the myriad behavioral effects associated with smoking marijuana. The EPCS, therefore, appears to play a central role in regulating the neural substrate underlying many aspects of drug addiction, including craving and relapse (Yamamoto, Anggadiredja, & Hiranita, 2004). The findings that the EPCS is involved in the reinstatement model provided evidence of the EPCS in the neural machinery underlying relapse. Relapse, the resumption of drug taking following a period of drug abstinence, is considered the main hurdle in treating drug addiction, and pharmacological modulation of the endocannabinoid tone with rimonabant gave positive results in human trials. A summary of data from recent studies of the efficacies of cannabinoid antagonist and mutant mice have recently been reviewed (Parolaro et al., 2005). As the usefulness of the pharmacotherapy of substance abuse has been limited, there is sufficient preclinical evidence for clinical trials to evaluate the efficacy of cannabinoid-based drugs in the treatment of drug dependency.

INTERACTION BETWEEN CB1 AND CB2 RECEPTORS IN DRUG ABUSE AND ADDICTION

The expression of CB1 cannabinoid receptors (CB1-Rs) in the brain and periphery has been well studied, but the brain neuronal expression of CB2-Rs had been ambiguous and controversial and its role in substance abuse is unknown. There is now ample evidence for the functional presence of CB2-Rs in mammalian brain neurons (Gong et al., 2006; Onaivi, 2006; Van Sickle et al., 2005). We have investigated the involvement of CB2-Rs in alcohol preference in mice and alcoholism in humans (Ishiguro et al., 2007). So we tested if CB2-Rs in the brain play a role in alcohol abuse/dependence in animal model and then examined an association between the CB2 gene polymorphism and alcoholism in a Japanese population. There is an association between the Q63R polymorphism of the CB2 gene and alcoholism in the Japanese population. Our data therefore revealed that CB2-Rs are functionally expressed in brain neurons and play a role in substance abuse and dependency (Gong et al., 2006; Ishiguro et al., 2007; Onaivi, 2006). The next question is now that we know that CB2-Rs are present in the brain, what is the nature of and contribution to the known effects of CB1-Rs in the rewarding effects of drug abuse? With

the recent definitive demonstration of neuronal CB2-Rs in the brain, one possible explanation may be that CB2-Rs and CB1-Rs work independently and/or cooperatively in different neuronal populations to regulate a number of physiological activities influenced by drugs of abuse, cannabinoids, endocannabinoids, and marijuana use. Nevertheless, our studies and those of others demonstrate the functional expression of CB2-Rs in the brain that may provide novel targets for the effects of cannabinoids in substance abuse disorders beyond neuro-immunocannabinoid activity.

NEW PERSPECTIVES IN STUDYING THE INVOLVEMENT OF THE ENDOCANNABINOID SYSTEM IN REWARD PROCESSES

We used the elevated plus-maze test—a validated method to measure the performance of rodents that are nocturnal in nature and to obtain an index of anxiety when control and experimental animals are exposed to the maze. The plus-maze consists of two open arms and two enclosed arms linked by a central platform and arranged in a plus sign (+). The elevated plus-maze system was used to study withdrawal anxiogenesis from selected drugs with abuse potential, including cocaine, diazepam, and ethanol. The synthetic methanandamide was included in the study. Adult C57Bl/6 mice were evaluated in the elevated plus-maze test of anxiety following abrupt cessation from chronic treatment with selected doses of cocaine, diazepam, ethanol, 8%w/v, and methanandamide. In a separate group of these mice, the ability of the CB1 cannabinoid antagonist, rimonabant, to block the withdrawal aversions of mice from alcohol and selected drugs with abuse potential was determined. The in-vivo pharmacological interaction was evaluated by the co-administration of cannabinoids and vanilloid ligands. Capsaicin known to activate CB-Rs and vanilloid receptors (VR1-Rs) in the central nervous system (CNS) was used to study the involvement of the ECS in the habit-forming properties of capsaicin using mice. The interaction between the vanilloid and cannabinoid system was performed using selected agonists and antagonists. The ability of the antagonist drug to block agonist drug effect was also evaluated in this paradigm.

INTERACTION OF CANNABINOIDS AND VANILLOIDS: A BIOLOGICAL BASIS OF WHY SOME LIKE IT HOT AND OTHERS DO NOT

We tested the hypothesis that the endocannabinoid physiological control system (ECS) may play a role in the habit-forming properties of capsaicin and

may also be involved in the rewarding effects of abused substances. In the first set of studies, the cross-talk between cannabinoids and vanilloids was determined by evaluating the interactions of capsaicin, a vanilloid receptor 1 agonist, and WIN5512–2, a cannabinoid agonist. The effect of the vanilloid receptor antagonist, capsazepine, and the cannabinoid antagonist, rimonabant, in the actions of capsaicin and the WIN55212–2 were determined. The aversive behavior induced in mice following treatment with capsaicin, which was dependent on gender and strain of mice used, was enhanced by pretreatment with WIN55212–2. While the 30 minutes with WIN55212–2 enhanced aversions induced by capsaicin, capsazepine or rimonabant blocked the aversions induced by capsaicin and WIN55212–2. The effect of capsaicin on the performance of mice in the plus-maze test was dependent on the gender and mouse strain, with C57BL/J male mice being more susceptible to the behavioral aversions induced by capsaicin.

ANTAGONISM OF WITHDRAWAL REACTION FROM ALCOHOL AND DRUG ABUSE BY CB1 RECEPTOR ANTAGONISM IN THE PLUS-MAZE TEST

The effects of rimonabant on the withdrawal aversions from cessation with chronic treatment of mice with the selected addictive drugs were evaluated. Cannabinoid CB1 receptor antagonism reduced behavioral aversions following withdrawal from alcohol, cocaine, and diazepam. It is important to note that rimonabant, the CB1-R antagonist alone, produced variable effects characterized by reduced aversion at low dose and increased aversions to the open arms of the maze at higher doses.

THE ENDOCANNABINOID SYSTEM IN REWARD PROCESSES

The major goal of the study is to understand the role of endocannabinoids (the marijuana-like substances produced by the human body) in drug reward and addiction. Cannabinoids, the constituents in marijuana, mediate their effects by acting on the endocannabinoids and their receptors (CB-Rs), while capsaicin, the pungent chemical in hot chili peppers, a habit-forming food substance, activates the vanilloid type 1 (VR1) receptors to produce its effects. Marijuana and capsaicin enhance appetite, taste, and perhaps addiction and habit-forming properties through CB-Rs and VR1 receptors. The data obtained reveal differential sensitivities of capsaicin in mice that were gender- and strain-dependent that may indicate why some like hot chili peppers and

others do not. Mice naturally do not like capsaicin, and these data are supported by the finding that genetically modified mice lacking the VR1 receptor no longer avoid spicy peppers (Caterina et al., 2000). This may be due to the interaction between the cannabinoid and vanilloid systems. This is because both capsazepine and rimonabant (antagonists at vanilloid and cannabinoid receptors) blocked the aversions induced by WIN55212–2 and capsaicin, indicating a cross-talk between cannabinoid and vanilloid systems. Although the interaction between the EPCS and the vanilloid system is not well established and studied, the results from the investigation on whether the interaction between endocannabinoid and endovanilloid systems induced by the natural ligands could be a basis why some like hot chili peppers and others do not is intriguing. Therefore, it is tempting to speculate and extend the known regulation of the neural substrates altered by abused substances to an interaction or a cross-talk between the EPCS and the endovanilloid (VR1) system. The existence and involvement of the EPCS in this in-vivo model is presented as additional evidence that manipulating the EPCS could be exploited in reducing the behavioral consequences of withdrawal from drug dependency.

Finally, we tested the hypothesis that the EPCS is an integral component of the reward circuit using in-vivo tests. We determined the influence of CB-R antagonism on withdrawal anxiogenesis from chronic alcohol, cocaine, and diazepam treatment in vivo using the mouse plus-maze test. The CB1-R antagonist rimonabant blocked the behavioral aversions to the open arms of the plus-maze, which was precipitated from withdrawal from cocaine, diazepam, and alcohol. Similar to the withdrawal aversions in the plus-maze test, conditioned place preference (CPP) paradigm has been used to investigate the rewarding effects of cannabinoids. Rimonabant has been shown to counteract the CPP supported by classical reinforcers, including food, cocaine, and morphine (Chaperon, Soubrie, Puech, & Thiebot, 1998). This is in agreement with data that demonstrate the antagonistic activity of rimonabant against disruption of cognition or reward-enhancing properties of morphine, amphetamine, and cocaine (Poncelet, Barnouin, Breliere, Le Fur, & Soubrie, 1999), which we have extended to ethanol and diazepam. The blockade of the behavioral aversions by cannabinoid antagonist following chronic administration with alcohol, cocaine, and diazepam is in agreement with data obtained during cannabinoid-induced alterations in brain dispositions of drugs of abuse that correlated with behavioral alterations in mice (Reid & Bornheim, 2001). These results taken together suggest that in the CNS, the EPCS may be a directly important natural regulatory mechanism for reward in the brain and also contribute to reduction in aversive consequences of abused substances. Thus, the data presented, along with those of others, not only support the existence of the EPCS but also

an endocannabinoid hypothesis of drug reward and addiction that may last beyond the dopamine hypothesis of drug reward.

CONCLUSIONS

The preliminary data on the association between activation of cannabinoid and vanilloid receptors show that the interaction of abused substances with the endocannabinoid system is pivotal in habit forming and a neural basis of drug abuse and dependency. Cannabinoids therefore appear to be involved in adding to the rewarding effects of addictive substances, including cocaine, alcohol, and benzodiazepines. Again, these results taken together suggest that in the CNS the EPCS may be a directly important natural regulatory mechanism for reward in the brain and also contribute to reduction in aversive consequences of abused substances. The existence and involvement of an endocannabinoid physiological control system in this in-vivo model is presented as additional evidence that manipulating the EPCS could be exploited in reducing the behavioral consequences of withdrawal from alcohol and drug dependency. It is a good thing that controversy is one of the fuels of science. Thus, there is a lot more research to be done to better understand the nature and the neurobiology of the endocannabinoid physiological control system in health and disease. In the end, the eternal bliss may not be dopamine but endocannabinoids—the brain and body's marijuana and beyond (Onaivi, Sugiura, et al., 2006).

ACKNOWLEDGMENTS

This work would not have been possible without the support, in part, by William Paterson University, Center for Research, the Dean College of Science and Health, Dr. DeYoung Student Worker Fund for maintenance of research animals, and the Provost Office for release time. I thank my colleagues in the Biology Department, and especially the Chairperson, Dr. Gardner, and Norman Schanz in the mouse laboratory. I acknowledge the assistance and support of Dr. Patricia Tagliaferro and my collaborators, including Drs. Hiroki Ishiguro, B. Emmanuel Akinshola, and Sanika Chirwa. I wish to thank past and present students for technical assistance in working with me, especially, Zoila Mora, Alex Perchuk, Danielle Colas, and Chiara Brandoni for direct involvement with some part of these studies. I would also like to thank Drs. John McPartland, Richard Rothman, Mike Baumann, and William Freed for constructive comments. I am indebted to Dr. George Uhl, the Chief of Molecular Neurobiology Branch at NIDA-NIH, where I am a Guest Scientist.

Chapter **22**

Regulation of μ-Opioid Receptor Desensitization in Sensory Neurons

Cui-Wei Xie, MD, PhD

A common property of G protein-coupled-receptors (GPCRs) is desensitization, loss of signaling after repeated or continued stimulation of the receptor. Desensitization of the μ-opioid receptor, which is the primary target of clinical analgesia and drugs of abuse, has been a subject of intense investigation because of its potential role in the development of opiate tolerance and dependence. Recent studies examining μ-opioid desensitization in dorsal root ganglion (DRG) sensory neurons have revealed multiple mechanisms that regulate signaling and trafficking of the μ receptor, its interactions with other GPCRs, and G protein-effector interactions during acute and chronic opioid exposure. Several protein kinase systems, including phosphoinositide 3-kinase (PI3K), Akt, extracellular signal-regulated kinases (ErK) and p38 mitogen-activated protein kinase (p38 MAPK), have been shown to play important roles in these mechanisms. Adding another layer of complexity, emerging evidence indicates that formation of hetero-oligomers between the μ receptor and other GPCRs permits cross regulation of receptor signaling and trafficking, which in some cases leads to the development of cross desensitization. Further understanding of these dynamic processes could provide insight into the adaptive changes at cellular levels that initiate the complex behavioral changes in opiate tolerance and dependence.

DIFFERENT FORMS OF μ-OPIOID DESENSITIZATION IN DRG NEURONS

Primary cultures of rodent DRG neurons have been extensively used to study opioid regulation of voltage-gated Ca^{2+} channels (VGCCs). It is well documented that opioid receptors couple with Ca^{2+} channels through Gi and Go proteins. Activation of μ-opioid receptors significantly reduces multiple components of VGCC currents, predominantly N- and P/Q-type currents, through a mechanism involving direct interactions between G-protein βγ subunits (Gβγ) and the α_1 subunit of Ca^{2+} channels (Ikeda, 1996). The μ receptor-mediated VGCC inhibition contributes directly to the analgesic action of opiate drugs and has been demonstrated at multiple levels of the pain-processing pathways, including thalamic and periaqueductal grey neurons (Connor & Christie, 1998; Formenti et al., 1995) and peripheral sensory neurons (Nomura, Reuveny, & Narahashi, 1994; Taddese, Nah, & McCleskey, 1995). DRG sensory neurons in cultures express all major types of opioid receptors and VGCCs, providing a convenient model system to study opioid signaling and desensitization with regard to ion channel regulation. Notably, DRG cultures consist of a mixed population of neurons of various sizes. Expression of μ receptors in these neurons appears to be developmentally regulated with the highest level expressed in cells of all sizes during the first postnatal week. The expression then gradually declines in larger cells and is confined to small and medium cells by postnatal day 21 (Beland & Fitzgerald, 2001). Consistent with this expression pattern, only a subset of DRG neurons are sensitive to the effect of a selective μ agonist [D-Ala^2, N-$MePhe^4$, Gly-ol^5]-enkephalin (DAMGO) in cultures derived from adult animals (Schroeder & McCleskey, 1993), whereas the majority of DRG neurons (~90%) respond to DAMGO in cultures derived from early postnatal mice (Tan et al., 2003). The latter can therefore be readily used for the study of μ opioid desensitization.

Desensitization, defined as a loss of cell responsiveness to the agonist, can be mediated by a number of cellular regulatory events. At the receptor level, opioid desensitization has been associated with agonist-induced rapid receptor uncoupling with G proteins, reduction in cell surface receptors, or downregulation of total receptors (Connor, Osborne, & Christie, 2004; Johnson, Christie, & Connor, 2005; Marie, Aguila, & Allouche, 2006). Postreceptor changes that affect Gi/Go proteins, downstream signaling pathways, and the final effector such as ion channels can also contribute to desensitization of opioid signaling (Tan et al., 2003). Two relevant terms often mentioned in this context are the *homologous* and *heterologous* desensitization. Homologous desensitization

refers to the process in which only the activated receptor reduces its responsiveness. Heterologous desensitization, however, reduces signaling of other receptors not activated by the agonist. Another way to define opioid desensitization is based on its time course. With regard to VGCC modulation, acute or rapid desensitization can occur within minutes of agonist exposure, whereas chronic desensitization often develops gradually over several hours. In DRG cultures, both acute and chronic μ opioid desensitization have been observed following DAMGO treatment (Nomura et al., 1994; Samoriski & Gross, 2000; Tan et al., 2003). The acute desensitization has rapid onset within one to five minutes, causes incomplete loss of opioid responses, and is often insensitive to the modulators of major protein kinases. In contrast, chronic desensitization has a much slower time course, leads to complete loss of opioid responses in 24 hours, and is heavily regulated by several protein kinase systems (Nomura et al., 1994; Tan et al., 2003). Acute and chronic μ opioid desensitization also differentially affect VGCC modulation by other Gi/Go-coupled receptors in DRG neurons. For example, γ-aminobutyric acid $(GABA)_B$ receptor-mediated VGCC inhibition can be heterologously reduced following acute but not chronic DAMGO desensitization. On the other hand, chronic DAMGO treatment induces heterologous desensitization to α2-adrenergic receptor-mediated VGCC inhibition (Samoriski & Gross, 2000; Tan et al., 2003). These findings suggest that acute and chronic desensitization are mechanistically different and may affect distinct components in the G protein-receptor-Ca^{2+} channel pathway.

How these different forms of desensitization are related to opioid tolerance in vivo remains an open question. Tolerance is defined as a decreased physiological response to the same dose of drug during repeated exposure. Compared to *in-vitro* desensitization, tolerance develops over a more extended period (hours to days) and involves complex changes not only at the cellular level but also in various neural networks. Many believe that cellular mechanisms of desensitization serve to initiate the cascade of events ultimately leading to opioid tolerance and dependence (Bailey & Connor, 2005; Borgland, 2001; Marie et al., 2006). However, the exact role of desensitization-related processes in the development of tolerance remains to be clarified. Studies have shown that such roles may vary in different experimental settings, depending upon the agonist applied, cell types, and the form of desensitization examined (Connor et al., 2004). As discussed below, prolonged desensitization coupled with poor receptor recycling is likely to promote tolerance. On the other hand, desensitization associated with rapid receptor internalization and recycling may in fact be a protective mechanism that prevents extended receptor signaling leading to tolerance (Martini & Whistler, 2007).

Protein Kinase Modulation of Desensitization

Two major groups of protein kinases have been implicated in GPCR desensitization observed in nonneuronal cells: members of G-protein receptor kinase (GRK) family and second messenger-activated protein kinases. Agonist-induced receptor phosphorylation by GRKs, followed by binding of β-arrestin and receptor uncoupling from G proteins, is considered a common mechanism for acute homologous desensitization. This process is often complemented by feedback phosphorylation via second messenger-activated kinases, such as protein kinase A (PKA), protein kinase C (PKC), and MAPK. These kinases can target both homologous and heterologous receptors (Chuang, Iacovelli, Sallese, & De Blasi, 1996) and affect postreceptor components, including G proteins (Fields & Casey, 1995) and effector ion channels (Hamid et al., 1999). Thus, GPCR desensitization could be mediated by multiple protein kinases with changes occurring at the receptor, G_i/G_o proteins, effectors, or their regulators.

Numerous studies have examined whether the above general mechanisms can apply to desensitization of μ opioid signaling. The μ-opioid receptor has various phosphorylation sites on Ser, Thr, and Tyr residues located on its three cytoplasmic loops and intracellular carboxyl terminal domain. Phosphorylation of these sites regulates signaling efficacy (McLaughlin & Chavkin, 2001) and receptor trafficking (El Kouhen et al., 2001). In cells expressing modified μ receptors with C-terminal truncation or point mutation at the putative phosphorylation sites, DAMGO- or morphine-induced desensitization is significantly attenuated or completely abolished (Deng et al., 2000; Pak, O'Dowd, & George, 1997; Schulz et al., 2004). These findings support the view that μ receptor phosphorylation may be a major contributor to opioid desensitization. It is particularly tempting to link acute desensitization with agonist-induced, rapid μ receptor phosphorylation because of their similar time courses. However, several issues remain to be addressed with this assumption. First, despite extensive investigation, the kinases responsible for μ receptor phosphorylation have not been firmly established. Overexpression of GRK2 in heterologous cells reportedly increases agonist-induced μ receptor phosphorylation (Schulz et al., 2004; Zhang et al., 1998), but evidence exists that activation of μ receptors fails to trigger accumulation of GRKs at the plasma membrane, indicating a weak interaction between the two (Schulz, Wehmeyer, & Schulz, 2002). Second, many relevant studies are conducted using heterologous expression systems, and so far, direct evidence is still lacking to confirm phosphorylation of the μ receptor by GRKs or other kinases in native neurons. Finally, as shown in DRG neurons (Nomura et al., 1994; Tan et al., 2003) and

nonneuronal cells (Kaneko et al., 1997; Morikawa et al., 1998), acute desensitization of μ opioid regulation of VGCCs is not affected by altering the function of major protein kinases, including PKA, PKC, PI3K, Akt, and ErK, nor is it affected by nonspecific inhibitors of protein kinases or phosphatases such as H-8 and okadaic acid. These observations do not support a significant role of protein phosphorylation in this form of desensitization.

In contrast to the acute desensitization, our recent studies show that chronic desensitization in DRG neurons is regulated by a number of second messenger-activated protein kinases in the PI3K-Akt pathway and MAPK cascades (Tan et al., 2003). PI3K comprises a family of dual specificity enzymes with both lipid kinase and protein kinase activity, which can be directly activated by Gβγ dimmers upon activation of μ receptors. One of the key downstream targets of PI3K is Akt, a serine-threonine kinase. The activity of Akt is enhanced by the presence of phosphatidylinositol-3,4,5-P_3 (PIP_3), a lipid product of PI3K, but reduced by phosphates and tensin homolog (PTEN) that reduces the cellular level of PIP_3. In mouse DRG neurons, pharmacological blockade of PI3K activity during a four-hour DAMGO treatment significantly reduces the extent of chronic desensitization, whereas upregulation of cellular Akt levels in neurons lacking PTEN accelerates the desensitization in a PI3K-dependent manner. These findings clearly indicate a facilitating effect of the PI3K-Akt pathway on the chronic desensitization. Similarly, inhibition of the MAPK kinase (MEK)-Erk pathway with PD98059 attenuates DAMGO desensitization. Concurrent blockade of PI3K and Erk activity with selective inhibitors produces no additive relieve of the desensitization, suggesting that the two kinases act in a serial manner. This is consistent with the finding in other cell types that μ agonists activate Erk through Gβγ- and PI3K-dependent mechanisms (Ai, Gong, & Yu, 1999). Further analyses demonstrate that chronic DAMGO exposure leads to loss of prepulse facilitation (PPF), a measure of voltage-dependent Gβγ-Ca^{2+} channel interactions, and that such a loss can be partially reversed by inhibition of PI3K or Erk activity. Thus, PI3K and Erk cascades may facilitate chronic desensitization through postreceptor modifications that weaken Gβγ-Ca^{2+} channel interactions. Interestingly, another component of the MAPK cascade, p38 MAPK, is also crucially involved in DAMGO desensitization but through different mechanisms. In HEK293 cells, p38 MAPK facilitates DAMGO-induced μ receptor internalization by enhancing the function of endocytic machinery regulated by the small GTPase Rab5 (Cavalli et al., 2001; Mace, Miaczynska, Zerial, & Nebreda, 2005). Blocking p38 MAPK activity attenuates both desensitization and internalization of the μ receptor in chronic DAMGO-treated DRG neurons. On the other hand, inhibition of p38 MAPK does not affect desensitization induced by morphine, a μ agonist

triggering little receptor internalization. It is thus likely that involvement of p38 MAPK in the desensitization is closely related to its ability to regulate μ receptor internalization (Tan, Evans, & Xie, 2007).

μ-Opioid Receptor Trafficking and Desensitization

The μ-opioid receptor undergoes agonist-induced endocytosis via clathrin coated-pits, a process regulated by receptor phosphorylation and association with nonvisual β-arrestins. The exact role of this process in regulating opioid signaling has been a subject of intense investigation (Connor et al., 2004; Marie et al., 2006; Martini & Whistler, 2007). Studies in primary neurons and AtT20 cells have indicated that receptor internalization does not contribute to acute desensitization of μ receptors coupled to VGCCs (Borgland, Connor, Osborne, Furness, & Christie, 2003; Walwyn et al., 2006) or inward rectifying potassium channels (Arttamangkul, Torrecilla, Kobayashi, Okano, & Williams, 2006). The relationship between chronic desensitization and μ receptor internalization, however, is more complex. The internalization induced by prolonged agonist treatment not only attenuates opioid responsiveness via physical removal of the receptor from the cell surface but also promotes receptor dephosphorylation and recycling (Qiu, Law, & Loh, 2003). The internalized GPCRs can return to the cell surface through at least two recycling pathways, a fast/early sorting pathway occurring within minutes and a slow/late sorting pathway taking several hours (Sheff, Daro, Hull, & Mellman, 1999). When rapid recycling occurs, the internalization serves as an important means for receptor resensitization, effectively reducing the extent of apparent desensitization (Koch et al., 1998; Qiu et al., 2003). Alternatively, if the internalized receptors are trapped in late endosomes, desensitization can be enhanced because of significant loss of surface receptors (Law et al., 2000). Extended or repeated opioid exposure can also target internalized receptor to lysosomes for degradation, causing receptor downregulation and more persistent signaling reduction. Thus the functional consequence of μ receptor internalization may vary in different model systems, depending upon the rate and extent of endocytosis as well as its coupling with distinct intracellular sorting pathways that determine the postendocytic fate of the receptor.

In mouse DRG neurons, DAMGO treatment induces substantial μ receptor endocytosis within 20 minutes and results in an approximately 40 percent loss in surface μ receptors after 4- to 24-hour treatments. The internalized receptors are found to colocalize with Rab4 and Rab11, the respective marker of the early and late endosomes, suggesting that both the fast and slow sorting pathways participate in μ receptor recycling in these neurons (Walwyn et

al., 2006). Chronic DAMGO desensitization can be prevented or significantly reduced when receptor endocytosis is abolished with p38 MAPK inhibitors (Tan et al., 2007) or when the number of surface μ receptors increases dramatically through adenovirus-mediated overexpression (Walwyn et al., 2004). It is hence conceivable that chronic DAMGO-induced μ receptor internalization may be coupled with delayed recycling through the late sorting pathway, resulting in sustained loss of surface receptors and desensitization. Such a link between internalization and chronic desensitization appears to be agonist selective. After a four-hour exposure to morphine, VGCC inhibition by morphine is significantly reduced but there is no evident μ receptor internalization (Tan et al., 2007). Interestingly, the effect of DAMGO remains relatively intact in chronic morphine-treated neurons (Walwyn et al., 2006). These findings indicate that morphine can induce desensitization through internalization-independent mechanisms, but such desensitization may be incomplete as revealed by testing with DAMGO, a more efficacious full agonist of the μ receptor. A possible interpretation here is that inability of morphine to stimulate endocytosis-related cellular processes, such as activation of p38 MAPK (Mace et al., 2005), may have prevented development of a full-fledged μ opioid desensitization in DRG neurons.

The differences in internalization efficacy of various opiate drugs have been linked with their distinct propensity in promoting tolerance and dependence. Full μ receptor agonists that stimulate internalization, such as etorphine and fentanyl, tend to produce less pronounced tolerance compared to morphine that is least effective in triggering internalization (Duttaroy & Yoburn, 1995). Expression in HEK293 cells of a chimeric receptor (μ/δ receptor), in which the C-terminus of the μ receptor is replaced with that of the δ opioid receptor, facilitates morphine-induced internalization and reduces cellular tolerance and cAMP superactivation, a cellular hallmark of opiate withdrawal (Finn & Whistler, 2001). More recent studies have provided *in-vivo* evidence that morphine tolerance and withdrawal are significantly reduced in a knockin mouse expressing a mutant μ receptor that internalizes in response to morphine (Kim et al., 2008). Thus, internalization could reduce the liability of opiate drugs for promoting tolerance and dependence, likely by limiting receptor signaling and downstream adaptive changes such as superactivation of the cAMP pathway.

Receptor Oligomerization and Desensitization

GPCRs interact with each other through formation of homo- or heteromeric receptor complexes. Such events have divergent impact on receptor binding, signaling or trafficking, and allow cross-regulation between different

receptor systems (Bouvier, 2001; Devi, 2001). An increasing number of studies have shown that heterodimerization between the μ-opioid receptor and other GPCRs often reduces signaling of both receptors, promoting heterologous or cross-desensitization. In HEK293 cells expressing the heterodimer of μ and sst_{2A} somatostatin receptors, exposure to the selective agonist of either receptor induces phosphorylation and desensitization of both receptors (Pfeiffer et al., 2002). Similarly, oligomerization of the μ receptor with the substance P receptor (NK1) facilitates agonist-induced cross-phosphorylation and cointernalization of μ and NK1 receptors in HEK293 cells (Pfeiffer et al., 2003). Another example is hetero-oligomerization of μ opioid and α_{2A} adrenergic receptors. When both receptors are expressed in cell lines or transfected neurons, the heterocomplex formation enhances μ receptor signaling in response to morphine, but significantly reduces opioid responses following simultaneous application of morphine and the α_{2A} agonist clonidine (Jordan, Gomes, Rios, Filipovska, & Devi, 2003). In DRG neurons, functional interactions between naturally existing μ and α_{2A} receptors promote chronic cross-desensitization and cointernalization of the two receptors (Tan, 2005). An interesting common finding in these studies is modification of trafficking profiles of μ receptors in the presence of receptor oligomers. The observed cointernalization of the two interactive receptors in response to a single selective agonist may be explained by the "dragging" phenomenon in which the ligand-activated receptor can "drag" another receptor in the same complex to the endocytic pathway (He, Fong, von Zastrow, & Whistler, 2002). Formation of receptor complexes can also alter receptor interactions with β-arrestin, a key adaptor protein regulating receptor endocytosis and sorting, causing delayed receptor recycling and resensitization (Pfeiffer et al., 2003). As it often occurs between functionally related GPCRs, this type of heterodimeric interaction may serve as a negative feedback mechanism to suppress the activity of shared downstream signaling pathways during prolonged receptor stimulation.

While receptor cotrafficking may contribute significantly to the chronic cross-desensitization, direct inter-receptor communication within hetero-oligomers by conformational changes has been proposed for more rapid signaling regulation (Franco et al., 2005; George, O'Dowd, & Lee, 2002). Using fluorescence resonance energy transfer microscopy, a recent report demonstrates that μ and α_{2A} receptors communicate with each other in the heterodimer through a cross-conformational switch that permits direct inhibition of one receptor by the other with subsecond kinetics (Vilardaga et al., 2008). It should also be noted that not all events of heteromerization lead to cross inactivation or desensitization. Formation of μ and δ opioid receptor heterodimers, for example, results in synergistic enhancement of receptor binding and signaling

by μ and δ ligands (Gomes et al., 2000). Taken together, receptor oligomerization is a dynamic process regulated by different cellular mechanisms; further investigation is required to fully understand its molecular basis and functional consequence. Finally, most studies addressing this issue to date have been conducted in heterologous cells or in systems where receptors are overexpressed. This may lead to interactions nonexistent with endogenously expressed receptors. It is therefore necessary for future study to identify and characterize interactions between endogenous receptors in native neurons. Such knowledge could shed light on the control of opioid receptor signaling and treatment of opiate tolerance and dependence.

About the Editor and Contributors

EDITOR

Angela Browne-Miller, PhD, DSW, MPH, is the Set Editor of the *Praeger International Collection on Addictions* (2009), Director of Metaxis Institute for Personal, Social, and Systems Change, based in northern California, United States; Director of Browne and Associates Violence, Substance Abuse, and Trauma Treatment and Prevention Program, also in northern California; has been a keynote speaker at conferences around the world on addiction, violence, and behavior change; and is the author of numerous books, including *To Have and to Hurt: Seeing, Changing or Escaping Patterns of Abuse in Relationships* (2007) and *Rewiring Your Brain to Change Your Behavior* (2009). Dr. Browne-Miller earned two doctorates and two master's degrees at the University of California, Berkeley, where she lectured in three departments for 14 years, and has served as a National Institute of Mental Health Postdoctoral Fellow, a U.S. Department of Public Health Fellow, the public relations director for Californians for Drug Free Youth, the Research Education and Treatment Director for the Cokenders Alcohol and Drug Program, a member of the board of directors of the Employee Assistance Society of North America, an advisor to addiction treatment programs in the United States and several other countries, and project director on three California Department of Health violence prevention projects.

CONTRIBUTORS

Atul Ambekar, MD, is Assistant Professor at the National Drug Dependence Treatment Centre and Department of Psychiatry, All India Institute of Medical Sciences in New Delhi, Delhi, India. He earned his MD degree from All India Institute of Medical Sciences, a prestigious and internationally recognized institute in India. He worked as Senior Resident and later joined the United Nations Office on Drugs and Crime (UNODC), Regional Office for South Asia, New Delhi, as Research Officer. Subsequently, Dr. Ambekar joined the All India Institute of Medical Sciences as Assistant Professor. He is a resource person for trainings and research for various national and international organizations, such as UNODC, Joint United Nations Programme on HIV/AIDS (UNAIDS), and the government of India. He has several publications to his credit.

Charlotte A. Boettiger, PhD, is Assistant Professor of Psychology and Biomedical Research Imaging at the University of North Carolina Chapel Hill, in Chapel Hill, North Carolina, United States. She was formerly an Associate Investigator at the Ernest Gallo Clinic and Research Center and an Adjunct Assistant Professor in the University of California, San Francisco, Department of Neurology. She studied Biology as an undergraduate at the University of California Berkeley, and received her PhD in Neuroscience at UCSF, where she studied the cellular and synaptic mechanisms of vocal learning. She completed a postdoctoral fellowship with Dr. Mark D. Esposito at the Henry H. Wheeler, Jr., Brain Imaging Center in the Helen Wills Neuroscience Institute at UC Berkeley. Her research focuses on the cognitive neurobiology of addiction. Her experimental approach employs neuroimaging, behavioral techniques, genetics, and pharmacology studies in humans. Dr. Boettiger was awarded the Hugh O'Connor Memorial Fellowship by the Wheeler Center for the Neurobiology of Addiction in 2002.

Kathleen Bradbury-Golas, DNP, RN, APN, is Assistant Professor of Nursing at Richard Stockton College of New Jersey in Pomona, New Jersey, United States. She currently teaches across the nursing curriculum in both undergraduate and graduate nursing programs. She also practices part-time as a family nurse practitioner in southern New Jersey. Dr. Bradbury-Golas holds a Doctorate in Nursing Practice from Case Western Reserve University of Cleveland, Ohio, United States. She is certified as both a Family Nurse Practitioner, by the American Association of Nurse Practitioners, and an Adult Health Clinical Nurse Specialist, by the American Nurses' Credentialing Center. Dr. Bradbury-Golas completed her dissertation research studying health promotion practices and opiate-dependent users.

Giuseppe Carrà, MD, MSc, PhD, Consultant Psychiatrist and Research Fellow at University College London, England, studied Medicine at Milan University in Italy, and did his psychiatric training at Pavia University in Pavia, Italy. He has a PhD in Public Mental Health from the University of Pavia. Dr. Carrà did an MSc in Psychiatric Research at University College London. Since 1995, he has been a Consultant Psychiatrist at S. Paolo University Hospital Trust, Milan, though he worked for two years (2004–2006) in the Camden and Islington CMHTs. Since 2004, Dr. Carrà has been a Research Fellow at UCL. He is a Board Member of the International Society of Addiction. He claims the following governmental and institutional appointments: Member of the Guideline Development Group for Schizophrenia at the Italian National Institute of Health; Member of the Addiction Panel at the Italian Department of Health; Member of the panel of independent experts assisting the European Commission at Directorate General of Justice, Freedom and Security in the priority field "Prevent Drug Consumption and Inform the Public," July 2007–June 2010. Research interests include "dual diagnosis" of psychosis and substance misuse, psychoeducational interventions in schizophrenia, and adaptation and implementation of local guidelines.

Vicki W. Chanon, PhD, completed her PhD in the Cognitive Psychology Program at the University of North Carolina at Chapel Hill in 2007. Her dissertation focused on the neural correlates of varying types of attentional allocation (voluntary, reflexive, and social) in healthy adults using event-related potentials. As an undergraduate, Vicki earned her BA in Psychology and Philosophy at the University of Delaware. She is currently a postdoctoral researcher working with Dr. Charlotte Boettiger in the Behavioral Neuroscience Program at the University of North Carolina at Chapel Hill in Chapel Hill, North Carolina, United States. Her current research focuses on dysfunctional attentional processes in addictive disorders. Specifically, she is using behavioral, neuroimaging, and pharmacological methods to gain an understanding of the neurobiological underpinnings of attentional biases toward drug-related words and images in those suffering with addictive disorders.

Kyle M. Clayton, MS, is a Clinical Psychology graduate student at the University of Texas Tyler, in Tyler, Texas, United States. While at UT Tyler, he has been involved in research concerning neuropsychological testing for children with learning disabilities, correlations between olfaction and Alzheimer's disease, the impact of Lorazepam on neuropsychological measures in suspected dementia patients, the effect of exercise on cognition in women receiving adjuvant chemotherapy for breast cancer, and family-focused treatment of juvenile sex offenders. Mr. Clayton provides intervention for children and families as a counselor at a residential treatment center, a teacher/mentor for a youth center,

and a caseworker for a foster care/adoption agency. Following the completion of his master's degree in May 2008, Mr. Clayton entered the doctoral program in clinical psychology at the University of Texas Southwestern Medical Center in Dallas.

Herbert C. Covey, PhD, of the Adams County Social Services Department, and the College of Continuing Education, University of Colorado Boulder in Boulder, Colorado, United States, and has taught juvenile delinquency for more than two decades. Dr. Covey received his PhD in Sociology from the University of Colorado at Boulder. He has published several articles on a wide array of subjects, including community corrections, disabilities, religion, street gangs, crime measurement, boomtown crime, research methods, determinant sentencing, violent mentally ill offenders, and social gerontology, among other topics. His current research involves substance abuse treatment and dietary practices of enslaved African Americans. He has also served as an academic journal reviewer for *Criminal Justice Review*, *Journal of Contemporary Criminal Justice*, *The Gerontologist*, *Journal of Applied Sociology*, and *Journal of Crime and Justice*. He is also a part-time instructor at the University of Colorado at Boulder. He has encountered many families and youth who have been involved with meth use and manufacture. He has authored or coauthored nine books and numerous academic articles. He is the editor of *The Meth Crisis* (2006), to which he contributed three chapters. He was a coauthor of the text *Youth Gangs* (2006) and sole author of *African American Slave Medicine: Herb and Non-Herbal Treatments* (2007). He coordinated four major symposiums on methamphetamine for judges, caseworkers, public health officers, law enforcement officers, child protection caseworkers, public administrators, ex-users, and other stakeholders.
