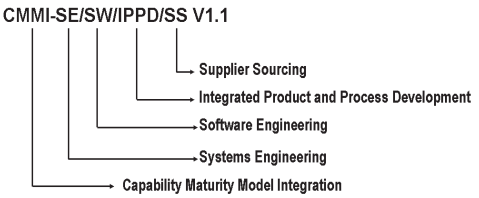
The CMMI version 1.1 was published in 2003 and incorporates the following 4 disciplines altogether. Systems engineering and software engineering are the two core disciplines. Integrated product and process development and supplier sourcing are two additional sets of practices that can be incorporated by organizations that whish or must implement them.



Process areas (PA's) are the major building blocks in establishing the process capability of an organization. Each PA defines a set of specific goals that can be achieved by performing a collection of related practices. There are 25 process areas (PA's) in the CMMI-SE/SW/IPPD/SS that encompass more than 500 practices altogether.

The CMMI has two representations:

- The staged representation groups the PA's in 5 maturity levels. Each process area has been defined to reside at one the 5 maturity levels in the staged representation. To reach a given maturity level, the organization has to satisfy the goals associated with all the PA's at that level and below.
- In the continuous representation, the PA's are organized in 4 categories: project management, process management, engineering, and support. In a formal SCAMPI [6] appraisal, a capability level from 0 to 5 is assigned to each PA, thus defining the capability profile of the organization.

Figure 1 shows the CMMI staged and continuous representations. They both have the same 25 process areas, but organized differently. In our project we used the staged representation.

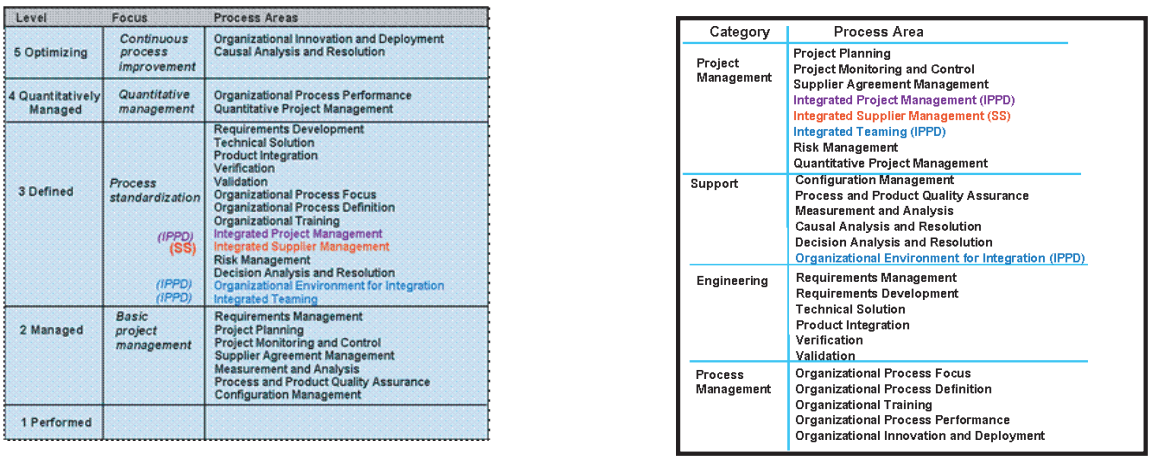
3. IMPLEMENTATION OF OUR PROJECT

3.1 The Project Tasks

The first phase of our improvement project was focused on the 7 process areas at CMMI level 2. During the 9-month period between July 2005 and April 2006 we performed the following tasks:

1. Basic CMMI training (3 days) for key personnel in the 9 companies.
2. CMMI level 2 implementation training (3 days) for key personnel in the 9 companies.
3. Conduct an initial assessment in each one of the 9 organizations
   - Perform the first SCAMPI type C assessment (SEI, 2001) of CMMI level 2 in each organization (1 day per company).

Figure 1. The CMMI staged representation (left) and continuous representation (right).



Level	Focus	Process Areas
5 Optimizing	*Continuous process improvement*	Organizational Innovation and Deployment Causal Analysis and Resolution
4 Quantitatively Managed	*Quantitative management*	Organizational Process Performance Quantitative Project Management
3 Defined	*Process standardization*	Requirements Development Technical Solution Product Integration Verification Validation Organizational Process Focus Organizational Process Definition Organizational Training (IPPD) Integrated Project Management (SS) Integrated Supplier Management Risk Management Decision Analysis and Resolution (IPPD) Organizational Environment for Integration (IPPD) Integrated Teaming

Support	Configuration Management Process and Product Quality Assurance Measurement and Analysis Causal Analysis and Resolution Decision Analysis and Resolution Organizational Environment for Integration (IPPD)
Engineering	Requirements Management Requirements Development Technical Solution Product Integration Verification Validation
Process Management	Organizational Process Focus Organizational Process Definition Organizational Training Organizational Process Performance Organizational Innovation and Deployment

- Define a process improvement plan for each organization based on the assessment's results.

4. Each organization implemented its improvement plan for the next 5 months performing the following tasks:
   - Define the process architecture.
   - Document the organizational policies.
   - Define the software product templates for the main software work products.
   - Plan the definition and implementation of the organization's procedures.
   - Define the software metrics to be used in the software process.
   - Define the organizational procedures.
   - Implement the procedures and software metrics program.
5. Perform the second SCAMPI type C assessment of CMMI level 2 in each organization (1 day per company).
6. Close the gaps found in the second assessment (3 months).
7. Perform the third SCAMPI type C assessment of CMMI level 2 in each organization (1 day per company).
8. Report final results to Management in each organization.
9. Close this phase of the improvement project.

3.2 The Assessments

As part of our project we performed a total of 3 SCAMPI type C assessments in each one of the 9 organizations. They were aimed at verifying "coverage" of the organization's defined process with the goals and practices contained in the 7 process areas at CMMI level 2. The objective is to determine the existing gaps between the current process and the CMMI model just for internal process improvement. This assessment is a quick look at the state of the organization's process and does not verify implementation of that process in specific projects, a task that would require a SCAMPI type A or B assessment (SEI, 2001).

For documenting the assessments results, we defined a simple 3-level ranking system to determine the level of coverage of the organization's process for each one of the 7 process areas at CMMI level2. Each CMMI specific practice is compared against the practices in the organization's process and assigned a ranking value as follows:

1. Red: the practice is not covered at all. This has a value of 0.
2. Yellow: the practice is partially covered. This has value of 1.
3. Green: the practice is fully covered in the process definition. This has a value of 2.

This simple evaluation system allows us to quantify the level of coverage of a given process with respect to the CMMI level 2.

The percentage of coverage for each PA is calculated as a weighted average as follows:

$$\%\ \text{coverage PA} = \frac{(\#\text{red} * 0) + (\#\text{yellow} * 1) + (\#\text{green} * 2)}{\text{Total Number of PA practices} * 2} \times 100\%$$

The same formula is used to compute the coverage of the entire CMMI level 2, as follows:

$$\%\ \text{coverage PA} = \frac{(\#\text{red} * 0) + (\#\text{yellow} * 1) + (\#\text{green} * 2)}{\text{Total Number of CMMI level 2 practices} * 2} \times 100\%$$

Table 1 below shows a portion of the findings of an assessment at one of the organizations.

The first column specifies the CMMI-expected practices and sub-practices; the second column is to checkmark once the practice is verified. The third column lists all the documentation reviewed for the analysis, and the last column contains a justification of the evaluation and any additional observations, including opportunities for improvement. In this example, there are a total of 7 practices with 2 in red (0 points each), 1 in yellow (1 point each), and 4 in green (2 points each). Therefore, the coverage of this portion of PP is calculated as follows.

$$\%\ \text{coverage PP} = \frac{(2 * 0) + (1 * 1) + (4 * 2)}{7 * 2} \times 100\% = 64\%$$

4. THE PROJECT´S RESULTS

The improvement achieved by some of the organizations in documenting and implementing their processes was remarkable. Figure 2 shows the progress obtained by company X in each one of the 7 PA´s of the CMMI level 2 through out the 3 assessments.

Figure 3 shows the CMMI level 2 overall coverage of company X, one of the organizations that achieved the most progress. They started this project with a coverage of 17%, increased to 59% in the second assessment, and finished with 82% of CMMI level 2 covered.

Figure 4 shows the coverage of CMMI level 2 obtained by each organization at the end of this project. The straight line shows de average coverage for the 9 organizations at 67%. Five organizations were above average, one was at 54%, and the remaining three were lagging behind in the 30´s. The relatively slow progress achieved by these 3 organizations is due mainly to the lack of commitment from the organizations Management, lack of available resources to invest in the improvement project, and their inexperience in defining and implementing quality management systems.

Table 1. An example of the assessment of a group of project planning practices

Goals and Practices	Verifications		Notes
SG2 - A project plan is established and maintained as the basis for managing the project.	**Verified Yes No**	**Document Reference**	
SP2.1-1 Establish and maintain the project's budget and schedule.	X ☐	KJ:24 Task schedule KJ:25 Control Plan KJ:21 Software Development Plan Sales Management Procedure	The Schedule is created in Project 2003 based on a RUP template. The project's budget is manager using a standard Excel spreadsheet apart from the main plan. There is no documented procedure to create the project's budget.
1 Identify major milestones.	☐ ☐		
2 Identify schedule assumptions.	☐ ☐		
3 Identify constraints.	☐ ☐		
4 Identify task dependencies.	☐ ☐		
5 Define the budget and schedule.	☐ ☐		
6 Establish corrective action criteria.	☐ ☐		
SP2.2-1 Identify and analyze project risks.	X ☐	KJ-20 Risk list	There are three RUP templates to specify the project's risks.
1 Identify risks.	☐ ☐		
2 Document the risks.	☐ ☐		
3 Review and obtain agreement with relevant stakeholders on the completeness and correctness of the documented risks.	☐ ☐		
4 Revise the risks as appropriate.	☐ ☐		
SP2.3-1 Plan for the management of project data.	X ☐	None	The information of the projects is stored in carpets on the server. There are confidentiality letters signed with customers. The development plan defines the list of deliverables. There are no documented policies or procedures to manage the project´s information.
1 Establish requirements and procedures to ensure privacy and security of the data.	☐ ☐		
2 Establish a mechanism to archive data and to access archived data.	☐ ☐		
3 Determine the project data to be identified, collected, and distributed.	☐ ☐		
SP2.4-1 Plan for necessary resources to perform the project.	X ☐	KJ:24 Task schedule KJ:25 Control Plan KJ:21 Software Development Plan Outsourcing of technical resources Sales Management Procedure	The project's plan and Schedule include the required human resources. The other resources are specified in the bid to the customer.
1 Determine process requirements.	☐ ☐		
2 Determine staffing requirements.	☐ ☐		
3 Determine facilities, equipment, and component requirements.	☐ ☐		
SP2.5-1 Plan for knowledge and skills needed to perform the project.	X ☐	KJ:24 Task schedule KJ:25 Control Plan KJ:21 Software Development Plan LD-03 Description of roles and positions	The project's schedule includes all training activities. The project's plan defines the roles and responsibilities of the development team. Although there is an organizational training plan, the template for the project's development plan does not contain a section to plan the development of the skills needed to perform the project. The H.R. Department manages a skill matrix for all the team members. There is a documented description of the roles and positions in the organization.
1 Identify the knowledge and skills needed to perform the project.	☐ ☐		
2 Assess the knowledge and skills available.	☐ ☐		
3 Select mechanisms for providing needed knowledge and skills.	☐ ☐		
4 Incorporate selected mechanisms in the project plan.	☐ ☐		
SP2.6-1 Plan the involvement with identified stakeholders.	X ☐	KJ:24 Task schedule KJ:25 Control Plan KJ:21 Software Development Plan	The development plan includes the identification of all project stakeholders
SP2.7-1 Establish and maintain the overall project plan content.	X ☐	KJ:24 Task schedule KJ:25 Control Plan KJ:21 Software Development Plan LR-07 Repository location definition	A plan, schedule and proposal are documented. Each document is signed and approved. LR-07 Repository location definition defines the structure and location of the project's repository.

Figure 5 shows the average percentage of coverage of the 9 companies for each PA at CMMI level 2. Clearly the most difficult PA's to cover and the ones with the least progress are Measurement and Analysis (MA) and Process and Product Quality Assurance (PPQA), whose final average coverage was 51% y 47% respectively. Supplier Management agreement (SAM) was only evaluated in the third assessment for only 3 of the 9 organizations because the other 6 companies do not sub-contract projects.

5. CONCLUSIONS

The different organizations initiated this project at different levels of process maturity, commitment to the project, and process improvement experience. For example, three of them already had an ISO 9000:2000 certification when the project started, thus they already had experience documenting and deploying processes, so they were able to hit the road running. On the other hand, other companies had virtually no experience in process management, so for them it was extremely difficult to roll out the project.

The following are the main problems we faced during this project:

1. Lack of commitment from upper management.
2. Absence of a project manager and appropriate human resources for the SPI project.
3. Inexperience in designing and implementing software processes.
4. Some organizations went through a restructuring process that hampered the SPI project.

Figure 2. Progress made by company X in each of PA´s through out the project

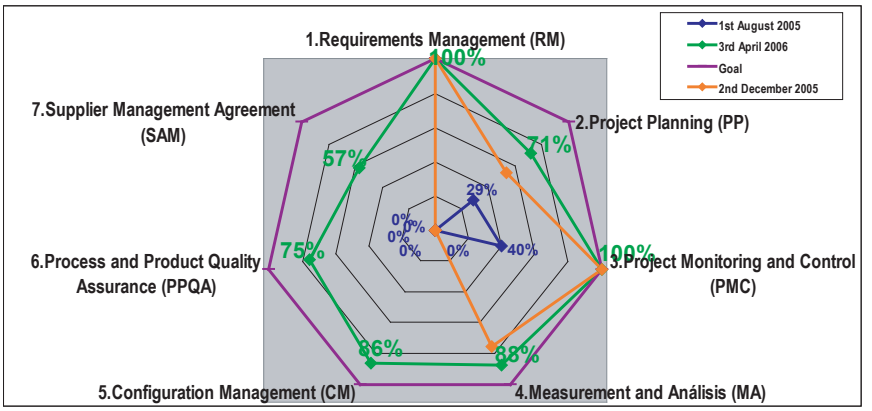

Figure 3. Overall progress made by company X through out the project

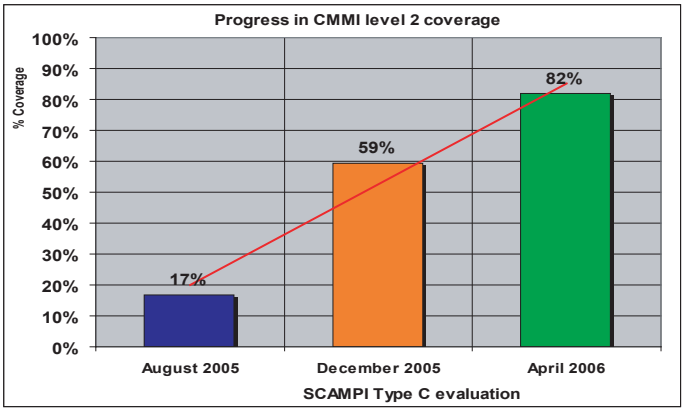

5. Change of organizational priorities due to market fluctuations or change of company's business model.

The organizations that achieved the greatest progress were those in which management was fully committed to the project, they designated a person directly responsible for it, and had previous experience with process management. Our experience shows that these are three of the most important success factors in SPI projects.

The three organizations with ISO 9000:2000 certifications had initial CMMI level 2 coverages of 23%, 66%, and 52% respectively. This demonstrates that in software organizations ISO 9000 quality systems generally do not cover most of CMMI level two's practices. On the other hand, organizations using commercial available processes such as Rational Unified Process (RUP) (Kroll P., Kruchten P., 2003) or Microsoft Solutions Framework (MSF), find it much easier and quicker to develop their CMMI-compliant processes. This is because RUP and MSF were specifically designed to cover CMMI levels 2 and 3.

This group of software organizations is now working in a second phase of this improvement project which will focus con CMMI level 3, but this time we are going to select only those that are really committed with the project and work with only 4 or 5 of them to assure a more uniform progress.

Why Do Software Applications Fail and What Can Software Engineers Do About It? A Case Study

Peter Kueng, Credit Suisse, IT Architecture, 8070 Zurich, Switzerland; E-mail: pkueng@acm.org
Heinrich Krause, Credit Suisse, IT Architecture, 8070 Zurich, Switzerland

ABSTRACT

In many of today's companies application software has become a vital resource to successfully run the business. Since outages of application software may lead to operational and financial difficulties, companies have a vested interest to ensure high availability of their application software. In this paper, data from Credit Suisse, a large commercial bank operating internationally is examined. As a first step, the main causes that led to outages are analyzed. The analysis shows that administration-related tasks are the largest cause for application software outages. On the other hand, the analysis reveals that outages due to hardware failure plays an almost negligible role. In a second step, selected approaches on how availability of applications can be improved are presented. One of the most important means to reduce outages in our case is to address availability not only with system and platform engineers, but with software engineers in particular, since their awareness concerning availability has proven to be limited. Based on that, a set of recommended practices to be addressed by software engineers has been developed; a subset of them are presented here.

1. INTRODUCTION

More and more companies, in particular in the service industry, rely substantially on application software. The product creation, sales and after-sales processes depend heavily on up-to-date application software. Not only do company employees depend on enterprise-owned application software intensively, but external stakeholders such as private and corporate clients, providers, vendors and contractors also depend on such applications. This also implies that in most companies the number of software applications has increased over the years. In addition to that we have to consider that companies today operate in different times zones as their partner and branches are geographically dispersed. This in turn means that time periods for maintenance work have become smaller over time. Furthermore, in the era of the Internet, expectations in terms of availability, timeliness and response time have increased. All of these aspects lead to higher, more ambitious requirements in terms of availability. In short, many of today's applications have to run in a 7 day by 24h mode, the number of outages must be minimal to non-existent, and the time period to repair failures must be shortened.

The rest of the paper is structured as follows: Section 2 shortly describes the company this paper is based on. Section 3 analyses the outages that occurred within the last reporting period and shows the main causes. Section 4 presents some possible approaches on how availability can be improved. Section 5 presents selected software engineering-related approaches the company has chosen to improve availability of its custom-built software. Finally, section 6 summarizes the main points and states the main conclusions.

2. COMPANY PROFILE AND IT INFRASTRUCTURE

The empirical data presented in this case study stem from Credit Suisse, a global bank, operating in over 50 countries and headquartered in Zurich. The two main lines of business are private/retail and investment banking. The company employs over 40,000 people worldwide. The main geographic areas of employment are Asia, USA, and Europe.

To support the many employees, clients, third parties and the underlying business processes, hundreds of applications are in place and running today. Most of the banking-related applications are built and supported by the company's own IT department. The internal IT department not only provides application development and maintenance, but also systems engineering activities such as configuration of servers, middleware, components and networks. All application software runs in the internal data centre.

The number of applications we are concerned about in this study numbers approximately 300. The size of the application software is quite remarkable as it sums up to more than 30 million lines of code. The programming languages used are mainly PL/1 and Java. Some of the COTS applications are based on C and other languages. The runtime platforms are Sun (Solaris) and IBM (z/OS).

3. OUTAGES OF APPLICATION SOFTWARE

In order to improve availability of application software it is essential to know current statistics. For example: how many outages occurred over a certain period of time? What were the causes?

To properly understand the numbers given in Table 1, the measurement approach applied at Credit Suisse is described below:

- Data sources used: To gather the outages during the last reporting period, three different data sources were used: (a) outages reported by users; (b) outages reported via robots (artificial users); (c) outages reported via systems management software (in our case, Tivoli Enterprise Console is used)
- In scope: main banking applications (approximately 300)
- Out of scope: (a) industry-neutral support applications such as Microsoft Outlook; (b) applications used by small number of people (<50).

How is an outage defined? In this paper, the terms *outage* and *unavailability* are used interchangeably. Application unavailability or application outage means – in accordance to IEEE (2002) – that an application is not accessible when it is required for use.[1] 'When required for use' implies two things, for each application it must be known (specified) when the application is required for use and, second, an outage of an application is handled as an outage only if the outage falls into the period of time the application should be available. To practice the first aspect, the SLA[2] levels are used. At Credit Suisse every application must belong to one of three SLA levels. The most demanding SLA level is called 7x24. It means that the application should be available at all times.[3] The second-highest SLA level requires that applications are available from 6am to 11 pm; the third (lowest) SLA level requires that applications are available from 6am to 7 pm. Outages of applications that do not fall into these required up-times are not considered here.

Table 1 shows that a total of 222 outages have been registered during the last reporting period. To identify the hot spots, these 222 outages have been grouped into five categories: administration, software, hardware, environment, and unknown causes. These categories have been used by Gray (1985), who published the well-known causes of failures of Tandem systems. The use of the same categories makes it possible to compare the results.

- **Administration**: 36 percent of outages were caused by administration-related activities. Within this category the main cause for outages lies in operations

Table 1: Reported outages at Credit Suisse and Tandem systems

	Case Study		Results from Gray (1985)
Cause	Number of outages	Percent of outages	Percent of outages
Administration	80	36%	42%
Software	72	32%	25%
Hardware	4	2%	18%
Environment	18	8%	14%
Unknown cause	48	22%	3%
Total	222	100%	103% [1]

and configuration activities. To give a better idea of what is meant by operations and configuration-related causes, some examples of causes – taken from the outage reports – are listed: (a) "Database administration runs a job which exclusively reserved a pointer checker"; (b) "Database xyz was not available because of database reorganization"; (c) "Database reload locked some DB2 tables"; (d) "Change of certificate was not accomplished properly"; (e) "Volume copy action blocks transactions"; (f) "Web server was suspended"; (g) "Role for database access was removed"; (h) "Database files were overwritten due to incorrect software distribution"; (i) "The power for the technology centre wrongly switched off by construction worker!". Another subcategory of administration was labeled "unsatisfactory monitoring". Through a more intensive, and real-time monitoring, some outages of application could have been prevented. "Low on disk space", "too high CPU load", "queues were full" are typical examples that led to outages of applications.

- **Software**: According to our outage reports, errors in software represent the second largest cause that led to unavailable applications. Out of the 72 software-related outages, 37 were caused by erroneous application software whereas most of this software was custom-built. 35 outages were caused by incorrect system software. The rather high 'contribution' of system software is surprising as this category of software runs in hundreds or thousands of companies. What are examples of application software-related causes leading to outages? A few examples are listed here: (a) "Data sharing caused deadlocks"; (b) "An order without an amount was processed. This caused the crash of the program"; (c) "Duplication of a row caused a SQL-811 error"; (d) "Transaction xyz fails due to deadlocks"; (e) "Functional error in application". As mentioned earlier, not only flaws in application software cause outages but also erroneous system software. To illustrate this point again, a few examples are given: (a) "Error in load balancer"; (b) "Deadlocks in DB2"; (c) "Bug in operating system"; (d) "Database block is not working"; (e) "Malfunction of router".
- **Hardware**: Hardware-related outages were very rare. On the one hand, hardware over the years has become more and more reliable. On the other hand, monitoring of hardware components has become more common. In the case of Credit Suisse, only four outages (2 percent) were caused by hardware. In one instance, a broken fan led to an outage of the server, in another case the memory of a server was defective, and in a third case the power supply accumulator was damaged.
- **Environment**: The term 'environment' is vague. It has however been used to make the results comparable to the ones published by Gray (1985). In the case of Credit Suisse outages in the category 'environment' are mostly related to communication problems with company-external systems. A few examples which illustrate this are: (a) "No connection between Reuters and Credit Suisse"; (b) "Wide area network broken"; (c) "Network switch lost connection"; (d) "Fibre channel has been damaged".
- **Unknown**: According to Table 1, some 48 cases (22 percent of all outages) were not able to have been categorized properly. In a considerable number of these cases, it was not possible to identify the root cause of the outage. Many of the so-called unknown causes are transient and could not be traced. Examples are: (a) Server was down; (b) Memory leak; (c) "Hanging process"; (d) "Application not responding".

When comparing the data gathered from Credit Suisse with those published by Gray (1985), some interesting parallels arise. Firstly, both studies identify administration-related work as the primary cause for outages (36 percent vs. 42 percent).[4] The second most important 'contributor' to outages is the category of the software. While 32 percent of the outages are caused by software, this category accounts for 25 percent in the study of Gray (1985). However, Gray does mention in his paper, that this category is probably under-reported.

According to Gray, hardware represents the third category of causes as they caused 18 percent of outages at Tandem systems. In the case of Credit Suisse, the numbers are quite different as hardware-related problems caused only 2 percent of the outages. More than twenty years ago Gray wrote: "In the future, hardware will be even more reliable due to better design, …" (1985, p. 12). Based on our empirical data he was absolutely right.

4. HOW TO IMPROVE AVAILABILITY?

Over the years a large number of approaches, methods, and techniques have been suggested to improve availability and reliability[5] of systems and software. It is *not* the aim of this paper to present the sheer endless pallet of instruments suggested by scholars and practitioners,[6] instead, the aim is to illustrate the *range* of possible approaches, with some (rather accidental) approaches being mentioned in this section.

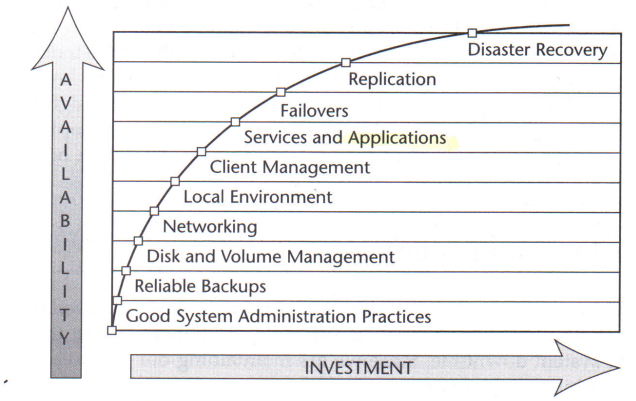
Probably the most commonly recommended approach is the use of *N-Version Programming (NVP)* described by Avižienis/Chen (1977). This approach implies that N-independent programs are executed in parallel on identical input, and the results are obtained by voting upon the outputs from individual programs. In order to ensure the development of independent program versions, different algorithms, programming languages, environments and tools must be used. Theoretical as well as empirical investigations indicate a positive effect of N-version programming (see Cai/Lyu/Vouk (2005)).

According to Viega/Voas (2000), aspect-oriented programming helps to improve availability and reliability as it offers powerful mechanisms for exception handling. Widmaier et al. (2000) propose the use of formal specifications. Green (1997) recommends to improve availability through the use of commercial off-the-shelf components. Candea/Fox (2001) emphasize the importance of recursively restartable systems as they make it possible to restart collections of components/subsystems with little or no advance warning.

By reading the various views that address availability and reliability engineering, one gets the impression that "you just have to do *this*" and everything will work properly. According to Meyer (1999) each community defines "this" differently. Meyer writes:

- *the management school*, which holds that all that really matters is better approaches in management;
- *the formal specification school*, which suggests we won't achieve anything unless we specify everything mathematically—and then we won't need testing at all;
- *the testing school*, which views formal specifications as an academic pastime and believes that the only meaningful solution is to devise systematic testing strategies;

Figure 1. Ten availability technologies (taken from Marcus/Stern, 2003, p.51)



- *the metrics school*, which focuses on assessing everything quantitatively;
- *the open source community*, which believe that only by extensive public scrutiny can we successfully develop reliable software".

The message put forward by Meyer is clear: Although the different communities claim to know what to do in order to improve availability there is no one best approach. Instead, problem and domain-specific approaches are more appropriate.

The richness of possible mechanisms to increase availability is well illustrated in the book by Marcus/Stern (2003); see Fig. 1. This model is conceptual in nature and does not attempt to graph particular levels of availability against specific amounts of investments. However, Marcus and Stern recommend to start with 'technologies' (to use their term) situated at the bottom and to gradually increase.

5. WHAT CAN SOFTWARE ENGINEERS DO TO IMPROVE AVAILABILITY?

As the previous section shows, there is no shortage of potential mechanisms and approaches to improve availability of application software. However, the mechanisms and techniques to be applied depend on various factors; e.g. on the causes that led to outages in the past, on the service or availability levels to be achieved, on the infrastructure in place, on the current software development processes, on awareness of software developers, etc.. Generally speaking, availability can be influenced by two groups of stakeholders, the *systems engineers* who provide the application platform the application runs on, and the *software engineers* who develop the application software; see Fig. 2. In this paper we discuss approaches to be applied be the software engineers.

To improve availability by means of software engineering we formulated twelve so-called 'recommended practices'. To give an idea how the issue is addressed at Credit Suisse some examples of recommended practices are presented here.

Two aspects have to be noted: (a) The recommended practices have not been deduced formally. They are based on both a gap analysis and best practices applied in selected areas. (b) The recommended practices are not universally valid. They fit to our environment.

A. Anticipate Outages of Subsystems and Components

Rationale: Applications are composed of subsystems and components. An outage of such a part should not lead to a full outage of the application. The impact to the user should be minimal.

Tasks for the Software Engineers:

- Ensure that an outage of a subsystem or a component (which are part of the application being built) has no or minimal impact on the use of the application.

Example: In an online-banking application for instance, an outage of the payments module should not impact the functions provided for brokerage.

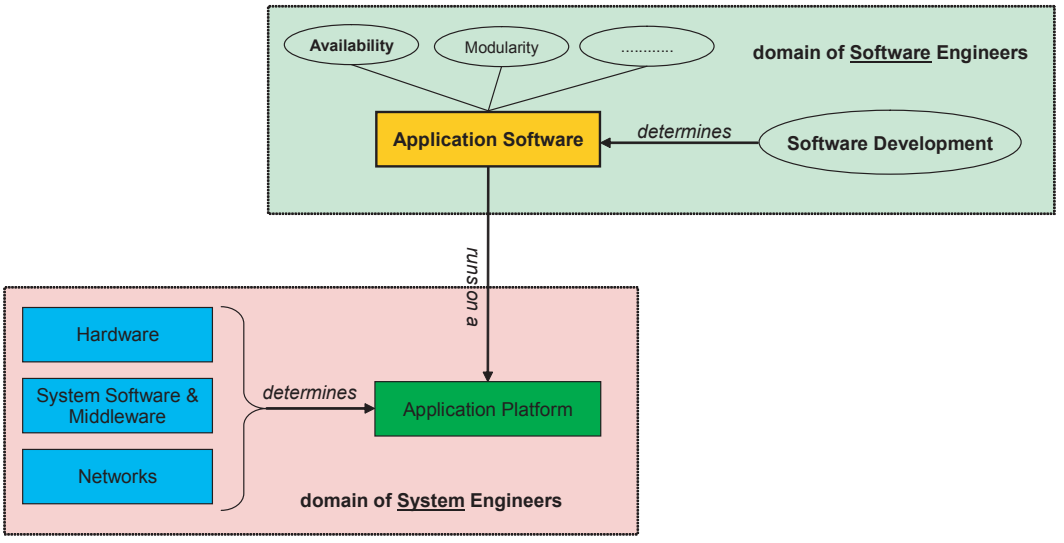
B. Minimize Exclusive Use of Shared Data in Terms of Scope and Time

Rationale: If large portions of a database are exclusively used by a single application, or if small portions of a database are locked for long periods of time, other applications are negatively impacted in terms of availability. Therefore the portion of data exclusively used by one application at a certain moment in time should be as small as possible.

Tasks for the Software Engineers:

- Minimize exclusive use of shared data in terms of scope and time.
- Keep the Logical Unit of Work[7] short.

Figure 2. Leveraging availability by system and software engineers



Example: An end of day batch job must not exclusively reserve tables of an online application.

C. Select Appropriate Processing Mode

Rationale: In terms of processing modes, there are two extremes: *real-time processing* (e.g. on-line transaction processing) and *batch processing* (e.g. end of day processing). In between there are two other options: *asynchronous processing* and *asynchronous processing plus latency*.

Synchronous processing (real-time processing) requires that all components involved are able to execute the requests immediately (i.e. in the same logical unit of work). This may in turn negatively impact availability and robustness of the applications being built. From an availability point of view, the synchronous processing mode should be implemented only when absolutely necessary; i.e. when immediate response and timeliness of data are critical.

Tasks for the Software Engineers:

- Use asynchronous processing as much as possible.

Example: To create a statistical report, synchronous processing is not required. From an availability point of view, asynchronous processing plus latency is more appropriate.

D. Test Behavior of Application when Selected Components and Interfaces are 'Switched Off'

Rationale: It must be guaranteed that mechanisms which have been implemented to treat unavailable or malfunctioning components/interfaces function as planned. Failures of one or several parts of a system must be observed. The planned utilization of imperfect parts (components, interfaces, etc.) is sometimes called "fault injection testing".

Tasks for the Software Engineers:

- Identify the application-*internal* and application-*external* availability-critical components and interfaces that may fail. Test the behavior (robustness) of the application by 'switching-off" (or not providing) selected components and interfaces.
- Specify the required test environment and test cases.

Example: When an online-banking application is to be tested, the interface providing the current exchange rates should be switched off in order to check whether the application's behavior is compliant to the design.

E. Build Applications that Require No Manual Administration

Rationale: Since human error is a leading cause of downtime, one important way to improve availability is to reduce the number of mistakes that humans (administrators) can make on critical systems. By making systems simpler you do just that. Simpler systems require less administrative attention, so there is less chance for human error which can lead to an outage of the application, see Marcus/Stern (2003), p. 103.

Tasks for the Software Engineers:

- Build applications that require no manual administration or intervention.
- If manual administration cannot be made obsolete, incorporate a mechanism that checks the outcome of tasks performed immediately. It must not be the case that an incorrect execution is detected with delay.
- Design all applications in such a way that they can be run in a 7x24h mode.

Example: If an application has been designed in such a way that a periodical reorganization of the database has to be initiated manually, then the principle mentioned above is not met.

6. CONCLUSIONS

The analysis of 222 outages of application software shows that (a) administration-related task are the largest cause of application software unavailability, (b) imperfect software (custom-built application software and system software) represents the second largest contributors, (c) environment-related causes 'occupy' the third place, and (d) outages of applications caused by defective hardware is very rare in the company considered.

As there is no best approach to improve availability, the various options have to be considered. They include *systems management-related approaches* such as disk and volume management and the use of redundant hardware as well as more *application software-related approaches*. In our case the focus has been put on the second category, since the potential to improve availability has been considered as being most effective in this area.

Where do we stand today at Credit Suisse? Twelve so-called recommended practices have been defined and communicated to software engineers. None of these recommended practices require additional infrastructure in order to be implemented. The enforcement of these practices takes place on the one hand via company-internal education. On the other hand, software engineers have to demonstrate just how the recommended practices have been applied in their software development projects. The initial feedback from software engineers has been quite positive. They now see the software development discipline broader than before (as many of them have not spent a lot of attention to availability issues in the past) and, not of lesser importance, the teamwork between system engineers and software engineers has become closer.

The primary conclusion is as follows: Every company who builds and uses application software to a larger extent should analyze the causes of outages carefully. Based on both the cause analysis and the mechanisms already in place, company-specific measures can be taken. If these two steps are omitted, inadequate or even useless actions might be implemented, which in turn, lead to unnecessary costs. Our impression is that the power of *system and hardware-related mechanisms* to improve availability is overestimated, while *software engineering-based approaches* are not adequately rated. One reason behind that behavior might be that some mechanisms addressing the first category can be bought, while the second category has to be addressed mainly via awareness, motivation, education, inspiration, and knowledge.

Finally, our literature research has revealed that the issue of availability of application software has not been intensively addressed up to now. In particular, software-engineering related approaches, to ensure high availability of large sets of applications, have been treated only fragmentarily. From our perspective, this in turn means that it would be fruitful for the software engineering community to further consider this topic in future research and teaching activities.

ENDNOTE

[1] Availability is defined as follows: "The degree to which a system or component is operational and accessible when required for use." IEEE (2002).

[2] SLA stands for *S*ervice *L*evel *A*greement

[3] To be precise, even in a 7 by 24h operation mode short periods of time for maintenance work (e.g. deployment of new versions) are inevitable. These periods of unavailability depend on the type of software. E.g. for the software that controls the cash machines the interruptions should be below one minute.

[4] The relevance of administrator-related failures is further supported by the empirical study of Oppenheimer et al., (2003).

[5] "Reliability. The ability of a system or component to perform its required functions under stated conditions for a specified period of time." (IEEE, 2000).

[6] A good overview can be found in Lyu (1996)

[7] A logical unit of work is a set of transactions where either all are successfully applied against the database, or none have any impact on the database.

[8] This number (103%) has been taken from Gray (1985).

Reviewing 802.11 Wireless LANs Security: A Case Study Approach

Yue Cai, The University of Auckland, Private Bag 92019, Auckland, New Zealand; E-mail: ycai015@auckland.ac.nz
Jairo A. Gutiérrez, The University of Auckland, Private Bag 92019, Auckland, New Zealand; E-mail: j.gutierrez@auckland.ac.nz

ABSTRACT
This paper proposes a set of technical and managerial solutions which can be adopted by organizations to protect their 802.11 wireless LANs. A case study methodology was carried out by selecting five individual cases, including two wireless vendor cases and three organizational user cases. The primary source of data was face-to-face interviews. Another portion of the data came from extensive secondary materials. Findings from the case study were integrated with the ones from the existing literature to shape the final conclusions and recommendations of this research.

Keywords: 802.11 Wireless LANs; security; guidelines; case study

1. INTRODUCTION
Compared with wired networks, wireless networks may be more vulnerable and easy to attack. In a wired network, an attacker must penetrate some physical security perimeter to gain network access. In a wireless environment, attackers can easily gain access to the wireless network without getting into the building. The broadcast nature of wireless networks also makes traditional link-layer attacks readily available to anyone (Arbaugh 2003). According to a survey conducted by Computer Weekly's InfoSecurity User Group (CWIUG), more than four companies in five are worried about the security of wireless mobile products and services (O'Halloran 2004).

This research aims to present a set of security solutions, from both the technical and managerial perspectives, which can be adopted by organizations to protect their 802.11 wireless LANs. The paper is organized as follows: the next section discusses the literature review. After that, the research method employed in this work is described. Thirdly, a case study analysis is carried out to further improve the research findings. Lastly, based on the findings from the literature review and the case studies, a set of operational guidelines is proposed.

2. LITERATURE REVIEW
The solutions to address different aspects of 802.11 wireless LANs security fall into two main categories: technical solutions and managerial solutions, which mainly concentrate on the theory and practice of sound security management processes.

2.1 Technical Solutions
2.1.1 Authentication and Encryption
Mishra & Arbaugh (2002) argued that, due to the broadcast nature of wireless LANs, strong access control must be a feature of the security solutions used to protect wireless LANs from various attacks. Mutual authentication should also be implemented because access points are untrusted. Moreover, they emphasized that strong confidentiality should be addressed and dynamic rekeying is needed as an inherent part of the design. Williams (2004) also stated that authentication and encryption are the basic requirements of wireless LANs security.

2.1.2 Detection
Several authors (Karygiannis and Owens 2003; Rittinghouse and Ransome 2004) believe that if organizations require high levels of security, they should implement an Intrusion Detection System (IDS) because it provides an added layer of wireless LANs security. Rittinghouse & Ransome (2004) also pointed out that, network design, projected transactional load, the depth of security policy desired, the real and future costs, implementation, and management overhead are critical factors that should be considered when organizations configure a wireless IDS security product. Other authors (Gast 2004; Solms and Marais 2004; Williams 2004) highlight that organizations need to have a solution in place to combat rogue access points, which is a serious problem with 802.11 wireless LANs.

2.1.3 Additional technical enhancements
Researchers (Wong 2003; Mateti 2004; Rittinghouse and Ransome 2004) have argued that wireless LANs security can be enhanced by using firewalls, antivirus software and application layer security technologies such as Secure Shell (SSH) and Kerberos. They also suggest installing personal firewall and antivirus software on each client.

2.1.4 Segmentation between the Wireless LAN and the Wired LAN
Rittinghouse (2004) pointed out that, in order to reduce the chances of the wired network being attacked via a wireless LAN, organizations need to separate wireless LANs from the wired network using segmentation devices, such as routers, layer 3 switches, VPN concentrators, firewalls, enterprise encryption gateways and enterprise wireless gateways.

2.2 Managerial Solutions
Current research suggests that wireless security is not solely a technical issue. "There is also a human element that must be addressed by appropriate employee awareness of the issues, user education, and a clear statement of acceptable organization policies, procedures, and practices by management" (Pike 2002, p.2). As pointed out by Potter (2004), relying on technology itself can't solve the problems created by wireless security. "Without users, a secure wireless network is simply an expensive atmospheric heater" (Potter 2004, p.5). Therefore, Karygiannis & Owens (2003, p.ES-3) commented, "security management practices and controls are especially critical to maintaining and operating a secure wireless network".

In summary, current research suggested seven categories of management practices for deploying and maintaining a secure wireless LAN. These practices include:

- Control wireless LANs coverage area and reduce RF leaking
- Management of access points, including proper configuration of access points, controlling reset functions, access points inventory and proper placement of access points.
- Establish security policies
- Regularly check patches and upgrades
- Regularly conduct security audits
- Provide user education
- Control physical security regarding wireless network facilities

2.2.1 Control Wireless LANs Coverage Area and Reduce RF Leaking
A number of researchers (Hassick 2002; Maxim and Pollino 2002) argued that, the chances of attacks resulting from the broadcasting nature of the wireless networks can be reduced by controlling the coverage area and reducing RF leakings. These measures can be accomplished by using site surveys, appropriate access point placement and RF containment.

Generally, a site survey involves evaluating the building, including surrounding areas and the obstacles that need to be overcome. Outer and inner wall construction, window treatments and window glass material must all be identified and considered. Access points and roaming wireless clients should also be used to decide the network coverage with optimal performance and security. (Maxim and Pollino 2002). The objective of RF containment is to limit the scope of the wireless networks within the known boundaries. Although coverage control provides certain level of security, it is not an absolute solution. Karygiannis & Owens (2003) argued that attackers still can use high-gain antennas to eavesdrop on the wireless network traffic.

2.2.2 Management of Access Points

Proper Configuration of Access Points

Many authors (Karygiannis and Owens 2003; Wong 2003; Mateti 2004; Rittinghouse and Ransome 2004) suggested that the default settings of an access point should be changed before its deployment. They also described some guidelines on access point configuration:

- Update the default administrator password
- Use the MAC access control list function
- Change the default SSID
- Change the default shared keys
- Establish proper encryption settings
- Change SNMP parameters
- Change default Channels
- Disable DHCP and use static IPs if feasible. If using a static IP is not feasible and offers little value, two solutions can be adopted by organizations. One solution is to implement a DHCP server behind the wired network's firewall, which grants access to a wireless network located outside of the wired network's firewall. Another solution is to use access points with an integrated firewall, moving authentication and access control to the link layer

Rittinghouse & Ransome (2004) suggested using a local serial port interface to configure the access points in order to minimize the exposure of sensitive management. They also suggested enabling a user authentication mechanism for the management interfaces of the access points.

Control the Reset Functions

A reset function may return the access point to its default settings. If an access point is placed in an insecure place and the attacker has gained physical access to the access point, he/she may reset the access point and cancel all the security settings. Therefore several researchers (Karygiannis and Owens 2003; Rittinghouse and Ransome 2004) suggested that the reset functions should be used only when needed and should be only invoked by an authorized group of people.

Access Point Inventory

Williams (2002) suggests that organizations keep the access point infrastructure current by tracking the locations of all access points and recording the configuration of all access points to ensure each access point follows corporate standards and uses the latest software patches and firmware upgrades.

2.2.3 Establish Security Policies

Several authors (Maxim and Pollino 2002; Karygiannis and Owens 2003; Potter 2003; Regan 2003; Rittinghouse and Ransome 2004) made the point that security policies are a critical and essential part of wireless security and they should cover the following areas:

- Issues of wireless devices
- Wireless users configuration and activity
- Link level security
- Network and application level security
- Level of security protection
- Patches upgrade
- Offsite use of wireless devices
- Security audit

2.2.4 Regularly Check Patches and Upgrades

A number of researchers (Karygiannis and Owens 2003; Wong 2003) suggested that network administrators need to check with the vendor the availability of security patches and upgrades regularly, and apply them as needed.

2.2.5 Regularly Conduct Security Audits

Karygiannis & Owens (2003) argued that security audits are essential tools for organizations to check the security of a wireless network and determine corrective action to make sure it remains secure. They argued that the security assessment approach should be holistic and two methods can be adopted by organizations to perform security audits:

- Use wireless network analyzers and other tools, such as ***Netstumbler***, to check whether access points transmit data correctly and operate on the correct channels.
- Conduct third party audits. Organizations providing audit services are usually more up-to-date on security vulnerabilities, better trained on security solutions, and well equipped to assess the security of a wireless LAN.

2.2.6 Provide User Education

Keenan (2004) argued that every organization deploying a wireless LAN needs to develop a serious user training program to assure that users understand they each have a personal responsibility to keep their wireless network safe from intrusion. In addition, the user training should not only let users know about security protocols and how to follow them, but also let them know why these protocols exist. He also stated that, although wireless security protocols are set by the IT department, education and enforcement are best implemented by the Human Resources department. Karygiannis & Owens (2003) held a similar opinion on the importance of training users and making them aware of wireless risks. Moreover, they pointed out that network administrators also need to be fully aware of the security risks associated with wireless LANs. The administrators must work to ensure security policy compliance and to know what steps they need to take if an attack occurs.

2.2.7 Control Physical Security

Karygiannis & Owens (2003) argued that physical security is the most fundamental step to ensure that only authorized users have access to wireless network facilities. Two measures can be adopted by organizations to ensure physical security of the wireless network facilities:

- Conduct physical access control, such as photo identification, card badge readers or biometric devices, to minimize the risk of improper penetration of wireless network facilities.
- Deploy external boundary protection, including locking doors and installing video cameras around the perimeter to discourage unauthorized access to wireless network facilities such as access points.

3. RESEARCH METHOD

Multiple-case design is chosen instead of single-case because the evidence from multiple cases is often considered as "being more compelling and the overall study is therefore regarded as more robust" (Yin 1994, p.45).

Two cases were selected from wireless vendors and three organizational user cases were respectively selected from the education sector and the commercial sector. These cases include:

- ***Vendor A***: a leading wireless infrastructure provider. Its main wireless products include access points, wireless bridges, wireless security servers and intrusion detection systems.
- ***Vendor B***: a leading wireless management system provider. Its main wireless products include wireless gateways and wireless intrusion detection systems.
- ***User C***: a New Zealand secondary school
- ***User D***: an international real estate company
- ***User E***: a New Zealand university

Two data collection techniques are adopted: interviews and documentation. Six face-to-face interviews were conducted with IT directors, network administrators

and security consultants coming from vendors and users. All the interviews were audio-taped. When interviewing the vendors, two main topics were discussed:

- Technical products they provide or security technologies they recommend to protect 802.11 wireless LANs .
- Network management practices they perceive to be the must-use practices for organizations.

When interviewing the users, three main topics were covered:

- Motivation for deploying their wireless LANs
- Perception of the main risks associated with their wireless LANs
- Technical and managerial solutions they have adopted to secure their wireless LANs

4. ANALYSIS OF THE CASE STUDY FINDINGS

This section contains a summary description of the five cases. A detailed description can be found in [eliminated for blind peer-review].

4.1 Technical Solutions

As revealed in the case studies, all the technical solutions compiled from the literature review are either provided by the vendors in their wireless products or adopted by the organizational users. The case study also revealed some findings which were not discussed in the literature.

4.1.1 Finding 1: Evaluation of Technical Solutions

As discovered in the case study, both the vendors and organizational users agree on the following issues which need to be considered to evaluate the technical solutions:

- Network infrastructure and security requirements
- Interoperability of the different technical solutions
- Secure roaming across the subnets
- Administration burden
- Ease of use
- Transparency to the users
- Cost

4.1.2 Finding 2: Current Authentication and Encryption Technologies in the Industry

With regards to the technologies that provide authentication and encryption, the two vendors pointed out that SSID, MAC access control lists and WEP are not sufficient for enterprise-level security, because a MAC address is easy to forge and WEP has many fatal flaws. The two vendors suggested that organizations use 802.1x/EAP+TKIP (or AES) or IPsec VPN to provide strong authentication and encryption. As revealed in the case studies, three users are currently using these two technologies. Moreover, the case studies revealed that 802.1x/EAP+TKIP (or AES) can be used when an organization wants both reasonable assurance of confidentiality and a transparent user security experience, while IPsec can be chosen when organizations have utmost concern for the sensitivity of the transported data.

Furthermore, guidelines are suggested by the wireless vendors for choosing the authentication and encryption technologies. Firstly, it is recommended that the authentication should be user-specific not device-specific. Ideally, strong authentication should be tied to the use of multiple factors of information, including something you know (a password), something you have (a hardware token card, a digital certificate) and something you are (biometrics). Secondly, it is recommended that, when evaluating encryption technologies, organizations need to consider ease of use, administration load, CPU/battery load and support for mobility across subnets.

4.1.3 Finding 3: Current Intrusion Detection Technologies in the Industry

As revealed in the case studies, intrusion detection systems and rogue access point detection are already available in current wireless products. Intrusion detection is built into Vendor B's wireless gateway. Vendor A's access point is also capable of detecting rogue access points. Moreover, current wireless products also provide the capability of detecting unassociated clients, ad-hoc networks and interference. Except the detection functions provided by Vendor A and Vendor B, the three organizational users also rely on a third party product. User C utilizes *AirMagnet*, User D relies on *Snort*, and User E uses *Argus*.

Furthermore, it is identified from the case studies that traditional ways of detecting intrusions which are used in wired networks could also be utilized in the wireless environment. For example, in the case of User D, they rely on some traditional ways, such as monitoring log files, to detect wireless intrusions.

4.1.4 Finding 4: Bandwidth Management

As revealed in the case studies, bandwidth management is suggested by Vendor B as one component of the wireless security solution. This solution is available in Vendor B's wireless gateways, enabling network administrator to assign a maximum bandwidth to each user. Two organizational users, User C and D are also running bandwidth management tools to carry out bandwidth management, such as bandwidth differentiation based on the roles of the users.

4.1.5 Finding 5: Authorization

Authorization is another new component of the solutions, which is discovered in the case studies. As a wireless management system provider, Vendor B points out that organizations need to differentiate access to network resources based on each user's role. Therefore, Vendor B has developed role-based access control to provide the correct level of access for each user.

4.2 Managerial Solutions

The solutions found in the literature review suggest seven management practices for organizations to deploy and maintain a secure wireless LAN. Furthermore, the cases studies indicated that the technical solutions and managerial solutions should not be separated from each other. Technologies can assist in some management practices, such as management of access points and security audits. There are plenty of tools available in the market for assisting in the inventory of access points. For example, Vendor A's wireless management solution offers the functions of displaying the location and configuration of each access point. All the three organizational users also use Vendor A's wireless management solution to control the access point reset function.

5. FORMULATION OF THE GUIDELINES

Based on the information gathered from the literature review and the case studies, a set of operational guidelines are proposed to assist organizations in protecting their 802.11 wireless LANs. The proposed guidelines are divided into two parts: technical and managerial.

5.1 Technical Guidelines

Guideline 1: Choose the technical solutions that are suitable for your network infrastructure and security requirements. When evaluating technical solutions, you need to consider interoperability, administration burden, ease of use, transparency to the users, secure roaming across the subnets and cost.

Guideline 2: Have an authentication and encryption solution in place.

- The authentication solution should be user-based, not device-based. Consider deploying authentication that is tied to multiple factors of information, i.e. something you know (username/password), something you have (digital certificate) and something you are (biometrics). Consider user-friendliness when choosing the authentication solution, for instance, the authentication process needs to avoid multiple user steps.
- When evaluating the encryption solution, consider ease of use, administration burden, CPU battery load and support for mobility across the subnets.
- Recommend two solutions: 802.1x/EAP+TKIP (or AES) and IPsec. 802.1x/EAP can be adopted when you want both reasonable assurance of confidentiality and transparent user security experience. IPsec can be adopted when you have utmost concern for the sensitivity of the transported data.

Guideline 3: Have an intrusion detection solution in place. The solution is at least capable of detecting general network intrusions, rogue access points, unassociated clients, ad-hoc networks and interferences.

Guideline 4: Have a solution in place to manage the bandwidth.
- Bandwidth differentiation based on the roles of the users.
- Monitor bandwidth usage of each user.
- Block unneeded applications, such as video.

Guideline 5: Have a solution in place to enable differentiating users' access to your network resources.

Guideline 6: Have a worm-protection solution in place. Install antivirus software on each wireless client if it is feasible. If not, have a solution in place to detect the virus and prevent the virus-infected client from accessing the wireless LAN.

Guideline 7: Separate your wireless LAN from your wired network by using segmentation devices, such as routers, layer 3 switches, VPN concentrators, firewalls, enterprise encryption gateways and wireless gateways.

5.2 Managerial Guidelines

Guideline 1: Control the coverage of your wireless LAN and reduce the leaking of radio frequencies. For doing this, you can adopt the following three approaches:

Approach 1: Conduct a site survey

Approach 2: Place the access points strategically to reduce the radio frequency leakage and focus the majority of the coverage within the building.

Approach 3: Implement radio frequency containment. This can be achieved by:
- Minimizing the transmission power of the access points.
- Modifying the building by installing metallic film or foil under the drywall, applying metallic paint to walls to add layer of attenuation and using metallic window blinds to provide better attenuation.

Guideline 2: Change the default settings of the access points and configure the access points properly. The followings are some guidelines:
- Disable any insecure and nonessential settings.
- Update the default administrator password. Recommend implementing strong passwords with both alphanumeric and special characters and a minimum password length of eight characters. In addition, passwords should be changed regularly.
- Change default SSID.
- Choose strong community strings for SNMP and change them often. Consider using ***SNMP Read Only*** if the management infrastructure allows it.
- Ensure the access points have at least three channels different from any other nearby wireless networks to prevent interference.
- Utilize secure management protocols, such as SSH for web and SSL for telnet, to configure the access points.
- Limit management traffic to a dedicated wired subnet.
- Isolate management traffic from user traffic and encrypt all management traffic where possible.

Guideline 3: Control the reset function of the access points.
- Make sure that only an authorized group of people can reset the access points.
- Have a solution in place that allows the reset access points to restore themselves to the latest security settings.

Guideline 4: Track the locations of all the access points and record the configuration of all the access points to ensure each access point follows the security standards and uses the latest patches. Recommend using vendor-specific tools to do this.

Guideline 5: Establish security policies regarding wireless security. The security policies need to be expressed in a way that everyone can easily understand. Moreover, the security policies are recommended to address the following issues:
- **Wireless users**: Identify who may use the wireless LAN in the organization and specify the acceptable and unacceptable behavior of the wireless users.
- **Wireless communications**: Identify what type of information may be sent over the wireless network and define the security level of the information.
- **Use of wireless devices**: Specify who is authorized to install wireless equipments, such as the access points, the acceptable and unacceptable offsite use of the corporate wireless devices, and the procedures on reporting losses of the wireless devices and security incidents.
- **Network configuration**: Define standard security configurations of network devices, such as access points. Provide guidelines on the use of encryption and other security technologies.
- **Security management**: Define procedures of network security management, including virus control, password management, security upgrades and security audit.

Guideline 6: Regularly check the security patches and only apply the ***needed*** ones. Make sure that the antivirus software has the latest virus definition.

Guideline 7: Conduct a security audit regularly. You may choose the following two approaches to do this:

Approach 1: Use public tools (such as ***NetStumbler***) or vendor-specific tools (such as ***AirMagnet***) to check if access points are transmitting correctly and are deployed on the correct/authorized channel and to check for rogue access points and other unauthorized access.

Approach 2: Ask professional companies to conduct a security audit of your wireless LAN. Usually these companies provide audit services that are more up-to-date on security vulnerabilities than most organisation's IT departments.

Guideline 8: Provide user training for those who operate and manage your wireless LAN. The training at least covers the following areas:
- Make sure the relevant people understand that they have personal responsibility to keep the wireless LAN safe from intrusion.
- Let the relevant people know about the risks associated with the wireless LAN.
- Let the relevant people know about security protocols, why these protocols exist, and how to follow them.

Guideline 9: Cultivate good communication between your IT staff and end users. Encourage the users to consult IT staff if they are uncertain about some computer or network operations.

Guideline 10: Protect your wireless network facilities physically, especially the access points.
- Conduct physical access controls, such as using security cards, to minimize the risk of improper penetration of wireless network facilities.
- Install access points out of the normal reach of people. If possible, conceal the access points from sight.
- Deploy external boundary protection, including locking doors and installing video cameras around the perimeter to discourage unauthorized access to wireless network facilities, such as access points.

6. CONCLUSIONS AND LIMITATIONS

As revealed in this research, 802.11 wireless LANs security must be achieved by the integration of security technologies and good management practices. On one hand, technologies can secure the wireless LANs only when they meet the organizational security requirements, are applied to an appropriate network environment, and are implemented properly. This is actually associated with an organization's security management practices. On the other hand, technologies can assist in good security management practices. With the help of the adequate technology it is easy to carry out good management practices.

This research has three main limitations. Firstly, the findings are only applicable to 802.11 wireless LANs, not to the other types of wireless networks. Secondly, the findings are only suitable for organizational users, not for home users. Finally, the technical solutions proposed in this research do not consider the issue of network performance, which is also an important factor that organizations need to consider when evaluating the possible technical solutions.

Saving Endangered Species: The Application of Computer-Based Radio Coverage Modelling to Wildlife Telemetry Systems

David Wilton, Massey University Albany Campus, New Zealand; E-mail: D.R.Wilton@Massey.ac.nz

ABSTRACT

The research described in this paper is aimed at improving wildlife telemetry systems by the use of computer-based radio frequency (RF) visualization and planning, and enhancing RF coverage by adoption of improved techniques and tactics. The use of a computer-based modelling application has proved to be of benefit in the area of visualisation and planning. Use of this tool and other work in this area has led to the identification of opportunities to improve field practice, including staff training in RF techniques and tactics, selection of optimum receiver sites, improved receive antenna systems, and better planning for airborne monitoring and tracking.

Keywords: Information systems, information systems applications, wildlife telemetry

INTRODUCTION

Kiwi – a New Zealand national icon – is one of several endangered species subject to national conservation and recovery programmes. This paper describes research conducted for the kiwi recovery program of the NZ Department of Conservation (DOC) (Bank of NZ, 2005). During 2004, the author spent some time working as a volunteer with DOC staff at the Moehau[1] kiwi sanctuary, mainly assisting in the location of kiwi to enable the annual change of telemetry transmitter, undertaken because of limited battery life. This process is normally undertaken in the May-June period each year.

While engaged in this work, two issues became apparent. Firstly, the terrain of the Moehau area is very rugged: the northern part of the Coromandel Peninsula is only about 10 km wide, and the main mountain range rises to a height of nearly 1000m. Most of the area is clad with dense primary bush or secondary-growth scrub. The terrain means that vehicle movement is mainly restricted to one road around the coast, foot movement is difficult and radio coverage, which is in the very high frequency (VHF) band (30-300 Mhz) and limited to radio line-of-sight, is also problematical.

Secondly, the majority of work involving monitoring and tracking of birds utilizing telemetry involves long periods of time in the field for relatively few detections. (For example, in one day that the author was out with a DOC team, only one bird was located, and that was found by a trained kiwi dog, rather than using the telemetry system.) Although monitoring and tracking by aircraft is possible (and actually undertaken once or twice a year) the cost makes regular use prohibitive, and the rugged nature of the terrain creates problems even for this mode, as will be outlined later in the paper.

As a result of these experiences, an informal research question was formulated: can improvements (that are cost-effective and practicable to implement) be made to the telemetry system, to enhance the effectiveness of endangered species management and research?

The approach taken to the problem was one of incremental and piecemeal improvement: that is, visualizing the problem, formulating ideas for improvement and then evaluating these ideas from the points of view of functionality improvement potential, economic feasibility and practicality. Lack of resources within DOC meant that a "big bang" approach to upgrade or replace the current system is just not feasible. This paper summarizes work to date - albeit still at an early stage. The results are applicable to any wildlife telemetry scenario that uses RF techniques, not just the kiwi recovery program. The majority of the work can be considered as being in the category of *critical research*: "… the specific purpose of a critical IS research project ranges from creating knowledge as a catalyst for change … to playing an active role in transforming IS practices …" (Cecez-Kecmanovic, 2005). A variety of methods have been employed, including the positivist methods of laboratory and field experiments (Galliers, 1994) and the critical research method of *participatory action research* (Baskerville, 1999).

RADIO COVERAGE MODELLING

Wildlife telemetry has gained increasing prominence in NZ conservation management and research over the past two decades (e.g. Thomas, 1982, Taborsky and Taborsky, 1995, Gibbs and Clout, 2003, Seddon and Maloney, 2004). There is good general coverage of wildlife telemetry systems in the literature (e.g. Mech, 1983, Kenward, 1987, Priede, 1992, Geers et al., 1997, Government of British Columbia, 1998, Mech and Barber, 2002). Most of these references give a high-level overview of RF technology (e.g. frequency bands and their propagation characteristics, and antenna types and characteristics) but there is no in-depth coverage of RF techniques or tactics.[2] Nor does the main wildlife telemetry literature mention the use of RF coverage modeling (either manual or computer-based) to assist in improving detection rates in the field, an approach which could also lead to savings of time and resources.

On the basis that, often, a good start point for solving a complex problem is being able to visualize the problem, the initial step was to carry out some radio coverage modelling over the Moehau Sanctuary area. The first intention was to use an orthodox geographic information system (GIS) application such as ESRI ArcInfo or ArcView. However, these applications support only optical line-of-sight coverage modeling and the incorporation of RF coverage capabilities would have required significant programming effort. Therefore, an off-the-shelf RF coverage planning tool was identified – the *Radio Mapper* application developed for military tactical radio planning at the University of NSW.

Radio Mapper requires Digital Terrain Elevation Data (DTED) to provide the terrain model base for radio coverage modelling. DTED is a well-known topographic data standard that essentially represents terrain as a set of (x,y,z) coordinates. There are three levels, representing different coverage granularities: level 0 has horizontal cell widths of 1 km, level 1 has cells of 90m and level 2 has cells of 25m. An approach was made to the NZ Defence Force Joint Geospatial Support Facility at Devonport Naval Base, who agreed to supply DTED level 2 coverage of the Coromandel area. After assembling the necessary application software, data and hardware, modeling activities commenced in early March 2005.

The initial use of Radio Mapper was to assist in problem visualisation. This is consistent with the use of computer models or simulations in orthodox decision

support applications (e.g. Turban and Aronson, 1998 77). However, the tool proved to be far more effective and useful than originally envisaged, and probably offers the following lessons for IS designers (and educationalists):

- A decision support application can sometimes be utilised successfully in a problem domain significantly different from that for which it was originally intended.
- The use of Radio Mapper, in this instance, has contributed far more to the problem domain than could possibly have been imagined at the outset. In that regard, the tool can be thought of as a key element in a learning process and can be equated to what Papert terms *objects to think with* (Papert, 1993 11).

Figure 1. Radio mapper display showing selected radio sites

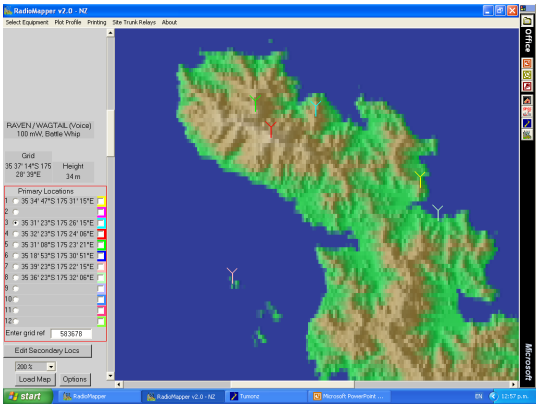

Figure 2. Predicted coverage from a single site

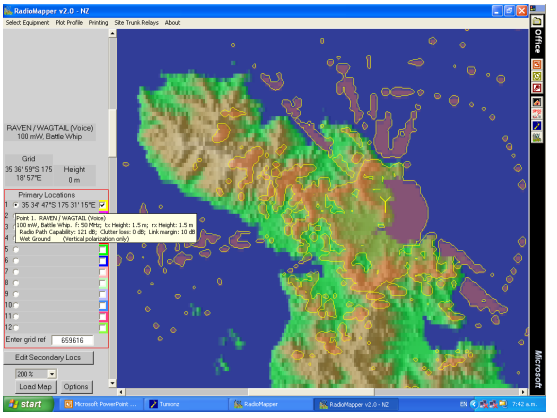


INITIAL RESULTS AND OBSERVATIONS

Radio Mapper is a radio communications path-planning tool that assists planners in predicting performance using both point-to-point and area coverage calculations. Parameters which can be varied include transmitted frequency and power, antenna and antenna feeder gains or losses, receiver sensitivity, ground type (e.g. wet, dry, urban) and transmit and receive antenna heights above ground level (AGL). Modelling can be conducted for any area for which a DTED data set is available. Examples of outputs from Radio Mapper are shown at Figures 1 and 2 below.

As Radio Mapper displays only include terrain-related information (i.e. horizontal coordinates and height), it was discovered that toggling between Radio Mapper and another digital mapping application (in this case TUMONZ[3] was used) allowed selection of likely sites taking into account natural and artificial features such as streams, roads, tracks, built up areas etc not shown on Radio Mapper. At a later stage of the work, Radio Mapper coverage diagrams were able to be geo-referenced, imported into a GIS, and displayed as overlays to topographic maps.

By varying the site locations and other non-constant parameters such as receive antenna height, a "profile" of the sanctuary area was compiled. It was notable that raising the receive antenna height to around 100m had a large effect on coverage - of the order of 7-8 times that obtained at 1.5m, the typical height of a hand-held antenna. This is shown in Figure 3. This result has a bearing on techniques and tactics which could be adopted to improve coverage – some of these are discussed in following sections.

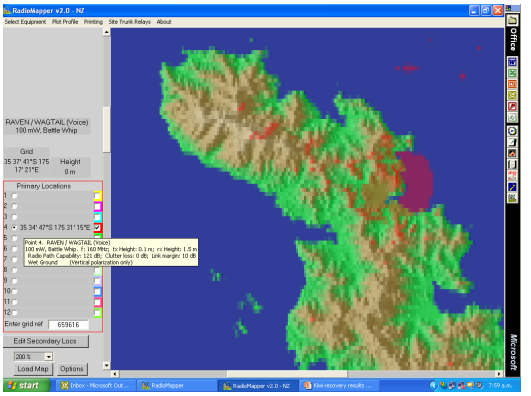
Another interesting result is that Radio Mapper predicts that the whole of the sanctuary area could be covered by five carefully sited receivers, provided the antennas were 100m AGL.

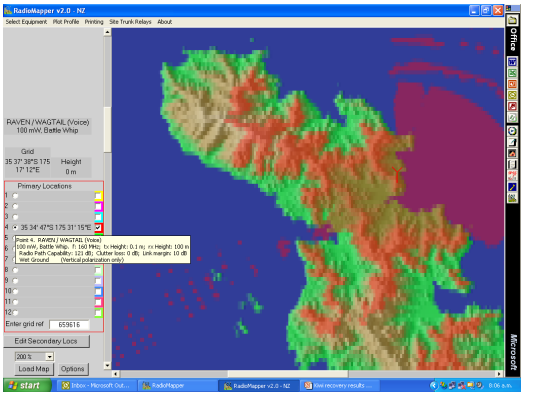
Practical validation of the RF coverage modeling results has been undertaken to a limited extent; for example:

- The tool predicts that receivers active on the high points of the main Moehau Range should be able to pick up transmitters operating on Great Barrier Island (some 25 km to the north east of Moehau) and from the Hunua Ranges (some 50 km south west of Moehau). Practical results have confirmed that that is the case.
- The selection of a migration monitoring site, described in the next section, also confirmed the predictions of Radio Mapper.
- Field trials were conducted over a three day period in the Moehau Sanctuary area. These compared actual radio telemetry coverage with that predicted using Radio Mapper, and very close correspondence was obtained.

Although only limited in-field validation has been conducted, results are sufficient to give a reasonable degree of confidence in the coverage predictions. Validation will be extended as time permits.

Figure 3. 1.5m receive antenna height (on left) compared with 100m receive antenna height





SOME PRACTICAL APPLICATIONS OF RADIO COVERAGE MODELLING

Following presentation of initial results of this work at the national kiwi recovery conference in March 2005, DOC staff met with the author and suggested a number of tasks that could make use of the RF coverage modeling capability:

- Selection of a radio receiver site at the southern end of the sanctuary area where a receiver/data logger could be installed to monitor transmitter-equipped kiwi entering or leaving the sanctuary area.
- Investigation, design and construction of prototype elevated antennas, to improve telemetry coverage.
- Predictions for the best altitude and track to fly while undertaking airborne monitoring.
- Analysis of the telemetry monitoring sites currently used by staff in the sanctuary area, to identify gaps in coverage and possible identification of better sites.
- Enhancing staff tracking performance, by appropriate training in RF techniques and tactics.

Progress has been made in all five of these areas. However, due to space limitations, only the first two are described in this paper. Work was carried out commencing late- 2005 and continues in 2006. The results are reported in the remainder of this section.

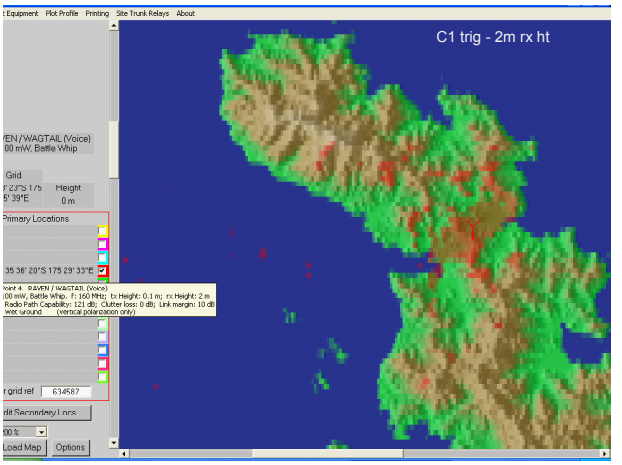
SELECTION OF A MIGRATION MONITORING SITE

The aim of this task was to determine if there are suitable site(s) where a receiver/data logger system could be installed to monitor, on a long-term basis, transmitter-equipped birds entering or leaving the sanctuary area. Experimentation with Radio Mapper identified four possible sites – one to the north of, and three to the south of, the Colville-Port Charles road. Figure 4 below shows predicted coverage from one of these sites. In April 2005, the author and a small group of DOC staff and volunteers undertook a site survey of the three southern sites, to assess their suitability, in terms of access, security, space to erect antennas etc. All three sites proved to be suitable from a practical point of view.

A communications test was also performed from one of the sites. Two people were equipped with telemetry transmitters tied to their bootlaces and they walked from the selected site down to the sea on each side (about 5 km each way). On the hill, staff were able to receive the signals continuously, down to the sea on each side. This demonstrated that the location is viable as a migration monitoring site, and also reinforces confidence in the Radio Mapper tool.

The use of Radio Mapper in the selection of this site and the subsequent communications test indicate that there should not be a significant issue of "false negative" results. That is, transmitter-equipped birds should not be able to move through the monitoring zone undetected, unless there is a failure of the receiver/data logger equipment, which is a separate management issue.

Figure 4. Predicted coverage from selected migration monitoring site



A significant issue, however, is likely to be "false positives" – that is, detection of birds at high points on the main range that are within the coverage of the selected site, who are not actually emigrating from the area. It is considered that this risk can be managed – over time, such birds will be detected within the sanctuary area during normal monitoring operations, indicating they have not emigrated. Similarly, any birds that immigrate would be transmitting on channels not allocated within the Moehau area, so should be able to be located and identified once in the sanctuary area.

During the second half of calendar year 2005, detailed planning, funding approval, system selection and acquisition, installation, and commissioning of the system took place. The telemetry system selected was the Telonics TR5 with the data acquisition option enabled (see Telonics Inc, undated). Funding was provided jointly by the author's university and DOC. The system was installed by DOC volunteers during a weekend in December 2005 and the system went live in early January 2006. Initial results are promising, with up to 10 birds being detected and logged in each 24 hour period. Some of these had not been detected in their normal range for some months, probably indicating they were "wanderers", or in the process of emigrating from the sanctuary area.

At this early stage, careful interpretation of the results is required to avoid false positives – that is, to identify birds that are actually migrating, and not just resident within the coverage area of the receiver. Future enhancements to ease this problem could include things such as: reducing the receive antenna height, or the use of directional antennas oriented east and west, to avoid repeated detection of birds resident in the main sanctuary area.

ELEVATED ANTENNA SYSTEMS

Also in the area of improved techniques, as previously mentioned, Radio Mapper graphically demonstrates the effect of increasing the height of the receive antenna. (Obviously, increasing the height of the transmit antenna would have the same effect, but is not feasible in a wildlife telemetry scenario.) For example, Figure 3 above demonstrates that a receive antenna at 100m AGL would have a coverage roughly 7-8 times that of an antenna at 1.5m AGL. This effect could be exploited by a number of initiatives, for example:

- Investigate the feasibility of mounting a receive antenna under a tethered balloon or in an unattended airborne vehicle (UAV). Limited by payload, the most likely antenna configuration is something simple such as a half-wave dipole or quarter-wave monopole. Bosak (1992 p. 93) provides a design for a lightweight, improvised Yagi that could be mounted on the side of a balloon – the ability to roughly "steer" the balloon by tether ropes at either end could allow a rudimentary direction-finding capability.
- Investigate the feasibility of a quick-erect (e.g. by pneumatic means) antenna mast mounted in the back of a truck or utility vehicle. This would allow utilization of good reception sites accessible by vehicle. This concept is widely used in military tactical communications.
- Design and develop a range of cheap, lightweight, antennas that could be hoisted into tall trees at key reception sites and left there, so that staff could move to them and connect to their receiver on arrival. This concept is also widely used in military tactical communications, particularly for jungle operations. The improvised Yagi design by Bosak (1992) may be viable, and therefore provide a direction-finding capability.

During the second half of calendar year 2005, some research funding was obtained to investigate the third option; namely cheap, lightweight antennas that can be installed around the sanctuary area and left in position. A small number of trial antennas were designed and constructed, mainly consisting of half-wave dipoles, Yagis based on Bosak's design and the commercial Yagi currently used by DoC, elevated by various means.

Limited laboratory testing was undertaken, using the RF laboratory of the author's university, in the absence of an anechoic chamber. The laboratory results demonstrated that the antennas constructed exhibited expected properties: particularly gain (relative to each other) and frequency response.

A field antenna testing range (ATR) was selected in the Moehau area, due to the availability of telemetry equipment from the Moehau Kiwi Sanctuary. The terrain was selected by Radio Mapper modelling, physical reconnaissance and telemetry coverage tests. The actual antenna test site had to have tall trees to achieve appropriate elevation for the antenna under test (AUT), and the terrain ideally had

to provide intermittent coverage over a distance of 5-10 km along a traversable route radiating away from the antenna test site.

Antennas were set up at the test site and a research assistant equipped with a telemetry transmitter moved on foot along the chosen route. Other staff at the antenna test site monitored the RF signals using Telonics TR4 telemetry receivers. Up to three antennas were tested at a time. When a change occurred (e.g. signal was lost or regained) instructions were radioed to the surrogate "kiwi" to change position (e.g. back-track 50m). When it became apparent that a change had actually occurred, the "kiwi" was instructed to take a GPS waypoint of that position and then proceed along the route.

The results were recorded on TUMONZ by plotting the GPS waypoints, which were then linked up by line to show pictorially the coverage achieved for each AUT. The results are shown at Figure5 below. The field results graphically demonstrated the value of increasing receive antenna height to improve reception coverage. (The standard commercial Yagi, at 1.5m AGL, gave the worst performance of all the antennas tested.)

Other conclusions were as follows:

- The commercial Yagi, operated in an elevated mode, was quick to erect (of the order of 2-3 minutes) and provided superior performance, particularly over the same antenna when hand-held (the range obtained was of the order of four times greater, on the particular terrain where testing took place).
- Cheap, expendable dipoles could be erected and left in place in trees at key monitoring points, so that staff can connect to them on arrival. If RF signals are detected on significant channels, the standard commercial Yagi could be substituted for the dipole and hoisted into the tree if direction-finding is required.

The results have been passed to DOC with recommendations for further work and utilisation of the findings.

SUMMARY AND CONCLUSIONS

The research described in this paper is aimed at improving wildlife telemetry systems by means of computer-based RF visualization and planning, and improving RF coverage by adoption of enhanced techniques and tactics. The majority of the work can be considered as being in the category of *critical research.* A variety of methods have been employed, including the positivist methods of laboratory and field experiments and the critical research method of *participatory action research*.

The use of a computer-based modelling application – Radio Mapper – has proved to be of benefit in the area of RF visualisation and planning. It has been recommended that DOC consider acquiring a licence to operate Radio Mapper, or identify and procure a similar RF coverage modelling tool.

Use of Radio Mapper and other work in this area has led to the identification of opportunities to improve field practice: staff training in RF techniques and tactics, selection of optimum receiver sites, improved receive antenna systems, and better planning for airborne monitoring and tracking. It has been recommended that all DOC staff involved in field telemetry work undergo training (of the order of half a day is considered sufficient) in RF propagation techniques and tactics. In the kiwi recovery program, this could be run in conjunction with the annual national conference.

FUTURE WORK

There is considerable potential for further improvements to wildlife telemetry systems arising from the user of a radio coverage modeling tool and improved RF techniques and tactics. These include further work to improve conventional airborne tracking and monitoring (as mentioned in section 3.2); elevated antenna improvements, including vehicle- and ground-mounted masts; the use of alternative airborne platforms such as balloons and un-manned airborne vehicles (UAV); and investigation of automated space- and land-based detection and tracking systems.

The Relationship Between IS Strategic Planning and Enterprise Architectural Practice: A Study in NZ Enterprises

David Wilton, Massey University Albany Campus, New Zealand; E-mail: D.R.Wilton@Massey.ac.nz

ABSTRACT

Modern businesses face increased levels of competitive pressure, and the IT sector is going through a period of rapid change. These issues have resulted in a drive for new approaches to planning and managing IT services. Two approaches that have emerged in different eras are IS Strategic Planning (ISSP) and Enterprise Architectural Practice (EAP). Despite the apparent similarities between these two approaches, neither IS researchers, nor practitioners, have explored the relationship in any depth. This paper investigates the relationship between ISSP and EAP, utilising results from a survey in NZ enterprises.

INTRODUCTION

Modern businesses face increased levels of competitive pressure, and the following factors will influence the nature and duration of current and future strategic planning: (Wagner, 2004)

- Shorter planning and implementation cycles.
- Frequent and rapid environmental changes, possibly with discontinuities.
- Organization units that extend beyond a single company, such as supply chains or virtual organizations.

In addition, the IT sector is going through a period of rapid change, and the rate of change is expected to at least remain steady, if not accelerate. Many commentators regard rate of change as a key issue in the sector (e.g. CCTA, 1999 11). These pressures have resulted in a drive for new approaches to planning and managing IT services.

Within the corporate world and, to a certain extent, government organisations, ISSP was pre-eminent during the 1980s and 1990s. In the latter half of the 1990s, EAP became prominent in the US Department of Defense; a trend which has flowed on to the government and commercial sectors. Some similarities between ISSP and EAP are apparent.

This paper examines the relationship between ISSP and EAP. Such a comparison is made difficult by the large number of approaches towards ISSP and EAP that have emerged (including proprietary and in-house), and the inherent differences in scope and techniques. However, two typical approaches have been chosen, based on their widespread usage, to enable a theoretical comparison between ISSP (the CCTA methodology) and EAP (the US DoD C4ISR Architectural Framework). An empirical comparison, based on a survey of NZ organisations, has also been conducted. The paper concludes that there are strong similarities between the two activities, and that there are, indeed, opportunities to rationalise the two activities, to eliminate duplication of effort and to develop improved IT planning methodologies based on "best-of-breed" techniques from both.

THEORETICAL UNDERPINNINGS

ISSP

In discussing IT strategic planning, it is important to distinguish between *strategic information systems planning* (SISP) and strategic planning for *all* information systems (ISSP), terms often used interchangeably in the literature. The latter term, referring to the strategic planning of an enterprise's entire IT resources, is the term used in this paper. This is consistent with the terminology used by Fitzgerald (1993) and Cerpa and Verner (1998).

The Central Computer and Telecommunications Agency (CCTA[2]) of the UK Treasury highlights the following concerns of ISSP: (CCTA, 1988)

- Understanding the aims and objectives of the business,
- Establishing the information requirements of the business,
- Outlining the systems to provide the information, and determining the role of technology in supporting the information systems,
- Agreeing policies and plans to develop and implement the information systems,
- Determining the role and use of resources to achieve the information systems required, and
- Managing, reviewing and evolving the strategy.

There are numerous techniques, or *methods* that have been used for ISSP, including Critical Success Factors (CSF) (Rockart, 1979), Business Systems Planning (BSP) (Wiseman, 1988), Porter's Competitive Forces Model (Porter, 1980), Porter's Value Chain (Porter, 1985), and Scenarios (Schwartz, 1991). Methods can be grouped together to constitute a *methodology*. Methodologies used for ISSP include those of the CCTA (1988, 1999) and Boar (2001).

Many IT vendors and consultancy organizations use proprietary methods and/or methodologies, some of which are adaptations of open source approaches. Examples are Arthur Andersen's *Method/1* and Coopers and Lybrand's *Summit* (Lederer and Sethi, 1988, Min et al., 1999). It is also well known that organizations often develop their own in-house methodologies, often based on open or proprietary methods or approaches (Earl, 1993, Lederer and Sethi, 1988).

One open source methodology that has been successfully used for IT strategic planning in the government sectors of Australia, UK and NZ is that of the UK government CCTA (1988, 1999). The basic mechanism is a sequence of actions, grouped into the common-sense phases of:

- Where are we now?
- Where do we want to be?
- How do we get there?

The steps include a detailed inventory and cost model of existing systems, a study of business goals and objectives, and a scan of the environment in which the business will operate. Senior management define a vision of where they envisage the organisation will be at the end of the time "window[3]" of the study, both from a business and IT perspective. Options for the provision of systems and services are defined, which are evaluated by a high level steering committee, who decide on the (or a small number of) option(s) to be costed and developed in detail into a strategic plan. The options could include outsourcing, or other innovative approaches to service provision.

In summary, the main strength of CCTA (or a similar strategic planning methodology) is that it gives a methodical, business-driven approach to selecting, funding, operating and managing IT systems. The production of a comprehensive, top-down IT strategic plan represents a low risk approach to any organisation's requirement to manage its IT infrastructure. The existence of a comprehensive strategic plan will allow the organisation to make informed "what if" decisions, such as evaluating the benefits of outsourcing all or part of its IT infrastructure.

Enterprise Architectural Practice (EAP)

Many approaches to ISSP include *IS/IT architecture* as a deliverable of the process (e.g. O'Brien, 2004, CCTA, 1999). However, the scope of "architecture" envisaged in EAP is somewhat more significant – it actually subsumes many of the steps inherent in ISSP.

EAP first became prominent in US government circles. Frameworks include those developed by the US Department of the Treasury (2000) and US Department of Defense (DoD) (1997, 2003). The US Army has developed an extension of the DoD framework, that is described in a separate document (U.S. Army, 1998). Non-government approaches to EAP also exist; e.g. those developed by Zachman (1987), and The Open Group (2003).

The underlying vision of EAP is as follows:

"Architectures are developed to portray the evolution of an IT environment over various points in time, beginning with the baseline, or current situation. ... The architecture envisioned to meet all operational and business requirements is the objective architecture. Migration documents show the progression of architectures from baseline to objective ..." (U.S. DoD, 1997 1-2)

A complementary view of the purpose of EAP is as follows:

"Enterprise architecture is a far-reaching concept that comprises the vision, principles and standards that govern the acquisition and deployment of technology. As such, it provides the foundation for detailed data, application and network architectures. An enterprise IT architecture is a key component of a mature IS organisation that enables alignment of business goals, consistent processes and best practice in software reuse." (Cecere, 1998)

The US DoD framework describes the process of defining an EA in terms of the deliverables; that is, the steps to be undertaken to produce the various elements of the operational, systems and technical architectures. It does not describe in any detail the underlying rationale, or analysis that should be undertaken to produce the various deliverables:

"The situation is further complicated because the framework does not provide a process for generating the products. Thus, an organization developing an architecture that is compliant with the C4ISR Framework could be faced with an unbounded amount of effort." (Barbacci and Wood, 1999)

The opening paragraph of the C4ISR AF (U.S. DoD, 1997) states that: "the application of the Framework will enable architectures to contribute most effectively to building … cost effective military systems" (p. 1-1). However, there is no elaboration of this statement into the development of a business case, or costed options, as is integral to CCTA. There is also no indication in C4ISR AF of any specific time window on which the objective architecture should be based. With rapid advances in technology, it may not be possible to specify a firm objective architecture more than 3-5 years ahead.

THEORETICAL COMPARISON OF ISSP WITH EAP

Even from the cursory descriptions of ISSP and EAP in the preceding sections, there are similarities apparent. A more detailed comparison was conducted by Wilton (2001) who identified the following similarities and differences:

Similarities:

- Basic Intent/Vision: Both are high-level approaches, intended to realize a rational, affordable IT infrastructure that is consistent with business strategy and goals.
- Both include a baseline summary of existing IT infrastructure, and an objective architecture ("where do we want to be?").
- Both establish the information requirements of the business and determine the systems required, to provide and manage the information.
- Both include a financial dimension (however, this is much more heavily emphasized in ISSP).
- Both produce plans/architectures that are dynamic, and need to be reviewed regularly.

Table 1. ISSP and EAP - differences

	ISSP	EAP
Scalability	Tends to be targeted at a single enterprise entity	Can be adapted to fit a multi-level or multi-organisation enterprise (intended to produce nested architectures, or "systems of systems")
Deliverables	Not tightly defined within any particular methodology	Tend to be tightly defined, and grouped as mandatory and optional.
Process	Well defined. Tightly coupled to business strategy and cost effectiveness.	Not particularly well defined
Time window for objective strategy or architecture	3-5 years (limited by rapid advances in IT)	Not specified
Interoperability focus	Not specifically emphasized	Inter - and intra - organisational interoperability is a key focus
Summary of overall approach	Process-oriented	Product oriented

Differences are shown in Table 1.

In summary, the high-level intent of the two approaches is nearly identical, and the general scope and factors considered during the respective processes are very similar. However, the major difference is that ISSP tends to be process-oriented, with relatively little specification of the deliverables, whereas EAP is rather the opposite. US DoD EA practice, as espoused in (U.S. DoD, 1997, U.S. DoD, 2003), does not attempt to define any business processes or models which could be used to derive cost-effective objective architectures. The use of ISSP methods could remedy this shortfall.

The similarities between ISSP and EAP are reinforced by Beveridge and Perks (2003 12-13) who state:

"In many ways there is synergy between the Enterprise IT architecture and the concepts that embodies ... ISSP. Both provide a medium- to long-term vision and framework within which the IT environment is implemented, including people, structure and technologies. Both the ISSP and enterprise architecture provide guidelines for systems to be implemented, technologies to be considered, and information to be gained."

EMPIRICAL COMPARISON OF ISSP AND EAP

In order to compare ISSP and EAP from a more practical basis, a survey was conducted of NZ organisations. A research model was developed, containing the variables that are considered to be of interest in the problem domain and the anticipated inter-relationship between them. Some initial hypotheses were also proposed. These are not included in this paper due to space limitations. A survey instrument was designed utilising constructs and questions derived from the literature where possible. The draft survey was subjected to faculty review (including review by a senior statistics academic) and pilot tested on several large organisations and SMEs then subjected to fine tuning.

It is generally accepted in statistical analysis that a sample of at least 100 valid responses is required to constrain the margin of error to no more than 10%, and

therefore to provide results that can be generalised across the whole population. However, the use of a stratified sample (as used in this survey) introduces a design effect that reduces the likely margin for error to 80-90% of that of a truly random sample (Page and Meyer, 2003 pp.107-108). In this particular survey, there were difficulties in obtaining valid responses, due to the following reasons:

- The length and complexity of the survey instrument, which necessitated the use of a simplified instrument for small and medium organisations.
- The relatively small size of NZ, coupled with the fact that 97% of NZ enterprises are classified as small or medium. (N.Z. Ministry of Economic Development, 2003).

The small number of responses (53), and the even smaller number of organisations (26) which had (or were developing) an IS strategic plan and/or enterprise architecture represents a limitation on this study that must be taken into account when interpreting the results. However, according to the NZ Ministry of Economic Development (2005), as at February 2004, there were fewer than 2000 "large" enterprises in NZ. Therefore, a response by 20 large enterprises represents more than 1% of the population. Further, it is noted that surveys with less than 100 valid responses feature prominently in the IS strategic planning literature, for example: (Lederer and Sethi, 1988 - 80 responses, Flynn and Goleniewska, 1993 - 18 responses).

The small sample size must be regarded as a limitation on generalisability of the results, but does not negate this survey being used as the basis for a preliminary investigation into ISSP and EA practices and issues in NZ enterprises.

SURVEY RESULTS

The survey instrument used was intended to gather a wide variety of data. Only certain key results - those relating to a comparison of ISSP and EAP - are included in this paper due to space limitations. Data from the survey responses was entered into the statistics application *SPSS - Version 13 for Windows*, and processed using appropriate techniques. Results were as follows.

Existence of IS Strategic Plan and/or Enterprise Architecture

Grouping the results according to organisational size (small/medium or large) (see Figure 1), provides an interesting perspective.

All large organisations who responded have an ISSP or one under development, whereas only 87% of large organisations either have an EA (or one under development). A minority (20%) of small or medium organisations have an ISSP (or one under development) and only 17% have an EA (or one under development).

The low proportion of SMEs (20%) that have either an ISSP or EA, and the fact that around 97% of NZ enterprises are SMEs, is noteworthy. While the IT requirements of many SMEs may be relatively modest or simple, it is likely that a significant number of organisations are not realising the full benefits, or potential competitive advantage, that modern IT can offer. This may be having a detrimental effect on the national economy, but that is outside the scope of this research. One approach that could alleviate the situation would be the development of a simple, short-duration IS strategic planning methodology that the owners or staff of SMEs, who generally would not have in-depth IT knowledge, can conduct themselves. This would alleviate the need for costly consultancy services to produce ISSP and/or EA.

Figure 1. Existence of ISSP and/or EA – Small/medium and large enterprises

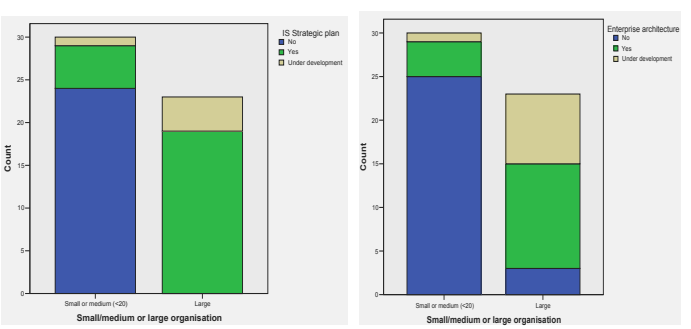

Table 2. Comparison of ISSP and EA development parameters

	Maximum	Minimum	Mean	Median
"Window" of ISSP (years)	10.0	3.0	4.4	3.0
"Window" of EA (years)	10.0	2.0	4.1	3.0
Internal staff effort for ISSP (person-months)	99.0	2.0	16.97	9.0
Internal staff effort for EA(person-months)	420.0	0[1]	38.8	12.0
Direct financial cost of ISSP	$600,000	$0	$66,833	$20,000
Direct financial cost of EA	$130,000	$0	$23,667	$0
Duration of ISSP development exercise (weeks)	52.0	5.0	23.6	24.0
Duration of EA development exercise (weeks)	52.00	0[1]	24.73	24.00

Characteristics of the Development Processes

A set of questions collected data associated with the ISSP and EA development processes, e.g. duration, cost, staff effort. Results are summarised in Table 2.

The mean cost of EA development is less than half that of ISSP, possibly indicating that EA development is not regarded as such a business-critical function as IS strategic planning. The fact that the median cost of EA development was zero (indicating that over half the organisations that had an EA developed it without dedicated funding) and the higher mean (almost double) for staff effort tend to reinforce this observation.

Investigating the Relationship between ISSP and EAP

One of the major goals of this research was to determine the relationship between ISSP and EAP. One of the key indicators of this was a hypothesis which examined the coincidence of topics in IS strategic plans and enterprise architectures:
Topics in ISSP] ∩ [Topics in EA] ≠ 0

To assist in visualising the situation, a comparative table was formed that displays the topics contained in an ISSP or EA (as reported by respondents) displayed as a percentage of organisations with that topic in their ISSP and/or EA. Results are presented in Table 3.

All listed topics (apart from two *other items* in ISSP) were present in both ISSP and EA. The lowest figure in any cell was 28.6%, representing the lowest incidence of topics in either type of document. This indicates a considerable overlap between the topics in ISSP and those in EA.

The results of a Spearman bivariate correlation test produced a correlation coefficient of 0.447, indicating significant correlation at the 0.05 level (two-tailed). Therefore, the hypothesis is demonstrated to be correct.

Another indicator of the relationship between ISSP and EA is a comparison of the ranked lists of objectives for both activities. These are shown in Table 4.

The primary objective is identical for both activities, but there is some variation in objectives 2-4 (in particular, *establish technology path and policies* is ranked 2nd in EA, but 4th in ISSP). Apart from this variation, the lists are identical.

The considerable overlap between the objectives and contents of ISSP and EA suggests that there may be confusion about the role and scope of both activities, and this could lead to a risk of duplication of effort and resources. One possible solution is to combine them into a (conceptually) single activity. This would not

Table 3. Topics included in ISSP and EA

Topic	Included in ISSP	Included in EA
	(% of organisations):	
Business objectives &/or vision	87.5	50.0
Model of the business	56.3	57.1
Business processes	37.5	42.9
Review of the business environment	68.8	35.7
Information requirements &/or flows	62.5	71.4
Enterprise data model	25.0	42.9
IT vision	75.0	71.4
Review of the technology environment	93.8	71.4
Applications portfolio	75.0	66.7
Networking requirements	37.5	57.1
Hardware requirements	31.3	57.1
Requirement for collaboration tools	37.5	28.6
Requirement for decision support tools	37.5	28.6
IT policies &/or procedures	50.0	35.7
IT standards and protocols	56.3	64.3
Security requirements or strategy	37.5	57.1
IT funding requirements &/or issues	62.5	28.6
IT procurement&/or sourcing strategies	56.3	35.7
IT organisation &/or management responsibilities	62.5	28.6
IT projects portfolio	81.3	50.0
IT architecture	68.8	64.3
Other items	12.5	0

preclude an approach where different deliverables are produced in successive phases.

This suggestion is in line with the statement that: "…there are distinct similarities in the objectives and scope of both approaches [ISSP and EA]. … The two approaches can be viewed as complementary, rather than mutually exclusive, and there could well be significant benefits in combining elements of both, to produce a new paradigm in IT planning and management." (Wilton, 2001)

SUMMARY AND CONCLUSIONS

Theoretical and empirical comparisons of ISSP and EAP indicate a strong correlation between these two activities. Organisations that undertake both, as separate activities, incur a risk of overlap, duplication of resources and possible difficulty in obtaining management commitment for both. There is the potential for development of a comprehensive methodology which combines best-of-breed methods from both disciplines. The research conducted in this area to date, has also produced some other significant results, such as the very low incidence of IS strategic plans and/or enterprise architectures in SMEs in NZ. Coupled with the fact that approximately 97% of NZ enterprises are SMEs, this may indicate that a significant number of organisations may not be realising the potential advantages that modern IT offers.

FUTURE WORK

The next stage of the study will consist of detailed Case Studies in a small number of selected organisations. The purpose of the studies will be to obtain detailed information on issues that emerged from the survey: in particular, the attitudes towards ISSP and EA, and detailed reasons why certain paths were followed (or not followed). This includes the low incidence of ISSP and/or EA in SMEs. The final stage will be the development and testing of an improved methodology that includes elements drawn from ISSP and EAP.

[3] Due to environmental volatility, a window of 3-5 years is fairly typical in a commercial organisation

Knowledge Harvesting System for a Business Enterprise

N. Raghavendra Rao, SSN School of Management & Computer Applications, Old Mahabalipuram Road, IT Highway, Off Chennai, Kalavakkam - 603 110, Kanchipuram DT, India; E-mail: drrao@ssnsomca.ac.in, drrao_edu@hotmail.com

ABSTRACT

Globalization has created new opportunities for business enterprises and their employees. Employees have started leaving the organization to avail themselves of the opportunities. Consequently knowledge gained and developed by them is lost when they quit the organization. Many business enterprises have started realizing that they need a solid and ongoing system that will capture and store the knowledge of their organizations and employees in information systems. It is required to establish synergy between the concepts of knowledge management and information technology for the creation of knowledge management system. This paper talks about the steps to be followed for incorporating the concept of knowledge harvesting with the human centered component in intellectual capital in business practices of an organization. Further it explains the role of Information and Communication Technologies (ICT) in this process.

Keywords: Knowledge harvesting, Intellectual capital, Knowledge worker, Data ware house, Data mining.

INTRODUCTION

The existing ways of doing business are constantly changing due to rapid changes in global economy. It is apt to recall here the observation of Arnold Kransdorff and Russell Williams(2000) who say that industrial conditions determine the options available and competitive advantage stems from business to it's environment (PP399). It has become a necessity for business enterprises to respond quickly to these changes. Many business enterprises have started realizing that managing knowledge as well as innovative process is the way to remain competitive in the changing business scenario. It is generally perceived by many business enterprises that knowledge management is a technology for preserving and enhancing the knowledge base of an organization. But after a close look at their own organization they may find that many elements related to knowledge management are already available in their own organization itself. In reality they are required to make use of the elements of knowledge source in their organization for their competitive advantage. George Friedman, Meredith Friedman, Colin Chapman, John S Baker Jr. (1997) rightly observe that the geography of information is not quite like a map of New Jersey. Information exists in a Variety of domains, some further away and harder to access, some closer and easily accessible. Further they say that we must draw a peculiar map to describe the geography of information, charting the zones or domains in which information resides (PP46-47). The overall challenge that many enterprises face today is identifying where the knowledge resides and to leverage it across to their organization. In spite of heavy investment in information technology business enterprises seem to think that they are fighting a losing battle. Business success lies in converting the information in their systems into knowledge. Now it has become important that one should use one's own wisdom to convert information into knowledge in the new scenario of business world. Business enterprises also seem to think that 'INTELLECTUAL CAPITAL' and 'KNOWLEDGE MANAGEMENT' are one and the same. The word 'MANAGEMENT' in knowledge management clearly indicates a process whereas 'INTELLECTUAL CAPITAL' is an entity and asset and not a process. This paper recommends a model for a business enterprise to design a knowledge harvesting system with the elements of Intellectual Capital. It comprises of five sections covering (1) Existing Scenario in Business Enterprises (2) Knowledge management and Intellectual capital (3) New Brand of Professionals (4) Steps in creation of knowledge harvesting system and (5) Globalization Scenario.

EXISTING SCENARIO IN BUSINESS ENTERPRISES

The greatest challenge in implementing effective knowledge management is helping employees make the transmission from knowledge hoarders to knowledge sharers. With knowledge comes power and influence in an organization and in today's business scenario one may find most employees working in knowledge hoarder's environment. Many of them also follow the practice of a selective distribution of knowledge. While comparing sharing patterns in knowledge, Melissa M.Appleyard (2002) gives an example of knowledge sharing in semi conductor industry in the US and Japan. Employees in the US semiconductor industry are more likely to rely on private channels of communication than their Japanese counterparts (PP 539). Generally executives do not intend remaining with an organization for long, they do not recognize the value of an accumulated knowledge. All they focus on is completing the tasks assigned to them as soon as possible in order to take on other assignments or leave the organization. This is one reason why they are unable to adapt to the new knowledge management environment. They need to realize that they have to work under competitive pressure in the present globalization scenario. Mary Crossan and John Hulland (2002) state that adjustment and joint action are crucial to the development of shared understanding (PP 714 – 715). This is most relevant in the present business scenario. Janie Nahapiet and Sumantra Ghosal (2002) explain that the cooperation among individuals in the organization will be possible only when individuals and functional experts are structured, coordinated and communicated (PP673). The essence of a knowledge management environment is to manage carefully 'Human centered assets' in business enterprises. What is required is a change in mindset among managers. Managers are expected to act as mentors to help employees change to knowledge workers and make use of the organizational knowledge base. Arjan Raven (2003) rightly points out that instead of looking at individuals as just information processors or decision makers, it is required to understand their work and support for making them feel their importance in the business of the organization (PP 292).

KNOWLEDGE MANAGEMENT AND INTELLECTUAL CAPITAL

Evolution of Knowledge Management

One would know from the study of history of any country that the concept of knowledge management is not new. The only difference one could observe is the methodology followed by them. Emperors of China preferred to have scholars as their advisors than politicians. The services of educated priests were used by Roman emperors like Greeks to know the possible trends in future. It is said that Kings in ancient India were particular mainly about four elements while developing a township in their Kingdom. They were places for worship (DEVALAYA), places for learning (VIDYALAYA), LIBRARIES (GRANDHALAYA) and Hospitals (OUSDALAYA). Indian kings seemed to be concerned with creation of knowledge among people by allocating places for schools and libraries. It may be interesting to note that a British stock broker in 1815 came to know about the defeat of Napoleon at the battle of Waterloo before it was known to others. It is said that this information helped him to make a fortune. In this context Thomas A. Stewart (2001) rightly says that industrial age was knowledge based too and the results of inventions such as steam engines, radio and telephones were based on this concept (PP XI). In the present day scenario these inventions would be classified under human centered assets.

Intellectual Capital

Intellectual capital or Intellectual assets are two words mentioned frequently in the present knowledge economy. The word 'CAPITAL' or 'ASSET' suffix to 'INTELLECTUAL' is not used in strict accounting terminology. It may be noted that the meaning of both the terms is the same. The components of intellectual capital can be classified under four heads. They are 1.Human Centered Assets 2.Intangible Assets 3. Market Assets and 4.Tangible assets. It is apt to recall the observation of Stephen E. Little (2002) on knowledge creation in a global context: "The speed of technical and infrastructural changes in business practice together with a new understanding of the centrality of intangible assets to wealth creation has brought the Silicon valley Paradigm of innovation to prominence (PP 369).

Knowledge Harvesting

The world 'Harvesting' generally applies to agriculture and refers to the practice of increasing the yield of cultivable land. In the same way organizational Intellectual asset is considered as equivalent to Cultivable land, where the employees' wisdom is the 'Manure'. With the help of employees' wisdom, the knowledge management process is developed by making use of the Intellectual assets of an enterprise. 'Knowledge Harvesting' means an integrated set of processes that capture the often hidden insight of human expertise in business. Just as individual skills are acquired through practice over a period of time, so are the skills of an organization developed and sustained only through experience.

Codification of Knowledge

It may be interesting to note that major portion of corporate knowledge is in employees' brains and documents. They are not easily shareable. Knowledge harvesting process is needed for making it shareable. The output of knowledge harvesting is the codification of Human centered assets in business enterprises. This is required to be stored in information systems. This creates value for business enterprises and it belongs to them. Further it has to be used for guidance and decision making. All critical decisions recorded will help to create Meta knowledge for adopting changes in business. The importance of reuse of intellectual capital can be understood from the statement of David E. Smith (2000) who says that reuse of intellectual capital is possible only when leveraging the experience of others who are not on the current team in an organization (PP XI).

New Brand of Professionals

Recent convergence of information and communication technologies has come to be termed as ICT. Professionals associated with these technologies are known as ICT Professionals.

STEPS IN CREATION OF KNOWLEDGE HARVESTING SYSTEM

Case Illustration

ROA Software Ltd was started two decades ago by a group of software professionals at Madras in India. Their area of operation mainly related to development of application software in the financial services sector across the globe. They have specialized in the segments such as Portfolio Services, Financial Services and Risk Management in Financial Sectors. Their approach has been to develop software on the basis of the business practice followed in the financial sector of the country concerned. It is because of this approach the members of the software development team have acquired good knowledge of their software. If any changes had to be carried out for any client, their efforts would be minimum. ROA Software Ltd has been considered as reliable and dependent IT solution provider in the global market. Their market share has been 75% and they were considered as market leaders. The policy of the company has been to group five project teams as one SBU (Strategic Business Unit). There are 7 to 10 such SBU's in every country wherever they have their business. Each SBU has its own team of Domain and Functional experts and software, hardware and telecommunication professionals. It has been the responsibility of the head of SBU to generate income for their operations. Capital Investments decisions are taken at head office and the funds are organized by them for acquisition of assets.

In recent times they have started feeling the impact of competition due to globalization policy followed by many countries. Consequent to this many of their seasoned employees have started leaving them to avail themselves of the various opportunities available in the global market. Knowledge gained and developed by them was lost due to their exit. The management has realized that a solid and ongoing system is required to archive the human centered assets and to have methods in place. This proposed system is expected to help their employees to share the knowledge that has been developed internally over a period of time. The management has created a task force consisting of senior executives who have rich experience in the business related to Portfolio Services, Financial Services and Risk Management in financial sector.

Observations of the Task Force

The task force has studied the existing practices, procedures and methods at various SBUS. They have also assessed the utilization of the resources such as Hardware and Software. They had interaction with the Domain and Functional experts, and ICT professionals at the SBUS. Their observations have been that neither knowledge nor the resources have been shared among the different SBUS in the same country. There has been no method to capture the knowledge and experience of their employees either by manual documents or electronic mode. While explaining culture and its relationship to knowledge Joseph M.Firestone and Mark W.Mcelroy (2004) state that to realize full value of the organizations' knowledge resource, if it is required culture in the organization has to be changed (PP 261).

Action Plan from the Task Force

The task force has created a core team. This team will consist of Domain and Functional experts, Human knowledge codifiers and ICT Professionals. The Core team has initiated the steps for creating knowledge harvesting system by integrating the components of Intellectual capital at ROA software Ltd. Table 1 – explains the components of Intellectual capital at ROA software Ltd. While establishing relationship between knowledge intensity and process complexity, Amrit Tiwana (2001) divides the business process in three phases such as Translation based, Activity based and Knowledge oriented base (PP 45-46). The core team identified the business activities in the countries of their operation as market assets. The three segments of the business activities in the financial sector have been classified under intangible assets. The various experts at ROA software Ltd are

Table 1. Intellectual capital at ROA Software Ltd.

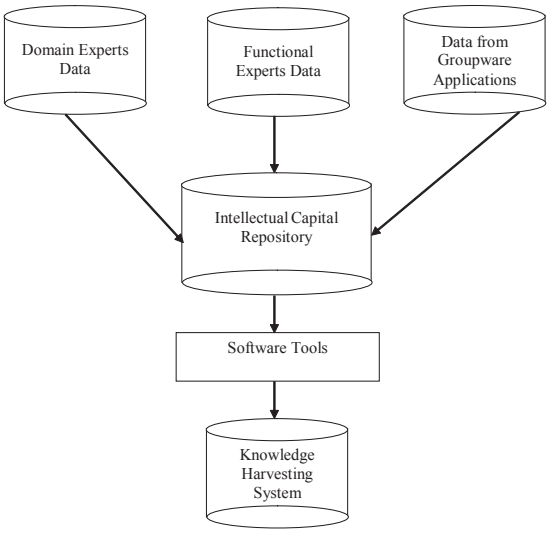
MARKET ASSETS
• BUSINESS ACTIVITIES IN • WESTERN COUNTRIES • ASIAN COUNTRIES • MIDDLE EAST COUNTRIES
INTANGIBLE ASSETS
• PORTFOLIO SERVICES • FINANCIAL SERVICES • RISK MANAGEMENT IN FINANCIAL SECTOR
HUMAN CENTERED ASSETS
• DOMAIN EXPERTS • FUNCTIONAL EXPERTS • KNOWLEDGE CODIFIERS • ICT PROFESSIONALS
TANGIBLE ASSETS
• HARDWARE • SYSTEM SOFTWARE • APPLICATION SOFTWARE

grouped under Human Centered assets. The elements needed for the process of their business activities are considered as tangible assets.

Role of Core Team

While understanding the importance of human-Centered assets, it would be apt to recall the observation of Arnold Kransdorff (1998) on sustaining internal knowledge: "One of the first things to do is to create a simple 'KNOWLEDGE MAP' that identifies an organization's key individuals whose functions and experiences are considered important for the smooth running of the business. In identifying them, the broad rule of thumb is: would we be in trouble if these people fell under a bus? (PP33). The role of Domain experts is to provide inputs for creating database in their areas of business activities at ROA software Ltd i.e.; Portfolio services, Financial services and Risk management. Their inputs will be based on their knowledge and experiences in their areas of specialization. The functional experts will explain the procedures, methods and practices followed in the above business activities and stored in a database. The Core team has decided the employees who are in the middle level management will be designated as knowledge workers. The core team has insisted that all interactions among the knowledge workers, Domain and Functional experts should be stored in a database by using Groupware software. Further the core team selected a group of knowledge workers who have created impact in their area of work have been given the responsibility as knowledge codifiers. ICT Professionals would design a system on the basis of the inputs provided by the other members of the core team. This design is termed as ROA Knowledge Harvesting System.

Figure 1. ROA knowledge harvesting system



System Software for ROA Knowledge Harvesting System

Information Technology is providing many concepts to face the new realities in the present business scenario. Data warehouse and Groupware are among a number of other concepts provided by information technology. Data mining is a software tool needed to make use of Data warehouse. The core team has decided to make use of the above software.

Data Warehouse

There are different definitions of Data warehouse. The essence of these definitions is extraction of the data from the legacy systems in enterprises, integrating it with the external data for analysis purpose. It can be inferred that the purpose of Data warehousing is (1) To slice and dice through data (2) To ensure that past data is stored actually (3) To provide one version of data (4) To operate analytical purpose and (5) To support the decision process. It may be noted that data warehouse is a central store of data that has been extracted from operational data.

Groupware

While describing the groupware applications Kate Ehrlich (2001) says: "Groupware Applications provide computer support for group work. At a general level, group work includes written and spoken communication, meetings, shared information and coordinated work. Some group work occurs where people interact with each other at the same time (SYNCHRONOUSLY). Face-to-face meetings are an example of people working together at the same time and often in the same place. People can also work together at different times (ASYNCHRONOUSLY). Where people leave messages in electronic mail, the communication occurs over a period of time. (PP138).

Data Mining

While explaining about Data mining PIETER ADRIAANS and DOLF ZANTINGE (1996) say that there is confusion about exact meaning of the terms 'DATA MINING' and KDD (Knowledge Discovery in Databases) among many authors and they regard them as synonymous (PP 79 – 81). At the first international KDD conference in MONTREAL in 1995, it was proposed that the term 'KDD' be employed to describe the whole process of extraction of knowledge from data. In this context knowledge means relationship and patterns between data elements. It was further proposed that the term 'Data mining' should be used exclusively for the discovery stage of the KDD process. While talking on KDD process they observe four types of knowledge can be distinguished. They are:

- **Shallow knowledge:** The information can be easily retrieved from databases using a query tool such as Structured Query Language (SQL)
- **Multi-Dimensional Knowledge:** The information that can be analyzed using online analytical processing tools.
- **Hidden Knowledge:** The data can be found relatively easily by using pattern recognition or machine learning algorithms
- **Deep knowledge:** The information stored in the data warehouse can only be located if we have a clue that tells us where to look. It is interesting to note the example given on 'CUE' in knowledge in organization by John Sparrow (1998) who says how courts have tried to formulate definitions of retrieved cues. In legal theory anything that actually refreshes a witness's memory may be used (PP171-172).

ROA Knowledge Harvesting System

Fig 1 –ROA Knowledge Harvesting System gives an overview of the system created by ICT professionals. The knowledge codifiers will coordinate and organize to codify the data from the three databases and store them in Intellectual Capital Repository. Data Warehouse software is used for Intellectual Capital Repository and Knowledge Harvesting System.

The intellectual asset repository is developed from Domain experts' data, Functional experts' data, and data from Groupware applications. This repository is the result of the application of Human centered assets on intangible and tangible assets at ROA software Ltd. The knowledge harvesting system is created by using the Software Tool (Data mining) on Intellectual Capital Repository.

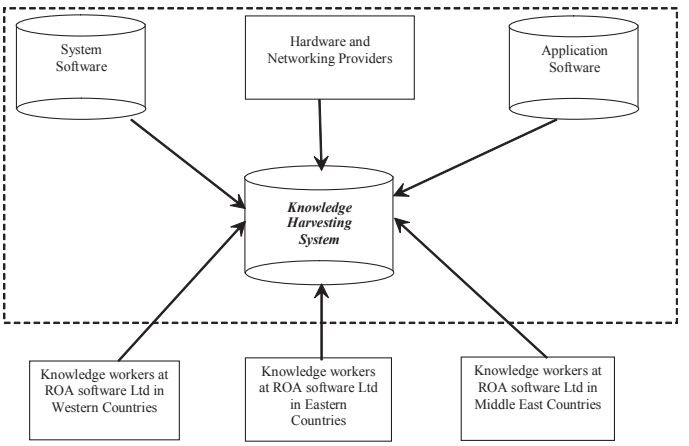
IMPORTANCE OF ROA KNOWLEDGE HARVESTING SYSTEM

The knowledge harvesting system developed at ROA Software Ltd is to facilitate the knowledge workers to understand the business process, procedures, discussions and decisions in their business activities. This system is the result of their knowledge coders who have strong ideas about knowledge to be grouped, classified and defined in their Intangible assets such as Portfolio Services, Financial Services and Risk Management in Financial Sector. The knowledge workers will tend to explore the knowledge in the system in terms of how it can be related in the context of their business activity. Further this system illustrates how business, ICT and human elements are integrated. This system ensures ROA Software Ltd to face the complex situations in the present globalization scenario.

GLOBALISATION SCENARIO

It may me noted that the concept of globalization has created virtual organizations. Further business requirements are also changing at rapid phase. Likewise ICT is also emerging with new concepts with an increase in computing power

Figure 2. ROA resource model



and communication capability. 'Grid Computing' is one more emerging concept provided by ICT. Virtual organization and Networking are the main elements in Grid Computing.

This concept has helped ROA Software Ltd making use of their intangible and tangible assets, and human centered assets across the globe. The knowledge workers have taken advantage of time difference for making use of the resources available at their offices in the respective countries. It enables them in minimizing capital and operational expenditure. The Fig 2 – ROA Global Resource Model explains how the resources at ROA Software Ltd are being used by their knowledge workers from their respective countries. This model facilitates to control and coordinate resources sharing and problem solving among knowledge workers across the countries of their operations. Sharing of resources range from simple file transfer to complex and collaborative problem solving among knowledge workers at ROA Software Ltd. The enormous competitive pressure in the International Market the knowledge workers at ROA Software Ltd can get, is advice and guidance for decision making from the human centered assets from any part of the world through this model.

CONCLUSION

Knowledge Harvesting System is not a Centralized database that contains all the information known by an organization. Business insight comes from capturing knowledge and giving it greater meaning through its relationship to the other information in business enterprises. ROA Software Ltd has illustrated how Knowledge Harvesting System can be developed applying Human Centered Assets in an organization from Tangible Assets. The important elements such as Market Assets and Intangible Assets are described as focal area on which the entire ROA Knowledge Harvesting System relies. It is interesting to note the observation of George Friedman, Meredith Friedman, Colin Chapman, John S. Baker Jr. (1997) who say that: "The core decision in every intelligence project is: How much time do you want to buy – where do you want to be on the knowledge curve?" (PP53).

Information Technology Outsourcing: An Institutional Theory Approach

Abhijit Chaudhury, Bryant University, 1150 Douglas Pike, Smithfield, RI 02917; E-mail: achaudhu@bryant.edu

ABSTRACT

The study explores factors contributing to adoption of information technology outsourcing (ITO). The focus is on adoption of ITO as a management innovation. The research model is motivated by institutional theory. The model posits that it is the fit among two factors that determines the adoption rate of ITO services: (1) institutional profile- propensity to adopt by a firm is influenced by factors such as prestige level of the firm, educational level, support from senior management and firm size; and (2) field level characteristics such as intensity of competition, density of inter-firm connections, service professionalization, skilled staff availability, knowledge codification in the field, and effort level by intermediaries in promoting legitimacy of ITO.

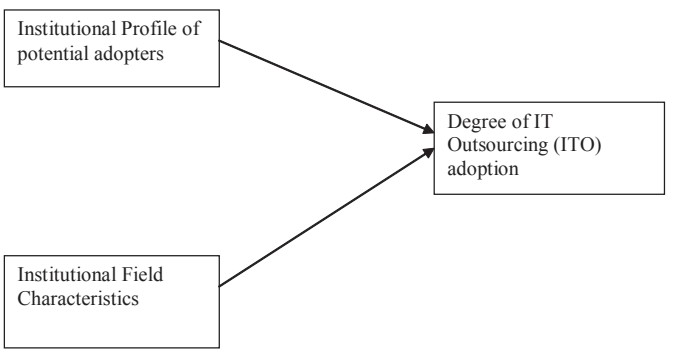
1. INTRODUCTION

Information technology outsourcing (ITO) is the contracting of a specific business task relating to development and management of IT to a third party service provider (Yourdon 2004). The service provider is then responsible for the day-to-day development, management, running and maintenance of the delegated task. The study investigates factors contributing to adoption of ITO. The research model is based on institutional theory (Scott 2001). In the paper, ITO is viewed as a management innovation that incorporates new procedures and routines in the management process (Hamel 2006).

The focus of this research is on adoption of ITO as a new idea. Our model (Figure 1) posits that it is the fit among two independent variables that determines the adoption rate of an innovation- the dependent variable. The two factors are:

1. Institutional profile: Damanpour (1991) listed following positive characteristics- size, professionalism, and specialization. Institutional theory has emphasized prestige level of firms (Sherer and Kyungmook 2002) and CEO background as crucial variables (Scott 2001).
2. Institutional field level characteristics such as competitive intensity, density of inter-firm connections, information flow, and the role of intermediaries such as professional associations, and consultants in promoting the legitimacy (DiMaggio 1991) of ITO as an institutional norm.

Figure 1. The basic model



The rest of the paper is organized as follows. In the next section, we discuss the issue of ITO as a form of management innovation. In section 3, the issue of institutional profile of a potential innovator is discussed. Section 4 outlines the institutional field level characteristics that are relevant for ITO adoption. Finally, we conclude in section 7.

2. ITO AS A MANAGEMENT INNOVATION

Afuah (2003) describes innovation in the context of for-profit firms as "the use of new knowledge to offer a new product or service that customers want". Similarly, according to Porter (1990, pg 780), innovation for for-profit firms is "a new way of doing things that is commercialized". In a more general vein, innovation for organizations has simply been defined as, " the adoption of ideas that are new to the organization" (Downs and Mohrs 1983). Rogers (2003, pg 12) provided a more general definition of innovation in the context of both individuals and organizations as "an idea, practice, or object that is perceived as new by an individual or other unit of adoption."

Hamel (2006) in a current article defines management innovation as a "marked departure from traditional management principles, processes, and practices or a departure from customary organizational forms that significantly alters the way management is performed. Put simply, management innovation changes how managers do what they do". In the context of firms in the western countries, outsourcing strategic IT services (such as new systems development) and functions (such as IT infrastructure management relating to networks and data services) to service providers from developing nations is a departure from what managers are wont to do. Role and responsibilities of managers alter considerably as important elements of management are farmed out to third party vendors abroad. In the context of this paper, outsourcing of services is taken as a form of management innovation on the part of firms as institutions.

3. POTENTIAL INNOVATOR PROFILE OF ITO CLIENTS

In institutional theory, institutions are patterns of social behavior (Breit and Troja 2003). In social sciences, patterns of interest are social norms, routines of behavior, legal regulations and distributional systems of power and resources (Breit and Troja 2003). In this paper, the terms institutions and organizations are used interchangeably.

A basic tenet of institutional theory is that institutions seek "legitimacy" in the eyes of both internal and external stakeholders (Parson 1960). Institutional theory attempts to explain why institutions of the same type, "such as schools and hospitals, located in widely scattered locales so closely resemble one another?" (Scott 2001). A key concept here is that of isomorphism- resemblance among institutions in terms of structures (DiMaggio and Powell 1983). Considerable evidence of such isomorphism has been provided by Slack and Hinnings (1995).

The theory has mostly focused on the "movement towards, and maintenance of, isomorphic institutional environments". Focus on institutional evolution and change has been weak (Powell 1991). However recent studies on birth, evolution, and diffusion of new institutional norms in the business sector have tried to mitigate this (Greenwood et al. 2002, in business services). Even though mimetic, coercive and normative forces drive institutions towards isomorphism, not all organizations in a field are alike.

Kondra and Hinnings (1998) provide a typology of institutions based on their degree of fit and institutionally defined performance norms. Their typology consists of: institutional operators, equifinalists, renegades and dogs.

- Institutions that have a high fit with both norms of operations and performance levels are called "institutional operators". Much of a field is likely to be populated by institutional operators.
- Institutions that operate differently but have performance that are within norms prevalent in the field are called "equifinalists".
- Institutions that are performing well above institutional norms are called "Renegades"
- Institutions performing below institutional norms are called "dogs". Dogs are likely to be weeded out due to lack of legitimacy in the field and are not likely to have any impact on institutional norms. There is no incentive to mimic these organizations.

Renegades according to Kondra and Hinnings (1998) are firms that are performing well above institutional norms. They may include firms that are new entrants to the field, and are able to have a novel operational model as they have not been subject to forces of isomorphism for long. They could also be existing firms that have deviated from norms knowingly (active agency) or unknowingly (passive agency). Organizations that are weakly bound to field norms are more willing to risk transgression of norms and operate in a manner that allows superior performance.

In organizational innovation literature, Rogers (2003, 411) describes organizational innovativeness as a dependent variable dependent on independent variables such as leader characteristics, internal characteristics of an organization such as size, complexity, and similar factors. Our model for predicting organizational propensity to innovate in the managerial field is shown in figure 2.

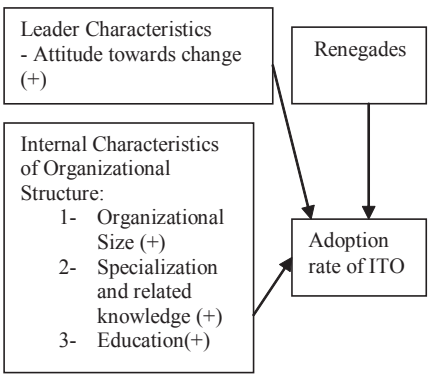
Renegades
By definition, firms that are star performers are likely to be "renegades" as their performance level is above field level norms.

Proposition 1a: Renegade firms are more likely to adopt outsourcing than non-renegade firms, and in turn act as exemplar for others in the institutional field.

Leader's Characteristic: Attitude Towards Change
IS research literature is replete with evidence that top management's support is crucial for technology adoption (Chatterjee et al. 2002).

Proposition 1b: More positive the attitude of top management towards outsourcing, greater the potential adoption rate of ITO related services .

Figure 2. Institutional profile variables related to adoption rate of ITO



Organizational Characteristics—Organizational Size
Mahler and Rogers (1999) found that organizational size, revenue, and people employed are positively correlated with telecommunication technology adoption. Sherer and Lee (2002) show that large law firms are more likely to adopt innovative HR practices.

Proposition 1c: Greater the organizational size, greater the potential adoption rate of ITO related services .

Organizational Characteristics—Specialization and Knowledge Diversity
Kimberely and Evanisko (1981) ascribe innovativeness of organizations to specialization in related activities.

Proposition 1d: Greater the specialization and knowledge employees have related to outsourcing, greater the potential adoption rate of ITO related services.

Organizational Characteristics—Education
Pierce and Delbecq (1977), and Fichman (2001) relate education to professionalism and thereby to ability to innovate.

Proposition 1e: Greater the employee education and training level in the firm, greater the potential adoption rate of ITO related services .

4. INSTITUTIONAL FIELD CHARACTERISTICS

There are three levels of analysis in institutional theory (Chiasson and Davidson 2005). Lowest level is that of a single institution. That is the main focus of institutional theory. The second level is that of population, which is a set of similar institutions that is entities that "produce similar products and services, operate is similar environment, share systems of meaning, and take actions that are influenced by shared normative, cognitive and regulatory structure" (Scott 2001). Then we have the level of institutional field which "includes those organizations that in the aggregate, constitute a recognized area of institutional life; key suppliers, resources and product consumers, regulatory agencies and other organizations that produce similar services and products" (DiMaggio and Powell 1983).

The field constitutes an environment, a material environment and an institutional environment. The material environment and also called the technical environment, provides (Chiasson and Davidson 2005, Scott 2001):

- demand side factors such as complexity, and variation in demand for product and services,
- the supply-side factors provide factors such as scarcity and concentration of key inputs,
- technologies provide skills and knowledge to produce outputs, including material technologies and
- market structure that includes alignment of suppliers and customers that influence flow of resources.

The institutional environment provides (Chiasson and Davidson 2005, Scott 2001):

- Institutional logic, that is, organizing principles underlying practices and belief systems.
- Institutional actors, which includes individuals and organizations that create and enact belief systems
- Governance systems, the system of regulatory and normative control

DiMaggio (1991) characterizes institutional fields in terms of dimensions related to professionalization (Larson 1977), and dimensions related to structuration (Giddens 1979). In terms of professionalization, Dimaggio (1991) listed factors such as (i) creation of body of knowledge, (ii) organizations of professional associations, and (iii) consolidation of a professional elite. He used these factors to demonstrate how the Carnegie Corporation facilitated the development of the organizational field of U.S. Art Museums.

More recently, we have IBM promoting the concept of service and process management and helping universities such as North Carolina State University

to come up with the first MBA program in the field (http://www.mgt.ncsu.edu/news/2006/mba_ssme.php dated 01/31/2006). One of the major sub-field in the proposed area is that of managing vendors engaged in outsourcing activities- "emphasizing the management of relationships between service providers and their clients". IBM had similarly helped consolidate the subject of Computer Science in 1960s, helped develop their many professional associations and encouraged universities to provide degrees in the subject and thus populate the professional world of computer science. This professionalization helped in legitimation of the subject and its subsequent widespread use in sciences, businesses and engineering (previous web site).

Proposition 2a: Creation of a body of knowledge, organization of professional associations and consolidation of a professional elite in the field of IT outsourcing will help in legitimation of the subject and its correspondent institutional forms, which in turn will promote its diffusion.

Motivated by Giddens (1979), DiMaggio (1991) suggested following structuration variables impact the development of an institutional field and its subsequent impact on institutional members: (i) density of inter-organizational contacts, (ii) rate of flow of information, and (iii) emergence of a center-periphery structure. Coleman (1939), showed how increasing contact among member museums led to smaller museums adopting professional methods. Lawrence et al. (2002) and Phillips et al. (2000) show the importance of information flows in fields for institutional effects to occur.

Proposition 2b: Increasing density of contacts, information flow and emergence of center-periphery structure leads to an institutional field exercising more influence on its members in the field of ITO adoption.

Following are the institutional actors in the material environment (Scott 2001) that are of interest to us:

1. Competitors and Customers
   Haveman (1993) and Clemons (1990) point to imitation effect in firm behavior in the airline and banking industry.

Proposition 2c: Greater pressure and influences from competitors and customers will leads to greater adoption rate of ITO services.

2. Suppliers and vendors
   Burt (1982) and Markus (1987) point to pressures from dyadic channel. Teo et al. (2003) find effect of suppliers on a firm's intention to adopt inter-organizational systems.

Proposition 2d: Greater assistance and influence from outsourcing suppliers and vendors will lead to greater adoption rate of ITO services.

3. Government Agencies and Trade Associations:
   King et al. (1994), and Teo et al. (2003) find evidence that participation in industry, trade associations and with government sanctioned bodies constitute pressure on a firm.

Proposition 2e: Greater positive influence from mass media, professional networks, and government agencies will lead to greater adoption rate of ITO services.

5. CONCLUSION

The purpose of this study is to explore factors contributing to adoption of ITO outsourcing (ITO) by firms in western countries. The focus is on adoption of ITO as a management innovation. The research model is motivated by institutional theory (Scott 2001).

The model posits that it is the fit among two factors that determines the adoption rate of ITO services: (1) innovator profile- propensity to adopt by a firm is influenced by factors such as prestige level of the firm, educational level, support from senior management and firm size; and (2) field level characteristics such as intensity of competition, and density of inter-firm connections, and effort level by intermediaries in promoting legitimacy of ITO, professionalization of outsourcing services, availability of managers skilled in ITO vendor management and knowledge codification in the field.

The ITO vendor community has a major role to play in enhancing popularity and legitimacy of outsourcing activity in western countries to third world country vendors. They need to follow IBM's role in this regard. The vendor community should attempt to reduce the initial learning cost in adopting this innovation on the part of customers. There are many steps that the vendor community can take in the country of operations. They can promote courses, programs of study, case studies, and industry projects in the outsourcing field in business schools, universities, and in the training industry. By helping outsourcing management achieve an identity as a subject and specialization, and promoting availability of study and training in the area, they will foster creation of a pool of outsourcing professionals that can be employed in both customer and vendor side. Easy availability of trained staff in outsourcing area will help in reducing initial adoption costs. Availability of courses, seminars, books and cases will lead to outsourcing activity getting legitimized within the community, and thus promoting its acceptability and popularity. ITO vendors are also advised to recruit sales staff from the community they will be selling to, as this will help overcome the initial reluctance on the part of firm owners and managers to deal with people with different cultural background.

ABSTRACT

Information Lifecycle Management (ILM) stores files according to their value. Therefore file valuation is a very important task in the ILM environment. In this paper we look at how the value of a file can be measured. Instead of traditional methods leading to a classical decimal-value, the method presented leads to a valuation in terms of a "probability of further use". Feasibility of the new method is verified using an ILM simulator.

1. INTRODUCTION

ILM is based on the idea that in an enterprise different information have different values. Valuable information is stored on systems with a high quality of service (QoS). The value changes over time and therefore migration of information is required to cheaper storage systems with a lower QoS. Automated migration makes ILM dynamic. Such automation requires storage systems to understand what files are important at what time so that right policies can be applied. In this point ILM nowadays lacks information valuation methods and tools.

The question is "How is the value of a file measured?". Storage Network Industry Association (SNIA) proposes measuring the value as an amount of money [1].

Other methods express the value as a decimal-value [2]. In section 3 we show how this type of value can be derived from a set of metadata. This method of valuation depends on different factors and has to be defined accurately. Obtaining metadata is not always easy or even possible. Therefore in section 4 we abandon metadata and show how the value can be derived using a probabilistic method. Here the value of a file is calculated from usage information and expressed as a probability of further use. This is a new method which allows valuation depending on the future importance of a file. Section 5 proves the capabilities of the new method using an ILM-simulator. Section 6 applies and combines both methods. The paper ends with a summary and an outlook on our future work.

The essence of this paper is as follows:

1. We present a new method of file valuation
2. We show that this probabilistic method works for ILM systems
3. We combine the new with an "old" method to optimize the performance.

2. RELATED WORK

Usage information is used for valuation in other system domains as well. Google uses PageRank algorithm to rank the importance of a web page [3, 4]. A page is ranked based mainly on how many other pages are linked to it. Such links represent a form of usage. They indicate how many other pages are using that particular page. Caching algorithms often rely on data usage information to determine what data are important and hence what to cache in buffers in file systems, databases, and storage controllers [5, 6, 7]. These algorithms cannot be directly applied to our problem due to different design purposes and different target data.

Usage was the focus of Strange, too, who examined the long-term access behaviour on files in an UNIX system [8]. His aim was to identify regularities and patterns which can be applied to automated migration strategies for Hierarchical Storage Management (HSM).

Schmitz has also analyzed the access behaviour of files on a supercomputer to be able to derive an optimal migration strategy [9].

Miller and Gibson examined the access behaviour in further studies in UNIX environments and designed a "file aging algorithm" as a migration rule [10].

The self-* storage system at Carnegie Mellon University aims to automate storage management tasks through self-managing techniques [11]. It describes how one can classify files based on the automatic learning of file properties using decision tree algorithms.

Chen focused on the file valuation for ILM. He erects value classes which are characterized by a unique set of attributes [2]. The valuation leads to a decimal value which can be normalized to the interval [0;1].

In contrast to other work the valuation presented in this paper offers a percent value. It demonstrates how great the probability of future accesses on a specific file is. Based on the percent value an ILM system can migrate files when their access probability falls below a predefined threshold.

3. FILE VALUATION USING METADATA

Metadata are data that describe other data. Therefore, in general, for accurate valuation the more metadata is useable the better the valuation will be. Relevant, but not limiting, factors for ILM are [12]:

- Legislation
- Cost
- User
- File size
- File type

This list could be extended to factors representing the value of knowledge and intellectual properties [13, 14]. These business focused valuation methods require intense human interaction and organizational support. Hence they are often hard to implement.

The five factors mentioned above have different characteristics. For example, some are steady others are discrete, some are string variables others are real variables.

To obtain the information a form has to be filled in. This needs human interaction and makes it difficult and expensive to receive the metadata. Nonetheless we discuss the parameters represented as a mapping which can be implemented into an online form. We will now consider each factor.

Legislation: Each file in an enterprise has its own file retention period. In Germany the period can vary between 0 and 10 years. In the American healthcare environment, for example, the period can be up to 100 years [15].

Let L(F) be the file retention period of file F determined by legislation. L(F) is a discrete function:

$$L(F) : F \mapsto L(F) \in \{0,1,2,5,10\} \subset N_0$$

Cost: Each file is important for the enterprise. Its importance is related to the cost originated from the absence of this specific file. Business importance is expressed in a currency (e.g. Dollar or Euro). Either the real value or a relative value is used.

Real values are difficult to obtain. Here the relative value is used. The value might vary between 0 and 10.000.

Let C(F) be the cost originating from the absence of file F. C(F) is a steady function:

$$C(F): F \mapsto C(F) \in [0;10.000] \subset R_0^+$$

User: Each file is intended to be used by specific users within the enterprise. If this factor is to be used for valuation, the users' importance is distinguished between "low", "medium" and "high".

Let U(F) be the intended user group of file F. U(F) is a discrete function:

$$U(F): F \mapsto U(F) \in \{low,\ medium,\ high\}$$

File size: The size of a specific file can be used as a factor for valuation, too. The intention is to reduce the needed space on the expensive storage hierarchies. Therefore there is a special focus on large files which represent a great capacity-saving potential. The file size is finite and varies between the values "small", "medium", "big" and "very big". Depending on the enterprise the thresholds are set, e.g. between "big" and "very big" it can lie at 1MegaByte or much higher [9].

Let S(F) be the size of file F where S(F) is a discrete function:

$$S(F): F \mapsto S(F) \in \{small, medium, big, very\ big\}$$

File type: The file type is determined by the application. In the office environment the most common file types are, for example, "doc", "xls" and "ppt".

A case study conducted in 2004 at an enterprise database identified 21 different file types with the following composition [16].

Let T(F) be the file type of file F where T(F) is a discrete function:

$$T(F): F \mapsto T(F) \in \{doc, xls, ppt, pdf, rest\}$$

Depending on the enterprise other file types like e.g. "jpg" or "mpg" can be assigned, too.

The five factors are summarized to a vector to derive the value of a file. Let V(F) be the value of file F where V(F) is an n-dimensional function (here n=5). It takes into consideration the factors "legislation", "cost", "user", "size" and "type" and determines the value as a decimal figure. The value is used to assign the files to the different hierarchies in an ILM environment.

$$V(F): F \mapsto V(F) =$$
$$V(L(F)\ C(F)\ U(F)\ S(F)\ T(F)) \in R_0^+$$

Currently V(F) is only a theoretical mapping. The definite procedure to derive the value from the vector consists of transformations and normalizations. First the string variables (U(F), S(F) and T(F)) are transformed to real variables. Then the real variables are normalized to [0;1].

At the end the n-dimensional vector is reduced to a one-dimensional figure. This might happen by simple actions like:

$$V^* := \max\ \{L^*, C^*, U^*, S^*, T^*\}^1 \in [0,1] \text{ or}$$
$$V^* := \text{mean}\ \{L^*, C^*, U^*, S^*, T^*\} \in [0,1]$$

This shows that the valuation using metadata works. The advantage of this type of valuation is that no history information is needed. On the other hand, this procedure is neither easy nor cheap.

4. FILE VALUATION WITHOUT METADATA

Instead of metadata we now uses usage information for the valuation process. This procedure results from one of the most intuitive metrics for file valuation "if a file is not used for a long time, it is not valuable".

In a case study on a database we provided following results [16]: There were more than 150,000 files on the system and 89 percent of them were not accessed 90 days after creation (see figure 2).

The intuitive method for valuation would lead to the following policy:

"A file is valuable if it has been accessed during the last 90 days and not valuable otherwise."

This is a simple way of measurement and one often used in HSM (Hierarchical Storage Management) solutions. It demonstrates that a simple history-based valuation without metadata has a wide-spread acceptance.

Nonetheless this method does not fit to ILM because it only focuses on time limits and not whether the file is needed in the business process which is the intention of ILM [1].

Figure 1. Distribution of file types

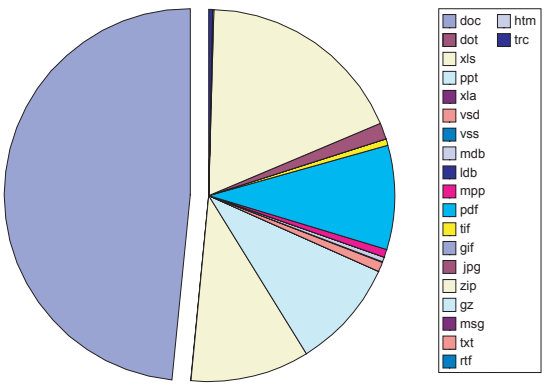

Figure 2. Access probability

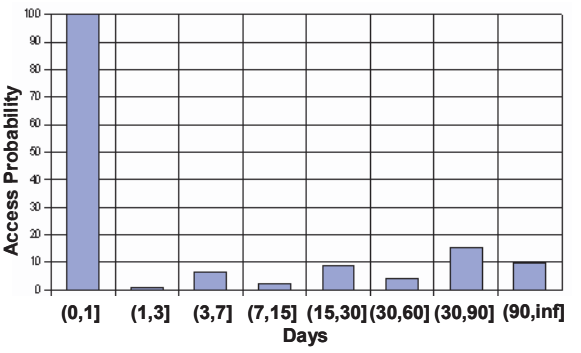

Table 1. Applied distribution functions

Number of accesses / File type	1-6	7-14	15-∞
doc	W(0,35;3,5)	G(0,32;183)	W(0,35;3,5)
xls	W(0,25;1,1)	W(0,25;1,1)	W(0,25;1,1)
ppt	W(0,38;14,3)	W(0,38;14,3)	W(0,38;14,3)
pdf	W(0,35;3,5)	G(0,32;183)	W(0,35;3,5)
other	W(0,46;27,7)	G(0,29;181)	W(0,46;27,7)

4.1 Case Study

We conducted another case study with the intention of obtaining a predictable measurement of whether or the file is needed in the future.

Our aim was to derive mathematical distribution functions for file accesses for several file types.

We took a sample of 1,000 files from a company's database.

Each file was characterized by the number of accesses per file, the size of the files, the size of the accesses, the age of the files, as well as the file types and access methods.

The file types doc, xls, ppt, pdf and zip are contained most frequently in the sample. The file types avi, cfg, csv, cti, dot, exe, gif, htm, jpg, log, mdb, mmap, mmp, mp3, mpg, mpp, pps, pst, rtf, sql, tif, trc, txt, vsd, vss, wav, wbk, wf2 and xml fall into the category "other".

Most accesses to files in the sample, i.e. 46.22 % of 7,911, are of the "version fetched" type. The access types "View" and "Version added" are represented with 19.20 % and 17.60 % at second and third place. Other frequently occurring access types are "Move", "Reserve", "Unreserve" and "Permission changed". The noticeably more seldom access types under "Miscellaneous" are "Attributes Changed", "Rename", "Copy", "Version Deleted", "Alias Created" and "Generation Created".

We derived distribution functions for file accesses in conjunction with the file type and access history [17]. Either the Weibull-distribution (W(α;β)) or Gamma-distribution (G(α;β)) were derived as distribution functions (see table 1).

Using this approach we were able to calculate the future access probability of a file.

The valuation is executed on a percentage basis: "A file is valuable if its access probability is higher than, e.g., 5% and not valuable otherwise".

This is a new quality of valuation using only the file type and the access history. This information is provided by the storage systems and does not need further metadata or user interaction.

5. PROOF OF CONCEPT

We implemented a simulator to analyse that the valuation based on "percentage of further accesses" can be used for ILM. Figure 3 shows an example using 5 hierarchies observed over 4,000 days. The lifecycle is illustrated graphically for one single file.

In figure 3 you can see that between day 1,300 and day 1,500 after generation of the file the access probability sinks remarkably. Therefore the file is moved to the lowest storage hierarchy in several steps. After approximately 1,800 days the file is accessed so that it must be shifted to the highest storage level again.

After about 3,800 days the information is again at the lowest level. The lifecycle follows the typical course of a file with a periodical access sample.

A graphic evaluation does not make sense for the simultaneous analysis of several files. Therefore examination of the relative capacity-need per hierarchy has to be performed.

Figure 4 depicts how an ILM system with 3 hierarchies and the described valuation works.

Figure 3. Migration of a file according to its value measured in "% of further accesses"

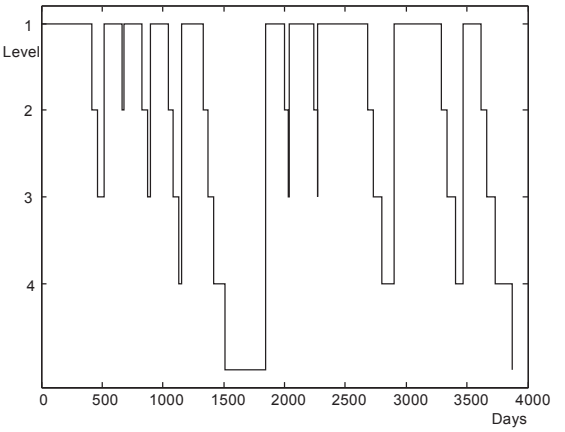

Figure 4. Relative capacity-needs in a 3-dim. ILM system

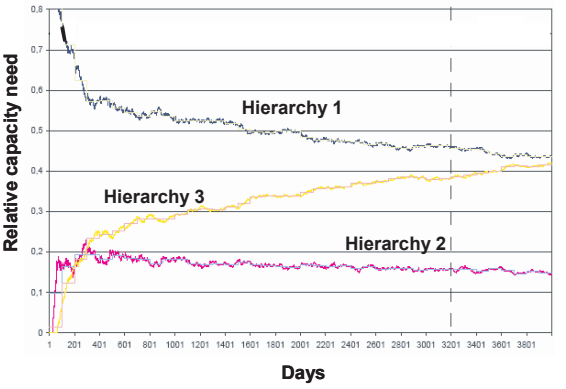

Since the method looks at the access history, it needs some time to stabilize the capacity-need in an ILM system.

6. COMBINATION OF THE DERIVED VALUATION METHODS

When metadata is available, it is advisable to use it in combination with the probabilistic method. Since the effort in dealing with metadata is quite high, it is advisable to use metadata only for the initiation of an ILM scenario.

There are two options for initiating an ILM scenario (see figure 5):

Option 1: Store all files on the highest hierarchy at the beginning.
Option 2: Valuate all files and presort them into the related hierarchy at the beginning.

Option 1 does not require metadata, of course. The files are stored in the highest hierarchy. Their valuation is done on the basis of file access patterns during the ILM process as shown in figure 4.

The advantage of option 2 compared to option 1 is that the capacity need for hierarchy 1 is below 100% from the beginning. This means that money is saved earlier on.

Figure 6 shows a simulation run in which the files were presorted according to option 2.

We notice that presorting has positive effects on reaching system stability.

Figure 5. Starting options in an ILM system

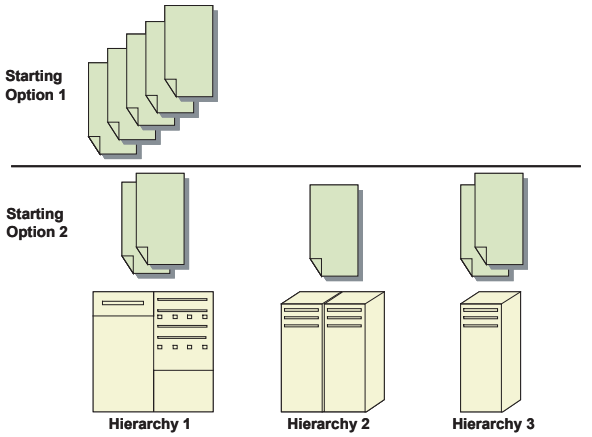

Figure 6: Relative capacity-needs in a presorted 3-dim. ILM system

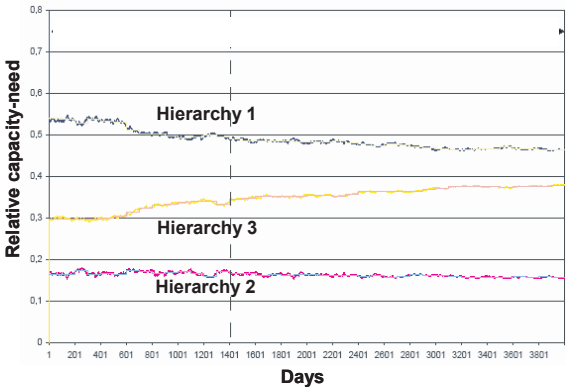

7. SUMMARY AND OUTLOOK

Proper information valuation is the first step towards ILM automation. Existing valuation methods either use metadata or look at the history and generate a value in terms of "amount of dollars" or "a decimal figure within an interval".

We demonstrated that the future access of a file can be predicted from observed access data and that this can be used as a metric for file valuation.

The value of a file is its percentage of further accesses. This is a new way of valuation. The advantages are that it is simple, does not need metadata and fits to ILM automation. Furthermore it is more sophisticated than the simple HSM-time-limit approach.

Application of the new method was shown by means of an ILM simulator. Therefore the first step towards automation is done.

Since the method looks at the access history, it needs some time to stabilize the capacity-needs in an ILM system.

This period can be shortened by presorting the files over the hierarchies. We showed that in combination with an initial valuation according traditional methods using metadata earlier cost gains in ILM-systems can be achieved.

In our future research we will continue to look at ILM automation. We will focus on the aspect of policy definition. In order to compare different policies, the existing simulator will be optimised.

Enhancing User Interactive Experience Through Diasporic Reception

Pai-Ling Chang, Vanung University, 6F, No.110, Alley 77, Sec.4, Hsin-Hai Rd., Taipei, Taiwan 116; E-mail: plchang66@yahoo.com.au

ABSTRACT

This paper focuses on the notion of interactivity and how ideas from outside the field of interaction design can expand the understanding and application of interactivity. Interactivity is generally seen as the user's ability to easily access information. For certain writers and practitioners, however, the idea of interactivity extends to user's capacity to shape content and meaning to extend the range of experience in digital media contexts. Using a combination of theoretical discussion, the research explores the second perspective, proposing a mode of interactivity that supports user's capacities for reflexivity and intervention. In the wake of poststructuralism, computer and digitally networked technologies are seen to challenge traditions of stable, a priori authorship by allowing users to construct meaning from the range of available content. Anthony Giddens's writings on human reflexivity support the idea of the 'knowledgeability' of human agents, that is, their capacity to understand the nature of their circumstances and to act upon them. Theories of diasporic reception argue that visualities produced by diasporic individuals reveal critical reflexivity in the mixing of cultural meanings and materials. The research draws on these ideas to suggest the importance of allowing users to experience autonomy, agency and self-determination in digital media contexts.

Keywords: interactivity, digital media, knowledgeability, diasporic reception, agency

INTRODUCTION

Most new media programs promise a high level of interaction and a richness of experience, ranging across animation, graphics, music, sound, text and video. The concept of interaction covers the connection between interface, content, computer and user. Implicit in its meaning is the idea of reciprocal exchange between users and content, suggesting that one will have an effect on the other and vice versa. For the majority of digital media designers, however, successful interactivity comes when design elements enhance browsing experience and access to content. According to Carrie Heeter, for example, design should make interaction an easy rather than a difficult process (Heeter 2003). Although clarity of meaning, accessibility and ease of use are important elements of interaction design perhaps the real promise of interactivity lies in its unpredictable dimensions. Interactivity can represent an open, creative process of content engagement. Navigation systems, for instance, should not force users into a path-following, choice-making state of mind. This represents a loss of self and limits the range of unfolding, on-screen possibilities. By contrast, Nathan Shedroff contends that the ability to formulate new content or new ways of interacting with content is critical to adding a creative dimension to the interactive experience (Shedroff 1999). As technology develops it is likely that many more dimensions of interactivity will become available, allying multimedia products more closely to human creative and conceptual capacities. Moreover, the pace and scale of change in information and communication technologies, combined with the possibility and complexity that comes with media convergence, suggest that although the nature of future technology resists prediction, designers must constantly reflect on their approach to interaction if they wish to harness design to emerging technological capabilities and human needs.

Presently, the fields of usability testing and computer studies, especially Human Computer Interfaces (HCI), dominate investigations into interaction and interface design, using empirical methods to understand user's reactions to interface design and to test the effectiveness of specific products. These fields favour the stringent analysis of phenomena without the intrusion of enquirer's subjective judgments. The rise of scientific methodology in modern, technocratic society has given rise to the tendency to dismiss anything that cannot be open to empirical scrutiny, including aesthetic principles, emotional responses and taste preferences. The broad consequences of this have been the creation of putative rules for interaction design, which insist that designers keep things as simple as possible in the design of the graphical user interface (GUI). Recently, designers including Nathan Shedrofff and John Lenker have advanced the idea of 'experience design', arguing that for design to be effective as mass communication it must offer more than simple, practical approaches to the presentation of information in a digital context by satisfying audiences at an aesthetic, emotional and social level (Lenker 2002). Designer's capacity to invent alternative models of interaction and interface design could open up new possibilities in the use and experience of information technology in an age where knowledge is a vital commodity and society regards the capacity to identify, create and apply useful knowledge as crucial skills.

In seeking to understand the potential of interaction design it is vital not to simply fix and control it, thereby limiting the range of human experiences and capacities in the digital realm. This paper explores how interaction design can create the conditions which allow individuals to experience new levels of engagement with content, shifting the focus from path finding and selection to the user's ability to create content and meaning. It brings multi-disciplinarity to the discussion of interaction design, believing that to develop new design possibilities it is necessary to 'think outside the box' and challenge existing paradigms. Although interactivity should continue to provide effective paths and comprehensible information structures it should also prioritize models that generate meaningful experiences and empower users.

INTERPRETATIVE AUTONOMY AND DIGITAL MEDIA DESIGN

My interest in the interpretative autonomy of users evolved from the idea that audiences, rather than senders, construct meaning. According to Roland Barthes' classic essay 'The Death of the Author', writing transcends the author, focusing on the reader's response, rather than the author's intentions. (Barthes 1977). A founding statement of postmodernism, 'The Death of the Author' overturned common understanding of cultural texts by encouraging open interpretation. Barthes' essay encapsulated many ideological dimensions, arguing that an author is not an integral "person" but a subject, constituted through society and history, which does not exist, outside language. He maintained it is writing—itself a product of society, history and ideology—that makes the author. On this point, Barthes wrote, "The writer can only imitate a gesture that is always anterior, never original. His only power is to mix writings ... in such a way as never to rest on any one of them" (Barthes 1977). Many see the interactive hypermedia environment as realizing Barthes' radical agenda, which liberates meaning from the tyranny of singular authorship. A reader's capacity to follow individual paths, through text and information, which do not conform to linear order, mirrors the way reading affects writing; allowing the user to so engage, suggests empowerment.

Poststructuralism sees meaning as generated within language, which symbolically constructs the reality we experience from a storehouse of existing meanings. Judith Butler describes this conception of language as a process of reiteration (Butler 1993). She accepts that in speaking or writing individuals conform to established meanings, and other rules and conventions of language, reinforcing the semantic construction of the world and the speaking subject. While the subject does not create meaning, and is largely an effect of the language practices used when speaking or writing, Butler identifies the possibility that new or changed meanings emerge in the process. For Butler, reiteration incorporates inherent

contextual shifts of meaning through the specific combinations of meanings and the temporal and social context in which reiteration occurs. She argues that the process of reiteration slowly but inescapably changes meanings, resulting in the continual renovation of language as old meanings adjust and new meanings emerge. For Butler the transformation of language derives from the fact that it is a social system in continuous use, the iteration of meaning through time and space molding the sense of things in ways that nobody can control or predict.

Rethinking interactivity involves developing an expanded concept of receptivity in new media communication. British social theorist, Anthony Giddens' 1984 book *The Constitution of Society: Outline of the Theory of Structuration* offers ideas for rethinking the nature and process of interaction, as well its design concepts and strategies. Giddens emphasizes the capacity of social agents for self-reproduction, self-transformation and self-deconstruction (Giddens 1984). His primary contention is that social patterns and structures do not exist, outside of individual agents, who continually reproduce or change them, making them simultaneously enabling and constraining. He emphasizes the active and reflexive characteristics of human conduct, stressing that in modern society, individuals and institutions encompass high reflexivity. Giddens' theory of modernity sees qualities of reflexivity informing the knowledgeability of human agents, monitoring self-action and correcting self-behavior, which depends on consciousness of complex social relations when judging or adjusting actions (Giddens 1984). For Giddens, this was extended to the way we construct ourselves.

Communications studies, which explores the way users negotiate the media of the World Wide Web through hyperlinks, also advances ideas of active readership and user agency, suggesting that browsing behavior should not be viewed as a passive process. For example Joyce (1995) defines hypertext as a medium that 'embodies information and communications, artistic and affective constructs, and conceptual abstractions alike into symbolic structures made visible on a computer-controlled display'. While these qualities may be implicit in the process of negotiating linked content interaction design has a clear role to play supporting users to initiate a whole range of actions, to structure their own paths following their interests, affecting the unfolding of events.

DIASPORIC RECEPTION

So far I have argued that Roland Barthes's idea of the illusory nature of authorship, Judith Butler's idea that iteration inevitably and inexorably shifts meaning, and Anthony Giddens's idea that individuals have the capacities of reflexivity to understand and act upon the structures they encounter in life, suggest the potential for an expanded view of interactivity in new media contexts. Even though these ideas are not addressed to the subject of interaction and interface design they have challenged me to formulate the fundamental proposition of this research, that to fulfill the promise of interactive multimedia (IMM) products should facilitate diverse modalities of meaning and experience.

Feminist, post-colonial and other theories of identity have valorized the critical and imaginative power of decentered subjectivity. Theories of diasporic reception argue that social and cultural context are basic frameworks of meaning, the translocation of cultural materials across boundaries of space, time, race, culture, language and history actively disrupting meaning. For Kate McFarlane, diasporic experience incorporates qualities of syncretic visuality that 'are multiperspectival and frame-breaking and exist in that provisional and productive site of diasporic in-betweenness.' (McFarlane 2004) She suggests that the reading of culture from different temporal and geographic locations involves the grafting and juxtaposing of multiple modes of visuality. In addition, she argues that 'this syncretic diasporic intervisuality often displays, through its intercultural mixing of modes of visuality, an attitude of irony and critique as regards the relations that exist between power, visuality, ethnicity and nationalism.' (McFarlane 2004) The 'multiperspectival' operations of diasporic cultural reception incorporate a reflexive or creative dimension that shifts ways of seeing and reading cultural objects because the subject is inclined to patterns of interpretation and identification grounded in dialectics of past and present, here and there. The reception of cultural texts particular to diasporic negotiations of cultural identity and meaning reflects the increasing fragmentation and dispersal of points of reference in an era of globalization. Julia Kristeva, in fact, argues 'we are all in the process of becoming foreigners in a universe that is being widened more than ever, that is more than ever heterogeneous beneath its apparent scientific and media-inspired unity' (Kristeva 1991).

Structuration theory and ideas of diasporic visuality, that is instances of critical looking bound up in seeing things from a different cultural context, describe orders of reception that go well beyond the basic idea that all cultural materials are intertextual because audiences filter them through their different experiences and cultural literacies. In highlighting the complexity and ambiguity of contemporary subjectivity and the critical dimensions of cultural syncretism, theories of diasporic reception challenge new media designers to accept the protean nature of meaning production while embracing the creative agency of users in new media contexts as something positive. Designers may agree in principle that interactivity should support a range of on-screen possibilities that shift the emphasis away from fixed outcomes and offer users the freedom to explore in ways that liberate the intellect and imagination. However, the fundamental challenge is to create designs that allow users to understand interaction as productive, to think consciously about the relationships between linked materials and to visualize the unfolding contours of what might be produced.

RESHAPING MEANINGS IN DIASPORA AND HYPERMEDIA ENVIRONMENTS

In an age of globalization meaning is inevitably negotiated between cultures. Globalization challenges designers to draw on the diverse sources of knowledge and understanding encapsulated in different cultures in order to expand on general understandings of design. In 1985 Eisner raised the idea of 'aesthetic modes of knowing', seeing creative activity as a form of reflective practice that allowed people to make sense of things. Diasporic visuality may be a prime example of the effects that Eisner writes of, the work of diasporic visual artists revealing a capacity to reconstitute culture and meaning in critical ways. According to McFarlane (2004), 'diasporic visuality involves the deployment of tactics such as syncretism, irony, juxtapositioning and intercultural aesthetic cross-hatching which operate collectively to enact both the specificities of diasporic cultural identity and a cultural politics which challenges exclusionary norms of nationalist subjectivity and culture.' McFarlane sees cultural identity as being reconstituted in ways that escape contemporary cultural structures and understandings because of their complex and dynamic nature. Diasporic visuality is embedded in interpretative processes where individuals and communities attempt to understand their identity by negotiating a path between their present circumstances and their cultural roots. Consideration of this showed it was possible to develop a critical relationship to identity and this became intrinsic to the form and content of the project, which aimed for a much richer experience of interaction based around reflexive ways of seeing, knowing and understanding.

As Butler suggests, the iteration of meaning is a continual occurrence in a culture and society that produces new cognitive positions and fresh ways to conceive the world. For Butler, iterative processes draws attention to the absence of essential, natural or ideal categories of meaning prior to each appearance within a causal chain, suggesting only continual shifts between pre-existing categories and new representations (Butler 1997). Postcolonial theory and theories of diasporic visuality challenge the division of the world into simple opposites. Both emphasize the individual and the cultural diversity of diasporic and colonized peoples, suggesting that while such individuals may stand apart as a group from their colonizers or from original populations, they are different one from each other despite their shared pasts, and should not be seen in a singular sense.

McFarlane argues that diasporic intervisuality can produce ironic outcomes, critically reflecting on the relationships between power, visuality, ethnicity and nationalism (McFarlane 2004). The dimension of 'play' challenges traditional ways of seeing and reading in digital media environment, positioning the user as an active producer of content. For McFarlane, diaspora can be experienced both as a dynamic tension and as a space of opening in which issues such as the narratives and visualizations of nation and the politics and stylistic consequences of diasporic interventions into cultural practices can be explored (McFarlane 2004). The potential of interactive multimedia to facilitate multiple viewpoints, double consciousness, differential pathways and in-betweenness is high if designers move beyond the current paradigm of clear communication and efficiency of use, replacing hierarchical patterns of use defined by the designer with interpolating experiences based around provisionality of meaning and the productiveness of users.

CONCLUSIONS

This paper has sought to redefine the nature and purpose of interactivity in digital media contexts, principally by thinking about the idea of user power. In this it has drawn substantially on theoretical ideas concerning the reflexivity of social subjects, especially the critical imagination bound up in diasporic visuality. Arjun

Appadurai (Appadurai 1996) characterizes the workings of the contemporary imagination as both a form of labour and a potential conduit for individual resistance, arguing:

No longer mere fantasy (opium for the masses whose real work is elsewhere), no longer simple escape (from a world defined principally by more concrete purposes and structures), no longer elite pastime (thus not relevant to the lives of ordinary people), and no longer mere contemplation (irrelevant for new forms of desire and subjectivity), the imagination has become an organized field of social practices, a form of work (in the sense of both labor and culturally organized practice), and a form of negotiation between sites of agency (individuals) and globally defined fields of possibility. (Appadurai 1996)

In an age of mass information and communications, individual acts of the imagination are routinely mediated by digital technology while the use of information and communications technology is more or less synonymous with citizenship in many nations. Developments of this scale reinforce the need for interface and interaction designers to keep pace with social and technological change on at least two levels. At the most basic, *inter*active mediums imply input and effort on the part of the user that product developers need to harness in the most effective ways. The question that I have pursued in this study is whether the empirical concepts of effectiveness delivered to design from the fields of usability and HCI should be supplanted by more complex models of the role of the user that merge consumption with production and understand effectiveness more in the sense of whether the interactive experience is compelling.

In redefining the potential for user agency in IMM contexts, new media designers could do well to take account of evolving concepts of the audience in media studies, where, as Elihu Katz (Katz 1996) argues, New theories of the audience maintain that viewer's add value to what they view. Going far beyond functional theories of media use, they proclaim the competence and creativity of the individual. They suggest that viewers do work—not just by staying awake, but by investing effort, by being critical, by making "public" (Katz 1996). This research has speculated on the potential for this to happen through the theoretical discussion from different field of studies, outlining the current limitations in the understanding of interactivity and then using ideas of critical reflexivity and diasporic visuality to encourage designers to unleash the potential creativity and productivity implied in user interaction processes.

IT Educational Challenges for the Internet Generation

Wai K. Law, University of Guam, Mangilao, Guam 96923, USA; E-mail: lawuog@gmail.com

INTRODUCTION

The Net (Internet) generation generally refers to those children born between 1986 and 2000. Although there are different opinions on the exact current age range of the Net generation, it is well accepted that the first waves of these youngsters are already on university campuses (Internet Generation, 2006). The Net generation is expected to trigger major challenges in the educational process, especially in IT education.

The Net generation has been brought up among edutainment, and expects learning to be fun. They are avid users of computer and Internet, and are much less tolerant of boredom than previous generations. They exhibit no fear for computers and feel no need for computer literacy training. They probably have experienced and even master technology that baffles many instructors of the current generation. They are accustomed to search information on their own and expect instant feedback. They learn just in time, and are less willing to memorize information as a necessary part of the leaning process. They will not hesitate to turn to powerful computational machines to complete tasks, and they are well aware of the limitation of textbooks. The Net generation will be less inclined to follow a curriculum, simply digest bundled knowledge, and equate hard work with learning (Hay, L.E. (2000).

EDUCATIONAL CHALLENGES FOR THE NET GENERATIONS

The Net generation grew up with technology, and in certain ways more technically savvy than instructors who are slowly adapting to the "new" technology. They were accustomed to high-speed interactive communication, and quickly lose interest in the gradual dispensation of small doses of knowledge. The instructional method of sequential presentation of information embedded in traditional textbook could be ineffective for this generation.

Members of the Net Generation acquired keen ability to find resources on the Internet. They were equally at ease at the crafty assembly of freely adopted excerpts from the web toward the formation of research reports (Smith, 1999). Many perceived the web as the whole of Internet and the world of network computing. They also inclined to believe that the Web holds the entire knowledge depository. As such, they habitually based their learning experience outside of the traditional scope of academic knowledge domain, prompting challenges to instructor roles and relevancy of learning goals.

The Net Generation was accustomed to networked microcomputers with little appreciation for the professional computing technology in the world of mainframe and data communication. As end-users of powerful 4GLs, they would amplify the recent trend towards user-developed applications, posting risks in design, development, maintenance, and infrastructure supports for information resources (Barker, 2002). For this new generation, programming is neither desirable nor challenging. The knowledge gap posted threat to the support and usage of core information technology.

Being very comfortable with mobile communication and wireless services, with the broad availability of software and hardware, the Net Generation no long value a full service central computing facility. Many of this generation either own microcomputers, or have easy access to technology. A new challenge in academic computing support shifts to the orchestration of linking compatible technology rather than ensuring the accessibility of standardized technology.

CHANGING IT EDUCATIONAL ENVIRONMENTS

The Net Generation grew up among technology long before they began formal education. Very often, the introductory IT training in school paled in comparison to the sophisticated technology penetrating households. The vigorous disciplining of IT training lost ground to multimedia e-learning. An overabundant supply of technology distorted the perceived needs for further information system development. The Net Generation was more interested in end-user IT issues, than business issues on IT management. A mass failure of IT ventures followed by off-shore outsourcing of technical positions erased the attractiveness of IT careers, draining potential talents from the IT fields.

The widespread availability of application software based on 4GLs drew great interests in end-user IT training. E-learning technology greatly promoted the training opportunity for non-IS professionals, and these end-users eventually assumed primary development responsibility for computer-based applications. Corporate training programs and private trainers filled the void of training needs unfulfilled by university IS programs, which were slow to retool to meet demands for end-user computing training.

On university campuses, multiple disciplines were eager to offer their versions of IT training, leading to the dilution of resources as well as student pool. Indeed, students unprepared for the more vigorous IS program would flee to other programs. The educational attention was shifted from the quality of IT education to the relevancy of IT training. Debates began to arise surrounding standards for technology, rather than the effectiveness of IT education. In many cases, group and department secured exclusive rights to selected areas of IT trainings, feuding and fighting over shrinking student interests.

The diversification of technology deployment in organizations also made it more difficult to train students to meet the expectation of recruiters. Increasingly, firms turned to internal training programs to inject the needed IT skills to the new recruits, thus decreasing the value of IT training from university programs. Changing funding and reward practices drove innovation out from university campuses to high technology industries, widening the technology gap.

New requirements on program assessment prompted IT curricula changes to align instructional activities with measurable student learning outcomes. An effective IT educational program must begin to build on top of the existing skills and knowledge of students. A new generation of technologically literate students challenged the educational effectiveness of existing IT courses.

With an increasing recognition of IT as an essential communication skill, a new influx of demand arose from non-IS students, who were less motivated, and less prepared for vigorous IT training. IS programs encountered new challenges to retool to meet the demands for cross disciplinary IT training.

IT AND KEY EDUCATIONAL OUTCOMES

The Association of American Colleges and Universities specifies five key educational outcomes (Ehrmann, 2004):

1. Strong analytical, communication, quantitative, and information skills
2. Deep understanding and hands-on experience
3. Intercultural knowledge and collaborative problem-solving skills
4. Sense of responsibility
5. Thinking mind and knowledge transfer skills

Information technology assumes a critical role providing tools to facilitate information gathering, analysis, aggregation and finally sharing information with others through various communication channels. It is no longer a specialized tool reserved for the IS professionals, but an essential component in supporting the primary educational outcomes.

IT enhanced problem visualization represents efforts to promoting deep learning in many disciplines. Simulation provides realistic environment for training, and for complex skills development. Digital e-learning tools increase opportunity for hands-on experience at affordable costs. IT tools allow students to be in charge of exploratory learning experience, rather than being constraint to pre-defined, instructor-led, exposure to a limited domain of knowledge.

Powerful networks and conversion tools bring the world to students through their communication devices. IT helps to overcome geographical barriers, national boundaries and cultural presuppositions, supporting free exchanges of ideas and knowledge across the world in matters of seconds. Knowledge and technology transfers enhance a growing trend towards multicultural collaboration.

IT promotes free speech and free communication. New forms of communication channel expose social challenges; increase awareness, thus enhancing informed choices. It is much easier to keep informed about world events, and participate in social activities. Electronic forums and messages are leveling the playing field to allow easy access to a global audience, bypassing intermediaries and filters, providing a far richer communicative environment.

IT ties groups and disciplines together through common tools and communicative habits. Knowledge sharing enhances multidisciplinary approaches to problem solving. The continuous growing deposits of knowledge bases enhance just in time learning, bridging knowledge gaps resulting from specialization and fragmentation of organizations and societies. At the same time, it is challenging for the IS professionals to morph from being IS service providers to become members of learning communities.

IT EDUCATIONAL CHALLENGES

There is a need for IT educators to reexamine the current environment, and refresh IT educational goals. The emerging roles of IT educators can be roughly divided into three areas.

1. Preparing future IS professionals as effective IT providers
2. Nurturing the next generation of IT innovators
3. Training technically savvy IT end-users

Different programs, depending on their available faculty resources, institutional resources, industrial relationships, and ability to attract student talents, may have to make hard choices and begin retooling the IS programs for the Net Generation and future generations of students. For many institutions, the emerging demands for IT training may gradually shift to the last category of training IT end-users.

Preparing the Net Generation for IS Professions

Many IS curricula have been designed to train IS students to develop and construct information systems. The Net Generation will face a world with an over abundant of information systems. There is a great need for skillful workers to adapt existing information systems to support the integration of functional applications. It will be challenging to support training for the large variety of programming languages, especially those for maintaining open source systems. In the future, IS professionals will need to be resourceful besides mastering basic computer skills. On the other hand, the Net Generation, while resourceful, is more inclined to use 4GLs, ignoring the role of basic programming skills and efficient coding. The new generation will be impatient with research methods, and problem solving methodology, quickly turning to powerful information searching tools, and experiential problem solving – trail and error approach.

Many IS programs have invested substantial resources in constructing computer labs and training facility. However the Net Generation is a highly mobile group. The plummeting of computer prices allows many of the new generation to haul around their laptop computer and mobile devices. They have a strong preference for using their own personal computing device for learning and rebel against the restrictive time and location of centralized computing facilities.

The Net Generation arrives college with substantial computing experience, thus shows little interest in the basic computing concepts. They are motivated by the sophisticated applications such as simulations and multimedia tools, which are seldom included in college level curricula. Their prior computing experience could create motivation problems and distort the assessment of learning outcomes.

The lack of knowledge and lack of interest about computing technology outside of the microcomputer based technology present a major challenge to prepare students for workplace where they have to work with those technology. There are limited opportunities for students to gain hands on experience with high-end systems such as ERP, SCM and CRM. The Net Generation could totally ignore the relevancy of these integrative information systems because of the vagueness of these concepts in comparison to attractive simulation and virtual reality gaming software. The knowledge gap limits the career options for the future generation of IS students, who at the same time are expected to spend an increasing portion of their college experience in non-technical studies.

Increasingly, an effective IS professional must be competent in interpersonal communication, organizational management, and the business processes. Numerous IS projects must support initiatives such as those in human resource development, organizational reengineering, and business process improvement. With the increasing integration of IT into the business process, there are increasing needs to address IT strategy and the design of IT architecture. Case studies, project management, system integration, collaboration, multi-cultural team, security and social issues, are examples of the numerous challenges for IS programs to recruit motivated students and produce IS graduates that can quickly fit into the work environment.

Preparing the Net Generation to be IT Innovators

Historically, businesses are the leaders in IT adoption, and thus the driving forces behind IT innovation. IS curricula train students to support the numerous IT projects of business corporations, and maintain their IT assets. IS graduates contribute to centralized IS supporting services. The widespread available of web technologies and inexpensive, yet powerful computers decentralized IS services. Increasingly, businesses realize that it is insufficient to draw customers through powerful technology; they must also learn to accommodate customers who own sophisticated technology and expect businesses to support their IT applications. Many successful business ventures prove that non-technical innovations are just as important as basic IT innovation.

The Net Generation is well tuned in with the recent technology innovation. Early habits of self-reliance make them good candidates for problem-based learning, where they learn by exploration. The potentially richer learning environment can better prepare the Net Generation to be life-long learner, rather than swallowing down blocks of textbook based knowledge. There is the need to equip students with problem solving skills, beyond concepts of system designs.

It will be difficult for the typical IS program to find sufficient funding to provide the IT architecture and technical supports to nurture students to be IT innovators. Many IS programs will have to turn to alliances with businesses to gain access to the expensive IT infrastructure to properly train the next generation of IT innovators. Increasingly, instructors will become coaches or mentors, guiding the learning paths of students, instead of the actual dispensing of IS trainings to students. A new challenge will be for higher educational institution to recognize the new roles of faculty as facilitators. Even more challenging will be to find ways to document student accomplishments, much of which will be proprietary information due to corporate sponsorship.

The traditional assessment methods of testing and quizzing will lose effectiveness, since it will be difficult to find effective measurement for innovative ideas, which take long period of time to prove their value, or the lack of it. The sole assessment by course instructor will also be an incomplete measurement of student growth, especially when students start to work on projects outside of the campus environment. However, these challenges should not prevent the development of new curricula to better align academic and industrial resources to prepare the next generation of IT innovators.

Preparing the Net Generation to be Savvy IT End Users

The widespread adoption of IT creates a new wave of demand for IT education. These are the end-users who do not plan to become providers of IS services, but

have strong interests in IT skills to open up career opportunities, or to prepare themselves for their career of choice. The traditional IS program must compete with other programs sharing the interests in providing IT education. However, IS program could benefit from its current availability of IT resources and IT staffs, supporting easy transition to meet the emerging IT educational needs.

It is challenging to design curricula for end-users. The end-users tend to be practically oriented, and demonstrated little interest in computational theory. A lot of end-users could have prior exposure to application software, and developed bad habits that must be undone through the training process. The end-users come from all backgrounds, and show limited interest in training materials that are designed for business applications. The end-users tend to learn at a slower pace, testing the patient of IS instructors. Lastly, the end-users arrive with different level of computing experience, and expectation, thus requiring flexibility in the curriculum design to accommodate the broader range of prior experience and capabilities. A lot of end-users have work experience, or currently working in an official environment with exposure to IT. The end-user experience challenges the adequacy and currency of IT contents in courses, and requires careful selection of IT architecture and technical supports. The Net Generation exhibits characteristics of end-users.

The Net Generation is intolerant of inferior technology, and antiquated software, which unfortunately remain as the core IT technology for many IS programs due to budgetary constraints. The Net Generation wants mobility, and prefers to center their learning and works around their personal computing devices. A new challenge involves placing software in the computers of the Net Generation at affordable costs. The rapid changing technology also prompts many institutions to take a serious look at refreshing the campus IT technology in short cycles, demanding close coordination between campus technology and academic programs.

The profuse availability of online resources and training opportunities poses another challenge for preparing IT education for the Net Generation. The Net Generation is resourceful enough to find resources superior to contents of most basic textbooks. The IT education of the Net Generation must incorporate Internet resources, and adopt pedagogical approach that takes advantage of the Internet skills of the Net Generation. At the same time, the challenge remains to prove to the Net Generation that core IS theories are necessary components in preparing them to become effective, and technically savvy end-users.

Perhaps one of the greatest challenge yet is to demonstrate to the end-users that college level IS training is delivering additional value beyond the proliferation of IT training opportunities from self-learning tools, online programs, workshops, short courses, and on the job training. This is especially true when students enrolling in IS courses may arrive with expectation inconsistent with the learning objectives of the courses, thus evaluating their learning experience based on the perceived benefits of the course, rather than the achievement of course goals that they are least concern about. As a result, the learning assessment should measure value delivery as well as the relevancy of goals set by the faculty curriculum committee.

Although IS programs can choose not to service the end-user IT educational market, they risk the alienation of end-users who eventually will become the decision makers on IT adoption, and setting paths for the future development of IT. There is a need to bridge the knowledge gap between IT end-users and the IS professionals, so that a healthy collaborative relationship will be maintained, and the IS program can remain its influence on the proper approach to IT education for the future generations.

New challenges arise to position IS programs not merely to prepare providers of IS services, but also as agents to ensure the proper implementation of IT to support educational outcomes, to promote deeper understanding of natural and social phenomenon, to bridge cultural gaps, to expand the scope of learning experience, to enrich insight on relationships and social concerns through IT, and to stimulate thinking and expand knowledge through IT applications

MEETING THE IT EDUCATIONAL CHALLENGES

After the selection of program goals and target student markets, each IT program must also tackle important challenges in five major areas:

a. Curriculum design
b. IT architecture for technical support
c. Pedagogical approach
d. Assessment method
e. Bridging to Workplace competency expectation

A brief discussion of these challenges will follow, and the interested reader is referred to the abundance of literatures in these areas. IS programs is facing the challenge of embracing cross disciplinary IS curriculum design, recognizing that IS innovations could emerge from multiple disciplines. The core IT architecture needs to emphasize connectivity standards rather than maintenance of physical facilities. Learner-based pedagogical approaches will be desirable, and learning outcome assessment will be expected. Students and recruiters will demand relevancy of IT education, and the tight integration of theory with practical applications.

CHALLENGES TO IS PROGRAM TRANSFORMATIONS

Embracing change is a difficult experience, but change is inevitable. There are numerous responses of IS programs to the IT educational challenges. Proposals on IT educational challenges are often reactive to emerging problems. The following discussion will address some of these efforts, and emerging new challenges.

Expansion of Program Offerings

Some IS programs enrich their curricula with new courses, providing more tracks of specialized training for student pursuing different IS careers. However, waning student interests in the IS fields strain the resources of the programs with small enrollments. The increase in the assortment of courses may be insufficient to address a fundamental educational issue – The Net Generation is expecting learning to be fun, meaningful and with immediate success. Some programs turn to Distance Education to attract a broader student base, only to find out that they are attractive students with "Net expectations" – highly competitive costs, customized services, fast response, continuous interaction and sophisticated information supports. Many IS programs and their faculty members underestimate the "Net Challenges".

Merging of Academic Programs

Some institution merged IT related academic programs, consolidating the student pools. The merging of technical programs under one roof could reduce administrative overhead, and eliminate duplication. However, the reorganization may have little impact on promoting cross-disciplinary IT training. Students are merely allowed to select from a consolidated menu, but the Net Generation expects flexible and ubiquitous computing, prompting the reengineering of the educational process. In some cases, merging IS programs into other programs could limit innovation and growth of the IT educational curricula, further widening the gap of technology relevancy of these programs.

Corporate Alliance

A newly rekindled interest in collaboration between academic institutions and business corporations could revive the support for IT education. However, the challenge remains on the acceptance of business sponsored training and research as legitimate academic exercises. Corporate alliance requires the diversion of valuable faculty resource to nurture the relationship, which may interfere with other academic missions, and requires a strong organizational infrastructure to support and sustain. On the other hand, corporate alliance could serve to draw student talents to the IS programs, but at the same time, requiring a shift in the role-play of the IS programs. A key issue is to find a delicate balance in the mix of knowledge versus relevant skills in an academic program.

CONCLUSION

IT education is no longer merely for a small group of individuals seeking careers in IS professions. The omnipresence of IT creates great demand for IT education for people from all walks of life. The Net Generation represents the first wave of students who expects a richer and interesting learning experience. Thus the challenges in IT education are no longer about incremental adjustments of the IT curricula. A fundamental rethinking of IT educational goals, and bold reengineering of the educational process will prepare IS programs for emerging opportunities and new missions for IT education. The globalization process will hasten changes and create multiple missions for IT education for different regions of the world. The Net Generation will not hesitate to seek alternative channels to fulfill educational needs, including crossing the geographic boundaries of IT educational services.

Portals as a Multidisciplinary Field

INTRODUCTION

Portals often fall into two major categories: as gateways purposed to consolidate services or applications, or to assist in community building. In the latter case, extensive communication tools (such as instant messengers, event calendars, and forums) facilitate and build networks within the community. It must be noted that these suggested categories do not assume exclusivity – and there are increasing instances of portals that are built for multiple purposes.

Various cases of portals have been studied with their technological applications, software, and business applications for communities and organisations. The portals that have emerged on the web, such as Smart Mobs (http://www.smartmobs.com) and YouTube (http://www.youtube.com), reflect communal identities of communities. There is often a core group of people identifying themselves as part of that community, and a mechanism for contributions from community members, which act to cement the communal identities that people in the community share with one another. This paper argues that the emergence and popularity of portals is not driven by technologies, but more by this sense of communal identity within communities.

Its broader goal is to identify a research agenda for the Community Informatics Research Network (CIRN) in the Asia-Pacific region, using the case of a portal informed by structuration theory and the notion of the knowledge commons, here considered as a virtual space dedicated to the sharing of understanding, memory, and practical know-how.

Through Giddens' structurational theory (1986), the paper first demonstrates how portals provide a sense of collective identity for communities and thereafter cultivate a knowledge commons space within the portal. Using this discussion, research dialogues are introduced to demonstrate the multidisciplinary nature of portals. The paper then presents a case study of a portal that is being developing for the upcoming Beijing Humanistic Olympics, and focuses on the role of that portal in contributing to the establishment of the knowledge commons.

STRUCTURATION THEORY AND PORTALS

Giddens (1984) offers the insight that

> *The best and most interesting ideas in the social sciences (a) participate in fostering the climate of opinion and the social processes which give rise to them, (b) are in greater or lesser degree entwined with theories-in-use which help to constitute those processes and (c) are thus unlikely to be clearly distinct from considered reflection which lay actors may bring to bear in so far as they discursively articulate, or improve upon, theories-in-use (Giddens, 1984, pp 34).*

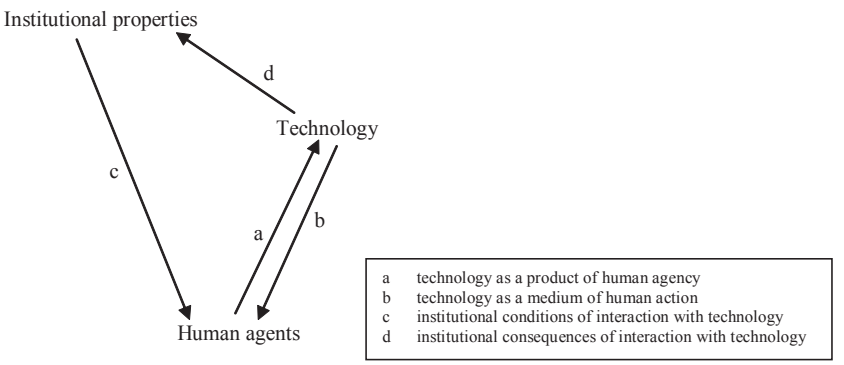
This insight implies the interdependencies of meanings, actions, and structures. The cumulative effect of people's living and working within social frameworks (through a dynamic that Giddens calls structuration) is the production and re-production of culture. According to Giddens, community cultures are generated and re-generated through the interplay of action and structure. Social structure both supports and constrains the endeavours of individuals, communities and societies. Giddens' theory of structuration is the cornerstone concept for this paper.

In Giddens' theory of structuration, he proposes what is known as the 'duality of structure', where human actions create structure or institutional properties of social systems, which in turn shape human actions (Giddens, 1986). It recognises that 'man actively shapes the world he lives in at the same time it shapes him' (Giddens, 1984). Information technology is well posited in the theory of structuration – its very nature reflects an underlying structurational duality: where human actions, the needs, wants, skills, and collaborative tasks of communities create requirements for technological systems, and with these structures, shape human actions.

Portals, when considered as an object of study, require constantly renewed effort at definition -- depending on context. It is now a reality of the techno-social condition that people need to grapple continuously with the multiple personae projected by portals and their enabling functions. It is worth explaining this interaction with portals. Orlikowski (1992) depicts a recursive model of information technology using structuration theory, applied to a vision of portals in this paper (figure 1).

The recursive nature of technology based on structuration theory is reflected in the structurational properties of portals as being created and changed by human action; but also supporting and constraining such actions. Through such interplays, memories of people are cultivated within portals.

Figure 1. Structurational model of technology (Orlikowski, 1992)



PORTALS PURPOSED FOR KNOWLEDGE CREATION

Pearce (2003) noted that portals have evolved and are expected to perform a number of diverse functions, including the access, storage, and organisation of information, gateway to enterprise applications, communication, and so on. Strauss (c.f. Pearce, 2003) suggested a trend of 'portalization', where organisations 'are rushing to produce portalware and portal-like Web pages without fully understanding the scope of a portal undertaking'.

This paper argues that the sustainability and usefulness of portals lie in the dynamics of the user communities and, in the same way, portals function as an important platform for the sustainability of communities. 'Community' as used here is intended in its widest sense, and includes communities of practice, communities of interest, and both local and virtual communities (Wellman and Haythornthwaite, 2000; Wenger and Snyder, 2000). Thus the scope of a community includes not only corporate-based communities, but also the vast variety of communities that make up the civil society as defined by the World Summit on the Information Society (Schauder, Johanson, Taylor 2005).

Figallo (1998) argues that a true community exists when 'a member feels part of the larger social whole', when 'there is ongoing exchange between members of commonly valued things', when there is an interwoven web of relationships between people, and when these relationships last through time, creating shared meanings and histories. Thus, the ties that bind people together transcend their formal tasks and work practices. As noted by Figallo (1998), this view of communities is altogether dialectic and multifaceted.

Behind the knowledge commons lies the memory of community for the common good: humans hunting together for food and developing conventions for shared use of grazing lands. Benkler and Lessig (c.f. Levine, 2002) defines a 'commons' as resources that are not possessed or controlled by any one individual, company, or government. The commons is rooted in communities of social trust and cooperation (Bollier, 2004) and is distinct from the market. Active defenders of the commons, such as the Friends of the Commons (2004) refer to the commons as 'a generic term which embraces all creations of nature and society that we inherit jointly and freely, and hold in trust for future generations'.

Such defenders regard it as critical that we make distinctions between what is shared and common to the society – so as not to allow market forces to create fragmentations caused by social differences such as income and literacy. The current movement of the knowledge commons focuses on knowledge-creating communities using technologies to empower or constrain their shared spaces and resources.

However promising it may sound, sceptics have referred to this concept as merely a metaphor – and regard it as risky to guide decisions based just on a metaphor. Others defend it fiercely – arguing that without it resources would be taken over by market forces (Bollier, 2004). Hardin (1968) writes about the tragedy of the concept of the commons, based on the assumption that equitable access and use would result in the degrading of quality, and emptying of resources. This suggested tragedy is based on the idea that in the commons, where lemming-like, 'every man is locked into a system that compels him to increase his herd without limit – in a world that is limited. Ruin is the destination toward which all men rush, each pursuing his own best interest in a society that believes in the freedom of the commons. Freedom in a commons brings ruin to all.' (Claude, 2002).

This paper argues that such ideas may be invalidated due to the changing nature of participative technologies, contemporary media scenarios, and the applicability of portals as a form of both structure and agent to sustain the commons within a specific community. Massimo (2006) further supports this claim, by stating that 'there is no common without community within which the modalities of access to common resources are negotiated' (Massimo, 2006).

Portals are gateways and central points of access to applications, services, and more importantly, networks of people within the community. Belonging and having access to a portal allows members to feel part of the community, to contribute and exchange commonly valued knowledge and resources with one another. In this way portals present an opportunity for a true community to exist. It must be emphasised that the communal identity does not imply compromise with the self. The portal as a participative and mediating technology allows for both the construction of self and communal knowledge of individuals and their communities. In fact, knowledge of both the self and the community are mandatory for each other to exist. The emergence and popularity of portals might be argued as evidence of a desire of people in a community to connect with the like-minded, alongside with the need to construct self-knowledge. This desire, or innate nature of people, is described by Calhoun (c.f. Castells, 2003):

We know of no people without names, no languages or cultures in which some manner of distinctions between self and other, we and they, are not made ... Self-knowledge – always a construction no matter how much it feels like a discovery – is never altogether separable from claims to be known in specific ways by others. (Calhoun c.f. Castells, 2003)

Castells (2003) argued that the construction of self-knowledge is an inevitable process when people come together as a community. In the process of constructing self-knowledge, one makes sense of existence, presence, and roles in the world. In doing so, people in communities make sense of their relationships with other people, and end up with multiple associations with various communities. Very often, the behaviour and roles they eventually take up in different communities are not independent of each other. Because there is such a multiplicity of intertwining of community consciousness in people, it is not possible to only include one aspect of a community without considering all of aspects.

People try to make sense of their identities in multiple communities, reducing the tensions between identities, and eventually it results in a glut of communities trying to collaborate within and with each other. As a result of such courses and discourses, it is necessary for technology, spaces, and other resources to be utilised.

Web portals present an interesting contemporary media environment which is a remarkably different state of the knowledge commons that Hardin (1968) spoke against. Equitable access that was thought by Hardin (1968) to be disastrous is now extremely easy within a web portal, as an individual frequently moves from creating his own knowledge to sharing it with others. The distinctions between knowledge for oneself and for collective action are often blurred, as individuals move back and forth within those realms. In the portal, knowledge that is produced also has the characteristic of increasing in value as it is used and shared. There are many examples such as Wikipedia (http://en.wikipedia.org), a web-based encyclopaedia leveraging the collective knowledge and collaboration of many people, not all experts. In this way, web portals present structure and agency properties as suggested by Giddens' structuration theory (adapted by Orlikowoski, 1992 in figure 1), and potentially a discourse against the suggested tragedy of the commons (Hardin, 1968).

Portals provide access to information technologies, resources, and contexts of use – they also provide a method by which multiple layers of identities, memories, and knowledge can be construed by communities. In examining the social reality of portals, they are regarded as forms of structure (Orlikowski and Robey, 1991) – created by and shaping human actions. Together with a vision of portals informed by structurational theory, this paper presents a snapshot of a case and examines the research dialogues which it stimulates.

THE CASE OF THE BEIJING HUMANISTIC OLYMPICS (2008)

The case study presented has been commissioned by the Humanistic Olympics Studies Centre for Beijing Olympics 2008, co-funded by the Chinese Ministry of Education, and with support from China State Administration of Radio, Film and TV (SARFT).

With the successful bid to hold the 2008 Olympics in Beijing, a team in CUC (Communication University of China), also a member of METIS Global Network (www.metis-global.net), the cross-cultural research organization in multimedia studies, began working on the project of producing an 'advertainment' (so called because the production would implicate the purpose of entertainment and advertising, whether commercial or not) portal for use in the Beijing Olympics.

The broad goal of the portal is to allow volunteers, spectators, and other participants in the Beijing Olympics to upload self-directed pictures, stories, video clips, and relevant advertisement clips associated with either the event itself or the lead-up to it, and to interact with one another within the portal. There are various reasons for them to do so – most of which are associated to their sense of belonging to the event. Access to these resources is open to these communities and facilitated through a web interface in the portal. This also includes business sponsors.

A prototype of this portal is being developed at present, optimised for streaming media content delivery. As informed by structuration theory and the recursive nature of technology, user studies were carried out iteratively with observations made in tandem in the manner of arrows a, b, and c of Figure 1. With the portal still in its prototyping stage, it has not yet been possible to study any possible institutional consequences.

The notion of 'advertainment' as the emphasis of the portal presents a case of an innovative portal that is born out of an age of convergence – as described by Price Waterhouse Coopers (2006) -- to refer to the ability of different network platforms to implement different services and the merger of consumer devices. In the case of the portal, this translates into layers of meanings and constructions contained in information objects. This in turn, results in the special treatment of information objects being deployed and redeployed in the functions of the website. The requirement imposed on the portal is a demonstration of institutional conditions that are reflected in the interaction between institutions and technology.

Each content object potentially belongs to, or can be used by more than one entity. From the user studies, it was found that different observers or users would evaluate the same content object based on diversified experience and knowledge, resulting in inconsistency in the interpretation of content features (Pang, Cao and Schauder, 2005). For example, users from diverse backgrounds and cultures, of various religions, and disparate social classes, could view a same colour with dissimilar sentiments. This finding, along with other findings from iterative user studies, was used to revise the functional specifications of the portal.

A strategy has been adopted to reinforce one of the preconditions of the commons – the idea that no resources are owned or controlled by a single entities but are shared by people in communities. The approach to developing metadata for information objects and resources has also been intricately designed to allow users to define their own tags to the multimedia objects they create and share, while including them in the description model of the portal's infrastructure, to manage uncertainties in such metadata.

This rationale is also based on the assumption that resources in the knowledge commons should not be controlled or manipulated by any one entity alone. Further user studies (Pang, Cao and Schauder, 2005) support the multifaceted meanings embedded in multimedia objects such as videos and pictures, which were expressed and categorised differently by users. As a medium of human action, the portal acted as a facilitator and repository where such meanings were exchanged, shared, and stored. At the same time, interactions also result in the shaping of the portal design, where humans act as the main agents.

As reflected in the recursive interactions between the portal and user groups, one of the main foci of the portal lies in the sharing of resources by the community. This is designed with the intention to cultivate shared memories of the event: public video captures of various members are shared with others, and through these shared resources, the sharing of stories on viewing the same event in the Olympics are elicited. At the same time, advertising videos are put up and shared by the business stakeholders, facilitating further identifications with the event as a whole, and cultivating further memories of the event as a community.

PORTALS AS A MULTIDISCIPLINARY FIELD: RESEARCH DIALOGUES

The focus of the project on the design, development, implementation and use of the portal has led to several multidisciplinary research ideas. The lens of the knowledge commons that has been borrowed to study the portal has been very useful to contribute to emerging dialogues. Development of the project that is ongoing has served to demonstrate that the study of portals is a multidisciplinary field.

The Case for the Knowledge Commons

The idea of having a portal advocating advertising values may trigger arguments that advertising and commercial sponsorship are opposed to the development of the commons (Levine, 2002). However, Bollier (2004) highlights that the commons is not necessarily unsympathetic to the market, pointing out both are needed to 'invigorate each other' or, in other words, to inspire and supplement each other. In the example of the open source versus proprietary software, while one encourages creativity, learning, and accessibility to knowledge, the very culture of such environments inspires and permits marketability. Even so, examples that could demonstrate the co-existence of both the market and the commons are few and far between, making this case study seem somewhat unique. Online donations to non-government organisations via a portal as a means of fund-raising may be another (Johnson and Johanson 2005).

In the case discussed, the notion of 'advertainment' is one that seeks to advocate a 'healthy' infusion of market forces. Information objects are seen to include advertising or entertainment (or possibly, both) values; and whether they originate from commercial sources are considered of little importance. The emphasis in this portal lies in the sharing of memories of the event from cross-cultural communities, of which commercial entities are a part, either as communities of business providers, or of consumers.

The paper has so far discussed a view of portals that is necessary for their sustainability – one that sees portals as not being driven by technologies or even accessibility, but sees portals as driven by the identities, resources, and spaces which people in communities share with each other. This concept of sharing and inclusion of community dialogue is congruent with the concept of the knowledge commons.

Communities are seen working and coming together for the production of knowledge, using portals (as viewed through the lens of structuration theory) as tools to facilitate the construction of knowledge and cultures. As with the knowledge commons, communities see themselves not merely as users and exchangers of information, but in themselves coming together to contribute to the knowledge commons belonging to the community. Portals provide such a space for this interplay and interaction; and in the process, establish a knowledge commons space consisting of both physical and virtual dimensions.

Research Dialogues

As a result of the ongoing work, a field trip was made to Beijing in July 2006, where researchers from Australia and China came together to study the development of the portal, and to reflect on the larger changes that were happening (such as the development of the Olympics venue, changes to the infrastructure of the city of Beijing, and the emergent social agendas in Beijing and other parts of China). Research interests emerging in China that were relevant to the project's work in developing the portal were also identified.

The outcome of such dialogues has been the identification of a number of themes that could form the basis of a research agenda for a CIRN (Community Informatics Research Network) group in Asia-Pacific, guiding cross-cultural perspectives in a field that has become multidisciplinary in nature. Some of these themes are:

- Digital storytelling and the use of communicative technologies.
- The capture, representation, sharing, and shaping of artefacts.
- Human-computer interaction of portals.
- Collaborative and commons-based design for cultural communities.
- New business models in the contemporary media environment.
- Search and retrieval of rich indigenous media objects.
- Research annotations and the making of meaning by communities.
- Issues around design and use of digital repositories for communities.

CONCLUSION AND FUTURE WORK

The project discussed has been concerned about the making, conservation and the transmission of community and individual knowledge, identities, and memories within a community bounded by a significant event.

Using the concept of the commons, the paper has demonstrated how portals can be used as a structure and agent to sustain communities and their resources. Although the concept of the knowledge commons is not new, there has been a considerable amount of interest in looking at it as a framework for considering the dynamics of communities and the successful design (and redesign) of technological applications and workspaces. More research findings from empirical case studies are desired. The knowledge commons movement also calls for radical rethinking of design methodologies to guide the design and developments of portals and informational resources accessed through portals.

This paper has also discussed the key features of the portal, designed to capture and share stories of the event, and cultivate memories for cross-cultural communities. The inclusion of collaborative tasks is another key feature of the portal that lends supports to the larger goal of cultivating cohesiveness and establishing a commons within the diverse communities of the Olympics.

This approach has assisted in the setting up of a research agenda for a CIRN group in Asia, set to convene in 2007. Such dialogues are ongoing, and raise

opportunities for future work in developing research around portals and their implementations.

State Portals: Empowering E-Government via Software Engineering

Paul M. Chalekian, University of Nevada-Reno, 3585 Ormsby Lane, Carson City, NV 89704, USA; E-mail: pmc@unr.edu

ABSTRACT

In an effort to deliver efficient and effective e-government services State portals are playing a prominent role. Software engineers are able to facilitate the convergence of politics and administration. On November 8, 2000, U.S. voters received conflicting media projections, but the Secretary of State's Office in Florida was able to provide them with that state's most timely election counts. With this example, software engineering factors, such as the use of dynamic web programming, can suddenly spring to the forefront of attention. For almost all federated entities, the establishment of state portals has become an advanced stage of e-government. Most states now have them and they can provide a wide variety of public services. Portals can be used as a gateway or central access point, but to appear coordinated, they should be based on a sound software engineering framework. This article presents the convergence of advanced software engineering practices with the empowerment of public administration standards and the swift enabling of public policy via state portals.

INTRODUCTION

Years ago many government agencies progressed from simply republishing forms on a front-end website. However, fewer have advanced to developing back-end web applications. Advanced portal features can now be extended and implemented to include more file-intensive processing. Because software is a form of organizational memory, it has been called a type of federated governance (Strassmann, 1995). E-government portals now include self-service applications and may enable the ability to initiate government contacts, interactivity and consultation (Curtin, Sommer & Vis-Sommer, 2003; Sharma & Gupta, 2003; Thomas & Streib, 2003; West, 2004; Aitkenhead, 2005). Further, citizens will demand more of these interaction capabilities in the future (Thomas & Streib, 2003). It is prudent for the chief executive, or his/her designee, to take control of such developments. Factors to consider among agencies would include the quality, accessibility, privacy and security of their website functions.

In theoretical terms, the concept of a state provides for a framework for analyzing the organizational and ethical complexities of life. Further, a state can provide a unity of attention amid a diversity of details and speculation (Farr, 1993). Using software engineering principles, a new focal point of contact can be achieved. As a minimum, a government-wide portal should provide links to various applications on the Internet "…organized in a way that makes the site easy to navigate and desired links easy to locate" (Edmiston, 2003, pp. 23-24). A state portal is a specific form of government portal. In almost all instances, there are one-to-many states, and within those states there may be one-to-many disparate functions. Yet, a government portal should be fully executable with integrated online services offering considerable convenience to its visitors (West, 2004). This attribute is desired for most of the organizational entities, even those at a peer level. In short, government portals are "…the entry point for business and citizens to access information or services that are for the good of the community" (Aitkenhead, 2005, p. 214) and, like with software engineering, state portals should attempt to have replicate functionality.

Various types of portals have been categorized (Tatnall, 2005) and a state variety could be thought of as being a General/Mega type. While vigilantly considering the needs of state constituents, these portals try to be a "one-stop" source for services, thus the mega description. It is also hoped that the user would return to the same portal for yearly government renewals. Examples may include intermittent visits, such as the payment of parking tickets, or yearly visits, like the payment of taxes or motor vehicle fees (Johnson, 2002). A uniform belief is that these fee-based interactions would be considered encroachments on a constituent's time and resources. As such, states do their utmost to make the experience politically acceptable.

A common goal for state portals is for the web-enabled services to have a similar look and feel. The front-end graphical user interface (GUI) should not be a source of client frustration. This goes for both functionally specific and centralized processing agencies. Resources may vary from state to state as each provides a wide variety of services. However, most want their constituents to be comfortable with the use of their website. Factors of consistency and application reuse are primary among the various organizations of a state. A well-designed enterprise framework, similar to those crafted by software engineers, may be the best way to ensure that consistency.

PUBLIC ADMINISTRATION

The Weberian notion of a bureau maintaining files is at the crux of public administration. Very publicly, a state's web portal has the ability to greatly increase agency efficiency. Standardization, a form of coordination, was identified by Weber as a form of rationalization and is still essential to bureaucracies. Most agencies are rule bound, but presenting their regulations via the web is transformational. Due to information and communication technology (ICT), it has been said how the implementation of law has been virtually perfected (Bovens & Zouridis, 2002). Inter-organizational exchanges are now quite commonplace and state portals provide a focal point for individual government entities to provide their services and information.

This is especially so if one or more agencies have the same types of files or database management systems (DBMS). The software engineers for those agencies play a huge role. For a front-end developer in a functionally specific agency, it may be easy to post regulations in a hypertext markup language format. However, in more file-intensive bureaus, and to incorporate conditional processing, sophisticated back-end programmers or engineers may be required. Regardless of agency size, client views of agencies are more likely now to originate from the web.

Shrewd public administrators may obtain or borrow parts or wholly functional enterprise frameworks while striving to develop greater efficiencies. For instance, e-payment options may be transferable within a state between various state agencies. In much less frequent (but notable) instances, entire software engineering frameworks have been ported to other state jurisdictions. The enabling factor may have been the ability of the designers to distinguish between functionally specific attributes of a state and core features when the base-classed functions appeared to be the same. Ask seasoned programmers and, if they have worked with government projects, see if they are aware of adaptations involving intra- or interstate endeavors.

POLITICS

For the usability reasons above, the chief executive of a state may want a prominent role in the portal's capabilities, development and content. This is because e-government "…is as much about politics as it is about government…" (Curtin, Sommer & Vis-Sommer, 2003, p. 14). That individual should be able to enlist (or coordinate) staff from executive branch agencies. It is less likely that a software engineer would reside in peripheral agencies as these entities usually hire specialists and/or programmers. However, without proper planning, the developers would still need to converge to ensure that their efforts yield a uniform look and feel. Thus, the administration of software engineering and standardization between agencies becomes key.

Exceptions may pertain to autonomous elected officials positioned below the chief executive. They may choose to be less standardized. These offices often have links from the main portal, and those officials may or may not follow standardization attempts as closely. They may try to look similar if they are from the same party as the chief executive; if not, they may try to differentiate themselves. In some instances, the autonomous offices employ their own programming, networking and/or outsourced staff. The degree of uniqueness may be an attempt to contrast with the chief executive's site, but seldom is an elected official's website less usable. Sometimes, due to the nature of those elected offices, they may have less budgetary oversight and more specialized features.

INFORMATION TECHNOLOGY STANDARDS

The technical standards regarding web development have evolved a great deal. This pertains to both hardware and software engineering. In terms of telecommunications and networking techniques, it has been recognized that lesser developed states often borrow standards from others. However, in a collaborative way, they too must provide input to achieve full participation (Chauvel, 2003). This includes interactions with other federated entities. In terms of e-accessibility, the state portal host and sponsors will not want any weak or inconsistent links.

In contrast to modular software and programming practices, which have been in place for decades, the most popular client services often have links originating directly from a state's homepage. Facilitated by the portal, this is often the case regardless of government entity. By utilizing cascading style sheets (CSS) and other common techniques, the same GUI can be achieved. Large and established software frameworks such as Microsoft's .Net and Java Community Process' J2EE may be utilized. Regardless of the state's framework of choice, the standards of web services need to be employed to achieve a common communications infrastructure (Williams, 2003). This may facilitate greater inter-organizational exchanges, whether they originate publicly or privately.

INFORMATION RESOURCE MANAGEMENT

Some have recognized how "[m]ulti-organizational collaborations need an institutional framework" (Dawes & Prefontaine, 2003, p. 42) and it is the state's portal that provides one. Teams within a state, regardless of executive department, may be enlisted in the development of a state's portal or web architecture. This is also an overseeing function of information resource management (IRM) entities. The teams that participate early may have greater influence as their ideas and practices would be foundational. However, if the back-end programs are long-linked and/or lack modularity, the ability to extend and reuse the code may be limited. It may be necessary to have software engineers and object-oriented programming experts as part of a design team(s) as they begin to discern the capabilities (or restrictions) of such code.

For instance, one agency's programming staff, having more technical skills than others, may provide an interface to a back-end DBMS. This is commonly referred to as middleware and some database vendors can provide it. Once those interfaces are achieved, the success may be disseminated among state entities, and soon implemented by the agencies. If agencies use the same DBMS, such as those with centralized systems, they may be able to reuse the code objects, segments or libraries. Thus, the encapsulation, extensibility and documentation of such code becomes key. Through the use of secure web services, units may also gain the ability to seamlessly access and display other agency's data.

CONTROL AND COORDINATION

Both control and coordination should occur when administering state portals. For some staff, a state portal may be their first attempt at information technology (IT) and/or front-end application development. With the use of electronic templates, the scope of administrative discretion has been reduced (Bovens & Zouridis, 2002). A simple web page has content, but when forced to integrate that information into the format of a state portal, some advanced software engineering techniques may be required. An IRM entity may be responsible for coordinating that integration. Even the use of CSS may be beneficial when considering simple application code reuse. The dissemination of at least some documentation should occur in preparation for agencies to assimilate clients from the state's portal (Oliveira, Alencar, Filho, Lucena & Cowan, 2004), and many states provide that guidance.

More so than in the private sector, state representatives must be aware of the digital divide or how some individuals are either new to computing or have no access to networked systems. Broadband versus dial up modem accessibility is a common issue. In the private sector, an unavailable website means lost sales, whereas in the public sector, it could mean lost votes. According to one researcher, most state and federal government sites had not made much progress at incorporating democracy-enhancing features (West, 2004), although lower level browser versions try to be accommodated. For instance, agencies should be aware of the browser capabilities of Internet Explorer, Netscape, Navigator, Mozilla, Firebird, Camino, OmniWeb, Opera, Lynx and others. This is because constituents may be using Windows, Macintosh, Unix/Linux or other operating systems. Further, they should encourage technologies that facilitate Internet use by the handicapped. State representatives may require a minimum level of quality, accessibility and privacy as a prerequisite to having an agency's website linked to the portal.

BUDGETARY BENEFITS

By charging convenience fees and reducing staff, state agency revenues and expenditure savings can be substantial. As mentioned above and if enabled by law, convenience fees may be charged. Waiting lines could be reduced, and in areas where population growth is occurring, capital expenditures may be saved. Although constituents can usually find and download forms without a state portal, as advertised by the agency or documented in correspondence, more personalized documents with agency planning can sometimes be obtained.

In public organizations normally known for growth, increased staffing can be curtailed. Along with the development of seemingly personal information, the agency can develop a queuing sequence of events for whenever the client arrives or connects. In some instances the client interfaces the information, not a clerk. For instance, with pre-assigned access numbers or barcodes, an efficient delivery of services may result. Such numbers would originate from a holding table or database, ready to initiate a set of processes when the client keys, swipes or pays. Be it a web, interactive voice response, e-payment or web service transaction, a pre-established number would be anticipated and foreknown by the originating agency.

It may seem to the client that delivery is different, but deep within the back office processes, the sequential numbering of transactions is very likely the same. This, along with stringent DBMS table designs, could reduce the likelihood of redundant data and, as a result, promote more efficiency. With pre-established information the clients can be better prepared before accessing a government website, and the portal support staff can be better prepared (if necessary) to serve them. To the casual user, this might not be entirely evident; however, in a well-designed system, hidden access codes can provide a great deal of functionality, security and personnel savings.

COMMON ELEMENTS

Beyond a search engine and a gateway to sites of a jurisdiction, a state portal should provide access to all network-accessible resources. These include intranets, extranets and the Internet. Table 1 lists a few of the most prominent state portal features.

FUTURE TRENDS

Future trends include facilitating web-enabled voting, the use of inter-organizational transactions and vigilant security. As opposed to yearly transactions, voting periodicity may be as needed, biennially or once every four years. So timed, the stakes and risk can be quite high. To prevent duplicate votes, at least some association should be done between the interfacing voters, their domains and electoral choices. Jurisdictions may be overwhelmed with the coordination of electronic voting systems, and systems would need to be certified by the state (Deutch & Berger, 2004). Even though e-voting may be routed through the state portal, a specific office may head up this responsibility. To instill confidence in voting, the level of transactional integrity needs to be high as well as secure. As such, verifications of voter registrations may be increasingly been done between agencies.

As in the past, state organizations will try to integrate the Internet services of subunits within and between each other. It has been recognized how this trend will require oversight institutions to use more horizontal forms of management (Fountain, 2001). But web-enabled transactions usually start under the domain of a single agency and are not fully integrated into the holistic government structure (Sharma & Gupta, 2003). An example of these types of transactions may be found

Table 1. Common state portal features

Alphabetic list of executive departments and agencies[1]
Links to the legislative branch
Links to judicial entities
Lists of councils, committees and boards
Lists of political organizations outside of the executive domain
Executive press releases
Maps of government service locations
State phone/e-mail directories[2]
Links to peer level states[3]
Access to the other states entities[4]
Links to laws
State calendars
Language translations
Business
Education
Employment
Public assistance
Tourism
Emergency and safety

[1] The names of the departments and common abbreviation often follow in parentheses.
[2] A central payroll entity may maintain employee phone numbers and e-mail addresses.
[3] The sub-domain suffix or domain extension will be similar (such as *.gov.uk).
[4] For example, Germany has all of portals listed, accompanied by supporting maps.

with the need to process bad debt payments and their subsequent collections. Transactionally, one agency may attempt to encumber a client's interaction with another. The use of sequentially assigned numbers, as described above, could provide needed tracking. This is so regardless of service delivery technique and may be inter-organizational as long as the jurisdictional boundaries and accountability remain clear. Data intensive collaborations, such as those associated with state portals, usually face issues of data ownership (Dawes & Prefontaine, 2003) and this becomes increasingly so as one or more agencies access or process the data of another. The privacy of constituents, whether election-related or not, is of primary importance. State portals should collect, store and redistribute private information only to the extent required for their proper application (Felten, 2005). Although all agencies must be vigilant in terms of security, the use of a state portal can have a focusing effect on those efforts.

Of the utmost importance to each state, now and in the future, is security. An IT, IRM or public safety agency may be directed to control and coordinate this effort. Because a state portal is often associated with an IRM agency, they usually take the lead. This is especially so with the establishment of firewalls and other advanced security. Intranets are often established to allow access within and between agencies. Users accessibility may be the same within a portal, but restrictions may reduce the hazards of full Internet access. By having an IRM agency as the state's lead, the portal usability trends and security may be forecast, budgeted and planned.

CONCLUSION

Software engineering innovations represent challenges to organizations when they consider IT standards, IRM and the need for coordination and control. But opportunities can exist with a state portal as they have been known to influence government budgets, public administration and public policy. As software engineering innovations are developed, communicated and subsequently discovered by the sub-agencies of a state, they may be shared between entities within a state framework. Inherently, they are borrowing from core software engineering and object-oriented principles. Code reuse, especially in the form of accessing a large DBMS, could help agencies bring more transactional and inter-organizational applications to the web. This interlacing enables sound public administration standards and the timely implementation of public policy. State portals can encourage a vibrant development environment, facilitated by an extendable software engineering framework, for the creation, maintenance and accessibility of secure websites.

Researching the Portal

Arthur Tatnall, Victoria University, Australia; E-mail: Arthur.Tatnall@vu.edu.au
Bill Davey, RMIT University, Australia; E-mail: Bill.Davey@rmit.edu.au

ABSTRACT

The Web portal is now ubiquitous, and a considerable amount of research has now been done into portal technology and applications. In this paper we will argue that research in portal applications should adopt a socio-technical stance, and should see the portal as an innovation which must be adopted before it can be used. We distinguish between inventions and innovations and argue that there is nothing automatic about adoption of an innovation, and that this can best be investigated through the lens of innovation theory. The paper also points out that from a socio-technical perspective some portal adoptions have had positive consequences while others have been negative. To fully appreciate all the human and non-human influences involved, research into the applications of portal technology should adopt a socio-technical approach that considers positive and negative consequences of this technology. We argue that a good way to do this is by considering the portal as an innovation and considering its adoption using the theory of innovation translation, informed by actor-network theory.

WHAT IS A WEB PORTAL?

Most people have a idea of how to answer this question, but not all the answers would be the same – there are many views on what constitutes a web portal. The term 'Web portal' is rather overused and takes on a somewhat different meaning depending on the viewpoint of the people involved in the discussion. Some people define a portal quite tightly suggesting, for example, that it must be customisable by the user or that it must have certain specific features (Tatnall 2005c). Although there are many different definitions, some simple and some quite technical, we will use a simple definition that suggests that as in general terms a portal is just a gateway, a web portal can thus be seen as a gateway to the information and services on the Web. More than this, a Web portal should be seen as providing a gateway not just to useful sites on the Web, but to *all network-accessible resources* whether they involve intranets, extranets, or the Internet (Tatnall 2005a). In other words a portal offers easy centralised access to all relevant network content and applications.

The first Web portals were designed by companies like Yahoo, Excite and Lycos to act as general jumping-off points to the contents of large parts of the Web. An early classification of portals had them being either horizontal or vertical (Lynch 1998). The original portal sites mentioned above would have been considered as horizontal portals because they were used by a broad base of users, whereas vertical portals were focused toward a particular audience. Davison, Burgess and Tatnall (2004) offer the following list of portal types: General Portals, Community Portals, Vertical Industry Portals, Horizontal Industry Portals, Enterprise Information Portals, e-Marketplace Portals, Personal/Mobile Portals, Information Portals and Niche Portals. A major problem, however, is that new types and categories of portal are appearing all the time, portal types are re-classified, and most classification schemes include overlapping categories. Even given the difficulty in classifying portals or attempting to count the numbers of each type, it has become clear that specific, rather than general portals are very much the topic of interest around the world (Tatnall 2005c).

THE GROWING IMPORTANCE OF WEB PORTALS

A crude measure of the growing importance of the portal comes from a Google search of the World Wide Web. In September 2006 this search produced ***1.5 billion*** entries relating to Portals. A similar search performed in October 2005 produced 425 million entries, and in December 2003 only 35.6 million. This measure is rather crude as definitions change and some entities that were not previously called portals now are. It is also the case that some of these entries refer to other types of portals, such as those providing entrance to medieval cathedrals. It is nevertheless clear that web portals have become an important topic for discussion, and one that is becoming more important as time goes on.

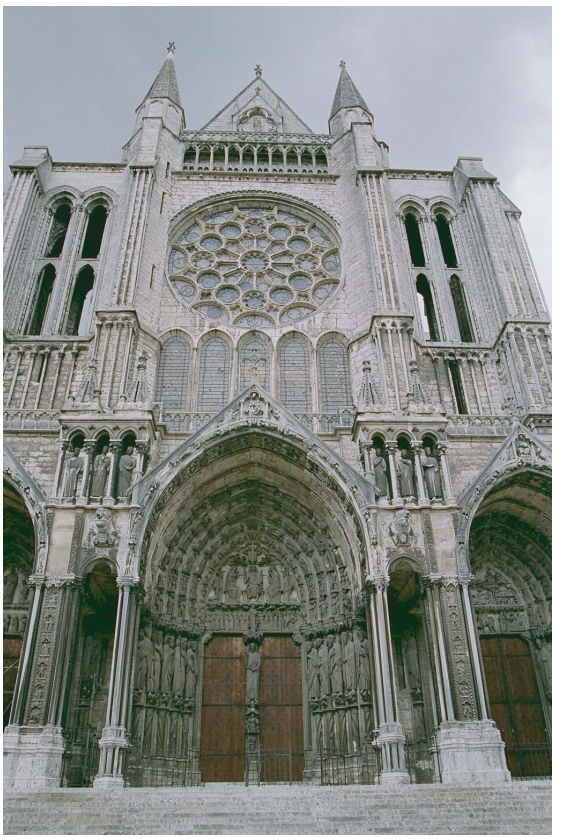
Portal research can be conveniently broken down into research on portal technology, and research on portal applications (Tatnall 2007 forthcoming). In this paper we will concentrate on portal applications.

RANGE OF PORTAL APPLICATIONS

Articles in the Encyclopaedia of Portal Technology and Applications (Tatnall 2007 forthcoming) cover a wide range of topic, ranging from the complex to the very simple. One area of research discusses the nature, characteristics, advantages, limitations, design and evolution of portals, while at the other end of the spectrum several investigations centre around semantic portals and some philosophical portal issues.

A major user of portal technology around the world is governments and the public sector. A large research effort describes and discusses public sector, education and government portals, while social and community-based portals are not forgotten. At the personal portal level, research is conducted in topics including Weblogs, widgets and MP3 players. Medical, health and bio-informatics portals form another significant group of applications.

Figure 1. The Great Portal, Chartres Cathedral, France



Another important research area is in the business and industrial sectors. This research investigates organisational and management issues regarding portal use, enterprise information portals, human resources portals, portals for small to medium enterprises and more specific topics including shopping, the automotive industry and wine industry portals. The economics of setting up and using these portals is also discussed, as are issues of strategic planning, user acceptance, security and the law.

Portal technology itself has been researched by many scholars, especially those involved in the design and implementation of portals. One important consideration is whether certain implementation factors are more likely to lead to successful adoption of portal technology than others. The design and development of portals is an issue, and applications and technologies such as business intelligence, artificial intelligence, semantic portals, intelligent agents and mobile technology are discussed.

TWO SIDES TO THE STORY

Research into adoption of portals has shown that there is a potential for both detriment and benefit to society from this wide range of portals applications. Sentences that start "all freedom loving people …" have been used over the years to justify everything from gun ownership to invasions of foreign countries. An argument for free exchange of information should not need to be made, but the complete licence of the Wild West should also be seen as potentially harmful. In this paper we will examine both sides of the freedom/licence question that have been researched in medicine, democracy and government, and intellectual property piracy. In each case we examine the research to show the dichotomy of the benefits of opening global communications through portals and the potential problems that can arise in an uncontrolled space.

Portals and Medicine

Medical portals abound on the internet. Almost every major disease is represented by at least a support group portal. These portals offer everything from emotional support, through possible treatment advice to contacts within the medical community.

(Lewis 2006) suggests that while the medical literature has a rather pessimistic take on issues like online health consumption, debates over cyberchondria and cyberquackery are underpinned by a recognition that doctors are no longer necessarily the sole holders of health knowledge and that many consumers are now increasingly taking control over their own health care management. Thus the 'quality' debate within the medical literature on online health consumption is underpinned by anxieties over what gets counted as legitimate health knowledge today. The penetration of the Internet into provision of medical information is startling. An independent US study conducted in 1999 found that 31 percent of respondents under the age of 60 had sought health information on the web (Brodie, Flournoy, Altman, Blendon, Benson and Rosenbaum 2000). In 2002 Harris Interactive, conducted a study in (Taylor 2002) whose key findings included the information than 80% of all adults who are online (i.e. 53% of all adults) sometimes use the Internet to look for health care information. A December 2005 survey found that 20% of online Americans said the Internet has greatly improved the way they get information about health care (Madden and Fox 2006), while in Europe a survey by market research company Datamonitor of over 4500 adults in France, Germany, Italy, Spain, the UK and the US, found that 57% of respondents had consulted Internet sources when looking for health information (BBC 2002).

Two reported problems with all this health information available through the various portals are: social alienation, and problems with the quality of health information available. Shields (Shields 1996) finds that one of the dominant popular discourses around web use is that it produces or worsens processes of social alienation, the argument being that it is possible for interaction through computer to replace person to person contact. Theodosiou and Green (Theodosiou and Green 2003) identify five important problems with patients using medical portals to satisfy their needs:

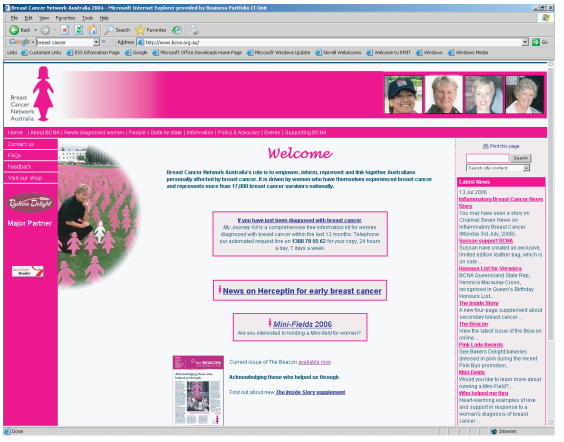
- Potentially dangerous drugs and other substances may be bought by individuals for themselves or their children
- Individuals can spend a lot of money on products or diagnostic procedures that have no scientific backing or benefit
- The information may be more negative than the reality of the situation
- Individuals may abandon treatment programmes of proven efficacy to pursue less-mainstream approaches
- Users' sites (e.g. for families affected by autism) may contain advice or opinions of questionable ethics (e.g. non-mainstream treatments that are intrusive or punitive)

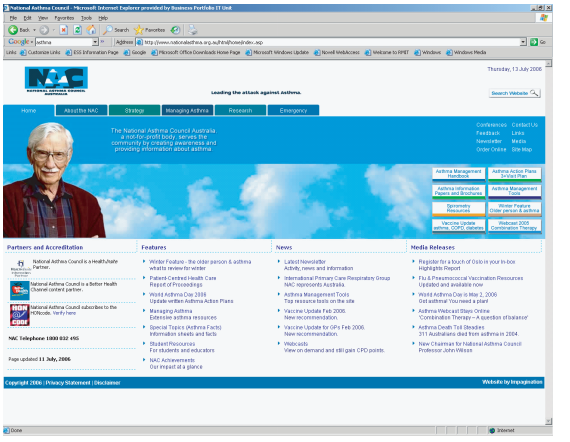
Portals and Democracy

Commentators are split on the issue of the Internet and democracy. For instance George (George 2005) asks "Does the internet democratize communication?" This is one of the big questions that has guided a decade of inquiry within media studies, political science, sociology and other disciplines. George suggests that the relationship between new media and political factors is far too dynamic and interdependent to be reduced to simple causal statements. The less democratic the society, the more attractive the Internet looks as an emancipatory medium – but the more likely radical Internet use will be blocked or punished. Furthermore, the Internet cannot be treated as an independent variable as the technology has been, and will continue to be, shaped by political and economic forces.

Studies of Internet use in Asia find the interaction between economic and geographical forces to be complex. A detailed study of Korea undertaken by Woo-Young (Woo-Young 2005) found Citizen e-participation in Korea is characterized by: (1) convenient access to detailed information, (2) free expression and exchange of opinions, (3) online activism led by politicized agenda, and (4) active formation of cyber groups. The Korean case shows that the electronic participation of citizens may even develop into off-line social mobilization.

Figure 2. Medical portals





Portals and Intellectual Property

Some researchers have evidence that the issue of piracy shows that lobby groups have criminalised the practice and are intent on confusing discussion of the issues in order to try to control activities on the Internet. (Yar 2005) finds two useful ways of looking at exchange of electronic information: "The first mode, proceeding in a largely 'realist' manner, sees the 'rise of piracy' as the outcome of a range of social, economic, political and technological changes that are radically reconfiguring the global political and cultural coordinates within which the consumption of media goods takes place. From this point of view, globalization, socio-economic 'development' and innovation in information technology help to establish the conditions for expanded production and consumption of 'pirate' audio-visual goods. However, the second mode, juxtaposed to the first, proceeds in a 'social constructionist' mode to view the emergence of the 'piracy epidemic' as the product of shifting legal regimes, lobbying activities, rhetorical manoeuvres, criminal justice agendas, and 'interested' or 'partial' processes of statistical inference." Yar sees the expansion of proprietary copyrights, and the criminalization of their violation, is part of a larger 'game' in which struggles to dominate the uses of information are being played out within the new 'knowledge economy'. Rather than taking industry or government claims about film 'piracy' (its scope, scale, location, perpetrators, costs or impact) at face value, we would do well to subject them to a critical scrutiny that asks in whose interests such claims ultimately work.

SOCIO-TECHNICAL RESEARCH ON PORTAL APPLICATIONS

The mixed outcomes illustrated by research into portal applications points to a need to develop a research approach that will bring more understanding of the mechanisms that lead to either great benefit or considerable risk to those exposed to the ubiquity of portals. Recent success in socio-technical approaches to this type of research point a way forward.

Just because a portal exists it cannot be assumed that organisations or individual people will want to adopt or use it. A portal will only be adopted if potential users make a decision to do so, and adoption of technological innovations, such as a portal, occurs for a variety of reasons. The first step to researching the use of a portal by an organisation (or individual) though is to investigate why it was adopted. The remainder of this paper will consider the portal as a technological innovation and consider portal adoption through the lens of innovation theory.

It is important to distinguish between *invention* and *innovation*. Invention refers to the construction of new artefacts or the discovery of new ideas, while innovation involves making use of these artefacts or ideas in commercial or organisational practice (Maguire, Kazlauskas and Weir 1994). Invention does not necessarily invoke innovation and it does not follow that invention is necessary and sufficient for innovation to occur (Tatnall 2005b). Clearly the portal can be seen as an invention, but the point here is that it will not be used unless it is adopted, and that means looking at it also as a technological innovation. Of course, the application of innovation theory to the adoption of a technological innovation assumes that the potential adopter has some choice in deciding whether or not to make the adoption. In the case of an organisation or individual considering the adoption and use of a portal, however, it is difficult to see any reason why they would not have a large measure of choice in this adoption decision. This makes the application of adoption theory quite appropriate when considering the use of Web portals.

INNOVATION TRANSLATION

Compared to the better known innovation approaches of Diffusion of Innovations (Rogers 1995) and the Technology Acceptance Model (TAM) (Davis 1986), an alternative view is that of Innovation Translation proposed in actor-network theory (ANT). This approach considers the world to be full of hybrid entities (Latour 1993) containing both human and non-human elements. It offers the notion of heterogeneity to describe projects such as the adoption of portal technology which involves computer technology, the Internet, the Web portal, broadband connections, Internet service providers (ISP) and the individual or organisation considering the adoption. More specifically though, ANT makes use of a model of technological innovation which considers these ideas along with the concept that innovations are often not adopted in their entirety but only after 'translation' into a form that is more appropriate for the potential adopter.

The core of the actor-network approach is translation (Law 1992), which can be defined as: "... the means by which one entity gives a role to others." (Singleton and Michael 1993 :229). Rather than recognising in advance supposed essential characteristics of humans and of social organisations and distinguishing their actions from the inanimate behaviour of technological and natural objects (Latour, Mauguin and Teil 1992), ANT adopts an anti-essentialist position in which it rejects there being some difference in essence between humans and non-humans. ANT makes use of the concept of an actor (or actant), that can be either human or non-human, and can make its presence individually felt by other actors (Law 1987).

It is often the case that when an organisation (or individual) is considering a technological innovation they are interested in *only some aspects* of this innovation and not others (Tatnall 2002; Tatnall and Burgess 2002). In actor-network terms it needs to *translate* (Callon 1986) this piece of technology into a form where it can be adopted, which may mean choosing some elements of the technology and leaving out others. What results is that the innovation finally adopted is not the innovation in its original form, but a translation of it into a form that is suitable for use by the recipient (Tatnall 2002).

RESEARCHING THE ADOPTION OF WEB PORTALS

Adoption of a portal is not a straightforward process and researching this adoption is particularly complex when the topic is determining detriment or benefit to society. By its very nature such an investigation must involve both humans and technology and be treated as a socio-technical study. We suggest that innovation translation (and actor-network theory) has many advantages as an explanatory framework over both Innovation Diffusion and TAM in socio-technical studies like this.

Both Innovation Diffusion (Rogers 1995) and TAM (Davis 1986) suggest that adoption decisions are made primarily on the basis of perceptions of the characteristics of the technology concerned. Using an Innovation Diffusion approach a researcher would probably begin by looking for characteristics of the specific portal technology to be adopted, and the advantages and problems associated with its use. They would think in terms of the advantages offered by portals in offering a user the possibility of finding information, but would do so in a fairly mechanistic way that does not allow for an individual to adopt the portal in a way other than that intended by its proponent – it does not really allow for any form of translation. If using TAM this researcher would similarly have looked at characteristics of the technology to see whether the potential user might perceive it to be useful and easy to use.

A researcher using an Innovation Translation approach to studying innovation, on the other hand, would concentrate on issues of network formation, investigating the human and non-human actors and the alliances and networks they build up. They would attempt to identify the actors and then to follow them (Latour 1996) in identifying their involvement with the innovation and how they affect the involvement of others. The researcher would then investigate how the strength of these alliances may have enticed the individual or organisation to adopt the portal or, on the other hand, to have deterred them from doing so (Tatnall and Gilding 1999; Tatnall 2002) (Tatnall and Burgess 2006). Especially in investigations involving interaction of humans and non-humans (technical artefacts) such an approach has much value.

CONCLUSION

Web portals are now quite ubiquitous and researching their use in organisations and by individuals is an important aspect of Information Systems research. It is useful to consider the portal as a technological innovation and to research it using an approach based on innovation theory.

While there is a significant amount of research into impacts of the use of web portals, the outcomes of much research are inconclusive when attempting to explain the uptake of the technology. It seems clear that a socio-technical perspective is need in the research effort. ANT provides a perspective that can produce resolution of the conflicting research results and provide an explanatory system.

Implementing E-Procurement Systems: The Promise, Reality, and Lessons Learned

Jeff Picchione, Northern Illinois University, Dekalb, IL 60115, USA; E-mail: jeff.picchione@gmail.com
Chang Liu, Northern Illinois University, Dekalb, IL 60115, USA; E-mail: cliu@niu.edu

INTRODUCTION

For most of the 20th century, the housing and auto industries were the key drivers of the United States economy. By the late 1990's, information technology (IT) accounted for a quarter to a third of economic growth. The increased productivity resulting from this IT growth, combined with the trend of globalization, together spawned what was coined as the "new economy."

THE PROMISE

A 1997 *Business Week* editorial touted that IT "boosts productivity, reduces costs, cuts inventories, and facilitates electronic commerce. It is, in short, a transcendent technology--like railroads in the 19th century and automobiles in the 20th [1]." There is little doubt that ease of access to the World Wide Web over the Internet was the catalyst of this "transcendent" technology. Businesses saw the potential for greatly increased markets, with significantly increased efficiency and productivity – a truly revolutionary development in the world of commerce.

One of the first and most obvious applications of B2B eCommerce was in the common function of corporate procurement. eCommerce was not new in this arena. Electronic Data Interchange (EDI) transactions over Value-Added Networks (VAN's) had been conducted since the 1970's as a technology that evolved completely separate from the Internet. These transactions, however, proved to be costly, required significant configuration, and forced trading-partner relationships that were formed out of convenience rather than for sound business decisions.

Commerce One, Ariba, and FreeMarkets were some of the more prevalent B2B eProcurement dot.com startups that promised to make the new economy a reality. They enjoyed double-digit daily stock price gains while maintaining negative cash flows and earnings in the dot.com frenzy. They developed their own "standards" such as xCBL (Commerce One's XML Common Business Language) and cXML (Ariba's commerce XML). Both "standards" claimed to constitute the XML schema, which would define how procurement transactions (and eventually all business transactions) would be defined over the web. As customers realized the challenges of these marketplaces and of complex integration requirements with suppliers, sales fell off sharply by 2001. Today Commerce One is an obscure part of Perfect Commerce, a $13 Million company that focuses on Supplier Relationship Software and the Open Partner Network electronic Marketplace. xCBL has evolved into an open source eCommerce standard (xCBL.org), and has become the baseline for the evolving standard Universal Business Language (UBL).

What are the lessons to learn from Commerce One? As early as 2001, Commerce One was feeling its troubles: Commerce One must continue to innovate if it hopes to stay ahead of enterprise resource planning vendors such as Oracle Corp., SAP AG and i2 Technologies Inc., all of which continue to invade its turf [5]. It's refocusing on procurement rather than marketplaces. it really got involved with all these marketplaces that were popping up and took its eye off the procurement ball. The e-marketplace stuff was at a roadblock.

Ariba was Commerce One's main competitor in the dot com era. Ariba developed the Commerce Services Network electronic marketplace. In contract to Commerce One, Ariba's more conservative approach to providing "sourcing solutions" ensured its vitality and survival. Ariba has enjoyed a trend of increased revenues since 2002. In its Fiscal Year ended 2005, Ariba recognized $323 Million in revenues, of which $151 Million was in services (up from $84 Million in services in 2004). Although revenues are growing, so are expenses, to the point where Ariba has yet to recognize a net gain. Since 2001, net losses have ranged from $2.6 Billion in 2001 to $349 Million in 2005.

The following stated in Ariba's Annual Report's requisite risk factors, is true not only to Ariba but a reflection of the industry. It also sheds another view on the fate of its one-time competitors: "The markets in which we compete are characterized by rapid technological change, evolving customer needs and frequent introductions of new products and services. As we adjust to evolving customer requirements and competitive pressures, we may be required to further reposition our product and service offerings and introduce new products and services. We may not be successful in developing and marketing such product and service offerings, or we may experience difficulties that could delay or prevent the development and marketing of such product and service offerings, which could have a material adverse effect on our business, financial condition or results of operations [6]."

THE POTENTIAL

Supply-side B2B eCommerce was born. New web procurement specialists such as aforementioned Commerce One, Ariba, and FreeMarkets emerged. These startups offered procurement software, and fought for dominance to provide "the" web standard for electronic procurement.

Electronic Marketplaces including MarketPlace.net, Global Trading Web, Covisent, the Commerce Service Network, and scores of vertical marketplaces evolved. Many were created by and for software vendors, while others were created by and for specific industries. The goal was to increase the number of suppliers and the number of buyers. The concept being that more traders would yield higher volumes of transactions. With lower transaction costs, and exponentially higher sales volumes, lower margins could be accepted. Lower margins would yield lower prices and cyclically increased volume.

Long-time Enterprise Resource Planning (ERP) vendors including SAP, Oracle, PeopleSoft, Baan, I2, and JD Edwards scurried to update their application offerings and their technology platforms to be able to accommodate the web based eCommerce requirements of their procurement customers. Each of the ERP providers worked rapidly to re-engineer its products to work on a web services based platform. Many formed strategic partnerships with web services companies, others tried to develop their own. Thus emerged new solutions from the ERP players including Oracle 11i eApps, MySAP from SAP, PeopleSoft version 8 with "no code on the client", and JD Edwards OneWorld. The products were different in approach, but they all were leveraging web services in one way or another so not be overtaken by their low capital high promise startup rivals.

On the eProcurement front, these ERP stalwarts also needed to devise their own applications, and quickly. For example, PeopleSoft and SAP took turns having partnerships with Commerce One. SAP is attributed to contributing to the demise of Commerce One by draining Commerce One of its intellectual capital [7]. The partnership kept SAP in the game in the short-run, while they were able to invest their significant resources into developing their own web based solutions for the long run. Today, SAP, Oracle, and Microsoft each continue to offer eProcurement solutions. These solutions unlike their standalone competitors have the ERP advantage of full-integration of eProcurement to supply chain management (SCM), supplier relationship management (SRM), financials management systems (FMS),

and enterprise performance management systems (EPM).

THE REALITY

A March 2001 study from Gartner Group reported that there is no first-mover advantage in eProcurement. The study reported "being a pioneer in this market is a huge hassle" since "projects grow out of control, the software vendors are immature, the e-procurement software itself is immature, and very few consultants have much experience with it." The study also pointed out that "early adopters of e-procurement are likely to have to educate many of their suppliers," and that "those who expect a rapid return on investment are in for a big disappointment [2]".

However, not all analyst outlooks' were as bleak as Gartner's. In a 2002 study, IDC analysts observed "The extensive conversion of existing EDI systems to an Internet foundation will be the primary force behind the continued expansion in e-procurement." [3] By late 2003, the purchase of direct materials over the web surpassed the purchase of indirect materials for the first time, according to a study by Forrester Research Inc. Forrester attributed this increase to the number of available software tools available for companies to use for online procurement and an increased level of comfort with buying direct materials over the Internet. The study identified Ariba Inc., SAP AG, Oracle Corp. and PeopleSoft Inc. as top tools vendors in the e-procurement business. These software providers were applauded for providing eProcurement solutions that could focus on the intensive sourcing process involved with direct materials [4].

CASE ANALYSIS

Case 1: Department of Defense

The Department of Defense (DOD) announced in January of 2002 that it would integrate its own internal marketplace and procurement system with Ariba's Commerce Services Network. The integration efforts were being managed by webMethods. The plan was that "DOD workers will be able to search for goods using keywords, manufacturer names or Universal Product Code numbers. The webMethods technology would let them see all relevant product information on a single screen instead of having to separately look through multiple online catalogs." Plans were in place to add additional vertical marketplaces so that "data will be boiled down to provide easy access for end users" [8]. However, the project was halted soon after the project started, after facing harsh criticism from the Government Accountability Office (GAO). In 2004, the GAO reprimanded the DOD for not adhering to US Government best practices in its system implementation, and "made 14 recommendations aimed at strengthening the Pentagon's acquisition policies for business systems as well as its controls for ensuring that proper procedures are followed." [9]

By September, 2005, DOD was on its way to revamping its procurement problems, both technical and policy related. The technical problems stemmed from failed software integration efforts to back-office systems. The majority of the user systems were client/server, and not web based. The revamping effort included a radical overhaul of its integration strategy by establishing XML standards to eliminate hand coding, and creating automatic tools to assist in documentation and development, to assist in the shift to being fully web based. The new web based system was anticipated to be in production in late 2006.

Some valuable lessons to consider from the DOD project include:

1. **Synergize**: The 2002 integration to electronic marketplaces was completely independent of the longer-term procurement project, which was halted by GAO. Although the marketplace solution met the short-term need of part of the organization, its implementation could have provided valuable resources and lessons to the overall procurement project. The marketplace effort should have been included as a component of the larger procurement solution.
2. **Identify standards up-front.** Part of the procurement overhaul was defining XML standards to replace manual coding for each integration effort. Since there were hundreds of integration efforts, a standard and scalable model is essential. The lack of standards encountered by DOD caused each integration to be handled as a separate, sequential project.
3. **Continuously evaluate technology.** The timing of this project was at a time of the most significant changes in the IT industry – between the end of client/server and the beginning of web services. As web services started to grow in the marketplace, DoD under the enforcement of GOA was forced to re-evaluate the project technology, and make the changes accordingly.
4. **Involve end-users early and often.** This is a critical success factor of any change in any organization, particularly in the area of IT.

Case 2: United Nations Development Program

In September 2003 the United Nations Development Program (UNDP) Agency scrapped their legacy system in favor of PeopleSoft ERP in a $27.5M global rollout, including eProcurement. The New York-based UNDP fights poverty and diseases such as AIDS and helps countries stricken by crises such as the December 2004 tsunami in Southeast Asia.

The motivation for this change was that the UNDP's processes were supported by a hodgepodge of homegrown legacy systems, including 21 separate human resources, payroll and procurement applications. That myriad of software prompted the UNDP in 2002 to choose the centralized PeopleSoft system and have Unisys Corp. manage it [10].

By November of 2005 the agency entered "Wave II" of the implementation, now a $59 million rollout, and now Oracle Corp.'s PeopleSoft applications. In September, the UNDP began implementing PeopleSoft's eProcurement application, which would be deployed in the Americas, Asia, Europe and Africa by the end of the first quarter of 2006. The eProcurement module automated requisitioning processes, cutting the time between procurement and payment by 10% [10].

Although it is another large political organization similar to DOD, the UN approach varied for several reasons. The lessons learned include:

1. **Think Big Picture**. The UNDP's implementation of eProcurement was not a standalone project, but one component of a greater global ERP system rollout. The economies of scale of resources, and the implementation knowledge base attained and transferred were applied across multiple module rollouts. Extensive monitoring, status, and documentation of project benefits and challenges were critical to this success.
2. **Plan, Plan and Plan**. The UN took its time to evaluate, analyze, and setup a realistic, phased timetable for its ERP project. It documented and evaluated progress each step of the way. It didn't hop on the eProcurement bandwagon during its short ride, but patiently waited out the temptation. It effectively planned to implement the system to best compliment its current system and meet its business objectives.
3. **Management Sponsorship, End User Ownership, and Consistent Messaging from the top down.** The implementation not only had management sponsorship, but ownership at every level. The needs, challenges, proposed solution, and plan to implement those solutions were clearly identified, and clearly communicated to all the project stakeholders.

Case 3: Ford

Similar to the UN Project, Ford Motor Company made the effort to implement a procurement system built around an ERP Vendor's eProcurement system. In 1999 Ford undertook a project appropriately named Everest, and started to go live in 2000 and continued with a "rolling launch."

Despite four years in production and an investment of millions of dollars, by Q3 2004, Ford decided to abandon Everest, which was built around Oracle Corp.'s 11i E-Business Suite of applications. Sources indicated that Everest was hampered by poor performance [11]. Ford's next plan was to migrate any relevant new features from Everest to its legacy system using its house development staff. Apparently, the mainframe procurement software continued to run in coexistence with Everest, and company suppliers used both sets of applications to handle procurement transactions.

A June 2001 assessment in Automotive Manufacturing and Production suggests that procurement in the automotive industry has the most complex procurement requirements of any industry. The article points out how "current procurement practices are rife with inefficiencies, complexities, and costly procedures" and that "A lack of standardization and its extraordinary complexity preclude any simple fix." The charge is made that IT vendors underestimate the challenges in providing software solutions in this space [12].

Dave Stephens, a former Oracle iProcurement developer shed some light on the Everest project at Ford, summarizing that the project was over-ambitious, with lofty goals including the desire to "unify dozens of legacy procurement systems, - standardize procurement methodology across its feudally-run, fiercely independent plants, take on direct, indirect, and MRO at the same time, and

- rationalize its supply base while putting in the new system." [13]. Here are the lessons learned from Ford:

1. **Prioritize Solutions and Implement Accordingly**. Ford was attempting to solve all of its procurement issues with one monumental effort. These included systems and non-systems issues, supplier, buyer and management issues. The eProcurement initiative and rollout to its end users got lost in the "big bang" approach of the Everest project.
2. **Align the Technology with the Business Need.** The timing of the rollout of Everest (1999) was prompted by the Web Revolution. Given the haphazard approach to the project and ultimate failure, it would have been in Ford's best interest to address its business process needs, and determine how the web can best help it meet those needs. Although this effort was made, it obviously was not given due diligence.
3. **Have appropriate expectations when entering a software partnership.** Ford attempted to implement an off the shelf ERP system that had very little automotive industry specific functionality. As with any vendor solution, nor did it offer any Ford specific business processes. The integration and customization effort was so huge, that the software was modified beyond the point where it could be upgraded. Undoubtedly, this contributed to the ultimate result. Ford should have expected that it would be making significant modifications.
4. **Get Back to Basics**. Emphasizing focus on the core information of the business, and how that core information is used to accomplish overall corporate strategy. This also implies the opposite, get away from anything that is not basic, or core, to the overall corporate strategy.

THE NEW WAVE

Many eProcurement providers have learned from the mistakes of the past, and have invested time and resources in creating world-class software solutions. They also promise realistic savings in the 10-15% range, rather then revolutionizing and reshaping the business world. For example, PurchasingNet, Inc claims over 1400 satisfied customers. With the self-nomenclature of "PNet," the company's focus is to streamline the procurement process in medium to large organizations. The Procure to pay solution consists of three primary modules: eProcurement, ePayables, and Financial Management. The differentiator of PNet compared to its progenitors is that it claims on its website that it can be implemented in less than 5 weeks. Another claim, also justified through a marketing case study is its ability to be easily implemented with legacy systems.

In a case study citing Countrywide Mortgage services, PNet is attributed to allowing Countrywide to continue to grow at a rapid pace, while keeping procurement costs under control. The study claims an ROI in 18 months, that 98% of spend is managed through PNET (approximately 3400 Purchase Orders per month), and that there is a 65% reduction in Accounts Payable manpower [14].

Although PurchasingNet has maintained eProcurement as one of its three solutions, other providers prefer to nestle eProcurement into the confines of "Spend Management Solutions." Ketera claims to be "The Proven Spend Solution" with a products focusing on spend analysis, sourcing, contract management, procurement, invoice management and supplier connection [15]. The company has enjoyed quarter-to-quarter growth over the past 14 quarters, with an optimistic outlook.

Another example is SciQuest, Inc. The company features many pharmacutical, as well as higher education institutions as having successfully implemented and gain cost benefits from implementing its products. Glaxo Smith Kline (GSK) opted for SciQuest's Spend Director products which enhance existing procurement systems with content to increase on-contract spending, which was a business challenge at GSK). After implementing the product, GSK realized an improvement in contract compliance of over 20%, with 50% of all of its indirect purchases through the SciQuest product. It has also allowed GSK to integrate directly to their suppliers (over 200) avoiding a wholesales middleman, saving an additional $500,000 a year.

The aforementioned New Wave of eProcurement providers have some key differences from the DotCom era eProcurement vendors. First, they all try to cleverly minimize the 'eProcurement" term as a buzzword. Second, none are publicly trade. Third, each focuses on procurement and procurement related business objectives. Although some expand into materials management (SciQuest) and others in integrated Financials Management (PNet), each knows its limits and has developed and implemented ERP integration points. Finally, each focuses on the solution being one of enabling users to make more efficient and effective procurement choices. The focus on the earlier eProcurement vendors was on how technology would enable efficiency and effectiveness, grossly underestimating the critical need to incorporate the users as the key catalysts of change.

CONCLUSION

The philosophies, approaches, successful and failed eProcurement efforts over the past seven to eight years, are as various as the combined number of vendors and customers who have dabbled in or delved into eProcurement. However, the past in this case is not a clear indication of the future. Instead, the past offers many lessons learned from successes and failures that can serve as guiding factors for future implementations.

A December, 2005 Aberdeen Group study on eProcurement best practices sites [16]. The study claims there is now resurgence in eProcurement systems, and that the reasons for this resurgence include:

- Continued cost pressures, especially due to outsourcing
- Compliance issues that suppliers enforce compliance with purchasing contracts
- Advances in supplier enablement make it easier for more suppliers to be on board; including proliferation of supplier networks and catalog hubs
- Advances in eProcurement system functionality including integration and reporting
- New pricing models have made eProcurement more affordable for mid and small market companies.

The resurgence and noted successes of eProcurement in its second "wave" of less hype and greater returns is a testimony to the inherent human factors of competently addressing change management and project management. The cited critical lessons learned in this study are not unique to eProcurement, but are generally practiced for any successful change management or project implementation effort:

- Executive sponsorship has a direct relationship on the success of the project. Higher sponsorship yields greater chances for success.
- End-user involvement early and often has been cited as a critical success factor. This also involves extensive training of the system.
- Planning accordingly should be obvious, but especially in the dot com hype planning often took a back seat to the industry generated fear of being left behind.
- Putting company strategy first and IT strategy aligned with the company strategy should also be obvious, but also suffered during the dot com hype
- Consistent messaging across divisions, especially for large-scale projects, is critical for success. This can be hindered by poor planning and poor strategy alignment as well.

These human factors, combined with the fact that eProcurement systems involved people - lots of people – emphasize that it is truly the people that are the key implementation success factor, and not the technology. The implementers, the back-office experts, the systems experts, the supplier representatives, and thousands of potential end uses are all involved; each contributes and each makes a difference.

ABSTRACT

Modern Web Information System must answer "on the fly" to the company's change requirements. To do this, companies left the vertical vision that locates business logic in functional areas orienting them toward a transversal vision that, according to the process logic, tries to improve the management exploiting as much as possible the existing resources. Process vision seems a good way to guarantee to the manager a full business activity control and to increase the flexibility degree in the IS management in order to apply immediately changes. To reach a good flexibility level a company "process vision" is not enough: it is very important that processes are explicitly taken in consideration in the Information System and not hidden in the code. In this paper, our goal is to provide a methodological approach to the design of Web Information System in order to obtain a good flexibility level. We consider the two main aspects of the Web Information System that is the management of the user experience (a typical web application problem) and the design of the business process already made by business experts and we try to integrate them through methodological guidelines.

Keywords: Business Process Management, BPMN notation, Web Information System

1. INTRODUCTION AND BACKGROUND

Companies have abandoned a functional logic that provide a vertical vision and they are moving towards a horizontal vision that allows, thank to a correct use of business process, to provide the appropriate flexibility level to the Information System. This involve a change to the companies' Information Systems but, because the Information Systems are now oriented to the web (WIS-Web Information Systems) it is important to consider not only the process aspects (the business processes must be considered in a explicit way in order to reach a good flexibility level) but also the web application paradigm that is the information, navigation and the transactional aspects typical of Web Applications. According to these requirements, the WIS became more complex and they need a careful design phase made up by ad-hoc methodologies to manage the complexity.

In the traditional design and development of an Information System, it is important to consider two kinds of actors: internal actors and external actors. Today, because Information System is delivered on the web, this distinction is still important:

- *Internal actors* interact with the WIS through intranet considering the Information System as a job tool needful and irreplaceable.
- *External actors* (as an example customers or suppliers) take advantages of Information Systems only through Internet.

The two kinds of user and the two platforms (Intranet and Internet) share the same characteristics: the application implements one or more process in order to drive the user to execute them. The main difference is that the internal users actions are essentially process driven while, when external users interact with the application, they need information not strictly related to the processes (such as marketing information) that make easy the process execution by the final user.

Therefore, there are several approaches (methodological and technological) to follow in the design and implementation of a WIS process-oriented and the main difference concerns the necessity to manage or not the user experience (UX). The UX design is the design of the information and navigation aspects in a user centred style focusing on the dialogue between user and application so the information are presented to the user in order to facilitate this dialogue avoiding the user to lose in the web application.

We focus in this paper on the WIS design for the external actors, so we consider both the UX design and the business process design linking together the know-how coming from these two research area. We deal in the intranet design problems in a separate paper where we describe a methodological approach focused on the portlets.

Several methodologies attempt to solve the WIS design problem for external actors.

WebMl [1] is a web application design methodology: to support processes authors made an extension to meta-data and add the concept of interface in order to provide to the final user the interface to execute process. The authors of WebMl state that the methodology is not efficient when process hide sophisticated business logic.

UWE[2] start from an UML class diagram and from a process design made up by an UML activity diagram. The design methodology is made up of several steps starting from a refinement of the conceptual model adding new attributes in order to take in consideration the process logic. In the navigational model, the extension for business process adds new access structure (in order to support business process) and the rules of their use.

WSDM [3] extend itself in order to support processes with a first integration with the information aspect of the methodology: this integration is made up by a design of the information needed in each process task. In the Task Navigation Model, in order to complete the design, WSDM add the *process logic link* that express the link between tasks and semantic link.

Each methodology has its strengths and weaknesses; for example, all these methodologies are user-centred but just UWE provides support in order to stop the process execution and continue its execution later. Only few methodologies support a standard notation to design process and it is not always possible to make a clear distinction between process link and semantic links.

Our research work, starting from a Web Application design methodology that, focusing on the dialogue between user and application and using well-known techniques for process analysis, design and representation, defines methodological guidelines that drive the designer towards the design of complete WIS.

We selected IDM [4][5] as web application design methodology. IDM seems a good methodology to manage the UX aspects of WIS and we implemented, for IDM, a code generator [6] considering IDM as the domain specific language to design the web application. The code generator allows us to obtain in a few minutes the final application. Today, IDM does not provide guidelines about the integration with business processes.

Regarding business process design, we select BPMN [7] an OMG standard notation simple and effective.

In IDM, the main concepts are: *Topics* and *Relevant Relation*. Topics are made up by *Dialogue Acts* that are information unit of the main topic. The access structures express how the final user can reach and use the information. Each topic may be related to one or more *Introductory Act* that is the entry point to the topic's information. Furthermore, IDM provides the possibility to indicate that the topic

is related to an operation using the *Operation Act* but IDM does not provide any detailed description about the operation. IDM provides a specific design for each user and each device. Information contents are organized in page (*P-IDM*). Screens with input and/or output information contents make up each page; each screen has its own layout and belongs to a screen template. Pages are grouped in view; each view focuses on a specific aspect: the *structural view*, for example, represents the navigation within the same topic; the *association view*s represent the navigation between topics.

In this paper, we present in the section 2 the open issues in the WIS process-oriented design and in the section 3, we present the integration guidelines between IDM design and the business process. In section 4 we apply guidelines to a real world case study, finally, we present in section 5 conclusions and future works.

2. WEB INFORMATION SYSTEMS PROCESS-ORIENTED: OPEN ISSUES

Before to define the methodological guidelines we present here some open issues. We know that other works deal with the same open issue [8] but here we refer to a specific design methodology focused on the UX and not on a general UML-based methodology.

Several Types of Information in the Same Web Application

A traditional web application has the main goal to provide the user with information using a well-defined plan close to the user's expectation. The introduction of process logic, adds process information to typical web application information. In a WIS process-oriented, we can see three different kinds of information:

- Information used by process task: for example input and output data of each task.
- Information related to the process already finished;
- Hypermedia information that are data not related to the process: for example marketing information are related to a specific process but are not input and/or output information of the process task.

Information related to the UX design and information related to the process are not disjoint: it is possible that a UX information hide information related to one or more process tasks; in the same way, a process task may hide information related to different UX information unit.

Navigation Design

The navigation design plays a very important role in the web application design. In the WIS process-oriented, it is hard to make the navigation design because the final user must follow several steps coming from process logic in a well-defined order. We observe that process links (links coming from process design) must be related to the semantic links: an inconsistence between process link and semantic link warns the designer about the possibility of an error in the process and/or in the UX design.

Process State

The user during the task execution may want to exit from the process in order to read marketing information or information related to process instances yet finished. The user wants to continue the process later exactly where he/she leaves from. This is not only an implementation problem but this is a design problem: at design level, it is important to provide information about the process state in order to provide dynamically generating access structures that allow the user to continue the process execution.

Web Page for Task Execution

In the web page design, it is important to define if the process uses just one page or multiple pages. We observe that there is not a rule to assign a well define number of pages to a task: it depends on the graininess level of the process design. Sometimes a task execution ends in one page; sometimes the task execution require several pages, other times a task is an automatic task so web pages are not required.

3. WEB INFORMATION SYSTEM PROCESS-ORIENTED: GUIDELINES

To approach the open issues presented in section 2 we provide not a design methodology but integration guidelines: in this way the know-how coming both from web application design and from business process design are related in order to not lie the designer to many restrictions. In the guidelines definition our attention was oriented to the *traceability requirement*: in the web application process-oriented design, it is important to follow the process flow. In this way, it is simple to obtain quickly changes in the web application process oriented when a change in the business process happens: very often companies change their business process in order to answer to the companies' requirements changes.

Type of Users

There is a natural mapping between web application type of users and business process actors: each pool and each lane of pool can be mapped to a web application user. This is not a general rule; in fact, in BPMN notation it is possible to represent with pool and/or lanes non-human actors that are not related to a specific web page; pools can be black box (when they represent external institution related to the company but not directly involved in the process).

Mapping Between Process Information and UX Information

Starting from IDM design it is possible to identify topics, dialogue acts and slots belonging to the process. It is possible that information related to only one topic are enough to execute the process but it is also possible that information needed to execute the process are in several IDM topics. So, it is impossible to define a general rule in order to identify the information helpful to execute process starting from the UX design; in the same way it is impossible to define a general rule in order to identify where process information are located in the process depending on the specific case study.

Operations

Operations are very often not taken into consideration from design methodologies: operations are, instead, a key aspect to integrate process design and UX design but it is important to define the operation properties. For each process task, it is important to see if it requires one or more operations, a simple navigation or both. The operation act (the IDM element that defines the operation) may be related to a topic or to a dialogue act but may be related neither to a topic nor to a dialogue act. For example, if we think to an operation related to a message exchange the operation is not lies to any elements of the UX design. The operation act properties that we define are:

- *Name*: the same to the task related to the operation act (when exist);
- *Process name*: the name of the process;
- *Task:* the task related to the operation act (when exist);
- *Implementation*: the reference to the code that implements the operation;
- *Pre-condition*: the condition need to execute the task (when exist);
- *Output*: the output of the task related to the operation act (when exist);
- *Gateway*: is defined only if the operation is related to a gateway. It expresses the condition related to the gateway ;
- *Kind of topic*: identify the kind of topic where information are located;
- *Dialogue act*: identify the dialogue act where information are located;
- *Slot*: identify the slot where information are located;

Traceability Between UX Design and Business Process Design

As we state before, it is very important to provide traceability between UX design and business process design. We add to the IDM design the operation strategy ⇧ (to show the dialogue act or topic where the process starts) and the intermediate strategy ⇮ (to show a pause in the process execution) that is related to an intermediate event. Another important aspect is the introduction of the *process link*: it links together two operation acts in order to trace the process flow. The name of the process link is the name of the target operation act.

Access Structures

Access structure allows the user to access the web application. In the web application without business process, access structure allows to access to the information

Table 1. IDM extension

IDM extension for Business process integration	Comments
Structure of operation act	To provide the right structure to operations (very important in the process)
Intermediate strategy	Answer to the traceability requirement
Operation Strategy	Answer to the traceability requirement
Process link	To separate the free navigation from the navigation coming from the process logic
Specific access structure for process	User must be able to execute a task of the process
Management of the state of the process	Allow to stop and re-start process
Input form	Allow to insert input data in order to execute a process task
Screen with input form (<<P>>)	Answer to the correspondence requirement
Process view	Answer to the traceability requirement

according to the UX design; when the web application hides a business process, it is important to add access structures in order to allows the user to start the process and to continue its execution when he/she stop the process. We advise to define an access structure for each operation act.

Page Structure

The page structure design changes when we integrate the business process design in the UX design. In P-IDM each topic produce a structural view made up by screens aggregate to contents (in order to show information) or screens aggregate to an input form (in order to insert information). When the process design is taken into consideration, the same information may be, depending on the process state, input information or output information. We state that in the page design level must coexist both input form and content: the input form or the content will be dynamically presented to the final user depending on the *process state:* the screen has also information about the state. The input screen related to a process will be show with a <<P>> symbol.

If the information of the same topic is useful in order to execute two or more operation, the related screen will be linked together with a process link. In the structural view, we define the *intermediate link* in order to represent the intermediate strategy.

Regarding to the *template view*, it is important to define links that allow the user to continue the process: the state of the process allows to dynamically activate the correct link.

We recommend to add a process view in order to design in a single view all the process screens. The process view is useful when the information needed to execute a process are in several topics in order to understand how the process flow moves towards information. If the information to execute process is all in the same topic the process, view is the same of the structural view.

We summarize in table 1 the IDM extension proposed.

4. GUIDELINES IN PRACTICE: A CASE STUDY

We apply the guidelines proposed in section 3 to two different research project founded by Italian government: one project is related to the management of environment domain and another is related to the commerce of the wheat.

We present here the first project born with the goal to design and implement a family of web application compliant with European standard related to the environment. From this family it will be possible to obtain specific web application for several public administrations with different competencies and responsibilities. Obviously, the web application family will consider both the UX and the process aspects.

Figure 1. IDM design of the management flora and fauna census

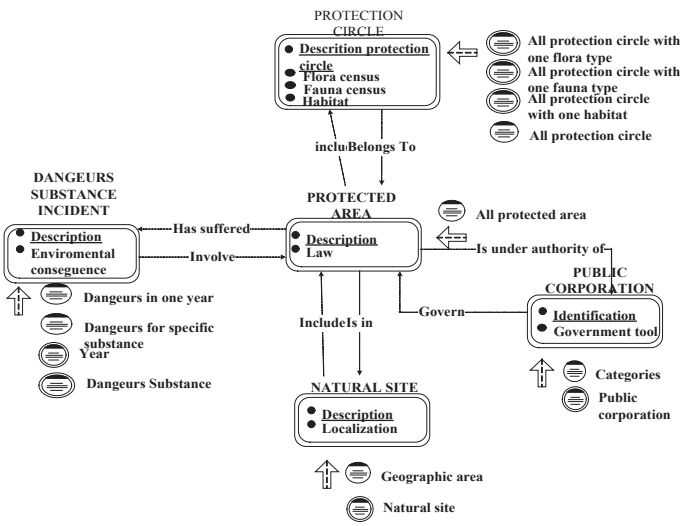

Figure 2. BPMN design of the management flora and fauna census process

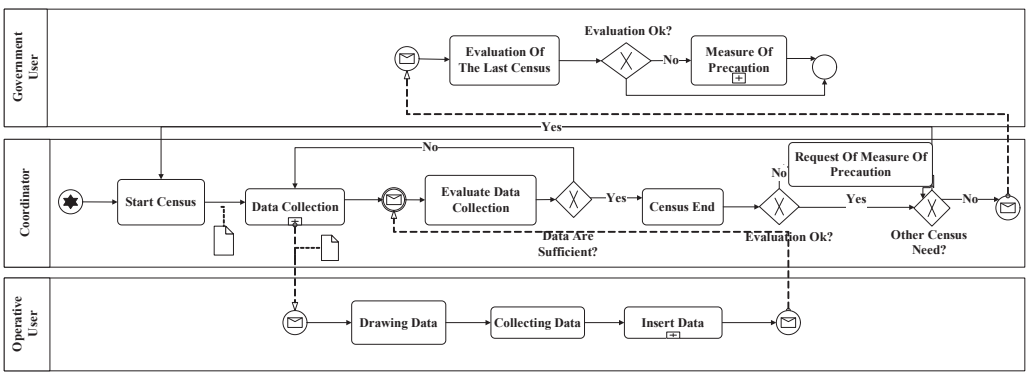

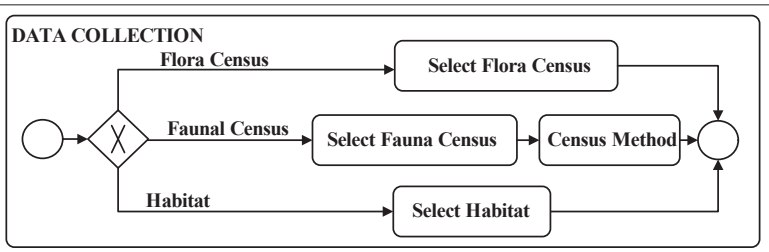

In this project business experts and IT experts' teams design, in a separate way, both the UX and the business process of the overall information system (Fig. 1 and Fig. 2).

We present here, due to space limitations, a fragment of the overall Information System: the management of flora and fauna census. The sub-process "data collection" considers three kinds of census but we are interested only to "faunal census".

In fig. 2 we can immediately observe three kinds of user one for each BPMN pool: we focus only on the coordinator user.

A careful analysis of the process design and of the UX design helps to select the process information defined also in the UX design. We observe that all process tasks refer to one dialogue act: "*faunal census*". Each task is related to a different slot of the dialogue act. As an example the task "*Start Census*" is related to the slot "*Description*" and "*Start date*" while the task "*End Census*" is related only to the slot "*End Date*".

The task "*Request Of Measure Of Precaution*" is not related to any slot: this task is the request of a precaution made up by the coordinator user to the government authority, so it does not require neither to write nor to read any slot.

In fig. 3 we show the process start on the integrated design with an *operation strategy* near to the dialogue act related to the first process activity (the first operation act).

We define now the operation act (in this case study all the operation act are on the topic *Protection circle*). In fig. 3 we show only the properties of the operation act related to the "*Start Census"* but all operation acts have its own structure. We

Figure 3. IDM Process of the management flora and fauna census process

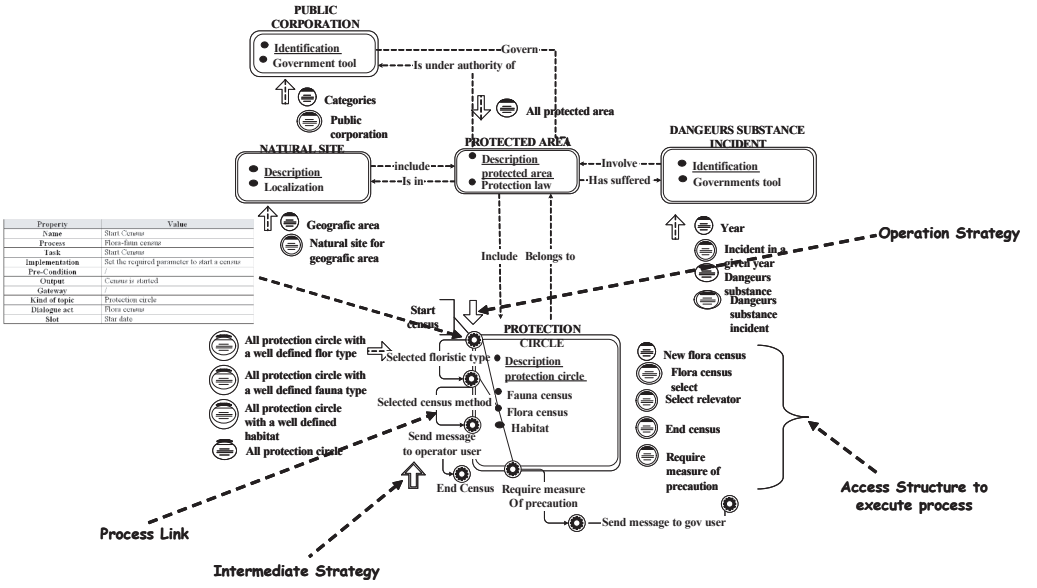

Figure 4. Structural view

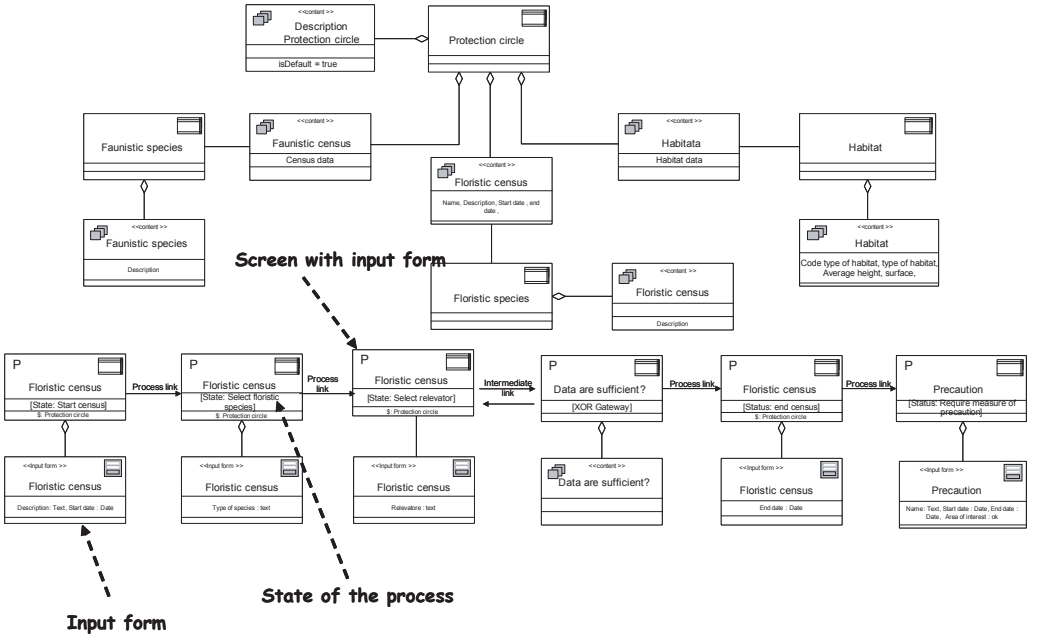

can see that there is an operation act related to each process task also for the task related to operation not directly related to the information.

At this point, we design the process link that links together, in a well-defined order and according to the process flow, the operation acts. The name of the process link is the name of the target operation act.

We define now the access structures (in IDM methodology named introductory act) in order to start a new process or to continue the process. There is an introductory act for New Flora Census that allows to make a new process instance; in the same way, we define an introductory act for each operation act. If the operation act represents only a message exchange there is not an access structure related.

Regarding the page design, we consider the structural view related to the *Protection Circle* Topic (Fig. 4). We can see that the screen related to each dialogue act has both content and input form. Process screens are marked with a <<P>> on the top and contain information about process state. *Process link* links together the process screens according to the process flow. We highlight that the process screen related to the gateway is related with content and not with an input form: a gateway does not require input data (defined through slot) but only an answer to a well-defined question. The slots needed to execute task are shown in the input form.

In the *page template view* (not shown here for space reasons) there are links that brings to the process screens. These links do not appear in all the pages but they will be dynamically generated depending on the process state and allow the user to start or to continue the process exactly where he/she left.

Finally, the process view contains the entire process screens and their relationships: in this case study the process view is the same of the structural view because all the information need to execute process are in the same topic.

5. CONCLUSIONS AND FUTURE WORK

To achieve the goal of the flexibility in the modern WIS process-oriented, it is important to think to a design methodology that links together the know-how coming from the UX design and the know-how coming from the process design. In this paper, we defined an integrated methodology focusing on the differences between kinds of information and between free navigation and navigation process-driven. We apply the guidelines to a real case study with good results. The buyer was very happy because it is possible to trace, in the final design, both the UX and the process design. Processes, was, also, defined by their business expert so, the final WIS matches exactly their needs with an added value. Public administration, that is the final user of the WIS, was very happy to work with a WIS where all the information are really where they need and are reachable exactly as they need. In addition, developers have a clear documentation.

Naturally, the implementation actually is made by hand but we are planning to extend our code generator in order to support also the introduction of these guidelines.

ABSTRACT

Discussions at previous HICSS conferences have shown that there is no general agreement on definitions of Knowledge Management (KM) and Knowledge Management Systems (KMS) success. A deep understanding of these concepts would help to design and implement efficient KM initiatives and systems. We present an exploratory research study to begin and facilitate a debate that will hopefully lead to a consensus definition of KM and KMS success. We chose an expert panel approach followed by an exploratory survey to approach the KM and KMS success definition. The research shows only a few points of consensus. However, we present some areas of agreement as well as of disagreement, which are a good starting point for further discussions on KM and KMS success.

1. INTRODUCTION

Knowledge Management (KM) and Knowledge Management System (KMS) success is an issue needing to be explored. The Knowledge Management Foundations workshop held at the Hawaii International Conference on System Sciences (HICSS-39) in January 2006 discussed this issue and reached agreement that it is important for the credibility of the KM discipline that we be able to define KM success. Additionally, from the perspective of KM academics and practitioners, identifying the factors, constructs, and variables that define KM success is crucial to understanding how these initiatives and systems should be designed and implemented. It is the purpose of this paper to initiate discussion on this topic and present results of a survey looking at how KM practitioners, academics, and students view what constitutes KM success. The paper presents some background on KM success and then a series of perspectives on KM/KMS success. These perspectives were derived by looking at responses to questions asking academics and practitioners how they defined KM/KMS success. The paper then concludes by presenting the results of an exploratory survey on KM/KMS success beliefs and attitudes. It is hoped that this paper will begin the debate that will lead to a consensus definition of KM/KMS success.

2. BACKGROUND ON KM SUCCESS

Jennex (2003) summarized various definitions of KM to propose that KM success be defined as reusing knowledge to improve organizational effectiveness by providing the appropriate knowledge to those that need it when it is needed. KM is expected to have a positive impact on the organization that improves organizational effectiveness. DeLone and McLean use the terms success and effectiveness interchangeably and one of the perspectives proposed in this paper does the same for KM (DeLone and McLean, 1992 and 2003).

Jennex and Olfman (2005) summarized and synthesized the literature on KM/KMS critical success factors, CSF, into a ordered set of 12 KM CSFs. CSFs were ordered based on the number of studies identifying the CSF. The following CSFs were identified from 17 studies looking at over 200 KM projects:

- A Knowledge Strategy that identifies users, sources, processes, storage strategy, knowledge and links to knowledge for the KMS.
- Motivation and Commitment of users including incentives and training
- Integrated Technical Infrastructure including networks, databases/repositories, computers, software, KMS experts
- An organizational culture and structure that supports learning and the sharing and use of knowledge
- A common enterprise wide knowledge structure that is clearly articulated and easily understood
- Senior Management support including allocation of resources, leadership, and providing training
- Learning Organization
- There is a clear goal and purpose for the KMS
- Measures are established to assess the impacts of the KMS and the use of knowledge as well as verifying that the right knowledge is being captured
- The search, retrieval, and visualization functions of the KMS support easy knowledge use
- Work processes are designed that incorporate knowledge capture and use
- Security/protection of knowledge

However, these CSFs do not define KM/KMS success; they just say what is needed to be successful. Without a definition of KM/KMS success it is difficult to measure actual success.

3. PERSPECTIVES ON KM/KMS SUCCESS

The KM workshop at the 2006 HICSS found that there were several perspectives on KM success. This section briefly summarizes these perspectives.

3.1. KM Success and Effectiveness

One perspective on KM success is that KM success and KM effectiveness are interchangeable and imply the same construct or variable. This is based on the view that effectiveness is a manifestation of success.

An example would be increasing decision making effectiveness to generate a positive impact on the organization resulting in successful KM. This perspective uses both process and outcome measures.

3.2. KM and KMS Success as Interchangeable

Another perspective is that KM and KMS success is interchangeable. KMS success can be defined as making KMS components more effective by improving search speed, accuracy, etc. As an example, a KMS that enhances search and retrieval functions enhances decision making effectiveness by improving the ability of the decision maker to find and retrieve appropriate knowledge in a more timely manner. The implication is that by increasing KMS effectiveness, KMS success is enhanced and decision making capability is enhanced leading to positive impacts on the organization. This is how KM success is defined and it is concluded that enhancing KMS effectiveness makes the KMS more successful as well as being a reflection of KM success. The Jennex and Olfman (2006) KM Success Model, based on the DeLone and McLean IS Success Model (2003), combines KM and KMS success and utilizes this perspective.

3.3. KM and KMS Success as Separate

As opposed to the previous section, this perspective views KM and KMS success as separate measures. It is based on a narrow system view that allows for KMS success that does not translate into KM success. KMS are often seen as a subfunction of KM comprising technical and organizational instruments to implement KM. Thus, KMS success addresses implementation and operation factors in terms

of system or process metrics whereas KM success is an assessment of the value that these systems and processes provide to an organization. KM focuses therefore more on the outcome, while KMS focus more on the process. These perspectives are introduced in the following sections.

3.4. KM Success as a Process Measure

This perspective views KM success as a process measure. KM success could be therefore described in terms of the efficient achievement of well defined organizational and process goals by means of the systematic employment of both organizational instruments and information and communication technologies for a targeted creation and utilization of knowledge as well as for making knowledge available. KM is a support function to improve knowledge-intensive business processes. An example would be supporting the technology forecasting process in an IT consulting firm by technical components of a KMS [6]. Complementary, the effective implementation of knowledge processes (i.e. acquisition, creation, sharing, and codification) is seen as a part of KM success. This perspective focuses therefore on measuring how much KM contributes to improving the effectiveness of business and knowledge processes.

3.5. KM Success as an Outcome Measure

In contrast, this perspective views KM success as an outcome measure. KM success is therefore seen as a measure of the various outcomes of knowledge process capabilities existing within an organization as a result of undertaken KM initiatives. Typical outcomes in terms of organizational performance are the enhancement of:

- product and service quality,
- productivity,
- innovative ability and activity,
- competitive capacity and position in the market,
- proximity to customers and customer satisfaction,
- employee satisfaction,
- communication and knowledge sharing, and
- knowledge transparency and retention.

3.6. KM Success as Combined Process and Outcome Measures

The last perspective views KM success as a combination of process and outcome measures. Respective descriptions of KM success focus on improved process effectiveness (cf. section 3.4.) as well as on achieving actionable outcomes (cf. section 3.5). Sections 3.1 and 3.3 contain examples for this combined approach.

4. METHODOLOGY

This paper is exploratory research with the goal of guiding the KM community towards a consensus definition of KM success. To achieve this, base data was obtained through an exploratory survey. The exploratory survey was generated through an expert panel approach. The 30 members of the editorial review board of the International Journal of Knowledge Management were asked to provide their definitions of KM success. Thirteen responses were received. These responses were used to generate an exploratory survey on KM success. The exploratory survey used 5 point Likert scale items to solicit agreement on various perspectives and proposed KM success definitions. The perspectives were generated by analyzing the responses of the expert board. These responses were found to be grouped two ways. The first grouping of responses looked at the measures used to determine KM success. Three groupings were observed: process based measures, outcome based measures, and combined process and outcome based measures. The second grouping of responses was in two groupings: those that combined KM and KMS success measures and those that viewed KM and KMS success as separate measures. A final observation was that many proposed definitions used success and effectiveness interchangeably.

The exploratory survey also collected data on the KM expertise and focus of the respondent. Also, the survey had text boxes that allowed for free form input on additional KM success factors or measures, KM success definitions, and thoughts on differences between KM and KMS success.

The exploratory survey was administered using a web form with data collected and stored automatically. Survey respondents were solicited via broadcast emails to the ISWorld and DSI email list servers, to lists of KM researchers maintained by the authors, and to the editorial review board and list of authors for the International Journal of Knowledge Management. An initial request was sent followed by a second request approximately one week later.

One hundred and three usable survey responses were received. Thirteen were from KM practitioners, 70 were from KM researchers, 6 were from KM students, and 14 were from academics interested in KM but not active KM researchers. Likert items were analyzed using means and standard deviations as no hypotheses have been proposed and need testing.

The results of the exploratory survey were used to generate a second survey. This survey presented a composite definition of KM success and a set of measures for each of the indicated dimensions. A 7 point Likert scale was used to solicit agreement on the composite definition and each set of measures. Additionally, as in the exploratory survey items were provided for collecting data on KM expertise and respondent focus. Also, each set of measures had boxes where respondents could indicate measures they would add or remove from each set of measures.

The second survey was also administered using a web form with respondents solicited in the same manner as the exploratory survey. One hundred and ninety-four usable survey responses were received. Sixteen were from KM practitioners, 114 were from KM researchers, 23 from KM students, and 41 were from others including academics interested in KM but not active KM researchers. Likert items were analyzed using means and standard deviations as no hypotheses have been proposed and need testing.

5. FINDINGS

There was little consensus on KM success perspective or definition from the first survey while we did find agreement on a definition of KM success and measures of success in the second survey. The results of the first survey are summarized in tables 1-3 while the results of the second survey are presented in Table 4. Table 1 looks at opinions with respect to the perspectives on KM success. The only perspective that tends to have any consensus agreement is that KM success is a combination of process and outcome measures and is NOT just process or just outcomes. We are undecided if success and effectiveness are equivalent measures and tend to be undecided to slightly against the idea that KM and KMS success are equivalent.

Table 2 summarizes opinions on five suggested components of KM and KMS success definitions. There appears to be consensus on using organization specific subjective measures derived for KM process capabilities. Examples of these capabilities include knowledge reuse, quality, relevance, effectiveness of acquisition, search, and application of knowledge, etc. There also appears to be consensus that any KM success definition should include providing the appropriate knowledge when needed. Additionally, there is consensus that use is not a good measure of KMS success. It is interesting to note that practitioners and students support the use of

Success of KMS should be measured in terms of "firm performance" should be included in a definition of KM success				
3.7 (1)	3.6 (1.1)	**4.1** (1)	3.5 (0.8)	**4** (0.9)
Providing the appropriate knowledge when 'needed'" should be included in a definition of KM success				
4.2 (0.9)	**4.2** (0.9)	**4.3** (0.9)	**4.4** (0.6)	**4.3** (0.5)

Overall n = 103, researcher n = 70, practitioner n=13, academics n=14, and student n=6

Values are rounded to 2 significant digits

firm performance measures as indicators of KM success while there is less support for these measures from researchers and academics. It is also interesting to note that academics and students tend to support the use of measures reflecting direct returns from organizational and individual learning and application of knowledge while researchers and practitioners are less favorable to them.

Table 3 summarizes opinions on five suggested definitions of KM and KMS success. There appears to be little consensus on these definitions other than a general neutrality on KM success as the flow of knowledge and KMS success as improving effectiveness of the KMS components. However, there are some interesting observations. KM success as the ability to leverage knowledge resources to achieve actionable outcomes is overall supported with the strongest support coming from practitioners. This is interesting but not surprising as practitioners tend to favor definitions and measures that are objective, readily measurable, and have an obvious impact on the organization. This is also why practitioners favor KM success as reusing knowledge to improve organizational effectiveness and KM success as the efficient achievement of well defined organizational goals for targeted creation and utilization of knowledge.

Table 3. Opinions on KM and KMS success definitions, mean (std dev)

Overall	Research	Practice	Academics	Students
KMS success can be defined as making KMS components more effective by improving search speed, accuracy, etc.				
3 (1.2)	2.8 (1.1)	3.6 (1.2)	3.1 (1.1)	3.2 (1)
KM success is the ability to leverage knowledge resources to achieve actionable outcomes.				
4 (1)	**4** (1)	**4.3** (0.9)	3.9 (0.9)	3.7 (1)

Table 4. Opinions on KM and KMS success definition and sets of measures, mean (std dev)

Overall	Research	Practice	Academics	Students
KM success is a multidimensional concept. It is defined by capturing the right knowledge, getting the right knowledge to the right user, and using this knowledge to improve organizational and/or individual performance. KM success is measured using the dimensions of impact on business processes, strategy, leadership, efficiency and effectiveness of KM processes, efficiency and effectiveness of the KM system, organizational culture, and knowledge content.				
5.4 (1.4)	5.3 (1.5)	6.1 (1.4)	5.6 (1.4)	5.5 (1.2)
Impact on business process measures.				
5.5 (1.3)	5.3 (1.4)	5.8 (1.4)	5.7 (1.2)	5.7 (1.0)
Strategy measures				
5.3 (1.4)	5.1 (1.6)	6.1 (0.6)	5.3 (1.4)	5.7 (1.0)
Leadership measures				
5.2 (1.5)	5.1 (1.5)	5.3 (1.5)	5.3 (1.3)	5.4 (1.6)
KM process effectiveness and efficiency measures				
5.7 (1.3)	5.5 (1.4)	6.2 (0.8)	5.8 (1.3)	5.7 (1.4)
KM system effectiveness and efficiency measures				
5.6 (1.3)	5.5 (1.4)	6.0 (0.7)	5.8 (1.2)	5.4 (1.3)
Learning culture measures				
5.6 (1.2)	5.5 (1.4)	6.0 (0.8)	5.7 (1.1)	5.6 (1.2)
Knowledge content measures				
5.4 (1.4)	5.2 (1.5)	6.0 (1.0)	5.7 (1.2)	5.5 (1.3)

Overall n = 194, researcher n = 114, practitioner n=16, others n=41, and student n=23

Values are rounded to 2 significant digits

Table 4 summarizes opinions from the second survey on a proposed success definition generated from the first survey and sets of measures for the dimensions listed in the proposed definition. There appears to be some level of consensus on the proposed definition and measures. However, we don't consider it strong consensus given that the mean response is between agree and somewhat agree. Still, this is considered a strong beginning to establishing a common definition and set of success measures.

6. DISCUSSION

This is exploratory research so few conclusions can be drawn. However, using two surveys has allowed us to reach some consensus on a KM success definition and set of success measures. The consensus KM success definition is:

"KM success is a multidimensional concept. It is defined by capturing the right knowledge, getting the right knowledge to the right user, and using this knowledge to improve organizational and/or individual performance. KM success is measured using the dimensions of impact on business processes, strategy, leadership, efficiency and effectiveness of KM processes, efficiency and effectiveness of the KM system, organizational culture, and knowledge content."

Also, there are a few points of consensus that can be identified from the initial survey:

- KM success and KMS success may not be the same thing.
- Usage is not a good measure of KM or KMS success.

Additionally, it is possible that there is a different focus on KM success between practitioners and researchers. Researchers do not seem to have a clear idea of KM success while practitioners appear focused on KM success as being tied to its impact on organizational performance and effectiveness. This can't be stated conclusively, the number of practitioner responses are too low (n=13) making this supposition. However, it isn't unexpected that practitioners would have a focus on organizational impact as a measure of KM and KMS success. Given that KM is an action discipline; researchers should accept this focus and incorporate it into their investigations.

There are some limitations to this research. It is quite possible that the reason little consensus has been observed is because KM and KMS success are complex constructs that are multi dimensional. It may be that KM and KMS success includes outcome measures, quality of knowledge, how well the KM processes function, organizational culture measures, usability measures, and strategy measures. This is consistent with the DeLone and McLean (1992, 2003) model of Information Systems success and there is much empirical evidence to support the correctness of this model. This model is also the basis of the Jennex and Olfman (2006) KM success model. It is quite likely that the exploratory survey used for this research, while generated using an expert panel, probably did not capture the multidimensional nature of the provided KM success definitions and therefore made it difficult for respondents to find statements they fully agreed with. This limitation was considered when generating the second survey and it appears that this has improved consensus with the KM success definition generated from the first survey.

7. CONCLUSIONS

It is difficult to reach any conclusions with this research; no hypotheses were proposed or tested. This is okay as the purpose of this paper is to start a focused discussion on KM and KMS success. The response to the exploratory survey shows this will happen as well as the minitrack focused on KM and KMS success and measurement at the Hawaii International Conference on System Sciences, HICSS.

To begin this dialogue it is important to identify areas of consensus and areas of disagreement. The following points are areas of agreement:

- KM and KMS success are likely different definitions (note that at least one of the authors greatly disagrees with this point).
- Use is a poor measure of KM and KMS success.
- KM success is likely a multidimensional construct that will include process and outcome measures.
- A base definition of KM success is: KM success is reusing knowledge to improve organizational effectiveness by providing the appropriate knowledge to those that need it when it is needed.

Additionally, a base definition of KM success can be established:

"KM success is a multidimensional concept. It is defined by capturing the right knowledge, getting the right knowledge to the right user, and using this knowledge to improve organizational and/or individual performance. KM success is measured using the dimensions of impact on business processes, strategy, leadership, efficiency and effectiveness of KM processes, efficiency and effectiveness of the KM system, organizational culture, and knowledge content."

Some areas of disagreement are in further need of discussion:

- KM success and effectiveness are likely the same and will be able to use the same measures.
- KM and KMS success are essentially the same (in deference to the authors and consistent with a Churchman view of a KMS and DeLone and McLean [1], [2]).
- The role of learning and firm performance in KM success.
- The role of outcome measures such as speed, accuracy, amount of knowledge stored and used, etc. in KM and KMS success.

It is expected that it will take a great deal of research before consensus is reached on what KM and KMS success is. It is concluded that this paper and these findings from an exploratory survey are a good starting point for this discussion.

Effects of Individualism-Collectivism in Computer Supported Collaborative Learning

Yingqin Zhong, National University of Singapore, 3 Science Drive 2, Singapore 117543; E-mail: zhongyin@comp.nus.edu.sg
John Lim, National University of Singapore, 3 Science Drive 2, Singapore 117543; E-mail: jlim@nus.edu.sg

ABSTRACT

There are few explorations of the effects of cultural orientation (collectivism vs. individualism) on users' perceptions in computer supported collaborative learning in spite of the increasing research attention received. This study investigates the differences in perceptions between collectivists and individualists regarding collaborative learning systems in facilitating collaborative learning, group wellbeing and member support. The effects of these user perceptions on the intention to use are also explored. An experiment involving seventy-three subjects from Asian as well as European countries was conducted to test the hypotheses. The study provides important guidelines in both theoretical and practical forms for future collaborative learning system design and usage.

1. INTRODUCTION

Collaborative learning is regarded as an important information processing activity in e-collaboration. Members learn from one another by actively engaging in exchanging knowledge and information based on their understanding as well as individual experiences (Leidner & Jarvenpaa, 1995). Growing interest in supporting the needs of active learning, along with concurrent improvements in computer networking technology, have prompted research on Computer Supported Collaborative Learning (CSCL). These systems enable effective learning to be achieved related to interactive communication and teamwork.

Individual members' cultural backgrounds influence how members collaborate and communicate (Feldman, 1984). Oetzel (2001) has identified the importance of a member's cultural orientation in influencing his/her participation in the groups that is undergoing adverse conditions. National cultures have been distinguished along a variety of dimensions (Hofstede, 1991). Arguably, the dimension of individualism- collectivism has received the most attention by psychologists specializing in cross-cultural research, particular in the context of group collaboration (Goncale & Staw, 2006). Most of the research on the individual-collectivism dimension has found that growing up in a particular country shapes the person's perceptions, and this element can be used to predict behaviors across a wide variety of situations (Brockner, 2003).

Relatively speaking, people from collectivistic cultures are presumed to care for the development of other members, whereas individualists care more for their self-development (Hofstede, 1991). Members with collectivistic culture background value greater the group needs and goals, social norms, and group cooperation (Cox et al., 1991). In contrast, members with individualistic culture background emphasize on self-interest and belief. They tend to value more personal time and freedom (Massey et al., 2001). Comparing the two types, collectivists are motivated to find a way to fit into the group, and in general become part of various interpersonal relationships (Goncale & Staw, 2006).

The cultural orientation impacts participants' perceptions, which in turn determine the intention to use a technology; this chain of relationships highlights the potential and importance of designing culturally appropriate systems in CSCL. This study concentrates on four common system features which are, according to literature and previous studies, very likely to trigger different perceptions between collectivists and individualists (Marcus & Gould, 2000; Massey et al., 2001); these features include template in posting, post statistics, personal contribution history, and synchronicity of communication.

Table 1. The constructs of PCL, PGW and PMS

Constructs defined in this study	Corresponding constructs in Dennis and Reinicke's (2004) work
Perceived facilitation of collaborative learning (PCL): This construct measures learners' perception of the effectiveness and efficiency of a CSCL feature in facilitating collaborative learning.	**Perceived task performance:** This factor inherited the common presumption of the construct perceived usefulness in literature; it refers to users' perception regarding the effectiveness and efficiency of the system in terms of performance.
Perceived facilitation of group wellbeing (PGW): This construct measures learners' perception of the effectiveness and efficiency of a CSCL feature in facilitating the socialization and relationship building in groups.	**Group wellbeing:** This factor measures users' perception of the ease of socializing and building relationships among members.
Perceived facilitation of member support (PMS): This construct refers to how learners perceive how a CSCL feature can facilitate them to be understood and known by other group members.	**Member support:** This factor refers to how the users perceive themselves are being understood by other group members and hence able to build network with others.

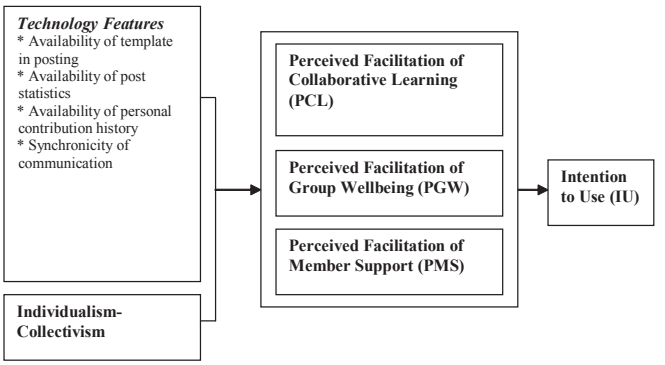
In line with Dennis and Reinicke's (2004) extended Technology Acceptance Model (TAM) in investigating the adoption behaviors of collaborative technologies, This study proposes an adoption model in CSCL by incorporating perceived facilitation of collaborative learning (PCL), perceived facilitation of group wellbeing (PGW) and perceived facilitation of member support (PMS) as antecedents of *perceived usefulness* (Davis, 1989), which in turn affects the intention to use (IU). We adopt these constructs in Dennis and Reinicks' (2004) work (see Table 1); the salient difference is that the current study focuses on the (perceived) effectiveness of the collaboration learning technologies.

This paper highlights the importance of culture sensitivity in CSCL design, which would cater to the cultural orientation, i.e., collectivism or individualism. Section 2 proposes an adoption model for CSCL. The next sections describe an experimental study and the data analysis. Findings are next discussed and implications are drawn.

2. PROPOSED MODEL AND RESEARCH HYPOTHESES

The diagram (Figure 1) depicts the theoretical model to be examined in this paper. The hypotheses are derived in the remaining of the section.

Figure 1. Research model



2.1 Availability of Templates in Posting

Previous instructional research has shown that providing students with templates in answering questions can guide the cognitive process and in turn enhance the learning (Cinneide, 1998). In CSCL, the templates can make the idea exchange among users easier because the flows of the posts are similar. However, individualists may tend to see a template is hindering uniqueness and creativity. Individualistic cultures encourage uniqueness; in contrast, uniqueness can be viewed as a threat to harmony in collectivist cultures (Goncale & Staw, 2006). The underlying psychological reason is that individualists are in favor of being unique and distinguished from other people; however, collectivists value their group as a whole and they generally tend to avoid being unique (Markus & Kitayama, 1994). In this connection, collectivists tend to appreciate the templates provided in the system more than individualists, because they tend to perceive the template as an easier way to achieve the group goal, and communicate with group members.

H1a. *Collectivists will report higher perceived facilitation of collaborative learning to the availability of templates in posting than individualists.*

H1b. *Collectivists will report higher perceived facilitation of group wellbeing to the availability of templates in posting than individualists.*

H1c. *Collectivists will report higher perceived facilitation of member support to the availability of templates in posting than individualists.*

2.2 Availability of Post Statistics

Some bulletin boards and discussion forums inform publicly the statistics regarding the responses to each post. Through this feature, users could gain a better sense of the degree of the consensus concerning a particular topic. Also the statistics reflect the social support among group members (Marcus & Gould, 2000). Collectivists are more incline to follow the consensus so as to promote feelings of harmony and cooperation (Kanter, 1988). This tendency is motivated by their concern for the well being of the larger social group.

However, because individualists tend to resist following the majority if majority's opinion is different from their preferences (Fiske et al., 1998); they are likely to be consistent in their views and maintain them in the face of opposition. As a result, the number shown in the statistics about the responses would not have as much effect on individualists as that on collectivists.

H2a. *Collectivists will report higher perceived facilitation of collaborative learning to the availability of post statistics than individualists.*

H2b. *Collectivists will report higher perceived facilitation of group wellbeing to the availability of post statistics than individualists.*

H2c. *Collectivists will report higher perceived facilitation of member support to the availability of post statistics than individualists.*

2.3 Availability of Personal Contribution History

Some systems allow users to search others' posts using the user login names, i.e. the personal contribution history of every individual is accessible to all users. The purpose of having this feature is to enable users a better understanding of others' arguments or ideas. However, the effects of this features triggers differently on users' emotion. Collectivists' self-esteem is not derived from calling attention to their own abilities or contributions; instead, their prime interest is to promote group interests (Wink, 1997). Thus, they tend to perceive the personal contribution history to be more useful in understand others' contributions rather than making themselves understood. Contrarily, in general, individualists tend to perceive that their contributions could arouse attention (Goncale & Staw, 2006); consequently, they are expected to perceive this function as a mechanism to promote themselves and consequently perceive greater member support from the other members.

H3a. *Collectivists will report higher perceived facilitation of collaborative learning to the availability of personal contribution history than individualists.*

H3b. *Collectivists will report higher perceived facilitation of group wellbeing to the availability of personal contribution history than individualists.*

H3c. *Individualists will report higher perceived facilitation of member support to the availability of personal contribution history than collectivists.*

2.4 Synchronicity of Communication

According to Dennis and Valacich (1999), communication media in CSCL may be differentiated in terms of their synchronicity (or lack of). For example, real-time text communication (e.g. chat) is a highly synchronous communication medium, while message board (e.g., bulletin board and discussion forum) are asynchronous media in which a discussion is carried over time (Bafoutsou & Mentzas, 2002). Generally, collectivists prefer the asynchronous media which allow them more time to compose messages and explain themselves; therefore, they tend to perceived asynchronous communication more helpful in facilitating learning than the synchronous communication (Massey et al., 2001). Collectivists also tend to prefer to reach decisions through indirect communication with a calculated degree of vagueness to avoid conflicts (Goncalo & Staw, 2006).

However, individualists generally prefer to reach decisions through synchronous communication that may invite debates - a practice not easily enacted to asynchronous groupware. The explanation here is that individualists value frankness and perceive conformity negatively, as compared to collectivists (Markus & Kitayama, 1994). Studies have shown that learners of individualistic cultures are generally more assertive than others (Goncalo & Staw, 2006).

H4a. *Collectivists will report higher perceived facilitation of collaborative learning to asynchronous medium than synchronous medium; individualists will report higher perceive facilitation of collaborative learning to synchronous medium than asynchronous medium.*

H4b. *Collectivists will report higher perceived facilitation of group wellbeing to asynchronous medium than synchronous medium; individualists will report higher perceived facilitation of group wellbeing to synchronous medium than asynchronous medium.*

H4c. *Collectivists will report higher perceived facilitation of member support to asynchronous medium than synchronous medium; individualists will report higher perceived facilitation of member support to synchronous medium than asynchronous medium.*

2.5 Relationships Between Perceived Facilitation and Intention to Use

Perceived usefulness has been studied widely in Information Systems literature as an important factor having a positive relation with users' intention to use (Lim & Bebhasat, 2000). Aligning with Dennis and Reinicke's (2004) work, perceived facilitation of collaborative learning, perceived facilitation of group wellbeing, and

perceived facilitation of member support are considered to be important aspects of perceived usefulness. Therefore, we expect they are positively related user's intention to use the technology features.

H5a. *Perceived facilitation of collaborative learning is positively related to intention to use.*

H5b. *Perceived facilitation of group wellbeing is positively related to intention to use.*

H5c. *Perceived facilitation of member support is positively related to intention to use.*

3 RESEARCH METHODOLOGY

3.1 Subjects and Manipulation Check

An experiment was conducted which involves seventy-three undergraduates participated in this study. For the collectivistic condition, forty subjects were recruited from Asian countries including China, Malaysia and Vietnam. For the individualistic condition, subjects were from European countries, mainly Sweden and Germany. Participation to this study was on a voluntary basis. Comparative research on Asian and European cultures suggests that the two cultures represent well the collectivistic and individualistic cultures respectively (Hofstede, 1991). Manipulation check was conducted by using Hofstede's scales to test subjects' cultural orientation in terms of individualism-collectivism, and it was found successful ($p < 0.01$).

3.2 Experimental Procedure

Prior to the experiment, all participants completed a questionnaire to assess their experience in exploring sites and links, participating in online chat, posting in forum, and visiting the websites relating to their courses. Also subjects were assessed for their experience in collaborative learning. No significant differences were reported between the individualists and collectivists. Further, all subjects reported that they had previously participated in all the activities mentioned. Variables PCL, PGW, PMS and IU were measured through questionnaire items adapted from Dennis and Reinicke's (2004) work (see Appendix).

Table 2. Descriptive statistics: mean and standard deviation

Cultural Orientation	Functions	PHCL	PGW	PMS	IU
Collectivists	Templates in posting	3.53 (0.81)	3.23 (0.79)	3.28 (0.79)	3.30 (0.95)
	Post statistics	3.02 (0.75)	3.13 (0.81)	3.02 (0.73)	3.29 (0.82)
	Personal contribution history	3.51 (0.77)	3.54 (0.69)	3.54 (0.72)	3.66 (0.85)
	Asynchronous comm. (Forum)	3.72 (0.56)	3.73 (0.79)	3.71 (0.67)	3.75 (0.82)
	Synchronous comm. (Chat-room)	3.43 (0.78)	3.53 (0.89)	3.50 (0.90)	3.65 (0.82)
Individualists	Templates in posting	3.33 (0.88)	3.07 (0.91)	3.02 (1.02)	2.95 (1.03)
	Post statistics	2.59 (0.81)	2.73 (0.86)	2.89 (0.91)	3.05 (0.98)
	Personal contribution history	3.03 (0.87)	3.02 (1.00)	3.18 (1.03)	3.45 (0.92)
	Asynchronous comm. (Forum)	3.78 (0.64)	3.78 (0.67)	3.75 (0.81)	3.77 (0.81)
	Synchronous comm. (Chat-room)	3.41 (0.82)	4.05 (0.75)	4.03 (0.89)	3.76 (0.90)
Total	Templates in posting	3.44 (0.84)	3.16 (0.84)	3.16 (0.90)	3.15 (0.99)
	Post statistics	2.83 (0.89)	2.96 (0.85)	2.97 (0.81)	3.18 (0.89)
	Personal contribution history	3.30 (0.85)	3.32 (0.87)	3.39 (0.88)	3.57 (0.88)
	Asynchronous comm. (Forum)	3.74 (0.59)	3.75 (0.73)	3.73 (0.73)	3.76 (0.81)
	Synchronous comm. (Chat-room)	3.42 (0.79)	3.75 (0.87)	3.73 (0.93)	3.70 (0.85)

Table 3. Summary of hypotheses test results

H1, H2, H3 and H4				
Functions	Constructs	Hypothesis	ANOVA / T-test	Hypothesis supported?
Templates in posting	PHCL	Collectivists > Individualists	F = 0.91 , p = 0.35	H1a: No
	PGW		F = 0.42, p = 0.52	H1b: No
	PSS		F = 1.01 , p = 0.31	H1c: No
Statistics about the responses to posts	PHCL	Collectivists > Individualists	F = 0.03, p =0.86	H2a: No
	PGW		F = 3.15, p = 0.08	H2b: No
	PSS		F = 0.37, p = 0.55	H2c: No
Personal contribution history	PHCL	Collectivists > Individualists	F = 5.12 , p =0.03	H3a: Yes
	PGW		F =5.81 , p = 0.02	H3b: Yes
	PSS	Individualists > Collectivists	F =2.22 , p =0.14	H3c: No
Degree of synchronicity in communication	PHCL	Collectivists: Asynchronous>Synchronous	t = 1.25 , p = 0.22 t = 1.43 , p = 0.16	H4a: No
	PGW	Individualists: Synchronous>Asynchronous	t = 2.08, p = 0.04 t = 4.67, p = 0.00	H4b: Yes
	PSS		t = 2.23 , p =0.03 t = 4.01, p = 0.00	H4c: Yes

H5						
	Unstandardized Coefficients		Standardized Coefficients	T	Sig.	Hypothesis supported?
	B	Std. Error	Beta			
PHCL	0.18	0.03	0.28	7.03	0.00	H5a: Yes
PMS	0.20	0.07	0.18	2.92	0.00	H5b: Yes
PGW	0.30	0.07	0.27	4.34	0.00	H5c: Yes

We used a web-based learning environment, Future Learning Environment (FLE), to support collaborative learning among participants in this experiment (Leinonen et al., 2003). In the FLE, a course about the solar system was constructed. The subjects were informed that there were a total of 15 users (including the experimenter). These phantom users were played by the experimenter, who also served as the facilitator. Posts (by virtual participants) were pre-created and made identical for all experimental conditions.

Detailed instructions were provided to guide subjects to use the corresponding system features in performing a series of activities. Subjects were first asked to read through the materials as well as the posts in the system. Next, they were requested to compose in a forum two posts in two separate threads regarding two topics covered in the materials. In one thread, all posts were supposed to adopt a specific template. In the other thread, posts were composed without any templates. To combat any order effects in the experiment, the sequence of the two posting activities was randomly assigned to subjects. When the two posts were completed, subjects were asked to try out the chat-room feature, while the experiment administrators took the time to post replies to subjects' posts using the names of virtual participants. The subjects were next asked to check the response statistics about their posts, and access their own personal contribution history and also histories of other percipients in the forum. The relevant instrument was administrated at the appropriate point in time after the corresponding function was attended to.

4. DATA ANALYSIS

Factor analysis and reliability tests show that the instruments are suitable (see Appendix). The ANOVA model was used to detect significant effects; a 5% level of significance was used in all tests. Due to the different number of subject involved in the experimental conditions, steps have been taken prior to the analysis to ensure the satisfying of the three assumptions underlying the ANOVA model, namely homogeneity of variance, independent sample, and normality of error terms. Further, subjects have reported no significant differences in terms of computer experience and collaborative learning experience between the two experimental conditions; these factors are not included as covariates in the analysis. Next, linear regression model is used to test the relationships between the perception variables (PCL, PGW and PMS) and the intention to use (IU). Table 2 reports the descriptive statistics. Table 3 summarizes the results of the hypotheses testing.

5. DISCUSSION AND IMPLICATION

This study has the following limitations. First, the users have used the system for a relative short time. The time limitations could have affected the behaviors of members. This calls for longitudinal studies in future. Next, the relatively small number of subjects should be noted when interpreting the results. Lastly, the use of voluntary subjects in an optional course which may be quite different from the setting in a compulsory course; this may account for most of the unsupported hypotheses regarding the perceived facilitation of collaborative learning.

In terms of theoretical contributions, this exploratory study has examined the effects of culture orientation on perceptions pertinent to the collaborative learning, and how these perceptions affect the intention to use. In this research, the individualism-collectivism culture dimension was of focus. Future research could look into other dimensions such as power distance and uncertainty avoidance. The joint effects of culture and other factors are of interest; these factors include communication style, task nature and gender (Simon, 2000). For example, Chang and Lim (2003) also stated that gender effects may become salient only in individualists in online setting.

This study also highlights the importance of designing culturally sensitive system to facilitate CSCL. For users from collectivistic culture background, systems could include functions which facilitate social support to increase users' incentive and intention to use of the system.

6. CONCLUSION

This study investigates the differences in perceptions between collectivists and individualists regarding collaborative learning systems in facilitating collaborative learning, group wellbeing and member support. The effects of these user perceptions on the intention to use are also explored. An experiment involving seventy-three subjects from Asian as well as European countries was conducted to test the hypotheses. The study provides important guidelines in both theoretical and practical forms for future collaborative learning system design and usage.

APPENDIX MEASUREMENT ITEMS (5 POINT SCALES)

Perceived Facilitation of Collaborative Learning (PCL) (Alpha = 0.96)

PCLE1: Using <This function> enhances the quality of the message I composed. (loading = 0.92)

PCLE2: Using <This function> make the message easier to compose. (loading = 0.91)
PCLE3: Using <This function> is a good way to share my information with other users. (loading = 0.94)
PCLE4: If other users use <this function>, I can understand better their idea in the message. (loading = 0.92)
PCLE5: If other users use <this function>, I can improve my learning in CLS. (loading = 0.91)

Perceived Facilitation of Group Wellbeing (PGW) (Alpha = 0.87)
PGW1: <This function> is a good way to help all users to socialize and develop relationships. (loading = 0.84)
PGW2: <This function> is a good way to build and maintain all users as intact and continuing social group. (loading = 0.88)
PGW3: <This function> contributes to the cohesiveness among all users. (loading = 0.78)

Perceived Facilitation of Member Support (PMS) (Alpha = 0.76)
PMS1: <This function> is a good way to let other users in the system understands me more. (loading = 0.79)
PMS3: <This function> is a good way to create and maintain my role among all users. (loading = 0.75)

Intention to Use (IU) (Alpha = 0.93)
IU1: I intend to use <this function> for learning in CLS. (loading = 0.82)
IU2: Assuming I have access to <this function>; I predict that I would use it for learning in CLS. (loading = 0.82)
IU3: I plan to use <this function> to learning in CLS in future. (loading = 0.85)

Challenges in Building and Maturing of a Telecommunications Business Intelligence Solution in a Developing Country

D. P. du Plessis, University of the Free State, South Africa; E-mail: duplessisdp.sci@mail.uovs.ac.za
T. McDonald, University of the Free State, South Africa; E-mail: Theo.sci@mail.uovs.ac.za

ABSTRACT

South Africa as a developing country has since 1994 gone through a process of privatisation of some of the state departments. The Department of Post and Telecommunications was one of those departments. During this transition period, data warehousing and business intelligence has played a critical role in measuring the performance of the new telecommunications company against targets set by government. This new telecommunications company had to meet the targets set while also preparing for competition. This paper will describe the challenges that were faced during the privatisation. It will also describe a new business intelligence literacy and cultural maturity model and a new data warehouse lifecycle model that evolved from the struggle to overcome the challenges that existed.

1. INTRODUCTION

In 1994, just after the privatisation of the Department of Post and Telecommunication, the new democratic government of South Africa was the sole shareholder of the only landline telecommunications company in South Africa. The Government had vibrant discussions with all the relevant parties on how telecommunications might be restructured to create an even distribution of access to telecommunications services to all the people in the country. This resulted in a White Paper on Telecommunications policy which was released in March 1996 (Anon, 1996).

The major proposal contained in the White Paper was that the owner and operator of the fixed telephony infrastructure would be granted a limited period, the so-called exclusivity period, of monopoly in the provision of basic telecommunication services. This exclusivity period was to last for five years, until May 2002, but could be extended to six years, if the telecommunication operator met network rollout and service targets. The rollout targets included doubling its subscriber access lines by 2.7million; installing 120,000 new public telephones; connecting 3,200 villages for the first time and providing service to more than 20,000 priority customers such as schools and clinics. The exclusivity period was intended to allow them to expand the network as rapidly as possible in order to facilitate universal access and to move towards universal service. The agreement left the telecommunications provider with the challenge to plan and manage the implementation targets set by government while at the same time preparing for competition once the exclusivity period expired.

This paper will firstly provide a background of the status of business intelligence in the telecommunications company. That will be followed by challenges faced in building and maturing a business intelligence solution in the company. The paper will then conclude with two models that resulted from the challenges.

2. BACKGROUND

The new company already had a Data Mart (DM) on infrastructure information. Although the DM was in place it was not used at all. The main reason was that people did not know how to use it, simply because of the lack of technical knowledge and a lack of training on the business intelligence tools available to the business. The legal requirement to manage the agreement with government has forced the company to start using available data. When people started asking for information concerning spare infrastructure it was realized that the required information was available in the DM. However, people did not know how to access and/or use the information. The lack of knowledge on how to use the DM has resulted in sales people selling telephone services in areas where there was no infrastructure.

Williams and Williams (2004) stated that, historically, many data warehousing (DW) and business intelligence (BI) initiatives have been IT-driven, and much of the focus within the industry has been on the technical aspects of delivering information to the BI user community. Having arrived at a point where many of the technical challenges and trade-offs were at least well understood, more attention was needed on how BI can be used to deliver business value. The BI user is not interested in the technical working of the DW and BI solution. They are more interested in the value that it adds to the business. Does it create the right business questions and does it facilitate the correct answers to the critical business questions to ensure the competitive advantage? In the case of South Africa and the sole provider of telecommunications in the country, it was at that stage important to start using the DW and BI tools that were already available in the company.

3. CHALLENGES

3.1 BI literacy and culture

To be able to use the information and data available in the DM brought the company to a point that management had to make a decision between the following alternatives:

1. Train all the business people on the existing BI tool (Business Objects)
2. Implement a new BI tool which also needed training
3. Create a new division that will fill the gap between the technical working of the data warehouse (ICT) and the business.

The first two options were seen as expansive, risky and very time-consuming, as there was no culture for the use of electronic information in the company. Business people would have access to electronic information, but would print it out before using it. When going to a meeting managers would print reports and take a hardcopy with them to the meeting. Dashboards were on paper against the wall. Secretaries printed out the new information every day and stuck it on the wall. So, training alone would not be sufficient for the company and therefore it made sense to take the third option.

The third option was selected because it was seen as the quickest solution and also a steppingstone to get the BI literacy and cultural maturity level of the company to a level to use electronic information. In BI it is hard to split literacy from culture. Bodly (1994) believes that culture involves at lease three components: what people think, what they do, and the material products they produce. Literacy is considered as the ability to locate, evaluate, use and communicate. It was difficult to split the two realities, because the one could be the result of the other and that leaded to business not using the DW and BI solution.

A new division was consequently created to fill the gap between the ICT and business. The company was divided into six regions to render a telecommunications service in South Africa. A decision was taken to use that same regional approach to implement this new division called Knowledge and Information Management (KIM). One manager per region was appointed with between three to five knowledge

workers depending on the size of the region. Knowledge workers were people with a combination of ICT and business skills.

3.2 Plan and Manage the Implementation Targets Set by Government

The fact that a DM and BI solution was already in place as well as the establishment of the KIM division have helped a great deal in implementing and managing the targets set by government. South Africa has a 41% rural population and these rural communities have access to schools and clinic's which were also in the rural areas where there was no infrastructure. To start off with the urban schools and clinics was easy, but that would not fulfill the additional requirement for services to the priority customers. The same applied to prepaid phones. To install a payphone (coin or card) was also a way of taking a telephone service to these rural communities.

Therefore, to be able to start working on the targets set by government, the first step was to determine the spare infrastructure in order to send the sales teams to sell where there was infrastructure available. Otherwise sales personnel would have sold in areas where there was no infrastructure and that would result in customers waiting for their services while the company has to plan and build that infrastructure. Building the infrastructure could take months or years depending on the size of the project.

A report on infrastructure was initiated by the KIM division. The infrastructure consisted of two network areas:

1. Core network (exchanges and transmission systems)
2. Access network (cables to the different houses, coin phones and businesses)

Figure 1 below is a high-level graphical representation of the network of a landline telecommunications company.

On the core network each connection needed a telephone number and a port on the exchange. On the access network, each connection needed the following positions on the network:

1. strip and line on the Main Distribution Frame (MDF)
2. an exchange and distribution point position on the Street Distribution Cabinet (SDC)
3. one position on the Distribution Point (DP)

A sales list with the spare infrastructure was provided to the sales division in the different regions. Sales lists were made available on weekly basis. From the dimensional model in figure 2 below, it is clear that there were no facts; the information consisted of a combination of dimensions. Therefore a factless fact (Kimball, 2002) was used.

After the sales team went out and sold telephone services to these addresses, it was important to track the orders through the order system. Not only has the number of orders in the order system increased rapidly, it was also important to get the orders through the system as soon as possible to ensure that the services were provided to the customer to achieve the targets set by government.

3.3 The Order Process

The order process consisted of the following steps:

1. Capturing paper order on the system
2. Credit vetting of new customer
3. Allocate access network

Figure 1. Landline telecommunications network

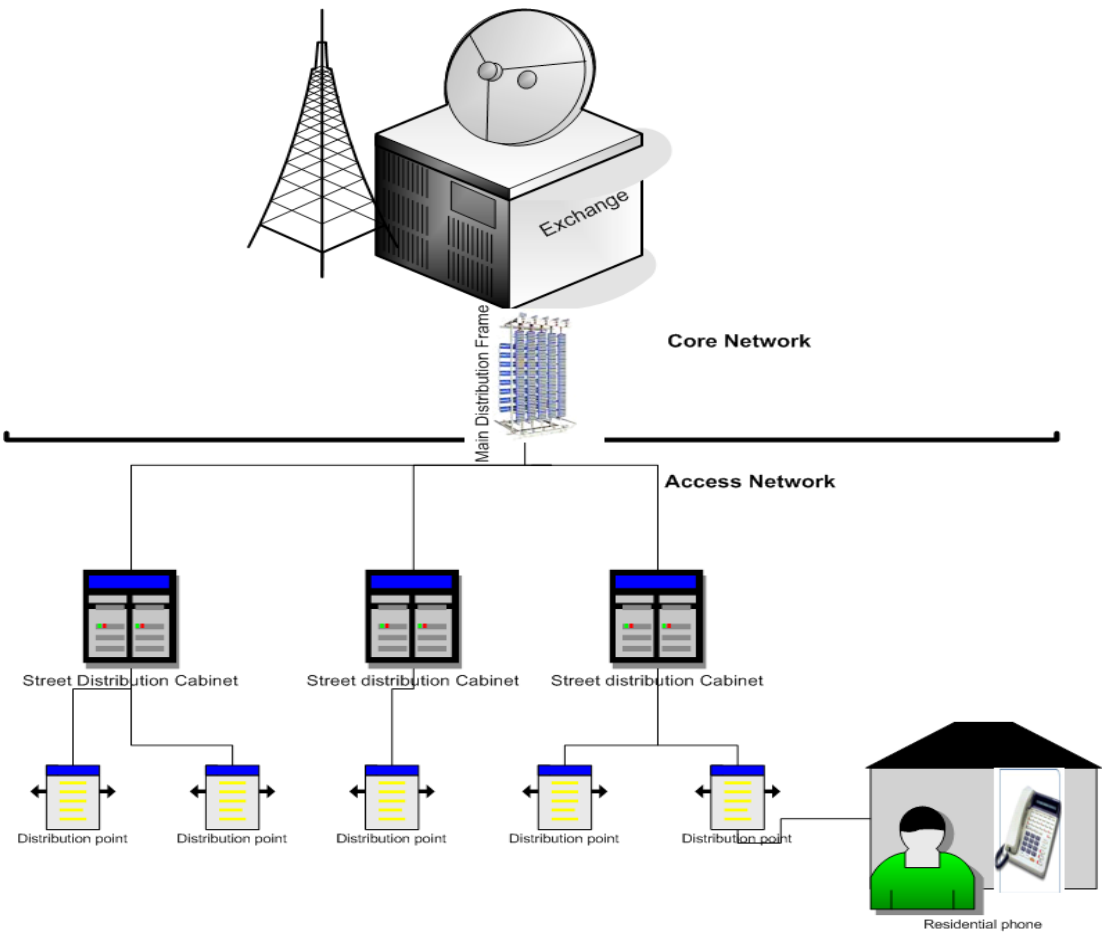

Figure 2. Infrastructure dimensional model

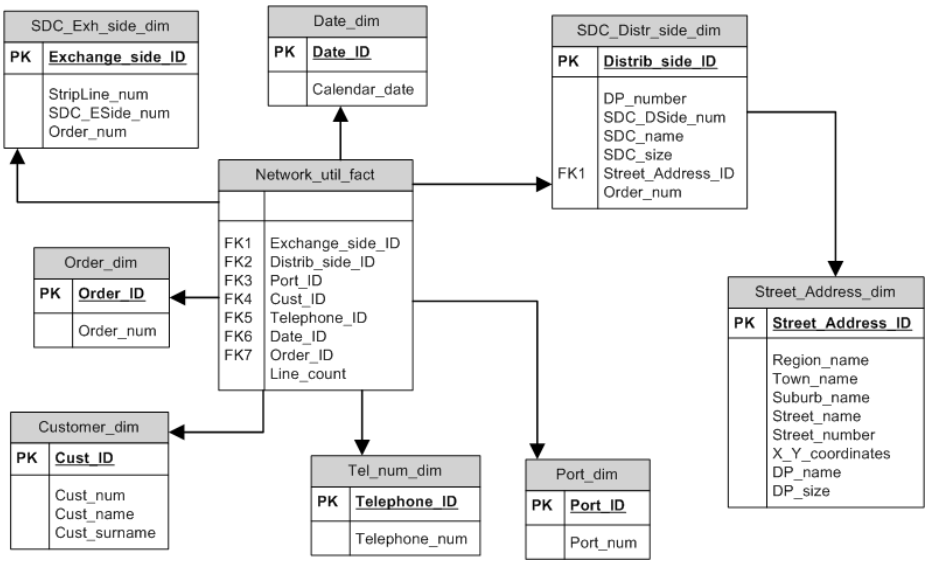
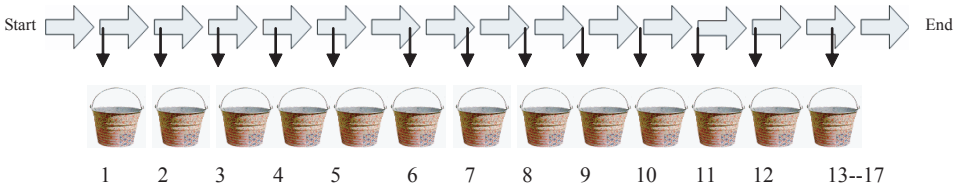


4. Allocate core network
5. Receive connection fee
6. Order sent to exchange to create a new port and telephone number
7. Order sent to main distribution frame for cross connection
8. Order sent to technical team for installation
9. Finished order sent to billing team to start the billing process

The nine step process would have been sufficient in the perfect world, but all orders could not go through the process without getting stuck somewhere in the process. These orders were dropping off the "order pipeline" and therefore the orders that got stuck in the system were grouped into, what was called buckets. Some examples of these drop-off conditions were as follow:

1. sometimes addresses were incorrect on the paper order and the capturing of the order could not be finished,

Figure 3. Bucket system



Bucket number	Bucket description
1	Street address or X and Y coordinates not completed
2	Postal or Billing address not completed
3	Wait for credit vetting results
4	Credit vetting score lower than required score, send letter to customer
5	Waiting for payment
6	Waiting to allocate access network
7	No distribution side access network available
8	Waiting to allocate exchange side network
9	No exchange side access network available
10	Waiting for cable repairs
11	Waiting for allocations of a port on the exchange
12	Waiting for telephone number to be allocated.
13	No core network available at the exchange
14	Waiting to run cross connection on the main distribution frame
15	Waiting for installation
16	Customer not at home
17	Installation completed, wait for billing

2. the information on the network was incorrect and no network existed for the address,
3. the customer was not available for the installation of the service, etc.

To make provision for all these conditions, the following process was modeled and all the different drop-out conditions were called buckets. Figure 3 represents the business requirement.

When the requirement occurred to track the orders through the OLTP system, the orders were already in the system. That meant that it was a business critical information requirement. There was no time to go through the data warehouse development lifecycle. A solution was needed immediately. The KIM section consequently designed the front-end solution for the order-tracking system and called it the bucket system.

The data warehouse Extract Transform and Load (ETL) team was asked to provide the information required in a flat file. The ETL process transformed the different conditions into buckets . That meant that depending on the order's condition, a bucket number was placed next to the order in the flat file. This bucket number was known as the current bucket and the snapshot date was known as the date that the order went into the particular bucket. This was only for the first run of the flat file. For the second run there were a current bucket and previous bucket and the number of days spent in the current bucket. The number of days in a bucket was calculated day by day from the first snapshot date that an order went into a specific bucket. This flat file was accessed by an excel pivot table. The advantage of this flat file was that it could be used while the bucket process was refined. Changes that occurred because of the refinement were easy to handle because it did not require a total redesign of the dimensional model. It required only small changes to the ETL and the flat file which could be done in minutes.

This bucket process was helping business to concentrate on orders that were longest in a particular bucket. The orders were also divided amongst the different sections. Core network sections were responsible for core network buckets, the access network sections were responsible for the access network buckets and finance was responsible for the financial buckets, etc. The responsible section would log into the order system and attend to the order. This bucket system was not only used to follow the orders through the order system, it was also used in the call centre for people phoning to find out where their orders were in the process.

After this bucket system was in place for a month and the KIM section was happy that all information needed was included and correct, the process was started to model this system into a proper dimensional model and business intelligence solution. The advantage of this quick Business Critical Information Solution (BCIS) was that the requirement was now understood very well and there was a proper interim solution in place that fulfilled the immediate need.

The flat file was modeled into a proper dimensional model and the ETL-process was now changed to load the tables of the dimensional model. Documentation was then done on the ETL and dimensional model. All of this was done without the user knowing that it happened. The only thing that could not be done without the user knowing or being interrupted was the user interface BI tool. Excel was used as the BI tool and it had to be changed with Business Objects (BO). The BO front-end was done in parallel and after it was completed the Excel front-end was switched off.

The question could be asked; why is a new solution built while the interim solution is working well. The answer is simple. With the interim solution the focus is on delivering the information and not to optimize the solution. It is for instance not possible to put indexes on a flat file.

4. BUSINESS INTELLIGENCE AND DATA WAREHOUSING MODELS

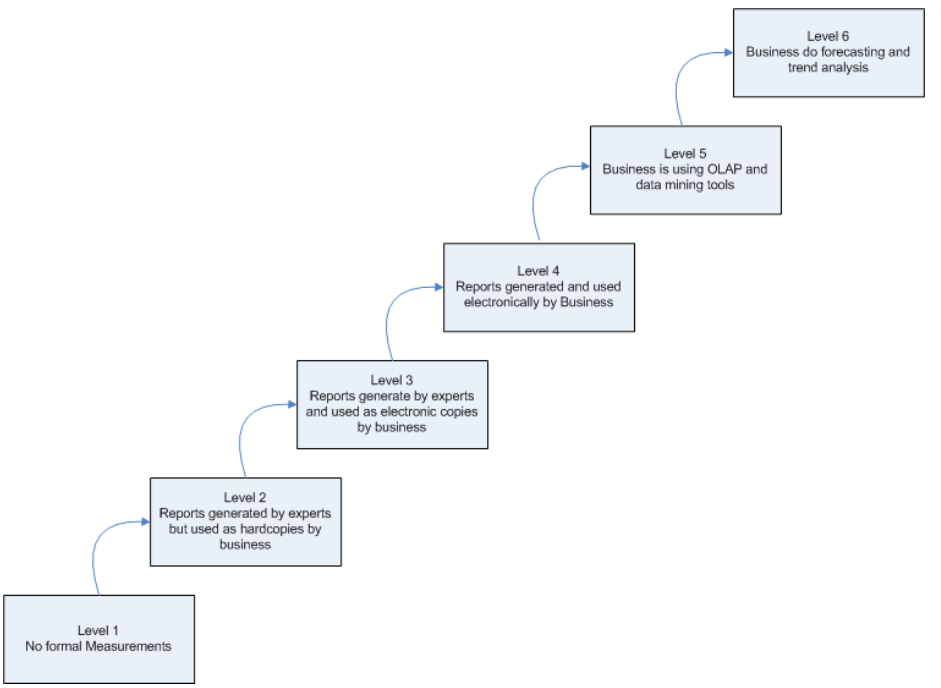
From this exercise the following two models resulted:

1. BI Literacy and Cultural Maturity Model
2. The data warehouse lifecycle model for Business Critical Information Solution called the Double Wave Data Warehouse Lifecycle Model.

4.1 BI Literacy and Cultural Maturity Model

Eckerman (2004) has developed the Data Warehousing Maturity Model. This model focuses on the maturity of the data warehouse. It consists of the following six stages: 1. Prenatal (System), 2. Infant (Individual), 3. Child (Department), 4. Teenager (Division), 5. Adult (Enterprise), 6 Sage (Internal enterprise). The Data Warehouse Maturity Model represents the incremental growth of the data warehouse. It enables an organization to know how mature the technical side of the data warehouse is. As we have mentioned earlier in this document, Williams and Williams (2004) stated that, historically, many data warehousing and business

Figure 4. BI literacy and culture maturity model



intelligence (BI) initiatives have been IT-driven, and much of the focus within the industry has been on the technical aspects of delivering information to the BI user community. The real success of the data warehouse and business intelligence of today lies in how well it is utilised by the business. How "BI literate" the business is, is important information for businesses. A BI Literacy and Cultural Maturity Model is needed to measure the literacy of the business users. This model also suggests ways to increase the maturity level of BI literacy in an organisation. An organisation can have the best DW with the best BI tools, if it is not used; it means nothing for the organisation.

From this study six maturity levels for BI literacy and culture materialized (*See Figure 4*).

Level 1: No formal Measurement
Level 1 does not appear in most new companies and is normally not a level that last very long in bigger companies because it is very hard to manage any organization without any form of measurement. The business management team therefore plays a major role in putting measures in place to manage the performance of the organization. Reports are in some instances built into OLTP systems and therefore results in a lack of integration in all business information.

Level 2: Reports Generated by Experts but Used as Hardcopies by Business
Business people in a company at this level are used to the fact that information is right in front of them on the wall. To run and use reports electronically forces people to change their comfort zone. This is a cultural change and this cultural change could be initiated and improved by creating a new section of people with both ICT and business skills (knowledge and information management section) as mentioned earlier in this document. The business people receive training to use the electronic reports and the Knowledge and Information Management (KIM) section is available to assist with any problems that might be experienced by the business people.

Level 3: Reports Generated by Experts and Used as an Electronic Copy by Business
This level is very prominent in organizations in developing countries where the ICT skills level amongst business people is low. The low ICT literacy could be as a result of the culture that exists in the organization. In companies at this level a culture exists that only ICT people are responsible to use ICT tools and can therefore not be addressed only by the provision of IT training to the business people. To get to the next level a new culture is needed where business people are responsible to use ICT tools and ICT people only maintain these ICT tools. This new culture need to be driven by the business management team which should lead by example. Business management should use electronic reports when doing management meetings. Using electronic reports would be difficult at first but the KIM team can play a huge role in educating business people in these meetings.

Level 4: Reports Generated and Used Electronically by Business Users
This level takes the longest to reach because it is not only dependent on the PC skills of the business people. Previously it was done by someone else, now they should do it for themselves. One way to get to this stage quicker is by only building BCIS that is needed urgently or by using this information for performance appraisals. The business people receive training to generate or run the reports with a proper BI tool and the KIM section is available to assist with any problems that might be experienced by the business people.

Level 5: Business is Using OLAP and Data Mining Tools
Moving from the use of reports to the use of online analytical processing (OLAP) could mean a lot to the business. This is the first step towards a complete business intelligent solution. This level of maturity within the business requires that The Data Warehousing Maturity Model (Ackerman 2004) is at level 5 (Adult). Data mining could result in new information that could be modeled back into the BI and DW solution. This level require creative KIM analysts who are very well equipped with both OLAP and business skills.

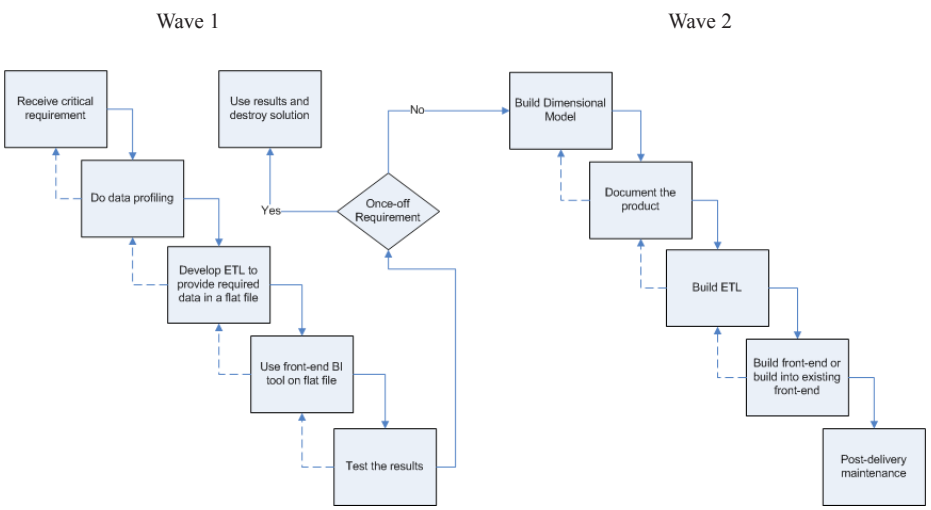
Level 6: Business Does Forecasting and Trend Analysis
Level 6 is to a certain degree not dependent on the literacy of the business people, it is a strategic decision made by top management and therefore dependent on the appointment of statisticians in the company. The approval of these statisticians is normally dependant on the value created by the BI solution up to level 5.

4.2 The Data Warehouse Lifecycle Model for Business Critical Information Solution

The Double Wave Data Warehouse (DWDW) lifecycle model consists of two iterations for the development of a BI and DW solution (*See figure 5*). Wave one concentrates on the rapid implementation of a BCIS. Wave 2 concentrates on modeling the ongoing requirement into a permanent dimensional model. The dimensional model leads to database optimization opportunities, because the dimensional model is a database design that supports extractions of large SQL queries and online analyses. Kimball (1998) has developed "The Business Dimensional Lifecycle diagram" that focuses on the development of a complete solution where there is enough time available for a complete solution.

The DWDW lifecycle model was created to build the BI and DW solution incrementally.

Figure 5. The double wave data warehouse lifecycle model



Information in business is often needed for a "window of opportunity" or legal requirement which cannot wait for a project to finish. When this need arise, there is often not enough time to go through a full software development lifecycle. The requirement can also sometimes be a once-off requirement and the information will not be used in future again. In this case it doesn't make sense to model it into the data warehouse. It is safer to wait for a BCIS to arise and build the BI solution the less expensive way. As soon as this interim solution satisfies the need of the customer, then a proper model can be built and integrated with the exiting BI and DW solution.

5. CONCLUSION

This paper discussed some of the challenges faced by developing countries in building and maturing a telecommunications business intelligence solution. The Double Wave Data Warehouse Lifecycle Model was created to construct a robust source (Data warehouse) for the electronic information in an organization while the BI Literacy and Culture Maturity Model was created to monitor and grow the BI maturity of the organization. The first wave of the Double Wave Data Warehouse Lifecycle Model enable the BI team to deliver business critical information to the business in the shortest possible time with the main focus on delivering the information, while wave two is focused on ensuring the robustness of the solution.

The BI Literacy and Culture Maturity Model ensures that the technical part of the BI solutions grows at the same pace as the human (soft) part of solution. A BI solution that is not used by the business cannot be described as a successful BI solution even though it is technically sound.

Firm-Level Determinants of Business Process Outsourcing Decisions

ABSTRACT

Although there are numerous contributions why firms outsource IT activities, research on Business Process Outsourcing (BPO) decisions is scarce. As BPO might affect outsourcer's core, decisions are likely to be taken on firm level. We therefore aim at answering the following research question: What is the impact of firm-level characteristics on the decision to outsource business processes? Using publicly available data we analyze BPO decisions in the German banking market. Our findings show that BPO is perceived to provide significant strategic value for outsourcers. We provide evidence that large and diversified banks with low cost efficiency are more likely to outsource. Contradictory to prior research findings we further demonstrate that more activities are sourced out, if outsourcer's profit increases. Further research is suggested to explain BPO success using publicly available data.

Keywords: Business Process Outsourcing, outsourcing decision, firm characteristics, banking, JEL Classification: G21, G34

1. INTRODUCTION

The examination of outsourcing — the purchase of a good or service that was previously provided internally (Lacity and Hirschheim (1993)) — has been a domain of IS research for several years now. When considering outsourcing, most of the academic discussions have addressed the questions of "why", "what", "which" and "how" to outsource (Dibbern, Goles, Hirschheim and Jayatilaka (2004)). As several motives for outsourcing have been analyzed in prior IT outsourcing research, little is known in the context of Business Process Outsourcing (BPO) (Dibbern et al. (2004)). This is especially surprising as BPO is a fast growing area in the outsourcing market (Gartner (2004)). One of the unique characteristics of BPO seems to be its proximity to outsourcer's core: several researchers (see e.g. Rouse and Corbitt (2004); Franke and Wüllenweber (2006); Gewald (2006)) showed that benefits and risks of BPO are closely related to firm-level objectives and strategic directions. However, these findings provide an incomplete picture as they are drawn from empirical studies with process owners and thus provide only a process-level perspective. Taking a firm-level view, we therefore aim at answering the following research question:

What is the impact of firm-level characteristics on the decision to outsource business processes?

To answer our research question, we first review prior studies on business process outsourcing and motives for outsourcing decisions (section 2). In section 3, we derive our hypotheses and explain the methodology used. Section 4 presents descriptive statistics of our data. The results of our study are given in section 5. Finally, we summarize our findings and discuss further research (section 6).

2. LITERATURE REVIEW

In the last two decades academic research on outsourcing, especially IT-outsourcing, has evolved rapidly. According to Dibbern et al. (2004) most researcher have focused on determinants and motives to outsource IT operations. As current outsourcing literature provides for very few comparative studies, differences between IT outsourcing and business process outsourcing have been suggested as promising research path (Dibbern et al. (2004)). However, little is known on BPO motives at all. Gewald (2006) as well as Gewald, Wüllenweber and Weitzel (2006) outline BPO's strategic importance. The authors analyze potential BPO benefits and risks as perceived by German bank managers. Focusing on core competencies has been identified in these studies as most important benefit associated with BPO. From the risk perspective, process's closeness to outsourcer's core was amongst the most significant inhibitors as BPO may result in substantial loss of know-how and innovative capabilities.

Besides these studies, empirical evidence is rare. Thus, we draw on prior research analyzing firm-level financial characteristics of companies involved in IT outsourcing arrangements. Loh and Venkatraman (1992) find that high overall costs as well as high IT costs and a poor IT performance are significantly correlated with outsourcing. Smith, Mitra and Narasimhan (1998) concluded that low overhead costs, low cash reserves, high debt, and declining growth rates determine outsourcing decisions. Hall and Liedtka (2005) demonstrate that IT outsourcing is determined by poor performance, poor cost control, and short term cash needs of the firms. Ang and Straub (1998) show that IT outsourcing is best explained by high production costs. The authors further outline that outsourcer's size is negatively related to outsourcing.

As the above studies focus on outsourcing decisions, there are several contributions on the firm-level effects *after* outsourcing. Most studies find outsourcing influencing firm's performance negatively Kotabe, Murray and Javalgi (1998); Görzig and Andreas (2003), marginally D'Aveni and Ravenscraft (1994) or having no significant effect (Gilley and Rasheed (2000)). Holzhäuser (2006) find that banks benefit from either a very high or a low vertical integration. Studying the influence of outsourcing on productivity, Girma and Gorg (2004) find labor productivity and total productivity growth positively related to outsourcing.

None of the literature we reviewed was attributed to pre-event firm characteristics of business process outsourcing. Within this paper, BPO is defined as the delegation of one or more entire business processes to third party providers, including the software and hardware that support those processes Halvey and Melby (2000). A business process is defined as a "set of logically related tasks performed to achieve a defined business outcome" (Davenport (2005)). Thus, BPO is the combination of application development/maintenance outsourcing, IT infrastructure outsourcing and the outsourcing of business activities which are not IT supported like business process re-design.

3. RESEARCH MODEL AND METHODOLOGY

3.1 Hypotheses

Following the studies outlined in section 2, we look at three categories of firm characteristics that might influence the BPO decisions: outsourcer's size, firm performance, cost efficiency, and degree of diversification.

Size. Concerning the outsourcer's size ambiguous explanations can be found in the literature. Ang et al. (1998) as well as Girma et al. (2004) argue that it is more difficult for smaller firms to achieve economies of scale and therefore outsource their operations. However, only Ang et al. (1998) confirm this hypothesis. Smith et al. (1998); Girma et al. (2004) as well as Hall et al. (2005) find a positive relation

of firm size and outsourcing as the absolute amount of outsourcing deals should be greater in larger firms than in smaller firms. We follow the later argument and propose that larger outsourcers tend to outsource business processes as for smaller outsourcers the efforts to monitor and control outsourced processes will exceed cost savings. In addition to firm size, we look at firm growth to account for size changes. Smith et al. (1998) find that declining growth rates entail outsourcing. They argue that firms who are lacking growth opportunities focus on cost reduction strategies and therefore tend to outsource.

H1: Firm size is positively, growth rates are negatively related to the decision to outsource business processes.

Firm performance. Hall et al. (2005) suggest that poorly performing firms are more prone to outsourcing as they will try to increase their short term performance. Outsourcing contracts can especially help to increase reported earnings in the year of the outsourcing event by selling their assets through the transfer of operations to the insourcer above book value. Loh et al. (1992) argue that under conditions of poor business performance firms seek to streamline their operations. Kotabe et al. (1998) postulate that outsourcing is negatively related to financial performance as it can be seen as a strategic reaction to declining competitiveness.

H2: Firm performance is negatively related to the decision to outsource business processes.

Cost efficiency. Most research articles on outsourcing show that firms outsource part of their operations, if cost efficiency is low. Hall et al. (2005) as well as Loh et al. (1992) find that high administrative costs and operating expenses – used as a synonym of low cost efficiency - are positively associated with outsourcing. In particular, we will draw special attention to wage levels as Girma et al. (2004) show that firms with high labor costs are more prone towards outsourcing in order to gain cost reductions.

H3: Cost efficiency is negatively, wage levels are positively related to the decision to outsource business processes.

Diversification. In the outsourcing literature hardly any study discusses the influence of diversification on outsourcing decisions. Only Holzhäuser (2006) find that diversified banks tend to operate at a lower level of vertical integration. However, empirical studies show that diversification is associated with higher costs (Holzhäuser (2006)). Thus, diversified banks will have a greater need to reduce costs and will purse cost cutting strategies including BPO.

H4: Diversification is positively related to the decision to outsource business processes.

Finally, we control whether the banks are a savings institute ('Sparkasse'). In Germany, these institutes are institutionally tied and might decide within their group that all institutes source out. In this case, we would have to reduce our sample to count all 'Sparkasse' outsourcing deals as one single outsourcing event. To control for this effect we use a dummy variable which is set to one, if the bank is a savings bank and zero otherwise.

3.2 Methodology

We chose to analyze BPO arrangements in the German banking area. As IS research should account for industry-specific results Chiasson and Davidson (2005), we selected the financial services sector as research object, since it is the second largest buyer of outsourcing services Gartner (2004). We use publicly available accounting data to explain outsourcing decisions as audited financial data provide a more objective evaluation of a firm's performance than the perception-based intermediate metrics typically used in case studies (Smith et al. (1998)). Further, respondents answers in surveys may by self justifying (Ang et al. (1998)).

To derive factors explaining outsourcing decisions we compare firm characteristics of banks where we observed BPO the year prior to the outsourcing event to the characteristics of the control group without BPO in the same year. We apply nonparametric tests to analyze the influence of each variable identified on the outsourcing decision as described by Smith et al. (1998) as well as Hall et al. (2005) and control for multivariate effects of our variables using a logistic panel regression model Hall et al. (2005):

$$\eta\left(\frac{\pi_{i,t}}{1-\pi_{i,t}}\right) = \beta_0 + \beta_1 \cdot SIZE_{i,t-1} + \beta_2 \cdot GROWTH_{i,t-1} + \beta_3 \cdot ROA_{i,t-1} + \beta_4 \cdot CIR_{i,t-1} + \beta_5 \cdot COSTASS_{i,t-1} + \beta_6 \cdot EMPLCOST_{i,t-1} + \beta_7 \cdot DIV_{i,t-1} + \beta_8 \cdot SPARKASSE_{i,t-1} + \varepsilon_{i,t}$$

where $\pi_{i,t} = p(BPO_{i,t} = 1)$ BPO is one, if bank i has sourced out a business process in year t, and zero otherwise. The independent variables are described in Table 2. The measure of diversification is taken from Elsas, Hackethal and Holzhäuser (2006).

4. THE DATA

The information on outsourced business processes was retrieved from a survey, which was sent out in May 2005 among the 200 largest banks in Germany. Responses from 126 banks were received resulting in a response rate of 63%. Twelve responses were anonymous and therefore had to be excluded. To obtain the accounting data we used Fitch IBCA Bankscope. Due to limited availability of accounting data before the year 1997 we had to restrict our study on outsourcing deals that occurred between 1998 and 2005, as we are interested in the accounting data the year before the outsourcing. We included all banks in our sample where at least one year of accounting data in the range between 1997 and 2004 were available. In addition, we excluded all banks that had any process sourced out before 1998 or where the accounting data in the year before the BPO were not available. This selection process reduces our sample to 101 banks for which we obtained 743 years of accounting data over the years between 1997 and 2004.

In this sample we find 41 BPO events. Three banks sourced out two processes in the same year, which we counted as one outsourcing event in the respective year, which leaves us with a total of 38 outsourcing events for our observed time frame (Table 1).

5. STATISTICAL ANALYSIS

5.1 Non Parametric Analysis

Starting with the results of the median difference test (Table 4) we observe the univariate influence of the variables on the decision to outsource business processes. A positive value in the median difference column indicates a positive effect of the variable on outsourcing, while a negative value indicates that the variable has a negative effect on the outsourcing decision.

The variable SIZE is positively correlated to outsourcing and the Wilcoxon test shows significance at the 1% level, indicating that larger bank tend to source out business processes more likely than smaller banks. The median difference for GROWTH is slightly positive but not significant. The same applies for ROA

Table 1. Sample

Year	Number of banks with BPO event	Number of banks in control group	Total
1998	2	76	78
1999	1	90	91
2000	1	91	92
2001	5	89	94
2002	5	90	95
2003	4	94	98
2004	6	92	98
2005	14	85	99
Total	38	707	745

Table 2. Definition of variables

Variable	Description	Definition
SIZE	Size	Logarithm of total assets of the bank
GROWTH	Annual growth of total assets	Total assets divided by total assets of previous year
ROA	Return over assets	Net income divided by total assets of the bank
CIR	Cost-to-income ratio	Total operating costs divided by total operating income of the bank
COSTASS	Total operating cost/total assets	Total operating costs divided by total assets of the bank
EMPCOST	Cost per employee	Wages and salaries plus social security contributions plus pension contributions divided by number of employees
DIV	Diversification	$DIV = 1 - \left(\left(\frac{INT}{TOR} \right)^2 + \left(\frac{COM}{TOR} \right)^2 + \left(\frac{OTI}{TOR} \right)^2 \right)$ INT =interest revenue; COM =net commission revenue, OTI =all other net revenue; TOR=sum of the absolute values of INT, COM, and OTI. DIV increases in the degree of revenue diversification. By definition DIV can take on values between 0 (the bank is fully specialized on one revenue source) and 0.75 (the bank generates a fully balanced revenue mix from all four revenue sources).
SPARKASSE	Dummy for Sparkasse	Binary dummy variable: 1 for state owned, 0 for privately owned

Table 3. Characteristics of independent variables

Variable	N	Mean	Median	Std. Dev.	Min.	Max.
SIZE	745	9.0809	8.5767	1.3885	6.0154	13.1690
GROWTH	644	1.0663	1.0405	0.2528	0.6237	6.7580
ROA	744	0.2118	0.1900	0.3657	-6.0300	4.3500
CIR	744	64.6929	65.1750	14.8277	18.3300	177.0300
COSTASS	744	0.0168	0.0185	0.0088	0.0005	0.1076
EMPCOST	742	0.0557	0.0478	0.0239	0.0145	0.3393
DIV	744	0.1790	0.1741	0.1004	0.0011	0.6026
SPARKASSE	745				0	1

Table 4. Median difference test

		Wilcoxon signed rank test	
Variable	Median Difference	Z-statitic	p-value
SIZE	0.775	2.632 ***	0.009
GROWTH	0.046	0.049	0.961
ROA	0.163	-0.341	0.733
CIR	4.530	1.994 **	0.046
COSTASS	0.002	1.835 *	0.067
EMPCOST	0.014	2.748 ***	0.006
DIV	0.059	3.009 ***	0.003

*=significant at the 10% level, **=significant at the 5% level, ***=significant at the 1% level

which measures the return over assets and is our proxy for the performance of the banks. The variables that measure cost efficiency are higher for the banks with BPO than the median of the peer group at a significance level of 5% (CIR) and 10% (COSTASS). Hence we conclude, that banks with a high costs and a low cost efficiency tend to source out business processes. The same applies for the wage level (EMPCOST) which is higher for the outsourcing banks at a significance level of 1%. Finally, a higher diversification can be observed for banks that have sourced out than for the industry control group (at a 1% significance level).

5.2 Logistic Regression Analysis

We tested several models in our logistic regression analysis. Correlation among the independent variables does not allow including all variables in one model. The

results from the regression mainly support the findings of the univariate median difference test. Only the variable for return over assets (ROA), which was not significant in the median difference test, is significantly positive related to outsourcing in our regression analysis. All other variables show the same influence on business process outsourcing in both the univariate and the multivariate analysis. The dummy variable SPARKASSE, controlling for the firm being a German savings bank does not show significant influence on outsourcing in any model.

5.3 Discussion

Our first hypothesis is partly supported by our findings. We can provide evidence that firm size is positively related to BPO. Research provides findings on 'diseconomies of scale" where coordination and control costs exceed cost savings retrieved from the utilization of economies of scales (Graves and Langowitz (1993); Zanger (1994)). If this is the case, firms tend to focus on core competencies (Prahalad and Hamel (1990); Cross (1995); McFarlan and Nolan (1995)) and outsource non-core activities. Our results contradict prior research findings (e.g. Ang et al. (1998)) as this tradeoff (economies vs. diseconomies of scale) entails that large firms engage in outsourcing activities more often than small firms. We conclude that the processes analyzed here do not belong to bank's core. Thus large banks are not willing to bear high coordination and control costs for those activities which do not provide any value for the firm, if they are internally produced. On the other hand, we did not find a significant influence of growth rates on BPO. Thus, we presume that BPO is not perceived as short-term instrument to improve profitability.

Our second hypothesis is contradicted by our findings: the more profitable a bank operates, the more likely it will engage in BPO activities. To our knowledge, this relation has not been shown in prior outsourcing studies. Firms are only able to invest in new business opportunities, if profit increases. Thus, our data provide evidence that BPO is not only perceived as cost reduction instrument but also as strategic instrument through leveraging the capabilities of the service provider. This finding is in line with outsourcing research where outsourcers gain or sustain competitive advantage through the use of vendor's resources (Lacity and Willcocks (1998); Quinn (1999); Goles (2003); Lammers (2004)).

Nevertheless, BPO seems to be part of cost cutting strategies as our third hypothesis is fully supported by our data. Thus, poor cost efficiency entails BPO. In particular, banks with high wages levels tend to outsource more often than banks with lower wage levels. In the case of high wage levels, it is believed to be easier for the insourcer to provide the services at lower cost as the difference of personnel expenses between the outsourcer and insourcer is larger.

Finally, our data support our fourth hypothesis that the degree of diversification is positively related to BPO. Thus, banks try to streamline their operations and thereby reduce operating costs while still benefiting from diversified revenue. This finding supports prior findings in outsourcing research and transfers them to BPO context (Prahalad et al. (1990); Cross (1995); McFarlan et al. (1995)).

Our control variable for 'Sparkasse' does not show any significance. Thus, we are allowed to count each 'Sparkasse' separately.

5.4 Limitations

As our findings provide for interesting insights on BPO decisions, several limitations have to be considered. First, we rely on those data which are publicly available and cannot account for internal matters. For example, if the bank sourced out to improve process quality, we will not be able to reproduce this parameter as there is no quality measure available. Second, due to limited availability of older accounting data, we only use data from one year prior to outsourcing. Although this is a valid approach used in other research studies (e.g. Smith et al. (1998)), more data would be appropriate to strengthen our results.

6. CONCLUSIONS

This paper empirically addresses the factors that influence BPO decisions. As BPO is considered as strategic instrument through leverage of vendor's capabilities, we advocate a firm-level instead of a process-level analysis. In addition, we aim to overcome respondent's biases from case studies and survey data and therefore rely on publicly available data.

Our findings are somewhat contradictory to current outsourcing research and emphasize the strategic value of BPO. As large banks with high performance tend to outsource more activities, we conclude that BPO is seen as strategic instrument to sustain or further gain competitive advantage. Since especially diversified banks are not able to generate these advantages with internal resources, they are interested in accessing vendor's more specialized resources to complement their resource portfolio. Nevertheless, potential cost savings seem to be a relevant motive for BPO as especially high wages could be reduced significantly (similar findings in Gewald (2006)).

From our data, we were not able to identify whether potential process improvements is the reason why firms outsource their business processes. However, as this has been shown as important factor influencing the outsourcing decision (e.g. Gewald (2006)), further research might analyze the importance of quality from the firm-level perspective. In addition, since our research focus on decision criteria prior to outsourcing, it would be interesting to see if these 'predictions' hold for the future. Thus, publicly available data should be used *after* outsourcing to analyze *achieved* benefits from BPO.

Evaluating E-Business Applications Priorities: The E-Business Planning and Analysis Framework

Boon Tan, University of Sunderland, UK; E-mail: boon.tan-1@sunderland.ac.uk
Ben Clegg, Aston University, UK; E-mail: b.t.clegg@aston.ac.uk

ABSTRACT

An e-business planning framework is proposed here which links both strategic and operations management to improve the online service quality of a manufacturing SME. A standard systems development lifecycle has been used in the overall approach. However, the initial 'systems analysis phase' of this a unique combination of analytical tools draws upon the Balanced Scorecard (BSC), Value Chain Analysis (VCA) and Quality Function Deployment (QFD) which are integrated into a new practical 'e-business analysis framework'. The paper explains the use of the framework by using a practical case study based upon a manufacturing SME based in the UK. The company realised that information technology can have a great impact on their business, especially on the potential benefits that e-business applications can offer. In light of this the company reviewed the value proposition it deliver to offered its customers and business partners; its internal resource base; its levels of process maturity and the supporting information and technological systems by using the 'E-Business Planning and Analysis Framework' (E-PAF). The result of this research gives a set of recommendations to help the company grow and become more customer focused whilst simultaneously increasing revenue and profitability principally via the deployment of new customer relationship management (CRM) technologies.

Keywords: e-business, analysis and planning framework, systems development lifecycle, manufacturing SME, customer relationship management, quality function deployment

INTRODUCTION

Since the early 1990s, much had been expected in engaging the Internet as a platform for business transactions and business management. However, it was only in the late 1990s that the terms e-business and e-manufacturing began to appear on management agendas, probably due to the phenomenal growth of 'dotcom' companies (Cross, 2000; Gromov, 2000; KPMG Consulting, 2000; Lang et al., 2001; Forrester Research, 2002; Cheung and Huang, 2003; Chen, 2003). Although SMEs realised the need to develop sustainable business models and intermediate into established business sectors to survive, many of them are not able to manage this transition effectively as it requires not only technical knowledge but also a social, economic, political and legal awareness. Whilst a successful implementation could enable the SME to create competitive advantage, a failed implementation could be fatal for the business.

The aim of the paper is to illustrate how an established manufacturing SME based in the UK has analysed and improved the quality of its online services through a structured approach. This paper will provide an in-depth account of that unique analysis framework and demonstrate how it may assist SMEs in e-business analysis. This includes an overview of the 3 existing techniques that are integrated to form the analysis framework. These 3 techniques are Quality Function Deployment (QFD) (Akao, 1972), Balanced Scorecard (BSC) (Kaplan and Norton, 1992) and Value Chain Analysis (VCA) (Porter, 1985). A case study using this approach is presented in detail in this paper based upon an established manufacturing SME based in the UK.

CHARACTERISTICS OF A GOOD BUSINESS FRAMEWORK

Wu (1992) stated that good frameworks should be able to guide managers towards a method or solution uniquely suitable to a particular situation in question. On the whole, frameworks should not be too complex to use and information interaction within the framework should be clear and concise to avoid information overload.

IDEF (U.S. Air Force, 1981) is one potential analytical framework for processes, but is often thought of as too complex and time intensive for small or rapidly developing situations. In contrast, Lee and Ko (2000) proposed a strategic framework for strategic business analysis, by integrating SWOT (strengths, weaknesses, opportunities and threats) (de Witt and Meyer, 1998), Balanced Scorecard (BSC), Quality Function Deployment (QFD) and 'Sun Tzu's the art of business management strategies' techniques. These frameworks demonstrate the value of integrating different analysis tools. Similarly, the authors use a different combination of analysis tools to produce another analysis framework, for a different purpose (i.e. e-business planning).

Whilst many analytical techniques such as the SWOT, SLEPT (political, economic, social, technical and legal) (Op. Cit.:135) and the BSC analyses can be used to identify the strategic needs of an organisation, none provide a direct mechanism to prioritise the needs and convert them into operational processes, or to then translate those processes into a specification that can be used to develop or acquire supportive software systems. In contrast, other analytical techniques such as Porter's Value Chain Analysis (VCA) (Porter, 1985) facilitates the analysis of processes within a company but does not provide an easy mechanism to link these to high level business objectives.

One analytical tool that does provide the ability to convert high level business objectives ('what' the business wants), into processes ('how' the business delivers those 'what's') is QFD, which has had these benefits discussed widely by Akao (1972), Mazur (1992) and more recently by Ko and Lee (2000); and Lee et al. (2000), However, QFD has its own weaknesses; two of these lie in the initial generation of the 'what's' and 'how's'. The analytical framework presented in this paper deals with the weakness of QFD directly by integrating QFD with two other complementary analytical techniques. These are to use the main strengths of the:

- BSC to generate a set of high level business objectives, targets, measures and initiatives for finance, internal operations, learning and growth and customer satisfaction. The outputs from this analysis become the 'what's' in the initial QFD analysis.
- VCA to generate detail about operational processes. The outputs from this analysis become the 'how's' in the initial QFD analysis.

It is through this complementary use of the existing BSC, VCA and QFD that a new successful analytical framework has been produced for analysing and designing the e-business process re-engineering of an established manufacturing SME in the UK. The analysis framework developed by the authors is now outlined within the context of the wider systems development lifecycle. Further details can be found in earlier publications by the authors (Tan et al., 2004).

THE E-BUSINESS ANALYSIS FRAMEWORK FOR MANUFACTURING SMES

An 8-step approach was developed to assist in the understanding and creation of the analysis framework as shown in Figure 1 (Tan et al., 2004). The 8 steps are identified as:

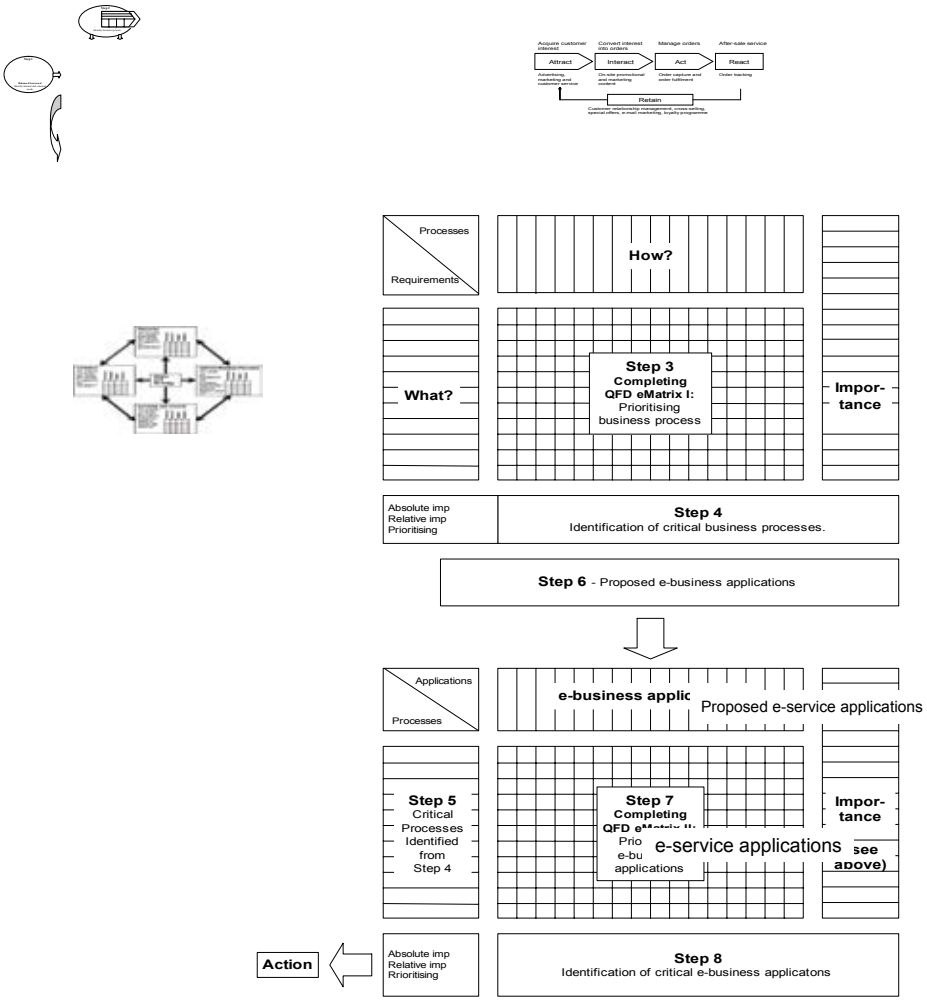
- Step 1 – Using BSC to develop the 'what's' for QFD Matrix I
- Step 2 – Using VCA to develop the 'how's' in QFD Matrix I
- Step 3 – Completing the interrelationships of QFD Matrix I
- Step 4 – Identification of critical business processes from QFD Matrix I
- Step 5 – Inputting critical business processes to the 'what's' of QFD Matrix II
- Step 6 – List of e-CRM (e-Customer Relationship Management) applications to the 'how's' of QFD Matrix II
- Step 7 – Completing the interrelationships of QFD Matrix II
- Step 8 – Identify the most suitable e-CRM solutions from QFD Matrix II inter-relationships.

The analysis framework was first presented as a prototype utilising a data set from the case study on Marshall Industries, US (Olofson, 2000). The purpose of this paper is to illustrate the use of the analysis framework for implementation in an established manufacturing SME. The paper now presents the findings from the case study company – MT Mounts (the name is a pseudonym in order to preserve the sensitive nature of the information disclosed in this paper). MT Mounts is an established manufacturing SME in the UK specialising in the manufacturing of shock and anti-vibration mounts. It should also be noted that all of this analysis is contained within the initial part of the systems development lifecycle (i.e. the 'systems analysis phase').

CASE STUDY: MT MOUNTS – A MANUFACTURING SME

The management at MT Mounts recognise the importance of I.T. to improve its business and has successfully implemented an in-house system for: order entry and processing; accounts (customer and purchasing); stock control and production planning. As a result of these systems, tasks have been improved in terms of time, cost and usability. In addition, MT Mounts had also begun to develop a

Figure 1. E-business analysis framework (source: Tan et al.)



number of supporting I.T. applications to provide more functionality to the sales and marketing activities. However, at the moment the company's presence on the Web is barely visible as it is part of the MT Group's website, and is mainly only informational. The only interactive element was a downloadable form for potential customers to make enquiries. Therefore, the main driving force behind any new investment at MT Mounts is to generate more sales and interface with their customers better.

Due to the R&D culture of the MT Group, most of investments have been going towards product development and design. The challenge was therefore to convince to the MT Group management team towards investing further in online customer interfacing processes. Besides recognising the need to upgrade current e-business applications, MT Mounts also recognised that there was no available in-house resource to conduct such an analysis. Thus, the authors were approached to take up the role of expert consultants to research and create a report on applying customer interfacing processes for MT Mounts.

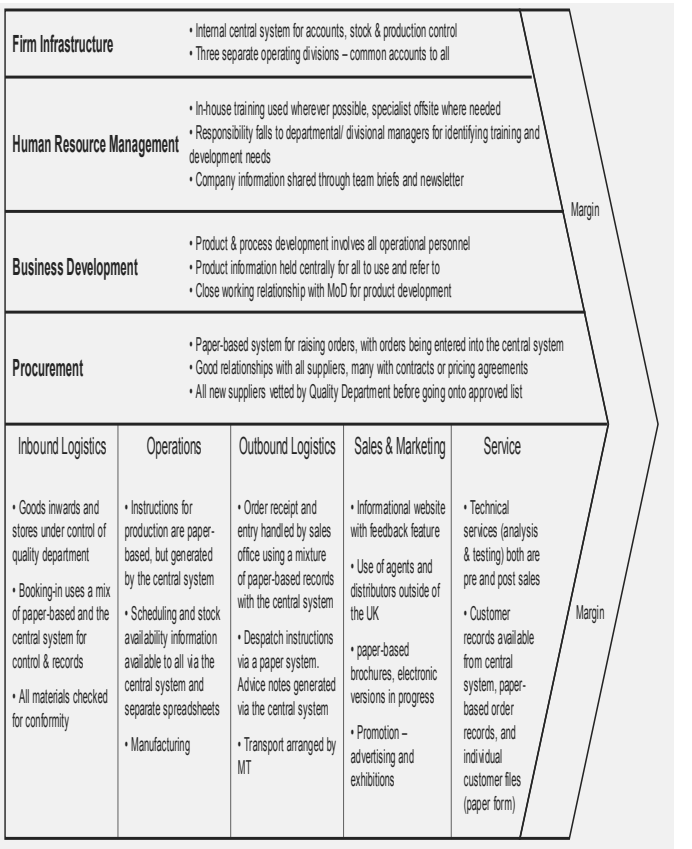
Generating the Balanced Score Card for MT Mounts ('what's')

The first step of the E-PAF is to establish the company's Balanced Scorecard (BSC) to generate a list of 'what's' for QFDI Matrix. The vision of MT Mounts was clearly stated as "to be the number one manufacturer and service provider of vibration, shock, and noise control products in the world". It is therefore important for the business to build sustained growth and ongoing innovation. A summary of the BSC analysis can be seen in Table 1. Expert advice from senior managers with extensive industrial experience, assisted in the ranking of these initial 'what's': the 'what's' deemed most important were awarded the highest points, and the lower scored were given to those which were felt to be of lesser importance.

Table 1. Summary of the BSC analysis

	Objectives	Measures: Target	Initiatives	Weight (1 low, 5 high)
Financial	Sales growth	Turnover: Year on year growth of 10%	• New products • Improvements to existing products • New markets	5
	Product profitability	Profit margin: Average of 30% or better across whole product range	• Improvements to production processes • Involve suppliers to reduce material costs	3
	Minimise costs	Administrative costs, consumables costs, equipment costs: Reduction year on year of at least 10%	• Streamline/ automate administrative processes • Identify and reduce costly consumable use • Reduce prices of items • Improvements to existing processes • Introduce new processes	3
Customer	High retention	No. of repeat orders and new enquiries: obtain enquiries from > 90% of current customer base, and >90% orders.	• Regular contact with entire customer base through various means	5
	Customer satisfaction	Number of complaints: Zero complaints	• Ensure that requirements are fully understood and communicated throughout the company • All problems (or potential problems) to be discussed with customers before escalating	5
	Market share	Number of new customers: Growth of 20 new customers each year	• Targeting specific customers • Advertising	3
Internal Business Process	Product quality	% of rejected production: Zero %	• Improvements to production processes • Improvements to supplied materials	5
	Product cycle time	Direct labour time: Labour times to be reduced by 10%	• Improvements to production processes	3
	Production planning	Waiting time and number delays: Reduce all idle times to minimum, target at 10%	• Coordinate production stages • Improve suppliers coordination	3
	On-time delivery	Number of days late: All orders to be delivered within 5 days of customer due date	• All quoted lead times to be realistic • Improvements to internal processes to reduce lead times • Involve suppliers , reduce leadtimes	5
	Process reliability	Number of machine breakdowns, downtime due to breakdowns: No breakdowns	• Preventive maintenance routine to be set up • Operators training for correct use and routine maintenance	3
Learning and Growth	Staff training	Number of staff involved in training: 100% of all junior staff and 50% of all senior staff	• Examination of skills matrix • In-depth discussion during appraisal	3
	New products and services	Introduce more new products and services: At least five viable new products to be suggested each year	• Suggestion scheme • "Innovation" competition	3
	Employee satisfaction	Staff retention level: No staff leaving due to dissatisfaction	• Staff feedback system	3

Figure 2. Value chain analysis for MT mounts



Generating the Key Business Processes of MT Mounts with the VCA ('how's')

Using the VCA, the authors are able to identify the main categories of business processes and critical customer interfacing activities within the company. The VCA for MT Mounts is shown in Figure 2.

QFDI Matrix

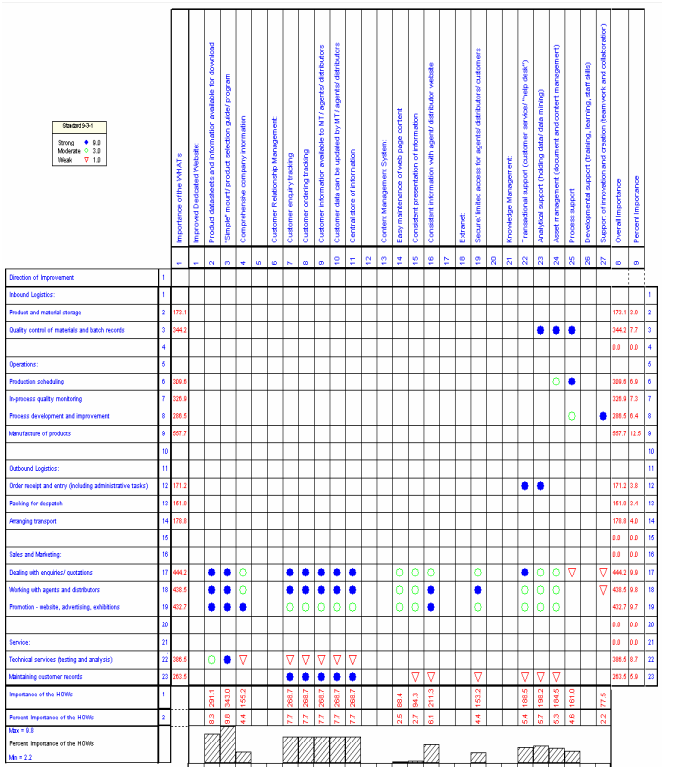
The list of 'what's' and "how's' as generated in the previous steps, are entered into the QFDI Matrix. Expert insight was again sought from MT Mounts at this step to determine the strengths of the relationships between the 'what's' and "how's'. Once these ratings were allocated they were keyed into the QFD/CAPTURE™ software; the software automatically prioritised each key business processes ('how's') in order of importance, according to the capability of each process to meet the requirements of the 'what's' (that were rated in importance). Therefore, the more relevant the business process was in meeting the requirements of the higher ranked 'what's', the higher the business process is prioritised.

The fact that the QFDI matrix showed manufacturing to be the most important process is not surprising since the business is built around producing products and these processes are currently well supported. However, the next four processes are all related to customers in a sales and marketing capacity, the technical services are also tied into sales both before and after a sale has been made.

QFDII Matrix

The 'what's' inputted into the QFDII matrix were transferred from the results of QFDI matrix. The important point to note is that the prioritised scorings of the business processes from QFDI matrix were entered as the rating scores for the business processes (as the business processes are now serving the function of 'what's' in QFDII Matrix).

Figure 3. MT mounts QFDII matrix



The results of this analysis found the following e-business support application to be the most important:

1. Manufacturing of products with a score of 557.7.
2. Dealing with enquiries/ quotations with a score of 444.2.
3. Working with agents/ distributors with a score of 438.5.
4. Promotion (advertising, website, exhibitions) with a score of 432.7.
5. Technical services (testing and analysis) with a score of 386.5

These scores are obtained for each e-business support application by the following formula:

$\sum$ (importance weight of the business objectives x prioritisation score given in QFDII x prioritisation given in QFDII).

Since MT Mounts is not cash rich, it was only practical to focus on one or two e-business implementations. These results indicate that the use of a dedicated and improved website, together with better Customer Relationship Management would be the most important and most suitable (non direct manufacturing) e-business applications to apply in order to achieve the overall company vision. The provision of simple product selection tools and product data availability came in first and second respectively, while all aspects of a CRM system came in jointly third. The QFDII matrix can be seen in Figure 3.

The findings gained by applying this planning and analysis framework were numerous. A dedicated website would allow MT Mounts to showcase their products and services offered to provide a clearer identity, separating them from other divisions of the MT Group that are not related to shock and vibration equipment. Providing data on the web for immediate download after registration will enable customers to review information immediately, before deciding whether or not to make further enquiries. Gathering customer registrations will in turn provide MT Mounts with new market intelligence, customer profiles and increased response rates.

Having technical information available freely also encourages equipment designers to incorporate MT's products into their designs. An improved website will also help to speed up the enquiry process by providing simple mounting selection tools, though this will only be appropriate for very simple selection and more detailed analysis has to be referred back to MT Mounts. A more detailed "technical form" can also speed up the enquiry process by making the customer think about their application before contacting MT Mounts.

Central to a CRM system is a single database that stores all of the customer information collected together from the various communication channels. This database provides complete visibility of customers to employees. Web-log activities can therefore be collected from the website to allow MT Mounts to track the frequency of the items being looked at, the patterns on which the products are viewed and then enquired. This information can thus also be used for further development to improve the website. A centralised CRM system will also allow all relevant staff within MT Mounts and its overseas agents and distributors access to information with increased speed and accuracy. This will reduce duplication of activities such as MT Mounts and their agents responding to the same customer enquiry, saving both time and effort, and increasing professionalism.

A CRM system can also allow MT Mounts to get more information and feedback on the activities of its agents, which has been lacking and may be one of the contributing factors to relatively poor performance by agents in certain areas. Greater visibility will allow MT Mounts to identify and address trends where quotes have been unsuccessful, perhaps through a price reviews or by offering further technical assistance. With an increasingly global marketplace, a CRM system can help to minimise instances where MT Mounts spends money to 'compete' with its own agents to get first contact, which may be counter-productive. For that reason, records contained within CRM could provide the necessary evidence for making the decision process easier.

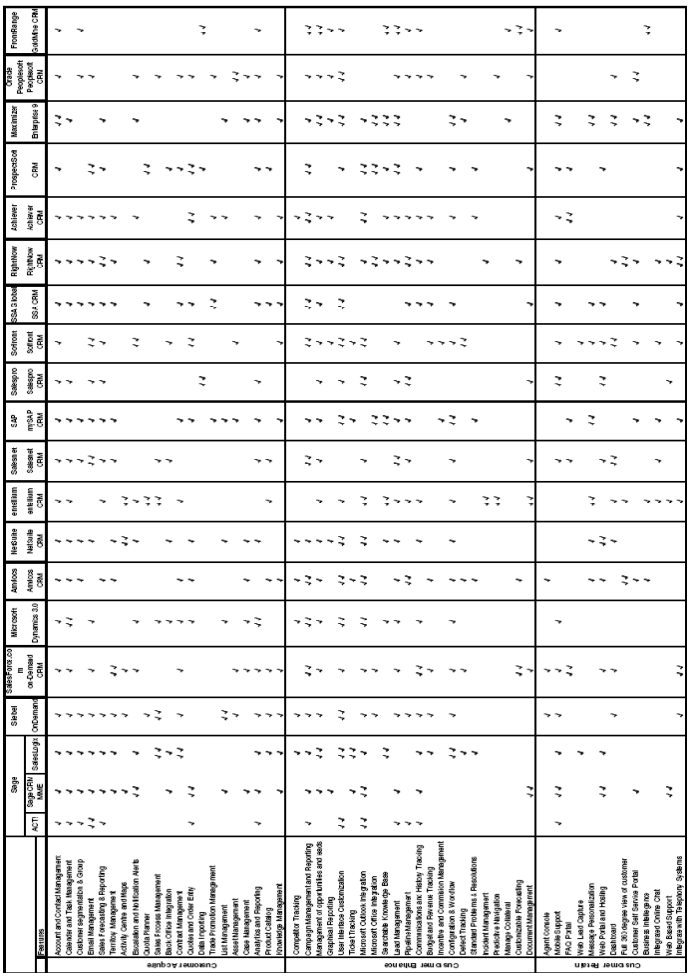
However, there are many CRM vendor solutions from about 18 different leading companies currently available on the market. Therefore, in order to assist MT Mounts further in choosing the right vendor solution, there is a need to provide more in-depth analysis in order to highlight the differences between the software on the three pre-determined features that are significant to MT Mount on its needs to employ a CRM system. These features are divided into customer acquiring, customer enhancing and customer retaining (Table 2). The methodology used to analyse the vendor solution's strength on the feature being looked at are determined to be (a) 2 ticks for a particular feature that is a present and highly sought after; (b) 1 tick for a particular feature present in the vendor solution regarded as desirable; and (c) no tick means the feature is not present in the evaluated vendor solution. Thus, from Table 2, it can be seen that further study may still be required to determine the right CRM vendor solution for MT Mounts.

CONCLUSION AND FUTURE WORKS

The academic contribution that this paper has made has been to select and implement three complementary tools, the Balanced Scorecard (BSC), the Value Chain Analysis (VCA) and Quality Function Deployment (QFD) to provide a comprehensive approach to analysing a business from both a strategic and operational point of view which can define and prioritise actions for process development and the implementation of candidate software solutions to support them. The strengths of the BSC allowed the generation of 'what's' for the initial QFDI matrix. The strengths of the VCA enable the initial 'how's' for the QFD to be generated. An interesting observation was that coupled with the measurement functions typical of any BSC, the QFD becomes more robust by incorporating the 'voice of customer' generated from the BSC. This can eliminate the need for customer surveys, which are mostly vague in their findings, since these 'voices' can now be constructed by using the BSC framework. The QFD can therefore provide integration between top-level objectives and operational-level activities, a major deficiency in the typical BSC approach, by making it possible for managers to prioritise needs while taking into account the business processes, ultimately providing a blueprint for e-business planning. QFD can also facilitate planning at the lowest level of implementation through the deployment of multi-level matrices as deemed necessary by the company for the specific e-business planning.

By using the balanced scorecard technique both internal and external 'what's' for QFDI Matrix were collected. The value chain analysis provided an analysis of the business processes of the company and gave the foundations for the generation of 'how's'. By entering the data through the balanced scorecard and the value

Table 2. Summary of vendor e-business solutions analysis



chain analysis into the quality function deployment matrices managers were able to prioritise the business processes according to the ability of the process to meet both internal and external needs. Once this is achieved, the potential e-business applications can be identified.

The practical contribution that this research has made to MT Mount has been to highlight the internal resource based factors of the company and the industrial scenario in which it is currently operating. The research has also given direction to future developments that the company should take if it is to stay competitive and continue to grow amidst competition. For example, the research has highlighted 'what' is important from the customers' point of view and 'what' is important from a business' point of view for the future, and then 'how' those issues should be delivered through new processes, new software application types and even to propose specific candidate solutions.

Future work planned by MT Mounts will be the implementation of these solutions after approval has been given by MT Group management. Further academic work will continue to deploy this framework in other industrial scenarios to increase its robustness and generic applicability.

The Influence of Culture on Enterprise Portal Design in a Global Environment

Xiuzhen Feng, Beijing University of Technology, P.R. China; E-mail: xfeng@bjut.edu.cn

Yibin Hou, Beijing University of Technology, P.R. China

ABSTRACT

Enterprise portals collect and synthesize information from various systems to deliver personalized and highly relevant information to suppliers, customers and employees. While enterprise portal design and portal applications have been widely discussed in the literature, the implications that arise when the scope of such portals is global have not yet been explored. Thus, this paper aims to highlight the implications and the opportunities of enterprise portals for international, transnational and multinational businesses, paying special attention to the influence of culture on portal design. More specifically, we argue that culture has a significant influence on a number of important portal design considerations—including color, icons, symbols, language use and portal layout.

INTRODUCTION

Sifting through voluminous amounts of Internet and intranet information to find relevant material is a daily nuisance for people all over the world. General search engines provide quick results, but one is very dependant on finding just the right combination of keywords, and, even for the best search engine the coverage of its search index is no more than 16% of all the material available on the Internet (Lawrence & Giles 1999). A number of strategies have been employed to reduce this nuisance, including the use of categories, filter sites and the grouping of results according to content—e.g. sports, tourism, finances, news, culture, etc. Functionality has also been expanded to include membership in virtual communities, real time chats, personalized search engine interfaces like My Yahoo and My Excite, and access to specialized commercial content. This aggregation and bundling of information, distributed to various users by a single access point - be it through intranets, extranets, or the Internet – is commonly referred to as a portal (Tatnall 2004). Our definition of a portal is: an integrated and personalized web-based application that provides the end user with a single point of access to a wide variety of aggregated content anytime and anywhere using any web-enabled client device.

The evolution of portal applications has attracted the attention of the business world, because the same underlying technology can also be adopted to manage, structure, and facilitate access to enterprise information as well. Most contemporary organizations use portals to identify, capture, store, retrieve or distribute great amounts of information from multiple internal and external information sources. Portals are used to deliver information and applications to their employees (Counsell, 2004; Daniel & Ward, 2003); to provide staff with job- or task-related information and knowledge (Detlor, 2004; Terra & Gordon, 2003); and as a way to enable collaboration and interaction with external business partners (Detlor, 2000; Dias, 2001). Portals not only deliver information, but improve the usefulness of the information itself by tailoring it according to the role, location or interest of the individual user (Ben-Arieh & Pollatscheck, 2002).

With the continuing rapid development of internet technology, portals have emerged as one of the most promising opportunities in the management of enterprise information—including information dissemination, information access, information sharing, and information exchange (Collins, 2002; Terra and Gordon, 2003; Detlor, 2004). Numerous 'enterprise portals' have been developed, including employee portals, e-market portals, enterprise collaboration portals, enterprise knowledge portals, and others. Research on enterprise portals is also abundant, but most studies have concentrated either on enterprise portal design (Detlor, 2000; Bock, 2001; Ben-Arieh & Pollatscheck, 2002), enterprise portal applications (Dias, 2001; Collins, 2002; Terra and Gordon, 2003; Daniel and Ward, 2003, Detlor, 2004) or on content management and the customization or personalization according to portal-users' roles and information requirements. Whereas portals provide great opportunities to business, *global* portals provide even larger opportunities due to the larger scale, but also the larger diversity of the information represented. Thus, an important yet under-represented area in research to date is culture, and specifically the influence of culture on enterprise portal design. The purpose of this paper is therefore to fill this research gap and highlight the implications and the opportunities of enterprise portals for international, transnational and multinational businesses, paying special attention to the influence of culture on portal design in a global environment. We will show how culture influences several factors of the design, implementation and usage of portals in a global context. This study should be of benefit to managers, educators, and students involved in international business intelligence, information systems management, information resource management, and knowledge management. The structure of the paper is as follows: First, we draw attention to the opportunities enterprise portals provide for improving the daily information flows within an enterprise. Then, we discuss the influence of culture on global enterprise portal design by means of five elementary points. The final section then summarizes our key findings and highlights important implications for management and research.

BUSINESS OPPORTUNITIES FOR ENTERPRISE PORTALS

By serving the needs of large and diverse number of users, enterprise portals can be extremely helpful in the alignment of business and IT. This is not an easy task as the portal must integrate information from a large number of different functions, including purchasing, R&D, manufacturing and production, finance, sales and marketing, etc. The enterprise portal delineates and explicates the internal collaborations and interoperability requirements among these various functions and collaborating groups. Since an enterprise portal offers a single point of access and a single point of information interchange (Hazra, 2002), an enterprise portal could integrate business events across existing information systems and departmental boundaries thus facilitating the internal collaborations and promoting interoperability among the different departments within the enterprise.

Furthermore, the enterprise portal can help employee to be highly productive and competitive. Those capabilities of an enterprise portal give employees a resourceful and aspiring role in the organization because they could personalize information for business decision making. Meanwhile, the personalized information allows employees to find high quality information without having to spend copious amounts of time browsing. It also reduces massive quantities of information into the customized set. The effective information acquisition and utilization make employees more productive in doing their job and thus businesses more competitive.

In addition, the enterprise portal introduces business information management for enterprises with an extension to reach the customers, suppliers, and business partners in their network. In this way, the enterprise portal can support supply chain management and customer relationship management for both businesses and customers. In practice, business relationships evolve in multiple directions

in which buyers, sellers, and brokers of goods and services come together to exchange information, obtain specific knowledge, and conduct transactions. An enterprise portal could extend to potential customers worldwide as well as in the search for optimized suppliers by comparing supplier offerings and prices instantly in a real-time manner. Additionally, the collaboration relationship with suitable business partners is possible, such as collaboratively designing products, matching and responding to customer demands by the entire value chain players, etc. Accordingly, an enterprise portal can provide enterprises with a genuine capacity to enable real-time, interactive exchange of business transaction information and integration of business processes in a network; e.g. of trading partners, buyers, sellers, brokers or intermediaries, and e-business service providers.

The enterprise portal and its various applications shown above strongly suggest that an enterprise portal can contribute to both internal and external integration of enterprise businesses. The internal integration includes the back-end processes required for complete fulfillment of customer requests, which may involve the major customer-client interactions (such as registration, marketing, payment, and so on) and management of customer transactions (such as accommodating requests from the website for products and services, or integration of the vast amounts of customer information). The external integration combines services from multiple providers (such as partners of a supply chain) to support extended transaction management, information exchange, coordination, and collaboration along the entire business value chain. In addition, personalization can help in providing more relevant information, as opposed to more information.

CULTURAL INFLUENCES ON THE DESIGN OF ENTERPRISE PORTALS

From a technical point of view, extending an enterprise to global scale presents challenges, but none that cannot be overcome. But what of the users? Global scale also brings different languages, different life styles and different cultures, all of which affect the perceptions and expectations of users (Ruta, 2005). Two users may have completely different interpretations of a single message displayed on a portal. What are the portal design factors that are influenced by culture, and what are the possible differing perceptions, expectations and interpretations of international portal-users? We highlight five design factors that need to be considered. Next to language differences, important roles are also played by color, icons, symbols, and layout (e.g. Choong & Salvendy 1998; Del Galdo, 1990; Fang & Rau, 2003; Ossner, 1990; Rau, Choong & Salvendy, 2004; Spencer, 1988; Tractinsky 2000).

Language-differences between countries are one of the more obvious hurdles that global portals must overcome. The differences require more than just translation of text, but call for consideration of the meaning and implications attached to words and phrases and how those meanings and implications vary across borders (see for instance the UNESCO B@bel initiative). There are technical considerations as well, such as the difference between single- and double-byte characters for Western and Chinese text, respectively. But in addition to the more obvious language differences, we like to draw attention to numerous other, often overlooked yet important factors that also differ by country and must be considered when designing portals that are global in scope. The factors include color, the use of icons, symbols and portal layout. We consider each of these in turn.

Color is a useful and important consideration, as it both catch and hold the user's attention. It can also help to sustain, reinforce and enhance a positive experience during searching or browsing. However, in a global context, colors connote very different meanings. For instance, colors that are sacred differ between Judeo-Christian West (red blue, white, gold), Buddhist (saffron yellow) and Islamic (green) traditions. Subdued Finnish designs for background screen patterns might, or might not be suitable in Mediterranean climates (Marcus, 2003). Based on Russo and Boor **(1993) s**ome significations of colors related to several countries are adopted, and presented below in table 1.

As shown in table 1, a single color will have very different meanings from country to country; while similar meanings may be represented with completely different colors. For example, red means happiness, prosperity, and success in China, and is the most preferred color for celebrations, such as weddings. It is also often used to decorate festivals sites, important events, or to welcome very important persons. Nevertheless, red color represents danger for Anglo-American, anger for Japanese, and death for Arabs. A similar example is white color, which represent purity for Anglo-American and is commonly used for weddings, but represents death for Chinese and is normally used during funerals. Thus, in a global environment, differences in color go deeper than just appearance, and the selection of colors can be a difficult and sensitive decision for designers of global portals.

Table 1. Colors related to some countries--adapted based on Russo and Boor (1993)

Color / Country	Red	Green	Yellow	White
Anglo-American	Danger	Success; Safety	Coward	Purity
French	Aristocrat	Crime	Lucky; Temporary	Neutral
Chinese	Happy; Success	Life; Hope	Wealthy; Powerful	Death
Japanese	Anger; Danger	Young; Energetic	Grace; Nobility	Death
Arab	Death	Fertile; Strong	Happy; Wealthy	Joy
Indian	Life	Wealth; Fertile	Success	Death

Similar to color, the meaning of *icons* also varies from one country to the next. Icons that represent everyday objects or functions in one country may be perceived as obstacles by users in another country. Nielsen (1999) suggested that, in general, hands or feet as icons should be avoided. Additionally, animal icons may have subtly different meanings by country. For instance, an owl represents wisdom in many western countries but implies something evil in some eastern countries. To most westerners, the dragon is a fearsome mythical animal, but to the Chinese, the dragon has a more positive and mythological connotation. Chinese people considered the dragon as a representative of wisdom and a source of blessings. Another example is that a dog can be a lovely image in some countries, but it is seen as the lowest form of life in some other countries. Some icons may convey meanings that are not only different, but contradictory. Sabre's Planet Sabre, one of the world's largest extranets, whose UI+IV was designed by the authors' firm, uses multiple variations of icons for an e-mail 'mailbox,' to account for national differences (Marcus, Armitage, Frank & Guttman, 1999).

Symbols are also commonly used for international communication, but similarly to colors and icons, the meanings of symbols are country and culturally specific. One example to consider is whether selecting symbols such as the "X" or check marks convey the correct distinctions as to 'selected' or 'de-selected. Looking again to China, an "X" is most commonly used to cross out what is not desired rather than indicating what is to be selected, which is precisely the opposite in many western countries.

Regarding the *layout of portals,* reading direction across the world can be generally divided into three types, the most popular being left-to-right, and row-by-row, from top to bottom. However, in some regions people read from *right-to-left*, and row-by-row, from top to bottom. Moreover, a third way to read is from right-to-left and *column-by-column*, such as in traditional Chinese layout that is still very popular in Taiwan, Hong Kong and certain locations in mainland China. Obviously, left-to-right sequencing may be inappropriate or confusing for use with right-to-left reading scripts or with icon layout. Studies have shown how pictorial information should be presented and organized for scanning on a display according the direction the script flows naturally in the user's first language (Badre, 2000). The early version of a website called Arabia.On.Line, for example, intended to be a place where western readers could learn about Arab countries, mistakenly laid out its contents as though the text were written in Arabic, for Arabic readers. The result was an arrangement of icons that was misleading for the (Western) viewer's eye, and led them in directions inconsistent with that intended by the designers (Marcus, Armitage, Frank & Guttman, 1999). As a final, somewhat humorous example, consider a billboard where a woman on the left is shown unhappy, next to a pile of dirty laundry, while the woman on the right of the billboard is shown smiling, next to clean laundry and holding a certain brand of washing powder. Now imagine how the message might change for viewers who are accustomed to reading from right to left!

CONCLUSION

In this paper we have focused on the business opportunities for enterprise portals and subsequently the influence of culture on enterprise portal design. Enterprise portals can help in integrating internal as well external information flows. Internally, to be effective, enterprise portals require seamless information flows across the organization. When enterprises are bold enough to provide their employees such broad access, cross-linking between all sorts of departments becomes possible. Employees are enabled to consider issues and opportunities—and potentially adding value—well beyond their own functional domain. Similarly, external integration can lead to the development of value networks which extend beyond enterprise boundaries, linking together the information systems of supplies and customers, to minimize order-to-cash, production, and other key cycle times. Furthermore, personalization can enhance the productivity of employees as information is filtered for relevance and the effectiveness of search results—and the work that depends on them—is improved. Capturing these benefits for global enterprise portals, however, requires careful consideration of the influence of culture. Not only language, but also color, icons, symbols and layout—these are examples of portal design considerations that are relatively simple, but that have a strong impact on the successful deployment of an enterprise portal in a global environment (Fang & Rau, 2003).

Managers and portal designers need to consider that enterprise portals will only be successful when a portal can provide most of the services, information, and links that users want (Tatnall, 2004). Nonetheless, portal design has been limited to portals providing user-customizable access to information and applications through a browser (White, 2000). In other words, user-customization does not yet include personalizing the cultural factors, e.g. color, icon, symbol, language, and layout, when portal-users are granted access to portals. To meet the requirements of international portal-users, portal designers should be sensitive to such user-customization in a global context. Next to improving portal design, this knowledge can also be used to improve portal utilization. When enterprise portals are used much less in certain regions than in other regions, perhaps the designers should look for possible conflicts in the meaning of colors, icons, symbols, language and layout.

Finally, we propose that future research be directed at studying various cases of portal design and use and verify how the influence of culture affects portal design and use in a global environment. It would be particularly meaningful if the study results could indicate specifically which factors most influence portal utilization across national borders. The findings of case studies would greatly contribute to the international portal design and development. To satisfy a wider range of users in different locations globally, future research efforts are needed for portal products that can be further customized or personalized. Although portals currently allow users to customize the applications and information they need, the customization should go further in a global environment to include personalization of appearance as well. For example, investigation of "reusable libraries" in which various optional and pre-configured packages or palettes of colors, images, icons, symbols, languages, templates, etc. may prove useful. These optional components are reusable and can be seen as building blocks, which could better fit specific national and/or cultural requirements. Only after consideration of these cultural influences can enterprise portal design become truly global.

Challenges in Developing a Data Warehouse to Manage the Rollout of Antiretroviral Therapy in a Developing Country

J. E. Kotzé, University of the Free State, South Africa; E-mail: eduan@xsinet.co.za
T. McDonald, University of the Free State, South Africa; E-mail: Theo.SCI@mail.uovs.ac.za

ABSTRACT

With a global HIV/AIDS epidemic, developing countries are facing an enormous challenge in combating the disease. Public health will be placed under severe pressure in providing treatment such as highly active antiretroviral therapy to all its HIV infected patients. This paper will describe the challenges involved in establishing a data warehouse to provide strategic information during the rollout of antiretroviral therapy (ART). The construction of a Human Resources Data Mart, which is critical to the successful rollout of antiretroviral therapy in South Africa, will be discussed in detail. Special attention will be given to extraction, transformation and loading, slowly changing dimensions type 2 and materialized views.

Keywords: Data Warehousing, Healthcare, Human Resource Data Mart, Antiretroviral Treatment, Developing Countries.

1. INTRODUCTION

The HIV/AIDS epidemic is a global crisis which threatens development gains, economies and societies. At the end of 2004, the total number of people worldwide living with HIV/AIDS was estimated to be just under 40 million. In South Africa the estimated number of AIDS related deaths in 2003 ranged anywhere between 270 000 and 520 000 according to the UNAIDS Global Report (UNAIDS, 2004).

In response to this epidemic, the South African Government created the HIV/AIDS and STD Strategic Plan. This plan includes the provision of antiretroviral therapy in the public health sector in an attempt to reduce AIDS mortalities. Antiretroviral treatment (ART) for HIV infection consists of drugs that slow down the reproduction of the HIV virus in the body.

The Free State Department of Health (FSDOH) launched its provincial antiretroviral treatment program during May 2004. By the end of June 2006 a total of 31 public health facilities were empowered to provide antiretroviral drugs for 6200 patients in the Free State. The Actuarial Society of South Africa (ASSA) has developed an AIDS Demographic Model that can be used to project the impact of this disease on each province in South Africa. According to Chapman (2003) using the ASSA 2000 Model, it is estimated that in the Free State

- Approximately 480 000 people are HIV positive (based on 30.1% HIV positive mothers in the 2003 HIV Antenatal Survey);
- Seven percent (7%) of all HIV infected patients are in a World Health Organization (WHO) Stage 4 AIDS defining illness, which is approximately 31 111 patients;
- Annually, 28 290 patients will develop a WHO Stage 4 AIDS defining illness.

The WHO recommends that all people in a WHO stage 4 AIDS defining illness should commence with antiretroviral treatment immediately. This recommendation will pose serious challenges in managing the resources required for treating all these patients by the FSDOH. Mechanisms have to be developed to effectively monitor the antiretroviral treatment programme but at the same time provide the necessary **strategic information** in managing and evaluating the programme as well. It is clear that a number of factors are forcing the FSDOH in the direction of a data warehouse (DW).

This paper will indicate how a Health Department in South Africa, the FSDOH, tackled and successfully managed the challenges of creating a data warehouse. A background section will provide the history of the current operational system and the shortcomings of the system. That will be followed by a detailed discussion of the challenges involved in constructing the human resource data mart (HRDM) which is critical to the successful rollout of ART in South Africa. The Extraction, Transformation and Loading (ETL) process will be examined and slowly changing dimensions will be addressed. The paper then concludes with a discussion of a modified staging area that uses a materialized views approach to provide the platform for developing the human resource (HR) online analytical processing (OLAP) cube.

2. BACKGROUND

2.1 General

A data warehouse differs significantly from a conventional operational or transactional database in several aspects. First of all, a complex data structure must be maintained in order to offer flexible and dynamic retrieval of rich decision-support knowledge (Shin, 2003). For this, it maintains data that is more integrated, subject-oriented, non-volatile and time-variant in comparison with transactional or operational databases (Dodge & Gorman, 2000; Hristovski *et. al.,* 2000; Shin, 2003). Data structures of a data warehouse should also be more cross-functional (Shin, 2003) and support management decisions (Hristovski *et. al.,* 2000).

According to Saraceni *et. al.,* (2005), the linkage of several databases can assist with studying the distribution of diseases and for analysis of AIDS-related mortalities in Brazil. Although the linkage of databases is in essence not a data warehouse, it demonstrates the importance of analyzing information and using it to provide strategic information for the decision-making process.

Data warehouses have previously been used in the areas of health and public health (Davis *et. al.*, 2002; Lau & Catchpole, 2001; Prather *et. al.,* 1997). However, most data warehouses in the health areas are used for ***clinical treatment outcome*** or for ***biomedical studies*** and limited research has been done on the usage of data warehouses in public health for holistic decision-making.

2.2 Lack of Strategic Information

The Personnel and Salary (PERSAL) system is an online transaction processing (OLTP) based payroll system and is used by all the National and Provincial governments in South Africa. The system has been in a production environment since 1990 and was developed in Natural Adabas. At present, the system is being maintained by a private company.

Because the system is OLTP based, it proved inadequate in providing the necessary human resource statistics needed by antiretroviral programme managers.

Furthermore, every new change or new report must be submitted to a central *System Change Control* system. From there it will be prioritised and once accepted, handed over to the private company for development.

This process was cumbersome, inflexible and time consuming which led to overall frustration. In 2004, the FSDOH received approval from National Treasury to extract all relevant human resource data from PERSAL, thus allowing them the freedom of incorporating the data into a data warehouse.

3. CHALLENGES

The following sections will provide details on the challenges that were faced during the development of a data warehouse.

3.1 Limited Budget

According to Schubart & Einbinder (2000), research has showed that the key factors for successful data warehouse implementation are organizational in nature. Management support and adequate resources are most important because these address political resistance. Gatziu & Vavouras (1999) stated that data warehouse development is a demanding and costly activity of which the establishment thereof could be in excess of $1m. This can be a major obstacle in a developing country.

Taking these factors into consideration, top management was approached to direct the development of the data warehouse in early 2005. Because of a limited IT budget (0.68%), a decision was taken to break the project down into several data marts and to develop the data warehouse over a longer period of time. To cut back on costs, in-house existing staff was used to construct the data warehouse in lieu of making use of expensive outside consultancy firms.

Oracle is the current worldwide leader in the data warehouse tools marketplace (Vesset, 2006). Furthermore, Oracle 10.2g also offers all the functionalities required in both OLTP and DW based databases. Both these reasons guided the FSDOH decision to upgrade their existing Oracle9i infrastructure to Oracle 10.2g and make use of it for the data warehouse. The upgrade process was covered in an existing maintenance contract, resulting in no additional expenditure.

Human resources and pharmaceutical (ART drugs) costs were identified as the main cost drivers, and more strategic information was required in order to obtain sufficient funding for the ART programme.

Listed below are the identified data marts:

- human resources
- clinical patient ART treatment
- pharmaceuticals (ART drugs)
- patient mortalities
- tuberculosis

The Human Resource Data Mart (HRDM) was chosen as the first data mart to be constructed and will be the focus of the rest of this paper.

3.2 Extraction, Transformation and Loading Challenges

3.2.1 Data Extraction

The data in the OLTP system (PERSAL) is *transient data* of nature. According to Bruckner & Tjoa (2002), the key characteristic of *transient data* is that alterations and deletions of existing records physically destroy the previous data content. In order to keep the history of the data in tact, all modifications to the data had to be considered.

The ETL processes commenced with a data extraction process which are performed **twice** a month by Treasury. At the beginning of every month, the FSDOH will receive two sets of data. The reason for this approach is entrenched in the manner in which government officials receive their salaries in South Africa. The salary of permanent staff is paid on the 15th of each month. All the information related to this event constitutes data set one. However, additional or supplementary payments (i.e. S&T claims, overtime, fuel allowance) and workforce operations (promotions, staff re-allocations) can be made to government officials from the 16th until the end of the month. All these additional information constitutes data set two.

In essence, the first extraction consists of a full *data snapshot* taken on the 15th of the month from the *transient data set*. This includes **staff, posts** and the **hierarchical organization structure**. According to Bruckner & Tjoa (2002), a *data snapshot* is a stable view of data as it exists at some point in time. It is a special kind of periodic data. Snapshots usually represent the data at some time in the past, and a series of snapshots can provide a view of the history of an organization.

The second extraction consists of the supplementary changes to the *data snapshot* picture of the first extraction set in terms of **staff** and **posts** but **exclude** any changes to the hierarchical organization structure. This extraction process was preformed at the end of the month. It can be regarded as *semi-periodic data*. According to Bruckner & Tjoa (2002), almost all operational systems retain only a small history of data changes due to performance and/or storage constraints.

The challenge pertaining to more than one set of extraction data in the update window is the issue of *late-arriving data.* According to Bruckner & Tjoa (2002), *late-arriving data* is bothersome because it is difficult to integrate with existing fact and dimension tables, especially when surrogate keys are used in order to cope with slowly changing dimensions. Aggregates have to be updated, because the newly integrated data sets will change counts and totals of the prior history. Late-arriving data can therefore possibly change analysis results unexpectedly from the analyst's perspective.

In order to deal with the problem of late-arriving data, it was agreed that the data warehouse will be updated during the **first week** of the following month, reflecting the *transient data picture* and supplementary changes (*semi-periodic data)* that was made to it.

3.2.2 Time Stamping

The standard approach for storing periodic data (typically found in Data warehouses) is to use time stamped status fields for each record. For the HRDM the *load timestamp* method was used.

Slow changing dimensions (SCD) Type 2 will be used as far as possible. According to Berndt & Fisher (2001), this type of change adds rows to maintain an arbitrarily long history. The keys must be "generalized" in this approach by using a version number or some other mechanism, so that related rows can be retrieved as a coherent history.

Each table in the staging area had a column added called EXTRACT_DATE which translated to the record *load timestamp.*

3.2.3 Dealing with Slowly Changing Dimensions

One of the biggest challenges with the HRDM was the monthly changes to the organizational structure. Changes occur when new components (organizational units) are created, moved or become obsolete during the month. Components contain the posts for that particular unit and the links of the child components directly reporting to it.

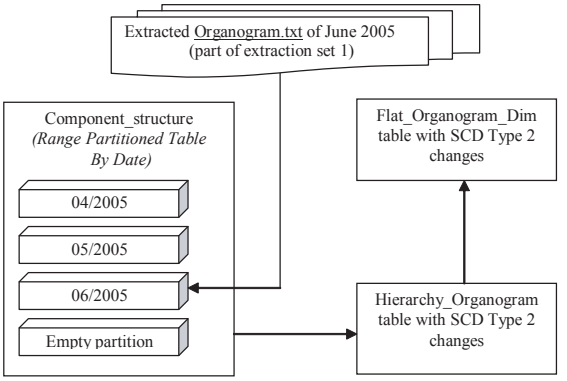
Changes in the organizational structure were not directly reflected in each month's download and had to be identified with specially developed algorithms in order to perform SCD Type 2. This was because the organizational structure was only included in extraction set 1 as a *data snapshot picture* called **Organogram.txt** and not a list of changes. See Figure 1 for the organizational structure data flow of June 2005 as an example.

The data for the organizational structure was imported into the COMPONENT_STRUCTURE partitioned table from the Organogram.txt file. This partitioned table then contained the organizational hierarchy for each month. The organizational hierarchy in turn, consisted of component details and linkages between child and parent components.

A table called HIERARCHY_ORGANOGRAM was constructed and populated with the hierarchy on the date the HRDM project commenced (April 2005). For each following month, COMPONENT_STRUCTURE was algorithmically compared to HIERARCHY_ORGANOGRAM using complex SQL statements and SET operators to help identify the following changes:

- New Component
- Component name change
- Parent component position change
- Parent component name change
- Deleted Component

Figure 1. Data flow for extracted organogram.txt (June 2005)



Each time a change was detected, a new record was inserted into HIERARCHY_ORGANOGRAM, with a new surrogate key. The superseding record was changed to the last date of the previous month. A surrogate key called ORGANOGRAM_KEY was created with the extract date (or *load timestamp*) concatenated with the component number to stay within the bounds of SCD Type 2.

Kimball & Margy (2002) pointed out that hierarchical structures of variable depth presents several problems in the relational environment. Some examples are the difficulty of navigation or rolling up of facts within these hierarchies using non-procedural SQL. This posed a problem for the FSDOH when using Oracle 'CONNECT BY' SQL extension in the same statement as a join. While 'CONNECT BY' is very useful when navigating recursive points in a dimension table, it can not be used by an ad hoc query tool. If the tool could generate this syntax to explore the recursive relationship, it cannot in the same statement be joined to a fact table. Even if Oracle was to remove this somewhat arbitrary limitation, the performance at query time would probably be not too good (Corr, 2001).

To overcome this problem, a bridge table or often called helper tables are inserted between the hierarchical dimension table and the fact table (Kimball & Margy, 2002). The problem the FSDOH experienced with this approach was entrenched in the manner the multidimensional online analytical processing (MOLAP) tool used the dimensional model for its analytical model. The MOLAP tool required a flat organizational view which in theory meant a totally denormalized view of the hierarchical organizational structure and relationships in HIERARCHY_ORGANOGRAM.

Kimball & Margy (2002) also pointed out that when navigating the bridge table via the standard SQL code, it is not for the faint of heart. In order to overcome the prerequisite of the MOLAP tool together with minimizing the SQL complexity for the FSDOH users, a ***modified version*** of a bridge table was introduced. The table FLAT_ORGANOGRAM_DIM was created and used as one of the dimensions in the dimensional model (See Figure 2).

This ***modified version*** of a bridge table might not be the perfect solution should the organizational structure consist of more than 10 levels. To overcome this, the table is re-created every month from all the SCD Type 2 changes captured within HIERARCHY_ORGANOGRAM. In this manner the algorithm will allow an extra level (meaning an extra table column) when it detects it, thus avoiding the possibility of missing data. However, the only manual action to be taken is to insert this additional level (table column) within the MOLAP tool.

3.2.4 Example of a SCD Type 2 on a Parent Component

The following example (See Figure 3) will illustrate a SCD Type 2 on a parent Organizational Unit (Component) between April 2005 and June 2005 and the domino effect it will have on its child components.

- Step 1: Algorithm detects a change in *parent name* in component 011200
- Step 2: Perform SCD Type 2 and load changes into HIERARCHY_ORGANOGRAM

HIERARCHY_ORGANOGRAM

Organogram Key	Extract date	Component Name	Parent Component	Date From	Date To
01-APR-2005-011200	01-APR-2005	Hospital A	011000	01/04/2005	30/06/2006
01-JUL-2006-011200	01-JUL-2006	Pelonomi Hospital	011000	01/06/2006	

- Step 3: Force the change in all child components of component 011200. Only ***Component 011333*** will be illustrated below.

HIERARCHY_ORGANOGRAM

Organogram Key	Extract date	Component Name	Parent Component	Date From	Date To
01-APR-2005-011333	01-APR-2005	AIDS (Unit)	011200	01/04/2005	30/06/2006
01-JUL-2006-011333	01-JUL-2006	AIDS (Unit)	011200	01/06/2006	

- Step 4: Convert the hierarchical organizational structure into a flat organizational structure

Figure 2. Dimensional model

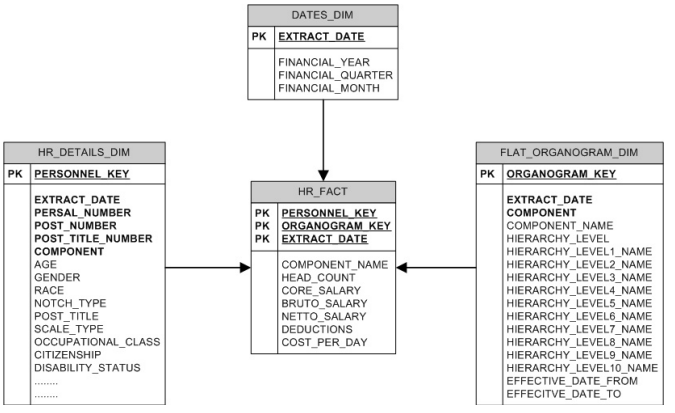


Figure 3. Parent component name change

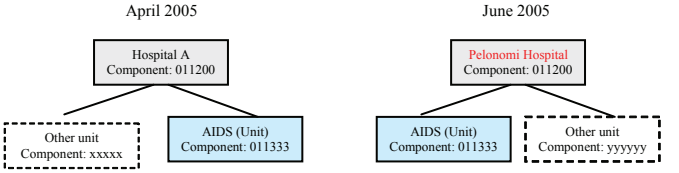


FLAT_ORGANOGRAM_DIM							
Organo-gram Key	Extract date	Component Name	Effective Date From	Effective Date To	Level 1	…	Level x
01-APR-2005-011200	01-APR-2005	Hospital A	01/04/2005	30/06/2006	HEALTH		Region A
01-JUL-2006-011200	01-JUL-2006	Pelonomi Hospital	01/06/2006		HEALTH		Region A
01-APR-2005-011333	01-APR-2005	AIDS (Unit)	01/04/2005	30/06/2006	HEALTH	….	Hospital A
01-JUL-2006-011333	01-JUL-2006	AIDS (Unit)	01/06/2006		HEALTH	….	Pelonomi Hospital

3.2.5 Using Materialized Views and SCD Type 2

According to Becker (2004), one of the problems of the SCD Type 2 technique is the large number of additional rows required to support all the changes. Barbusinski *et. al.*, (2003) pointed out that joining the fact and associated dimensions would also require complex temporal joins at analysis time. Furthermore the SQL statement must include time reference for both the fact and associated dimensions. All these factors will lead to an undesired environment for non-sophisticated users such as in the case of the FSDOH.

One possible way of overcoming these obstacles, is by using a materialized view (mview) to hide the complexity. A materialized view also physically stores the data that corresponds to the view's defined query (Dodge & Gorman, 2000). According to Goldstein & Larson (2001) query processing time can be improved through the use of materialized views.

For these reasons it was decided to make use of Oracle's materialized views. HR_DETAILS_DIM (mview) was created by joining all the posts with the matching staff member details. A staff member could also belong to more than one post. In order to uniquely identify a staff member with a particular post, a surrogate key called PERSONNEL_KEY was constructed for this purpose.

The PERSONNEL_KEY was constructed using a concatenated combination of the following fields from the posts and staff tables:

- EXTRACT_DATE (staff details)
- PERSAL_NUMBER (staff details)
- POST_NUMBER (post details)
- POST_TITLE (post details)
- COMPONENT (post details)

Thereafter, HR_FACT (mview) was created by joining FLAT_ORGANOGRAM_DIM (table) and HR_DETAILS_DIM (mview) to ensure consistency with all the SCD Type 2 changes in FLAT_ORGANOGRAM_DIM.

3.2.6 Building OLAP Cubes

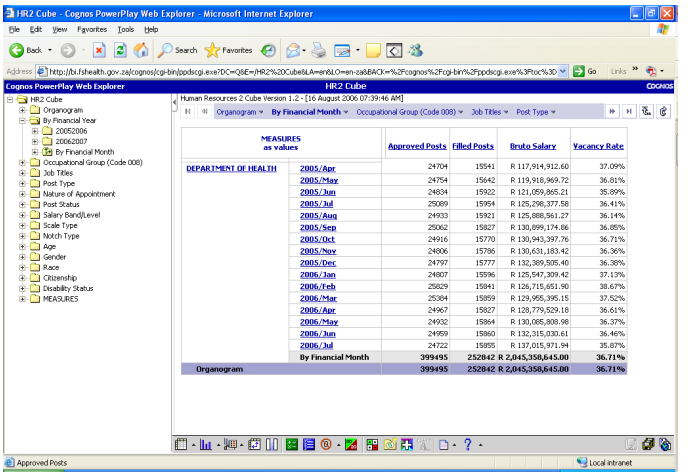
The HRDM OLAP cube was constructed from the dimensional model (See Figure 4). This was all done using Cognos Framework Manager and Cognos Transformer Series 7.

Research done by Gorla (2003) to evaluate OLAP tools in ease of use and usefulness, suggested that MOLAP be used for non-sophisticated computer users and relational online analytical processing (ROLAP) for sophisticated users.

Since most of the users at FSDOH can be categorized as non-sophisticated computer users, the **MOLAP** architecture was the choice of platform. The cube was deployed using Cognos Enterprise Server Series 7 which delivers **Web-based OLAP (WOLAP)** content, but using an underlying architecture that is still MOLAP. According to De Beer (2006), WOLAP is also seen as the next generation BI tool providing "thin-client" viewing tools for analyzing information.

The users were able to generate pivot tables (See Figure 4) from the WOLAP cube to assist them in obtaining strategic human resource information.

Figure 4. Pivot table from human resource data mart



4. CONCLUSION

Efficient resource management is critical for the success of the rollout of antiretroviral therapy in South Africa. Human resources management and ART drugs management was identified as the key factors but also the main cost drivers. A HRDM was built to provide strategic information for the ART programme. FSDOH management was now able to perform efficient staff allocations, monitor absenteeism and identify overworked personnel in time. Problematic ART clinics and hospitals in terms of staff turnaround could now also be easily identified by using trends, providing the FSDOH management team enough time to address the problem.

Future work and research could be done to link the HRDM to the ART clinical data set to identify health workers infected with HIV and AIDS. With this information, FSDOH management can obtain a better picture on the infection rate of HIV and AIDS on its health workers.

In conclusion, this paper demonstrated that it is possible to overcome the challenges of building a large-scale data warehouse, by starting small, using in-house knowledge and skills and to build data mart by data mart. The ETL process was modified to overcome the challenge of using SCD Type 2 within a hierarchical dimension. Materialized views were used to assist with the construction of the OLAP cube by camouflaging the complexities created by SCD Type 2. The end result was a MOLAP cube which provided an environment, conducive for analytical HR operations.

A Story on "Story Telling" in a Virtual Learn-Work Environment

Paul Oord, Open Universiteit Nederland, MKE 3.69, Postbus 2960, 6401 DL Heerlen, The Netherlands; E-mail: paul.oord@ou.nl
Cecile K. M. Crutzen, Open Universiteit Nederland, MKE 3.69, Postbus 2960, 6401 DL Heerlen, The Netherlands; E-mail: Cecile.Crutzen@ou.nl

1. INTRODUCTION

The Open University of the Netherlands (OUNL) is an institution for higher distance education. At the School of Computer Science 70% of the students already have other degrees and are in paid employment. They want to acquire additional know-how or retrain for a different occupation. In order to meet today's learning needs of the bachelor students in Computer Science and the needs of ICT-industries for employees with up-to-date domain expertise together with academic team competencies, the OUNL has designed and implemented in the year 2001 the course 'Design Project' (400 hours of study). This course has an open learn-work environment 'OTO'[2], designed as a virtual company (VC). Students in this course (re)design a solution for a real-world company's problem in the domain of computer science. Since 2001 14 teams (about 95 students) have been active in OTO.

Knowledge construction in organizations is crucial for the continuous improvement of products and services. ICT-professionals (should) need to learn to focus on users and consumers, and to regard clients as co-developers of an ICT-product. This article (story) describes OTO, and how internal knowledge management is implemented to enable students to preserve their experiences in an informal and narrative way.

2. THE COURSE DESIGN PROJECT AND THE LEARN-WORK ENVIRONMENT OTO

What students know and understand is grounded in perceived experiences from their interaction in the worlds they live in (Jonassen, 1991 p. 10; Jonassen, 1994 p. 34-35). Their experiences are situated in the interaction world of their study and professional job. In all these worlds they have developed routines and habits.

A learn-work environment as OTO should give students the opportunity for doubting their obvious acting, questioning the behaviour of others and transforming their habits developed through participating in their interaction worlds. However changing 'routine acting' is always very difficult. Routine does not have much presence in a world of interaction and a lot of people, especially computer scientist whose focus is security and nonambiguity, see doubt as a feeling of insecurity. Creating doubt is considered as an unpleasant activity and not as a necessary prerequisite for change (Bitter & Crutzen, 2002; Crutzen, 2005). The culture of Computer Science differs from the culture of the worlds in which their products will be used. The invisibility of 'routine-acting' is precisely the problem of computer scientist designing ICT-representations for actors in other interaction worlds.

The course Design Project is built on notions of social constructivism and critical transformative interactions. It is an example of computer supported collaborative learning and is competence and experience based (Westera, Sloep & Gerrissen, 2000). These premises are expressed in the goals of OTO and in the responsibilities of the students. The business goal of the company OTO is to offer to other organisations a cooperative and participative redesign of the relation between the business processes and their information system. The internal business goal is competence development of each employee, of each team and of OTO itself by means of knowledge and human resource management and by evaluation of the internal business processes, strengthening the changing potential of OTO. Students succeed in this course if they show sufficient involvement, participation and responsibility in designing the learning and working process of themselves, of their team and of OTO. During the project students are temporary employees in OTO and work collaboratively in teams of 5 to 10 members. The workload for students is generally 15 hours a week during half a year. They are guided in respect to their organizational and social competencies. The OTO-staff members (a director, a human resource manager, a project manager and some coaches) are all members of the OUNL organization. They are responsible for making OTO ready, for the exploitation of OTO and the support of students. The director in cooperation with the project manager is responsible for the contacts with external clients and acquires project proposals from which the student teams can choose. External client organizations must make a commitment that they are willing to give participation time in the project. The team refines the chosen initial project proposal together with the representatives of the external organization to a project draft, a first product idea and later on to an external project planning script and a final contract. This contract symbolises the end of the A(cquisition)-phase (about 1,5 month) and the beginning of the P(roject)-phase (about 4,5 months) of the working process (Figure 1)

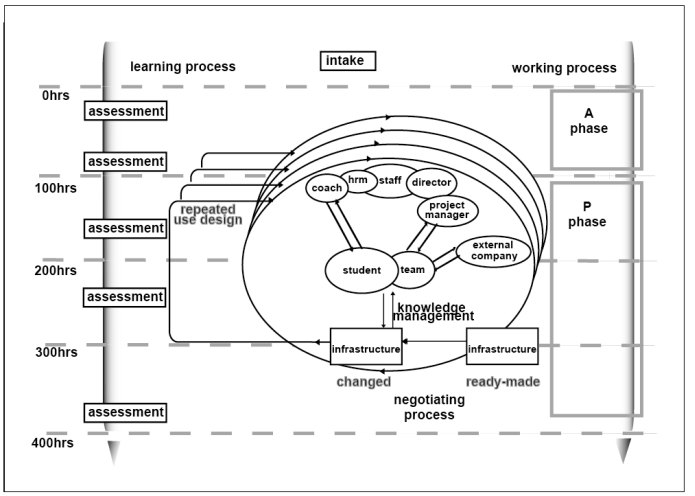
3. THE LEARNING AND WORKING-PROCESS IN THE VC OTO

The main processes in OTO, working and learning, cannot be completely planned in advance. Students are responsible for detailed design of the working process. OTO is not supposed to be a working environment in which learning results depend on learning occurring by chance. On the contrary OTO is purposefully designed to facilitate critical transformative learning. OTO offers the students a set of well-defined competencies they can develop. They are regarded as key objectives for learning on the job, and are essential for preparation for professional practice. The personal growth objectives for each OTO professional are laid down in a personal development contract initiated in the intake. The contract will be renewed constantly through peer-, coach- and self-assessments. Each assessment is followed by a coach-student consultation. The personal coach supports the learning process of each student employee.

Together with the external planning script each team composes at the end of the A-phase an internal planning script in which the tasks and the roles of each team member are mentioned. These tasks and roles are linked to the competencies they want to explore. It is the responsibility of the team to combine the working and learning process in the internal planning script. During the P-phase these planning scripts are continuously adjusted to the circumstances in the project interaction. A project manager from the OTO staff supports the working process in each team. A very useful instrument is the personal reflection document in the electronic student portfolio in which coach, project manager and student comment the ongoing activities in relation to the chosen tasks and competencies. This commenting enables the student to reflect on her/his performance and to relate activities in the working process to the chosen objectives of the learning process.

OTO provides in its infrastructure a variety of tools to support electronic communication, collaboration, planning, knowledge management, and tools for assessment, design and development. In the knowledge base are templates, skeleton contracts and a library with relevant articles on methods and theories. Regular face-to-face meetings on the initiative of the students appear to be indispensable for this kind of collaboration. In the electronic course material a global description of the working and learning processes and of the competencies is provided. The infrastructure is offered to students mainly as an open structure with only minimal prescriptive elements. The teams can decide autonomously which tools, methods and theories they want to use for making the product. Client's close involvement is the only constraint. Using this structure, students and teams can negotiate a tailored, personal growth. Due to its critical use by students, teams and staff, OTO is growing into a virtual environment of differences in acting.

Figure 1. The structure of the working and learning process in OTO



So the name 'Design Project' refers to several design-aspects associated with this course. Seen from the outside world, students are designing an ICT-product for an external client. Internally, OTO students are defied to design ('to construct') their own learning and working process on an individual level by critical reflection on their competencies, roles and tasks within this course and, as a spin-off, also in their daily work. Team members negotiate their individual goals and (re)design their learning processes at an early stage on a team level in order to come to the best expectancy on learning and working for the team as a whole. Only a high degree of participation of all team members can lead to mutual responsibility for the learning processes. The design process of the students stretches even further to an organizational level. Each team is responsible to attribute to the design of OTO in the form of a team-reflection on what is learned during the course. This leads to knowledge about used methods, practices and experiences and contributes to the learning organization OTO.

Apart from designing their learning process students design their working process according to the requirements and the hectic of the ICT-project at hand. This is a continuous team process, based on the individual competencies and participation. Here students design e.g. procedures for communication, for decision-making and for their division of labour. Designing participation of clients and future users is an important part of this working process.

4. THE IDEAL INTERNAL KNOWLEDGE MANAGEMENT (KM)

OTO develops solutions in dialogue with its customers and creates ict-products like analyses, design proposals, software, prototypes and working procedures. Quality of products and processes depends primary on making acquired insights and knowledge productive for the actual and future projects. OTO wants to perform as a learning organisation. The arrangements in and the structure of OTO should sustain knowledgebased working and learning as pleasant, successful and efficiently as possible. To turn this into reality, OTO needs a knowledge management process together with according roles. This was originally designed as follows. Each team has an internal knowledge manager. These managers are alert on relevant experiences, turn them into 'lessons learned' for future working and learning in OTO on all levels. They are responsible to store this knowledge within the electronic environment and make it accessible for the actual and future teams. It is their task to question periodically OTO-employees about their important experiences. They stimulate discussion and reflection concerning the good and bad practices, which pitfalls appeared and how these latter can be avoided.

Knowledge managers are also responsible for archiving the team documents and making an accessible team archive structure with relevant comments for future use. Although they are finally responsible for ensuring that relevant knowledge and experiences are in an accessible form for renewed consultation or reuse, they do not have to carry out all these activities themselves. All members of the team actively contribute to the permanent KM process.

To guarantee the KM process quality, it is a fixed item in the team leader's two-weekly report to the project manager. Also at the end of the project the internal knowledge manager must, together with the team, write an evaluation report whose emphasis must lie on the following three aspects: working in a virtual space, working with a virtual team, and working for a design task, containing also recommendations for the following teams; lessons learned how the working and learning culture should be changed. The evaluation text will be discussed in a closing meeting of staff and team. The knowledge manager is also responsible for clarifying the electronic working environment in a final state, reusable and accessible for future teams.

5. ENCOUNTERED PROBLEMS IN KM

However in spite of this ideal KM process an evaluation of OTO of the first five teams in OTO shows a serious problem to solve (Oord, 2004). Students experienced an overload of formal information produced by the staff and previous teams on relevant subjects for performing their tasks. This problem will become larger because the growing amount of information will go together with a decrease of accessibility Students need more condensed, accessible and reusable information about working in OTO as well as about specific subjects in their working process. The mere existence of electronic facilities and a well-defined structure for storing team documents was no guarantee that new knowledge is meaningful constructed, is accessible and reused by future teams. Formal KM is done by the students only within their own project horizon and is hardly accessible for future teams and focussed only on the production and not on the transfer and reuse of this knowledge. Successful KM in OTO should become a part of the students' habits. However it depends highly on the acceptance by all OTO members. Making KM ready therefore needs strong participation of all involved.

6. STORYTELLING AS A SOLUTION

The expectation of the OTO-staff was that a participatory design project with the students could guarantee meeting the goal of a KM that can create a "critical transformative room"(Crutzen, 2005). At the beginning of the study period 2004-2005 an iterative design and implementation process for renewing KM was started. The knowledge managers of a number of successive and parallel teams adopted the idea of the OTO-staff for storytelling as a form of KM for virtual work-environments with strongly changing teams.

6.1 Why Storytelling

According to Snowden the key of using storytelling as a disclosure technique is having groups of social cohesive communities who will have a sufficient body of common experience to enable a story base to emerge. The OTO teams are communities of practice and in a collective process of individual competence development. The teams share a common interest and task. They have together a time-bounded experience for good and ill. (Snowden, 2000) The aim of storytelling is telling current and future employees of OTO on experiences, tips, failures and successes in an informal, readable way that could be very close to their own experiences. This kind of information was not explicitly present in the course material but the informal character of stories could be a starting point and a pointer to parts of the formal information produced by OTO.

Storytelling can "engage, involve and inspire" staff and students, "using language that is more authentic and a narrative " and "provides the context in which knowledge arises as well as the knowledge itself, and hence can increase the likelihood of accurate and meaningful knowledge transfer." Stories can "communicate ideas holistically" in an "easy-to-understand form". The emotional component of stories can help students to articulate tacit knowledge and to tell implicit knowledge wrapped up in their own interpretation. Stories are open for reinterpretation and can be connected to the own interest. "Stories are memorable and (...) can provide a 'living, breathing' example of how to do something and why it works". The character of formal information has a more descriptive character. On the other hand stories are more concrete and can lead to direct action - they can help to close the 'knowing-doing gap'. Reading and producing stories is learning in an open transformative and amusing way. Slandering incorporates always the challenge to search for the truth, the lies and all interpretations in-between.[3]

6.2 The Process of Design and Implementation of Storytelling in OTO

At first the knowledge managers of the teams SideFlux and PreMath (2004-2005)[4], have designed a procedure for storytelling which was workable for their own OTO-teams on the basis of the existing situation at OTO. The target group for the design was the actual active employees and also the future employees. The fellow-team members of the knowledge managers have participated in the design process. The knowledge managers, responsible for the introduction of the process of storytelling in their own team, discussed the procedure and the way in which it should be carried out within that team. The result of these efforts was that each team member of SideFlux and PreMath wrote a number of stories, where upon the managers wrote the cover stories to indicate the interrelationships between the stories. These products are transferred to the managers of the teams KryptosLogos, Meta/Z and UseIt[5] (2005-2006). They have refined the procedure and made the functional specifications for an electronic environment that could support the story-telling procedure. On that basis they have searched for a suitable web-based open source application and choose Plone[6]. This choice was particularly based on the feature of redefining a workflow for the story-telling procedure. Also the possibility of commenting already placed stories was an important requirement. In their first prototype they have implemented the agreed workflow and they have shown that the system meets largely the requirements. At present at the start of two new teams the prototype is turned into a more final product, with available stories for these teams and the staff. They can read them, comment them and tell new stories. The commenting is important: future students can make their own interpretations visible and add useful pointers to the formal, general or specific team documents of OTO.

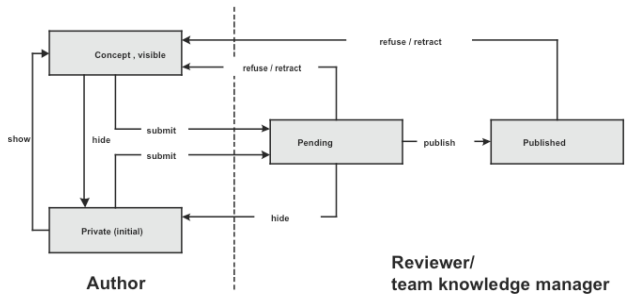
6.3 The Workflow of a Story

In this new system a story is initially created in a strictly personal folder with the state "Private (initial)" (Figure 2). Stories in this state are only accessible by the author: the author can change the content of the story and it's "properties" such as keywords, publication dates, and extended author-information. The author can also determine which other stories (content) are related.

The author can change the story to the state "Visible/concept". The story then is visible to all other users but might be filtered from search-folders, depending on the search-criteria. It stays visible after submitting the story to the reviewer, a role defined by the system but in OTO performed by the knowledge manager. Only if the author chooses for a submission out of the "Private (initial)" then the story is only visible for a reviewer. The contents of stories with status "Published" or "Pending" cannot be changed anymore by the author. In all states it is possible for the author to change the sharing property, important for co-authoring and reviewing. In all states the author can remove the story.

Upon entering the system, the reviewer's attention is drawn to the 'Revision list' where the entries to be reviewed are listed. 'Reviewing' here means changing the contents and the properties of the stories. These options are useful to make the stories 'fit' in the story-hierarchy, by classifying the story by adding or removing content, keywords or links to related content. The reviewer alone is responsible for these actions. Both the author and the reviewer can retract a story from the state "Published".

Figure 2. The state transition diagram of a story



6.4 The Structure of the "Unstructured" Story Base

The stories do not have a predefined structure, and are not restricted to certain subjects. A story is just a piece of free text, sometimes some illustrations are added, and contain meta-information about author, publication-date, state and keywords. Searching in these stories is supported by different techniques:

- Using keywords
  Using keywords is a means to classify stories along more dimensions, for example in time (periods), in working-categories, in activities and so on. This implies that every storyteller and reviewer must add the appropriate keywords to every story. In a two-dimensional classification in relative time and process at least two keywords must be added to every story (Table 1). There is an extended list of keywords, maintained by the reviewers to enable a precise tagging of the stories.
  Classification of stories by means of keywords is visible in the form of 'Related subjects'. While reading a story, a list is presented of other stories that use the same keywords. Jumping back and forth between related stories is easy as long as the used keywords are significant and the list of related stories is not too long.
- Full text searching
  Full text searching is based on all words in the stories. Extended search enables searching on text, title, keywords, publication date, author and status.
- Search folders
  A third technique is the use of search folders whose contents are dynamically determined by a set of criteria. These search folders can e.g. be used to filter stories from certain authors or teams, and/or on certain subjects. The content of these folders is refreshed every time it is accessed.

6.5 The Content of the Story Base

After the engagement of 5 teams the story base is filled with 92 stories. In Table 1 an overview of all the themes are given. In one story on "story telling" a student gave an overview on possible subjects:

- "Our project" (stories which concern your project)
- "Tutorials" (stories with tips and/or best practice concerning a certain subject)
- "Complain & critical department" (basic idea: I find it this way heavy/difficult/not nice/why I must this or that?)
- "Nonsense" (humour, ironic, stupid subjects)

He did also give the advice that stories should not be just the channel for one's frustrations but should be a positive support for future employees. A lot of stories have links to relevant formal knowledge. Mostly individual good and bad experiences in OTO are reported, accompanied with advices. Not all stories are just positive: a lot of critical remarks are made on the concept VC as a learn/work environment for distance education. The most popular themes are "competencies" and "assessment", because that is the part of the learning process that most students are not familiar with. For the working process a lot of stories are related to planning. Students are frustrated that many activities consume more time as planned, especially when the client interactions are not always going very smoothly.

One of the difficult issues for every team is building up a communication structure, students live in the Netherlands and in Belgium and their geographical distance could be up to 400 km. They have to create an effective combination of several means of meeting and contacting in a regular time schedule.

The story base reflects the communication problems. A lot of advices, technical and organisational are given. This kind of stories might prepare future students by helping them to build alternatives and flexibility in their internal and client contacts.

7. CONCLUSIONS

So far story telling was a successful internal project with engaged participation of students and staff. But it can only be called successful if a next generation of students use the story base and add their comments to the stories. The amount and content of the comments will indicate whether story telling is successful for transferring knowledge.

With the process of implementing storytelling and the storytelling process the prerequisites of a constructive learning environment are enhanced because knowledge and skills are best acquired in the context of a real life experience, preserving the

complexities and uncertainties of real life. Storytelling enables team members to be connected over time and allow negotiating the constructed meaning on the VC OTO intensively and differentiated. The stories of the student represent the work they are doing. The students are the persons who are "making the show happen". Their stories and the formal information of the staff "fashions a web of stories" in which the tension of a constructive learning process can be perceived (Boje, 2001, p. 8, 61). The stories express the fragile balance between the prescriptive elements and the variety of free choices in the course "Design project".

10. ACKNOWLEDGMENT

We thank all the team's knowledge managers during the period 2004-2006 for their valuable contributions: Maiko van Dalen, Olaf Haarman, Erik Schouten, Erik-Jan Spaans, Han Opgenoort, Jorgen de Wit, Raymond Waaijer.

Value Creation: The Next Generation of Knowledge Management

C. Vorakulpipat, University of Salford, Salford, Greater Manchester, M5 4WT, UK; E-mail: c.vorakulpipat@pgr.salford.ac.uk
Y. Rezgui, University of Salford, Salford, Greater Manchester, M5 4WT, UK; E-mail: y.rezgui@salford.ac.uk

ABSTRACT

This paper provides a review of value creation literature by adapting and extending KM generations models (Koenig, 2002; Vorakulpipat & Rezgui, 2006). An interpretive stance is adopted so as to provide a holistic understanding and interpretation of organizational KM research and related Knowledge Management Systems (KMS) and models. It is suggested that once organizations promote knowledge sharing (past generation KM) and knowledge creation (present generation KM), it is necessary to create sustained organizational and societal values. Value creation forms the next generation KM and represents key challenges faced by modern organizations. The research shows that value creation is grounded in the appropriate combination of human networks, social capital, intellectual capital, technology assets, and change processes.

INTRODUCTION

A knowledge-based perspective of the organization has emerged in the strategic management literature (Alavi & Leidner, 2001; Nonaka & Takeuchi, 1995). Organizational knowledge is recognized as a key resource and a variety of perspectives suggest that the ability to marshal and deploy knowledge dispersed across the organization is an important source of organizational advantage (Teece, 1998; Tsai & Ghoshal, 1998). Furthermore, it is widely acknowledged that one of the key sustainable advantages that a firm can have comes from what it collectively knows, how efficiently it uses what it knows, and how readily it acquires and uses new knowledge (Davenport & Prusak, 1998). Traditional organizations are beginning to comprehend that knowledge and its inter-organizational management, as well as individual and organizational capability building, are becoming crucial factors for gaining and sustaining competitive advantages (Preiss, Goldman, & Nagel, 1996). The gaining popularity of Knowledge Management (KM) has been reinforced by the quest for innovation and value creation. In this context, KM is perceived as a framework for designing an organization's goals, structures, and processes so that the organization can use what it knows to learn and create value for its customers and community (Choo, 1999).

Different views of knowledge lead to different perspectives of KM: (a) information technology (IT) perspective focusing on the use of various technologies to acquire or store knowledge resources (Borghoff & Pareschi, 1998); (b) socialization perspective focusing on understanding organizational nature (Becerra-Fernandez & Sabherwal, 2001; Gold, Malhotra, & Segars, 2001); and (c) information system (IS) perspective focusing on both IT and organizational capability perspectives and emphasizing the use of knowledge management systems (KMS) (Schultze & Leidner, 2002; Tiwana, 2000). The latter perspective forms the focus of the present paper.

The scope and definition of KM has evolved over the years. At present, it is argued that there are three generations of KM (Vorakulpipat & Rezgui, 2006). The first generation takes into account knowledge sharing or "supply-side KM" focusing on IT-driven KM (Koenig, 2002; McElroy, 1999). The second generation emphasizes knowledge creation or "demand-side KM" (McElroy, 1999). The third generation (or next generation) emphasizes value creation (Vorakulpipat & Rezgui, 2006).

The aim of the paper is to provide a review of value creation from a knowledge management perspective by adapting and extending McElroy's (1999) and Vorakulpipat and Rezgui's (2006) KM generation models. The paper, first, provides a general description of knowledge management systems (KMS). Then, presents an introduction of past and present generations of KM: knowledge sharing and knowledge creation, followed by a review of value creation presented as the next generation KM. The final section provides a conclusion with a summary of key findings from the review.

KNOWLEDGE MANAGEMENT SYSTEMS

Knowledge management systems (KMS) refer to a class of information systems applied to managing organizational knowledge (Alavi & Leidner, 2001). That is, they are IT-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application. Many KM initiatives rely on IT as an important enabler, and tend for some of them to overlook the socio-cultural aspects that underpin knowledge management (Davenport & Prusak, 1998; Malhotra, 1999).

Reviewing the literature discussing applications of IT to organizational knowledge management initiatives reveals three common applications (Alavi & Leidner, 2001): (a) the coding and sharing of best practices, (b) the creation of corporate knowledge directories, and (c) the creation of knowledge networks. One of the most common applications is internal benchmarking with the aim of transferring internal best practices (O'Dell & Grayson, 1998).

While KMS tend to follow the normative trend (Schultze & Leidner, 2002), the interpretive approach is best reflected in environments supporting the development of communities of practice (CoP) (Wenger, McDermott, & Snyder, 2002). The success of these individually led initiatives has gradually attracted interest from both the research community and corporate senior management staff within and outside these organizations. They relate more generally to groups of individuals within or across organizational boundaries that share a common concern, a set of problems, or a passion about a topic, and who deepen their understanding and knowledge of this area by interacting using face-to-face or virtual means (synchronous and asynchronous) on a continuous basis (Wenger, McDermott, & Snyder, 2002). The gaining popularity of Communities of Practice has been reinforced by the quest for innovation and value creation as it is widely recognized that these only happen when empowered individuals are well connected using a variety of means and communication mediums both inside and outside the organization.

KNOWLEDGE SHARING AND KNOWLEDGE CREATION: THE PAST AND PRESENT GENERATIONS OF KNOWLEDGE MANAGEMENT

The scope and definition of KM has evolved over the years. The authors argue that the research community has moved from knowledge sharing to knowledge creation challenges. The latter is perceived as the present generation of KM (McElroy, 1999; Vorakulpipat & Rezgui, 2006).

Knowledge Sharing

Information technology (IT) has played an important role for over decades. Many organizations have focused on information dissemination for effective decision support enabled by IT. Hence, the first stage of KM has a strong IT focus (Koenig, 2002). There was a strong belief that the use of IT, in particular the Internet, intranet, and tools for knowledge sharing and transfer has the potential to create added value to the enterprise. Furthermore, this stage has seen the development of solutions to capture and share "best practices" and "lessons learned". In this context, McElroy (1999) identifies knowledge sharing as "supply-side KM" and "It's all about capturing, codifying, and sharing valuable knowledge, and getting the right information to the right people at the right time".

Knowledge Creation

Once knowledge is shared, it is essential that this promotes creation of new knowledge. However, knowledge creation is nurtured through a supportive social environment. Hence, knowledge creation focuses on socialization issues (rather than technology issues), including human and cultural factors. This points to (a) the importance of organization learning, (b) knowledge creation adapted from the SECI model (Nonaka & Takeuchi, 1995) with an emphasis on tacit/explicit knowledge conversion, and (c) Communities of Practice. McElroy (1999) identifies knowledge creation as "demand-side KM".

Several authors (Koenig, 2002; Snowden, 2002) have explored and proposed what would form the next KM generation. For example, Koenig (2002) argues that next generation KM will pay attention to taxonomy development and content management. However, Firestone and McElroy (2003) argue that these technologies already exist. The present paper adopts and extends McElroy's (1999) and Vorakulpipat and Rezgui's (2006) generations of KM to propose a new generation: Value Creation. The following sections provide a review of value creation.

VALUE CREATION: THE NEXT GENERATION OF KNOWLEDGE MANAGEMENT

The relationship between value creation and KM has been argued by several scholars (Chase, 1997; Despres & Chauvel, 1999; Gebert, Geib, Kolbe, & Brenner, 2003; Liebowitz & Suen, 2000). Moreover, Despres and Chauvel (1999) suggest that knowledge can be described as a source of value creation. Liebowitz and Suen (2000) include value creation into KM metrics for measuring intellectual capital. In terms of organization processes, Gebert et al. (2003) suggest that knowledge management processes have inherent value creation capabilities. From a more pragmatic perspective, Løwendahl et al. (2001) propose a framework for the analysis of value and knowledge creation in professional service firms (PSFs). Knowledge creation in PSFs is identified as a knowledge-intensive dynamic activity, delivered by highly educated employees who are closely linked with research and scientific development. The framework integrates the relationship between the domain choice and the knowledge base and argues that the bridge between the two is best explained as value creation processes (VCPs) with two interrelated dimensions: direct and indirect value creation for the clients. This confirms the increasing interests in value creation from a knowledge management perspective.

Value creation is gradually being established as the next generation of KM (Vorakulpipat & Rezgui, 2006). Therefore, once knowledge is created, it is necessary to study the impact on people in terms of value (Vorakulpipat & Rezgui, 2006). Five major factors toward value creation emerge from the literature: (a) human networks, (b) social capital, (c) intellectual capital (d) technology assets, and (e) change processes.

Human Networks

Allen (2003) suggests that organizational learning should be dynamic and that intangible assets and social prosperity are anticipated to create major impacts on KM. For example, the concept of Community of Practice (CoP) (Wenger, McDermott, & Snyder, 2002) is introduced as an effective social activity to share tacit knowledge in Xerox. This had the effect of promoting human networks and motivating people to share and create knowledge.

Intangible assets have the potential to create more value than tangible or physical assets. Three factors of intangibles, consisting of human capital, external capital, and structure capital, are expected to generate future benefits and create sustained organizational and societal values (Allen, 2003; Blair & Wallman, 2001). These also include business relationships, internal structure, human competence, social citizenship, environment health, and corporate identity (Allen, 1999). Once created, intangible and tangible value are included as a part of value networks for creating relationships between people, groups, or organizations.

Human capital can improve value creation in several ways. For example, formal and informal communication using face-to-face (including scheduled meetings) and virtual (synchronous/asynchronous) means (e.g. telephone and e-mail) are perceived as effective to promote knowledge sharing and creation. Whittaker, Frohlich et al. (1994) show a preference for informal communications (e.g. unscheduled meetings or any face-to-face interactions). Early face-to-face meetings in team work tend to improve the team's project definition (Ramesh & Dennis, 2002), and to enhance the effectiveness of subsequent electronic communications (Powell & Dent-Micallef, 1999). Therefore, lack of human networks or communication is identified as a problem that may lead to the ineffectiveness of teamwork (Pynadath & Tambe, 2002) and may hinder any knowledge sharing and creation activity.

Social Capital

The concept of social capital has recently been researched in the context of KM (E. Lesser & Prusak, 1999; E. L. Lesser, 2000; Nahapiet & Ghoshal, 1998). The idea of social capital – physical capital, financial capital, and human capital – can be applied to create value-added for firms. Because of its emphasis on collectivism and co-operation rather than individualism, distributed community members will be more inclined to connect and use electronic networks when they are motivated to share knowledge (Huysman & Wulf, 2006). In terms of socio-technical design, KM tools to support social capital are aimed to bridge various social communities. The tools may foster social capital by offering virtual spaces for interaction, providing the context and history of interaction, and offering a motivational element (e.g. score) to encourage people to share knowledge with each other (Huysman & Wulf, 2006). Tsai and Ghoshal's research reveals an association between social capital and firms' value creation (Tsai & Ghoshal, 1998). This relationship is supported by related research (Nahapiet & Ghoshal, 1998). Moreover, in terms of organizational structure, social capital helps people develop trust, respect, and understanding of others, especially in the context of a strong organizational bureaucratic culture. This contributes indirectly to value creation.

Intellectual Capital

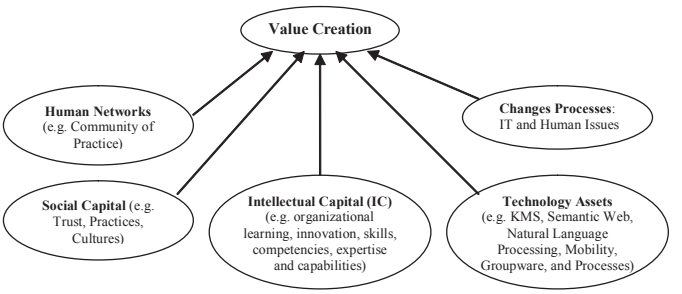
Intellectual capital (IC) has enjoyed a very rapid diffusion over recent years and is also a growing area of interest in KM. It encompasses organizational learning, innovation, skills, competencies, expertise and capabilities (Rastogi, 2000). Liebowitz and Suen (2000) exhibit that value creation is used as a KM metric for measuring intellectual capital. The value creation metric includes training, R&D investment, employee satisfaction, relationships development, etc. Nonaka et al. (2000) suggest that learning by doing can embody explicit knowledge into tacit knowledge through Internalization in the SECI process. Also, training programs can help trainees understand themselves, and reading documents or manuals can internalize the explicit knowledge written in such documents to enrich their tacit knowledge base. Adapted training can foster cohesiveness, trust, teamwork, individual satisfaction, and higher perceived decision quality, as highlighted in the literature (Tan, Wei, Huang, & Ng, 2000; Van Ryssen & Hayes Godar, 2000; Warkentin & Beranek, 1999). In addition, IPR and confidentiality issues should not be overlooked as Denning (1999) suggests that external knowledge sharing poses greater risks than internal sharing as they raise complex issues of confidentiality, copyright, and in the case of the private sector, the protection of proprietary assets. Overall, an interdependent convergence of intellectual assets and collaboration capabilities, underpinned by the use of collaboration technology, and KM activities is suggested to increase the potential of an organization to create value (Qureshi, Briggs, & Hlupic, 2006).

Technology Assets

Managing and enhancing the organizational processes of knowledge creation, storage/retrieval, transfer, and application have relied on the wide use of Knowledge Management Systems (KMS). This suggests that technology, including KMS, is an essential ingredient to sustain value creation. Applications of IT to organizational knowledge management initiatives has focused on three common applications (Alavi & Leidner, 2001): (a) the coding and sharing of best practices, (b) the creation of corporate knowledge directories, and (c) the creation of knowledge networks. While KMS initiatives rely on IT as an important enabler, they tend to overlook the socio-cultural aspects that underpin knowledge management (Davenport & Prusak, 1998; Huysman & Wulf, 2006; Malhotra, 1999; O'Dell & Grayson, 1998).

Moreover, the future KM can be envisioned as (a) the emphasis on the design of KM technology to fit organization culture; (b) the ability to embed KM technology in natural surroundings, and be able to retrieve knowledge whenever and wherever it is needed; and (c) the simple and effortless use of technology to create interaction (VISION, 2003). Semantic web, natural language processing, mobility, virtual collaborative workspaces are the important facets for future KM (VISION, 2003). Next generation KM will also be impacted and shaped by changes in IT

Figure 1. Value creation



and artificial intelligence development, and by the changes expected in people-centric practices to support innovative works (Wiig, 1999).

Change Processes

In this context, change management plays an increasingly important role in sustaining "leading edge" competitiveness for organizations in times of rapid change and increased competition (McAdam & Galloway, 2005). The future has only two predictable features – 'change and resistance to change' and the very survival of organizations will depend upon their ability not only to adapt to, but also to master these challenges.

Organizational change can be divided into two issues: IT and human issues. In terms of human issues, adapting organizational policies to motivate employees to share and create knowledge by providing monetary reward or recognition is suggested, as confirmed by Rus, Lindvall et al. (2002). On the other hand, technology adoption in organizations should not be overlooked. Technology Adoption Model (TAM) (Davis, 1989) proposes that perceived usefulness and perceived ease of use influence the use of information systems innovations and that this effect is mediated through behavioral intentions to use. Christiansson (2003) also agrees that study of the change process is necessary to create the requisite organizational and societal values. A KM maturity roadmap is an important milestone to enable organizations to assess the effectiveness of their KM implementations in the future.

A true value creation culture can be found through the appropriate combination of human networks, social capital, intellectual capital, technology assets, and change processes (Figure 1) where issues such as learning and trust must be blended successfully towards the vision of knowledge-enabled value creation.

CONCLUSION

The paper has presented a discussion of KM, generations of KM (knowledge sharing and knowledge creation, and value creation) based on a review and synthesis of a broad range of relevant literature. The definition of KM has evolved over the years. The paper defined knowledge sharing as the past generation KM, knowledge creation as the current generation KM, and value creation as the future generation KM. Value creation focuses on the organizational and societal impact of knowledge management. Human network, social capital, intellectual capital, technology assets, and change processes emerge as essential conditions to enable value creation. Focusing on social capital, the paper refers to collective capabilities derived from social networks. The higher the level of social capital, the more distributed communities are stimulated to connect and share knowledge (Huysman & Wulf, 2006). In terms of technology, members of communities will be more inclined to use adapted KMS when they are motivated to share knowledge with others. KMS that embed social awareness can play an important role in addressing these requirements, promote social capital in fragmented and distributed networks, and enable KM initiatives in an organization. However, the organization's ability to effectively use, acquire, share, apply and create knowledge is more important and should not be overlooked.

KM has major implications in the learning capability of an organization and its ability to adapt to an ever changing and competitive environment. Therefore, migration from knowledge sharing to knowledge creation and from knowledge creation to value creation is necessary although it may be difficult to negotiate and achieve. The authors are currently working on a KM capability and maturity framework that will facilitate these transitions, and an empirical research on value creation capabilities in a KM perspective.

Clearly, it is important for researchers conducting KM-related research to understand the various factors that affect value-added KM. The authors hope that the present review will contribute to the ongoing debate on KM and its future evolution.

Corporate Social Responsibility in the Dynamic Information Age of Inter-Systems Connectivity

Arvind Ashta, CEREN, Burgundy School of Business (Groupe ESC Dijon-Bourgogne), 29 rue Sambin, 21000 Dijon, France; E-mail: aashta@escdijon.com

ABSTRACT

The Information age has caused an explosion of information through rapidly changing technologies. This technological change is accompanied by an accelerating shift in work relations, of which this paper focuses on connectivity, interdependence and dynamism. Along with this change in relations, new ethical cultures are evolving at different levels: individual, corporate, governmental, NGO and global. This paper then focuses on the work done in the Corporate Social Responsibility field to see how it has evolved to adapt to the new mode of inter-dependent connectivity in a dynamic environment of changing relationships.

Keywords: Corporate Social Responsibility, Information Age, connectivity, inter-dependent systems, economic relations

CORPORATE SOCIAL RESPONSIBILITY IN THE DYNAMIC INFORMATION AGE OF INTER-SYSTEMS CONNECTIVITY

With the wide diffusion of information on the internet, consumerist and environmental movements have become more powerful, as they are able to play on the trust that the brand is supposed to provide (Clarke, 2003). Their role has been to focus on fairness in corporate practices: those who violated expected norms of fairness would get punished (Kahneman et al, 1986 a & b). This paper seeks to take into account additional features of the information age: connectivity, dynamism and inter-system dependence and see how these have influenced the concept of corporate social responsibility. Part I describes the Information Age and explains how different concepts of Social responsibility relate to the new economic relations created by this Age; where possible the examples are limited to Information Technology (IT), even though in the information age all industries are affected by IT. Part II zooms in on the evolution of some of the different concepts and theories in the Corporate Social Responsibility (CSR) area before and after the era of connectivity and tries to show how theory has evolved and the debate has shifted to take into consideration the connectivity and inter-dependence questions.

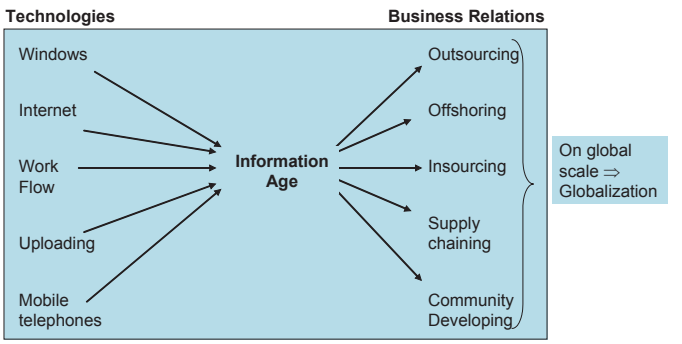
I. INFORMATION AGE OF INTER-DEPENDENT CONNECTIVITY AND SOCIAL RESPONSIBILITY

A. Interdependent Conncetiviy and Information Needs

The information age is characterised by new technologies, which have led to globalization (Friedman, 2006). Some salient new technologies include windows, internet, workflow software, uploading and mobile telephones. The combination of these technologies has resulted in an accelerated shift to new work relations such as outsourcing, offshoring, insourcing, supply chaining and community developing (see Figure 1).

The key words in these new work relations are connectivity and collaborating. These collaborative forms replace hierarchical modes and the balance of countervailing power is continuously changing. It may be IBM today, Intel tomorrow, and Microsoft the next day, and so on... Thus, it is not only connectivity and collaborating but dynamic connectivity and collaborating. This is not to say that there are no issues of countervailing power on any given day. Within the information field, somebody will decide which information technology to use, who has authorization to upload or download, etc. However, neither the relationships nor the technologies are frozen.

Figure 1. Information age: Technological causes and business outcomes



In the prior vertical hierarchical mode, a person owed responsibilities to his superior in terms of accountability and to his subordinates in terms of caring and protection. Now, in this new horizontal collaborationist mode, the stakeholder becomes all-important. This is a two-way stakeholder relationship among equals (or more equal than before). The supplier needs the customer and the customer needs the supplier but they are both looking for better and more profitable relationships (leapfrogging) as well as trying to embed the existing relationship. A key element in these relationships therefore is the tension created by this conflict between trust and abandonment. Trust is required to ensure that gains would be equitably distributed across the supply chain and that everyone involved survives, at least while the relationship is ongoing. This trust requires new institutional arrangements. If the connections and collaborations are global, the institutional arrangements also need to be global.

One of the key elements required to ensure continuity of trust is the ability to control the stakeholder, and to obtain pertinent information. In the old hierarchical framework, the trust was obtained by the provision of information. The shareholders were provided annual accounting reports, the employees were asked to provide weekly or daily performance reports.

In the new horizontal mode (see figure 2), the information cannot come from authority: it has to come from sharing. Since the stakeholders are interdependent, they may need to pool their information to be able to control each other. However, all information flow is asymmetric leading to joint problems of adverse selection (who is going to be my partner among the whole lot of Indians in the field) and moral hazard (what if he takes the advance and does not deliver). What complicates things further is that in this information age, every person connected to the internet is a stakeholder in the connectivity itself. He can thus create or destroy relationships and even the internet (virus attacks, see Holzinger, 2000 for examples). He can also use the rapid speed of communications to launch speculative attacks on currencies. Terrorists can also use a global supply chain to manufacture bombs. Thus, each person or stakeholder in this network has information about his intentions, which no one else may have. This asymmetric information problem could be solved if there are guaranteeing institutions (governments, rating agencies). These institutions again require information dissemination to be able to exercise

Figure 2. Information needs in an information age of connectivity

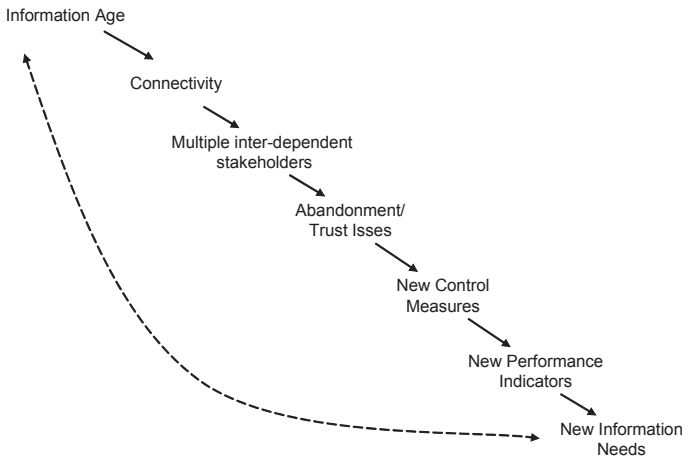


Figure 3. The corporate centric vision relationships of social responsibility between actors

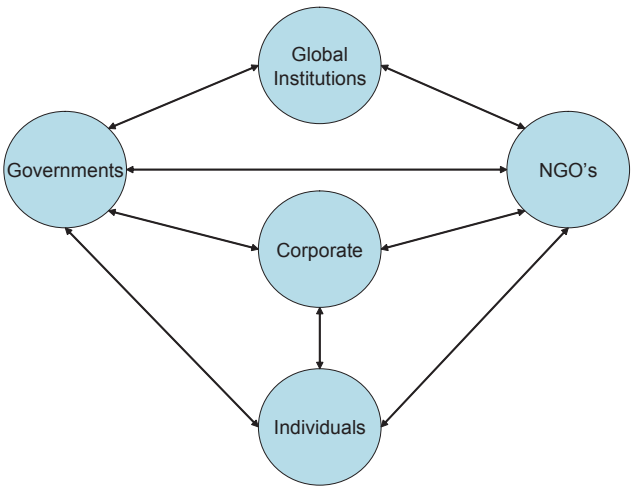


their function. What kind of information is pertinent to control in this new information age of dynamic connectivity would be a central question for research. However, the information needs would themselves modify the information age as new technologies are developed to provide this information.

Information needs depend on performance indicators required. These performance indicators need to respond to the critical success factors that need to be controlled. In an old-world economy, profits may have been enough (Friedman, 1970). However, in the information age, where many pressure groups can widely disseminate information, a corporation now has to meet many other ethical, social and environmental criteria. The information needs therefore also depend upon the (social) responsibilities of different actors.

B. Social Responsibilities in the Age of Inter-Dependent Connectivity

There are a multitude of actors involved: individuals, corporations, governments, non-governmental organisations (NGOs), and global institutions such as the World Trade Organization, World Bank, etc, and the information age has modified all their responsibilities. Figure 3 indicates the relationships between these actors: the two-way arrows suggest that each influences the others. Firms and their corporate responsibilities play a central role because they have the economic power to back whatever role they wish to play. The other actors, notably the governments and NGO's but also individuals as employees or customers try to influence this role. The payments of firms to these actors (taxes, donations, bonus, discounts) allow them to nuance the policies of the other actors. Global institutions usually act through governments or NGO's since they would not be able to afford constant interaction with millions of firms or billions of individuals.

For individuals, the survival of the system requires efficiency, equity as well as environmental protection. Efficiency requires a responsibility to continuing education and keeping oneself informed of all relevant changes in technology. Equity requires a responsibility to respect intellectual property of others' websites and to create inter-dependencies by educating others so that they can use the individual's abilities. These inter-dependencies are acutely highlighted in value-based networks (Wheeler, Volbert & Freeman, 2003) such as e-Bay, IBM, HP and Cisco. Environmental protection requires, for example, not overloading the system by spamming and limiting the use of printers.

At the corporate level, the Social Responsibilities of the information age could require helping staff evolve so that they can keep their jobs in a dynamic environment, outsourcing and downsizing if this will help survival and create growth elsewhere, and adding diversity to add value. Hoekstra (2003) indicates that the IT outsourcing to India has reduced the brain drain from that country since IT skilled people can earn as much sitting in their own cultural milieu. CSR also requires providing transparent reliable information to the network partners, based on reality and not hope (Hoekstra, 2003). If one plans a 30% growth, all other partners prepare for it. If this growth is far off the mark, it creates problems for all. Failure of one major actor could drown thousands of collaborators, as evidenced by Enron. This includes failure of an actor owing to war in one country. The global consequences of war in any member country of a global supply chain have resulted in corporations reminding the concerned governments of the global economic costs of war (Fort & Schipani, 2002; Friedman, 2006). Both mention that the Indian IT industry exerted diplomatic pressure on the US and Indian governments to avoid an India-Pakistan war in 2002, mentioning clearly that India's presence in the global supply chain could create economic disruptions and costs well beyond India's borders. The Indian IT industry did this fearing that their customers would go elsewhere if there were a political risk in doing business within India. Thus the CSR in the age of connectivity goes much further than the internal security risk of virus attacks and robbing banks expressed by Holzinger, 2000.

Fort and Schipani (2002) find that the global corporation has power over the developing States because they pay local taxes and provide jobs, education, skills and transfer of technology. Therefore, they argue that a firm's Social Responsibility includes leveraging these to support the establishment of democratic regimes wherever they do business and, to set a model, establishing democratic regimes in its own internal governance structure. In this line, Hoekstra (2003) indicates that IT industries have invariably transported stakeholder-sharing concepts, such as stock options and performance incentives to reward employees and partners, to developing countries in advance of other industries. Fort and Schipani (2002) also add that the corporation should structure itself in a way that develops small communities working together with face-to-face interaction and consensual decision-making, with should lead to sustainable peace.

Government Social Responsibilities may mean providing continuing education, disseminating information on new technologies, making infrastructure such as bandwidth accessible to all, and promoting environmental safeguards from virus attacks as well as military attacks (Friedman, 2006). Government responsibility would also include creating new legal institutions to adapt to the new economic relations, such as intellectual property right protection for software and intangible music and books, which help add to the trust necessary to collaborate, as well as transparency and disclosure requirements from corporations. The latter is especially important in an information age to limit losses from asymmetric information, and thus permit collaboration between distant stakeholders (Fort and Schipani, 2002).

NGOs play a role as pressure groups to impose ethical guidelines, stimulate voluntary codes of conduct and warn away terrorists: for example, the existence of associations like ATTAC (advocating a Tobin Tax) may deter financial speculators. These NGOs use information technology to disseminate information and they would not be such powerful stakeholders without this tool (Waddock, 2005). NGOs also serve as venues for discussions of issues of citizenship between the spreading forces of corporate globalization and the pressing desires for individuality (Fort & Schipani, 2002).

Figure 4. Should business be invested with social responsibility?

Arguments for Corporate Social Responsibility	Arguments Against Corporate Social Responsibility
Long-run self interest	Profit Maximization
Public Image	Costs of Social Involvement
Viability of Business	Lack of Social Skills
Avoidance of government regulation	Dilution of Business's Primary Purpose
Sociocultural Norms	Weakened International Balance of Payments
Stockholder interest	Business has enough power
Let Business Try	Lack of Accountability
Business has the resources	Lack of Broad Support
Problems can become profits	CSR idea is grounded on economics, and ignores history, religion, culture, etc.
Prevention in better than curing	CSR idea is based on fixing capitalism's woes: this is too conservative
	CSR idea separate's business ethics from society's ethics
	CSR idea is based on limited rights and responsiblities

Extracted from Davis (1973) and Freeman & Liedtka (1991)

The Global institutions have the primary responsibility to ensure harmonization of essential business laws so that the necessary infrastructure for trading across nations is created. They also have the responsibility of deciding what the global CSRs are. For the moment, a voluntary set of principles, such as UN Global Compact and Global Reporting Initiatives, have been initiated. However, voluntary efforts lack the stamp of legitimacy. At the same time, there are now a number of agencies which rate CSR of the world's leading firms. These include, for example, Accountability, FTSE-4good, Business in The Community, Dow Jones Sustainability Index, Business Ethics 100 (Hopkins, 2005) and Vigeo. However, none of these considers whether the firm takes into account the dynamic nature of supply chain relationships in the IT world and the responsibilities of firms to each other.

Having discussed the evolution of the new information age and seen how it has affected the social responsibility of different actors, the next section sees how the theoretical discussion of the concept of CSR has evolved to take into account the new needs of dynamic interconnectivity.

II THE EVOLUTION OF CORPORATE SOCIAL RESPONSIBILITY IN A CONNECTIVITY MODE

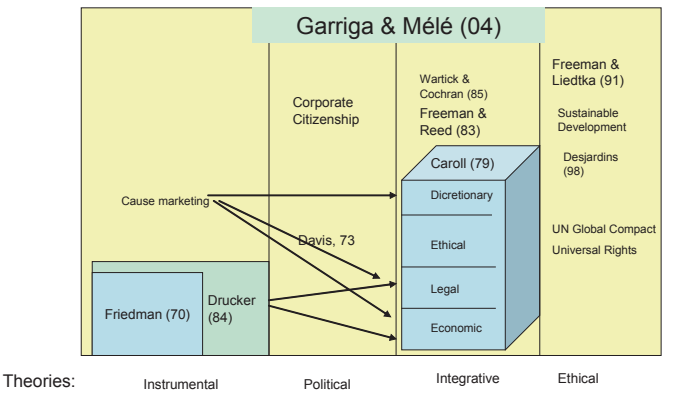
A. Evolution of the CSR Concept

There is a debate on what CSR is. There are so many theories that there are now papers classifying the theories (Carroll, 1979; Garriga & Mélé, 2004) and we will just look at a few of these. The basic minimum in terms of CSR was set by Nobel laureate Milton Friedman (1970) for whom the only responsibility of business is to use its resources to increase profits while conforming to laws. All other responsibilities are for the government to deal with. Otherwise, there is an agency problem between a manager's desire to instil his views of what is good for society by using corporate funds. This is tantamount to imposing an illegitimate tax on the corporation. At the other extreme are people who lobby for increased corporate philanthropy (Brammer and Millington, 2003 study the evolution of charitable contributions in the UK). Between corporate philanthropy and Milton Friedman's "only profit" goals, there is Drucker's (1984) definition of CSR: « to turn a social problem into economic opportunity and economic benefit, into productive capacity, into human competence, into well paid jobs, and into wealth». While Friedman (1970) left these problems to governments, Drucker (1984) explained that government is not in a position to solve the problems because in any action it takes, it creates vested interests that keep it from realizing the option value of abandoning a course of action. Therefore, governments cannot experiment. Thus, he felt that NGOs would need to step in as they at least have competition between themselves. In most cases, the responsibility of corporations is to ensure that there is enough capital formation for their own survival. Additionally, companies may have certain capabilities and strengths which may make them more suitable to serve the community (Hoekstra; 2003). This is fortunate in a world where the increase in information has led to harmful tax competition, reducing the government's ability to provide services, thus renewing the call for Corporate Citizenship to mend society's broken contracts (Waddock, 2005).

Davis (1973) resumes the reasons for and against social responsibilities of business, as summarised in figure 4, and suggests that a trade-off needs to be established. Many authors (Purcell et al, 1974; Carroll, 1979) feel that CSR means going beyond the legal minimum advocated by Friedman (1970), with a point to combining profitable activity with meeting the common good. Carroll (1979) summarises the different positions of different authors and concludes that there is a hierarchy (not mutually exclusive) between meeting economic responsibilities, meeting legal responsibilities, meeting ethical responsibilities and finally discretionary responsibilities (which would include philanthropy). This hierarchy can be for different social issues such as consumerism, environment, occupational safety etc. He adds a third dimension by suggesting that enterprises have different response mechanisms such as reaction, defence, accommodation and proaction. Wartick and Cochran (1985) indicate how the Carroll (1979) model incorporates the challenges to CSR such as economic responsibility, public responsibility and social responsiveness. More recently, we have seen how CSR has been developed in cause marketing to marry promotional appeals with philanthropic giving (Smith & Alcorn, 1991) in order to attract customers for the firm (Irwin et al, 2003), thus creating connectivity between corporations and NGOs. This is a manifestation of the enlightened self-interest argument (Purcell et all, 1977; Besser, 1999): business benefits indirectly from socially responsible behaviour, for example from higher employee motivation and better reputation. Brammer and Millington (2003) indicate that charitable contributions may also result from a need to influence stakeholders. Negative reasons within this framework would include firms resorting to social responsibility for fear of punishment by consumers if they did not follow fairness standards (Kahneman et al 1986a and1986b; Campbell, 1999). Desjardins (1998) argues that economic growth meets the economic and legal minima concepts but it also causes environmental degradation that would ultimately cause the business to be non-sustainable. Thus, there is a need for a business to look at its responsibility not only to the whole social body of stakeholders but also to the physical environment in which it is operating. While environmental waste has been discussed at lengths, the information waste discussion should go on similar lines. So far, we are not aware of the health hazards to the environment by storing so much information on line. However, the duplication and waste does cause psychological fatigue for researchers who come up with many pages providing the same information, and are led to the paradox of choice: when more is less (Schwartz, 2004). More recently, Garriga and Mélé (2004) have classified CSR theories into instrumental, political, integrative and ethical theories. For example, Friedman's "economic and legal minimum" view is an instrumental theory, Davis (1973) is representative of a political theory, Carroll's (1979) Corporate Social Performance model is an integrative theory and Freeman's Stakeholder approach is an ethical theory. Figure 5 attempts to put some of these theories in Carroll's perspective which itself is within the perspective of Garriga & Mélé (2004).

Thus, the debate on the role of CSR and related concepts has moved in recent years to try to capture the changing economic and social relations caused by in-

Figure 5. Mapping the theories



ter-dependent connectivity, as can be seen by the addition of stakeholder theory to the CSR phenomena.

B. How Inter-Dependent Connectivity has impacted the CSR Concept

Within the CSR discussion, different authors have included connectivity from different perspectives in their models. Some of these are presented here to the extent they are required to bring out this paper's perspective, and are illustrated in Figure 6.

The starting point to such an interconnected view comes from the Stakeholder approach (Freeman & Reed, 1983) which views the interests of all stakeholders (employees, customers, suppliers, governments; consumer groups, NGOs) as important and not just the shareholders. Thus, the enterprise owed a responsibility to all the people with which it was connected, internally and externally. The focus is on the enterprise.

Within this framework, a narrow view is that of Holzinger (2000) who looks at information security leaks and fixes a minimal social responsibility of business to its partners (customers, suppliers) to have good internal governance procedures to protect against hackers. This social responsibility could be reinforced by pressure groups such as insurance companies and governments. We note that in this view, we see shades of Friedman (1970) and this could be considered as a corresponding minimalist CSR view in the age of inter-dependent connectivity.

Inspite of the continuing linking of the Stakeholder concept to CSR, Freeman & Liedtka (1991) insist that the "CSR" concept is not a good one. Their reasons overlap some of the reasons given by Davis (1973) and the others are incorporated in Figure 4. They suggest that Corporations be viewed as connected networks of stakeholder interests. In this network, human beings and communities aim for mutual support and unparalleled achievement. They would like to see corporations as the means by which human beings create their visions for self and community. From this work, the paper takes the focus on the individual human being. Therefore, in figure 6, we've added shapes for the stakeholders and shown interconnected people within the company.

More specifically to the Interconnectivity question, Wheeler, Colbert and Freeman (2003) look at CSR in a network world. After explaining Value-Based Networks and the importance of CSR (specifically ensuring that all stakeholders benefit and corporate philanthropy) in information technology companies using networks, they use a three level pyramid to classify corporate cultures from doing minimum harm to doing maximum good: Compliance Culture, Relationship Management Culture and Sustainable Organization Culture. These require, respectively, a close watch over societal needs and societal frameworks, ensuring all stakeholders are obtaining value in the short term, and that this is sustainable over time. Thus, figure 6 adds that the stakeholders also get some focus (and are shaded).

An associated stream dealing with Value Added Communities was "MetaCapitalism" started by Means and Schneider (2000). These authors predicted a radical transformation of the corporate world into scarcely capitalised, brand focussed, highly flexible, customer oriented firms engaged in on-line exchanges or networks, driven by the new information technology. This paper therefore assumes an expectation for business corporations to atomize with time. (In figure 6, this is manifested by the smaller corporation size).

The last viewpoint presented here to develop this paper's perspective is the Inter-Systems Model of business proposed by Stormer (2003), in which the business cannot be taken as an independent system, but as a network of communities operating within the firm and the firm as an interdependent actor in a larger system. Thus, there is a need to analyse how changes in one part of the larger system can affect the corporation and vice versa. This viewpoint allows transcending the stakeholder theory (Freeman & Reed, 1983) where the central focus remains on the corporation in which all the stakeholders are interested. In the Inter-Systems model, each stakeholder becomes a separate system, and thus equally important. Stormer (2003) concludes that strategy becomes more complex because of the interdependence of the systems with which the firm is attached. (In figure 6, all the stakeholders are linked to each other with double-sided arrows).

Putting together what we have extracted from the above literature we can say that pushed to its limit, each inter-dependent stakeholder becomes an individual. Thus, the connectivity between individuals and their connected clusters (termed firms or governments, or NGO's) and the connectivity between clusters becomes focused on the needs of the individuals, all of whom are equally important. In all these recent evolutions, therefore, one thing seems to be clear: the importance of the individual seems to be expanding and that of the corporation seems to be reducing. Thus, the focus is on what the individual is able to do. Hence, the rights and responsibilities are those centred on individuals as indicated in Figure 7 and not those centred on organizational types (corporate, government, NGO or global), as depicted earlier in Figure 3.

However, Mickhail and Ostrovsky (2005) looked at the MetaCapitalism prophesy outlined above. They find little connection between the predicted outsourcing and the predicted boom in share prices. They offer various reasons for this including inability in a changing world to distinguish between core and non-core; inability to extract maximum from employees and stakeholders if relationships are perceived as short-term; the need for companies to retain facilities to retain flexibility; the inherent conflict of interest for sharing the cake that sets a limit to the model; dominant firms continue to control smaller firms and thus extract economic rent from their size and also determine the conditions necessary for entry into the VAC. Thus, reality requires viewing the IT as a continuum of unequal partners, competing and collaborating with each other at the same time.

Another view is a naturological view of the corporate community relationships and the extended skew selection theory proposed by Hill and Cassill (2004). In this view, the corporation is inter-dependent with its community, taking resources and energy from it and giving back goods, services and philanthropy. The sustainability

Figure 6. New approaches to take into account interconnectivity

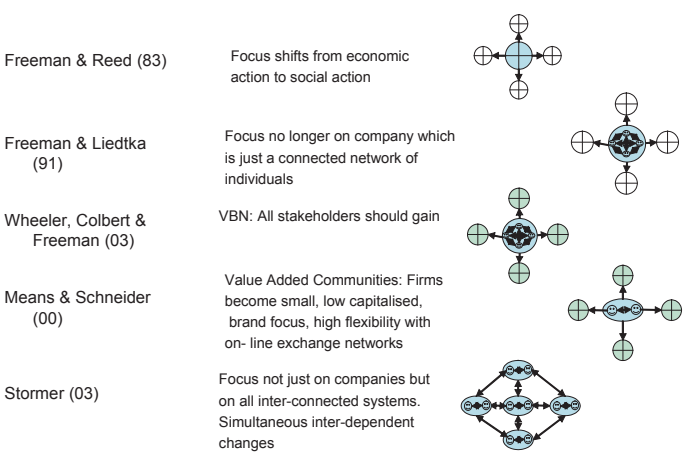


Figure 7. The person-centric vision relationships of social responsibility between actors

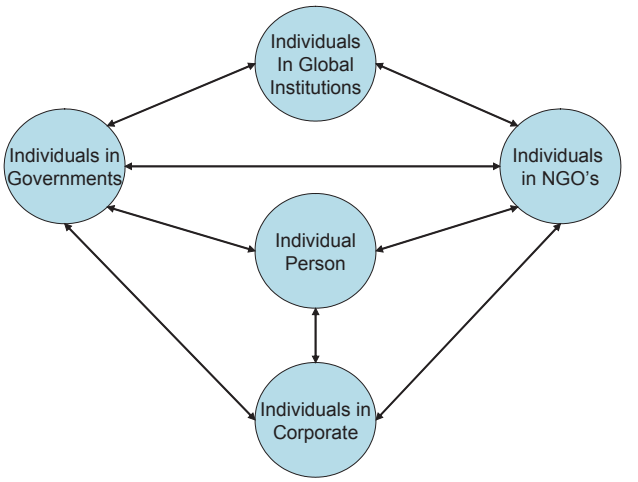

of an actor (the corporation) depends on its ability to produce income and capital in oscillating good times and bad, and in its ability to share it with its community to ensure the survival of the community. Without the community, the corporation cannot survive. Thus, the corporation would like to be larger and more powerful, but it also recognizes the biological viewpoint of safety in numbers. Thus, it needs to share part of its wealth with its community. Thus sharing offsets greed to some extent. Hill and Cassill (2004) state "Sharing a finite proportion of resources with others can help quell the impulse of advocacy firms, government agencies, and the judicial system to take a corporation's resources by force".

Thus, this set of authors would nuance our propos: we can see that neither the corporate centric view of figure 3 nor person centric view of figure 7 reflects the reality of today's position. There is however a possibility that there will be an evolution from the former to the latter.

CONCLUSION

The Information age has caused an explosion of information through rapidly changing technologies. This technological change has been accompanied by an accelerating shift in economic and social relations, of which this paper focused on connectivity, interdependence and dynamism. A key observation found common in much of the literature is the increasing focus on the individual's capacity to connect. This has created new information needs required for monitoring and controlling connectivity and the associated issues of trust and abandonment.

Along with this change in relations, new ethical cultures are evolving at different levels: individual, corporate, governmental, NGO and global to incorporate the needs of the information age.

This paper also looked at the work done in the CSR field to see how it has evolved to adapt to the new mode of inter-dependent connectivity in a dynamic environment of changing relationships. The role of the corporation is being questioned: is it the means (agency) to individual (principal) satisfaction or is it the principal, determining human (agency) roles?

While many of the theoretical concepts can be adapted, there is much more work required in the measures of the degree of connectivity and to associate appropriate responsibility. The determination of information needs required for strategic control in this age of dynamic inter-dependent connectivity is a possible area for future research. At the very least information required would need to come from a multitude of stakeholders or systems.

The Hill and Cassill (2004) study also opens up questions for future research, including the resource allocation decision between the organization and the community, member's propensity for greed and sharing, and the impact of sharing on the quantity and quality of social capital available to the focal corporation with different levels of resource abundance.

Another area of future research is to establish what kind of responsibilities a firm has to its partners to reduce the tension between trust and leapfrogging. Although work in this area is being done by behavioural economists, an area to extend that work would be what responsibility one has to usher in trust and to make soften abandonment. Perhaps as a start, every actor needs to understand his own personal responsibility to evolve with the system and not to hold on to the old power syndrome inherent in hierarchical organizations.

There is also scope for studying the origins of the field of management thought: whether the recent application of systems approach are embedded in European or American roots.

The entire systems approach to social responsibility might also include research into the constituents of the social utility function to decide the gamut of areas which could be included. If a detailed Leontief type input-analysis is required, perhaps there are linkages to be looked at with this area of economics.

ACKNOWLEDGMENTS

My thanks to Emmanuelle Ashta, Joel Ernult, Serge Hayward and to three anonymous reviewers of the IRMA conference for reading and making suggestions and to the members of our research centre CEREN (especially Roxanna Bobulescu) to help me develop links between this paper and other areas/disciplines for future research. Thanks, especially, to the staff of our school's documentation center, for all the inter-library loan of articles and to Caisse d'Epargne Bourgogne Franche-Comté for funding this research.

ABSTRACT

This paper aims to explore potential differences in financial performance of Internet companies and the traditional brick-and-mortar companies. A compressive financial ratio analysis is used to investigate these differences for the period from 1998 to 2003. Contrary to our expectations, the average performance of the Internet companies was significantly worse than that of traditional brick-and-mortar companies.

INTRODUCTION

Since the late 1990s, buying and selling goods over the Internet has become a common business practice. Forrester research reported that E-commerce sales in 2005 increased 22% to $172 billion from $141 billion in 2004. This trend is expected to continue and according to Forrester, e-commerce sales will reach $228 billion in 2007 (Khan 2006). Even U.S. e-commerce sales in 2004 alone were estimated at $69.2 billion, which represent 23.5 percent increase from 2003 (U.S. Census Bureau 2005).

In spite of its importance and contribution to the whole economy, e-commerce is associated with the stock market bubble and the following crash. During this so-called dotcom crash, in 2000 and 2001, many, often very promising Internet companies, went out of business (Javalgi et al. 2004).

Practitioners and academic researchers provided a number of explanations for the dotcom crash (Shama 2001; Thornton and Marche 2003). The possible explanations included inexperienced management, absence of sound business model, and lack of attention to financial reality.

Prior to the dotcom crash, many business managers and investors followed the assumption that the traditional financial analysis tools are restricted to old economy. For example, a systematic ratio analysis has been rarely conducted for Internet companies. This is very surprising due to the fact that ratio analysis is one of the most common tools used for measuring financial performance (Bharadwaj 2000; Hunton et al. 2003; Kudyba and Vitaliano 2003; Santhanam and Hartono 2003; Motiwalla et al. 2005; Bose and Pal 2006).

According to a rich body of research, ratio analysis is a powerful tool in assessing the financial health of companies and predicting business failures (Beaver 1966; Altman 1968). However, regarding the Internet companies, it is not clear whether this method needs to be adjusted and what the reasonable ratios are.

This scarcity of financial ratio research in Internet companies provides motivation for our study. Although Motiwalla et al. (2005) examined the impact of e-business on financial performance, the study focused on an intra- and inter-industry level of three industries. Besides, the examined firms were not pure "click" companies but "brick and click" companies, which decided to embrace the Internet in order to support their traditional operations and to improve the bottom-line performance. In contrast, our study focuses on the financial performance of pure "click" companies and compares it with that of the traditional brick-and-mortar companies.

The structure of our paper is as follows: the next section, based on literature review, introduces a set of hypotheses; research methodology section describes the methodology, the results section presents the empirical results, and the discussion section includes a brief discussion of the results. The final section provides conclusions of the paper and offers some ideas for future research.

BACKGROUND AND RESEARCH HYPOTHESES

The Internet has changed the way the organizations conduct their business today. The number of firms that take advantage of Internet technology has grown rapidly in the late 1990s. Firms that heavily use the Internet for their business activities are commonly defined as the dotcoms, Internet firms or pure "click" companies. Consequently, many of these companies conduct their business almost exclusively over the Internet. Dotcoms can be classified into two categories: the digital and physical dotcoms depends on the products and services that they sell (Barua et al. 2004a). Yahoo and eBay are examples of digital dotcoms that deliver services directly over the Internet. Amazon.com is an example of physical dotcoms, which are often referred to as e-retailers that sells physical products on the Internet.

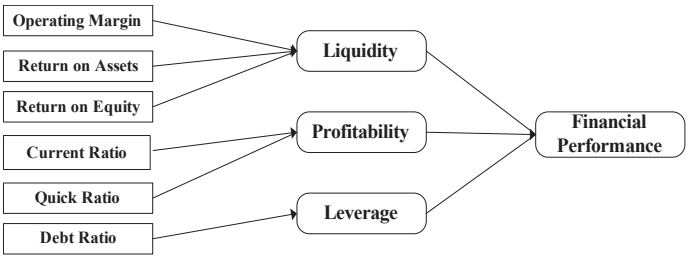
As described previously, Internet companies are often associated with dotcom crash. During this period, many firms run out of cash, closed their doors for business or become easy acquisition targets. Liquidity, or ability to meet financial obligations in short term, is important factor in avoiding financial difficulties. Thus, Internet companies may be expected to have liquidity problems. However, we argue that most of the Internet companies which managed to survive the dotcom crash and are in operations for several years must have a better position in liquidity. In other words, their liquidity is not worse than the established brick-and-mortar companies. The most well known measure of liquidity of the firms are current and quick ratios (Yang et al. 2001; Pasiouras et al. 2006). Therefore, the following hypothesis is proposed.

H1: Internet companies' liquidity, measured in terms of *current ratio* and *quick ratio,* is comparable to the traditional companies' liquidity.

Internet related technologies enable firms to reduce inventory, decrease stock-out situations, and improve response time (Barua et al. 2004b), and organization's operational efficiency and effectiveness (Chang et al. 2003). For example, these dotcoms can enjoy the benefits of reduced transactions cost, smaller or no inventory, 24/7 access with minimal cost (Motiwalla et al. 2005). Thus, we assume that Internet companies have greater operational efficiency as compared with traditional brick-and-mortar companies. There are several common measures of profitability. *Operating margin* (OM) is considered as one of important profitability measures since it measure a firm's core operations by excluding interest expenses, other financing costs, and other non-operating income (Kudyba and Vitaliano 2003). *Return on assets* (ROA) has been the most commonly used measure of firm performance (Hitt and Brynjolfsson 1996; Bharadwaj 2000) and a useful performance measure since it incorporates organizational profitability and efficiency (Hunton et al. 2003). *Return on equity* (ROE) is also another performance indicator that was often used in previous research (Hitt and Brynjolfsson 1996; Wheale and Amin 2003; Shin 2006). Regarding the Internet companies, the obvious ability of reaching a large customer base combined with the indisputable advantages of reduced costs should translate into higher profitability. Thus, the following hypothesis is proposed.

H2: Internet companies' profitability, measured in terms of *operating margin* (OM), *return on assets* (ROA), and *return on equity* (ROE), is greater than traditional companies' profitability.

Figure 1. Financial performance measure



Most of Internet companies finance their operations mainly with help of the venture capital and the stock market (Wheale and Amin 2003). More traditional sources of financing, such as bank loans, prevalent in the brick-and-mortar firms, are rather uncommon for Internet companies. Leverage, defined as ability to meet financial obligations in long-term, is also another important factor identifying financial difficulty. *Debt ratio* is a commonly used measure of leverage (Yang et al. 2001). Therefore, the following hypothesis is proposed.

H3: Internet companies' financial leverage, measured in terms of *debt ratio*, is lower than traditional companies' financial leverage.

The hypotheses can be summarized into the research model shown in Figure 1.

RESEARCH METHODOLOGY

The "matched sample comparison group" methodology is used to explore the potential differences in financial performance between Internet based and traditional brick-and-mortar companies. This method has also been used in previous studies (Bharadwaj 2000; Hunton et al. 2003). Our sample includes two groups; the treatment and control groups. The treatment group represents a sample of Internet companies and the control group represents companies that were selected to match the treatment group by size and industry.

Sample Selection

To select Internet firms, we started out with the list from USA Today Internet 100 Index (as of August, 9, 1999). This index consisted of 100 most relevant Internet companies at this time. To be included, the companies needed to have market capitalization of $200 millions and their share price needed to be at least $12 (Smith 1999). The selection from USA Today Internet 100 Index, assured that our treatment group included only firms which can be considered as Internet companies with relatively established business. Furthermore, this selection procedure increased comparability of the firms and minimized selection bias. From this initial list of 100 Internet companies, firms that are not included in Compustat were removed. Furthermore, firms that have merged with another firm or had missing data during the period from 1998 to 2003 were removed. As a result, the treatment group includes 16 firms.

To control for confounding changes in industry and the firm size, we followed some steps to select a matching control firm that is comparable to the treatment firm. Initially, firms from the same primary four-digit code as the treatment firm were selected from Compustat as potential control firms. Then, we used total assets and annual sales as the size measure, which are commonly used as proxies for the firm size and chose the firm that has the closest to the corresponding treatment firm's values in 1998. When no comparable control firms were available, we allowed the size measures to be between 70% and 130% of the treatment firm's values. Next, we allowed using three-digit SIC codes, and then if no potential firms are found, two-digit SIC codes are finally used to select the control firm. This method was also used in previous studies for selecting matching control group from the same industry and similar in size as the treatment group (Barber and Lyon 1996; Hunton et al. 2003). Once the potential control firm is selected, the firm is evaluated carefully to make sure that it is a traditional brick-and-mortar company. Companies with substantial portion of sales on Internet were not considered for the control group since they are considered "brick and click" companies. See the Appendix for the list of treatment and control groups.

For all treatment and control firms, we selected six years' (1998 – 2003) financial data. As a result, 192 data points were included in our analysis.

Table 1. List of financial ratios studied

Ratio	Category	Description
Current Ratio	Liquidity	Current assets / Current liabilities
Quick Ratio	Liquidity	(Current assets – inventories)/ Current liabilities
OM (Operating Margin)	Profitability	Operating income / Net sales
ROA (Return on Assets)	Profitability	Net income / Total assets
ROE (Return on Equity)	Profitability	Net income / Stockholders' equity
Debt Ratio	Leverage	Total debt / Total assets

Measuring Performance

To evaluate financial performance, we used ratio analysis, which is the most commonly used approach to measure a firm's performance (Beaver 1966; Altman 1968; Barney 1997; Bharadwaj 2000; Hunton et al. 2003). We used two liquidity based ratios (*current* and *quick* ratios), three profit based ratios (OM, ROA, and ROE) and one leverage ratio (*debt ratio*) for investigating the performance of 16 Internet companies and 16 traditional brick-and-mortar companies. Financial data from Compustat are pulled for these companies for the years from 1998 to 2003.

Liquidity ratios are used to examine the firm's ability to meet its current debts. Profitability ratios are used to determine firm's profitability or efficiency. Leverage ratios are used to predict the long-term solvency of the firm. The list of the financial ratios included in this study is shown in Table 1.

RESULTS

Descriptive Statistics

To assure the comparability between the treatment and control groups, a t-test and non-parametric (Mann-Whitney) tests were carried out. As depicted in Table 2, on average, treatment group's total assets were slightly larger and control group's sales were slightly larger. However, these differences were statistically insignificant. Therefore, it could be assumed that the characteristic of companies included in the control group is comparable to these selected for the treatment group.

Results of the Differences Between Two Groups

Table 3 summarizes the results of the differences of financial performance, as captured by studied ratios, between the treatment and control groups. The t-statistics from the t-test and the Z-statistics from the Mann-Whitney (non-parametric) test

Table 2. Descriptive statistics for Internet (Treatment) and traditional (Control) firms

Variables	Treatment group		Control group		T-test (p value)	Mann-Whitney Test (p value)
	Mean	Std. dev.	Mean	Std. dev.		
Total assets (in million)	266.3	338.6	225.1	226.5	-0.405 (0.323)	0.226 (0.821)
Sales (in million)	109.0	154.9	147.2	148.9	0.712 (0.765)	-1.131 (0.258)

Table 3. Performance differences between treatment and control firms

[a] *1 % level*
[b] *5 % level*
[c] *10 % level*

are reported. A negative sign before the test statistic indicates that the performance of the treatment group (Internet firms) is lower than the control group (brick-and-mortar companies) and a positive sign indicates otherwise.

Results from the analysis were as follows: First, the Internet firms' *current* and *quick* ratios were higher than the traditional firms in 1998, 1999, and 2003 although they were not significant in 2003. The positive signs of these ratios indicate the Internet firms' ability to meet short-term obligations is high. However, these ratios have changed to negative and low during 2000 to 2002 although they were not significant. The unusually high ratios in 1998 and 1999 could be easily explained with high cash reserves initially raised from investors. In contrast, beginning in 2000 the *current* and *quick* ratios of the Internet and traditional companies are not significantly different. Based on these results our hypothesis 1 seems to be supported.

All differences in profit ratios in each of the six years were negative. Thus, the average performance of the treatment group was significantly lower than that of the control group.

For example, OM was significant and negative for all years except for 2003. This shows that, on average, Internet companies were not able deliver their products or services at high price while keeping their costs low. ROA was significant and negative for all years except for 2003. Also, ROE was significant and negative in 2001 to 2003. These profitability ratios indicate that Internet firms were not as profitable as the traditional firms. Therefore, our hypothesis 2 is not supported.

The negative *debt ratio* in each of the six years indicates that the treatment group's leverage ratios were lower than that of the control firms. Thus, it indicates that Internet firms are considered to be less leveraged than traditional firms. Companies that are highly leveraged are believed to be at greater risk of bankruptcy if they cannot make payments on their debt. In other words, when financing their business operations, Internet companies seem to rely more on equity investors than on banks and other creditors. Our hypothesis 3 seems to be supported.

DISCUSSION OF RESULTS

The results of our analysis show substantial similarities and differences in accounting measures of Internet as compared to the traditional brick-and-mortar companies. In the line with our expectations, the liquidity (as measured by *current* and *quick* ratios) of Internet companies is comparable to the liquidity of brick-and-mortar companies. In addition, as we expected, the Internet companies still rely on investors and equity as main source of financing their business and their average *debt ratio* is low.

Contrary to our expectations, the average performance of the Internet companies was significantly worse than that of traditional brick-and-mortar companies. Our results are also contrary to the common theory that companies constantly learn to be more efficient as they stay in business (Jovanovic 1982). Accordingly to this theory, companies which are not able to learn and improve their efficiency to match their competitors are not likely to survive over long term.

Surprisingly, the differences in performance did not prevent the studied Internet companies to successfully survive the dotcom crash. Moreover, these differences did not diminish over the time and even the most current financial records of Internet companies are still dissimilar from the brick-and-mortar companies. One possible explanation could be that the negative differences in the business performance (as measured by OM, ROA, and ROE) reflect the relatively early stage in the development of these companies and very vibrant but growing market. Contrary to the brick-and-mortar companies, Internet companies must invest heavily to protect and build their market shares. They are less likely to have the luxury to rely on established brands, protected or highly regulated markets, or loyal customer base. This claim could be supported by the observation that in Internet companies financial accounting losses are accepted by the investors as necessary strategic investments and often rewarded with increasing stock prices (Wheale and Amin 2003).

Results of our study are summarized in Table 4.

Table 4. Summary of results

Hypothesis	Supported?	Results
H1	Yes	Liquidity of Internet companies is comparable with traditional brick-and-mortar companies
H2	No	Profitability of Internet is lower than the profitability of traditional brick-and-mortar companies
H3	Yes	Financial leverage of Internet companies is lower as compared with traditional brick-and-mortar companies

CONCLUSIONS AND FUTURE RESEARCH PLANS

Contrary to our expectations, the average financial performance of the Internet companies was significantly worse than that of traditional brick-and-mortar companies. Although we expected that the Internet companies should be more efficient since these companies made great deal of investment in technology to support e-commerce business operations, our results indicated otherwise.

There are several limitations of our study. First, Internet companies in our sample are those who survived after the dotcom crash and did not go bankrupt or merged. All Internet companies studied were still in operations as of year 2003. Second limitation of our study is that accounting measures might not be the best measures although they are the most commonly used financial performance measure in the previous studies. Third our results are limited to only six ratios. A greater number of ratios may yield different results. In addition, our results are based on relatively short series of data. As mentioned earlier in our analysis, we only used available financial information from the years 1998-2003. It is possible that a longer time period might produce different results. Finally, another limitation is our relatively small sample size of companies studied, which might limit the generalizability of the findings although it does not affect our ability to draw the conclusion.

In spite of these limitations, we believe our study made an important contribution to the research by exploring financial performance of Internet companies using ratio analysis. Research comparing the Internet companies with traditional companies can provide valuable information to IT managers searching for higher productivity or profitability. For companies engaged in e-commerce, this kind of research could help to determine their optimal level of IT investments. Furthermore, it points out the potential gaps in performance which can then be addressed by business managers.

There are plenty of research opportunities related to our study. One future research could simply validate our results with the expanded sample size of companies and an expanded set of financial ratios. Further research opportunity is also to find out the portion of technology investment of Internet companies and determine the productivity or profitability impact from IT. Although Internet companies were not as profitable or efficient as the traditional companies in our study, the years that we have studies might have caused the different outcome since many of Internet companies went out of business during this period. It might be worth investigating using financial data beyond year 2003 to determine if these companies' performance is improving.

ABSTRACT

In an effort to find interesting information in a volume of crime data provided by the Secure Police Department (a fictitious name), we applied data mining techniques and algorithms to this data. We discovered that data mining is an effort that takes a lot of planning and preparation, requires domain expertise, and is extremely resource intensive. The results we got are lackluster, for instance, correlations and patterns from the results are readily apparent, they are very rarely of the "interesting" variety. However, we think the experience and lessons learned have helped us and will help others be prepared for any future similar endeavors. The lessons can be summarized as: 1) Planning and preparation is a key to successful data mining, 2) Domain expertise is a necessity to perform successful data mining, 3) Data mining applications are extremely processor and main memory resource intensive and the appropriate hardware and software are necessary for successful data mining.

INTRODUCTION AND BACKGROUND

In the United States today crime is a major concern. The CIA, FBI, and other federal agencies are concerned with national security; city and county law enforcement agencies keep a constant vigil on criminal activities in their own jurisdictions; and individuals are worried about their safety within the community. In the meantime, the budget for local law enforcement and intelligence agencies takes a hit due to mediocre economic growth, which leads to downsizing of both personnel and programs. To better make decisions and optimally allocate limited resources, local law enforcement and intelligence agencies need better quality information in a timely manner.

It has been observed that "A major challenge facing all law-enforcement and intelligence-gathering organizations is accurately and efficiently analyzing the growing volume of crime data" (Chen et al., 2004). As the volume of this crime data becomes enormously large, new techniques have to be used to turn this data into usable information and knowledge; and thus, appropriate actions can be taken accordingly. Data mining holds the promise of making it easy, convenient, and practical to explore very large databases for law enforcement and intelligence agencies. Data mining is a powerful tool that uses complex algorithms to look for patterns in very large sets of data. Criminal investigators who may lack extensive training as data analysis can easily explore large databases quickly and efficiently through the implementation of data mining techniques in the form of commercial and other applications (Chen et al., 2004; Fayyad and Uthurusamy, 2002).

The Shared Urban Data System (SUDS) is a web based secure portal that has been created as part of the Community Information Project by the Center for Community Criminology and Research at the *Academic University* (a fictitious name) located in the Mid-south area. SUDS provides a host of information-based services for the local community including neighborhood planning and development, public safety, and public health, etc. While SUDS is a portal to all information and services housed in a large number of databases, the CRISP (Crime Research Information Statistics Portal) system is a more specific subset of information services tied to a single database. The CRISP database is of crime incident information provided by the *Secure Police Department* as part of the Community Information Project. The database is used for queries and reports centered on offense types, geographic locations (through a GIS mapping interface), dates and time ranges, and suspect and victim information.

This paper describes a project that applied a variety of data mining techniques to the CRISP database using a commercial data-mining tool. The tool selection was based on the tool availability, usage characteristics, and architecture. The tools evaluated were IBM Intelligent Miner, SPSS Clementine, and Megaputer PolyAnalyst. Our eventual decision to use Megaputer PolyAnalyst 5.0 was due to the availability to the student for a research product, the ability to use the tool directly, via ODBC, in connection with an SQL Server 2000 server without an intermediate tier, and the incorporation of a large number of data mining algorithms available within the base program.

LITERATURE REVIEW

Our summary of existing research literature on data mining of crime data is organized as follows. We first talk about the imperatives of applying data mining techniques to crime data and we then go into details on different data mining techniques that have been successfully applied to crime data.

To us, the marriage between data mining techniques and crime data happened naturally. A retrospective review tells that there are roughly three major reasons why this happened. First, the volume of crime data has become unwieldy. When investigating a crime, law enforcement agencies usually record as much information as possible about the crime. After the attack on WTC in New York City on September 11, 2001, concern about national and local security has increased dramatically. At a national level, the FBI, CIA and Homeland Security are all acting to collect and analyze information to prevent further terror attacks. These efforts have had an affect on local authorities, motivating them to monitor criminal activities in their own jurisdictions using similar intelligence techniques (Chen et al., 2004). All above activities result an exponential increase in the volume of crime data. Manual processing of this data is not feasible anymore; new techniques to accurately and efficiently process crime data had to be found.

Second, the budget for local law enforcement and intelligence agencies continues to see reductions due to mediocre economic growth (as of this writing in 2006). These economic factors lead to downsizing of both law enforcement personnel and programs. To better make decisions and optimally allocate limited resources, leadership in law enforcement needs quality information in a timely manner.

Third, its ability to reveal patterns in extremely large data sets makes data mining a tool that fits this job perfectly (Brown, 1998). Compared to manual processing, which is time and labor intensive, data mining holds the promise of making it easy, convenient, and practical to explore very large stores of crime data for law enforcement organizations and users.

There are many data mining techniques can be applied to crime data. Some examples of the specific applications and techniques of this work are given below as derived from current scholarly literature on the data mining of crime data.

Lin and Brown (2006) present an outlier-based data association method for linking criminal incidents. In this technique, according to them, "an outlier score function is defined to measure the extremeness of an observation, and a data association method is developed based upon the outlier score function." They applied this

method to the robbery data in Richmond, Virginia, and compared the result with a similarity-based association method. Their results show that the outlier-based data association method is promising.

Estivill-Castro and Lee (2001) incorporate two knowledge discovery techniques, clustering and association-rule mining, into a fruitful exploratory tool for the discovery of spatial-temporal patterns. They present two methods for this exploratory analysis and the detail algorithms to effectively explore geo-referenced data. They illustrate the algorithms with real crime data. They demonstrate their approach to a new type of analysis of the spatial-temporal dimensions of records of criminal events.

Brown (1998) describes a software framework for building and applying data mining algorithms to crime analysis problems. This framework provides specific focus on spatial data mining. The author provides several reasons to justify this focus: 1) spatial queries are more time consuming, 2) spatial analysis is harder to do than analyses based on attribute matching, 3) spatial data mining has the potential to yield important immediate benefits for crime analysis as crimes have an inherently spatial component (Brantingham and Brantingham, 1984), and 4) spatial analysis is a key to law enforcement resource allocation.

Chen et al. (2004) present a general framework that shows the relationship between data mining techniques applied in criminal and intelligence analysis and the crime types. They identify and arrange eight crime types (traffic violations, sex crime, theft, fraud, arson, gang/drug offences, violent crime, and cyber crime) in increasing order of public harm on the horizontal axis. On the vertical axis, they arrange the techniques in increasing order of analysis capability. They identified four major categories of crime data mining techniques: entity extraction, association, prediction, and pattern visualization. Each category represents a set of techniques for use in certain types of crime analysis. They then identified the intersection of the techniques with the crime types denoting where each technique could be effectively used for each crime type, completing the framework.

THE ARCHITECTURE USED IN THIS STUDY

PolyAnalyst is a product of Megaputer, and Version 5.0 is the latest version of PolyAnalyst. It is a data-mining tool that incorporates a large number of data mining algorithms in a single package. It can be configured to work as a traditional client server application or can be set up in a multi-tier architecture with a dedicated PolyAnalyst server. The client server implementation can be configured to read the data from the database importing all of the data into the project file created by PolyAnalyst or, alternatively, a subset of the algorithms can be used, via OLEDB to mine the data in place. We took the conventional means of using a traditional client server approach and allowed the application to import the data. Our connection to the database was done over a wide area link via a secure VPN connection to the network of *Academic University* to the SQL Server 2000 server where the CRISP data was located.

Some challenges encountered were the ability of the program to deal with the large amount of data and the physical limitations of the client server infrastructure. With the size of our datasets being much larger than 500,000 records, the PolyAnalyst program seemed to have some difficulty reading and dealing with a dataset this size given the simple client server configuration. In talking with the representatives of Megaputer, many of these shortcomings would be addressed by moving to a multi-ties architecture, using more advanced, server-based, architecture. Running the client under Windows XP Professional or Windows 2000 workstation would often reach the 4 GB limit on the operating systems address space.

To get around some of the limitations, we used a strategy that allowed us to work with smaller subsets of the data. Since we had to select our data via a join across six tables to get the information that we need, we included conditions that would select one year at a time in our data selection statements. Once we had the data imported into PolyAnalyst in a project file, we further subdivided the data into more manageable sections for testing different algorithms prior to starting large mining runs.

DATA PREPARATION AND ANALYSIS

Discussions with criminologists to narrow area of interest and type of discovery led us to believe that weapons crimes, specifically gun related crimes, were of particular interest to the SUDS team. There is a special program within the *Secure Police Department* at this time to crack down on gun crime. Anything that could be found to assist in the pursuit of this endeavor would be seen as a positive production of information from a data mining perspective.

Prediction and prevention are other major goals of the *Secure Police Department* and something that they would like to be able to do better. If a model can successfully predict some criminal activities, prevention mechanism can be deployed to effectively prevent some crimes from being committed. This would aid in crime deterrence and more effective utilization of police resources. Any information that data mining could provide to assist in the mission of prediction and prevention would be seen as positive generation of information.

Geospatial Modeling using Geographic Information Systems (GIS) is a very powerful tool that can be used to visually present crime data based on geospatial features. These kinds of presentation can be used to spot crime patterns. This type of information and modeling is being done on a small scale through the SUDS project at this time. A larger and more automated effort than the current one is desirable. There is the potential to create such special game maps from the data used from the CRISP database.

Data preparation for our task was significant and mostly a trial-and-error experience. The data had been pre-cleaned for the SUDS project so most problems had been dealt with. Other than having to tune our selection SQL to return meaningful, yet manageable dataset, we had to convert string values to categorical and Boolean fields that PolyAnalyst could interpret and also to handle some missing values that were in the data. In the creation of a commercially viable data-mining tool, Megaputer had to create generic algorithms that could be used under a wide variety of circumstances. In doing so they had to place some restrictions and criteria on the input of data to the algorithms. Such restriction took the form of selective data types, for example. When using a directed algorithm, such as a Decision Tree, a target attribute could only be of certain data types (say, categorical). A previous understanding of the direction of the inquiries and the organization of the data will help greatly in setting up the data sets for analysis.

Part of the data preparation was to study the metadata that we had been provided by the criminologists and system administrators of the SUDS database for context and use of the attributes. While a lot of the variables appeared straightforward, some variables needed explanation as to their particular use or importance, relevant to our tasks of data exploration. Redundancies and other dimensionality reductions were done at this point. There was often overlap from one table to another that was not apparent due to lack of naming conventions and other factors.

The analysis that we performed on the dataset was largely explorative in nature. We looked at many algorithms to see if we could apply some of them to our project. Below are a list of the techniques we considered and a brief description of the algorithms used taken from the PolyAnalyst User Manual.

- Nearest Neighbor - The Nearest Neighbor exploration engine uses a memory-based classification system: assigning values to data points based on their "proximity" to other data points.
- Market Basket - The explored dataset consists of some number of records which are referenced below as "transactions" and a number of attributes or "products." The Basket Analysis engine finds sets of products that are present together in a significant part of all transactions. Such typical sets are called baskets of products. Certain additional limitations can be imposed when searching for these baskets, such as specifying the minimum portion, in percent, of all transactions containing a discovered basket.
- Cluster - Clustering is one of typical problems solved by data mining methods. This is a process of grouping cases or database records into subsets, such that the degree of similarity between cases in one group is significantly higher than between members of different groups. An exact definition of the similarity between cases as well as other details varies for different clustering methods.
- Decision Tree – This is the name given to large family of machine learning algorithms for the automated construction of tree-like classification rules for categorizing structured data. The process of creating a Decision Tree can be represented as splitting the analyzed dataset into diminishing parts consisting of increasingly homogeneous records: in terms of the percentage of different values of the target field.
- Text Analysis - The Text Analysis exploration engine performs morphological and semantic analysis of unstructured textual notes in a database format. Text Analysis extracts and counts the most important words and word combinations from textual notes, and stores terms-rules for tokenizing database records with patterns encountered terms.

Once we had created subsets of our main dataset it was easy to test many algorithms for their appropriateness. The subsets of the datasets were done with tools in PolyAnalyst that would let you take random, top or bottom samples to create data subsets. They could be done on a percentage of total records or a total count basis. You could also decide which of the attributes to include in the subsets of data. Once the subsets were created it was a simple matter to choose that subset and apply a technique to it. Similarly, you could use a subset to train a directed algorithm and then apply the rule set generated by the training to the remaining data, or the World data as it was referred to in PolyAnalyst.

The analyses that we completed included a Link Analysis, a Decision Tree, and a Text Analysis. We directed our decision tree and link analysis algorithms to target the attribute that contained values for "Weapon Type" and our text search was directed to search for weapons in the text phrases of the narratives given with each of the cases. PolyAnalyst contained built-in semantic libraries through a connection to external rule base for guiding the text search as well as common files of stop words. The results of the classification and association routines provided a large number of links, most of which were meaningless. Some of the more meaningful links, that had stronger correlation and coverage were also, unfortunately, quite intuitive. The text analysis looked primarily at occurrences and the results there seemed good, but not perfect. For example the semantic database picked up on 35 occurrences of the term "cutlass" in the narratives and determined that it was a weapon. Although this is possible, we found it more probable that these occurrences were in reference to an Oldsmobile and not to a sword fight.

RESULTS AND DISCUSSION

A result that became readily apparent in all of our analyses was that correlations are easily found and meaningless correlations are even easier to find. For example, the use of a weapon in crimes of type "Assault" had a large correlation and coverage from several of the algorithms giving the rule:

Assaults ⇔ Weapon Use

Similarly the absence of the use of a weapon in crimes of type "Home Burglary" had a large correlation and coverage from several of the algorithms giving the rule:

Home Burglary ⇔ No Weapon

Even more simplistically the correlations where 2 geographic location identifications were used in the same algorithm they were both correlated as can be seen by the following rule:

Zip code ⇔ Precinct and Ward

It was the "interesting" correlations that proved to be elusive to our exploration.

CONCLUSIONS, LESSONS LEARNED, AND FUTURE DIRECTION

Although the things that were learned here are not ground breaking or revolutionary, they were situations that we encountered in the actual attempt to perform a data mining exercise from scratch. While there are many studies and publications that talk about data mining and crime data analysis, these lessons "from the field" are presented here as practical information for both researchers and practitioners.

A major revelation in our data mining trials was that the preparation and planning is central to data mining; whereas the execution of algorithm and analysis can be an easy part. We spent much more time up front researching the importation, mapping, cleaning, and retyping of data than we did on the exploration phase of the project. Similarly we found that setting up a tool to mine existing data can be a challenging and time consuming process. The data preparation could have been done better to accommodate the tool and made the data mining process a lot easier. The data, which was primarily in string fields for use in a web portal environment, was not conducive to data mining. For example, it would have been much easier to manipulate those fields with a value of "True" or "False" if the field values were 1 or 0, respectively, in a data-mining context.

Another finding from this study was that this type of analysis is highly domain exclusive and a domain expert is an important resource. Without the assistance of criminology resources and even resources that had domain knowledge specific to our dataset, the task of exploration would have been much more difficult.

We also developed a new appreciation for how resource intensive data mining is. The ability to saturate a 4 GB address space in a matter of minutes of processing was impressive and let us know just how important it is to use well tuned and efficient algorithms and code in the data mining task. It was also apparent that these analyses were very processor intensive as well as main memory intensive. Some of the algorithms took several hours to run on datasets that were 80-90 thousand records in size.

In the future, we plan to develop a better understanding of tool and data handling inside the tool. This would make it much easier and less time consuming for us to choose the algorithm and prepare the data for that algorithm. This would also let us have more precision in selecting and assigning values to parameters of the algorithms. We would also like to be able to determine more interesting questions for exploration and analysis. This would involve a great deal more time with the criminologist and possibly with the police departments to find out what is of interest and helpful to them as we choose datasets, attributes and algorithms. Another improvement that could be done to advance this line of study would be to improve the infrastructure to handle larger datasets. The addition of another tier with a dedicated PolyAnalyst server would facilitate the use of larger datasets and give quicker processing times.

Applying data mining techniques on crime data is not an option, but a necessity. Data mining, given quality data and the appropriate techniques, can bring forth accurate information in a timely fashion and this information can enhance decision-making and analysis for all law enforcement agencies. Past successes in crime data mining suggest the future of it is very promising. We think our experience and lessons learned during this exploratory study have helped us and will help others be prepared in any future similar endeavors.

ABSTRACT

Data Quality (DQ) has been an acknowledged issue for a long time. Researches have indicated that maintaining the quality of data is often acknowledged as problematic, but is also seen as critical to effective decision-making. This paper investigates the issues emerging from unique nature of engineering asset data. It discusses the various asset management (AM) DQ issues and presents exploratory research on how engineering asset organizations in Australia are addressing DQ issues based on a large scale national-wide DQ survey that was conducted. It provides a better understanding of AM DQ issues and assists in identifying elements which will contribute towards the development of an AM specific DQ framework. The research findings suggest that while the organizations are concerning the quality of data, there is a disconnection between data custodians and data producers and high level data owners. The majority of AM organizations still adopt a reactive approach on DQ management.

1. INTRODUCTION

Almost every process and activity in the organisations involves data. Levitan and Redman (1998) suggest that data provides the foundation for operational, tactical, and strategic decisions. As data becomes increasingly important in supporting organizational decisions, modern organizations, both public and private, are now continually generating more data than at any other time before. More data, however, does not necessarily mean better information, or more informed business decisions. In fact, many are finding it difficult to use the data. It is estimated that more than 70% of generated data is never used (Koronios, 2006). Gartner Research (Desisto, 2004) found that bad data is worse than no data at all. There is strong evidence that most organisations have far more data than they possibly use; yet, at the same time, they do not have the data they really need (Levitan and Redman, 1998). Despite this apparent explosion in the generation of data it appears that, at the management level, executives are not confident that they have enough correct, reliable, consistent and timely data upon which to make decisions. Many say they are drowning in data and are starved of information.

Consequently, the quality of the data that managers use becomes critical. Poor-quality data, if not identified and corrected, often leads to decisions being made more on the basis of judgment rather than being data driven (Koronios et al., 2005). Without quality data, organisations are running blind and make any decision a gamble (ARC, 2004). This can lead to disastrous economic impacts on the health of the company. In some cases, it could also lead to catastrophic social consequences such massive power failures, industrial or aviation disasters.

Industry has recently put a strong emphasis on to the area of asset management (AM). In order for engineering organizations to generate revenue they need to utilize assets in an effective and efficient way. Often the success of an enterprise depends largely on its ability to utilize assets efficiently. In other words, asset management has been regarded as an essential business process in many organizations, and is moving to the forefront of contributing to an organization's financial objectives.

Previous studies in asset management suggest that a common, critical concern with engineering asset management is the lack of quality data (Eerens, 2003; IPWEA, 2002). Recent researches by U.S. GAO (2004) clearly demonstrates that achieving data quality is the key challenge engineering organisations face today in successfully implementing effective engineering asset management. Saunders (2004) indicated that although very large amounts of data is being generated from asset condition monitoring systems, little thought has been given to the quality of such generated data. Thus the quality of data from such systems may suffer from severe quality limitations.

As an important initiative proposed by the Australian federal government and the industry sector, studies were commenced in 2003 into the impact of the quality of data on AM organisations including the Royal Australian Navy, utilities, transportation and mining companies, and local governments. In 2006, a large scale national-wide survey was conducted into data quality issues in engineering asset management, with a sample size of 2000 and a response rate of over 23.9%. This is one of the largest nation-wide surveys of its kind, aimed as directly addressing data quality issues in engineering asset management organisations in Australia. This paper discusses the development of the data quality framework through this survey and presents some of its findings. Data and information are often used synonymously. In practice, managers differentiate information from data intuitively, and describe information as data that has been processed. Unless specified otherwise, this paper will use data interchangeably with information.

2. DATA QUALITY

Numerous researchers have attempted to define data quality (DQ) and to identify its dimensions (Wang et al., 1993; Fox et al., 1994; Wand et al., 1996; Wang et al., 1996; Shanks et al., 1998; Kahn et al., 2002). Traditionally, data quality has been described from the perspective of accuracy. However, many researches have indicated that DQ should be defined as beyond accuracy and is identified as encompassing multiple dimensions. Through literature, many authors have tried to explain the meaning of all relevant dimensions from several points of view (Strong, 1997; English, 1999; Ballou et al., 1998; Orr, 1998). Even, any of them have tried to identify a standard set of DQ dimensions valid for any data product; but as Huang et al. (1999) state, it is nearly impossible due to different nature of different data environment.

Four most frequently mentioned data quality dimensions in the literature are accuracy, completeness, timeliness and consistency (Liu, 2002; Naumann, 2002; Bouzeghoub et al., 2004; Batini et al., 2004; Strong, 1997). Unfortunately, a set of data may be completely satisfactory on most dimensions but inadequate on a critical few. Furthermore, improving on one DQ dimension can impair another dimension. For example, it may be possible to improve the timeliness of data at the expense of accuracy (Ballou et al., 1995). It may be complete at the cost of concise representation (Neely 2002). Moreover, different stakeholders in an organisation may have different DQ requirements and concerns (Giannoccaro et al., 1999). Data whose quality is appropriate for one may not be sufficient for another (Neely, 2002). The DQ dimensions considered appropriate for one decision may not be sufficient for other types of decisions. As a result, Wang and Strong (1996)'s widely-accepted definition of data quality "*quality data are data that are fit for use by the data consumer*" is adopted in this research.

Maintaining the quality of data is often acknowledged as problematic, but is also seen as critical to effective decision-making. Examples of the many factors that can impede data quality are identified within various elements of the data quality literature. These include: inadequate management structures for ensuring complete, timely and accurate reporting of data; inadequate rules, training, and procedural guidelines for those involved in data collection; fragmentation and inconsistencies among the services associated with data collection; and the requirement for new management methods which utilize accurate and relevant data to support the dynamic management environment.

Clearly, personnel management and organizational factors, as well as effective technological mechanisms, affect the ability to maintain data quality. Wang (1998) clarifies this relationship by drawing an analogy between manufacturing and the production of data. In this way they derive a hierarchy of DQ responsibilities, ranging from management processes down to individual procedures and mechanisms (Wang et al., 1995). Their framework specifies a top management role for DQ policy, i.e. overall intention and direction related to DQ, and a DQ management function to determine how that policy is to be implemented. This, in turn, should result in a DQ system for implementing DQ management, within which DQ control is enforced through operational techniques and activities. DQ assurance then comprises all of the planned and systematic actions required to provide confidence that data meet the quality requirements. With the aim of improving DQ, Wang (1998) also suggests a Total Data Quality Management (TDQM) framework (define, measure, analyze and improve) for continuously managing data quality problems.

3. ENGINEERING ASSET MANAGEMENT

According to British Standards Institute (2004), asset management encompasses activities that are aimed at establishing the optimum way of managing assets to achieve a desired and sustained outcome. The objective of asset management is to optimize the lifecycle value of the physical assets by minimizing the long term cost of owning, operating, maintaining, and replacing the asset, while ensuring the required level of reliable and uninterrupted delivery of quality service (Eerens, 2003; Spires, 1996; IPWEA, 2002). At its core, asset management seeks to manage the facility's asset from before it is operationally activated until long after it has been deactivated. This is because, in addition to managing the present and active asset, asset management also addresses planning and historical requirements.

Asset management is process-oriented. The AM process itself is quite sophisticated and involves the whole asset lifecycle that can span a long period of time (Steed, 1988). The lifecycle for a typical asset involves several interdependent stages including design, plan, acquisition, installation, operation, maintenance, rehabilitation and disposal. At every stage of the process, AM also needs to collaborate and synchronize with other business processes, which is vital to the effective management of engineering assets. The cost and complexity of engineering assets demands considerable planning to identify appropriate solutions and evaluate investment opportunities. These same characteristics are reflected in the need for an extended acquisition process, a comprehensive request for proposal, and an equally comprehensive purchase agreement that addresses guarantees and warranties. Installation and placing in service of engineering assets is also complex and requires a proper set of processes to manage contractors. Once the asset is acquired, it must be tracked throughout its useful life. Finally, records must be made of its eventual disposition.

The sophistication of the engineering asset management process requires substantial information to be collected throughout all stages of a typical asset's lifecycle. This information needs to be maintained for a very long time, often dozens of years in order to identify long-term trends. This kind of process also uses this information to plan and schedule asset maintenance, rehabilitation, and replacement activities. In order to manage and support the complicated AM process and its data requirements, a variety of specialized technical, operational and administrative systems exist in asset management. These not only manage, control and track the asset through its entire lifecycle, but also provide maintenance support throughout the lifecycle of the asset. Considering the complexity and importance of asset management, these systems are normally bought from multiple vendors and each is specialized to accomplish its task. Unfortunately, this leads to an extremely difficult integration job for the end-user.

Engineering processes rely heavily on input of data and also produce a large amount data. Engineering data itself is quite different to typical business-oriented data as illustrated in Table 1. It has unique data characteristics and complex data capture processes from a large variety of data sources. This large amount of data therefore can suffer from data quality problems. The nature of such data quality problems has not previously been investigated in Australian engineering-oriented organizations.

4. RESEARCH DESIGN

In DQ studies, four types of stakeholders have been identified: data collector, data custodian, data consumer, and data owner (Strong, 1997; Wang, 1998). In this study, DQ stakeholders in asset management are defined as follow:

- Data collectors are those who create or collect asset data e.g. technician, data entry staff;
- Data custodians are those who design, develop, manage, and operate the asset management information systems e.g. IT manager, data manager;
- Data consumers are those who use the asset information in their work activities e.g. maintenance engineer, senior manager;
- Data owners are those who own and responsible for managing the entire data in asset management systems e.g. asset manager.

The DQ survey was designed to address the questions developed in the literature review, in order to understand the general perceptions towards data management issues and further establish the extent of data quality maturity. A multi-section questionnaire were mailed to a 2000 large random sample of asset manager, data collector, data custodian and data consumer, in 1100 geographically dispersed engineering asset management organizations in Australia (including 572 organizations in the public sector). The questionnaire provided a guideline in the beginning to ensure that respondents had a common understanding of the various sections and definitions. The questionnaire was pre-tested by initially mailing it to 15 companies. Changes were incorporated and the questionnaires were then mailed to the remaining companies. The survey population for the questionnaire was chosen from engineering asset management organizations based in Australia. These organizations represent a variety of industries:

- utility (water, electricity, gas, oil);
- mining & resources;
- transport (rail, airline, ship, automobile);
- defence; and
- local government.

This list was matched with databases like the Business Who's Who of Australia and the specific industry-related associations to develop a list of Australian AM organizations. We believed that being the key participants or leaders in the major areas of engineering asset management, these organizations would be potential candidates for having AM information systems. Once the data was collected, statistical tools & methods were used to analyze the data and report the results. The results of this survey study were used to develop an AM DQ framework. The AM DQ framework will form the foundation for further research in order to perform data audit to identify nature and volume of DQ problems, and to develop a specification of the functional requirements for asset management data cleansing & enrichment software packages

5. THE AM DQ FRAMEWORK

Based on the analysis of DQ and AM literature together with the empirical findings from the DQ survey, *an* AM specific DQ framework was developed as shown in Figure 1. This framework is useful to guide the research into AM DQ issues, because it highlights the root perspectives on DQ problems, illustrates how they emerge during the process of AM; and outlines the basic DQ management criteria.

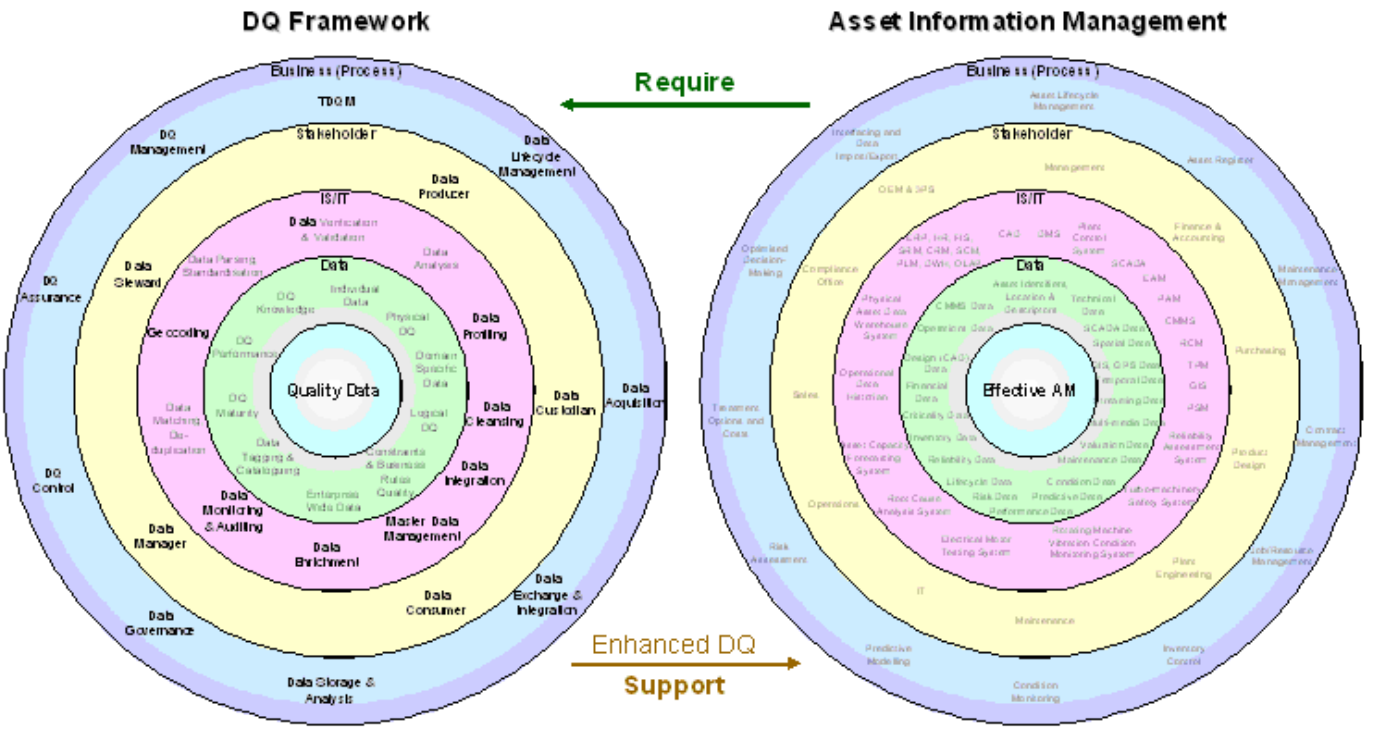
Asset data is the key enabler in gaining control of assets. These asset data is created, processed, stored, and used throughout an asset's lifecycle by a variety of stakeholders together with an assortment of technical and business systems during the whole AM process. The quality asset data in turn provides foundation for effective asset management. As asset information management underlies all the asset-based management processes, the ensured DQ for asset information management assists the optimization of AM decision-making.

Because these asset data are quite different to typical business data, in order to ensure the quality of these asset data, AM DQ also has its own process, which also involve multiple DQ stakeholders such as data collector, data custodian, and

Table 1. Differences between engineering asset data and typical business data (Source: Developed by the authors)

Element	Typical Business Environment	Engineering Asset Management
Data Environment	Transaction-driven, product-centric business data environments	Continuous data, process-centric open control system and manufacturing data environments
Data Characteristics	• Self-descriptive • Static • Intrinsic quality • Discrete value with fewer or no constraints • Current • Transactional data • Often structured • Easy to audit • Can be cleansed using existing tools • Similar data types	• Non self-descriptive • Dynamic • Intrinsic / extrinsic quality • Continuous value with constraints (e.g. within a range), precision value • Temporal • Time-series streaming data • Often unstructured • Difficult to be audited • Difficult to be cleansed using existing tools • Diversity of data types
Data Category	Inventory data, customer data, financial data, supplier data, transaction data etc	Inventory data, condition data, performance data, criticality data, lifecycle data, valuation data, financial data, risk data, reliability data, technical data, physical data, GPS data etc
Data Sources	Mainly transaction-based textual records from business activities	Disparate data sources • Spatial data – plans/maps, drawings, photo • Textual records – inspection sheets, payment schedules • Attribute records – separate databases, maintenance/renewal records, fault/failure records, field books • Real-time CMS/SCADA • Other sources – existing/previous staff and contractors, photos
Data Capture	• Often manually by data providers in fixed format • Data often entered by reasonably trained, dedicated personnel with proper relevant knowledge • Data collection environment is stable, well pre-organized • Data entry point is within the business	• Electronically, involving sensors, technical systems such as SCADA systems, condition monitoring systems • Manually, involving field devices, field force, contractors, business rules • Data collected in a variety of formats • Requires to collect substantial data from many different parts of the organization • Data often entered by less/un trained, less dedicated personnel without proper relevant knowledge • Data entry environment can be unstable, harsh, less pre-organized • Data entry point can be far from the organization site
Data Storage	• Data to be kept in accordance with appropriate compliance requirements • Data stored on functional information systems	• Very large amount of data to be maintained for extended time for AM engineering and planning process • Data stored on various operational and administrative systems
Data Processing	• Comprehensive • Process independent • Easy for data integration	• Not comprehensive • Process dependent • Complex to integrate data, need both vertical and horizontal data integration
Data Usage & Analysis	o Data to be shared only among relevant business systems o Data to be communicated to internal stakeholders o Use general, common knowledge to interpret data o Easy for management use	o Data to be shared among various technical (e.g. design, operations, maintenance) and business systems o Data to be communicated to an array of stakeholders, business partners and contractors, subcontractors o Need experts with professional knowledge to interpret data o Difficult to translate asset data into meaningful management information

Figure 1. The AM DQ framework (Source: Developed by the authors)



require specialised supports of DQ technology and systems. The AM data will need to go through the DQ process, by a variety of DQ stakeholders and various DQ technology & systems, in order to ensure its quality. The asset data of enhanced DQ can then provide the foundation for effective asset management.

6. RESEARCH FINDINGS

This survey is the first national data quality survey performed in Australia, focusing specifically on the data quality issues of engineering asset management organisations. The following findings show the different attitudes and perceptions towards data quality. More importantly, it shows that the current strategy, policy and tools that the organisations employ for their data management solution.

6.1 Current Attitude & Awareness Towards Data Quality

The above result shows that the majority of survey participants recognise the important role that data quality is playing in achieving the success of an asset-intensive organisation.

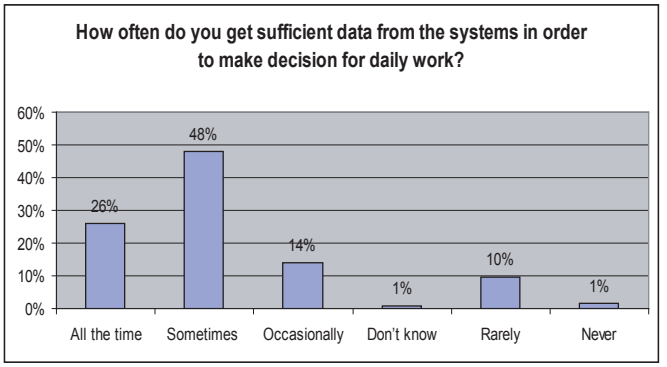
TOP Approach	Element	Chi-square Test	Kruskal-Wallis Test
Organisation	Industry	0.012	0.000
	Organisation size	0.772	0.459
	Organisation site(s)	0.215	0.007
People	Job position level	0.037	0.020
	Job function	0.704	0.138
	Data role	0.164	0.016

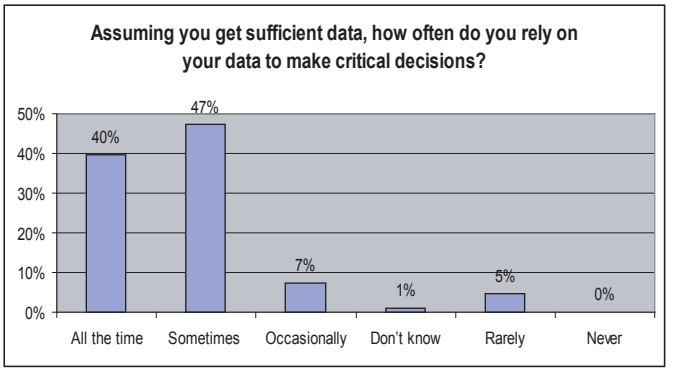
However, there is a statistically significant difference in the levels of DQ awareness across the different industry groups, and various job position levels as shown in Chi-square test and Kruskal-Wallist test. An inspection on the mean rank for the industry groups suggests that defence had the highest awareness scores, with local government reporting the lowest. In terms of job position levels, senior manager in strategic level had the highest awareness of DQ importance, with operational staff in lower level being the lowest. There is no significant relationship found between DQ awareness level and organisation size or job function.

6.2 Current Perception of DQ Confidence

Despite the overwhelming DQ awareness, a DQ confidence gap exists among the different data roles.

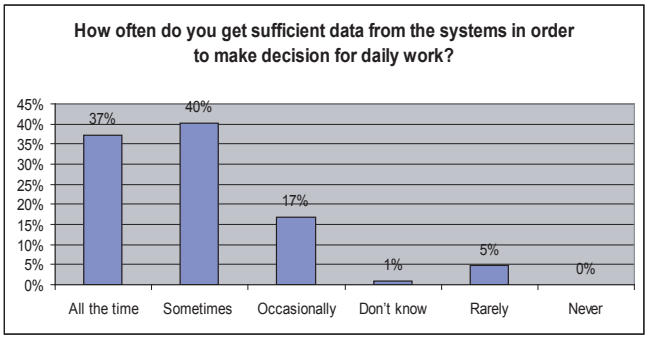
6.2.1 From Data Owners' Point of View

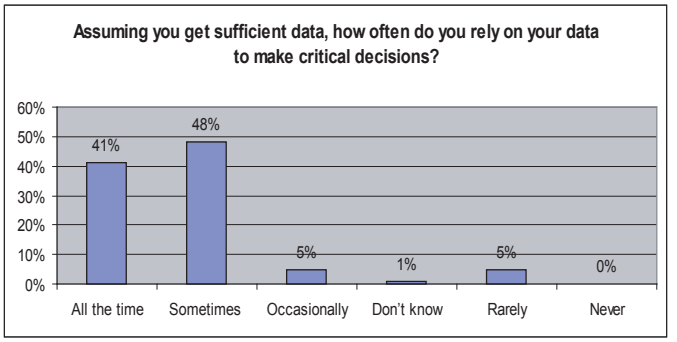




The above left figure shows that the majority of data owners (Asset managers) are happy with the amount of the data that they can access. However, there is a relatively small group (about 7%), who is not satisfied with the quality of data for decision making as shown in the figure on the right.

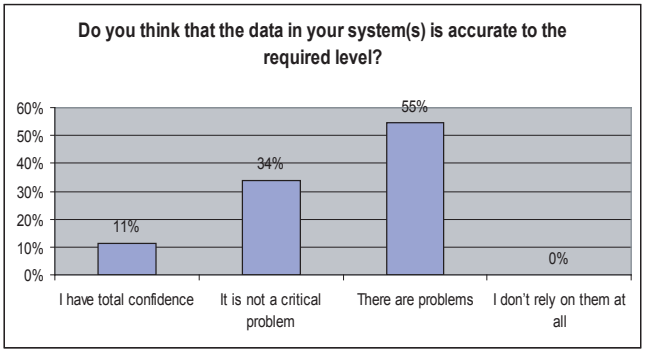
6.2.2 From Data Consumers' Point of View

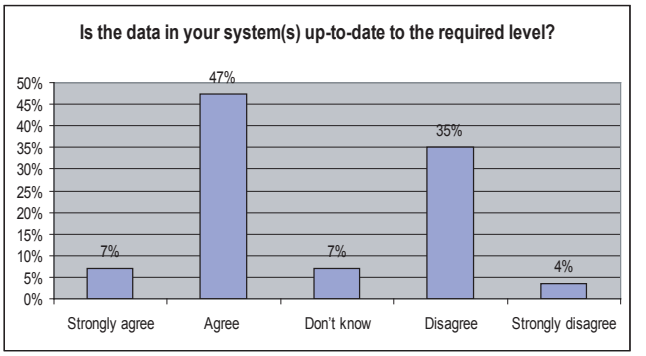




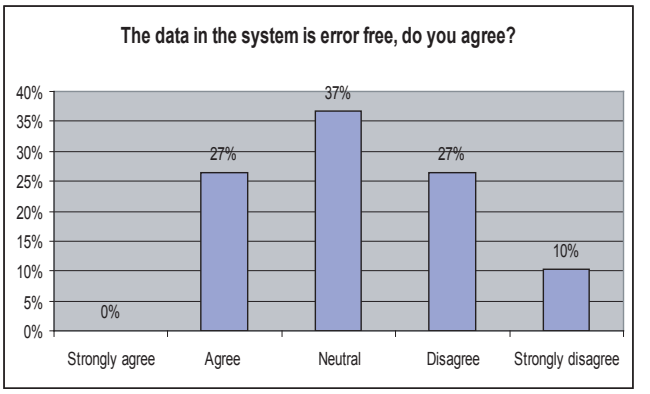
A consistent opinion is suggested by the data consumers' group. However, it does necessarily show that the data quality problem is not a major concern within the participating organisations.

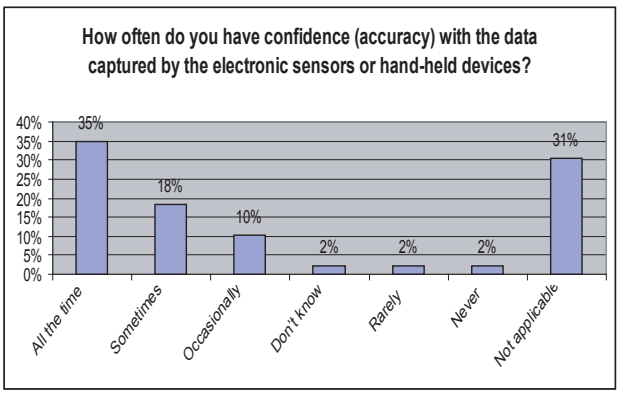
6.2.3 From Data Custodians' Point of View





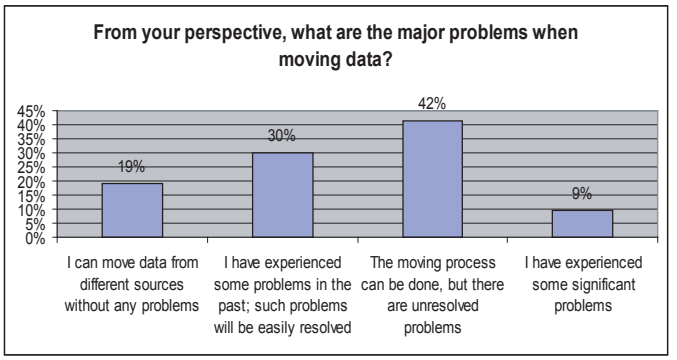
6.2.4 From Data Producers' Point of View





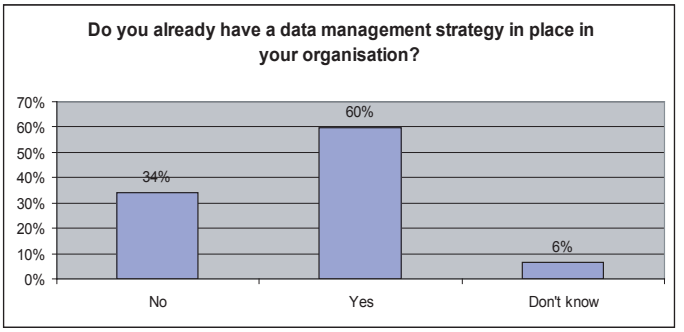
The above figures shows that the data producers and data custodians acknowledged that there were data quality problems. Especially, data producers do not have much confidence on their data quality. Perhaps, the data owners and data consumers may have higher levels tolerance of poor quality data. Nevertheless data quality problem is still facing critical challenges in most organisations. Also, the different attitudes found between groups may ring the alert bell that there may be a disconnection between the operational level personnel and the strategic level managers.

Some problems are suggested by the data custodians. For example, it suggests that moving/migrating data may generate many quality related problems, as shown below.

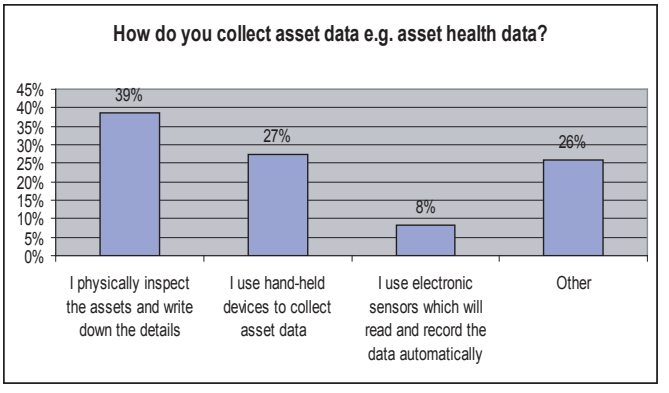


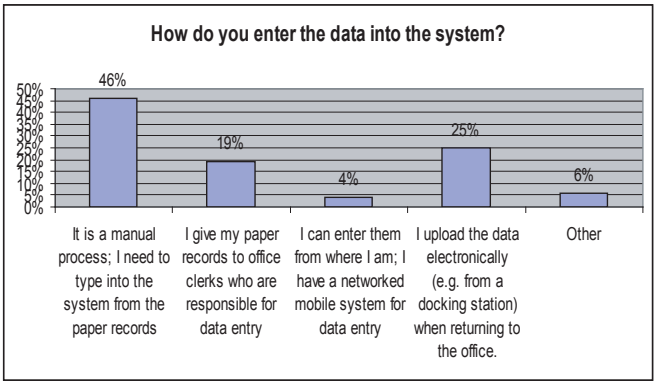
6.3 Current Strategies, Policies & Tools Employed for Achieving High Quality of Data

According to the 60% of data owners, there is data management strategy for data quality in place in their organisations, as shown in below.

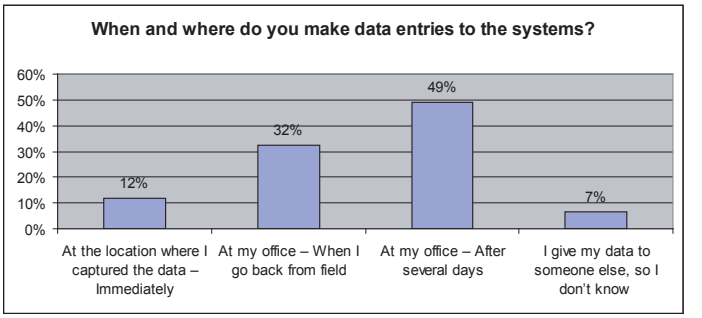


Down to the data capture level, data producers listed different ways of data collection and entry.



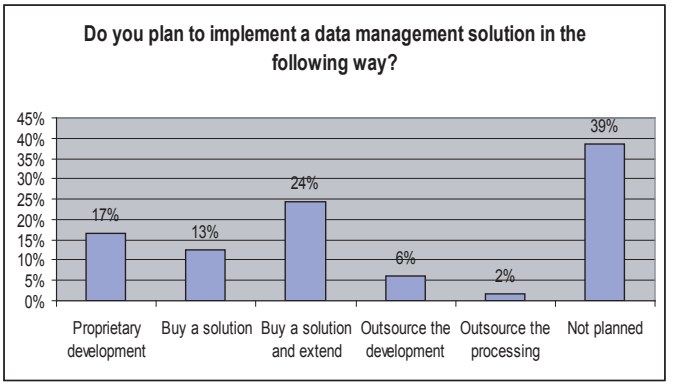


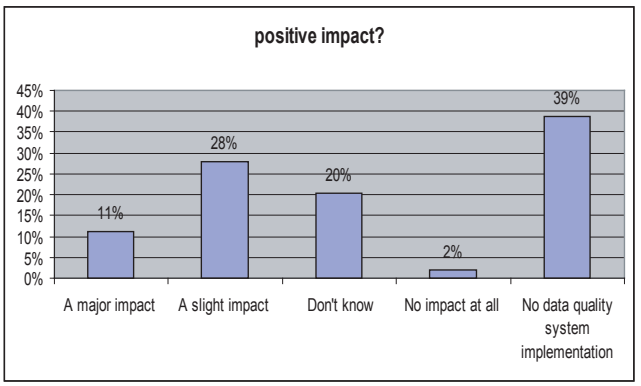
The majority of data producers still adopt a manual data entry process, which primarily rely on paper records. Especially, the figure below suggests that these data may not be entered immediately on site. Approximately 49% of these data were entered at the office after several days. Thus, the accuracy and completeness of these data may not be satisfactorily achieved.



6.4 Towards Future

It is "interesting" to find that 39% of asset owners have no plans to implement any data management solutions in near future. While the answer from Data custodians to the question *"Has implementing a data quality system had a positive impact on the success of any major IT implementations which your organization has put in place (e.g. Enterprise Resource Planning)?"* shows that no data quality systems (e.g. data profiling and cleansing systems) were implemented or planned to be implemented.





7. CONCLUSION

This paper included a proportion of survey findings. Nevertheless, these results suggest that while the organizations are concerned about the quality of data, there is lack of scrutinized discussion on the various issues associated with data quality problems. More importantly, there is a disconnection between data custodians and data producers and high level data owners. The majority of engineering asset organisations in Australia has no plans to neither implement any data quality management solutions nor develop any strategic plans. This finding is very different from AIM and PricewaterhouseCoopers findings. Perhaps, the engineering asset management organisations in Australia still adopt a reactive approach and only focus on the daily operations. A more comprehensive analysis will show the different attitudes and management strategies in relation to sizes of the organisations and the industries that they operate within. Further, these findings will be compared with the general data quality surveys.

This paper provided a better understanding of data quality issues for asset management and is assisting in identifying elements which will contribute towards the development of a data quality framework specific to engineering asset management. This in turn will assist in providing useful advice for improving data quality in this area. As an increasing number of organisations are putting in resources in data management solutions, there is growing need for suitable guidelines to help them develop appropriate strategies and employ right tools. Perhaps this is why data quality research becomes more critical.

Anticipated and Unanticipated Consequences of the Development of Accounting Information Systems

Mohamed A. Elbannan, Cairo University, Orman, 12613 Giza, Egypt; E-mail: elbannan@cu.edu.eg

ABSTRACT

This paper aims at objectively viewing the consequences of the development of a typical accounting information system. Accounting is a tool for organization, documentation, and rationalization of economic decisions. Some of the significant consequences, such as rationalization and legitimization of economic action, were unanticipated at the early stages of evolution of financial accounting. In making the distinction between intended and unintended consequences, the goal is to understand how the primary components of the system evolved.

INTRODUCTION

The purpose of this paper is to demonstrate different consequences of the development of accounting information systems and to weigh the opposing arguments of whether the consequences of accounting were actually anticipated by those who developed early accounting techniques. Behavior is a complex interaction of several human processes aimed at achieving a goal. It involves conscious or unconscious selection of particular choices of actions. The selection refers to the fact that there are other courses of action that are foregone by the individual. Based on the selection, the desired consequences are elicited. Nevertheless, the mind cannot grasp the entire consequences of a chosen course of action (Simon, 1945). Implicit in this argument is that anticipated consequences might bring around, inadvertently, other unanticipated consequences. Accounting is more important now more than it ever was, and studying its history is significant to understand its roots, impact, and the early influences that shaped those techniques.

LITERATURE REVIEW

Accounting is "the process of identifying, measuring, and communicating economic information to permit informed judgments and decisions by users of the information" (American Accounting Association, 1966). The definition is broad because it describes accounting as a measurement and reporting instrument for any activity with financial ramifications.

History of Accounting

Accounting, as a tool for control and accountability, existed in a primitive form thousands of years ago in early civilizations. The Chaldean-Babylonian, Assyrian and Sumerian civilizations all had highly organized systems of government and also had the oldest surviving business records, dating as far back as 3500 BC. The records kept relate to counting crops and grain (Mann, 1994). Evidence also exists that a powerful bureaucracy, supported by accounting techniques, coordinated the political and economic domains in ancient Egypt in the New Kingdom (1552-1069 BC). Kemp (1989) argues that the bureaucratic system was rooted in devising routines for measuring, inspecting, checking, and controlling other people's activities. Detailed accounting records were kept for taxation, documentation of income and barter transactions and listing of inventory and workers' wages.

Luca Pacioli is well known today for suggesting the double-entry bookkeeping system (or the "Method of Venice"), even though the system was widely used in Italy and very refined at that time. He discussed the Journal, the Ledger, barter, company or joint venture, agency and bank accounts, income and expenditure accounts, the balance sheet, and the general rules of bookkeeping. Italian merchants helped introduce the system in the 1600s to merchants in other countries that had less organized means of record keeping.

Double-entry system was a means of reducing the uncertainty faced by the merchants and the incidence of bankruptcy, which was often due to poor bookkeeping (Mann, 1994). Mills (1994) adds that two events, the commercial revolution and printing, came together in Northern Italy to create the conditions whereby the region could invent double-entry. He attributes the commercial revolution in Italy to the expansion of population and the Crusades. Both events increased the trade passing through the Italian cities of Genoa and Venice.

Rationality and Social Action

A distinction is made between anticipated and unanticipated consequences of purposive social action. While anticipated consequences are desired objectives of the action, unanticipated consequences are unintended products of the action that were not expected in advance (Merton, 1936). Some of the institutions, tools and techniques taken for granted in the modern days are, in fact, unintended consequences of some action. In his thesis regarding the emergence of modern capitalist thinking, Weber (1958) argues that Capitalism, as an economic ideological model, has not developed to its modern form until the West applied its "rational" thinking to commercial activity in the eighteenth century.

Though debatable, Weber's theory argues that the eighteenth century merchant did not *intend* to build the modern, well-integrated web of institutions, ethics, and technologies. All he wanted was to seek the divine salvation that only came to those who perform economically well in their daily calling. Those rational institutions that exist today are unanticipated consequences to the merchant's behavior in his quest for salvation. These consequences may be more frequent the farther one moves from the action.

THEORETICAL FRAMEWORK

Researchers have enthusiastically attributed several aspects of our modern life to the development of accounting information systems. Highly regarded academics, such as Schumpeter, Sombart and Weber, in different disciplines have provided a great deal of arguments that accounting, either directly or indirectly, is responsible for the society's economic development, the creation of several institutional arrangements, and the emergence of large businesses. While these arguments might be true, the original intent of the developers of financial accounting during the fourteenth and fifteenth century did not receive the due attention. This section aims at presenting views regarding the anticipated versus the unanticipated consequences of accounting systems development.

Anticipated Consequences

There is not much debate that accounting in general is a useful business tool. From Italian merchants in medieval ages to multinationals in the twenty-first century, accounting has evolved in application. Since the medieval ages, basic accounting techniques provided enterprises with an organized tabulation of accounts and the relationships among them, an efficient method of tracking funds owed to and by others, and a clear representation of how a specific business operation affects a firm. Several researchers contend that the intended consequences were (depicted in figure 1): to allow the business owner to keep track of his dealings through recording details of transactions, to hold agents accountable, and to objectively determine fair share of revenue in transactions that included partners (Carruthers and Espeland, 1997).

Even though early accounts were narrational, with all kinds of information presented, they served mainly to assist the memory of the businessman. The double-entry method could save time and prevent disputes by reducing suspicion, ignorance, and memory lapses. The audience for the account was the proprietor or record keeper alone, to whom the account answered the following two questions: "What do I own? What have I done?"

Further challenges for financial accounting came about due to business activities growing complex, in terms of value and parties involved. Accounting techniques were gradually refined to provide an objective assessment for the effect of ventures on a merchant's capital and profit motive. Even though profits were a minor concern at these early times, the maintenance of capital and improvement of a country's wealth were major ones. According to Carruthers and Espeland (1997), the audience for the accounts was separate from the record keeper and the question that these accounts answered was: "Am I being cheated?"

Through the use of primitive accounting techniques, single merchants were able to unite their resources in partnerships and trade collectively overseas for better bargains in the name of the partnership. They pooled their resources without fear of losing track of their invested capital or confusing percentages of ownership. An account in each partner's name recorded the partner's investments, withdrawals and share of profits or losses, thus providing a readily available balance. When a partner wanted to terminate his association with the partnership, he would withdraw his known amount of capital, which was recorded in his account and maintained separately from partnership operations (Schumpeter, 1939). The continuity of the business was therefore not upset, lending more credibility to the merchants and their venture and gaining more confidence from banks and customers.

Accounting also provided merchants with the ability to invest in several ventures and trade with several merchants without fear of losing money due to confusion. Merchants adapted accounting techniques to include partners' personal accounts. Their question was: "What is my fair share of the Revenues?" Additionally, the proliferation of joint stock companies in the nineteenth century still created wider audiences for accounts, ones who are even less familiar with the operations of a company. Further, investors diversified into several ventures, making knowledge of these ventures less likely. They now relied on accounts to provide needed information (Yamey, 1962).

During the nineteenth century, two important changes took place that influenced both accounting theory and practice. First, the industrial revolution brought the need for permanent, large-scale, fixed capital investment, which complicated the accounting practice because consistent allocation of expenses and revenues to artificial accounting periods became necessary. Second, depreciation was incorporated into the valuation of assets leading to a more arbitrary determination of income (Chatfield, 1977).

Moreover, the proliferation of joint stock companies in the nineteenth century made it necessary to keep track of capital and distinguish it from income, in order to avoid the reduction of invested capital. Governments in the UK and the US intervened to ensure the maintenance of capital, the preparation of fair financial statements and the regular audits of the accounts by independent auditors. Accounts now were *legally* required to answer the questions: Are investors being cheated? Is capital being maintained? (Carruthers and Espeland, 1991). Later, accounting also started serving regulatory compliance purposes, including tax reports.

The above arguments suggest that accounting has developed gradually to its sophisticated form known today. Although it started as primitive documentation

Figure 1. The need for accounting techniques in modern societies

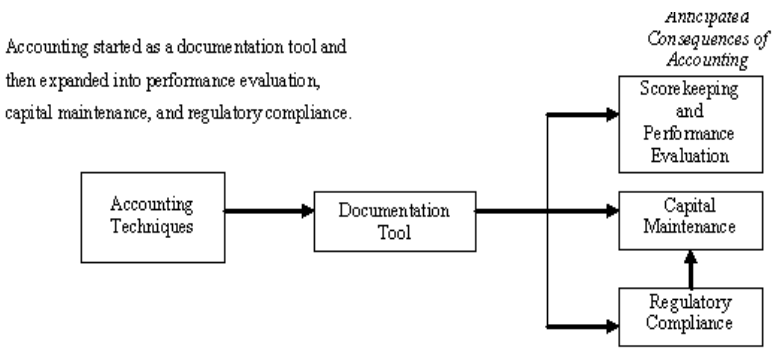

Figure 2. Accounting techniques, reinforced by institutional factors, achieve several functions that help form the reality seen by users of financial statements who attempt to shape accounting techniques through the institutions

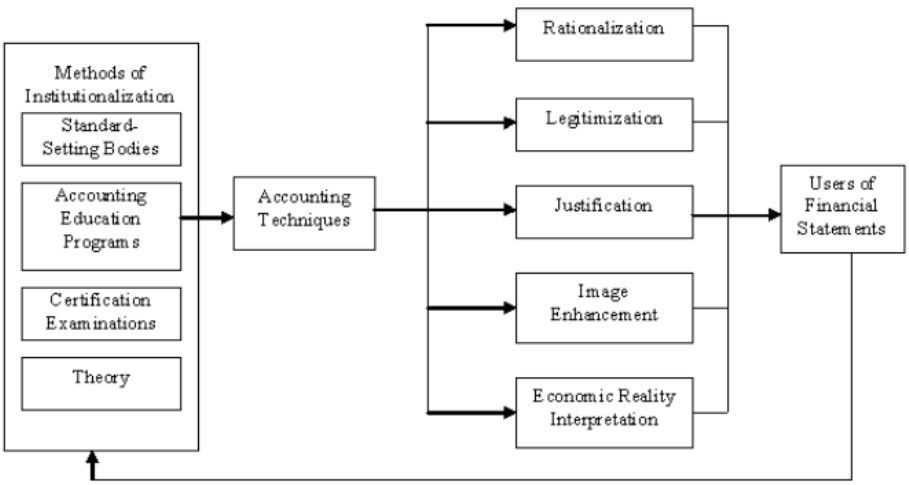

tool, it developed incrementally as businesses started growing more complex, to serve as a tool for capital maintenance, performance evaluation, and regulatory compliance. The following propositions are made:

Proposition 1: Accounting systems were mainly used in the fifteenth and sixteenth century as a documentation tool.

Proposition 2: Accounting systems evolved during the period between the seventeenth and twentieth centuries from a documentation tool to performance evaluation, capital maintenance, and regulatory compliance tools.

Unanticipated Consequences

Weber (1958) argues the eighteenth century merchant did not *intend* to build the modern, well-integrated web of institutions, ethics, and technologies. The theme of Weber's (1958) thesis can be equally applied to the development of accounting as an information system. Accounting has been in existence for some time and was claimed to have set in motion the wheels of development for several institutions. Two of the unintended consequences of accounting systems development are as follows. First, accounting helped enhance rationality, maximize investment outcomes, and extend the development of capitalist production methods. Second, the institutionalization of accounting took place through the development of a whole infrastructure of educational and professional bodies (see figure 2 below).

1. Accounting as a Key to Enhance Rationality and Maximize Wealth

a. The Technical Role

Prominent social theorists claim that accounting played a key *technical* role in enhancing rationality and furthering the development of capitalist methods of production. "The most general presupposition for the existence of this present-day capitalism is that of rational capital accounting as the norm for all large industrial undertakings which are concerned with provision for everyday wants" (Weber, 1927). Accounting allows capitalists to evaluate rationally the consequences of their past decisions and to calculate current and future resources. Weber argues that rational capital accounting, along with calculable law, rational technology (mechanization), free labor, and the commercialization of economic life is an element in a general process of rationalization that is both the antecedent to and the consequence of modern capitalism.

Weber's argument is consistent with his thesis in "*The Protestant Ethic and the Spirit of Capitalism"* (1958), which concedes that rational economic behavior was essential for Protestants who sought salvation. This rational behavior could be attained only if the individual accumulates wealth through careful, rational investment. Accounting steps in by providing a means of measuring alternative investment opportunities and efficiently managing daily business activities.

Schumpeter (1950) argues that economic activity in general brings about a rational attitude, stating that "The capitalist practice turns the unit of money into a tool of rational cost-profit calculations, of which the towering monument is double-entry bookkeeping". Also, Sombart (1953) argues that capital, that amount of wealth which is used in making profits and which enters into the accounts, did not exist before double-entry bookkeeping. Through double-entry bookkeeping possibilities were created and the ideas of acquisition and economic rationalism were developed.

Weber believes that for-profit enterprises would not survive if they were not sufficiently profitable (Weber, 1978). Those enterprises that adopted the double-entry method were at a technical advantage over those that did not and, in the long run, the latter would be driven out of the market. In addition, accounts provide the necessary information to measure and compare the alternatives of a certain choice, allowing individuals to estimate the probabilities of success and the possible payoffs associated with various alternatives (Carruthers and Espeland, 1991).

Several other researchers have advocated the role of accounting in investment evaluation. Accounts provide technical information on the outcome of previous business actions (Littleton and Zimmerman, 1962), and hence an accurate assessment of the relative success of particular investments. Accounts provide a businessman with a record of current assets, which indicates the economic means at his disposal and they help make decision making more rational and so contribute to the maximization of profits (Chambers, 1966). One can safely assume that the original developers of financial accounting did not have investment decision-support as one of their main goals for accounting development.

b. The Rhetorical Role

Accounting was also used as a tool for projecting signals about an individual or an organization. The efficacy of pious invocations in establishing legitimacy and enhancing credibility was recognized. The account books of Italian merchants invoked the name of God for centuries. At times where papal prohibition on usury was a concern for merchants, double-entry bookkeeping was used to explicitly document the balanced nature of firm transactions (Carruthers and Espeland, 1991). Thus proving the legitimacy and justness of the business and the moral legitimacy of profits.

In addition, double-entry bookkeeping was recognized as a vehicle for self-transformation, because it required curiosity and intelligence. Failure to adhere to this method, in fact, aroused suspicion regarding one's character and resulted in degeneration. Businessmen who had to rely on others to help them manage their affairs required them to know the principles of the double-entry system and employ it in a systematic, standardized, and tabulated manner. Self-transformation was conductive to capitalist activity. Weber (1956) argues that caution, informed decision-making and the avoidance of speculation, values promoted by double-entry bookkeeping, became celebrated values and a crucial feature of advanced capitalist societies.

Accounts have been manipulated to convey a desired impression, legitimate someone's performance, or strengthen a particular position. The dependence of businessmen on credit means they are especially vulnerable to expectations and standards of other businessmen because one's credit depends on one's reputation. The extent of careful record keeping was a decisive factor in building one's good personal reputation. At early times, double-entry accounts documented a man's frugality and diligence (Earle, 1989). So individuals held accurate records to obtain credit at favorable rates. Managers always try to negotiate numbers that will make them look good. Accounts are also used to justify decisions and to excuse mistakes (Watts and Zimmerman, 1979). Income numbers are sometimes artificially smoothed to enhance retrospective appearance of predictability and certainty or to signal expectations (Barnea, Ronen, and Sadan, 1976).

Thompson's (1967) argues that organizations act to reduce the uncertainties surrounding them in the complex real world through such actions as sealing off their technical core and reducing dependencies on others. Organizations use their technical knowledge of accounting for "window-dressing". Accounting was also used to predict future environmental factors that impact an organization (e.g. future sales, expenses and demand).

Double-entry bookkeeping reduces the complexity of the economic reality and presents decision makers with a simple "bottom-line" that does not reflect all possible interpretations and judgments. As March and Simon (1958) put it, accounting is a cognitive device that influences the "premises of decision making", by determining the kind of information that was available to various audiences.

c. Accounting and Impact on Rationality

Skeptics of the importance of accounting argue that little theoretical change took place in the 300 years after Pacioli and that the techniques of double-entry took a long time to diffuse throughout Europe and become rigorously adhered to by most practicing businesses (Winjum, 1972). Ideally, double-entry facilitates the "economic rationality" described by Weber, Schumpeter, Sombart and modern accountants. In practice, however, the full potential of double entry was rarely exploited (Connell-Smith, 1951). Accounts were infrequently balanced (Coleman, 1963).

Yamey (1956, 1962, 1964) cautions against reading modern economic conceptions of profit and capital into pre-nineteenth century uses of double entry. Not only were such modern concepts of the organizational economy still emergent, but also the institutions of the marketplace themselves provided information adequate for the needs of the time. Virtually all economic activity in that earlier era was controlled either by market transactions or by administrative fiat, which meant that prices and rules provided the information needed for rational decision making. Account books were not an important source of information for economic decision making. They were kept primarily to provoke the memory, support claims in court, and sometimes as a way to handle negative numbers in the arithmetically unsophisticated era (Winjum, 1972). Yamey believes that the arguments of Sombart and Weber, giving strong credit to accounting for stimulating the "rationalistic pursuit of unlimited profits as an essential element in the capitalistic spirit", are overestimated.

These criticisms are consistent with Chandler (1977) who believes that until late in the nineteenth century, the invisible hand of market processes did most of the coordination and product pricing. Accounting was not seriously called for until modern firms, resulting from vertical and horizontal integration, appeared and the visible hand of managerial administration took over the coordination. Only then, accounting emerged as a powerful tool for resource allocation and control. The following propositions are needed to test the above arguments:

Proposition 3: In its technical sense, accounting was used as a tool for economic rationalization, investment outcome maximization, and production method development.

Proposition 4: In its rhetorical sense, accounting was used as a tool for self-transformation, legitimization, justification, image improvement, and selective information presentation tool.

2. The Institutionalization of Accounting

On the other hand, accounting is now an established discipline. The organizations, certification and qualification processes, education programs, and theory that underlie the practice of accounting today are consequences that were not envisioned by the early developers. The early institutionalization of accounting was produced by two things: education and mercantile networks (Carruthers and Espeland, 1991). The specialized education of merchants, either in schools or in apprenticeships, familiarized them with the double-entry method. Commercialization helped diffuse the double-entry method from Italy over the rest of Western Europe. The network of businessmen helped foster the formal adherence to this method, because reputation and creditworthiness within the business community were necessary for solvency and were maintained with the help of one's accounts. In the twentieth century, the dependence on accounting became very strong. Organizations can neither manage their daily operations nor design strategic plans unless a reliable accounting system provides accurate and useful information.

Standard-setting organizations, certification, and education programs were not intended as institutionalization mechanisms by the early developers of accounting. These institutions did not emerge until late nineteenth century, and since then they are in constant evolution. Early developers of financial accounting were more interested in keeping primitive records (e.g. the Journal) where transactions were recorded in a narrational form. They were not interested in preparing financial statements in their current format and thus did not conceive of standards that would govern the format and content of these statements. The following proposition is suggested:

Proposition 5: Early practitioners of accounting were not concerned with creating universal standards as much they were concerned with crude recording of daily events in journals.

CONCLUSION

This paper aims at objectively viewing the consequences of the development of accounting as a system. Testing the propositions empirically may substantiate the different arguments regarding intended versus unintended consequences of the development of accounting. Based on the findings, researchers might be interested in (1) identifying a pattern of accounting development and relating it to a particular practice or institution, such as stock markets, multinationals, among others. This might prove very important to a field such as international accounting, where researchers are struggling to attribute differences in accounting practices around the world to certain events or environmental factors. It may also be important to study (2) why the unintended consequences were described as closely associated with accounting, explaining more the position of accounting in a macroeconomic setting.

Further, the degree of development of accounting at different times can be an important factor in analyzing the decisions of investors or organizations. Accounting, in its rhetoric role, may have had a stronger impact than its technical role, although the latter was studied much more extensively. Also, the resolution of the conflict of opinions between Yamey and Weber and Sombart will provide a more clear indication of the relative strength of accounting as one of the building blocks of capitalism.

Conceptual Design for Personalized Situation-Aware Information Seeking and Retrieval Services in Data Intensive Domains

Nong Chen, Delft University of Technology, 2628 BX, Delft, The Netherlands; E-mail: nongc@tbm.tudelft.nl

ABSTRACT

Personalized information seeking and retrieval is regarded as the solution to the problem of information overload. Personalization algorithms and techniques are maturing, but their centralized implementation solutions are becoming less efficient for dealing with ever changing user information needs in data intensive, dynamic and distributed environments. In this paper, we present a conceptual design for personalized, situation-aware information seeking and retrieval services, which offers a new way of thinking about the retrieval of personalized information for time critical applications.

Keywords: *personalization, information seeking and retrieval, situation awareness, service-oriented architecture*

1. INTRODUCTION

Today information is distributed globally. Organizations and information seekers can now access information anywhere anytime via wired or wireless networks. The coordination of organizational processes distributed over various independent locations has improved significantly. However, this increase in information availability cannot guarantee that users are able to retrieve and access all the information that specifically meets their needs. Organizations have to operate in increasingly complex environments, where, dynamically changing information structures, and distributed heterogeneous data resources make it increasing difficult to find the 'right information' at the 'right level of details' in the 'right format' , and at the 'right time'. The problem is amplified in domains such as crisis response networks, medical and healthcare networks, where the accuracy of the retrieved information and obtaining it in a time critical manner are extremely important.

Personalized information seeking and retrieval is regarded as the remedy when it comes to relieving the problem of information overload. Research in the field mainly focuses on developing models, methods and tools that can be used to adapt information content and its presentation to the individual user's information search goals and preferences. Today, personalized techniques are able to provide feasible solutions to the problem of inappropriate information overload at technological level ranging from simple user-controlled information personalization to autonomous system-controlled adaptation [Mizzaro & Tasso, 2002]. Many academic and commercial off-the-shelf information search services and tools are available to filter out irrelevant information effectively, and to rank and present information in a user preferred way.

Although these personalization techniques and algorithms are maturing, their centralized implementation solutions are becoming less efficient for supporting the rapidly changing information needs in dynamic and distributed environments. Changes in organizational or personal information needs may lead to a need to redesign a complete application. Therefore, it is necessary to design personalized information seeking and retrieval application in an agile and flexible way, to provide personalized information in a time critical manner, which can be adapted easily to meet changing information needs. Our increasing understanding of component-based design principles, service-oriented architectures and other aspects of complex information retrieval achievements provide the possibility to achieve this objective. The modularization of complex systems into components, or services that interoperate primarily via exchanging standardized messages at interfaces has become IT technology evolution. All these advances in IT have stimulated a new requirement concerning on modeling and designing personalized information search services in a dynamic and distributed environment to satisfy high-level functional requirements for personalization flexibly in one hand, and to use the specific personalization techniques, algorithms and available technology infrastructure to realize these requirements on the other. Building on the advantages of a service-oriented approach, we propose a new conceptual design for personalized, situation-aware information seeking and retrieval services. We believe this approach provides a new way of thinking about the retrieval of time critical, personalized, situation-aware information in data intensive domains.

Our conceptual design is presented in section 2. We tested and evaluated our conceptual design by applying it in a real-life case. The results are presented in section 3. Our conclusions and an outline for future work are presented in section 4

2. CONCEPTUAL DESIGN

2.1 The Concept of Information Seeking and Retrieval

Information seeking and retrieval is a human-IT system interaction activity in the sense of an IT supported environment. According to research into user information behavior, users' information needs are stimulated when they lack the information required to solve a problem [Wilson, 1998]. Problem solving occupies an important place in the research on information seeking and retrieval [Gaslikova, 1998]. [Gaslikova, 1998] summarizes problem solving in the context of information seeking and retrieval in three stages: problem identification, query formulation, and validation of received information. She claims that any information seeking and retrieval system has to provide suitable software tools for realizing each stage of a problem-solving process. Taking this into account, we regard information seeking and retrieval as a user-system interaction process. It comprises three sub-processes shown below.

- *The information seeking process*: This is the process used, generally or precisely, to identify the problem that initializes a user's information acquisition activity. This covers the question: what is the problem?
- *The information searching process:* This is the process used to identify and structure the specific information required to solve the problem, and to find the locations of required information. It concerns on the questions what information is required? Where to find the required information? And how to access to it?
- *The information obtaining process:* This is the process used to obtain the required information from the various resources and to return the information back to the user.

Users validate the received information during the interaction process with the system.

2.2 Personalized Information Needs

Personalized information needs play an essential role in determining the relevance of any delivered information. The literature shows a deepening understanding of the concept information needs and its role in the information seeking and retrieval. [Taylor, 1968] and [Belkin, 1982] argue that users' characteristics, e.g. users' personality, knowledge, personal interest and preferences etc., determine their information needs. [Wilson, 1994] and [Niedźwiedzka, 2003] shows that social placement or a professional role, e.g. users' professional roles connected with their occupied positions, are the most important determinants of users' information needs. [Wilson, 1999]'s problem solving model abstracts the process of problem solving from context.

Since our research is confined to domains such as crisis response and management networks, healthcare and medical networks, etc., we argue that individuals' personal interests and preferences may not strongly influence their information needs. Although different users in these contexts may have different knowledge levels about their professional role, we consider that their knowledge will be inherent to the professional role they play within their work situations. Therefore, we regard the professional roles users adopt in the society to be one of the most important factors influencing their specific information needs although their personalities and/or knowledge may influence their search strategies.

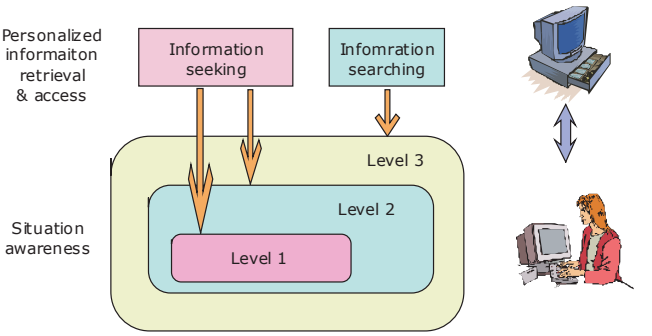
However, users' roles are not sufficient to reflect their actual needs. Information needs change as the users' situation changes, and this directly influences users' judgment regarding information relevance. Role-based information needs are relatively stable and predictable, while an ongoing situation may change these information needs. When users are able to be aware of their situation, in which they are involved, the users are able to identify their problem, and to formulate their information needs. Based on our previous arguments, we believe that personalized information seeking and retrieval is triggered by users' role-based perceptions of a problem they need to solve. We therefore define personalized information seeking and retrieval as an information acquisition process, aimed at providing users, with their role relevant personalized information based on dynamically and automatically perceiving and responding to the users' situations.

2.3 Situation Awareness

2.3.1 Situation Awareness in the Context of Information Seeking and Retrieval

The concept situation awareness (SA) is usually applied to operational situations, especially in the fields of artificial intelligence, agent-based systems, crisis response and management, military planning, etc. [Endsley, Bolte & Jones 2003]. Research in the field of SA focuses mainly on helping persons to be aware of their situations so that they can make informed decision about future actions [Endsley, Bolte & Jones 2003]. [Endsley & Rodgers, 1998] formally defines SA as "the perception of elements in the environment along with a comprehension of their meaning and along with a projection of their status in the near future" [Endsley & Rodgers, 1998]. This definition breaks down into three separate levels [Endsley, Bolte & Jones 2003].

Figure 1. Information seeking and retrieval to support SA process



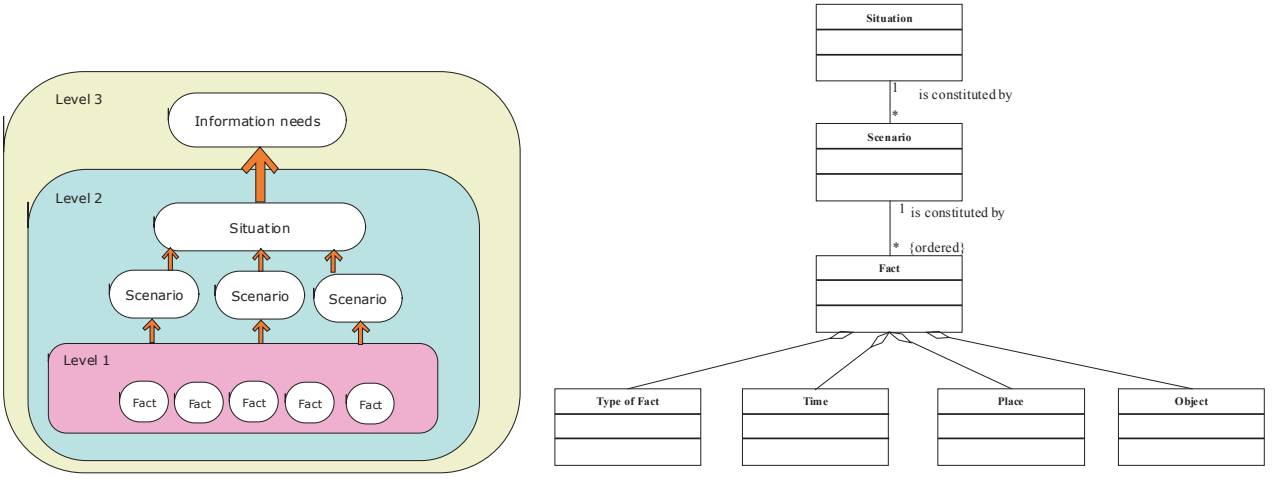
- Level 1—perception of the elements in the environment
- Level 2—comprehension of the current situation, and
- Level 3—projection of future status.

These three levels reflect the process of how people are aware of their situations mentally. Although today's advanced IT technology can replace a huge amount of information processing work, until now, it cannot replace a human's mental information processing process. We regard the information seeking and retrieval provided in our approach as a means to provide support for the users' SA process. We claim that our definition of information seeking and retrieval can be used to provide suitable support for all three steps of SA defined by [Endsley, Bolte & Jones 2003] shown in Figure 1. Levels 1 and 2 of [Endsley, Bolte & Jones 2003] are supported by the information seeking process, aimed at identifying the problem. Level 3 is supported by the information searching process, aiming at defining what information is needed.

2.3.2 Situation Model

Users perceive the problem they need to solve when their situation is described clearly. We choose to use the term situation since it can imply dynamic changes in users' surroundings, the influence of changes on the users, and the users' stable or permanent surroundings. Situation is defined in the [Merriam-Webster] as "the relative position or combination of circumstances at a certain moment". In the [Dictionary], situation is defined as "the combination of circumstances at a given

Figure 2. SA process



(a) (b)

moment; a state of affairs". From these definitions, we can see that, a situation consists of a concrete story describing where what happened, when, who are involved, and their relationships.

It is not feasible to specify all possible situations in the context of information seeking and retrieval for any domain. Historical usage data is required to detect situations. This argument is also used in [Endsley, Bolte & Jones 2003]'s three levels of SA model, where an unknown situation is derived from known information. The question, what historical data or information is required to be collected at different level of the SA processes for the users to realize their situation, becomes important; and can be reformulated as what information can be used to describe and model the situation. Based on the [Endsley, Bolte & Jones 2003] 's three levels of SA model, we need to perceive the elements in the environment (Level 1 in the SA) as the information that can be used to comprehend current situation (Level 2 in the SA), in order to project future status (Level 3 in the SA).

The first step in the SA process is to perceive the elements in an environment. The information elements that can be directly perceived describe the things that are known to have happened or to exist, i.e. the concept fact. Therefore, the information describing those things that have happened or existing things can be abstracted and conceptualized as a combination of 'type of fact', 'time', 'place' and 'involved objects'. The description of a fact can be made by combining 'type of fact' and any or all other three concepts.

Perceived facts are only direct observations made in the environment. They cannot provide narrative descriptions of users' situation. Therefore, facts do not supply sufficient information to understand a situation fully. To support the second level of the users' SA, we use the concept scenario in our research. We define *scenario* as a *short story reflecting a situation*. In this scenario, known outcomes are described, in conjunction with the casual relationships of a group of detected facts. Unknown scenarios can be derived by combining known facts, or from known scenarios. The SA process in our research is presented in Figure 2 (a), and the situation model is presented in Figure 2 (b).

2.4 Service-Oriented Approach for Personalized Information Seeking and Retrieval

A service-oriented approach provides a design principle for the handling of complex, dynamic and distributed information systems. Personalization can be provided by composing existing services, which are implemented on the basis of well-defined service behaviors and interfaces. This design principle is suitable for a distributed, dynamic and heterogeneous environment. According to the service-oriented system design principle, we assume that a solution for the detected information needs in users' specific situations can be quickly reconfigured by using a composition of encapsulated, replaceable and reusable services [Stojanovic, Dahanayake & Sol, 2004]. Based on sub-sections 2.2 and 2.3, we can now formulate the complete framework for personalized, situation-aware information seeking and retrieval, as shown below in Figure 3.

2.4.1 The Concept Service

According to the literature [Papazoglou, 2003, Stojanovic, Dahanayake & Sol, 2004, Douglas, 2003. etc], in the initial phase of our research, we informally defined the term *service* as "*A service is planned and designed in such a way that it has a specific functionality and it is very simple, but together they perform relatively complex tasks*". This informal definition gives the basic requirements for defining a service in the service-oriented approach. A service must have a specific functionality. As mentioned before, the solution for a detected problem is constituted of a service or a combination of services. Therefore, the specific functionality a service must have in our design is that it provides information. As a result, we simply define the services that consume information and provide information as information services. We assume that the solution to satisfy user's information needs is constituted by an information service or a group of information services. The information provided by a group of services is the collective outcome of all involved information services instead of a simple combination of outcomes of each service. Information services can be assembled and composed by smaller information services. At the level of a simple information service, its required operation and output is realized by grouping a specific collection of information search software components. We present the concept of service in Figure 4.

Figure 3: A framework of personalized situation-aware information seeking and retrieval

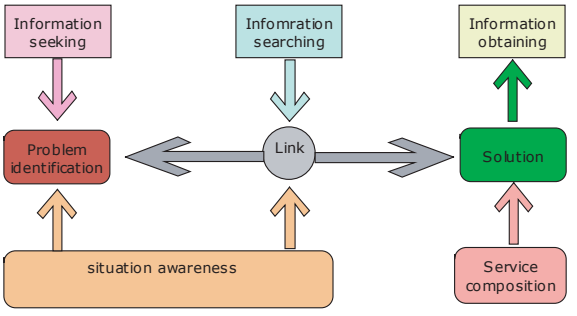


Figure 4. The concept of information service

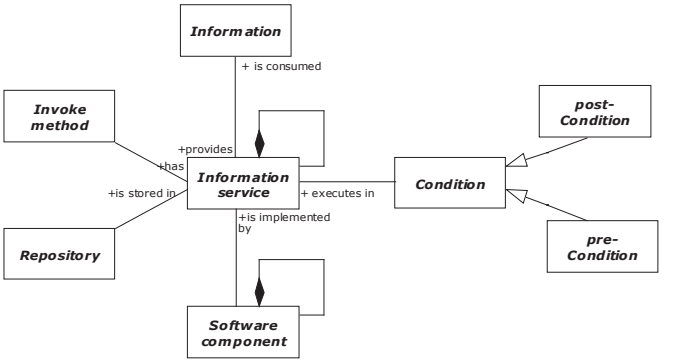


2.4.2 Task Model

After the appearance of task-oriented information seek and retrieval in the 1990s [Vakkari, 2003], the concept task has been diligently used in the context of information search as [Byström & Hansen, 2005]. The concept task has gained increasing attention as it provides an important cue to help us to understand why people seek information, what type of information they need, and how they are going to use the information [Byström & Hansen, 2005; Taylor, 1991]. Our definition of a task is mainly based on the research of [Vakkari, 2003; Byström & Hansen, 2005; Vakkari, 2003]. We regard *a task to be a specific piece of work, in which a person or a group of persons undertakes a series of actions in a situation*. Defining a task as a piece of work indicates that it has a performer, a meaningful purpose, and an undertaken context [Hackman, 1969; Byström & Hansen, 2005]. This is a definition, which emphasizes the conceptualizing of tasks more from the point of view of the actors and the social context of the task performance [Checkland & Holwell, 1998, Suchman, 1995].

We define *the organizations or organizational units as actors*. Each actor has a list of professional roles. A role is defined in [Merriam-Webster] as "a function or part performed especially in a particular operation or process". Obviously, role is a function relevant concept. *The professional roles of an actor are defined in terms of functions an actor must provide.* Therefore, actors are exclusive, and based on the functions they provide, i.e. their professional roles. A task is performed when an actor adopts one of its professional roles. A task can be composed of smaller tasks. At the level of a simple task, it is constituted of a series of interconnected actions. A task is undertaken in a context, i.e. the situation, where an actor is required to adopt one of its professional roles. According to the definition of task in our research, tasks are required to be identified from an actor's professional roles, i.e. from the functions an actor can provide. However situation is a dynamic concept, as perceived by the SA process defined in section 2.3.2. It s not feasible to define all tasks corresponding to a specific situation. Instead, the tasks can be defined in facts, which are more concrete and tangible. Since a task can be composed of smaller tasks, required tasks in a detected situation can be composed of sub-tasks identified using the relevant facts. Tasks are undertaken in a process to formulate the solution for an existing fact.

Based on the concepts defined in the previous subsections, we formulate a meta-model of personalized information seeking and retrieval on the basis of service-oriented system design principle. The meta-model is shown in Appendix 1.

3. CASE STUDY

We tested the conceptual design by applying it in a real life case. The case study presented in this section was taken from an ongoing EU research project. The harbor described in this case study is one of the largest and most important harbor infrastructures in the world. Global collaborations for natural disasters recovery and anti-terrorism cooperation have encouraged management at this harbor to take put in global information networking, designed to share information with other crisis experts and professionals. The harbor management intends to build a more flexible and extendable information platform to provide all authorized and involved actors with access to their role-based personalized, situation-aware information to facilitate the performance of their tasks during a crisis response.

Since the development of a complete system is not yet feasible, due to the difficulty of building trust between the various crisis relief/response organizations, and getting them to share their information, we built an early prototype demonstration to show that it would be possible to build such a service-oriented platform to provide personalized, situation-aware information seeking and retrieval services for crisis response situation.

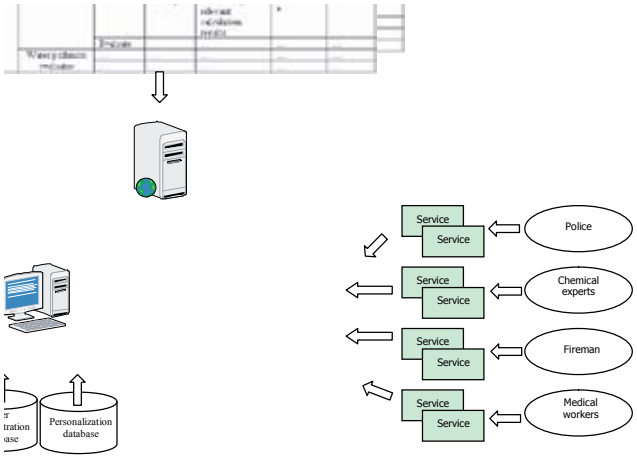
We utilized three computers in our prototype implementation shown in Figure 5, representing the service consumer, service provider, and service broker in a SOA respectively. The information provided by the actors involved was encapsulated as information services. We believe there are four main actors in crisis response: police, medical experts, fireman, and chemical experts. We implemented several information services for these 4 actors as jini services in our prototype. These jini services were required to be registered on a jini lookup server. The requested registration information is shown in the table in Figure 5. We used a simple example from a chemical expert to show what, and how, the required information on information services is registered in the jini lookup server. In the client PC, we use Liferay 4.0[1] as the portal software, and embedded Tomcat 5.0[2] as the web server to build the 'crisis response and management portal'. We built two databases, a user administration database and a personalization database, which were used to support personalized information seeking and retrieval applications running on this portal. User's role-based profiles, stored in the user administration database, were used to control their information access. The personalization database was built based on the meta-model presented in Appendix 1. Previous existing crisis situations, their constituting scenarios, scenarios' constituting facts, facts' solutions, etc, were stored in the tables of situations, scenarios, facts, solutions and tasks as the historical information in the personalization database. The personalization database was implemented in MySQL[3].

Tasks are keys that are used to search for the required information services provided by the different organizations. When a task is selected, it generates a service search template, which is constituted of three attributes, actor, role and task. A selected task generates this service search template by filling in the actor name, role name and task name. The service search template will then be sent to the jini lookup server to look for the relevant information services. All the information services of a selected task are returned to the user. Information service name, information service description, service status and location are also returned to the user. It is the users' work to figure out their required information services based on the returned service information.

4. CONCLUSION & FUTURE WORK

In this paper, we presented a new way of thinking of retrieving personalized information based on service-oriented design principle. Our situation model is capable of reflecting and inferring the unpredictable and dynamic situation users are facing. Our task model is capable of personalizing users' information needs in a dynamic situation according to their professional role(s). The combination of the situation model and task model allows users' role-based personalized, situation-aware information needs to be sufficiently inferred, and well structured in a meaningful way. Simultaneously, applying service-oriented design principle in our conceptual design allows us to realize independent service implementation and service modeling, and quickly to configure information acquisition applications

Figure 5. Prototype architecture



to satisfy users' dynamic information needs by choosing the required services. We believe that our conceptual design provides a possible solution to building a bridge between high-level functional requirements and low-level technology availability.

The next step of our research is to focus on how to reduce the time to action in a time critical situation using an effective information coordination service for situation aware process orchestration [González-Rivera, 2006].

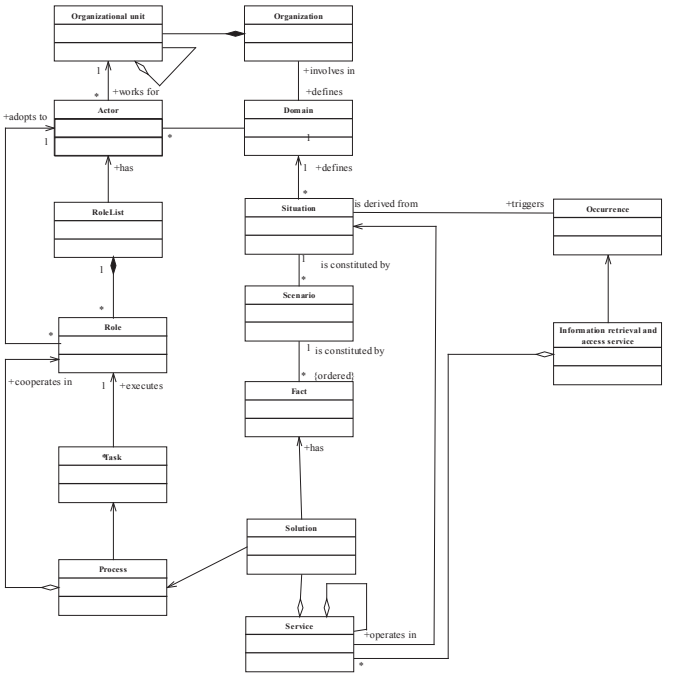
APPENDIX 1



Achieving Business Benefits from a Global ERP Implementation

Lorraine J. Staehr, La Trobe University, Australia; E-mail: l.staehr@latrobe.edu.au

ABSTRACT

This paper provides an understanding of the implementation, use and business benefits achieved from a global ERP system by an Australian manufacturing organisation. Using an interpretive case study approach ERP implementation and use were examined retrospectively as processes within context over time. The business benefits achieved were assessed using Shang & Seddon's (2000) ERP business benefits framework. The business benefits achieved are explained in terms of the ERP implementation success factor literature, and themes relating to the use of the ERP system that were identified from the empirical findings.

INTRODUCTION

For more than ten years there has been an increasing industry trend to buy off-the-shelf software rather than custom build software to provide an integrated solution for the business transaction processing requirements of organizations. These Enterprise Resource Planning (ERP) systems are large, complex software packages that provide an integrated real-time environment based on an enterprise wide data model with a set of software applications which allow processing of all the data of the organization (Bancroft, Seip and Sprengel, 1998). Collective investment by organizations worldwide in ERP systems since the early 1990s has been in the order of many billions of dollars. However there have been widely varying outcomes from ERP system implementations with a high degree of risk associated with implementation and use.

To date most ERP research has concentrated on the implementation project itself. However the primary focus of this research was on the post-implementation period i.e. the use of the ERP system. The implementation and use of an ERP system was viewed in this research from the perspective of organizational change (Davenport, 2000). The specific research question addressed was:

How and why do business benefits evolve during ERP system use?

The rest of paper begins by placing the study within the existing ERP literature. A brief outline of the research design follows, including details of the characteristics of the case study organization. The results are presented and discussed, followed by concluding remarks.

BACKGROUND

Four strands of the existing ERP literature provide the background to this research. The first is the literature that has proposed ERP life cycles (e.g. Markus and Tanis 2000, Parr and Shanks 2000, Ross and Vitale 2000). Markus and Tanis (2000) propose four phases in the ERP life cycle: "Chartering", "Project", "Shakedown" and "Onward and Upward". The Chartering phase is an initial planning phase however there is some evidence to suggest that in practice some organizations omit the activities in this phase (Markus, Axline, Petrie and Tanis 2000). The Project phase involves getting the system up and running in one or more business units in the organization. The extent of planning undertaken for the ERP system by the organization, and any effects of the Project phase, for example, time relative to schedule, cost relative to budget and functionality relative to original proposed scope (Markus et al. 2000) influences the business benefits gained. The Shakedown phase starts when the system goes "live" and finishes when normal operations are achieved. The final phase, Onward and Upward, starts when normal operations are achieved and lasts until the system is replaced. The research described in this paper, although focussed on the Shakedown and Onward and Upward phases which together make up the post implementation period, examines the influence of the previous phases on the business benefits achieved by the organisation.

The second group of ERP literature has concentrated primarily on the Project phase of ERP systems and proposed critical success factors (e.g. Holland and Light 1999, Parr, Shanks and Darke 1999) or "recipes" for success with ERP implementation (e.g. Markus and Tanis 2000). Some of these studies have included issues or problems and/or business benefits achieved in the Shakedown and Onward and Upward phases (e.g. Markus et al. 2000, Chang and Gable 2002). And a third strand of the literature has developed models for assessing the business benefits achieved with ERP systems. There are two viable measurement models for assessing the business benefits of ERP systems in use. Compared with the Gable, Sedera and Chan (2003) model, the Shang and Seddon (2000) business benefits framework was developed using data from a much larger number of organizations (233) from different industry sectors. Shang and Seddon's (2000) framework for assessing the business benefits of ERP systems includes five dimensions of benefits: operational, managerial, strategic, IT infrastructure, and organizational, with multiple possible benefits within each dimension. It also has the advantage of assessing business benefits from a single perspective i.e. that of the business managers. This benefits framework was used to assess the business benefits achieved during the post-implementation period in the manufacturing company studied in this research.

Finally, some studies have looked at the ERP system in use in order to explain the business benefits achieved from ERP systems. Markus and Tanis (2000) and Markus et al. (2000) related the business consequences to events in the earlier ERP life cycle phases and to external influences due to changing business conditions. However, there is little information provided on the internal organizational influences on the business benefits, such as changes to organizational structure and culture. Neither is there any attempt to assess the "success" of the individual organizations studied.

In a study of manufacturing organizations Ross and Vitale (2000) identified four obstacles to achieving business benefits from ERP systems. They were failure to plan and implement performance metrics for the new system, inadequately resourcing the Shakedown and Onward and Upward phases, no improved management decision making and inadequately addressing resistance to change. Two studies have looked at the business benefits from ERP systems and the factors that contribute to them. The first study (Davenport, Harris and Cantrell 2004) developed a statistical model that identified three main factors (integrate, optimize and informate) that predict perceived business value to the organization as a whole. In contrast Gattiker and Goodhue (2005) focused on benefits from ERP systems at an individual manufacturing plant rather than the organization as a whole. The Gattiker and Goodhue (2005) model identified four factors contributing to plant level benefits in manufacturing organizations: interdependence (between plants), differentiation (i.e. between plant differences), time elapsed since implementation and customization. Both the Davenport et al. (2004) and Gattiker and Goodhue (2005) models are predictive rather than explanatory. This study differs by aiming to understand and explain how and why the case study organization achieved business benefits from its ERP system.

RESEARCH DESIGN

An interpretive case study method was used to answer the research question. The case study organization (ManB) had begun implementation more than four years prior to data collection. Since business benefits take time to accrue it was expected that with this time frame business benefits from the ERP system would be clearly evident.

Table 1. Background data for the ManB ERP implementation

Motivation for Implementing SAP	Strategic business reasons
Cost of Implementation	~AUD$25 million
Sites	Multiple (65 sites in 5 countries)
Modules	FI, CO, MM, PP, SD, AM
Version of SAP implemented	3.0F , then upgrade to 4.6B
Implementation Strategy	Small Bang (all modules at one site, or small group of sites, at a time)
Implementation Approach	System replacement
Implementation Partner	Yes
Business process reengineering	No
Customisation?	Yes, but minimal
Business Restructuring	Accounts payable and accounts receivable shared services after go-live
Was project completed on time, within budget and within original scope?	Yes
Number of users	~1000
When were the business benefits assessed?	Four years after the first site went live. One and a half years after last site went live i.e. full implementation.

An overview of the ManB ERP implementation is shown in Table 1.

The theoretical framework that underpinned data collection was adapted from Orlikowski (1993). The Shang and Seddon (2000) ERP benefits framework was used to assess the business benefits achieved. The adapted Orlikowski framework and the Shang and Seddon (2000) framework provided the main basis for the semi-structured interview protocol.

The primary source of data was from in-depth interviews with key informants chosen because of their position within the organization. The interviewees included a senior manager (General Manager IT and Business Solutions), the Group Business Solutions Manager (Finance), the Group Business Solutions Manager (Manufacturing), the Group Project Manager and the SAP Applications Manager. Interviews were tape recorded to ensure accuracy and were returned to interviewees for verification. To provide triangulation other sources of data collected were company documentary evidence and archival data such as post implementation reviews etc.

The case study research design conformed to the principles for conducting interpretive field studies in IS developed by Klein and Myers (1999). Full details of the research design can be found in Staehr, Shanks and Seddon (2002).

RESULTS AND DISCUSSION

ManB achieved extensive business benefits from its ERP implementation. The business benefits achieved at ManB are shown in Figure 1 using the Shang and Seddon (2000) benefits framework. Some additional business benefits not in the original Shang and Seddon benefits framework were achieved at ManB and these are shown in bold italic in Figure 1. The business benefits at ManB were not uniform across all sites. This variation in business benefits also occurred within a particular functional area. The fact that different business benefits were realized not only in different functional areas but also at different sites within the same organization highlights the difficulty in assessing the business benefits overall that an organization achieves with its ERP system.

Table 2 below shows the major situations and/or actions that influenced the eventual achievement of extensive business benefits at ManB. The first column in Table 2 lists the contextual influences, both internal and external to the company, followed by the phases of the ERP lifecycle. Column 2 specifies the situation/action at ManB that influenced the achievement of business benefits, while column 3 explains the influence and indicates in parentheses the subsequent phases of the ERP lifecycle affected. Column 4 shows whether the situation/action resulted in a positive or negative influence.

The results in Table 2 provide a process oriented view of the ERP implementation at ManB. The two contexts, external and internal to the organization, had the potential to influence the achievement of business benefits right across the ERP lifecycle. Each phase of the ERP lifecycle had the potential to influence the current and subsequent phases of the ERP lifecycle. Examination of the influences of situations/actions contributes to understanding how and why ManB achieved extensive business benefits from its ERP implementation. The external and internal contexts provided mainly positive contextual influences across the entire ERP lifecycle.

During the Chartering and Project phases of the ERP lifecycle critical success factors (CSF) reported in prior ERP research were identified at ManB. Examples of each of these CSFs at ManB appear matched by number in Table 2 below:

1. Top management support (e.g. Holland and Light, 1999; Parr et al., 1999; Brown and Vessey, 2003)
2. Project champion (e.g. Parr et al., 1999; Sumner, 2000; Somers and Nelson, 2001)
3. Project management (e.g. Holland and Light, 1999; Parr et al., 1999; Duplaga and Astani, 2003)
4. Change management (e.g. Markus and Tanis, 2000; Aladwani, 2001; Brown and Vessey, 2003; Markus, 2004)
5. Minimal customization (e.g. Holland and Light, 1999; Parr et al., 1999; Brehm, Heinzl and Markus, 2001; Somers and Nelson, 2001; Soh and Sia, 2005)
6. Project team characteristics (e.g. Parr et al., 1999; Ross and Vitale, 2000; Robey, Ross and Boudreau, 2002)
7. Implementation strategy (e.g. Holland and Light, 1999; Duplaga and Astani, 2003)
8. Education and training (e.g. Somers and Nelson, 2001; Robey et al., 2002; Sumner, 2000)

However, despite the presence of these CSFs at ManB, and no major issues due to the contexts and earlier phases that needed resolving during the Shakedown

Figure 1. Business benefits achieved at ManB (adapted from Shang and Seddon (2000))

BENEFIT DIMENSION	BENEFIT CATEGORIES
1. OPERATIONAL	1.1 Cost reduction 1.2 Cycle time reduction 1.3 Productivity improvement 1.4 Data quality improvement 1.5 Customer services improvement *1.6 User accountability*
2. MANAGERIAL	2.1 Better resource management 2.2 Better decision making 2.3 Better performance control
3. STRATEGIC	3.1 Supports current and future business growth plan 3.2 Supports business alliances 3.3 Supports business innovation 3.4 Supports cost leadership 3.5 Supports product *and service* differentiation 3.6 Supports external linkages 3.7 Enables world wide expansion 3.8 Enables ebusiness
4. IT INFRASTRUCTURE	4.1 Increased business flexibility 1.2 IT cost reduction 4.3 Increased IT infrastructure capability
5. ORGANIZATIONAL	5.1 Supports business organizational changes 5.2 Facilitate business learning and broaden employee skills 5.3 Empowerment 5.4 Changed culture with a common vision 5.5 Changed employee behaviour with a shifted focus 5.6 Better employee morale and satisfaction *5.7 Standardization*

KEY: Benefit category = business benefit achieved
Benefit category = new business benefit

Table 2. Overview of ManB ERP implementation and use **(KEY:** *"+ve" and "–ve" indicates positive or negative influence, C = Chartering, P = Project, S = Shakedown, OU = Onward and Upward)*

	Situation/Action	Influence (Phase affected)	
External context	Demand for SAP experts in the Australian IT industry	ManB did not lose IT staff. The policy of training existing IT staff to support SAP after implementation, the excellent communication between the existing ManB staff and the implementation partner consultants during the project, and the payment of bonuses to the ManB staff at the completion of the project all contributed. (**C**, **P, S** and **OU**)	+ve
		Changes/enhancements to the software to fit existing business processes not easy to obtain. (**C** and **P**)	
	Dependence on software vendor		–ve
Internal context	ManB's motivation for the SAP implementation involved strategic business reasons including risk reduction.	The SAP implementation proceeded despite a forecast negative return on investment. (**C, P**, **S** and **OU**)	+ve
	Although SAP software used by another part of the parent organization there was no compulsion to choose SAP.	Software chosen was capable of meeting the requirements of the business. (**S** and **OU)**	+ve
	Restructure to shared services after go-live.	Managers/users already had some working knowledge of the software when shared services were implemented. (**OU**)	+ve
Chartering and Project phases (C and P)	[1]Management understood the scale of the project and the need for comprehensive planning process.	(**C**, **P**, **S** and **OU)**	+ve
	[2]Experienced project manager and champion.		
	[3]Project completed on time, within budget and with original scope.	(**P**, **S** and **OU**)	+ve
		(**S** and **OU**)	+ve
	[4]Comprehensive and well thought out change management plan.	(**P**, **S** and **OU**)	+ve
	[5]Minimal customization of the SAP software.		
	[5]Used several different templates across the sites i.e. did not use a "one template fits all" approach	(**P**, **S** and **OU**)	+ve
		(**S** and **OU**)	+ve
	[6]Excellent working relationship with implementation partner.		
	Best business people on the implementation team.		
	[7]Small bang implementation strategy.	Facilitated a quality configuration (**P, S** and **OU**)	+ve
	[8]Used learning from early implementations to improve subsequent implementations.	Low risk implementation strategy (**S** and **OU**)	
	[8]Existing IT staff trained to support SAP post go-live.	Some training deferred until after go-live when users could learn using	+ve
	Few issues remaining from these phases to be solved in subsequent phases.	"real" data. (**P**and **S**)	+ve
		(**S** and **OU**)	
			+ve
		(**S** and **OU**)	
			+ve
Shakedown (S)	Some issues with user education and training.	Users not aware of their scope of influence with integrated software (**S** and **OU**)	–ve
		Users did not understand the increased need for data quality (**S** and **OU**)	–ve
		Results didn't look as good after go-live as they did before (**S**)	
	Issues with poor management control practices	Users "didn't know what they didn't know" (**S** and **OU**)	–ve
		A disincentive to having properly trained staff (**S** and **OU**)	
	Phone support inadequate	Limited availability of IT staff for training and support (**P**, **S** and **OU**)	–ve
	Businesses had to pay for extra training		–ve
	IT staff involved in other site implementations/new project work		–ve
Onward and Upward (OU)	Use of key users and professionals (e.g. accountants, engineers) for support services		+ve
	Sweeps of sites for training		+ve
	Issues with shared services		–ve
	Some productivity issues with poorly trained staff		–ve
	Business suggesting improvements to existing processes		
	Business suggesting new projects to leverage off the SAP system		+ve
	Business has a common language for strategic planning		+ve
			+ve

phase, other issues surfaced during the Shakedown phase that provided negative influences affecting the achievement of business benefits (see Table 2). This should not be considered unusual, since, consistent with the effect of organizational change (Eason, 1988), in this phase the process of adapting to the new system typically results in a performance dip (Markus and Tanis 2000; Ross and Vitale 2000) which may last up to 12 months or more. However, at ManB most sites were back to normal operations within 6 months.

A number of themes emerged in the Shakedown phase that highlighted areas for improvement. There were ongoing issues with education, training and support and change management. The deficiencies in education and training in the Project phase meant that users were not sufficiently aware of the integrated nature of the software and the increased need for data quality. The telephone support provided once the implementation team left the site was a problem for users who "didn't know what they didn't know". Additional training and support was required at some sites but the resources were often not available since the same team was used for ongoing implementations and for training. Also the business unit requesting additional training had to pay for it, surely a disincentive.

Change management was required to deal with issues of poor management practice:

"Basically, it hit the fan, where there were poor management practices. They were flushed out in the early days. SAP was accused of actually having wrong numbers. We went through, did a whole lot of work as to whether the configuration was right, whether the reporting was right, all those sorts of things. Time and time again it was proven that the system was doing what the system should do and that the poor practices were very much made visible and led to improved practices over time." (General Manager Information Technology & Business Solutions)

In the Onward and Upward phase there were sweeps of all sites to ascertain training needs. Key users and professionals who moved from site to site were used to provide more support opportunities:

"I spend a lot of my day just connecting people between plants and saying, well this plant does it this way, why don't you talk to this person. They might be completely different business units, but they can share information and they can talk the same language." (Group Business Solutions Manager - Manufacturing)

This reduced the load on the centralized support facility.

During the Onward and Upward phase process improvements and new projects to leverage off the ERP system were suggested by the business rather than being initiated from the IT staff. This occurred as business users came to better understand the capabilities of the ERP system.

Although not entirely free of problems the ERP implementation at ManB did achieve extensive business benefits. Two major contributing influences emerged from analysis of the empirical data and the ERP research literature. The first was that the approach ManB adopted towards its ERP implementation indicated a strategic business motivation which has been linked by Markus (2000) to achieving more business benefits from ERP systems. The second influence involved the individual manufacturing plant level. ManB showed a variation in business benefits from site to site. In their study of local plant level benefits from ERP systems Gattiker and Goodhue (2005) found that interdependence between plants increases the business benefits achieved through the integration provided by the ERP system. There was substantial interplant trading at ManB. However, Gattiker and Goodhue (2005) also found that differences between plants decreased benefits. They suggested that customization is one way to alleviate this although they could not provide supporting evidence. ManB was able to accommodate the differences between plants by using several different templates, and in the case of one plant, letting it keep its legacy system (see number 5 in Table 2). Therefore the interdependence between plants and the accommodation of variation between plants contributed to the extensive business benefits achieved.

CONCLUSION

ManB achieved extensive business benefits from its ERP implementation (see Figure 1). At ManB the possible negative consequences due to external and internal contextual influences on the organization did not eventuate due to management's strategic business motivation, planning and foresight during the Chartering and Project phases. The successful Chartering and Project phases set the scene for the achievement of business benefits during ERP system use. During the Project phase the accommodation of differences between manufacturing plants contributed to the business benefits achieved. Although there were some issues that arose during Shakedown these were overcome in readiness for the Onward and Upward phase. During the Shakedown and Onward and Upward phases some themes that influenced the achievement of business benefits at ManB emerged. They were *education, training and support*, *change management*, and the need for adequate *people resources*. Once the business users fully understood the capabilities of the ERP system business benefits were achieved through *business process improvement* and *new projects that leveraged off the ERP system*. These results are of interest not only to IS researchers and IS practitioners but to senior management in organizations. They contribute to our understanding of how and why some organizations gain more business benefits from their ERP systems than others.

The Importance of "Emotional" Features in Web-Based CRM System

Noor Raihan Ab Hamid, Multimedia University, Cyberjaya 63100 Selangor, Malaysia; E-mail: raihan.abdulhamid@mmu.edu.my
Ali Khatibi, Multimedia University, Cyberjaya 63100 Selangor, Malaysia; E-mail: ali.khatibi@mmu.edu.my

ABSTRACT

The notion of managing customer relationships would lead to better profitability has gained more attention from companies today. Companies' CRM efforts are not only limited to the physical contact points with customers: CRM program extends even to the online channel. However, recently researchers tend to focus on the importance of managing customer experience within the CRM initiatives. Past studies claim that CRM is not just a system solution to improve marketing and selling product/services. CRM system should also enable the features that would increase customers' emotional value and better experience. However, what are the "emotional features" that can be delivered in an online environment and what are the effects of those features on customer retention? Based on the literature, this study investigates the relationships between emotional features and customer retention. As such, questionnaire surveys were used to gather consumers' perceptions toward the internet as a shopping medium. In this study, we use structural equation model to test the fitness of data to the research model and reported the path loadings of studied variables. The findings determine that "emotional" constructs: personalization, place/track orders and online community influence customer retention. We discuss the results and suggest some directions for future research.

1.0 INTRODUCTION

The battle for customers has never been more intense. Heighten customer expectation and globalizations of trades are the uprising pressures which lead to a rise in competition. These factors force companies to switch from a product-centric approach to a customer-centric approach (Xu, Yen, Lin & Chou, 2002). At this junction, retailers who are at the front end of the supply chain and interact directly with customers are in a critical position to fully comprehend what induces repeat purchases (retention) (Feinberg & Kadam, 2002). Many researchers argue that in order to keep customers companies need to emphasize on customers emotional values, that is, the service attributes that make customers feel they are treated well enough to attract them to keep coming back (Anonymous, 2006). These "emotional" features can provide better customer experience leading to higher retention rates (Markwick, 2006).

Past studies have examined the roles of customer experience and emotional values in the traditional marketing environment (Schmitt, 1999; Wolf, 1999). However, limited research focuses on the influences of "emotional" features in an online environment. Since the Internet has become a significant (if not the only) channel of marketing for many firms, the study to understand the effect of emotional features on online retention merits further investigations.

1.1 Why Electronic Customer Relationship Management (E-CRM)?

E-CRM refers to the marketing activities, tools and techniques, delivered via the Internet which includes email, world wide web, chat room, e-forums etc. bearing on locating, building and improving long-term customer relationships (*Lee-Kelley,Gilbert & Mannicom, 2003). Driven by economics of customer management – well defined segmentation will lead to cost effective marketing efforts and increased profits, enabling technology such as the Internet is vital for firms to identify the differences in customers' behavior- preferences and attitude toward company's products. Coupled with other technology at the back-end such as customers' database, warehousing and data mining, value adding and personalized products or services could be offered, which in turn create an edge over competing companies.*

Driven by intense competition and cost-efficiency inspiration, firms are closely looking at marketing strategies that could win consumer loyalty. Businesses on the Internet are confronted with greater challenges as consumers' searching costs for price, quality information and comparisons across stores are much lower (Bakos 1997; Lynch & Ariely 2000), hence switching barriers almost do not exist (Yang & Peterson 2004). Research in understanding consumer retention has been the subject of investigation in the marketing area for a few decades. The motivation is driven by consumer economics in which keeping consumers may lead to securing sales (Jackson 1985) and serving repeat consumers costs less than acquiring new ones (Reichheld 1996). Consumer retention has been a primary goal of almost all companies, including Web-based companies (Peppers & Rogers 1995; Reichheld and Schefter 2000).

1.2 The Internet as a Tool of Retaining Customers

Front-end internet applications such as email, World Wide Web and chat room need to be supported with a well-built back-end system that utilizes the power of, among others, intelligent agents and database engines. Without a powerful back-end system, these Internet applications will not be able to function effectively. The E-CRM process begins at the first customer contact point such as a browser. That is, when customers visit a company's website the activities will be captured by a cookie file and logged in a server for initial profiling purposes. In turn, this profile allows firm to understand customer's surfing pattern which may be useful for future marketing plans. Added with users' information obtained from a web form, individual customer's profile is built up and stored in a database at the back-end. At this point, customers can interact with the database to check product availability, retrieve order details, track an order as well as personalize certain services.

Subsequently, a data warehouse application can be applied to sort periodical reports of customers' activities, which in turn, serve as input to an entailing data mining process. Next, the extraction of valuable information from a mining process may be used to produce buying trends vital to determine particular patterns in customers' behaviour leading to more effective customer segmentation. Indeed a consumer will revisit a Web site until there is another Web site that offers better quality service. In other words, it is the quality of products/services that makes the difference (Feinberg & Kadam 2002). Thus the imperative of understanding the level of quality of service rendering better customer experience, which may lead to retention should be investigated and is discussed next.

2.0 THEORETICAL FRAMEWORK

2.1 Customer Experience

In recent years, there seemed to be an increase in interests toward understanding the roles of customer experience in managing relationships. In particular researchers shifted their focus from merely investigating the impact of CRM systems to Customer Experience Management, also known as CEM, on improving relationships. In fact, many researchers claim that the economy, in particular the service sector, has been transformed into an attention economy (Davenport & Beck, 2002), entertainment economy (Wolf, 1999), emotion economy (Gobe & Zyman, 2001) or an experience economy (Pine & Gilmore, 1998; Schmitt, 1999). As many of service offerings have been commoditized, firms are advised to seek new ways to achieve competitive advantage by focusing on management of customers' experiences (Pullman & Gross, 2004).

Customer experience has been defined as the quality of event that accounts for anticipation, ***emotional involvement***, a uniqueness that makes the aforementioned stand out from the ordinary, and reaches some form of completion (Dewey, 1963). In addition, Price et al. (1995) suggests that extraordinary experiences are those activities characterized by high levels of emotional intensity which is usually triggered by an unusual event. The goal of providing such experience is to orchestrate experiences that are functional, purposeful, engaging compelling and memorable (McLellan, 2000). Hence, properly executed experience management will induce sense of loyalty not only through a functional design but also by creating ***emotional connection*** through engaging, compelling and consistent context (Pullman & Gross, 2004). However, the literature lacks studies that investigate the importance of "emotional features" leading to customer retention in an online environment.

2.2 Putting Customer Experience into the Online CRM System

Since the goal of CRM systems is to increase customer retention, and managing customer experiences are vital to encourage retention, this study examines the effect of several "emotional features" available on companies' Web sites on customer retention. The emotional features included in this study are:

Personalization Component

Consumers' involvement in designing products/services offered by Web sites is imperative since consumers have the very best understanding of their needs and relay the information to the providers (Von Hippel 1998). This knowledge of consumers' preferences is vital to avoid the sacrifice of consumer goodwill and maintain superior satisfaction (Du et al. 2003). Indeed, personalization attracts consumers to come back repeatedly since it turns consumers into product 'makers' rather than simply product 'takers' (Winer 2001), Thus, consumers are empowered in ways that they can choose their own preferred design, colour, product updates and other attributes that go well with their tastes. Slywotsky (2000) refers to this process as a "choiceboard" where consumers take a list of product attributes and determine what they want. The consumers are actually facilitating the activities of the company especially in product design, data collection and consumer service, which in turn extract value from participating in the marketing process (Moon 1999). Hence, the first hypothesis is:

H1: Personalization component offered by companies' Web sites influence customer retention.

Placing Orders and Order Tracking Components

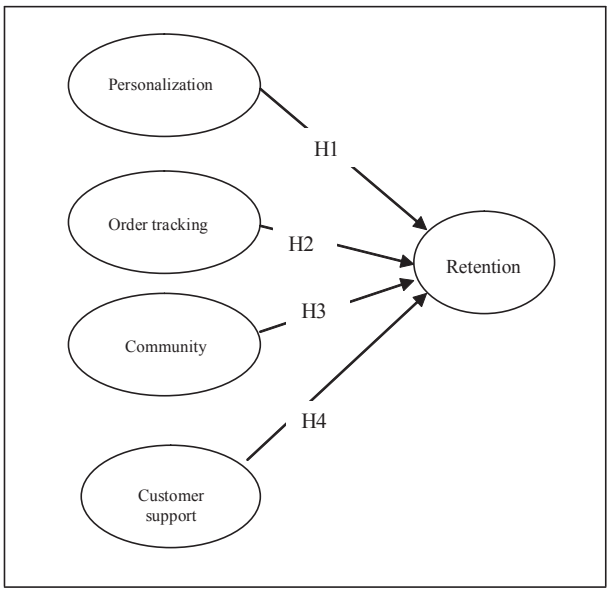
Certainly, consumers will feel empowered and in control when they are able to easily find a product/service, learn more about it and quickly make a purchase decision. For example, a site may provide features such as shopping carts, one-click ordering and order tracking to provide superior convenience and higher levels of consumer control (Batty & Lee 1995). Indeed, users who experienced superior values rendered by a site may never bother to switch and face uncertainties of service quality offered by other sites. A second hypothesis follows:

H2: Placing orders and order tracking components offered by companies' Web sites influence customer retention.

Online Community Component

To make a Web site more enticing Winer (2001) suggests building an *online community* of site users. This would make it more difficult for the consumer to leave the acquaintances who also patronize the company. Consumers can exchange information with each other and obtain online help from their online members when a product related problem arises (Moon 1999). These experiences create stickiness - the extent to which a company is able to attract consumers to use a site relatively longer and return (Strauss & Frost 1999), and consumers are more likely to revisit the site (Singh 2002). Therefore, online community can serve as an exit barrier since the relationship that develops among the members of the group may make it difficult for consumers to switch. Therefore, this study proposes the third hypothesis:

Figure 1. Hypothesized relationships



H3: Online community component offered by companies' Web sites influence customer retention.

Customer Support Component

It is a necessity that an online company maximizes its efforts in communicating the firm's image and purpose to its consumers (Bitner 1992). Consumers constantly demand for careful, continuous, and useful communication with company representatives (Lohse & Spiller 1998). Since these attributes are frequently identified as salient dimensions in store selection behaviour (Jarvenpaa & Todd 1997; Kolesar & Galbraith 2000), company representatives should have the knowledge and basic technology skills to answer online questions. They should understand consumer-specific needs, have the capacity to handle problems that arise and address consumer complaints in a friendly manner (Yang & Peterson 2004). Hence, the fourth hypothesis is:

H4: Customer support component offered by companies' Web sites influence customer retention.

Figure 1 depicts the relationships between the constructs being studied.

3.0 METHODOLOGY

3.1 Questionnaire Design

The questionnaire used in this study was designed based on the research objectives discussed. The questionnaire consisted of three parts. The first part, Section A, consisted of demographic information such as a respondent's age group and income level. Section B consisted of general information about a respondent's internet activities. These questions included respondents access location, number of years using the Internet, types of Internet activities and time spent in a week on the Internet. The third part, Section C, was designed to assess the attributes affecting respondents' satisfaction, retention and loyalty on the Internet respectively. The respondents were asked to indicate their opinions pertaining to various dimensions of the three variables being studied. A 5-point labelled Likert type scale was used with anchor from 1="Strongly Agree" to 5= "Strongly Disagree".

3.2 Operationalization of Variables

The items for the studied variables: *personalization, place/track orders, online community, customer support and retention* were constructed from the literature

Table 1. Measurement items

Variable	Items	Cronbach's Alpha
Emotional features: *Personalization*	Create my own account Knows my preferences Greet me by my name Offers what I want	0.86
Place/Track orders	Allows to check order status anytime Place orders anytime Keep me well informed	0.82
Online community	I feel sense of belonging Enjoy sharing ideas and information Enjoy exchanging information	0.75
Customer support	Quick response to enquiries Professional handling of complaints Always updated with customers' activities	0.74
Retention	I will re-visit the Web site I will recommend to my friends This is the site of my choice I will definitely return	0.89

pertaining to the respective subject matter. Table 1 summarizes the list of items used to measure each research variable.

3.3 Sampling

Primary data for this research were collected using a personally-administered questionnaire as this method will ensure a higher response rate. Research assistants helped in contacting respondents via email, and distributing and collecting the questionnaire in person. Secondary data for this study came mainly from newspapers, the Internet, journals, publications, magazines, books, and databases accessed via the Internet.

The main source of users list came from various education, government and corporate institutions in Klang Valley, Penang, Johor Bahru and Kuching. The nature of work that people do in these institutions requires the use of Internet hence they are appropriate source of primary data for this study. For example, it is common for university staff and students to use the internet for communication or to conduct research. Likewise, most companies in the selected cities have internet connections on their premises and the method of communication within these companies is mainly email. Malaysian government is one of the leading examples in implementing e-government in Asia. Most of the government offices are internet-enabled and in fact, the use of intranet within these departments is common. Thus, the choices of these institutions are deemed appropriate for this study. 1000 respondents were chosen using systematic random sampling. A total of 671 (67.1%) responded to the survey while the remaining respondents either could not be contacted or declined to participate. Descriptive analysis was used to report the profile of research respondents while measurement model was conducted to examine the items of research constructs: personalization, place/track orders, online community, customer support and retention. In addition, Structural Equation Model (SEM) was conducted to test the cause-effect relationships of these variables.

4.0 DATA ANALYSIS AND RESULTS

4.1 Respondent Profile

The respondents were almost evenly split by race (37 per cent Malay, 34 per cent Chinese, 24 per cent Indian and 5 per cent others) and gender (50 per cent were male and 50 per cent female). Most of the respondents were 21 to 30 years of age (51 per cent), followed by the age groups of 31 to 40 and below 20 years at 29 per cent and 10 per cent, respectively. These three groups contributed approximately 90 per cent of the overall total in term of age. 49 per cent of the respondents had spent at least 15 years in education. Most of the respondents were executives (48 per cent) and more than half of them earn between RM12, 000 to RM36, 000 per annum (51 per cent).

4.2 Structural Equation Model (SEM)

To test the fitness of research model to the data, SEM was conducted. Drawn from the literature, this study posits that customer retention on the Internet may be influenced by several emotional features: personalization, place/track orders, online community and customer support.

The results indicate that indicate a good fit to data: χ^2 /df= 2.88, RMSEA= 0.058, CFI=0.98, TLI= 0.96 and AGFI= 0.92 (see Table 2). Hence, the causal diagram fits the study data well. In terms of hypothesized relationships between the exogenous constructs, it can be seen personalization (β= 0.24), place/track orders (β= 0.46) and online community (β= 0.37) and favourably influence customer retention. However, this study indicates that customer support has no significant influence on customer experience (β= 0.11): the path coefficient was not significantly different from zero. The path loadings are illustrated in Figure 2 below.

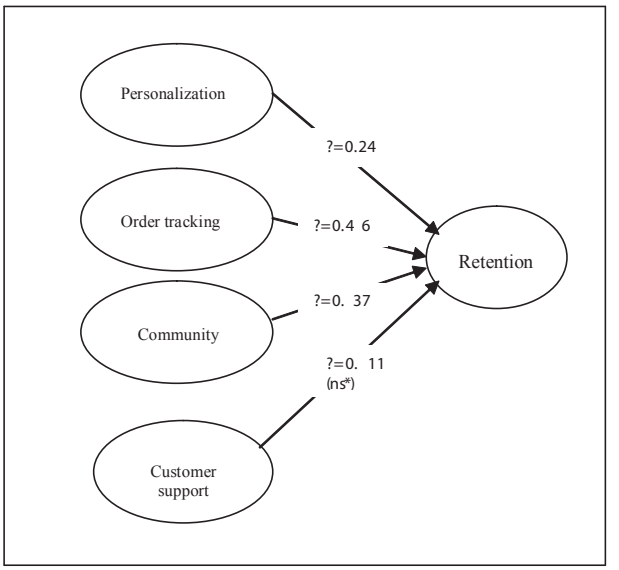
5.0 DISCUSSION AND CONCLUSION

Certainly, the internet is a "new" medium of commerce which attracts different types of consumers than that of traditional shopping channel. The internet channel is perceived as fast, real time access to information and process, and allowing some level of control, thus expectations of online service provider performance

Table 2. Goodness-of-fit statistics for the research model

Goodness-of-fit measures	4-dimension	Recommended value
Chi-square	176.30	
χ^2/df	2.88	≤3.0[a]
Root mean square of error of estimation (RMSEA)	0.060[1]	≤ 0.06[b]
Adjusted Goodness-of-fit index (AGFI)	0.92	close to 0.90[c]
Tucker-Lewis Index (TLI)	0.96	>0.95[d]
Comparative Fit Index (CFI)	0.98	>0.95

Figure 2. Path loadings from cause-effect tests



*Note: * non-significant path loadings*

are higher compared to the traditional channel. Undoubtedly, online consumers seek for better characteristics than those that merely satisfy them in order to entice consumers to come back; such as ability to personalize services, ability to decide on purchase immediately and track the status of their orders and offline-online synchronized orders. Facilities such as tracking order status, history of purchases or activities and allowing certain degree of customization enhances consumers' experience, in turn, these pleasant encounters form emotional values which attract customers to return. Evidently, companies like Amazon have gained competitive advantage from all these emotional features: one-click ordering, personal name greeting, product recommendation and reviews from previous users. Providing these features on one's site may improve their relationship with consumers and gain a competitive edge.

Interestingly, this study reports that customer support does not influence customer retention. A possible explanation for this is Internet customers have higher expectations of service if compared to the traditional channel. The Internet enhances customers' empowerment through its self-service oriented transactions. Hence, customers' expectations of service leading towards retention would be the features that encourage empowerment, sense of control and appreciation (such as personalization, tracking and online community). These emotional values may not be realized and achieved through mere email communication with customer support personnel, helpdesk or frequently-asked-questions (FAQ).

Our study emphasizes that firms striving for building long-term relationships with online consumers should be well aware of the emotional features that help them encourage customer retention. This study contributes in identifying the online features forming emotional values leading to increased retention. Indeed, on the Internet, consumers who are dissatisfied with the experience on a particular Web site may easily switch to another provider. Therefore, superior service quality placing reasonable attention on and delivering features that induce customer pleasant experience and increasing emotional value should be considered.

This study is subject to several limitations. Firstly, the respondents from this research were mainly working adults in urban localities, well educated and have at least three years of experience using the Internet. Further research is needed to generalize the results across different groups of Internet users in Malaysia. The results of this study may be applied to other countries with similar culture and business environment. Therefore, before conclusions and implications can be made to other countries with different culture and business environment (such as the Western region), further research should be conducted.

Developing Buddy: Towards Greater Dependability and Maintainability in Meta-Search

Naresh Kumar Agarwal, National University of Singapore, 3 Science Drive 2, Singapore 117543; E-mail: naresh@comp.nus.edu.sg
Danny C. C. Poo, National University of Singapore, 3 Science Drive 2, Singapore 117543; E-mail: dpoo@comp.nus.edu.sg
Dominick M. T. Leo, National University of Singapore, 3 Science Drive 2, Singapore 117543; E-mail: dominick_leo@comp.nus.edu.sg

ABSTRACT

Most meta-search engines use web scraping as an ad-hoc method to extract results from the output display of various search engine sources. However, a search engine may cease operation, merge with other engines or its display format may change. A dependable meta-search engine must, thus, adapt to display changes in search engine sources and be maintainable even by people with low programming skills. This paper describes the design and development of Buddy, a meta-search engine that is able to help web users search more effectively into multiple search engine sources. It allows integration of a new search source with minimum complexity and programming knowledge, leading to greater dependability and maintainability. Search results are aggregated from multiple sources to remove duplicate and sponsored links and to give the most relevant results each time. Buddy also allows query refinement and saving of search results locally in user computers or remotely in emails.

Keywords: Meta-search engine, Information Retrieval, Web scraping in Java

1. INTRODUCTION

The World Wide Web may be considered the largest database in the world, with its huge collection of data covering every part of our lives. Each day, each second, a humongous number of people search the Web for information and data of their interest, such as news, word documents, research papers, pictures, music and video. The sole aim of these searchers is to find answers to their queries.

However, they may not be able to find all the best answers in a single search engine. E.g. searching Google (www.google.com) alone is still considered insufficient even though it seems to have the largest repository of web pages [1]. This is because there is very little overlap in the databases of different search engines [2]. Since the top results ranked by different search engines are very different from each other, Web searchers potentially miss relevant results by using only one search engine. Here comes the need and relevance of meta-search engines that have the underlying philosophy that "having many heads is better than one" i.e. instead of searching into only one search engine, it may be worthwhile to get another opinion from other search engines. As searching manually into individual search engines is time-consuming and inefficient, meta-search engines (see [3] for a list of meta-search engines) allow searching into various search engines simultaneously.

1.1 Issues with Meta-Search Engines and Their Development

Unfortunately, meta-search engines today are too ad-laden [4]. They are becoming "meta-yellow pages" where searchers query paid listings and get advertisements in their search results. Searchers are forced to sieve through irrelevant sponsored sites ranked among the search results.

There are two ways in which meta-search engines are able to search into other search engines: 1) Using the APIs provided by search engines e.g. Google's Java-APIs. However, this method is not feasible when searching into many search engines. To connect to ten search engines that use different APIs, such a method will require learning how to apply ten different APIs. This will makes the connection to a search engine's database a tedious task and it would be difficult to maintain the system. Moreover, unlike Google, not many search engines are willing to share their APIs with the public. 2) To overcome this limitation, a web scraping technique [5] can be used to extract the results from the output display of various search engines. This allows connecting and extracting data from many search engine sources without having to learn new APIs.

This leads us to the most important issue, which is the focus of this paper – dependability and maintainability. The output display of search engines may change and cause extraction of results using web scraping method to fail. New search engines can emerge anytime in the World Wide Web. Existing search engines may cease to exist or merge with another engine. A dependable meta-search engine must, thus, adapt to display changes in search engine sources and be maintainable even by people with low programming skills.

In this paper, we describe the design and development of Buddy, a meta-search engine developed at the School of Computing, National University of Singapore and accessible at http://buddy.redirectme.net

The remainder of the paper is organized as follows. In Section 2, we briefly describe the features of Buddy that lead to greater maintainability and dependability. Target users and guiding objectives are also discussed. Section 3 discusses the system design considerations. In Section 4, we see the system architecture of Buddy. Section 5 highlights the experimental results on evaluating the system. Section 6 concludes the paper by sharing the lessons learnt and possible future enhancements.

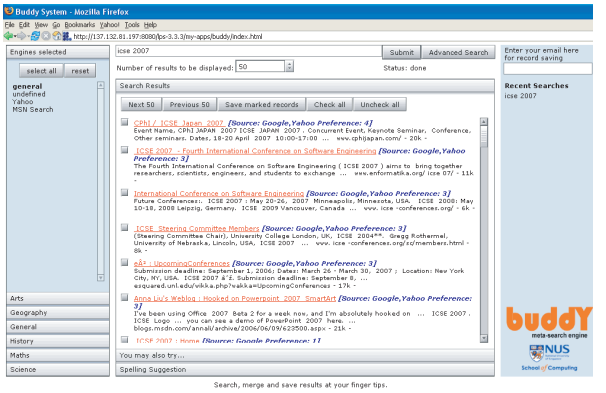
Let us now look at the Buddy Meta-search Engine.

2. THE BUDDY META-SEARCH ENGINE

Figure 1 shows a snapshot of the Buddy Meta-search Engine. Buddy extracts results directly from search engines chosen by the user. No paid links are added into the final merged results. Sponsored links from the source search engines are actually omitted. The system thus minimizes the occurrence of sponsored links in search results, while maximizing relevant links.

Buddy has been designed for dependability and maintainability – it can easily connect or disconnect to/from search engines. At the same time, it can adapt to display output changes in the search engine sources. In Buddy, adding a new source search engine does not require learning its APIs. Any changes to the output display of the source search engines will require minimal modification. The web scraping technique in Buddy makes use of existing Java's Regular Expression and Pattern matching capability [6]. If the output display of source search engines changes, the system administrator just needs to modify the Regular Expression that governs the web scraping structure. This means that there is no need to change the underlying data structures of the system. Maintaining the system will also require little programming knowledge. There is no need to recode the system or web scraping methods if changes occur to the source search engines. Modifications are done in a declarative approach (see Section 3.1).

Figure 1. Snap-shot of Buddy (accessible at http://buddy.redirectme.net)



Understanding searcher needs is important if we are to attract users to use Buddy. Besides being able to extract results from search engines, Buddy can also extract results from sites such as Dictionary.com (www.dictionary.com) to provide spelling suggestions for queries with spelling errors[1].

Buddy can extract query refinement suggestions from sites like Ask.com (www.ask.com) and Yahoo (www.yahoo.com) that provide query refinements together with the searched results. This shows the flexible web scraping method used in our proposed system.

Buddy also enables searchers to save their results locally in their computers or to send their results to their email so that they can access the results in future.

2.1. Target Users

Buddy, though a general-purpose meta-search engine, has been developed keeping in mind, the educational needs of students and teachers in Singapore. The education system in Singapore encourages schools to use materials outside their textbooks, including project-based learning. Earlier, students used encyclopedias to gather this extra information. With the technology available today, students have switched to gathering information from the World Wide Web. Search engines have thus become useful tools for students to do their learning or to gather data for their projects. Teachers can also turn to search engines to gather useful teaching materials. Buddy primarily aims to help such students and teachers in their needs by providing customizable mechanisms to search from specific sources.

Agarwal and Poo [7] discuss classifying a typical Internet searcher into one of 4 searcher modes (or categories) – 1) novice[2], 2) data gatherer, 3) location searcher and 4) focused searcher. In the novice mode, the searcher knows nothing about of the domain under search. As data gatherer, he/she is familiar with the domain or subjects under search. A data gatherer just needs information on the topic he/she is knowledgeable about. A location searcher just needs to locate information previously encountered. The searcher in focused searching mode needs a specific answer to a specific question.

As a novice, it is sometimes hard to decide which results are relevant and which are not. A novice is also unsure of what he/she is searching for. The web-based interface of Buddy has to provide an intuitive way of selecting the search engines. Buddy has separated search engine choices into categories, namely – Science, Math, Geography, History, Arts and General Search. This will helps students to better focus their search into specific domains. Buddy also provides query refinements and spelling suggestions for searchers. This is especially useful when the searcher is in a novice mode. Unlike existing meta-search engines, Buddy does not include sponsored links in its results.

As a data gather, a searcher's aim is to gather information. Searching one search engine is not enough. Searching many search engines manually is inefficient. Buddy is able to search multiple search engines concurrently and return merged results without duplicates or sponsored links. Hence a data gather can select the specific domains he/she wants to search into.

As a location searcher, a searcher wishes to find the results that he/she came across previously. Since Buddy provides utilities to let searchers save or email their results, these can be accessed again locally in user computers or remotely in their email account.

A focused searcher wishes to be able to query about a specific question. Buddy supports Boolean searching. This helps a focused searcher to obtain better results.

As students are still in a stage of learning, we expect more students to fall under the modes of *novice* and *data gatherer*, especially when searching for education-related materials. We would expect teachers to be in the *data gatherer, location searcher*, or *focused searcher* modes most of the times. Once the searchers get their answers, they might want to share the results with other students or teachers. This is where the save-results utility provided by Buddy comes in handy.

2.2. Objectives Guiding Buddy

To summarize, the objectives guiding the development of Buddy are twofold:

1. **Dependability and Maintainability.** This is the most important objective. Connecting to source search engines should be easy. Buddy should be adaptable to changes in search engine sources. Additional search engines could easily be added into Buddy without recoding the data structures and methods. Any changes to the source search engines should require minimal modifications to the system, keeping the underlying data structures untouched. Modification should be done in a declarative approach. People maintaining the system need not be proficient in their programming skills.
2. **To be an appropriate Learning tool** (the name 'Buddy' reflects this objective). Buddy must cater to the needs of a searcher in any of the 4 searcher modes described in Section 2.1. Besides being able to search into multiple search engine databases, Buddy must be able to provide tools for disambiguation, such as query refinement and spelling suggestions so as to guide searchers in the novice mode. Buddy must also allow searchers (data gatherers and focused searchers) to search into specific directories and subjects. Buddy must enable use of Boolean expressions to make queries specific for searchers (focused searchers). Buddy must enable searchers (location searchers) to keep track of the searches they had done and to retrieve their previous search results. Finally, the system must minimize the number of sponsored links in the results.

3. SYSTEM DESIGN CONSIDERATIONS

Buddy was implemented using Java Development Kit (JDK) version 1.4.2 and Sun System Application Server 8. Java codes were written with EditPlus2 text editor. The web-based user interface (GUI) was implemented in JSP and OpenLaszlo (www.openlaszlo.org), the open-source platform for rich Internet applications. JSP files were written with Macromedia Dreamweaver 4. Some of the decisions and considerations in designing Buddy are:

- **Declarative Approach.** Properties of the data structures of source search engines are described in script files, contributing to maintainability. The integration of new search engine is simple.
- **Web scraping method.** There are a few open-source parsing tools [5][8] However, these are usually complex and incur a steep learning curve. Hence, we defined a simple web scraping method that uses Java Regular Expression and Pattern Matching API [6] and requires knowing only Regular expressions to modify the web scraping structure. E.g. 3 parts of the search result (shown in 3 different lines)

  "
  Yahoo!
  Welcome to Yahoo!, the world's most visited …"

  can be extracted using

(?:)	match URL
(.*?)(?:?)	match Title
(.*?)(?: <small><i>?)	match Description

  Expressions in bold define the groups of string that we scrape from the HTML page.
- **Multithreading.** Multithreading enables parallel request and retrieval of results from the parent search engines. Experiments have shown that parallel searches perform better than sequential searches [9].

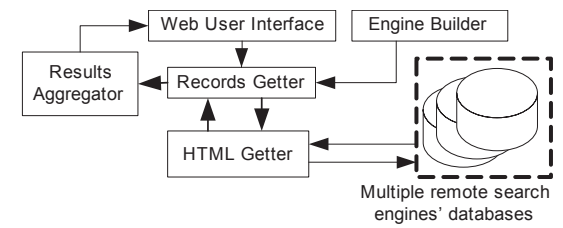
- **Query refinement method.** Most search engines use tools like WordNet [10] to help them perform query refinements. With the flexible web scraping method, Buddy scrapes query refinements and spelling suggestions from other search engines, as defined in configuration files. Hence, it is lightweight and useable on low-cost platforms.
- **Merging of results.** The simplest way of aggregation is to return all the results in one page without any post processing and re-ranking. This can lead to biased or overlapping results. In contrast, positional methods are computationally more efficient [11] and more precise. We use a positional method of ranking the merged results.
- **Web-based interface.** As the system was implemented using Java, Java Server Pages (JSP) was used to interact with the user and server. The GUI of the system aims to be intuitive and user-friendly. As the target users of the system are students and teachers, it is appropriate that the system is able to connect to subject-specific directories. Search engines are classified according to categories, namely Science, Math, Geography, History, Arts and General Search. E.g. Science category will include science-related search engines and directories – Scirus, Google's Science Directory and Yahoo's Science Directory. This will help searchers focus their search in a specific subject.

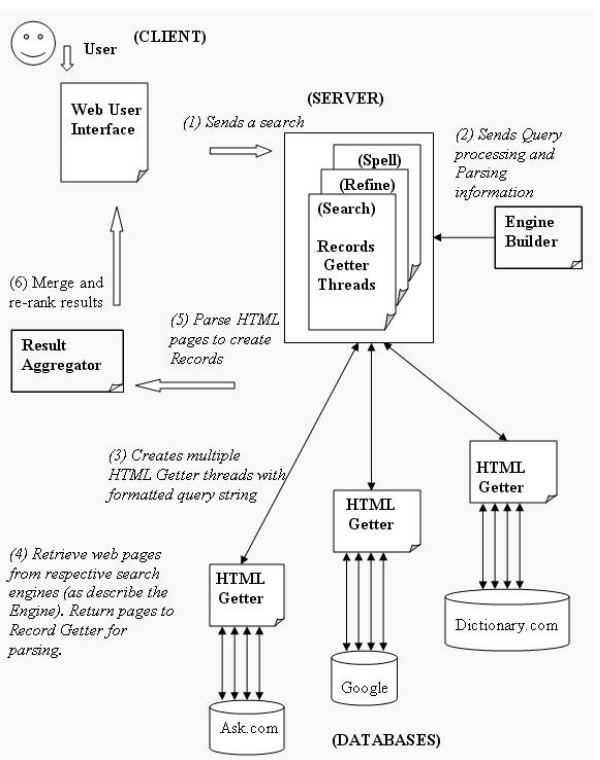
4. SYSTEM ARCHITECTURE

Buddy is made up of 5 components (see Figure 2):

1. **Web User Interface** – interacts with searchers
2. **Records Getter** – processes queries and parses/scrapes HTML pages; returns a vector of Records (results)
3. **HTML Getter** – retrieves HTML pages with the format query URL string; multithreading is used to speed up page retrieval.
4. **Engine Builder** – informs Records Getter to perform query processing and HTML parsing of different query/results format of different source search engines.
5. **Results aggregator** – merges, removes duplicates and re-ranks search records. Borda Positioning Rule was used to merge and re-rank the results, as it is relatively inexpensive, computationally efficient and has desirable properties such as anonymity, neutrality and consistency [11][12].

Figure 2. (Top) System architecture; (Bottom) Interaction among components





5. EXPERIMENTAL RESULTS

To test the performance of Buddy, 37 queries[3] were selected to obtain statistical results. These 37 search terms have been used previously in other studies [11] [12].

Experiments were done on a system with AMD Athlon XP 1600+ 1.4Ghz, 768 MB of RAM and a 2000 kbps Internet connection.

Two tests were conducted:

1. The first test connected the system to 6 search engines (Google, Yahoo, MSN Search, AllTheWeb, AltaVista, and Ask.com) individually to obtain 200 normal search results per query.
2. The second test meta-searched into 3 search engines (Google, Yahoo, and MSN Search) concurrently to return aggregated search results (only top 200 from each search engines is used; we would expect about 600 results per query). At the same time, we also searched for query refinements from Ask.com and Yahoo, and spelling suggestions from Dictionary.com.

The reader should note that we did not want to compare the performance of the various rank aggregation methods, nor compare performance with other meta-search engines. Instead, we wanted to evaluate the time taken to parse the HTML pages and aggregate the results against the total time taken to complete the task. This is to evaluate the amount of overhead (in terms of processing time) used for parsing and aggregating results. The tests were also to show that the system was running properly.

5.1. Test-1 Analysis

In this test, Buddy was used to search into 6 search engines individually to obtain 200 results per search engine per query.

Parsing Overhead

We are able to evaluate the parsing overhead incurred in this test. Parsing overhead is the amount of processing time required to parse HTML pages to create Vectors of Records.

From Figure 3, Buddy clocked an average of 2.5 seconds while searching into Google for 200 results per query. Ask.com took the longest time, with the bulk

Figure 3. Time taken for Buddy to search sequentially into each search engine

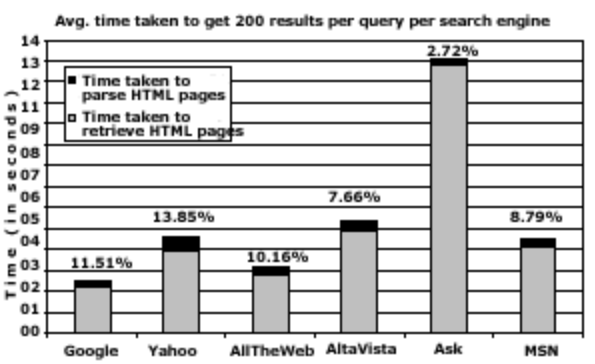


Table 1. Breakdown of records obtained by Buddy from each search engine (total 37 queries)

Search engine	Total no. of unique records	Total no. of duplicates	Total records
Google	7389	11	7400
Yahoo	7398	2	7400
AllTheWeb	7393	7	7400
Alta Vista	7395	1	7396
Ask	7357	11	7368
MSN Search	7312	48	7360
Total statistics	44244	80	44324

of the time spent on retrieving the HTML Page. We observed that on the average, only 7.24% of the processing time is involved in parsing. Bulk of the time is being used to retrieve the HTML pages instead.

Limitation Factor

We conclude that the performance of Buddy is limited by the connection speed to the search engines. We will expect the speed of combined search to be limited by the speed of slowest search engine selected. For instance, Searcher A selects Google and Ask.com. Searcher B selects Google and MSN Search. The system will take a longer time to obtain results for Searcher A because page retrieval from Ask.com is relatively the slowest (Figure 3).

Overlapping Records

It is interesting to note that there are actually a few (less than 1%) duplicates already present within the results of a search engine (Table 1). E.g. out of the 7400 records from Google, the system has removed 11 duplicates.

5.2. Test-2 Analysis

In Test Two, for every query, Buddy is used to perform the task of searching 3 search engines to obtain 600 results, to obtain query refinements and spelling suggestions. The final results are obtained by merging 200 results from each of the 3 search engines. We will expect some duplicated results to be removed. Here, we evaluated the overhead incurred for result aggregation. The top 3 fastest search engines from Test One (Google, Yahoo and MSN Search) were selected to participate in this test.

Results Aggregation Overhead and Performance

From Figure 4 (top), we can see that the average overhead cause by result aggregation is only 0.32%. The system has, on average, removed 21.78% of the total results that are overlapping. Also from Figure 4 (bottom), we can see that about one-fifth of the results are duplicates. For each query, the system takes about an average of 7.86 seconds to gather about 600 results from the 3 search engines, aggregates them and provides, on average, 90 query refinements. The performance is better than Helios [9], which took 12.4 seconds to retrieve 600 results.

In summary, the average time for Buddy to retrieve, parse and merge 600 results from Google, Yahoo and MSN Search is 7.8 seconds per query. This timing includes the retrieving and parsing of query refinement and spelling suggestions from Ask.com and Dictionary.com.

The performance of the system is greatly affected by the available bandwidth. Parsing and result aggregation overhead is not significant compared to that of HTML retrieving.

Figure 4. (Top) Statistics for Buddy to metasearch Google, Yahoo and MSN Search (200 results per search engine); (Bottom)Breakdown of records obtained per query

Search records from Google,Yahoo,MSN Search (200 results per search engine)							
	Query	No. of unique records	No. of duplicates	No. of Query refinements	No. of Spelling suggestions	Time Taken for Result Aggregations	Total Time taken (millisecs)

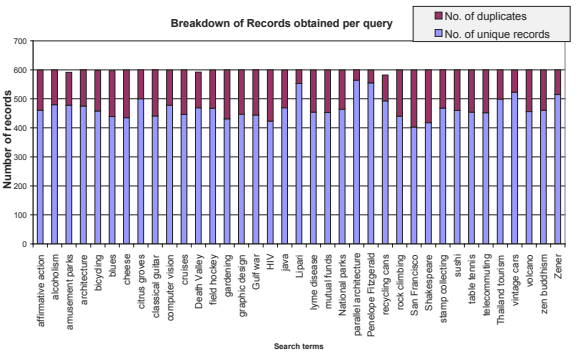
	% of records are duplicates=	Total number of duplicates/Total number of records=				4823/(17326+4823)	21.78%



6. CONCLUSIONS AND FUTURE WORK

Currently, Buddy can already connect and extract data from

1. 9 search engines (Google, Yahoo, MSN Search, AllTheWeb, AltaVista, Ask.com, Scirus, AOL and Lycos).
2. 15 Directories (Science, Math, Arts, History and Geography Directories) from Google, Yahoo and Open Directory Project.
3. Non-search engine sites such as Dictionary.com.

Web scraping has been an important method in the data extraction module of this system. It is an ad-hoc method that does not require us to learn extra APIs of the databases we want to connect to. It has enabled the system to extract data from virtually any free search engines that return results in HTML format.

It is interesting to note that the project has not involved external open source tools like XQuery or WordNet. The whole project has been done using standard Java

APIs. This shows the text processing power of Java language. Web scraping can be conveniently done using Java's Regular Expression and Patten Matching.

Declarative approach enables us to easily change the web scraping structure just by changing the regular expressions. We can also change the properties of the source search engines by editing the parameters in their descriptor script files. This does not require much programming knowledge to maintain the system.

This proposed meta-search system will be useful to searchers, especially to the target users in the education domain. The system is suitable for searchers who 1) want to have a wider range of answers to their queries from multiple sources 2) dread to see sponsored links 3) need help in query refinements and spelling suggestions 4) want to share their results with others or save their results for future reference. Thus, the system is certainly a suitable learning tool for students and teachers, and should find applicability in schools.

The system retrieves results straight from sources, without adding sponsored links to distract users. The system lets searchers have wider range of answers to their queries from multiple sources. The system is useful to novice searchers who need help in query refinements and spelling suggestions. The system also allows searchers to share their results with others or save their results for future reference. This system is certainly a suitable tool for learning for the students and teachers. Above all, it serves the primary objective of being a meta-search engine with increased dependability and maintainability.

Several problems were encountered and lessons learnt in the development of Buddy. The performance of the initial prototype was not desirable. This was because of the lack of parallelism being employed in the implementation. Retrieving HTML pages is usually the bottleneck of the whole search process because it takes a relatively long time to retrieve the pages. Subsequently, multithreading was used to retrieve the pages from the search engines, and the performance of the system is acceptable now. From the tests conducted (see Section 5), we can see that performance is greatly influenced by the amount of bandwidth available. The processing cost of parsing and result aggregations is not that high compared to that of retrieving HTML pages. Performance will be affected if the available connection speed is low. If we can speed up the HTML retrieval process by using faster Internet connection, the system's performance will improve.

Future work can include multi-language support, support for Really Simple Syndication (RSS) format [13] and classification of search results into appropriate categories.

Comparing Student Teachers' Preferences and Perceptions on E-Learning

Eugenia M. W. Ng, The Hong Kong Institute of Education, Hong Kong SAR; E-mail: Eugenia@ied.edu.hk

ABSTRACT

Electronic learning is a new trend in higher education institutes around the globe but there is a paucity of solid research concerning student teachers' readiness for this direction. A questionnaire was developed by adapting Hiltz's framework to determine student teachers' perceptions on areas that contribute to the success of electronic learning. A total of 70 student teachers participated in the survey. 44 of them took at least one information technology module and the remainder took no information technology modules. The two groups of students gave high ratings on most items asked. However, their perceptions on group dynamics and mode of teaching were significantly different. The research findings and the implications for use in teaching education are discussed.

1. INTRODUCTION

Information technology plays an important role in the modern world by providing easy access, flexibility, support for multimedia presentations, enabling communication virtually with anyone in the world. The development of information technology also has a significant impact on education by supporting a paradigm shift, i.e., shifting from a teacher-centred to a student-centred mode of teaching and learning. "We are finding that, for a small but growing percentage of people, new forms of communications, publications, and collaboration and the way data are accessed, represented and manipulated are changing the way knowledge is conceived, challenged, justified, and disseminated in their disciplines" [1]. Indeed, some universities offer online courses to cater for those who prefer to study using online platforms to complement face-to-face teaching. Myers, Bennett, Brown & Henderson [2] found that "Educational technologies may open new avenues for more students to access opportunities and information, increase forms of interactions among teachers and students and encourage collaboration across institutions" (p. 84). It was also suggested that academics who use E-learning may become better teachers as they may reflect on their teaching and also initiate more dialogue with other teachers on the potential benefits of various teaching methods [2].

The Hong Kong Institute of Education (HKIEd) is a tertiary teacher education institute in Hong Kong. It was realized that information technology has been used to support many projects related to assisting teaching and web-based learning in the past few years. HKIEd has adopted a popular learning platform, namely Blackboard, to facilitate this new mode of learning. Although there are many articles on methods for measuring the success of e-learning at different higher educational institutes [3, 4] there are very few articles that focus on factors affecting E-learning for teacher education. It is understood that it might not be feasible or desirable to completely replace face-to-face lectures with an e-learning mode as presentation and communication skills are considered essential attributes for effective teaching. However, given the positive feedback on the use of discussion forums to complement face-to-face learning at the HKIEd [5], and the easy access and high availability of computers at schools in Hong Kong [6], it is now an appropriate time to explore factors affecting the success of E-learning implementation, and also to determine whether student teachers are ready to learn some modules completely online.

2. A FRAMEWORK FOR E-LEARNING

The success of E-Learning can be measured from both students' and faculty members' perspectives by using educational outcomes as an indicator. To align with the educational reforms, learners should be prepared to develop "learning how to learn" skill and other generic skills in addition to basic content acquisition [7]. Drawing from diverse literature, Hiltz [8] came up with a research framework with the independent variables of technology, and course and student characteristics; intervening factors of amount and type of use of virtual classroom; and a dependent variable - better learning experiences.

Technological determinism - The efficiency and effectiveness of system design and implementation will directly influence user behaviour [9]. Specific resources such as hardware, software, and communication technologies could be important factors affecting user accessibility and reactions to particular aspects of E-Learning.

Social-psychological approach - The attitudes and capabilities of educators and learners when using information technology can be grouped as: 1) the perceived value of computer-based information, and 2) computer literacy. Both are accepted as important factors influencing the success of E-Learning [8, 10-12] .

Human relations school - The relationships and interactions among educators and students could be a significant facilitator or inhibitor to teaching and learning in the E-Learning mode. Implementing E-Learning successfully requires task interdependence in which agreement and collaboration of members are necessary and essential. It is imperative that members are comfortable with open discussion of and decision making in relation to E-Learning [8, 13].

Interactionist perspective - The success of E-learning depends on the interactivity among elements mentioned above, and these are influenced by information culture and national culture. Information culture refers to the characteristics of administrators, learners and educators in the use of collaborative information technology for knowledge sharing [12, 14]. National culture refers to "the collective programming of the mind that distinguishes the members of one group or category of people from another" [15]. In the learning environment, interactivity involves the way people think, act and communicate.

A questionnaire was developed based on Hiltz's [8] research framework. However, various independent variables are reworded so that they are more appropriate to the learning environment under study, they are: system resources, computer literacy, and perceived value of computer-based information, group dynamics and learning culture. Since it would be very difficult to measure human learning process and outcomes, the effectiveness of outcomes could be measured through the perception of students and their preferences [8, 16, 17]. Thus, the dependant variables for the success of E-Learning could be interpreted in terms of perception and preferences. Two sets of hypotheses are formulated as follows:

1(a): *System resources* are positively related to student teachers' *perceptions* of E-Learning for teacher education.
1(b): *Computer literacy* is positively related to student teachers' *perceptions* of E-Learning for teacher education.
1(c): *Perceived value of computer-based information* is positively related to student teachers' *perceptions* of E-Learning for teacher education.
1(d): *Group dynamics* are positively related to student teachers' *perceptions* of E-Learning for teacher education.
1(e): *Learning culture* is positively related to student teachers' *perceptions* of E-Learning for teacher education.

2(a): *System resources* are positively related to student teachers' *preferences* of E-Learning for teacher education.
2(b): *Computer literacy* is positively related to student teachers' *preferences* of E-Learning for teacher education.
2(c): *Perceived value of computer-based information* is positively related to student teachers' *preferences* of E-Learning for teacher education.

2(d): *Group dynamics* are positively related to student teachers' *preferences* of E-Learning for teacher education.

2(e): *Learning culture* is positively related to student teachers' *preferences* of E-Learning for teacher education.

3. THE STUDY

There were seventy participants who were pre-service student teachers studying for the Bachelor of Education (Primary) at the HKIEd. Forty four of them took an information technology (IT) module either as an elective or as one of their IT minor studies module. They were mainly year 1 or year 2 students and they were classified as IT students in this paper. The other twenty six participants took general studies as their major and did not take IT as their minor, and they did not take electives and they were year 4 students (non-IT students). IT student teachers were asked to fill in an online questionnaire during their break time towards the end of the semester whilst the non-IT student teachers filled in the same questionnaire using hard copies as there were only a few computers accessible in their classroom. They were not obliged to fill in the questionnaire as no identity was required.

4. FINDINGS AND DISCUSSION

The questionnaire was in a 5-likert scale with strongly disagree, disagree, agree, strongly agree and not applicable. It was found that participants were mostly positive on the items asked as most items had more than half as "agree" or "strongly agree" answers. The answers to "not applicable" are not shown as they were rather insignificant. When these two categories of answers are combined, it was found that they gave the highest rating to the *question 3.3 - usefulness of computer-based information* (95.77%), followed by *2.2 - My level of computer competency is good enough to access different materials* (90.14%) *1.1 - Easy to get access to computer facilities outside campus (88.73%)*. In fact, *question 1.1- easy to get access to computer facilities outside campus* had the highest strongly agree answer. This implies student teachers have good connected computer facilities at home.

It is interesting to observe that some items show dichotomous results. Two out of three items of learning culture had polarized results. About half of them enjoyed reading on-line materials and take part in on-line discussions whilst the other half preferred the opposite (question 5.1 and 5.2). There were slightly more students preferred more face-to-face learning (question 7.1).

Despite adequate student teachers' computer competence and having appropriate infrastructure in place, they were unwilling to take online modules. They gave the lowest rating to *question 7.2 - I prefer to take some modules completely delivered online (35.21%), 4.4 - if my views are different from others in a group, I am reluctant to express it out* (36.62%), and *6.4 - I learn more using traditional board and chalk method (40.85%).* The findings suggest that students were still more comfortable with the traditional mode of learning where the educator is the expert and they are not completely confidence on their own learning as they "*still need some instructions from instructors rather than control my own learning process"* (question 4.3, 88.13%). They were more likely to accept lectures' instruction rather than questioning them (question 4.2, 85.92%).

This finding is somewhat disturbing as they did not seem to have adapted to the new mode of learning and it seems that they may have been adopting a surface learning approach. "Students who believe that knowledge is handed down by authorities or experts would not bother too much in questioning or understanding the learning materials, which would be committed to memory by the surface strategy" [18]. Perhaps it is the Chinese culture to accept and respect their seniors that make them unwilling to take some modules online. The findings further suggest that the learning culture and perhaps the national culture have a strong impact on student teacher's preferences even though they had good perceptions on E-learning.

Multivariate Correlation was used to test the strength between two variables for the hypotheses under investigation. It was found that most variables were significant at the 0.05 level (see Table 4). Hypothesis *2(b): Computer Literacy is positively related to student teachers' preferences of E-Learning for teacher education* was not significant at 0.05 level, that means computer literacy does not affect respondents' preferences on e-learning. All other hypotheses were significant means that all other independent variables affect respondents' preferences and perceptions on e-learning.

The two groups of student teachers were analysed using One-way analysis. It was found that all 5 items of group dynamics (*question 4.1 - To express my views or ideas that contradict what instructors say is not comfortable, 4.2 - I am more likely*

Table 1. Top ranking

Rank	Items	S. Disagree	Disagree	Agree	S. Agree
1	3.3 Perceived value of computer-based information as Useful	2.82	1.41	73.24	22.54
2	2.2 My level of computer competency is good enough to access different materials	1.41	8.45	73.24	16.90
3	1.1 Easy to get access to computer facilities outside campus	4.23	7.04	56.34	32.39

Table 2. Ambivalent finding

Items	S. Disagree	Disagree	Agree	S. Agree
5.2 I like to take part in discussion about my learning with instructors or other students by using e-mail or discussion board rather than doing the work alone.	4.23	45.07	45.07	4.23
5.1 I enjoy reading academic material on-line rather than listening to instructors in classrooms.	2.82	42.25	45.07	5.63
7.1 I prefer to have more E-Learning "lecture" to replace face-to-face learning	5.63	47.89	39.44	4.23

Table 3. Bottom ranking

Rank	Items	S. Disagree	Disagree	Agree	S. Agree
Last	6.4 I learn more using traditional board and chalk method	47.89	33.8	7.04	9.86
2nd Last	4.4 If my views are different from others in a group, I am reluctant to express it out.	7.04	54.93	30.99	5.63
3rd Last	7.2 I prefer to take some modules completely delivered online	11.27	50.7	29.58	5.63

Table 4: The relationships between the dependent variables (Perceptions, Preferences) and the independent variables (Resources, Computer Literacy, Perceived value of computer-based information, Group Dynamic and Information Culture). (N=70)

Correlation	Resources	Computer Literacy	Perceived value	Group Dynamic	Information Culture
Resources	----				
Computer Literacy	0.2014	----			
Perceived value	0.5391*	0.4030*	----		
Group Dynamic	0.1082	0.4681*	0.3307*	----	
Information Culture	0.4535*	0.3854*	0.4401*	0.4539*	----
Perceptions	0.5086*	0.4012*	0.5692*	0.4770*	0.5918*
Preferences	0.5695*	0.2161	0.5085*	0.2868*	0.6160*

** Correlation is significant at the 0.05 level*

to accept lectures' instruction rather than questioning them, 4.3 - I still need some instructions from instructors rather than control my own learning process, 4.4 - If my views are different from others in a group, I am reluctant to express it out and *4.5 - I am more likely to discuss assignments with my friends rather than tackling them alone.*) and item *6.4 - I learn more using traditional board and chalk method* are significant at $p < 0.01$ level but all other comparisons between the two group of student are not statistically significant. This finding suggests both groups of student teachers are positive regarding their ability to adapt to e-learning, and yet their preferences of learning mode and learning style were very different.

5. LIMITATIONS

Although all the respondents were studying the same programme, the IT and non-IT respondents were studying at a different level. Furthermore, the sample sizes of the two groups of students were also rather different. Therefore, one would be cautions at generalizing the findings in this paper to the student teacher population at HKIEd.

6. CONCLUSION AND IMPLICATIONS

This research has provided a first step in exploring the different factors affecting the successful implementation of E-learning for teacher education and to determine the differences between IT module students and non-IT module students. It was encouraging that student teachers were positive regarding most of the items asked which showed that they were ready to take part of the modules using the E-learning mode but they were unwilling to take modules completely online. The group dynamic is the only critical factor that affects IT and non-IT groups in their own preferences and preferences on e-learning. This suggests it is the knowledge and exposure rather than the skills that affect the perceptions and preferences of e-learning.

The findings were very informative and have four major implications; the first implication is that the HKIEd have provided a conducive environment for learners to engage in E-learning. The second implication is that student teachers were well prepared to study online as they did not encounter any problems regarding systems resources, individual differences and learning culture. The third implication is that it would be best to teach using blended learning as there is no unanimous preference regarding face-to-face versus e-learning. The fourth and possibly the most important implication is that; knowledge and experience with using IT to learn rather than the skills makes a big difference to preferences and perceptions towards e-learning.

We are mindful that this is only a preliminary finding and there is a great need to determine whether the IT student teachers were influenced by the concepts they learnt from the IT module or whether they were a group of students who were more proactive and therefore more positive on initiatives and innovative practices. The findings can be constructively complemented by focus group meetings to search for patterns of inter-relationships between different variables. It is appropriate to adopt a holistic view for any forward planning. The results would become more comprehensive and convincing with a larger sample for investigation.

7. ACKNOWLEDGMENTS

The author would like to acknowledge Janice Burn and Nalinee Thongprasert for inspiring her to this research area. Special thanks must go to participants, colleagues namely, Drs. SC Kong, KT Lee and YY Yeung for asking their classes to participate in this research. Thanks also to her research assistants, Lee Lap Piu and Chan Ping Man who helped her in various areas of the research. The research funding from the Hong Kong Institute is also gratefully acknowledged (Project code: 1-4001-16-A377).

ABSTRACT

In Finland, a project designed to modernize processes and reduce the waiting list for joint replacement surgery has recently been completed. The new surgery arrangements for artificial joint patients were monitored for a period of one year. The new arrangements involved relocating the anaesthesia phase outside the operating theatre. The reorganization of the patient care process for joint replacement surgery succeeded in achieving a 50 per cent increase in operations. While conventional operations can often be pushed up a notch with state-of-the-art technology, for example, this article supports the argument that process thinking can be exploited effectively to support new ways of work and improve productivity in healthcare.

INTRODUCTION

The Care Guarantee Act, which came into force in Finland in March 2005, has made many healthcare units look at the arrangement of the services they produce in a new light. Particular attention is fixed on the legal obligation concerning the waiting times between treatment decisions and treatment measures, which is to be no more than six months. The need to increase the number of operations has become a matter of current debate particularly in orthopaedics, where the length of queues has become unlawfully long at several hospitals. Improvements in controlling the queues have previously been achieved by the more efficient handling of referrals (Harno et al., 2000), but with surgery this was felt to be ineffective (Harno et al., 2001). In special operative areas, making use of all the development potential available within the traditional treatment chains should be explored as a permanent remedy, after first-aid obtained in the form of outsourced services. In this article we illustrate a case where process thinking and process development tools where exploited to support new ways of work and improve productivity in healthcare.

PROCESS THINKING

The term 'process thinking' refers to a number of management theories that have been used by industry in its quest for better operating processes over the last few decades. Large-scale application of them in the healthcare sector should be seriously considered because it is time to take a critical look at the publicly funded system. The system is struggling with the combination of rising demand and escalating costs in specialist medical care, while at the same time, there is strong support for reduced public-sector healthcare spending but firm rejection of any cuts in service levels. If the two targets are to become reality simultaneously, the methods enabling them to be achieved should be chosen on the basis of how deep the cuts should be. Cosmetic improvements would be fairly painless: for example, Total Quality Management would result in long-term improvements in operating processes as a more efficient use of resources would bring gradual savings. Some scholars have, however, likened some quality management theories to a rain dance (Schaffer & Thomson, 1992). In their view they look good, sound good and allow those involved to feel good, while at the same time they may have no influence on the rain itself.

There are also other management theories in the field of process thinking. According to the time-based management approach, all development should focus on process lead-time (Stalk & Hout, 1990). In such an approach all other positive aspects, improved quality, cost savings and customer satisfaction will follow automatically. However, development measures do not need to mean squeezing more out of the stages intended to boost the value of the treatment process. In fact, industrial companies have been able to find larger savings in the way they use the time that brings no added value, which, after all, accounts for more than 95% of the total. Cutting consultation times in health care would be sheer folly as the measure would probably only result in additional repeat visits. At the same time, all solutions speeding up the flow of information and improving the service capability of the support processes would be a real 'shot in the arm' to the system: replacing piles of paper with a byte-based system would, for example, give surgeons real-time access to x-ray images, which would allow quicker decision-making and, consequently, help to shorten treatment times.

In contrast to Total Quality Management, which emphasizes continuous development, Business Process Reengineering proposes a radical revision of the business process. The aim is to start from scratch without the burden of old operating approaches (Oliver, 1993; Hammer & Champy, 1993). The reengineering starts with a definition of the desired end result. This will form the basis for the planning of the new process functions and sequences. The aim is to maximize value-adding functions and to get rid of all operations not adding to the value. Extensive use of the information technology is often used as the means for achieving the desired results.

Effecting the operational changes required by Business Process Reengineering has been somewhat problematic. Resistance to change, which is inherent in human nature, and the fact that reengineering is often a zero-sum game, make the implementation of the change process more difficult (Buchanan, 1997). Besides, reengineering thinking emerged just as the recession of the early 90s began to bite, and was often used as a justification for drastic job cuts. In fact, for a while BPR was almost likened to the Black Death in the industrial sector. Since then it has lost some of its reputation and has evolved from a much-feared consulting tool into a set of practical measures. The theory, though somewhat worn-out, is still useful, as it underlines the importance of the information technology in performance improvement. Great potential for applying the theory and information technology can be found in sectors that for ages have relied on well-entrenched operating models, such as health care (Evans, Hwang & Nagarajan, 1997).

This article presents a case from hospital environment where process thinking was utilized. Seinäjoki Central Hospital implemented a project to revise processes in order to reduce queues in surgery, particularly artificial-joint surgery. The project was part of the ProViisikko project of the Hospital District of South Ostrobothnia and Tekes. This article describes the results of the experiment for the benefit of, for example, other operation units that are taking a close look at their operations and of developers and management in health care as support for decision-making. Parts of the study have been published in Finnish language (Jokipii et al., 2006).

STARTING POINTS FOR CHANGE AND EXPERIMENT

Seinäjoki Central Hospital wanted to reorganize the operations for artificial-joint patients so that three operations could be performed in the same operating room in the course of a normal day's work instead of two. The experimental period lasted from November 1, 2004 to November 30, 2005.

The revision of the treatment process utilized process thinking and process development tools. Of these, the theory of constraints was thought the best applicable for examining the process for treating artificial-joint patients. The point in this approach is to identify those stages in the process that dictate the maximum current throughput (Goldratt, 1990). By allocating additional resources and development action to these bottlenecks, the throughput can be improved without needing to interfere in the other stages of the process. The main change for increasing the usage of the operating room capacity was transferring the anaesthetic stage from the operating room to separate induction facilities. Experiments on this had been reported earlier in medical journals (Hanss et al., 2005; Sandberg et al., 2005, Torkki et al., 2005).

In the new arrangement, the anaesthetic stage was transferred outside the operating room. At the same time, one anaesthesia nurse was added to the operating team, working both in the operating room and in anaesthetic. Another anaesthetic nurse took the next patient in good time to the recovery room or to the operating room's induction facilities to be anaesthetized. As soon as the operating room was cleaned after the previous operation, the next patient could be prepared for surgery. The next patient was brought to the operating room already anaesthetized and in the correct position for the operation.

The duties of the orthopaedist that were not part of the operations or preparation for them were scheduled outside the operation days. Thus, the surgeon whose turn it was to operate was able to focus exclusively on the work in the operating room. At the beginning of the experimental period, the same orthopaedist operated for one week at a time, but this practice had to be changed so that the operation days were rotated among different practitioners. At the beginning of 2005, there were five orthopaedists working at Seinäjoki Central Hospital.

MATERIAL, METHODS AND RESULTS

In Finland in 2003, about 6,800 artificial joint operations were carried out on the hip and some 7,200 on the knee, and there were more than 1,700 instances of further surgery. These operations are performed in almost 70 hospitals, but the minimum number of 200 operations recommended by the Ministry of Social Affairs and Health is only exceeded in 25 units. Every year the Hospital District of South Ostrobothnia performs between 550 and 600 artificial-joint operations.

In the study, quantitative material was collected from the operating days in the experimental period on which three artificial-joint operations were carried out (n=49); because of the small number of orthopaedists, there were 2-3 of these days in a week. Comparative material consisted of the days on which two artificial-joint operations were carried out between January 1 and June 30, 2004 (n=27).

The time when patients were in the operating room and changeover times were recorded in the operation database. The time-monitoring material consisted of the times when the operating room was in use. The median time that patients were in the operating room and the median changeover time, when there is no patient in the operating room, were used for comparison purposes.

Qualitative material was collected through interviews during the experimental period and by means of a work-satisfaction questionnaire carried out among doctors and nurses a year after the experiment started.

The new operating model made it possible to carry out three operations during a normal working day. The orthopaedists examined the patients during a pre-operative visit or on the day preceding the operation. The first patient of the morning was in the operating room in time, and the operation started on time at 8.30 a.m. The anaesthetization stages for the second and third patients, which were carried out staggered with the operation, took slightly longer than if carried out in the operating room.

As it was possible to separate some of the steps previously carried out in the operating room and have them done outside, the hospital succeeded in increasing the throughput of the process by 50%, even though the usage capacity of the operating room remained almost the same.

Adding four nurses to the operating team (2 for anaesthetization and 2 for the operation) made it possible to shorten the changeover times considerably: the average time was reduced from 54 minutes to 13 minutes. This was because the team was able to take coffee and meal breaks in turn. One of the operation nurses was able to help the orthopaedist as necessary.

In the three-operation model, anaesthetizing the second or third patient of the day in separate facilities reduced the time the patient was in the operating room by 20 minutes (149 minutes vs. 129 minutes).

According to the questionnaire, fifty per cent or more of the doctors who took part in the experiment felt that the meaningfulness of their work and work motivation had increased and thought that the three-operation experiment should become a permanent fixture. The nursing staff felt that minimizing the idle waiting improves the atmosphere and increases work motivation to some extent. The doctors felt the new operating model improves the meaningfulness of the work and work motivation more than the nursing staff did.

DISCUSSION

The usage capacity of the operating room is generally considered to be the bottleneck in the operation process. This generalization leads easily to a practice where outsourced services or increasing the number of a hospital's own operating rooms are seen as the only options for increasing output. From our experiences the throughput of the process for artificial-joint operations can be increased while the usage capacity of the operating room remains the same or even decreases. Focusing the operations on one operating room proved to be effective.

An increase in the throughput of the operation process was sought without increasing the workload of the staff. The hospital succeeded in doing this by firstly dealing with idle waiting. Targeting greater efficiency here and a simultaneous improvement in the throughput required development in several areas, e.g. adding one nurse to the operating team, a bigger work contribution from the hospital attendant in preparing patients, preparing the anaesthetic in a new way and changing the orthopaedist's work schedule. The justification for adding one nurse was that in the revised staggered operation stage, there was also one patient more.

It was not possible to anticipate all the effects of the change. In order to ensure that things went smoothly, specialist experienced doctors acted as anaesthetists and orthopaedists during the experimental period, but at the same time the arrangement narrowed the opportunities for training specializing doctors. Furthermore, not enough preparation was made for the increase in the number of operations at all stages of the treatment process. At times, the growth in the throughput caused congestion on the ward and especially in further treatment at health centres.

In financial terms, the transfer to the practice of three operations was worthwhile. The resources for arranging three operations were obtained principally by utilizing the fixed costs of the hospital more efficiently. In alternative cost accounting comparing the additional cost caused by a hospital's own activities with the cost of an artificial-joint operation acquired from the private sector or another provider (minus the costs of the prosthesis, materials and cost of the treatment days) shows a difference of some USD 4,000 between the hospital's own work and outsourcing with regard to the added third primary operation per day. Because of the limited number of orthopaedists, however, it was not possible in the experimental period to run 'flat out' five days a week.

15 complete operations a week would be enough to meet the need for artificial-joint surgery in the entire hospital district, and the revised treatment process would generate annual savings of between USD 700,000 and USD 800,000 for the Hospital District of South Ostrobothnia, even taking into account the additional recruitment required.

CONCLUSIONS

The project by Seinäjoki Central Hospital offers an encouraging example of a way to exploit process thinking and process development tools in health care. Seinäjoki Central Hospital succeeded in obtaining a 50% increase in flow-through in the process for treating artificial-joint patients with the transfer of the anaesthesia stage outside the operating room in the reorganization. For every two joint replacement operations previously conducted, there were now three operations performed in the same theatre and in a normal working day. In the longer term, the arrangement would mean that in Finland the entire country's need for artificial-joint surgery, about 15,600 operations per annum, could be dealt with in 30 operating rooms.

The introduction of the new patient care process demonstrated that the operating theatre capacity was not causing a bottleneck, but that it was the orthopaedic

surgeons brought in at the various intervals who formed the key resource. The reorganized care process for patients requiring joint replacement surgery should produce annual cost savings of USD 700,000 to USD 800,000 for the Hospital District of South Ostrobothnia. Following the experience gained in the project, the Seinäjoki Central Hospital has decided to adopt the project model on a permanent basis. A similar reorganization is also possible in other hospital districts.

The Use of Online Discussions to Enhance Face-to-Face Block Mode Teaching

Janette Agg, Monash University, Clayton, Victoria 3168, Australia; E-mail: Janette.Agg@med.monash.edu.au

ABSTRACT

This paper is a case study of the use of web-based communication technologies in conjunction with block mode teaching. It describes how an online discussion forum increased the participation of students, and provided feedback to the instructor on student interaction, learning and understanding. The contribution of the paper is its description of the specific advantages, both to the instructor and the student, of supplementing block mode teaching with online discussions. Guidelines for setting up an online discussion forum in block mode teaching contexts are provided, highlighting those of particular relevance to the block mode context.

Keywords: Block mode, online discussions, web-based technologies.

INTRODUCTION

Universities are increasingly choosing to present some course subjects via on-campus block mode or intensive programs presented over a one to four week period. One advantage of such programs is that they allow students to complete course requirements in a shorter time frame, whilst giving face-to-face access to instructors that may not be available on campus for longer periods. Another advantage is the opportunity to immerse students in a subject, with daily interactions giving both instructor and student the chance for more concentrated interaction. Use of visiting academics from other countries or specialized industrial or corporate instructors can enhance student opportunities for learning. Disadvantages of block mode teaching are that students do not have the time for wider reading and the deeper reflection and learning that may come when there is ample time for the linking of new knowledge to other subjects being studied at the same time (Burton & Nesbit, 2002; Davies, 2006).

These limitations can be partially overcome by providing students with greater opportunities for interaction with their fellow students and instructors both during and in between block mode sessions. One way of providing such increased opportunities is by supplementing formal lectures and tutorials with provision of an online discussion forum accessed using web-based communication technologies. Such web-based platforms for discussion can act as amplifiers, broadening the sharing of information beyond what is possible in an intense face-to-face environment (Tiene, 2000). Although the use of web-based communication technologies in conjunction with face-to-face instruction has been previously researched in detail (Dabbagh, 2002), their use in conjunction with block mode face-to-face teaching has been limited (Yorke et al., 2005; Fuller et al., 2003).

The focus of this paper is a case study that exemplifies the use of web-based communication technologies in conjunction with face-to-face block mode teaching. It describes how an online discussion forum increased the participation of students, and provided feedback to the instructor on student interaction, learning and understanding.

The contribution of the paper is its description of the specific advantages of supplementing block mode teaching with online discussions, both to the instructor and the student. It details how this can improve student participation and learning opportunities by expanding on already occurring classroom dynamics, and give the instructor greater awareness of student learning than would normally be available from face-to-face teaching alone. A set of guidelines is also provided for setting up an online discussion forum to be used in conjunction with block mode teaching.

USE OF ONLINE DISCUSSIONS IN EDUCATION

Online discussions are increasingly used in educational contexts as a component of both distance education and on-campus learning. Such discussions can produce more active engagement from students compared to the face-to-face environment (Muirhead, 2000; Thomerson & Smith, 1996) and have the potential to enhance student learning (Althaus, 1997; Dysthe, 2002; Vonderwell, 2002; Wu & Hiltz, 2004).

Students may find that the addition of online discussions to course teaching gives them more opportunity to reflect and respond to class material (Meyer, 2003; Wozniak & Silveira, 2004) as well as providing a space that suits some learning styles that are not well served in the face-to-face classroom (Poole, 2000; Scheiter, 1996). Minority or disenfranchised groups of students that avoid participation in face-to-face discussions will often express themselves more confidently in online discussions, although this may be dependent on use of a pseudonym (Anderson & Haddad, 2005; Chester & Gwynne, 1998).

Setting up an online discussion area does not guarantee its use. In all online environments, the role of the instructor in structuring and facilitating online discussions is critical to their success as a learning medium (Edelstein & Edwards, 2002; Gilbert & Dabbagh, 2005; Hiltz, 1993; Salmon, 2000). Online discussions can be effective however, in providing opportunities for collaborative peer learning, conversations with instructors, and enhanced understanding through reflection and communication of developing ideas (Cowan, 2006; Laurillard, 2002).

USING ONLINE DISCUSSIONS WITH BLOCK MODE TEACHING

The case being discussed here involved the teaching of an on-campus block-mode subject with 72 enrolled second-year undergraduate students at a university in the Asia-Pacific region. Students were majoring in either business, information technology or a combination of the two. The instructor was flown in from outside the country for two 2-week periods of instruction, separated by 5 weeks in between. The students all had a good level of adeptness with the use of technology and reasonable proficiency in written English. The instructor had previously taught both online and on campus, but had not taught in block mode. The block mode teaching consisted of 6 days a week of teaching in a combination of lectures and tutorials. Students had 2 one-hour lectures and a two-hour tutorial each day, all given by one instructor. As the subject matter involved the use of technology, tutorials were conducted in a computer lab, with each student on a dedicated computer with access to the Internet.

Students were first introduced to the online discussion forum to be used in a tutorial. A few students had previous experience of similar technologies, but for most it was a new experience. Each student was asked to logon to the online forum and post an introduction message. The instructor had already setup discussion topics, and posted an introduction prior to the class, modeling the kind of responses that were required. Students were asked specifically to *"...let us know who you are, where you are from, why you are doing this course, and what your hobbies and interests are. You can also include a photo or a link to your webpage if you have one"*.

The student who had been the first to ask a question in lectures was also the one who was first to post their introduction in the online forum. The level of personal disclosure varied, with some posting their name and course only, and others detailing their hopes, dreams and life philosophies. There was also some comment on first

impressions of learning in block mode. None posted photos, but a small number linked to their personal web pages, inviting response and comment.

One advantage of this process was that all students got to know a bit about the others. As there were four streams of tutorials, this could not have been achieved by asking students to stand and introduce themselves in the classroom. Online introductions also enabled students and the instructor to refer to a person's introduction later on in order to recall who they were. This was particularly useful in face-to-face block mode teaching, where there was less time to become familiar with faces and names through contact over a semester. A second advantage of the process was that it gave a voice to the quieter members of the class, and also enabled participation by those that were late or absent from the class. This was consistent with the greater confidence for some students that has been observed with anonymous interactions (Chester & Gwynne, 1998), although in this case, most students used their real names rather than a pseudonym.

As students became more familiar with using the online discussion forum, they began to adapt their use of it in different ways. For example, one student apologized to her fellow group assignment members,

" I wanna say sorry to my group mates ... for not being able to attend the discussions. When I feel better, then I'll be back!!! Any updates, pls let me know! " The disadvantage of having this visible communication available to students is that some learned they could sleep in and yet still log on to find out what was happening in the tutorial.

Using the first tutorial to get the students to post their introductions meant that the instructor was able to make sure that everyone was accounted for, match names to introductions, and assist anyone who was having difficulty with either registering or using the web-based software. It also allowed the instructor to ascertain whether people were having difficulties at an early stage of the classes.

Although the online forum was initially setup to teach students about internet technologies by first-hand experience, its advantages as a support to block mode teaching soon became apparent. Not only did it allow students and instructor to get to know more about each other, it provided feedback on course process and content, allowing changes to be made, or explanations to be provided in a more timely way than is possible when students are reluctant to ask questions face to face. It gave the instructor insight into attitudes about the course, as well as giving an indication of how engaged students were in their learning.

Initial use of the online forum as an addition to face-to-face classes received positive responses, as well as providing feedback on student apprehension about studying by block mode.

One student commented:

"I am actually finding this subject ...well actually this concept of just messaging and interacting while doing my ... course work quite interesting..... well the block mode system did not turn out that bad after all.... hope you ppl are enjoying this as much as I am".

Other positive comments were:

"I'm really looking forward to doing this subject now (yea...even though its a "block mode" subject)!" and "I'm very sleepy...it's 9.58 am on a rainy Saturday morning, usually I would still be sleeping, but this weekend I'm at uni!!! Although I must say, it isn't as bad as I thought it would be, this block mode isn't the nightmare I thought it would be."

There were, of course, also some negative responses:

"Aren't we getting a bit too excited over this message-posting business?" and "yes, finally!!!!!I just managed to get in....after struggling for say, almost half an hour!! Sigh.....how forgetful of me, really! Forgotten my username at first, then my password, then registered again and then waited for the acknowledgement, and then sigh...delaying here and there!!!!!"

Some of these responses were due to frustrations with the web-based technology itself, or with the process of its use interfering with what some considered "real learning".

A few students commented that they thought that interacting online was distracting from doing assignments and more serious study, and could not see any benefit from it. Once it was pointed out that some marks were to be allocated for online participation, everyone complied with at least the minimum interaction requirement.

As one student said:

"Well, I just can't find a time to log in here!! But let me introduce myself to you in this message board, as this will add some points into my record :)"

Although this means of getting student involvement detracted from the broader goal of peer learning, it did at least provide the opportunity for greater familiarity with the technology tools used, reflection on course content in responses to the required discussion topics, and a chance of increasing the interaction between the students themselves.

The responses also allowed the instructor to better ascertain the level of comfort each student had with English language, and pick up references to local language that was unfamiliar. This was important in giving assistance with assignment work, and referring students to appropriate support if it was necessary. Another benefit for the instructor was the information a few students provided about why they were not turning up to class. As one student said:

"Maybe I will be a while late for my tutorial .. since the sky is raining now .. I hope it won't traffic jam."

Not only was the instructor made aware of why, the student working from home could be brought up to date with the class material that they had missed.

During the break between the two 2-week teaching blocks, the instructor kept in touch with students via the online forum. Although a number of other communication channels were made available for contact with students during this time, such as email, phone and instant messaging, the predominant mode of contact the students chose was the online discussion forum.

This meant that students heard from the instructor even if they had not asked a question themselves, and everyone heard the answers to questions asked, so that no single student received unfair advantage from receiving information that others did not. It was also easier for the instructor to respond once in the online forum, rather than in a number of separate emails to students.

Although there was no new coursework during the break, students had been left with individual and group assignments to work on during this time. They were encouraged to report back regularly on their progress and any issues that arose, as well as give feedback on the conduct of the course, and ask questions on course content. This worked well, with students keeping their instructor in touch with progress on assignment work, and asking questions as they needed clarification on what was required of them.

One unexpected use of the Help Desk discussion area, set up by the instructor to answer student queries, was that it gained more use by the students helping each other.

Table 1 shows a list of the discussion topics, and the breakdown of student and instructor posts as a percentage of the total number of posts in each, giving an indication of where student participation was highest.

This shows that the Instructor made 25% of the postings, and the students the other 75%. This is a high workload for the instructor. It also shows the most active discussion to be the one on assessment tasks, which seems to fit with the common observation of student learning being dominated by a focus on what is required of them to pass the course, rather than the acquisition of knowledge for its own sake (Biggs, 1999). The low level of online discussion about course content was not surprising given that there was ample opportunity provided for such discussion in face-to-face lectures and tutorials.

The participation of students in interactions of this type demonstrated engagement both with the technology, and the course content. This was continued in the

Table 1. Instructor vs. student discussion posts

Discussion Topic	Number Total Posts	% Total Posts	Number Student Posts	% Student Posts	Number Instructor Posts	% Instructor Posts
Assessment Tasks	210	40	138	35	72	55
Introductions	144	27	133	34	11	8
Feedback	68	13	59	15	9	7
Informal Discussion	64	12	46	12	18	14
Notices	26	5	11	3	15	11
Course Content	9	2	5	1	4	3
Help Desk	8	2	5	1	3	2
	529	**100**	**397**	**75**	**132**	**25**

informal discussion area, which was used for discussing everything from politics and films, to asking questions about the exam.

The Assessment Tasks topic asked every student to choose a topic for their first assignment, and the topic and members for their group assignment. This was again easier than doing it in a classroom or tutorial format, as everyone could see what the others were suggesting, and there was no dispute over who got in first in choosing a particular topic. It also saved the instructor from having to write it all down, and kept track automatically of who had posted and who had not. This was a useful information management tool, and also helped in the process of familiarizing names and groups. It also allowed the instructor to follow up on anyone who appeared to be left without a group or not participating.

In terms of information management, use of the online forum provided a number of advantages to both the students and the instructor. For the students, it gave them a greater voice in talking to each other about the experience of block mode, and about the subject itself, as well as an outlet for those that might be isolated through not knowing other students enrolled in the course. For the instructor, it served as a vehicle to get to know the class, and documented examples of the issues of teaching in block mode. Overall, the online interaction was an aid to greater student engagement in the course and kept students involved in their learning activities between face-to-face teaching blocks.

SUGGESTED GUIDELINES FOR IMPROVING PARTICIPATION

Based on the online discussion forum interactions both in this case, and in comparison with similar online discussion forums discussed in the literature, a number of guidelines are recommended for improving student participation specifically in face-to-face block mode courses. Those of particular relevance to block mode teaching contexts are highlighted in bold type:

1. Introduce an online discussion forum as a supplement to face-to-face teaching.
2. As part of this initiative, setup an initial discussion framework prior to the commencement of block-mode teaching, with introductory posts by the instructor modeling the posts that students are to respond with.
3. It is generally best that the instructor sets up all discussion topics, otherwise students tend to start new topics without paying attention to topics that are already in existence. You can always add new topics later on if students request them.
4. Where possible, arrange for a tutorial session in a computer lab with all students, where they are introduced to the online discussion forum and asked to post their introduction to the rest of the class there and then. This overcomes the initial barrier of unfamiliarity with the technology, and allows the instructor to give immediate assistance.
5. Where introductions are being posted by a number of students at the same time in a computer lab environment, acknowledge all students individually, even if it is done within the one response. Students will notice if they are forgotten!
6. Unlike distance education courses which will have a lot of interaction in course content topics, block mode courses will tend to have more interaction in the social discussion topics unless they are specifically structured otherwise. Both block mode and distance education courses using web-based technologies will see a significant amount of interaction in topics related to assessment tasks. Take this into account by ensuring that both kinds of discussion topics are made available. If you want more online interaction around discussion of course content, then set this as a task for assessment.
7. Respond to all postings by students within 24 hours. This is important so that students remember what they posted, get immediate feedback, and do not feel disregarded. This does of course, mean that the instructor needs to schedule time each day to log in to the online discussion and respond to queries, and this should be taken into account in assessment of the instructor's overall academic load.
8. Have both formal and informal areas for conversation, and an area set aside for feedback.
9. Where feedback is posted by students, respond to each point raised, letting the student know that their feedback is appreciated, and what will be done about it.
10. Make participation in the online discussion forum a component of student assessment, so that students have a motivation to participate beyond it being a source of information.

CONCLUSION

In summary, use of web-based communication technologies can enhance the teaching of face-to-face block mode courses by allowing for interaction over an extended period of time, and increasing the depth of interaction. The most important issues to encourage student participation in such discussion forums are instructor interaction, timely response to student posts, provision of relevant information that meets the needs of students, and incorporation of an assessment component for the interactions.

The guidelines suggested are based on one example of teaching a face-to-face block mode course and need to be tested in a variety of block mode teaching contexts. They are suggested for use in conjunction with online discussion forums, but could be applied when using more recent and emerging communication tools such as wikis, blogs, write boards, and shared tagging (Alexander, 2006).

Software Piracy Determinants Among University Students: An Empirical Analysis

Arsalan Butt, Vancouver Coastal Health, Dept of Medicine, University of British Columbia, Vancouver, BC, Canada, ab@sfu.ca
Adeel I. Butt, Simon Fraser University, 6827 - 135A Street, Surrey, British Columbia, V3W4X2, Canada; E-mail: AIB@SFU.CA

ABSTRACT

Software piracy is widespread in many parts of the world. Websites such as Kazaa and more recently BitTorrent based websites have made it easier to access pirated software, which has resulted in increased emphasis on the issue of software piracy in both the software industry and research community. Earlier empirical studies have looked at software piracy as an intentional behaviour. This study explores the demographic, ethical and socio-economical factors that can represent software piracy as an unintentional behaviour among a developing country's university students. The authors have conducted a comparative analysis of university students from Pakistan and Canada, two countries that differ economically and culturally. The results of the study indicate that software piracy behaviour is different in both groups of students, but that there are also some similarities.

1. INTRODUCTION

According to Husted (2000), knowledge and information are now more important factors in a national economy than the traditional physical assets that previously indicated economic well-being. Therefore, the protection of intellectual property (IP) has received increased attention recently. Software is also an intellectual property and any unauthorized duplication of computer software is a crime. However, the practice of making illegal copies of software amounts to high rates in various parts of the world. Software piracy directly affects the earnings and profitability of the software industry. Software piracy causes loss of earnings to the firm and loss of tax revenue to the economy of the country (Simmons, 2004; Givon, Mahajan & Muller, 1995). A recent study claims that "For every two dollars' worth of software purchased legitimately [globally], one dollar's worth was obtained illegally" (BSA, 2005, p. 3). The same study claims that eight in every ten software programs installed on PCs in Pakistan are pirated, while the rate in Canada is 35%.

Studies have shown that low national income and low personal incomes are not the only reasons for which software is pirated; Swinyard, Rinne, & Kau (1990) observed that attitudes towards software piracy are affected by cultural standards and customs. Therefore, "the neglect of culture as an explanation of software piracy seems odd given the fact that cultural values have such a significant impact on a wide array of business practices in different countries" (Husted, 2000, p. 200). This study is therefore an attempt to understand those cultural, social and ethical factors that can determine attitudes of software piracy behavior among university students.

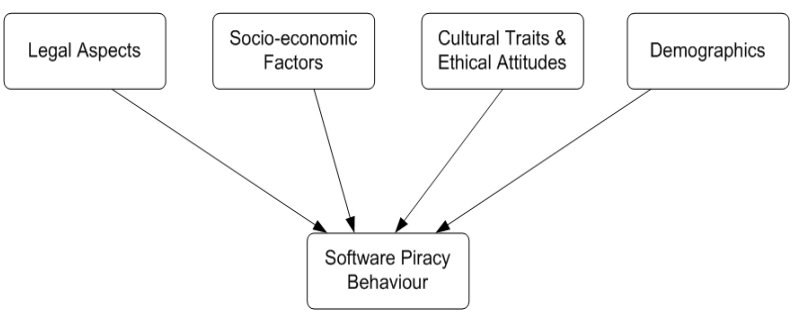
The next section presents a brief overview of the current literature along with a description of the research model developed of this study. Section three lists hypotheses of this study. Section four details the adopted research methodology followed by an analysis of the collected data. The results and their implication are discussed in section five, followed by the conclusion.

2. LITERATURE REVIEW & RESEARCH MODEL

Empirical studies have been done on the subject of software piracy in different developing countries such as Saudi Arabia (Al-Jabri & Abdul-Gader, 1997), Thailand (Kini, Ramakrishna & VijayaRama, 2003), People's Republic of China (Wang, Zhang, Zang & Ouyang, 2005) Malaysia (Rahim, Rahman & Seyal, 2000), India (Gopal & Sanders, 1998) and Jordan (El-Sheikh, Rashed & Peace, 2005). Although Husted (2000) and Proserpio et al. (2004) included Pakistan as one of the countries in their respective analytical studies of software piracy, empirical studies on the software piracy issues of Pakistan do not exist in the literature. This seems odd considering the fact that the software piracy rate in Pakistan is one of the highest in the world. A comparative study can therefore provide a means of highlighting differences and possible similarities of software piracy determinants between a developed and developing country. Therefore Canada was chosen for this purpose as it is culturally and economically different from Pakistan and can provide a contrasting view. Moreover, there hasn't been any recent Canadian scholarly literature[1] in this context. This research can therefore help fill a part of that void and the results can provide a better understanding of a developing country's software piracy issues that can help the policy makers to address the problem more effectively.

Theory of reasoned action (TRA) suggested by Fishbein & Ajzen (1975) and theory of planned behavior later developed by Ajzen (1991) have been used

Figure 1. Software piracy behavior model



Source: Butt (2006)

extensively in the literature to explain software piracy behavior and intentions. Both of these theories look at behavior as an intentional act. While it is true that the literature on software piracy (a significant portion of which is based on TRA and TPB) has helped in understanding various aspects of the matter, there have been no empirical studies to prove that software piracy can be conceptualized as an unintentional behavior or as a behavior that is the product of the social and cultural environment within which the behavior is carried out.

The model developed for this research[2] (shown in fig. 1) includes social norms as one of the variables. The basic structure of this model has been adopted and modified from a model that was used by Proserpio et al. (2004). Their model was based on a multi-causality approach to determine software piracy factors in 76 countries (including Pakistan and Canada) and is therefore appropriate for this research[3].

The research question for this project is to determine whether software piracy behavior among university students of a developing country can be conceptualized in terms of social and cultural norms and customs, rather than in terms of intentions as has been described (for piracy amongst university students) in most of the literature. We therefore contradict the notion of intentional software piracy behavior and suggest that software piracy can be represented as a consequential behavior that results from social norms of a developing country's society.

3. HYPOTHESES IN THIS STUDY

Earlier studies (Marron & Steel, 2000; Rapp & Richard, 1990) have found a strong inverse correlation between piracy rates and the income level of the country. Therefore, it is hypothesized that:

H1: Income will have a direct influence on piracy behavior of subjects.

H2: High price of original software will have a direct influence on the piracy behavior of subjects.

Many studies (Marron & Steel, 2000; Shin et al., 2004; Husted, 2000; Al-Jabri et al., 1997; Gopal & Sanders, 2000) have concluded that the collectivistic culture or the collectivistic nature of the society is to blame for the high software piracy rates. Moreover, "among high IDV [individualistic] countries, success is measured by personal achievement. Canadians tend to be self-confident and open to discussions on general topics; however they hold their personal privacy off limits to all but the closest friends" (Geert-Hofstede.com, 2006, para. 3). This implies that unlike Pakistan, Canada is based on an individualistic culture and therefore people would refrain from collectivistic activities. Therefore, social norms and culture will be taken into consideration as well and the following is hypothesized.

H3: Social/Cultural norms will have a direct influence on the piracy behavior of subjects.

Several studies (Moores & Dhillon, 2000; Moores & Dhaliwal, 2004; Simpson et al. 1994) concluded that high availability of illegal software and lack of legal implications thereof have an effect on piracy intentions and behavior. The following is therefore hypothesized:

H4: There will be a direct relationship between the availability of pirated software and the intent of subjects.

H5: Legal enforcement will have a direct influence on the intent of the subjects.

H6: Legal enforcement will have a direct influence on the social norms.

Several authors (Kini et al., 2003; Higgins & Makin, 2004; Sims et al., 1996) have found that males were more inclined towards pirating software. Therefore, the following is considered as the null hypothesis for gender.

H7: There will be no difference between males and females regarding their software piracy behavior.

"People's perceptions of a particular behavior are shaped by the existing value system of the society" (Lau, 2003, p. 234). Several studies (Jones, 1991; Swaidan, Rawwas, & Al-Khatib (2004); Siegfried, (2004); and Limayem et al. (1999)) have determined that ethical beliefs of individuals are crucial in their decision-making process. It is therefore hypothesized that:

H8: There will be a direct relationship between attitudes towards piracy and the piracy behavior of subjects.

The discussion that has been presented so far in this research extensively elaborates on the fact that current literature regards piracy behavior as intentional. To conform to the current literature, the following final hypothesis is made.

H9: There will be a direct relationship between intent and actual piracy behavior of subjects.

4. RESEARCH METHODOLOGY

4.1 Site Selection

As is the case with many research projects, this study also had limited resources in terms of time and money. The sites for the study were therefore chosen with these factors taken into consideration. For the Canadian part of the study, the authors' home university was chosen. For the Pakistani study, the city of Lahore was chosen since it has one of the biggest pirated software markets in Pakistan and also has several IT based institutions. Five universities were chosen in Lahore.

4.2 Sampling Characteristics

Students were chosen as the target population in order to conform to the existing research, most of which is based on samples of college and university students. Students at both undergraduate and graduate levels from information technology and computer science departments were included in this study.

4.3 Pilot & Actual Studies

A self-administered survey instrument/questionnaire was developed. This questionnaire consisted of closed-ended questions that were used to collect demographic details about the research participants. The questionnaire also consisted of 31 items, each rated on a 5-point Likert scale to assess respondents' attitude towards ethical, economical and demographic implications of software piracy. Negatively worded items were included to detect response patterns. Various items in the questionnaire were adopted from current literature including Moores & Dhaliwal (2004), Siegfried (2005) and Al-Jabri et al. (1997). Based on the feedback of a pilot study (conducted in Canada), minor changes were made to the format and content of the questionnaire, and it was also modified to make it adaptable in Pakistan.

While conducting the study in Pakistan, hard copies of the questionnaire were physically distributed at the same time in four classrooms and one computer laboratory at each of the five universities. The questionnaire at the university in Canada was administered through the Internet with the use of a secure program written in PHP/CGI to capture responses.

5. DATA ANALYSIS

5.1 Descriptive Statistics

The online survey conducted at the university in Canada returned 208 responses, out of which 196 were usable. Most of the Canadian respondents were under the age of 26 (n=172, 88%)[4]. There were 122 (62%) males and 74 (38%) female respondents. The survey in five Pakistani universities returned 365 responses, out of which 339 (n=339) were usable. As was the case in Canadian data, most of the respondents were under the age of 26 (n = 325, 96%). There were 221 (65%) males and 118 (35%) female respondents.

Table 1. Composite variables in the study

Pakistani Study – Variable (Group) Names	Canadian Study – Variable (Group) Names
Availability	Availability
Legal	Price
Intent	Norms
Norm-attd (i.e. socially or culturally mediated attitudes)	Ethical beliefs and Attitudes
Price	Legal Knowledge
-	Piracy Behavior
-	Intent

5.2 Hypotheses Testing

For testing hypotheses, the questionnaire items in both Pakistani and Canadian questionnaire were grouped together to make the statistical tests feasible. The groupings were made based on 1) the face validity, i.e. interpretability; 2) factor loadings; and 3) reliability aka Cronbach's alpha, sometimes also referred to as 'internal consistency', of the Likert items. This grouping is shown in table 1.

Structural Equation Modeling (SEM) with LISREL was used to test the relationships between the above groups/variables. Based on composite scores, the 'Norm-attd' group in the Pakistani data was further split into 'socnorm' for 'social norms' and 'attit' for 'attitude'. In the SEM for the Pakistani group, a latent variable called 'sociomor' was created which was composed of 'socnorm' and 'attit'.

In the Pakistani data, four of the six 'price' items (i.e. questions from the questionnaire grouped together as 'price' factor) loaded on one factor with internal validity of 0.719 (Cronbach's $\alpha = .719$). Similarly the reliability of the Canadian 'price' factor was high ($\alpha = .69$). All four 'availability' items in Pakistani data loaded on a single factor (Cronbach's $\alpha = .68$). The items were then optimally scaled using multiple correspondence analysis, and Cronbach's α for the four transformed 'availability' items increased to .76. All five Canadian items in this category loaded up with even a higher reliability (Cronbach's $\alpha = .813$). Principal Component Analysis conducted on the Pakistani 'legal' items resulted in a three factor solution that could be interpreted as being composed of the factors 'legal knowledge', 'legal actions', and 'moral principles'. However, this factor decomposition was not as clear cut as in the Canadian study, so for parsimony a one factor solution was retained. 'Legal' items in the Canadian study loaded up as a 'legal behavior' factor (Cronbach's $\alpha = .945$) and a 'legal knowledge' factor (Cronbach's $\alpha = .482$). This implies that the awareness of legal implications of software piracy was more significant among the Canadian respondents.

5.3 Fitting Data on Structural Models

LISREL was used to fit the Pakistani data on a structural equation model.[5] The resulting path coefficients are shown in figure 2. The Canadian data had a poor fit on this model. Therefore another model (shown in figure 3) was made on which Canadian data had a good fit.

The gender → piracy behavior path in the Pakistani model representing a fairly strong relationship with a coefficient of 0.23. hypothesis 7 is therefore rejected in this case. The same path in the Canadian model has a coefficient -0.13 implying acceptance of hypothesis 7. In the Pakistani model, the price factor (price → piracy behavior, 0.03) does not seem to have any effect at all on the piracy behavior, therefore rejecting hypothesis 2. However, it has strong negative relationship (-.047) with the intent variable, thus rejecting hypothesis 1. In the Canadian model, price has very weak relationships with both intent and piracy behavior, having path coefficients of 0.01 and 0.02 respectively. Thus both hypothesis 2 and hypothesis 1 are rejected in this case. Legal issues have a strong influence on both intent (0.54) and the sociomor variable (0.40) in the Pakistani model. Therefore, hypothesis 5 and hypothesis 6 are accepted in this case. The Canadian legal construct has a weak relationship with intent (0.07) and a significant relationship with ethical beliefs and attitudes, thus rejecting hypothesis 5 but accepting hypothesis 6. The availability of pirated software has a very small effect on the intent of Pakistani students (0.13) but has a fairly strong relationship with the sociomor (0.29). Hypothesis 4 is rejected in this case. The correlation between the availability of pirated software and the intent of Canadian students is 0.23. Hypothesis 4 is therefore accepted for the Canadian data. Intentions in the Pakistani model have a very high negative relationship (-0.76) with the piracy behavior. Hypothesis 9 is therefore rejected. The sociomor construct, on the other hand, has a very significant relationship (0.39) with the piracy behavior, thus accepting hypothesis 3. Since ethical attitudes towards piracy were included in sociomor variable in the Pakistani model, Hypothesis 8 is also accepted. As far as the Canadian model is concerned, the norms variable has a strong influence (0.52). The norms however do not have any effect on the piracy behavior as is evident with a very small path coefficient of 0.05 between the two. Intent on the other hand has a significant relationship (0.34) with the piracy behavior of the students. Hypothesis 9 and 3 are therefore accepted and rejected respectively.

Figure 2. Pakistani structural equation model

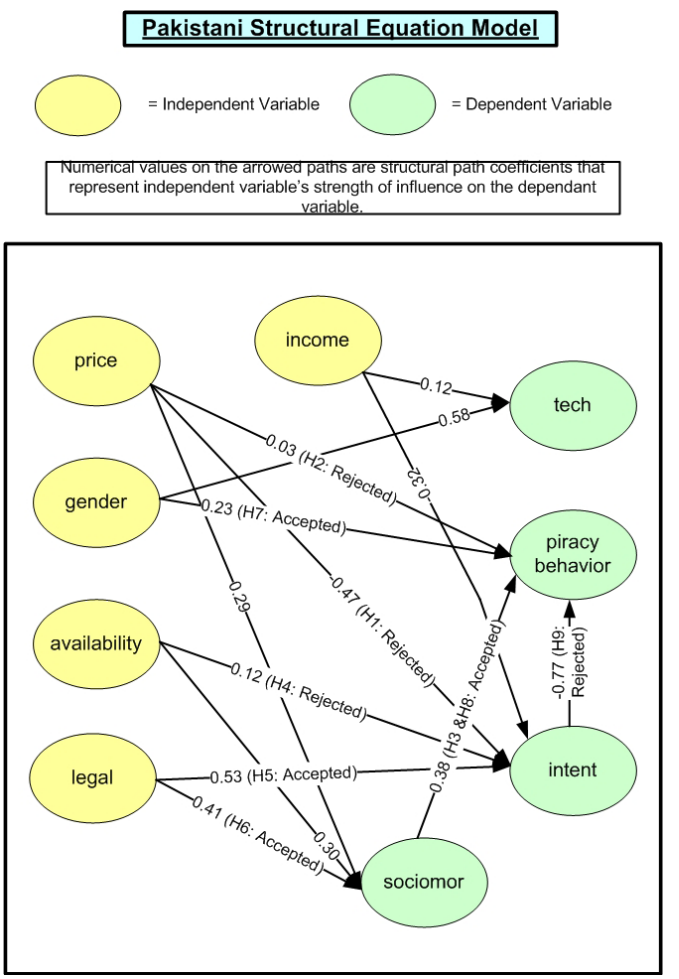


Figure 3. Canadian structural equation model

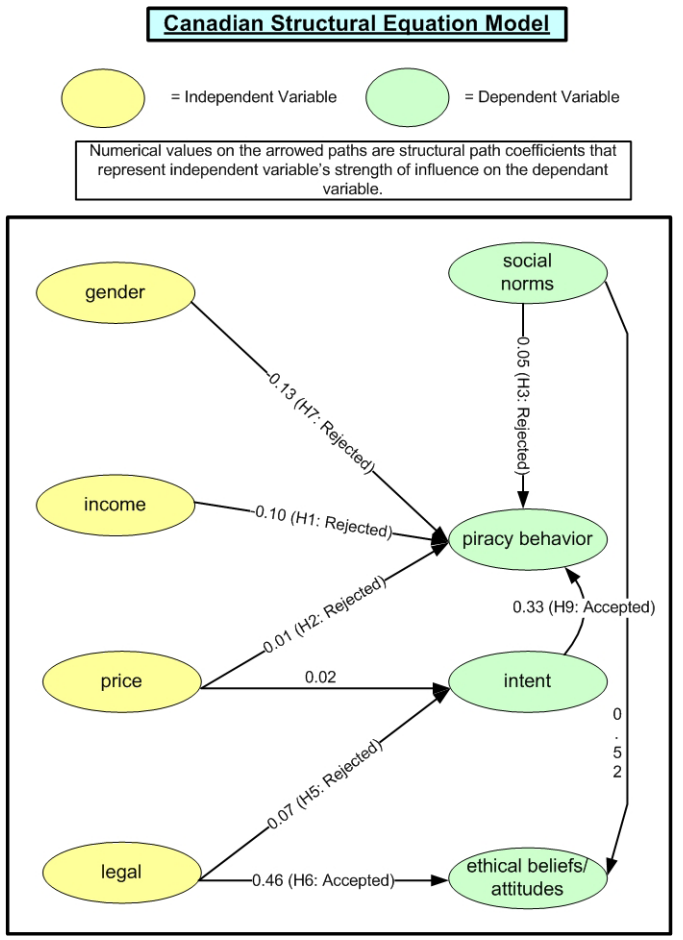

6. DISCUSSION

The analysis of economic factors (high price of legal software and low income) in this study provides a rationale for the reluctance of the Pakistani government to enforce intellectual property rights. Despite being aware of the rampant software piracy, governments of countries such as Pakistan are aware of the economic conditions of the mass population. People (students, in the context of this research) in the developing countries need to have cheap access to resources (software) in order to keep up with the rapid pace of technological advancement in the Western world. It can therefore be assumed that governments of developing countries are aware of this and therefore are always reluctant to enact and enforce strict IP protection laws.

The empirical evaluation provides strong support that social norms and positive attitudes are correlated with the actual piracy behavior of Pakistani students. This finding is similar to that of Proserpio et al., (2004), Seale et al., (1998), Limayem et al. (1998) and Al-Jabri, I. & Abdul-Gader (1997). On the other hand, intentions proved to be stronger predictors of piracy behavior of Canadian students and this finding conforms to the literature which regards piracy behavior as intentional. The achieved results answer the research question that this study was based upon; that is, it supports the hypothesis that software piracy behavior in Pakistan cannot be regarded as purely intentional. It should rather be conceptualized as a consequential behavior resulting from various elements, with customs or social norms being the strongest of them all.

Swinyard et al. (1990) noted that "the cultural history of Asia does not generally support the notion of protecting proprietary creative work. In many Asian nations the highest compliment one can be paid is to be copied" (p. 657). Due to a lack of IP related awareness (unlike the Western world), this culture of copyright infringement is deeply rooted in the Pakistani society in such a way that one buys and sells pirated software without even realizing that their action might be considered illegal and/or unethical. It is an established norm: a custom; the way an act is supposed to be normally carried by everyone. The abundance of pirated software markets and an almost absent IP related legal enforcement exaggerate an already piracy-favouring environment. Similar conditions are responsible for high piracy rates in other regions of the world as well.

7. CONCLUSION

This study has found that there is no one way of understanding piracy behavior across different countries. Although poor national economy plays a substantial role in software piracy rates, culture is also part of the equation. This study has also suggested that software piracy behavior in a developing country such as Pakistan cannot be conceptualized as an intentional behavior, but it can be in the case of a developed country such as Canada. Caution should be practiced in all future research that attempts to study piracy behavior as the applicability of Western constructs such as 'attitudes' and 'intentions' to collectivist societies must always be critically examined. Based on previous research results and the results of this study, authors of this study are confident that the structural models presented here represent a reasonable explanation of software piracy activity in the student population of Canadian and Pakistani universities included in the study. However, due to limited resources, this research was restricted. Subjects from more countries should be included in future cross-country studies of software piracy behavior so that the results of this study could not only be generalized for the general student population but also to the population at large. There is also a lack of longitudinal research and also of other forms of electronic piracy, such as the availability of pirated e-books on the Internet. Future research could therefore attempt to study both of these domains as well.

ENDNOTES

1. There was only one Canadian empirical (scholarly) study found in the literature (see Limayem et al., 1999). This study however relied on 98 research participants only and therefore cannot be considered very extensive.
2. It is important to emphasize here that the model shown in Figure 1 presents a very basic structure which represents the theoretical base of this research.
3. This model is an adaptation from one of the author's earlier work (Butt, 2006).
4. All percentages are rounded off.
5. Regression analysis of the data was also conducted using SPSS but due to word limitations is not presented here. Complete data analysis is given in the main author's graduate thesis available through his website: www.sfu.ca/~abutta

Knowledge Process Modeling in SME and Cost-Efficient Software Support: Theoretical Framework and Empirical Studies

Kerstin Fink, University of Innsbruck, Austria; E-mail: kerstin.fink@uibk.ac.at
Christian Ploder, University of Innsbruck, Austria; E-mail: christian.ploder@uibk.ac.at

ABSTRACT

Current research in knowledge management is concentrated on concepts for large companies. In this article the focus lies on the modeling of knowledge processes for small and medium-sized enterprises (SME). In the first part of this paper an empirical study conducted at the Department of Information Systems (University of Innsbruck) illustrates the key knowledge processes (knowledge identification, knowledge acquisition, knowledge arranging and knowledge transfer) for SME. The result of this survey is a knowledge process model which links efficient methods of the knowledge management to SME. Furthermore, this paper reports the findings of the empirical study designed to allocate cost-efficient software products to each of the four knowledge processes in SME. This paper analyzes knowledge processes and gives a framework of methods and cost-efficient software tools.

1. INTRODUCTION

Business process modeling [Hammer & Champy, 1993] has become a major research field in the information systems discipline in the last ten years. Davenport sees the term business process as "a structured, measured set of activities designed to produce a specified output from a particular customer or market" [Davenport, 1995]. However, in recent years, not only business process management, but also knowledge management is developing into a new research field [Probst et al., 2005; Rao, 2004]. The linkage of these two research fields is called knowledge process modeling. For Richter-von Hagen et al. "a process is knowledge intensive if its value can only be created through the fulfilment of the knowledge requirements of the process participants" [Richter-von Hagen, 2005, p. 358]. Gronau describes the following facts of knowledge intensive processes: diversity of sources and media, variance and dynamic development of the process organization, a plenty of process participants with different expertises, use of creativity, high level of innovation and influence on the area of the decision [Gronau, 2004, p. 410]. Edwards and Kidd [Edwards & Kidd, 2003, p. 124] named the following five characteristics to enforce the argument that knowledge management and business process management should be integrated:

- Knowledge management is important for business if the initiative implied an advantage for the customers. The idea to implement the customer's requests – may be internal or external – is the base for including the customer [Fink et al., 2006].
- Knowledge doesn't follow the business borders. Business processes also model activities by global trading companies and build the base for modeling knowledge intensive processes.
- Knowledge management can only be efficient if it follows a structured model. Business processes are modeled by structured actions and they are necessary to deduce knowledge intensive processes.
- The success of knowledge management depends on the measurement of knowledge. There exists a similarity to the measurement of business processes. The measurement of the knowledge potential provides a central position and biases the success [Fink, 2004].
- Knowledge management is affected by a holistic approach. Every part of the business process modeling is important for success but every aspect should be considered.

In addition, knowledge management and business process modeling initially focused on large companies. The knowledge economy has to shift from the view of large companies to small and medium-sized enterprises (SME) because of their importance for the industrial economics. A definition of SME will be given in the next chapter. The driving reason behind today's shift from large companies to SME is that all businesses are depending on methods and tools of knowledge management in order to gain competitive advantages and deal with the knowledge potential of their employees [Fink, 2004]. In western industrial economies SME have a share on the market of more than 95% and supply more than 60% of the employees [Statistical Yearbook Austria, 2005]. Therefore, in this paper the focus lies on the impact of knowledge process modeling for SME to help them getting a framework to be more innovative [Donnellan, 2006]. In Chapter Two the theoretical framework for the identification of knowledge processes in SME will be discussed. Chapter Three covers the use of cost-efficient software products for the implementation of knowledge processes in SME. Chapter Four gives an outlook of future research by the determination of innovation underlying knowledge processes.

2. THEORETICAL FRAMEWORK

This chapter introduces the framework for the definition of knowledge processes in SME and the realization of these processes through the use of cost-efficient software products – in this case the main focus lies on the investment costs.

2.1 Definition of SME

In the literature of business management there is a variety of about 200 different definitions of SME. A cause therefore can be the huge amount of possibilities of operationalization of the term SME. For this study it was not necessary to define SME qualitatively. So a quantitative definition was chosen by the use of the definition of the European Union which was established in the year 2005 [European Commission, 2006].

SME are quantitatively determined by three factors: (1) the number of employees, (2) the total assets and (3) the annual turnover. SME can be divided into three more detailed categories: (1) *middle enterprises* (less than 250 employees AND less than 50 Mio. EURO annual turnover OR less than 43 Mio. EURO total assets), (2) *small enterprises* (less than 50 employees AND less than 10 Mio. EURO annual turnover OR less than 10 Mio. EURO total assets) and (3) *tiny enterprises* (less than 10 employees AND less than 2 Mio. EURO annual turnover OR less than 2 Mio. EURO total assets).

This research focuses on SME which have less than 250 employees and less than 50 Mio. EURO annual turnover or less than 43 Mio. EURO total assets. The next sub-chapter will show the development of the knowledge processes for SME.

2.2 Knowledge Processes in SME

To make knowledge usable for all stakeholders of an organization a knowledge base must be implemented. This base covers all the knowledge which an organization needs to operate and solve problems: It should include individual but also collective parts of knowledge like abilities, skills, norms, routines experiences and myth. The theoretical approach of Probst, Raub, Romhardt [Probst et al., 2005] is the basic framework for the identification of knowledge processes in SME for this paper. [Probst et al., 2005] defined eight "building blocks of Knowledge Management" which are: (1) identification of knowledge, (2) acquisition of knowledge, (3) development of knowledge, (4) sharing of knowledge, (5) use of knowledge, (6) conservation of knowledge, (7) evaluation of knowledge and (8) aims of knowledge.

In the first step the authors conducted a study with the objective to find the key knowledge processes – based on the framework of [Probst et al., 2005] – for SME. The detailed research design is described in [Fink & Ploder, 2006]. In short, 20 expert interviews were conducted by the Department of Information Systems at the University of Innsbruck in summer 2005 [Fink & Ploder, 2006]. Ten experts from science and ten experts from practice were asked about the most important knowledge processes in SME. The result of the interviews was a knowledge process model for SME. Figure 1 illustrates the four key knowledge processes: (1) Knowledge Identification, (2) Knowledge Acquisition, (3) Knowledge Arranging and (4) Knowledge Transfer.

2.3 Quality Model (ISO/IEC 9126) for the Evaluation of Software Products

This knowledge process model for SME was the first step in the research work and the general research framework. The second step was to find out which process can be supported by which knowledge method. After a literature analysis [Coakes & Clarke, 2006] the following methods were identified to support the four processes [Fink et al., 2006].

In a third step, the objective was to match a cost-efficient software product to each knowledge method which are usable in practice. In the research design the focus lies on Freeware and Shareware software products in order to fulfil the presetting of cost-efficient software support. The research method was an online research with the result of a list of evaluated cost-efficient software products. The evaluation of each software product was conducted by applying the ISO/IEC 9126 norm. The Quality Model of the norm (ISO/IEC 9126-1) is divided into two parts which are important for the evaluation of the software products to support knowledge methods:

- the internal and the external quality of the software as well as
- the quality for use.

The ISO norm lists five characteristics to evaluate software products: (1) functionality, (2) reliability, (3) usability, (4) efficiency and (5) assign ability. For each characteristic a different number of items were assessed by a likert scale from -2 up to +2. The process how the authors did the assessment is shown in the appendix. The data sample of the quality model was more than 200 different software products. A key research finding was that some of the software products can not be used in practice because their quality was not sufficient. Finally there were 45 software products which are efficient for use in SME.

The following research question can be formulated: Which of the methods are efficient for use in SME and which software products will be implemented by SME? Therefore the authors formulated two key hypotheses:

Hypothesis 1: Knowledge Management Processes can be realized in SME with more than a 30% support of office similar software.

Hypothesis 2: More than 50% of the SME which can image to invest into Knowledge Management in the next year will invest more than 3.000 EURO per year.

2.4 Data Collection Procedure

The survey 2006 was developed and executed by the Department of Information Systems at the University of Innsbruck and is an update and extension of the empirical study conducted in 2004/2005 [Fink & Ploder, 2005a; Fink & Ploder, 2005b]. The objective of the empirical study was to find out which cost-efficient software products can support the efficient methods of the four knowledge processes (see chapter 2.1). For this approach the authors differ between two categories of software. At the one hand side there are the standard software products which are already in use in SME (for example: MS Office, Internet Explorer, Operating System and so on.) and at the other hand side there are software products like Shareware, Freeware and Open Source products characterized by the issue of cost-efficient software installation in SME. This described issue is the key objective of the empirical study. The research method for this study was the online question technique. The questionnaire was built with HTML, PHP and based on a MySQL database.

The data sample of 537 SME was average allocated over the regional federal states of Austria, Switzerland and Liechtenstein to get a representative result for

the whole sector and were opted stochastically. The population for the survey can be described as all SME in the three countries and got a number of about 540.000 SME. The online questionnaire was carried out in summer 2006 after a successful pre-test with 20 respondents. The online questionnaire was partitioned into three parts:

- Generally questions referring to the IT support and application of knowledge management within the enterprise itself.
- Rating relevance of the methods concerning the four knowledge processes for SME and get an idea of the favor supporting software tool.
- Information about future capital investment plans referring to knowledge management.

The return quote of the survey was about 40 percent. This means that 220 SME filled out the questionnaire. The failure rate was calculated as 6.63%. So all statements out of the survey are correct at a percentage of 93.61%. In the following chapter the research findings of the methods and the supporting software tools are presented and discussed.

3. RESULTS

The distribution of industries can be described as follows. The bigger part of the SME was from industrial SME with 30% and from Consulting and Information Technology with 22%. The bargaining SME got a level of 13% and the Handcraft 19%. The rest of 16% were divided to Banks and Affirmations 9%, Transport 2% and Tourism 5%. Fifty-seven percent of the SME already use knowledge management and 85% of the SME use a connected infrastructure. A web space is (hosted intern or extern) available in 78% which is necessary to deal with software products which need such an infrastructure.

3.1 Mapping of Cost-Efficient Software Products with Knowledge Processes

Table 2 gives an overview of all methods supporting the four knowledge processes for SME and the corresponding cost-efficient software products. Table 2 lists the absolute number of each method in the likert scale. The ranking of each method is the calculated value based on the likert scale. The "ISO Ranking" illustrates the assessment of the software based on the quality model (chapter 2.3). The absolute frequency of naming of the software through the respondents can be seen in the last column.

As the highly ranked method for the first process of the *identification of knowledge* the Knowledge Balance (92) was named. 56% of SME think that this is the best method to identify knowledge. Further methods are the Balanced Scorecard (89) and the Skandia Navigator (74). The methods Market-Asses Value-Method (-5) and Tobin`s q (-15) were rated by less than 30% of good use in SME.

Brainstorming (225) and Knowledge Network (203) are popular methods of the *acquisition of knowledge*. Also the Mind Mapping (195), eMail System (134), Scenario Technique (126) and System Simulation (98) are proper methods for this knowledge process. Business Games (91) are also a possibility. The method of "Synektik" was rated very bad because of the complexity of this method. The absolute star for acquisition of knowledge was the Search Engine (232) with a percentage of over 70% for efficient use in SME. In the case of the Search Engine the Google Desktop Search Engine was the prior selection of the software. eMail-Systems can be supported by the software Thunderbird1.5 which was chosen by 60% of the respondents. For Brainstorming a good tool will be Concept X7, for Mind Mapping the tools Free Mind (42%) and Think Graph (41%) were well rated. Gamma is software to support a Business Game and this product is well rated by 64%.

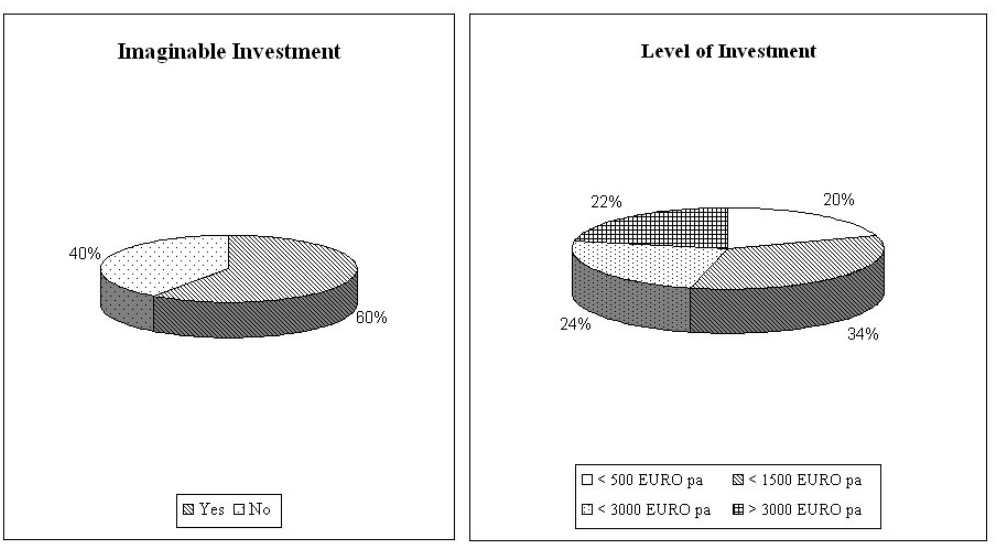
To realize the *arranging of knowledge* databases (242) are a proper method. 80% of the SME think that they will arrange their knowledge by databases. Mind Mapping (200), Document Management System (195) and Checklists (164) are further efficient methods. Content Management Systems (126), Project Review (122), Expert Systems (74) and Conceptualization (40) are methods which can be chosen but are not the favorite choice. Neural Network (-10) is no adequate method for arranging knowledge in SME. There were a lot of different software products to support the arranging of knowledge. These software products and the ratings of them are shown in table 2. MySQL is the favorite database software followed by the MSDE from Microsoft. Document management can be done by the Office Manager, the UDEX dotNETContact or the QVTutto. There are also software tools for the other methods which are described in table 2.

As it is illustrated in table 2 the methods eMail-System (185), Handbook FAQs (159), Communities of Practice (152), Groupware (139), Questionnaire (110) and Best Practice (108) are the favorites of the *transfer of knowledge*. It has to be pointed out that the methods Micro Article (2) and Chatroom (29) are rated not as well by the survey. The software products for the methods of the transfer of knowledge are InfoRapid supporting Knowledge Maps, EasySurvey supporting Questionnaire, Skype and MSN supporting Chatroom, eGRoupware1.2 and AlphaAgent1.6.0 supporting Groupware, CUCards 2000 supporting Checklists and Pegasus Mail, Thunderbird1.5 and Amicron Mailoffice 2.0 for the support of eMail-Systems.

3.2 Investment Allocation

75% of the respondents assumed that they are still using knowledge management in their SME. As it is shown in figure 2 the attendance to invest into knowledge

Figure 2. Investment allocation



management in the next year exists for 60% - 40% can not image to invest into knowledge management in the next year. 20% of SME which can fancy an investment in the next year want to spend less than 500 EURO, 58 % will spend between 500 and 3.000 EURO and only 22% will invest more than 3.000 EURO. The last question in the online questionnaire was about the knowing of the methods by the respondents. 49% of the respondents did not know one ore more methods which was not a problem for the survey because at every method it was possible to get a description of the method.

3.3 Hypotheses Test

The two hypotheses explained in Chapter One should be tested by the survey. For testing these hypotheses the authors choose a chi-square test at a level of confidence of 95%. The hypotheses are:

- *Hypothesis 1:* Knowledge Management Processes can be realized in SME with more than a 30% support of office similar software.
- *Hypothesis 2*: More than 50% of the SME which can image to invest into Knowledge Management in the next year will invest more than 3.000 EURO per year.

If the calculated chi-square score for the hypothesis is less then the score of a comparison table than there is a significant relationship between the two factors.

For the first hypothesis the calculated chi-square score was 2.58 and this is less than 9.49^{463} from the comparison table. In the next step the content must be valuated. 21.82% of the SME which use knowledge management already think that only less than 30% of the methods can be supported by Office products. So the hypothesis can be verified.

The second hypothesis was rated with a chi-square score of 3.89 and this is less than the score of the comparison table with 7.81^{466}. Because of the fact that only 18.11% of the SME which can image to invest into knowledge management will invest more than 3.000 EURO this hypothesis is incorrect.

4. CONCLUSION AND OUTLOOK

Knowledge process management is a research field that has attracted academic and practitioner's attention. The paper shows up a framework to implement knowledge management cost-efficient in SME and not only in large companies which can invest a large amount of money. The four important knowledge management processes in SME can also be supported by a large number of efficient methods which are supported by cost-efficient software products.

One future problem for the implementation of different software products could be the interfaces of the different applications. With Service Oriented Architecture (SOA) it would be possible to solve the problem of interoperability and the problem of security [Kang et al., 2006]. Future research will deal with SOA and should also consider Open Source Software (OSS).

Automating Customer Complaints Management Through Trust Accounts

Roman Beck, Johann Wolfgang Goethe University, Mertonstrasse 17, 60054 Frankfurt am Main, Germany; E-mail: rbeck@wiwi.uni-frankfurt.de
Jochen Franke, Johann Wolfgang Goethe University, Mertonstrasse 17, 60054 Frankfurt am Main, Germany

ABSTRACT

The automation of business processes by the use of paper-free EDI transmissions between business partners can be an incentive to advance the exchange of orders, invoices, and customer complaints without human interruptions by integrating and embedding trust mechanisms. This paper analyzes the applicability of automatically updated trust accounts for customer relationship management for the handling of customer complaints. The model introduced in this paper can help to reduce handling and shipping costs significantly and thereby improves customer benefits, resulting in higher customer loyalty.

1. INTRODUCTION

A promising application area to realize yet unexploited automation benefits in the area of customer relationship management is the handling of customer complaints. While empirical research and therefore data are very limited in this area, two figures might provide an idea of how much money possibly can be saved by an improved complaints handling process: Eastman Chemicals was able to save $2 million after improving its business processes associated with investigating and responding to complaints. They were able to cut expenses for waste removal and rework caused by off-quality products or incorrect paperwork (Hallen and Latino 2003). According to Schilling and Sobotta (1999), a medium-sized enterprise with approx. €5 million annual revenue, calculated the average processing costs with € 837.47 for each complaint handling process in 1997.

A major impediment to increasing the degree of automation in this area is the need for human interaction and decision, e.g., to check complaints or to prevent opportunistic customer behavior. Since the handling of complaints is costly not only for suppliers but also for customers, only 5-10% of all dissatisfied customers decide to complain at all (Tax and Brown 1998). But dissatisfied customers very likely switch their provider with consequential revenue losses higher than the costs caused by complaints in the first place (Fornell and Wernerfelt 1987). Therefore, suppliers have to cope with two dilemmas: Firstly, to date the suppliers they cannot automate or standardize the complaint-handling since opportunistically acting customers may benefit from this and, secondly, they might never get notice from a dissatisfied customer who has switched to another supplier because the manual complaint-handling is too expensive in comparison to the value of the defective or missing delivery. The remainder of the paper is organized as follows: an overview of relevant related research in trust and reputation is provided in section 2, followed by a modified customer complaints handling system in section 3. We discuss and conclude the paper in section 4.

2. REPUTATION AND CUSTOMER RELATIONSHIP MANAGEMENT AUTOMATION

Automation-Oriented Business Process Reengineering

Apart from the standardized exchange of electronic order or invoice messages there are further customer-related business processes which are so far not fully standardized and utilized. Most of those processes are related to trust or reputation aspects, i.e. are the data submitted up-to-date, is the sender or receiver reliable and solvent, or is a partner's claim justified? Costly human interaction is necessary to fix occurring problems, especially when it comes to irregularities in the value chain not covered by standardized processes. A common problem in every day product delivery is the handling of customer complaints of missing or broken items from an ordered lot. The customer complaints management process itself might be more expensive than the replacement value of the product, especially where missing or broken low-value products such as office supplies are concerned,. The customer has to decide whether to claim or not. If she does not, she has to pay for the incomplete delivery and the supplier cannot adjust its distribution because its quality management never gets the information that products have reached customers in an unsatisfactory condition.

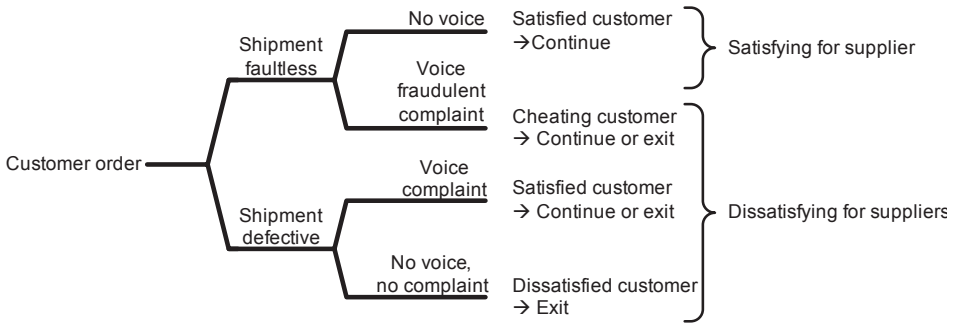
Reputation and Trust

Reputation reflects an aggregated ratio incorporating multiple factors: quality of merchandise, reliability of financial transactions, and/or level of customer service. It is often observed that reputation and trust acquire fundamental importance in long-term business relations. According to Mui et al. (2002b),, reputation is a "perception that an agent creates through past actions about its intentions and norms" and trust is a "subjective expectation an agent has about another's future behavior based on the history of their encounters". It can be shown that reputation reduces the complexity of the decision process through a better estimation of the likelihood of failed orders and through a reduction in the number of quality tests needed for a product (Marsh 1992). A broad overview of approaches to the use of reputation, e.g., in multi-agent systems, is provided by Mui et al. (2002a). Sabater and Sierra (2001) introduce a reputation model that takes the individual and social dimension of reputation into account. Carter, Bitting, and Ghorbani (2002) propose a formalization of reputation for multi-agent systems, applying the sociological concept of role fulfillment for establishing a positive reputation and for examining the link between reputation and trust. The role of trust in supply relationships and the underlying implications are addressed in an empirical study of business relationships in Germany and Britain (Lane and Bachmann 1996). As they point out, trust relations are highly dependent on stable social, institutional, and legal structures. Moorman et al. (1992) investigate the specific relationship between providers and users of market research reports and provide a good introduction to the role of trust in relationships. Das and Teng (1998) argue that trust and control are the two pivotal sources of confidence in the cooperative behavior of business partners in strategic alliances. Both sources of confidence are highly interdependent. A high level of control reflects a low level of trust and vice versa. Without any control, the trusting party takes the whole risk of the trustee's opportunistic behavior. As they point out, trust or control are two completely different kinds of approaches to business relationships.

Customer Complaint Alternatives and Implications

In order to discuss the complaint process both on the customer and supplier sides in more detail, the alternatives and relevant business cases are depicted in the following. Drawing from the "exit, voice, and loyalty" model provided by Hirschman (1970), and the customers "problem impact tree" framework of Rust, Subramanian, and Wells (1992), a problem tree of voice a complaint or exit without making a complaint is utilized. According to Hirschman, customers have two potential feedback options: (1) to voice complaints and thereby express the dissatisfaction directly to the supplier or (2) to stop buying and exit the relation. Both options have different, but always unfavorable impacts on suppliers: After submitting an order, the incoming orders are checked by the customer's receiving department. In the case of a faultless shipment, one expects that customers have no reason to complain (upper branch of Figure 1). This is true in nearly all cases: customers receiving correct deliveries will be satisfied, continue with the supplier, and will not place any complaints. The situation is different if complaints are not too costly and the supplier does not ask for the defective items to be sent back in order to validate the complaint. If customers do not perceive the recall of defec-

Figure 1. Customer action alternatives



tive items as a credible threat, then they might be tempted to cheat and complain about faultless shipments. Avoiding such an incentive is a pivotal element when designing an automated customer complaint-handling solution.

In the case of defective or partially missing items in the shipment (lower branch of Figure 1), the supplier must be contacted and/or the broken parts sent back. Afterward, the supplier sends the defective parts again and the customer tracks the complaint until all replacement parts are received. If the supplier handles the complaint satisfactorily, the customer will buy again. If this is not the case and the customer is dissatisfied with the process management, then the exit strategy might be chosen. In the latter case, the supplier has no chance to contact the dissatisfied customer if a defective shipment is delivered and the customer decides not to complain. This can be the case if the complaint process is more costly then the value of the defective products. Dissatisfied with the delivered quality, it is likely that such a customer will discontinue the business relationship.

3. CUSTOMER COMPLAINT ALTERNATIVES AND IMPLICATIONS

A Simplified Customer Complaint Process

In this section, a simplified customer complaint process is described to reduce the handling costs for suppliers and customers. It will be shown that from a game-theoretical point of view the simplified customer complaint-handling process dominates the conventional process if customers are always truthful. If customers cannot be assumed to be acting truthfully, a trust mechanism is introduced to inhibit cheating behavior by customers.

Our model is based on the following assumptions:

- Neither supplier nor customer knows the exact value of the defectiveness ratio "*d*". The exact quality of the products is not known (e.g., due to unknown conditions during the shipment).
- There is a long-term recurring business relationship between supplier and customer. Products are exchanged frequently between both of them.
- The value of a single order is relatively low, as can be observed for raw materials or office supplies.
- The customer complaint-handling costs of the new simplified process can be ignored. In the simplified process, the customer only has to send a notification to the supplier; the supplier does not have to perform a check if the products are indeed defective.

We will use a game-theoretical approach to analyze the trade situation for the conventional and the simplified complaints handling process. In a conventional complaint-handling process, the customer checks the shipment and if there are defects, the defective parts of the shipment are sent back to the supplier. The supplier has to check whether the complaint is justified or not. Both partners have expenses due to the manual processing and shipment of products. Table 1 depicts the cost matrix in a game with a conventional customer complaint process. If the shipment is indeed defective and the customer decides to reclaim, both customer and supplier have to pay for the cost-intensive manual handling of the customer complaints (c_C^C and c_S^C), respectively. Additionally, the supplier will not get paid for her defective products and the value "*v*" (ranging from 0 to the total value of the shipment if all parts are defective) of these parts is lost for her. When the customer decides not to reclaim the defective products, her loss equals the value of the defective shipped products *v*. If the shipped products have only minor defects, the consumer may be able to use the products partly, thereby reducing her loss to a fraction of *v* indicating the shipments remaining utility. Nonetheless, compared to flawless products, the consumer encounters loss costs ranging from 0 for minor defects to the value of the shipment *v* for major defects.

Table 1. Conventional customer complaint process cost matrix

Shipment defective?	Customer complaints ? Yes	Customer complaints ? No
Yes (d)	Customer: complaint costs (c_C^C) Supplier: {0; fraction of defective shipment (*v*)+} complaint costs (c_S^C)	Customer: {0; fraction of defective shipment (*v*)} Supplier: 0
No (1-d)	Customer: complaint costs (c_C^C) Supplier: complaint costs (c_S^C)	Customer: 0 Supplier: 0

Table 2. Simplified customer complaint process cost matrix

Shipment defective?	Customer complaints ? Yes	Customer complaints ? No
Yes (d)	Customer: 0 Supplier: fraction of defective shipment (*v*)	Customer: {0; fraction of defective shipment (*v*)} Supplier: 0
No (1-d)	Customer: - fraction of defective shipment (-*v*) Supplier: fraction of defective shipment (*v*)	Customer: 0 Supplier: 0

If the shipment is not defective and the customer decides to issue a complaint, both partners will have to pay complaint costs (c_C^C and c_S^C). After the order is sent back, the supplier checks the products and finds them non-defective, so she may re-ship them or sell them to another customer, so there are no further costs despite the complaint processing costs. In regular cases when the shipment is not defective and the customer does not decide to reclaim, the transaction is completed as originally intended.

Now a simplified customer complaint-handling process is implemented, significantly reducing complaint costs for both partners. In cases where the customer decides to complain about a shipment, the supplier trusts her customer, assuming the products are indeed defective without testing. The customer subtracts the invoice accordingly or a new shipment is immediately scheduled and the supplier does not audit the complaint any further. This new setting is described in Table 2.

If the shipment is not defective and the customer decides not to reclaim, the situation is unchanged. In cases where the products are defective the situation is unchanged despite the lack of complaint costs. The critical case is a cheating customer who pretends to complain for a shipment which is not defective at all. In this case, the customer does not have to pay for the products although she receives faultless products. She immediately earns the value of the products ("negative loss costs (-v)"). On the other hand, the supplier loses the value of the products shipped. Comparing both situations reveals that for defective product shipments, the second scenario with a simplified customer complaint process is advantageous in all situations. If supplier-side complaint costs are less than the value of the shipments, only the lower left quadrant of the cost-matrix is disadvantageous. This outcome, which implies a cheating customer, must therefore be avoided. Despite the savings by skipping reclaim checks, it can be rational for the supplier to ask the consumer to return the defective goods in order to be able to determine the source of the defects and improve quality by taking appropriate counter measures. Even if consumers are always acting truthfully or a reputation mechanism is applied, a random sample of claimed shipments should be returned to the supplier to analyze the source of defects. The costs of shipping and handling complaints in a specific market are also important for the applicability of the simplified customer complaints process. In the case of low or negligible shipping and complaint-handling costs, it might be rational to always return defective shipments. It depends on the relationship of total complaint costs to the individual value of a shipment whether the simplified complaint process is applicable or not. If total complaint costs are high in relation to the shipment's value, the simplified complaint process can realize substantial cost savings.

A Reputation Mechanism to Inhibit Fraudulent Behavior

In the case of accurate shipments, there is a significant difference between the conventional and simplified scenario. If the customer decides to complain for faultless shipment, then she will not have to pay for the faultless products and immediately gains their value. On the other hand, the supplier loses the equivalent value because she trusts her customer and does not perform a quality check on the reclaimed products. If there is no additional monitoring or control structure, the customer will always reclaim the delivered shipments, independent of the actual status of the shipment (whether it is indeed defective or not). It is the best strategy for the customer to complain always. The supplier therefore always loses the equivalent value of the shipment if no mechanism to counter cheating behavior is applied.

In an idealized world, a truthful acting customer would be the optimum to reduce transaction costs. Both partners could improve their respective position in all cases, because only the upper left and lower right sections in Table 2 would be relevant. If one can assume that a customer is always telling the truth, then the conventional complaint-handling mechanism is dominated by the simplified automated complaint handling. Both parties benefit from the reduction of transaction costs when processing complaints automatically. Nevertheless, the customer might be tempted always to complain about defective products even if this is not justified. The pivotal question is how to assure that the customer has no interest in cheating the supplier by applying an inexpensive mechanism at the same time. At this point, an automated complaint-handling mechanism might be suitable. Reputation in this context is based on business transactions with a certain customer in the past. The more orders successfully processed in the past, the higher the reputation account. Contrariwise, the customer withdraws from her reputation account on the supplier side if transactions failed in the past. For example, in the simplest case the supplier could estimate the defectiveness ratio d of his/her products r and adjust the customer's reputation account if her complaints rate significantly differs from the estimated quality, e.g., by applying a χ^2 test. The supplier's plausible threat is to switch back to the conventional customer complaints handling mechanism, inducing complaints processing costs on future transactions. This threat only works for infinitely repeated games as assumed for this model. Nevertheless, this assumption seems to be appropriate for our setting, since B2B-relationships can often be characterized as long-term, frequently recurring relations. The supplier can implement several strategies to ensure that the customer is truthful. The following strategies can be applied, if the supplier knows the defectiveness ratio d with high accuracy:

- The supplier can randomly select reclaimed shipments and request the customer to return the products for an intensive test. If the products are faultless, the customer cannot be trusted and she is removed from the simplified customer complaints handling process. The process is immediately switched back to the traditional handling process. This trigger-strategy is misleading if the customer accidentally complains about products that are not defective.
- The supplier can switch back to the conventional complaints handling process if the ratio of complained products significantly exceeds the defectiveness ratio d. This mechanism only works, if the supplier knows d with high accuracy.
- Each customer receives a reputation account for a given period, calculated as the product of the mean ordered value and the defectiveness ratio d. If a customer reclaims a shipment, the shipment's value is subtracted from this account and if the account is exhausted, the customer has to justify her behavior. This mechanism also relies strongly on the accuracy of the parameter d.

The threshold for identifying cheating behavior on the part of a customer should be chosen according to the accuracy with which d is known. If d is not exactly known and is subject to changes, this threshold should be increased or decreased accordingly. If the supplier herself does not know the defectiveness ratio d, she can improve the reputation mechanism by taking the responses of all other customers for each product into account. Each customer has individual reputation accounts for each product. If a customer reclaims a shipment, the value of this shipment is subtracted from her account, which refers to the affected products. Afterwards, the reputation accounts of all customers receive a bonus. This bonus for product r and customer i is calculated as an adjusted ratio of the mean quantity ordered by the customer. This value can be regularly recalculated for all orders of a given period (e.g., monthly). The following equation calculates the reputation bonus for each customer i and product r.

$$bonus_r^i = \frac{q_r^i}{\sum_{j=1}^{n} q_r^j} * p_r q_r^d$$

p_r : price of product r

q_r^i : aggregated quantity of product r ordered by customer i in a given period

q_r^j : aggregated quantity of product r ordered by customer j in a given period

n: number of customers with reputation accounts

q_r^d : quantity of defective product r that is reclaimed

If all customers are acting truthfully, the individual reputation accounts for every product will be zero on average. A brief example should illustrate the mechanism: a defectiveness ratio of 10%, a price of 1 for a given product r and three customers are assumed. The first customer regularly orders 1000 units, customer 2 orders 50 units and customer 3 orders 200 units. Each customer reclaims truthfully 10% of the shipments. When the first customer reclaims in total 100 units, her reputation account is immediately reduced by 100, equivalent to the total value of the complaint. Afterwards, all customers' reputation accounts are given a bonus (including the customer initiating the claim), resulting in 80 bonus points for customer 1, 4 bonus points for customer 2 and 16 bonus points for customer 3. This process is also applied for the complaints of the other customers, leading to neutral reputation accounts at the end of the selected period. If one of the customers decides to cheat and complains with a higher ratio, e.g., 15%, then her reputation account will be negative while the accounts of the other customers will be positive. If the first customer complains 15% of her shipments and the other customers complain about

10%, their respective reputation accounts for the illustrative example will be -10, +2 and +7.2. Customers with a higher complaint ratio than other customers can be identified by their negative reputation accounts. The first cheating customer will put herself into an inferior position compared to truthful customers. This system can only be cheated on if all customers together increase their complaints ratio. Furthermore, it does not work with a small number of customers. If there were only one customer, then this reputation account would always be neutral. From a macroeconomic and individual perspective, both partners can reduce their costs when the simplified mechanism is applied and supported by reputation accounts to foster truthful behavior of customers.

4. SUMMARY AND CONCLUSIONS

The combination of information systems and game-theory inspired trust accounts in a customer relationship management system establishes new solutions to automate business transactions where human decisions were formerly necessary. Through the reduction of manual handling and shipping costs, quality of the complaint-handling process may be increased both for customers and suppliers, resulting in higher customer retention.

A game-theoretic analysis of the order and customer complaint process has yielded insights into undesired outcomes of the interaction of suppliers and customers. While faulty deliveries will always remain a problem, costs associated with customer complaint-handling can be reduced significantly if substituting human decision competence with an automated information system. Thus, we believe that an economic interpretation of existing information systems may help to uncover as-yet unrealized potential for computer-mediated customer relationship management approaches. The system allows firms to deploy a simplified customer complaint-handling process while preventing customers from acting opportunistically.

In general, applying trust and reputation mechanisms can guard against otherwise unfavorable situations and create outcomes where all participants can benefit. The use of information systems mitigates the threat of opportunistic behavior in business transactions that could not be achieved previously.

ABSTRACT

Organizational memories play a significant role in knowledge management but several challenges confront their use. Artifacts of OM are many and varied. Access and use of the stored artifact is influenced by the user's understanding of these information objects as well as their context. Topic maps are used in this implementation to represent user cognition of contextualized information. Topic maps allow for access and analysis of stored memory artifacts. The paper presents the design and development of an organizational memory warehouse with web access via topic maps.

1. INTRODUCTION

Today an organization has to be able to make use of all of its available information in order to be competitive. In particular researchers have noted that organizational knowledge may be accumulated and retained using several organizational memory systems [6, 14, 15]. Advances in information technologies have helped in accumulating knowledge but the paradigms applicable to collecting and storing the knowledge do little to motivate its use by managers and decision makers. Accessing and using organizational memories, have been a challenge because of the multifaceted nature of memories and knowledge sources. Moreover, characteristics of the decision tasks where the knowledge and memory support are used, pose interesting challenges in designing and developing knowledge management systems. In this paper we describe the use of topic maps to navigate the network of organizational memory and employ appropriate knowledge management and analysis tools.

2. ORGANIZATIONAL MEMORY

Organizational memory (OM) is a stored, interrelated collection of organizational history reflected among the many parts [19]. It includes both stored records and tacit knowledge and covers the various facets of organizational tasks, employees, and their task environments [3, 5, 10, 16]. Because it can grow rapidly and become a vast repository of information and knowledge, several researchers have recognized the import of this organizational memory in effecting organizational performance [2, 4, 8, 9, 11]. Ackerman and Halverson [1], however, take a critical view of prior research on OM and argue for a theoretical base to properly define and empirically validate future research. They state that as socio-technical systems, organizations and their memories conform to social structures and norms while employing technical models. They use the theory of distributed cognition to develop a theoretical foundation for organizational memory. The basic tenets of this theory are that knowledge evolves from a community of practice and that cognition and inferences result from the shared meaning among the participants (hence the distribution) [7]. Communities of practice fulfill a number of functions with respect to the creation, accumulation, and diffusion of knowledge in an organization through exchange and interpretation of information, by retaining knowledge, by stewarding competencies, and providing homes for identities [20]. Collective thinking creates knowledge that otherwise would not be evident. Using empirical data and qualitative methods, Ackerman and Halverson [1] illustrate application of the theory of distributed cognition to validate the use of organizational memory in decision making.

Our paper presents the design and development of an organizational memory warehouse that supports the distributed cognition theory. We have adopted the design-science research paradigm to present our system design. Hevner et. al [25] argue that design-science research must addresses important unsolved problems in unique or innovative ways or solve problems in more effective or efficient ways[25]. Design-science research proponents identify six nominal process steps, namely problem identification and motivation, objectives of a solution, design and development, demonstration, evaluation, and communication [17]. The first four process steps are considered suitable for doing design research. In addition, when systems are built for testing and validating theory, the appropriate entry point for design research is indeed the design and development process. At this stage an artifact is built and theory is tested using the artifact. The main purpose is to yield a proof of concept of the theory and the system that supports it.

As social and linguistic dimensions of knowledge become pertinent, users need appropriate tools to support the search and analysis of knowledge. Topic maps are one such tool.

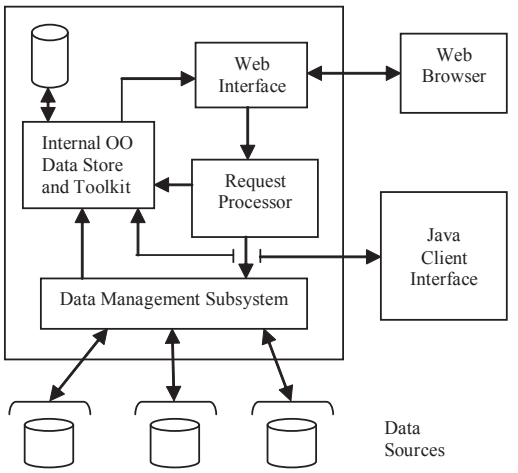
2.1 Topic Maps

Smolnik and Erdman [18] state that topic maps provide strong paradigms and concepts for the semantic structuring of link networks and therefore, they are a considerable solution for organizing and navigating large and, continuously growing network of organizational memories. Topic maps provide a subject based classification of resources where each resource represents a real world object. In topic maps, three constructs are provided for describing the subjects represented by the topics: names, occurrences, and associations. These describe the names, properties, and relationships of subjects, respectively. A name may be assigned to more than one topic and a topic may have more than one name. In addition by defining scope and types a name can become rich and complex. An occurrence links to one or more real knowledge sources. An occurrence, however, is not part of the topic map. Associations describe relationships among topics and are independent of the real knowledge objects. Associations add value through the relationships. An object in topic map would be a knowledge object such as a memory collection or a resource (e.g., an email analysis tool) that acts on the information object (e.g., an email collection).

3. WAREHOUSE MODEL

The goal of any organization is to make optimal use of the business knowledge that it has accumulated over the years. To do this, it is necessary to determine the sources of business knowledge and provide members of the organization access to it in a timely matter. Here we focus on the latter issue of providing access and assume that business knowledge sources are employee knowledge and artifacts (both internal and external).

Figure 3.1. Block diagram of the distributed organizational memory data warehouse model



The proposed environment has been designed to provide support for accessing and analyzing the collective memory of the organization. We start by providing a simplistic overview of the model and then briefly examining the important components in more detail.

3.1 Overview

An organization's memory can be seen as consisting of a space that includes knowledge of the expertise of current employees, artifacts, and the tools required to locate and/or interpret available information. The memory space is distributed across the organization and beyond.

Any organizational memory warehouse must be able to deal with the distributed nature of the memory space and be able to fully integrate the memory's information with the necessary tools. To deal with this problem, we introduce a distributed organizational data warehouse.

We see our contribution as being the development of an environment that provides a complete and easy to use solution to making the most of an organization's memory. The distributed format of the proposed warehouse provides a realistic mapping into the organizational memory space that is typical in organizations. Perhaps more important, the proposed model is highly scalable.

A block diagram of the complete model is shown in Figure 1. Artifacts and information about the expertise of current employees can either be stored in the data sources or in the Internal Object-Oriented Data Store and Toolkit. Artifacts in the data sources can be stored in any format to take advantage of existing software or compression techniques. To simplify communication between components and provide for standardization within the model, object views [21] are used to define data types. Data from the data sources are converted into object view instances using local interface views [21].

A topic map that supports visual access to the organization's memory space via a combination of search terms and tool interfaces serves as the user's entry point to the warehouse. Use of the topic map interface provides the user with an easy to use mechanism for defining search terms and choosing the appropriate interpretation/analysis/learning tools.

The remainder of this section briefly examines the main components of the model.

3.2 Object Views

The object view type [21] is defined as being an extension of the object model (EOM). The views have a traditional object structure (attributes and methods) with the restriction that they support a derivation method. The derivation method is used to generate the public and private attributes of each object instance created through a local interface view

3.2.1 Local Interface Views

The individual data sources are expected to have local control. The local interface view [21] is a view object type that is used by the local data administrator to provide a mechanism to make the local data accessible to the proposed model in object form. The local interface allows distribution transparency and representation transparency, while hiding or converting (mapping) some of the data from the data source. The local interface view belongs to the data source. It interacts directly with the data source and passes the result to the wrapper which controls communication with other components of the proposed model. A given data source and its wrapper can support multiple local interface views in order to present its data in different ways to different applications or users.

3.3 Topic Map

A topic map is used in the model to provide users with visual access to both search and analysis. It is this interesting blend of semantic search and analysis that motivates its use in the model.

Here we define a topic map to be the directed acyclic graph T = (N,E), where N is the set of topic map terms, data types, or search/analysis tools. The directed edges in E are of the type (n1,n2), where n1 is a topic map term or a data type and n2 is a topic map term, a data type, or a search/analysis tool. An implicit node, called the root, points to the topic map terms, data types and/or tools that make up the first level of the topic map. Nodes with out degree zero are said to be leaves of the topic map. Leaves point to the information in the organization's memory and carry any search terms and/or data types accumulated on the path form the root of the topic map to the leaf. Note that leaves that are either search terms or data types make use of an implicit search tool. In addition each non-leaf level of the topic map has a search tool that can be used to initiate a search based on the topic map terms that have been traversed to get to the topic level. To implement the topic map, we use duplication of nodes to convert the directed acyclic graph into a tree structure.

Topic maps are presented to the user via either the Web Interface or the Java Client Interface depending on the access mode chosen by the user. Regardless of the user's access mode the visual structure and use of the topic map interface remains unchanged. The primary difference between the modes is in the details of their respective implementations.

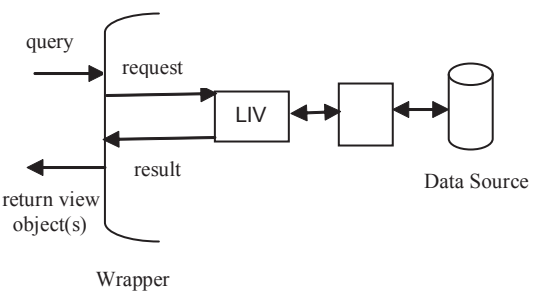
3.4 Data Types

The data types supported will depend to some extent on the nature of the organization. Typically, the data types will include the people that the organization relies on for expertise and the artifacts that make up the organizations' memory. In the implementation described in Section 4, the data types used are the typical artifacts, e.g., emails, meeting minutes, reports, and presentations. Extending the supported data types is simply a matter of ensuring that the appropriate tools for search and analysis are available in the set of supported tools.

3.5 Data Sources

A block diagram of the transformation of a data source is shown in Figure 2. The query is translated to the appropriate request string and passed to the local interface view (LIV). The LIV passes the request string to the data source and converts the response into the objects defined by the LIV view type. The set of

Figure 2. Data source node layout and request/data flow for retrieval



result view objects are then passed back to the Data Source Access Module and cached in the Internal Object Data Store for analysis.

3.6 Internal Object Data Store

The Internal Object Data Store is based on our earlier work on object-oriented data warehouses [13]. The Internal Object Data Store combines tools and the cached data to allow in depth analysis of artifacts. The tool set consists of a set of built in (kernel) tools for managing tools and data and a set of user added tools for creating and analyzing data [12].

3.7 Request Processor

The request processor receives a Request object from the User Interface Controller that defines the search criteria and the result format required to complete the request. The tool type and action required is built into the class structure by employing the Polymorphic design pattern. Each tool that is added either implicitly or explicitly to the topic map requires the definition of a class that extends the Request class. These new classes add any additional information/actions required by the tool.

4. IMPLEMENTATION

To illustrate the feasibility of the proposed model a prototype has been developed. Figure 4.1 shows the initial screen encountered by a user via his/her web browser. The topic map nodes are shown as either ovals or rectangles. Figure 3 shows the nodes in first level of the topic map. Any rectangles shown represent tools and the ovals represent topic nodes containing topics. Note that either type of node can occur at any level in the topic map.

Navigation in the topic map is flexible and can be controlled either by clicking on a topic map node (oval or rectangle) or using the level navigation icons at the top of the screen. Clicking on an oval moves to the next level below the oval and adds the associated topic to the path label for the user's current topic map search.

The icons have the normal meaning, i.e., the house allows the user to return to the starting topic map screen (Figure 3), the back arrow allows the user to move back one level in the topic map, and the forward arrow allows the user to move forward in the topic map. The actual forward move depends on the user's previous operation. If the previous operation was the result of clicking either the home or the back arrow, clicking on the forward arrow will return the user to her/his previous location in the topic map. If the previous operation was a click on a topic map node, then the forward arrow moves the user one level down in the topic map using one of the nodes as the default node. For example in both Figure 3 and 4, the default node is the Search By Topic node.

As expected, using the back and home icons strips the term(s) from the path label so that it is correct for the resulting topic map level. Using the forward arrow icon either reestablishes the previous path label or adds the topic associated with the default node to the current path label depending on the type of operation used before clicking on the forward arrow icon.

The two additional icons represent a keyword search (magnifying glass icon) and help (question mark icon), respectively. The keyword search initiated by clicking on the search icon generates a search tool screen that allows the user to use a vector space search of the organizational memory artifacts [22]. The search tool screen uses the current topic map path label to set up current conditions. Any topics that are in the path label are added to the search keyword list in the screen. If the topic map session was started by clicking on the Search Memory Collection oval, then the topic map moves to the level depicted in Figure 4. The Search Memory Collection topic is set as the current path label. When the user clicks on the Email, the topic map level shifts to the topic map screen shown in the top portion of Figure 5 and the artifact type (Email) is added to the path label. The artifact type in the path label will be used by the search tool to provide an initial choice of artifact type to search.

Figure 3. Initial screen representing the first level of the topic map

Figure 4. Screen shot of the topic map level for memory artifacts

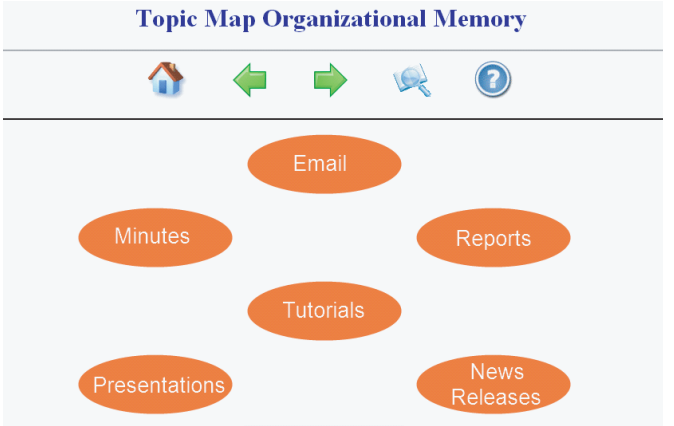


Figure 5. Screen shot showing the results of using the email frequency analysis tool

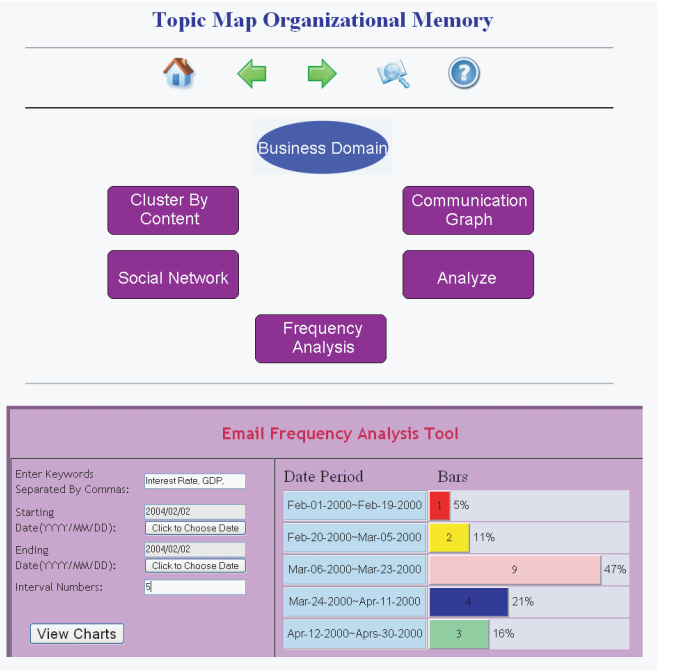

Figure 5 illustrates the use of a topic map tool in the web environment. To reach the topic map illustrated in Figure 4, the user would have clicked on the Search Memory Collection oval and then chosen the Email artifact type. Clicking on the Email Frequency Analysis tool rectangle opens up the input screen shown on the lower left corner of the screen. The tool allows the user to choose the keywords used to search the email collection, the start and stop dates of the time interval that the user is interested in and the number of intervals that the user wants the total interval divided into. Clicking on the View Charts button generates the bar graph shown in the lower right hand corner of the screen (Figure 5).

The topic map interface has been implemented using Ajax to simplify its use. As a result, the input page and the resulting bar graph for the Email Frequency Analysis tool are added to the same page and the status of the topic map remains unchanged. The Google Web Toolkit [23] has been used to generate the JavaScript that supports the generation of the topic map interface and the navigation with in the topic map. In the Email Frequency Analysis tool bar graph, the Date Period fields are viewed by the JavaScript for the page as buttons that bring up a new window containing the list of emails indicated by the associated bar.

The Web Interface has been implemented using Struts[24]. The Internal OO Data Store and Toolkit has been implemented in Java and Poet based on our earlier work on object-oriented data warehouses [12].

5. CONCLUSIONS AND FUTURE CONSIDERATIONS

A model of a distributed data warehouse using a topic map to access knowledge from an organization's collective memory has been presented. An initial version of the model has been implemented using Java as the programming language, Poet to store the objects, and Soap to communicate to data sources external to the system.

Future releases will make use of either Java Data Objects or a tool like Hibernate to replace the Poet database system.

Adoption of Internet Banking in Hong Kong Using Stakeholder Analysis

Chun Kit Lok, The Hong Kong Institute of Education, 10 Lo Ping Road, Tai Po, N.T., Hong Kong; E-mail: clok@ied.edu.hk

1. INTRODUCTION

The Internet is revolutionizing the banking industry by providing an innovative services channel (Dewan, Freimer, & Seidmann, 2000; Seitz & Stickel, 1988). With the impact of the Internet on the industry, Internet banking has emerged and is defined as a service that allows customers to perform a variety of banking transactions on the Internet via a bank's web site (Tan & Teo, 2000). Previous research studies have generally agreed that Internet banking offers advantages for both customers and banks (Birch & Young, 1997; Dannenberg & Kellner, 1998). Internet banking is an information technology tool that re-defines the way banks interact with their customers. Yet, it has not been as thoroughly investigated and researched in the IS literature as one would have expected. There are a rather limited number of research studies on the issue (Aladwani, 2001; Liao & Cheung, 2002; Mols, 2000; S. Liao & Y.P. Shao, 1999; Tan & Teo, 2000).

Being a major international financial center in the world, Hong Kong is witnessing a rapid growth of Internet banking. Hong Kong has a high concentration of banking institutions. By the end of September 2006, there were 137 licensed banks, 32 restricted license banks and 34 deposit-taking companies in business in Hong Kong (Hong Kong Monetary Authority, 2006e). These 228 authorized banking institutions operated a huge network of 1,301 local branches. In addition, there were 87 local representative offices of overseas banks in Hong Kong (Hong Kong Monetary Authority, 2006e). The density of local bank branches is so high that there is roughly one branch for every 4634 aged 19 or above Hong Kong citizens (Census and Statistics Department (HKSAR), 2006). Table 1 shows the top 6 licensed banks in terms of number of local branches in Hong Kong.

Among the 137 licensed banks in Hong Kong, 42 of them are offering online banking services. They manage around 90% of total customer deposits in Hong Kong (Hong Kong Monetary Authority, 2006c). The number of Internet banking accounts has also witnessed an uninterruptedly increasing trend. In 2005 alone, there was a 17.9% increase (Hong Kong Monetary Authority, 2006d). The top six banking institutions in Hong Kong, in terms of number of local branches, account for 77% of all Internet banking accounts (Hong Kong Monetary Authority, 2006b). One trend, which is shared among the first 5 banks, is that their number of branches has all dropped from as much as 28.7% to 11.5%. It is argued that such a decrease is attributed to the adoption and implementation of Internet banking in Hong Kong. One compelling reason for that is the total amount of deposits have increased with a decreased number of branches, from HK$3,527.8 billion (or US$452.3 billion) in 2000 to HK$4,067.9 billion (or US$521.5 billion) in 2005. There must be a channel other than branch that allows customers to manage their larger amount of fund. Online banking is definitely the alternative.

Many banks in Hong Kong have already seized their early Internet banking adopters. The next logical step will be to capture "wait-and-see" customers. It is definitely not an easy task and requires sufficient incentives to be provided. However, before banks take Internet banking even more seriously, there is a central question to ask. Will Internet banking best be a market-share game (with the possibility of a negative-sum game) (Beckerling, 2000)? Will it just become another banking channel, a strategic tool – a new and cost-effective distribution channel or competitive necessity? The answer to these questions comes down to a key issue: how likely will those "wait-and-see" customers adopt Internet banking eventually? According to the ACNielsen Financial Services Study conducted in 2004 and 2005 in Hong Kong (ACNielsen, 2005), around 1/5 of the respondents indicated that they had used online banking. The adoption intention of the non-users is crucial to how banks in Hong Kong should formulate their Internet banking strategies in both short and long-run.

An insight into the possible large scale adoption of Internet banking in Hong Kong is of significant interest to at least three entities: (i) leading Internet banking operators are eager to find out where they should be prepared for larger online banking customer base; (ii) local banks that are lagging behind or adopting a follower strategy on Internet banking frontier need to know if Internet banking is a zero, positive, or negative sum game before they jump on the bandwagon; and (iii) HKSAR government, especially the Hong Kong Monetary Authority, needs to estimate the proliferation of Internet banking so that it can more effective serve one of its financial obligations – "promoting the safety of Hong Kong's banking system" (Hong Kong Monetary Authority, 2006a).

2. RESEARCH FRAMEWORK

The proposed research and the research framework to be adopted are grounded in the literatures of strategic management. The notion of stakeholder is no newcomer in information systems research. It does not represent a "paradigm shift" in information systems implementation. Rather, it signifies maturity of information systems research as it reflects a shift towards approaches that can afford a more holistic representation of parties (stakeholders) involved.

2.1 Stakeholder Analysis

Stakeholder (or multi-stakeholder) analysis can be defined as "an approach and procedure for gaining an understanding of a system by means of identifying the key actors or stakeholders in the system, and assessing their respective interests in that system" (Grimble & Chan, 1995).

Table 1. Top 6 licensed banks in terms of number of local branches in Hong Kong (Hong Kong Monetary Authority, 2006e)

Rank	Licensed Bank	No. of Local Branches		Drop in %
		2002	2006	
1	Bank of China (Hong Kong) Limited	281	225	20%
2	HSBC Limited	175	125	28.6%
3	Hang Seng Bank Limited	142	122	14.1%
4	The Bank of East Asia Limited	115	87	24.3%
5	Standard Chartered Bank Limited	78	69	11.5%
6	DBS Bank (Hong Kong) Limited (acquired Dao Heng Bank Limited which was ranked No. 6 in 2002)	0	62	N.A.

2.1.1 Stakeholder Analysis in Information Systems Literature

The use of the stakeholder concept has been extended to information systems research. The stakeholder term in the information systems literature was initially used to describe the knowledge gap between users and technical specialist (Currie, 2000). Three groups of stakeholders – users, managers and system developers are typically considered as the most important. Like stakeholder analysis in the management literature, the information systems literature employ stakeholder analysis to resolve the conflicting interests of these groups (Lacity & Hirschheim, 1995; Lyytinen, 1988; Ruohonen, 1991). It is evident that the consideration of the widest range of stakeholders is imperative for effective system management and implementation.

2.1.2 Using Stakeholder Analysis in Proposed Research

Large scale adoption of Internet banking by customers in Hong Kong is undoubtedly a multi-stakeholder problem. Identifying these stakeholders and exploring their perspectives is an essential task for understanding the complexity of the research subject. The stakeholders are likely to interact and influence each other, trying to promote their own interests. Stakeholder analysis facilitates a holistic view of stakeholders, reflecting multi-faceted concerns.

Stakeholder analysis in this research is to provide a tool for stakeholder modeling and analysis of interests, powers, and impacts of various stakeholders in the context. All in all, an investigation of adoption of Internet banking typically requires and benefits from the study of multiple and possibly conflicting stakeholder viewpoints, which in turn helps identify and understand success and failure factors for large scale adoption of Internet banking.

It is evident that from the divergence of definitions that are currently in use in both the management and information systems literature that the meaning of "stakeholder" is not straightforward and needs to be explicitly defined. Based on Freeman's (Freeman, 1984) definition of stakeholders, the following definition for stakeholder is recommended for the proposed research:

A stakeholder is any individual, group, organization or institution who can affect or be affected by large scale adoption of Internet banking by customers in Hong Kong.

3. RESEARCH OBJECTIVE

This research aims at applying stakeholder analysis to the study of information systems adoption – Internet banking in Hong Kong in this case as stakeholder analysis provides a mechanism to consider adoption issues from multiple perspectives.

4. RESEARCH METHODOLOGY

This research was a case study on the adoption of Internet banking in Hong Kong. Researchers (e.g. (Kaplan & Maxwell, 1994)) advocate qualitative research approach for its ability to understand a phenomenon from the point of view of the participants, which is largely lost when textual data are quantified. Such a research methodology is deemed appropriate for this study as it investigates a contemporary phenomenon within its real-life context (Yin, 2002). Data of this study came from secondary sources. The analysis was conducted by the researcher's evaluations and observations with the help of the analytical framework developed.

5. STAKEHOLDER ANALYSIS

5.1 Composing a Stakeholder Table

5.1.1 Defining Stakeholder Characteristics

The following information about stakeholders is assessed:

1. Knowledge: the level of accurate knowledge that stakeholders have regarding Internet banking, and how each stakeholder defines Internet banking. This is important for identifying stakeholders who oppose adopting Internet banking due to misunderstanding or lack of information.

Table 2. Stakeholder table

	Knowledge	Position	Interest	Alliances	Power	Leadership
Banks	Best knowledge	6 major banks support	Ample interest	Possible strong alliances	Strong	Strong
Customers	Moderate	Gaining support	Moderate	Not possible	Moderate	Weak
HKMA	Good knowledge	Passive support	Relatively strong interest	Possible with banks	Strongest	Relatively strong

Table 3. Cross-references of multiple dimensions

	Knowledge	Interests
Relative Importance	There is around 31% of the population in Hong Kong who are not Internet users (Miniwatts Marketing Group, 2006). Their attitude and intention to adopt of these Internet laggards (Cavaye, 1995) are critical to an extended proliferation of online banking. However, they will not stop online banking from penetrating further in Hong Kong since history has already proven that the number of online banking users has been increasingly in a healthy manner. Their resistance, if any, or non-participation will only lessen the chance of adoption of in an accelerated speed in future.	With all the stakeholders identified, a larger scale of adoption of online banking in Hong Kong benefits all of them. In particular, the authority – HKMA would welcome further development of online banking in Hong Kong. Hong Kong is a developed economy, where GDP and GDP per capita were US$177.2 billion and US$25,546 in 2005, respectively (Census and Statistics Department (HKSAR), 2005). A sustained development of online banking can help strengthen the financial position of Hong Kong in the world economy. It can also demonstrate that the financial system of Hong Kong is capable of staying abreast of technological development.
Positions	There is probably no stakeholder who opposes to online banking in Hong Kong. The major reason for those Hong Kong citizens who choose not to adopt online banking is a lack of computer self-efficacy and confidence (Chan & Lu, 2004). Education is probably the best way to encourage the potential adopters to try out the service. Success stories of online banking users are an effective measure for promoting intention to use.	Continued and further adoption of online banking in Hong Kong is to the advantages of both supporter and laggards of the service. With a growing customer base, network externalities will be achieved to attain economies of scale (Milne, 2006). As such, banks are to be able to provide improved online banking services in a more cost-effective manner. Existing and potential users will have incentives to continue or consider employing the service.

2. Position: whether a stakeholder supports, opposes, or is neutral about large scale adoption, which is key to establishing whether or not he or she will block such an adoption.
3. Interest: a stakeholder's interest in the advantages and disadvantages that large scale adoption may bring to him or her or his or her organization. Determining a stakeholder's vested interests helps better understand his or her position and address his or her concerns.
4. Alliances: organizations or persons that collaborate to support or oppose large scale adoption. Alliances can make a weak stakeholder stronger, or provide a way to influence several stakeholders by dealing with one key stakeholder.
5. Power: the ability of a stakeholder to affect large scale adoption.
6. Leadership: the willingness to initiate, convoke, or lead an action for or against large scale adoption. Establishing whether or not a stakeholder has leadership will help target those stakeholders who will be more likely to take active steps to support or oppose large scale adoption (and convince others to do so).

5.1.2 Obvious Stakeholders

The obvious stakeholders of large scale adoption of Internet banking include the following entities:

1. Banks in Hong Kong offering Internet banking at the moment are the *sponsors*, who are also *innovators* (Cavaye, 1995).
2. Banks in Hong Kong *not* offering Internet banking at the moment are the *adopters*, who may range from *innovators* to *laggards* (Cavaye, 1995).
3. Bank customers in Hong Kong are the *adopters*, who may range from *innovators* (active Internet users) to *laggards* (less-active and non-Internet users) (Cavaye, 1995).
4. HKSAR government, in particular HK Monetary Authority (HKMA), is a *policy maker* and *regulator*. It is utmost important for the government to consider all possible stakeholders in their policies regarding Internet banking (Hong Kong Monetary Authority, 2006a).

A stakeholder table is presented in Table 2 summarizing the characteristics of various stakeholders.

Stakeholder analysis can be more than just *descriptive* (Donaldson & Preston, 1995) – facilitating the description of the often conflicting interests and providing a richer understanding of who *all* the relevant stakeholders really are but also both *predictive* – foreshadowing the outcome of that innovation (e.g. degree of adoption), and *explanatory* – providing a rationale for the outcome. The descriptive aspect is particularly important to information systems implementation (Pouloudi, 1999).

5.2 Analyzing Stakeholder Table

Once a stakeholder table is completed, the information needs to be analyzed by cross-referencing multiple dimensions.Such an analysis focuses on comparing information and developing conclusions about the stakeholders' (i) relative importance (power and leadership provide the bases for determining relative importance), (ii) knowledge, (iii) interests, (iv) positions, and (v) possible allies. In this study, only relative importance, knowledge, interests and positions are cross-referenced as they are regarded as most appropriate in this case.

5.2.1 Cross-Referencing Multiple Dimensions

Cross-referencing multiple dimensions can provide more insights into the information collected. Table 3 shows the cross-referencing performed for the research.

6. CONCLUSIONS

According to the stakeholder analysis conducted, there is no obvious opposition to online banking in Hong Kong from the stakeholders identified. Internet banking is here to stay and will become more prevalent in Hong Kong. Relevant stakeholders in Hong Kong cannot afford not to embrace it. The growth of Internet banking is evidenced by increasing number of Internet banking customers, banks offering Internet banking services, and services available on existing Internet banking websites. Leading Internet banking operators seek to find out what can be done to attract laggard Internet banking customers, retain its own customers, or lure customers who are already banking online with competitors through marketing, education, re-assurance, better design of Internet banking website,…etc. Banks that are adopting a follower strategy are eager to find out the predicted growth of Internet banking so that they can decide whether to re-align their strategies. HKSAR government needs to forecast the growth of Internet banking before it strengthens its policies to regulate Internet banking to promote the safety of Hong Kong's banking environment.

The role of stakeholder analysis is significant in this research as it helps identify *all* stakeholders involved and assess their importance, knowledge, interests, positions, and alliances related to adoption of Internet banking. By doing so, the analysis provides a macro-analysis of the issue. It helps identify *key* stakeholders.

7. FUTURE RESEARCH DIRECTION

It is suggested stakeholder analysis be conducted *before* a technology acceptance model which is able to assess the likelihood of adoption at individual level. An appropriate model is the well-established Technology Acceptance Model (TAM) (Davis, 1989). Using a model such as TAM after stakeholder analysis is suggested because the analysis yields useful and accurate information about those persons and organizations that have highest relevance to successful large scale adoption. With the help of stakeholder analysis, stakeholders are identified and further analyzed by mapping multiple dimensions. After such a systematic analysis, it becomes clear who key stakeholders are. TAM is then applied to examine the adoption intentions and the reasons behind of each individual key stakeholder. In essence, the framework provides a micro-analysis of each stakeholder. Once the adoption intentions and the reasons behind are determined, a rather definite prediction of large scale adoption would emerge as it is argued that key stakeholders' adoption inclinations are the most vital determining factors of large scale adoption. Such a two-step analysis guarantees no key stakeholders are left out of the equation and adoption intention of each key stakeholder is thoroughly analyzed. Recommendations on how to accelerate adoption can also be formulated as antecedents of adoption decisions of key stakeholders are revealed. Sponsors of adoption can acquire information about what can be done to attract laggard Internet banking customers, retain existing customers, or even customers from competitors.

ABSTRACT

The universal concept and the general technical implementation of a Web Portal for Early Warning and Risk Management are described in this paper. As a prototype example for public access to a modern environmental monitoring and surveillance system, the Web Portal of a system for the remote monitoring of nuclear power plants is presented here in more detail. The concept, the architectural design and the user interface of this system had to meet high demands. Fulfilling the imposed requirements, a solution was developed which is universally suitable for environmental monitoring and surveillance, for early warning and for emergency management.

INTRODUCTION

Almost every day TV news reports on disastrous environmental events from somewhere in the world. Earthquakes, tsunamis, volcanic eruptions, hurricanes, heavy thunderstorms, floods and avalanches alternate with tanker collisions, oil spills, coastal pollution, wildfires, accidents in chemical or nuclear plants (related to the emission of toxic gases or radioactive nuclides) and terrorist attacks.

The loss of human life and the tremendous damages caused by those catastrophes as well as the increasing sensitivity of the general public make it reasonable to protect the population and the environment by means of a new generation of intelligent surveillance, information, early warning and emergency management systems. This includes a highly sensitive monitoring, fast and reliable prognostic calculations, but also a timely dissemination of the relevant information to the general public within the endangered area and in adjacent regions. A most comprehensive way to do this is to foresee public access to those systems via a dedicated web portal.

BACKBONE: THE OPERATIONAL SYSTEM

Due to the complexity of the challenge, it is obvious that only a network of computers with dedicated individual tasks and appropriate communication structures will provide a promising approach to solve the problem of monitoring, surveillance, threat prediction, decision support, early warning and emergency management. However, defining an adequate logical structure for those networks, a variety of subtasks and prerequisites have to be fulfilled in each case in order to include intelligence in various ways and to reach the goal of an integrated operational system:

- Development/integration of adequate sensor systems and sensor networks (autonomous or remotely controlled) providing data and background information. This may include mobile sensory platforms and remote sensing systems (air space surveillance and satellite systems).
- Advanced modelling, i.e. development/improvement of scientific prediction models for prognostic calculations of each disaster type supporting interpretation and extrapolation of data, e.g. calculation of the atmospheric dispersion in case of NBC releases, taking into account the current meteorological situation and the expected forecast values
- Integration of scientific prediction modules into operational systems and definition of adequate interfaces to allow for fast response actions even under critical conditions
- Integration of GIS functionality for an online situation display, using various types of geographical maps to facilitate the recognition of affected areas
- Development and implementation of risk analysis and decision support systems based on sensor data, prognostic calculations and disaster specific experience
- Development/improvement and inclusion of knowledge management components (in general and disaster specific) to integrate the long-term experience of experts and observations made in the past
- Definition of adequate information, alarm and warning strategies, using the full range of state-of-the-art technology, such as satellite communications, web technologies, radio broadcast, TV, telephone (fixed network and mobile systems), siren systems and loudspeakers
- Definition of appropriate interfaces to catastrophe handling and resource management subsystems (transport facilities, shelters, medical care....)

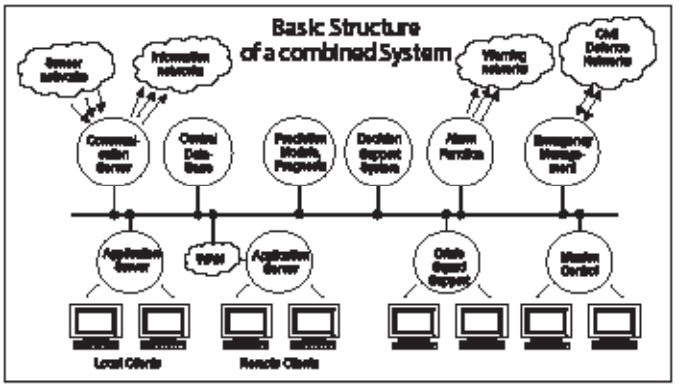
The proposed logical structure of such a combined system is shown in Figure 1 in the form of a Local Area Network (LAN), although some components may be linked together physically by means of a Wide Area Network (WAN), depending on the actual needs of the system under construction.

It is strongly recommended to use a communication server to handle the input data streams from various sensor systems and sensor networks and to convert different data formats, if necessary. This server may also handle the connection to external information networks. In case of higher system loads or larger systems, a specific server computer may be used for this purpose, e.g. a dedicated web server.

Since most of the data are usually needed for central access, the concept of a central database has been confirmed by practical experience. The distribution of specific subsets of the data for decentralized use (e.g. remote application servers) can be achieved by means of dedicated replication functions.

Prediction models and prognostic calculations, such as those for the atmospheric dispersion of toxic gases or radionuclides, tend to need large sets of data and

Figure 1. Structure of the system



therefore are also best served by a central access. Agent technologies and service accesslayer ontologies have proven to be most suitable for the integration of the various scientific components into an operational system.

Decision support systems, based on data describing the actual situation as well as the prognostic development, will reflect the implications for the population in the affected areas and thus help the crisis squad to make their decisions. These systems will have to include advanced knowledge management components and sets of metadata providing access to the long-term disaster specific experience of experts and to observations made in the past.

REQUIREMENTS AND BASIC CONCEPTS FOR THE WEB PORTAL

It is obvious that various user groups and stakeholders have their specific needs and therefore emphasize different aspects of the system. The following user groups can be identified and categorized (see Fig. 2):

- Administrative Sector
- Operational Sector
- Restricted Public Sector
- Public Sector

The administrative sector covers the system administration, maintenance of configuration lists, adaptation and optimization of the system itself and of the related workflows.

The operational sector deals with the main task of the system, i.e. surveillance and monitoring functions, display of the current and prognostic situation, risk assessment and decision support.

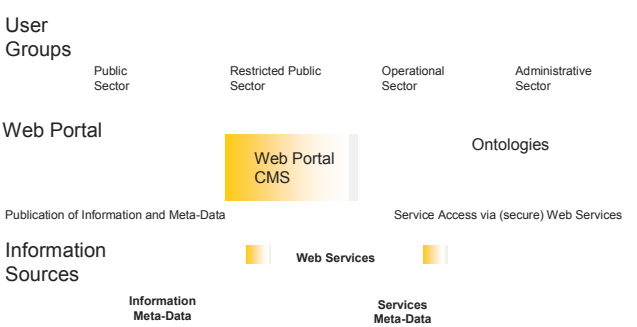
The restricted public sector will provide the necessary information for the crisis squad, for public services (the staff of rescue forces, fire brigades etc.) and all other authorities responsible for civil protection. This may contain confidential information or security related orders which are not foreseen for public disclosure, e.g. in order to avoid panic reactions and pillage.

Finally, the public sector will serve as an information platform for the general public, giving an overview about the current threat situation, exposure risks and the development of these risks. The public sector will also provide general and specific recommendations in case of an imminent dangerous situation. Special attention will have to be drawn onto the web accessibility according to W3C WAI, Section 508, and corresponding national laws.

The large extent and the complexity of the available information combined with various views of diverse user groups call for specific selection and preparation of the data for display in graphical and/or tabular form (depending on the user group). This is the core point for the design and implementation of the Web Portal: to provide for each user group a specific set of web pages which contain all information that is needed to achieve the assigned tasks in the best possible way.

By analyzing the required functionalities and the customer needs, a set of requirements can be derived. The main aspects are:

Figure 2. Basic concept, overview and structure



- Harmonization and matching of the heterogeneous sets of information
- Electronic situation display, incl. animation features
- Simplicity of the user interface
- Modern display capabilities, especially for graphical representations
- Possibility to combine various representations
- Easy-to-use approach by offering well structured information
- Definition of user groups by means of hierarchical access privileges
- Well targeted preparation of the presentations ("generated by experts, to be viewed by anybody")
- Automated, timely publication of (selected) information and metadata
- Publication of reports via secure web services (e.g. in alarm situations)
- Implementation of an "intelligent" public warning system
- Improvement of the emergency management capabilities by introducing workflow tools and corresponding templates
- High quality standards with respect to safety, security and system availability – even under emergency conditions

A first approach is to derive the coarse structure of the Web Portal from the structure of the various user groups, as indicated and illustrated in Fig. 2. Moreover, it may be useful to adapt the basic concept of different access privileges which may have been (successfully) applied in the Operational System, e.g. with respect to individual configuration capabilities for accessible data sets, allowed functionalities (function groups) and accessible server resources.

Further requirements can be deduced from the demand for reliability and high performance of the portal. According to the structure described above, the core functionality of the Web Portal will be allocated to a central Web Server. Therefore, a highly reliable network infrastructure with good performance will have to be provided.

THE IT CONCEPT

Again, it is logical and consistent to set up the IT design for the Web Portal on the basic system concept as described in the previous section and to make use of the existing structure of the Operational System.

This system is typically conceived in form of a client/server architecture with the following components:

- Communication Server (CS)
- Central Database (CDB)
- Application Server (AS)
- PC based User Interface (Clients)
- Integrated Information System (based on HTML)

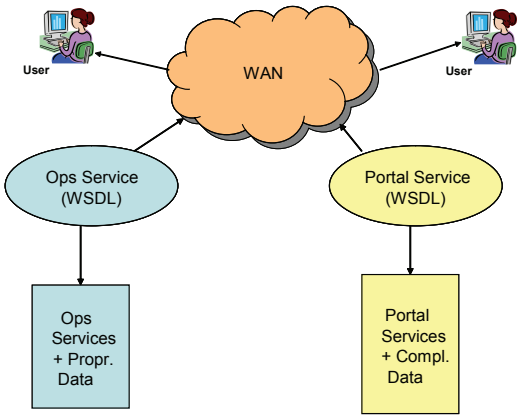
A web based solution is also conceivable for the Operational System (Intranet). However, for safety and security reasons, proprietary communication links would have to be provided.

Development costs for the Web Portal can be reduced by reusing existing facilities of the Operational System to the largest possible extent (provided that the requested views are already available) and to realize the connection with the Web Portal by means of a web service interface.

Given the current state-of-the-art, it is recommendable to use ontologies for modelling, classification, structuring of and navigation within the Web Portal. After a market analysis for adequate content management systems, a decision will have to be taken with respect to the product to be used, preferably one that is based on semantic-web technologies (like OWL-compliant ontologies) and web services for the development of content, knowledge and community management solutions. Due to the ontology based approach and open interfaces, those products allow for the modelling and input (distributed or automated) of very complex information as well as for maintenance, search/navigation and presentation of the information.

The publication of a report will now be realized by means of the communication between two web services (see Fig. 3). Proprietary data and operational services will be provided by the Operational System, whereas complementary data (originating from external sources) will be fed in by the Portal Service. The corresponding interfaces have to be implemented on both sides and have to be published by means of a so called WSDL specification (WSDL = Web Services Description Language; cf. W3C , 2002).

Figure 3. Publication of a report



Typical reports may a.o. include the following information:

- Protective measures, including their representation on geographical maps
- Evacuation areas/safe areas and their current availability status
- Overview of arterial roads, traffic flow and means of transportation (incl. status information)
- Layout plans for assembly and collecting points in case of collective transports
- Emergency stations for medical care, including hospital trains and hospital ships
- Overview of regular hospitals and medical centres (incl. status and capacity information)
- Layout plans of schools, kindergartens and retirement homes
- Layout plans of emergency sheltering capabilities, such as gymnasiums, roof covered stadiums

THE REFERENCE SYSTEM: A WEB PORTAL FOR RADIATION PROTECTION

As a prototype example for public access to a modern environmental monitoring and surveillance system, the web portal of a system for the remote monitoring of nuclear power plants (RM/NPP) will be presented here in more detail.

This system includes the collection of radiological and meteorological variables that have an influence on the diffusion and deposition of radioactive nuclides. A central role of the monitoring system is the use of these variables in the calculation of radiation exposure values and areas. These results are used for decision support, dissemination of information and the issuing of public warnings.

In the event of an imminent, occurring or already terminated release of radioactive nuclides, safety measures pertaining to disaster control and the provision of radiation protection could be required. For instance, the distribution of iodine tablets or a precautionary evacuation are included among these measures.

In its role as a supervisory authority for the nuclear facilities (Obrigheim, Philippsburg and Neckarwestheim) in the Federal State of Baden-Württemberg, Germany, and for foreign facilities close to the German border (Fessenheim/France and Leibstadt/ Switzerland), the Ministry of Environment in Baden-Württemberg has been operating such a remote monitoring system for nuclear power plants for almost 20 years. Recently, the system has been completely renewed using modern hardware platforms and software technologies (Obrecht et al., 2002, Hürster et al., 2005).

As described by Hürster et al. (2005), the RM/NPP is a complex measuring and information system which records and monitors approximately 20 million data sets per day. The actual operational state of the nuclear facilities including their radioactive and non-radioactive emissions are automatically recorded around the clock, independently of the operator of the nuclear power plant. In addition, the RM/NPP system continuously collects meteorological data at the sites and also receives data from external measuring networks (national and international). It provides numerous possibilities to visualize the data and to check them against threshold values and protection objectives. In the case of a radioactive leak, potentially affected areas can be determined at an early stage by a transport calculation (Schmidt et al., 2002) and protective measures can be adopted by the Ministry in cooperation with the authorities responsible for civil protection.

In order to allow for a broader but selective access to the information kept within the Operational System, the decision was taken by the Ministry to establish a web access function by means of a dedicated Web Portal (Hürster et al., 2006). Similar applications are envisaged by the Federal States Baden-Württemberg and Saxony-Anhalt in order to open the access to general environmental information, as imposed by legislation (Schlachter et al., 2006).

Both, the operational system and the web portal have been designed and developed in accordance with the logical structures described above (see Land Baden-Württemberg, 2004; Wilbois and Chaves, 2005). The client software offers numerous possibilities to visualize the data by means of a modern graphical user interface with GIS functions. Also, it provides standardized export interfaces to office and graphical applications.

As a result of a market analysis for adequate content management systems, the decision was taken to rely on WebGenesis®. This product fulfils the requirements mentioned above and it provides web service capabilities for external use, e.g. to establish or to shut down connections, for upload and download of data files etc. For this type of external access, WebGenesis® offers a Java subclass that can also be used from other programming languages, e.g. from C#/.NET (cf. Moßgraber et al., 2005).

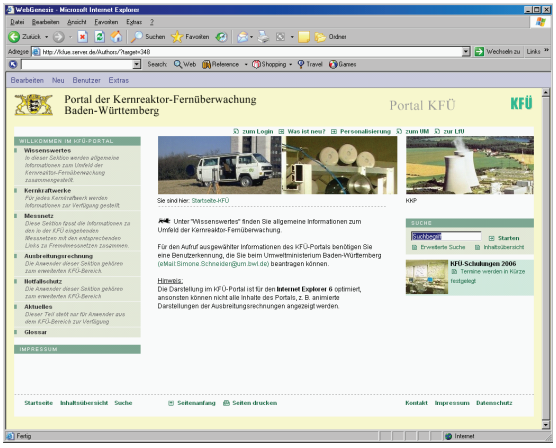
The production system itself is a dynamic web application based on .NET technologies (.NET Framework is a product by Microsoft Corporation). Reports are conceived as independent (or neutral) with respect to server platforms and are stored in the form of XML files. The graphical representation (layout) and the user interface of animated reports are separated from the contents and stored in the form of so called transformation templates (XSLT). This is achieved by using ECMA conformal Java Scripts and HTML+TIME (based on W3C SMIL2.0; cf. W3C, 2005).

PROTOTYPING

For demonstration purposes, a first prototype version has been implemented. Fig. 4 shows the current start page of the Portal which is being intensively used and is therefore considered to be highly accepted by the user groups. A specifically selected representation (generated in the Operational RM/NPP System) is automatically transferred to the Web Portal and thus made available to the connected user groups. Actually, an animated presentation of a propagation cloud has been

Figure 4. Current start page of the portal (prototype version)

Figure 5. Propagation cloud on the background of a topographical map



selected thus illustrating the results of a Dispersion Modelled Transport Calculation (DMTC) for radio nuclides. This type of calculation has to be carried out in case of a radioactive incident or accident and the result is of greatest importance for radiological protection and emergency management.

From a technical point of view, this demonstration prototype realizes the implementation of an interface (preferably via web services) between the .NET based applications on the side of the Operational RM/NPP System and their counterpart within the Content Management System (CMS) WebGenesis® of the Web Portal (based on JAVA Servlets). Navigation within the Web Portal can be achieved either by direct selection or via specific search masks.

In order to make sure that only authorized users have access to the propagation reports (see Fig. 5) the principles of access privileges, as described in the basic concept, have been implemented by using the corresponding features and mechanisms provided by WebGenesis®.

FUTURE TRENDS

The pilot installation of the Web Portal received a great deal of interest from the user groups. The good cooperation with all of them produced an optimistic view for further developments and implementations. The next steps will be:

- Evaluation of the pilot phase (experience and best practices)
- Workshops for dissemination of the results and extension of the user community
- Completion of the IT concept in accordance with the evaluation results
- Implementation of the full system and final acceptance test
- System clearance for full public access to the Web Portal

Due to the increasing importance of early warning and emergency management systems and recognizing the great attention paid to the subject by a sensitive general public, a large number of initiatives and projects on national, international and even global scale are searching for adequate solutions. Therefore, a demand for the commercial availability of such systems is foreseen in the near future.

CONCLUSION

Based on a detailed requirements analysis, the basic concept for a Web Portal for Early Warning and Risk Management has been derived. In a logical sequence, an IT concept has been produced in accordance with the basic concept and with the aim to fulfil the identified requirements to the largest possible extent. The feasibility of the concepts has been proven by the prototype implementation of the Web Portal for the Remote Monitoring of Nuclear Power Plants (Chaves et al., 2005; Hürster et al., 2006).

This Web Portal allows for public access to the monitoring functions, but also enables effective action to be taken in case of an incident or accident. It provides numerous possibilities to visualize data and to check them against threshold values and protection objectives. In case of a radioactive leak, potentially affected areas can be determined at an early stage by a transport calculation and thus protective measures can be adopted by the Ministry and by the public in cooperation with the authorities responsible for civil protection.

Having started with an improvement of radiation protection and the related emergency management, we are confident that the system presented here can significantly contribute to finding a general solution to the indicated problems. The proof will be left to international multi risk scenarios and corresponding across border exercises, supported by the Web Portal capabilities described above.

ACKNOWLEDGMENTS

The system “Remote Monitoring of Nuclear Power Plants” was contracted to T-Systems by the Federal State of Baden-Württemberg, Ministry of Environment, as a turnkey system, with the integrated service “DMTC” provided by the Institut für Kernergetik und Energiesysteme (Institute for Nuclear Energetics and Energy Systems) of the University of Stuttgart (IKE). The research work related to the development and integration of the DMTC was supported by the Ministry of Environment within the framework “Environmental Information System” Baden-Württemberg. The underlying program modules of the DMTC were taken from the library of the OECD Nuclear Energy Agency. WebGenesis® is a product of Fraunhofer IITB (Fraunhofer Institute for Information and Data Processing, Karlsruhe / Germany).

How World Leading Manufacturers Can Achieve Differentiation Through E-Business: New Services, Enhanced Relationships, and Reduced Costs

Daniel Kindström, Linkoping University, SE-581 83 Linkoping, Sweden; E-mail: daniel.kindstrom@liu.se
Christian Kowalkowski, Linkoping University, SE-581 83 Linkoping, Sweden; E-mail: christian.kowalkowski@liu.se

ABSTRACT

E-business development is today driven by mature and established companies and is becoming an important tool to increase competitive advantage and to sustain profitability. This paper investigates how world-leading manufacturers can achieve differentiation through their use of e-business. Many companies use e-business as vehicles to launch new information-based service, as an important enabler to enhance and deepen customer relationships, and to reduce costs associated with customer management. Using e-business in this way will increase the opportunities for differentiation and create sustainable competitive advantage. Successful employment of e-business creates services that retain current customers and attract new ones as well as justifies premium prices and keeps low-cost competitors in check.

Keywords: E-business, Differentiation, Value creation, Offerings, Services

INTRODUCTION

Today mature and established companies, as opposed to start-ups, are driving e-business development and are using these technologies, now often incorporated in the concept of Information and Communications Technologies (ICT), to increase competitiveness by the integration of e-business into their business. Evidence shows that e-business is making big strides into most aspects of companies' businesses and is enabling new avenues in business development (Kindström, 2005; Earl, 2000; Hackbarth and Kettinger, 2000). Using e-business to create new information-based services and offerings to increase possibilities for differentiation and profitability is one of the major areas of interests in industry.

One aspect of particular interest is to study how e-business can increase competitive advantage by the expansion of industrial offering through services. E-business can be used to improve the companies' existing service processes and develop new, more advanced services and solutions (Normann, 2000), thereby increasing customer value and keeping competitors in check. As it is becoming increasingly difficult to maintain market leadership based on product sales, due to the trend toward product commodization in many business markets (Ulaga and Eggert, 2006) and competition from low-cost competitors (Lovelock, 1995) many companies turn to the provision of services in order to increase profits and customer value. On many industrial markets, services are likely to give higher margins than manufacturing activities do and services are becoming a critical factor of competitiveness for targeting new customer segments as well as to retain existing customers (Henkel et al., 2004; Oliva and Kallenberg, 2003). When conducting a quantitative study among purchasing managers in US manufacturing firms, Ulaga and Eggert (2006) found that the core product and its price become less important differentiators for product suppliers and they identified service support, the customer-supplier relationship, and suppliers' know-how as core differentiators. In the context of this study, market leading manufacturing companies pursuing a premium price strategy, this is particularly interesting.

The objective of this paper is to address how market leading industry incumbents can use e-business services to create value through differentiation and thereby increase their competitive advantage. Four world-leading manufacturers are analyzed using a qualitative case study approach.

THEORETICAL BACKGROUND

Early on, e-business initiatives focused on transactions, reducing costs and the relatively low-risk and comparable, easily appropriable benefits that were possible from that perspective (see eg Kindström, 2005). This is to certain extent supported by Dilworth and Kochhar (2004) that found that companies in the UK (in particular large ones) seem to have emphasized a simpler, transaction-focused, use of e-business (such as e-mails and web-site access). Transactional efficiencies and inherent cost reductions are often tangible aspects of introducing e-business into companies (Kaefer and Bendoly, 2004).

However, e-business can also provide the platform for many organizations to engage in new marketplace strategies and to generate and deliver additional value (Amit and Zott, 2001; Zwass, 2003), and increase competitive advantage in novel ways (Fahey et al., 2001; Porter, 2001). Thus, e-business should make it possible for companies to both reduce the costs for providing services (internal efficiency) and increase service revenues by injecting higher value into the customers' value-creating processes (external effectiveness) (Anderson et al., 1997; Kowalkowski, 2007). When discussing value creation, Wikström and Normann (1994) refer to these two dimensions as cost efficiency and market efficiency. Market efficiency can be achieved by either relieving the customer (i.e. reducing customer costs) or enabling the customer (i.e. increasing customer business performance) (Ravald and Grönroos, 1996). Thus, a premium price can be justified through the use of either of the two mechanisms (Porter, 1985).

Because e-business has become commoditized and is not a differentiator by itself (Carr, 2003), differentiation lies in the new practices it enables (Brown and Hagel, 2003). Many processes can be dematerialized and services can be unbundled in terms of where and when they take place and who performs them, and thereafter be re-bundled into new offerings (Normann, 2001).

Hence, e-business, as a resource, may initiate a radical transformation of traditional customer-provider relationships (Nambisan, 2002) and the company's internal service processes through standardizing (and possibly automating or eliminating) processes (Koskela, 2002). Close proximity to the customer enable bonding and thus customer lock-in possibilities (Hax and Wilde, 1999), and customer relationship longevity improve the efficiency and effectiveness of service provision (Grönroos and Ojasalo, 2004). A perennial problem with differentiation is to make it sustainable. By using e-business technologies as vehicles for new services (based on knowledge residing within the company) and differentiation purposes (Kim et al., 2004), companies are also effectively raising the barriers for imitators as well as locking out competitors.

In the framework proposed by Porter (1985), *differentiation* is one of three distinct, generic strategies, the other two being *cost leadership* and *focus*. Treacy and Wiersema (1993) argue, close to Porter's discussion, that there are three competitive advantages that companies can pursue; *operational excellence*, *product leadership*, and *customer intimacy*. Both product leadership and customer intimacy holds great potential for e-business through new information-based services.

Hax and Wilde (1999) argue that Porter's strategic framework is insufficient to describe all the ways companies compete and instead they suggest three strategic options; *best product* (representing a continuum from low cost to differentiation), *customer solutions*, and *system lock-in* (by e.g. proprietary standards). Hence, the best product option includes Treacy and Wiersema's operational excellence and product leadership whereas customer solutions bear a close resemblance to customer intimacy, with focus on customer economics and lifetime value. Consequently, differentiation possibilities consist not only in enhanced product attributes.

To sum up, four main competitive advantages can be derived. The system lock-in dimension has little bearing on mature, established manufacturing companies' offerings (the context of this study) if related to e-business, as e.g. few dominant design proprietary standards for offerings exist. The remaining three dimensions are presented in Table 1. Offering leadership is not only goods-oriented, but refers to parts of or the total offering. For market-leading industry incumbents, low cost differentiation is not a strategic option (although cost efficient operations are critical) and the main potential for differentiation lays thus in offering leadership and customer intimacy.

It is especially worth noting the fact that customization is now possible without the often associated cost increase (Hitt et al., 2001). When focusing on customer intimacy and relationship longevity (in opposite to arm's-length relationships), emphasis lies on retaining customers (Grönroos, 2000). Accordingly, attracting new customers is achieved mainly through offering leadership.

According to Huizingh (2002) there are four strategic choices a company has when using e-business for value creation and thus differentiation purposes; *customize products*, *attract new customers*, *retain current customers* by providing added value, or to *reposition the company* in its business network. These choices primarily aim at increasing profitability through increasing revenue streams and adding value as opposed to decreasing costs. Amit and Zott (2001), in their useful framework, come close to the same notions when forwarding their four dimensions *novelty*, *efficiency*, *complementarities*, and *lock-in*.

RESEARCH METHOD

The research approach was, largely, exploratory and for our purpose, case study research was considered a useful strategy (Gummesson, 2000; Yin, 1994). The research process was an iterative process matching theory and reality, where advantage of the systematic combining of both the empirical world and the theoretical models was taken (Dubois and Gadde, 2002).

A multiple case study was adopted because, compared to a single case study, a multiple case study is often considered more compelling and robust (Yin, 1994). Specifically, cases were chosen that met four primary criteria: (1) the company is an international market leader, (2) the company pursues differentiation strategies, (3) e-business is used to increase the competitive advantage, and (4) access to key informants was possible. Eventually, four multinational, Swedish companies were selected for in-depth studies. Thus, the choice of companies was a deliberate research design parameter to ensure some degree of general applicability (Glaser and Strauss, 1967; Gummesson, 2000) and replication logic may be claimed (Yin, 1994). Accordingly, our findings are believed to apply also in other companies and industries.

The interviews were loosely structured with the help of an interview guide (i.e. a semi-structured approach) (Yin, 1994). Respondents were managers that worked with developing e-business and/or services within these companies. Furthermore, intranets, internal documents, project meetings and discussions were used as sources of information. In total, more than 30 meetings with respondents took place. Data collection and data analysis did, to a certain extent, overlap and thus a fruitful interaction resulted (Eisenhardt, 1989). A case study protocol was established to increase reliability and validation of the cases has been made with key respondents in order to ensure correctness (Pettigrew, 1997; Yin, 1994).

VOLVO BUS AB

Volvo Bus is the world's second largest bus manufacturer and most of their business is directed to large customers with extensive fleets of buses. In total, Volvo Bus estimates that there are approximately 130,000 company buses in operation worldwide.

Volvo Bus creates new information-based services (such as e.g. advanced online search functions for lead generation and skill location) through analyzing, understanding, and supporting customers' processes and needs. Volvo Bus does not just deliver "raw" information to their customers; instead, they provide ways and functions to use the information for e.g. business intelligence purposes. For example by allowing service bulletin (both tentative and official) to be distributed online turn-around time in workshops, both Volvo's own and independent, is reduced.

One of the most obvious added value for Volvo Bus internally as well as the customers is the fact that ICT has the potential of speeding up processes and making them easier, faster, more accurate, and hence cheaper. The better use of information as well as the new services has eg cut calls and created more trust between the parties, and is thus also strengthening the relationship. Furthermore, by empowering its customers by shifting information and tasks to them, Volvo Bus frees up time internally and instills a sense of ownership of the process and activities in the customers. Through this Volvo Bus manages to achieve lock-in effects and also switching costs can be raised. One example is allowing customers to print out their own bills directly from the system instead of sending them via fax/mail/e-mail reducing enquiries.

SANDVIK COROMANT AB

Sandvik Coromant is the world leading manufacturer of cutting tools and inserts for the metalworking industry with a catalogue of more than 25 000 products. They have a wide range of customer organizations ranging from major automotive companies to small metal workshops with just a few employees.

Sandvik Coromant's range of customers and products creates challenges since different customers demand different things from an e-business solution. For example, large customers, having their own e-exchange systems, have diametrically different demands than small metal work shops. Sandvik Coromant has not been efficient at handling very small customers (called micro customers). By adding e-functionality for e.g. credit card payments and making small orders directly on the Internet (in their web-based Shop-Online solution) Sandvik Coromant is able to capture the unrealized value that these small customers hold. Earlier these smaller orders were made through the telephone on an ad hoc basis making it hard to understand, and

Table 1. Strategic options for industry incumbents

Cost efficiency	Offering leadership	Customer intimacy
Cost leadership (Porter, 1985)	Differentiation (Porter, 1985)	Differentiation (Porter, 1985)
Operational excellence (Treacy and Wiersema, 1993)	**Product leadership (Treacy and Wiersema, 1993)**	**Focus (Porter, 1985)**
Low cost (Hax and Wilde, 1999)	Best product (Hax and Wilde, 1999)	Customer intimacy (Treacy and Wiersema, 1993)
		Customer solution (Hax and Wilde, 1999)

profit from, this group of customers. Because of this added information, a better segmentation of the customers also becomes possible. For the larger companies Sandvik is able to provide customized catalogues with a richness of details and information not possible without a sophisticated e-business solution.

By developing new e-enabled tools for the sales force that provide direct links to the company's legacy system as well as business intelligence applications Sandvik are able to increase productivity of the sales force and thus become more profitable.

BT INDUSTRIES

BT Industries Group is a global manufacturer and supplier of warehouse trucks and services, and part of the Toyota Group. Often, contracts with customers are gradually becoming increasingly advanced as the relationships develop and mutual knowledge improves, and customers are used in the service development process.

Since 2002, BT's service organization is using EASY, a mobile business system. Service technicians each have a PDA linked to the ERP system through GPRS where they receive and report work orders and have access to customer fleet data and spare parts information. While BT benefits from reduced administration cost and increased cash flow, customers have benefited from faster response to service calls. Administration is also reduced for the customer, who signs the completed work order digitally directly on the PDAs display. Several synergies have derived from the EASY implementation and one of the most appreciated things was the possibility for customers to receive work reports electronically.

Furthermore, value can be created by offering report packages and consultative services that enable customers to view the real-time utilization of the fleet, to view how trucks are driven, and how different customer sites perform.

ELECTROLUX LAUNDRY SYSTEMS

Electrolux Laundry Systems (ELS) is a worldwide supplier of professional laundry products and services. Managers have pointed at opportunities to increase the knowledge component in the service offerings through e-business. ELS has also recognized a need of knowing the knowledge profile of each individual, authorized service technician. Therefore, an online certification program has been launched to assure a homogeneous service quality worldwide.

ELS' management information system for laundries, CMIS, substitutes personnel for dematerialized information. With a CMIS port on the machine, it is possible to make changes to the laundry processes and still obtain more laundry per day, thereby obtaining better process optimization. Either CMIS can be run as a local network only or there can be a gateway to ELS so the company can monitor the processes. By governing the customer's process through CMIS, ELS can help to improve the laundry programs and maximize equipment uptime.

The creation of an installed base database, which provides the company with information about machinery type, actions taken, etc., has given ELS better knowledge about the customers and the database can thereby be used to support the provision of customized services.

DISCUSSION

E-business has a substantial effect on the Offering leadership dimension in establishing a differentiated offering to, especially new, customers (see Figure 1 below). This can probably be attributed to a traditional focus in most companies of emphasizing tangible offering features based e.g. on what technology allows. Furthermore, this has a primarily inside-out focus with companies creating services in a rather traditional fashion resembling product development. That is e-business is used to create *new services* from a perspective of what is possible and not necessarily what is needed and value creating. These new services can also either be bundled with existing offerings or provided as stand-alone unbundled services to both the installed-base and previously unrelated customers.

In the Customer intimacy dimension we see many activities regarding the *enhancing,* and deepening, of the *relationship* with the customer. This implies that companies are not just creating new services and offerings (as hinted above) but also addressing specific customer needs and processes, customization, with new services and offerings and are thus unlocking the true potential of e-business as a vehicle for value creation by both relieving customers (ie reducing cost) and enabling customers' business (ie increasing productivity) (cf Ralavd and Grönroos, 1996).

Finally we can see that e-business refines and extends the companies' core business (cf Kraemer et al., 2000) and is used to create new customized offerings and create new value not only for external customers (cf. Huizingh, 2002), but also internally (e.g. mobile business systems) through process automation and elimination, i e *cost reductions*. The cost reduction aspect also means that a company can profitably approach previously unprofitable customer segments such as small customers with low transaction value versus cost ratio.

By adding new value-creating services to the company's core products and enhancing the relationship with the customer, it seems possible to reduce the changeability of the offerings by e.g. increasing switching costs. This is possible due to e.g. increased lock-in effects as well as an enabling of deeper relationships between buyer and supplier, thus increasing customer retention. We can also see that this enables the companies to escape the product commoditization trap by establishing themselves as solution suppliers and thus creating new differentiation opportunities. Many companies do indeed try to differentiate themselves through improved customer interactions instead of through product features (Vanderbosch and Dawar, 2002).

E-business can improve relationships in two distinct ways touched upon above. First, it decreases the cost of upholding an existing relationship and secondly, it

Figure 1. The effects of e-business on differentiation within the studied companies. The upper part of the figure shows the general aspects and the lower part some specific examples. 1) – 3) are the synthesized mechanisms

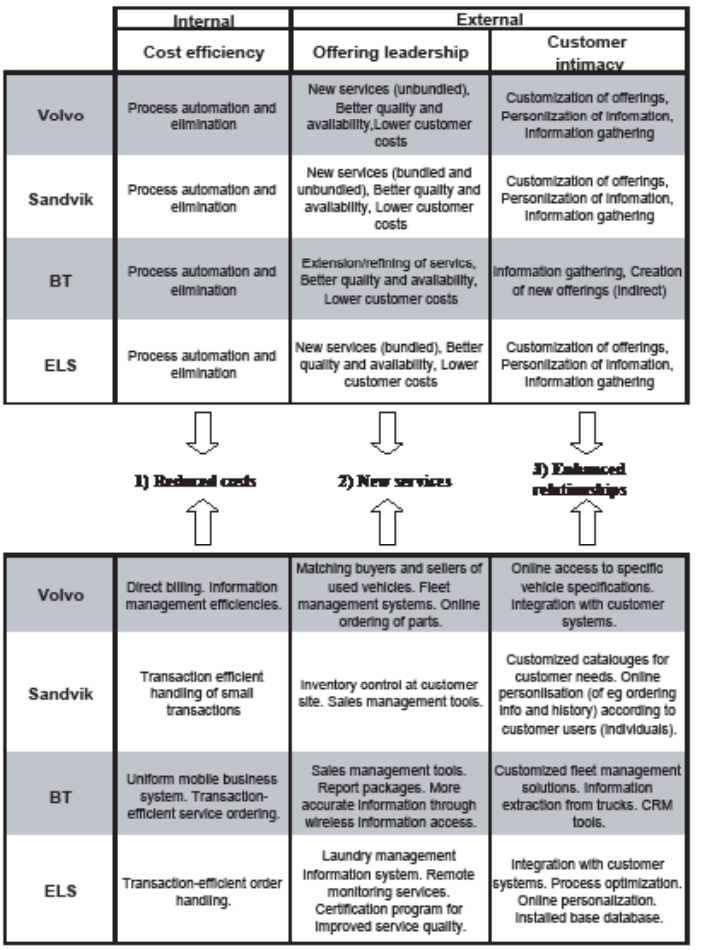

Figure 2. E-business and services can shift the competitive space

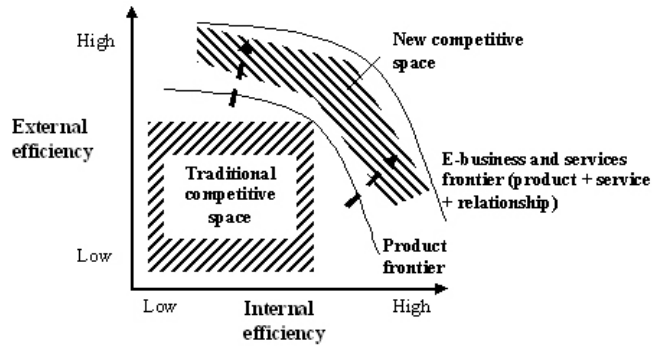

expands the width of the relationships by increasing contact points and integration by e.g. the inclusion of value-adding services in the offerings (based primarily on information gathering, analysis and distribution).

Through e-business, the case organizations have been able to cut administrative costs by re-engineering and even eliminating some administrative processes, typically the order process. This last point also has effects on the customer since an automated order process often can reduce costs for the customer as well. Furthermore it also increases the availability and simplicity of the interaction with the supplier thus creating value.

The three mechanisms discussed are not unrelated and can provide positive feedback loops to each other. For example, a customized solution provided to one customer can be generalized, and to a certain extent standardized, and rolled out as a new service in the company's total offering thus having a positive effect on offering leadership.

NEW COMPETITIVE SPACE

By using e-business and services, the studied companies stay ahead of competitors by effectively moving the competitive frontier further out into areas not covered by product features (these features are increasingly seen as qualifiers) but by "softer" issues (cf. Ulaga and Eggert, 2006). This new frontier is out of reach by low-cost competitors since they lack the necessary resources, such as well-functioning distribution and service networks, and can thus constitute a sustainable competitive advantage. If staying in the traditional competitive space, competitors will move closer and closer to the product frontier and thus erode any competitive advantage, whereas focus on service flows and customer processes (cf e.g. Day, 1994) enables companies to cross the traditional, technology-oriented chasm and increase both internal and external efficiency (see Figure 2) (cf also Normann, 2000).

In the traditional competitive space, value is largely created by technological advances regarding the products, and thus rather easily imitated, whereas in the new competitive space new services, information, and relationships (e.g. knowledge of customers and their processes) become of essence (Vargo and Lusch, 2004). Naturally, the company must have a reasonable cost level as well, thus not neglecting the cost-reduction aspect. This however is not a differentiator for the premium price strategy that the companies in this study have.

CONCLUSIONS

E-business can be used as a driver for new value in order to support differentiation strategies towards new customers as well as to retain current customers. Furthermore, e-business strengthens and adds value to the business model and enables its expansion and extension. An increasing part of all business development within companies today can be attributed to the development and inclusion of e-business and associated services into any companies (cf. Kindström, 2005).

One of the main purposes of e-business in this study is to create new services, for differentiation purposes, based on information gathering, analysis, and distribution. E-business supports and furthers the competitive position because it makes it possible to strengthen differentiation strategies (cf. Hackbarth and Kettinger, 2000). By using e-business to create new, often information-based, services and by tying customers closer, the companies establish and position themselves better on the marketplace by focusing on the customer relationship. This in turn enables the companies to understand their customers and the processes better and thus construct more attractive offerings tailored to the specific needs.

E-business can also enable the creating of more business and expand sales, i.e. increasing revenue, by e.g. being able to address previously unprofitable smaller customers with low transaction cost solutions and also to sustain new revenue streams based on services and complete offerings.

Evaluating Students' Acceptance of the Discussion Forum in the E-Learning Context

Kamla Ali Al-Busaidi, Sultan Qaboos University, Oman; E-mail: kamlaa@squ.edu.au

ABSTRACT

Recently, the popularity of e-learning systems has been growing in the academic and technical training world. Some academic and technical training organizations are adopting e-learning systems to support distance education, while others use these systems to supplement their traditional way of teaching. This pilot study evaluated the students' acceptance of the use of discussion forum in the context of using e-learning system as a supplementary tool, based on the technology acceptance model (TAM2). Data was collected through a questionnaire from undergraduate students in an academic institution in Oman. This study found that perceived usefulness is significantly determined by job relevance, image, result demonstrability and perceived ease of use of the system, but not by subjective norm and output quality. In addition, the use of the discussion forum in the e-learning context is determined by its perceived usefulness and perceived ease of use.

INTRODUCTION

Recently, the adoption of e-learning systems has been growing in the academic world. In 2004, the e-learning market was worth more than US $18 billion worldwide (Saady, 2005). In the Middle East, e-learning projects are expected to exceed a compound average growth rate of 32% by 2008, based on the Madar research group (Saady, 2005). Several international reports from the World Bank (2003) and the World Summit on the Information Society (2005) emphasized that the use of information communication technology (ICT), to build human resources is a vital prerequisite for the development of knowledge-based economy especially for developing country.

To be able to succeed on the deployment of e-learning systems, it is very essential to understand the determinants of this technology's acceptance. The technology's acceptance can be assessed at macro level (organizations or governments) or micro level (students and instructors). This study aimed to investigate this phenomenon from the students' perspective. Factors affecting information system usage are best investigated at the individual users' level (DeLone & McLean, 2002). Evaluating individual users' acceptance of the e-learning systems is a "basic marketing element" (Kelly & Bauer, 2004). Middle Eastern organizations are hesitant to adopt e-learning systems because of the limited Individual users' acceptance (Saady, 2005).

This study empirically examined factors that enhances students acceptance of e-learning initiative (specifically the use of discussion forum). Discussion forum is an online discussion group where people with similar interests engage in discussion, share and debate ideas. This study adopted Technology Acceptance Model (TAM2), which was proposed by Venkatesh and Davis (2000).

The next section provides a literature review of e-learning and technology acceptance models. The literature section is followed by sections on study framework, study methodology, data analysis, and discussion and conclusions.

LITERATURE REVIEW

E-Learning

E-learning is defined as "instruction delivered through purely digital technology using the Internet or private networks" (Laudon & Laudon, 2003, p. 268). It is the use of a web-based communication, collaboration, learning, knowledge transfer and training to add values to the learners and the businesses (Kelly & Bauer, 2004). Some academic and technical training institutions adopt the e-learning system to support distance learning, while others adopt this technology as a supplementary tool to their traditional way of teaching. E-learning provides several benefits for individuals and organizations. Such benefits are cost-effectiveness, consistency, timely content, flexible accessibility and customer value (Cantoni, Cellario & Porta, 2004; Kelly & Bauer, 2004). However, e-learning may cost a lot to develop, requires new skills on content producers and requires more responsibility and self-discipline from the learners (Cantoni et al, 2004); thus students might be intimidated to use the e-learning systems.

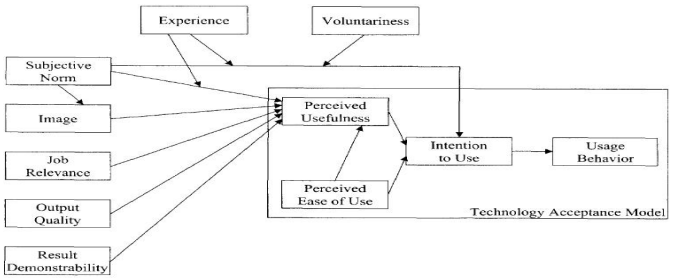
Thus, understanding the determinants of the learners' acceptance of the e-learning systems is vital to the promotion and exploitation of these systems. Limited studies investigated the e-learning acceptance such as those of Ashrafi, Al-Moharby and Salman (2005) and Abouchedid and Eid (2004). However, these studies assessed the instructors' acceptance of e-learning systems. Some Western studies empirically investigated the students' acceptance of e-learning. For instance, Roca and colleagues (2006) found that Information quality, ease of use, perceived usefulness, information quality, service quality and system quality determine the students' satisfaction and consequently their e-learning continuous intention. Gotthardt and colleagues (2006) indicated the success of e-learning strategy depends on content quality, system and content flexibility, system ease of use and others. Nevertheless, these two studies evaluated the individuals' acceptance of the entire e-learning system. However, an e-learning system incorporates various tools (such as online quizzes, files upload/download, chat rooms, discussion forums, instant messaging and email, quizzes, surveys etc.) that have diverse features. Thus, the determinants of these tools' acceptance may be different.

Technology Acceptance

User acceptance is a multidimensional attitude affected by various technical and social factors (Bailey & Pearson, 1983; DeLone & McLean, 2002). Technology acceptance has been assessed in the literature based on perceived usefulness, user's satisfaction, intention to use, and actual usage of the technology. Various frameworks, such as those of Bailey and Pearson (1983), Davis et al. (1989), Doll and Torkzadeh (1998), DeLone and McLean (2002), investigate the determinants of this individuals' acceptance. Baily and Pearson' and Delone and McLean's models focus mostly on the effects of information system's technical characteristics on IS effectiveness. However, discussion forum is a knowledge exchange tool. Knowledge management (KM) is a social and technical process (Scholl, Konig, Meyer & Heisig, 2004). Thus, investigating the social factors is as important as the technical factors. Venkatesh and Davis's TAM2 model (2000) is more suitable because it focuses on social and technical factors to measure the user's acceptance of information technology. *Figure 1* illustrates this model.

TAM was originally developed in 1989 based on the theory of reasoned action (TRA) in psychology, and was extended in 2000 (Venkatesh & Davis, 2000). Based on TAM2, user acceptance is determined by two factors: perceived usefulness (the extent to which a person perceives that using the system will improve his or her work performance), and perceived ease of use (the degree to which a person believes that using the system will be effortless). According to TAM, the effects of external variables on the intention to use are mediated by perceived usefulness and perceived ease of use; perceived ease of use also directly affects the perceived usefulness. TAM2 extends the external variables to include social influences (subjective norm, voluntaries and image) and cognitive influences (job

Figure 1. TAM2 (Source: Venkatesh & Davis (2000))



relevance, output quality, result demonstrability and perceived ease of use). The study framework section below provides more discussion on TAM2 model.

STUDY FRAMEWORK

This study examined the factors that determine the students' acceptance of the discussion forum use in the e-learning system based on TAM2. *Figure 2* illustrates the study framework. This study did not measure voluntariness because the use of the system in the participating sample is discretionary not mandatory. Experience was also excluded because to test the moderation effect of experience, a larger sample size is needed.

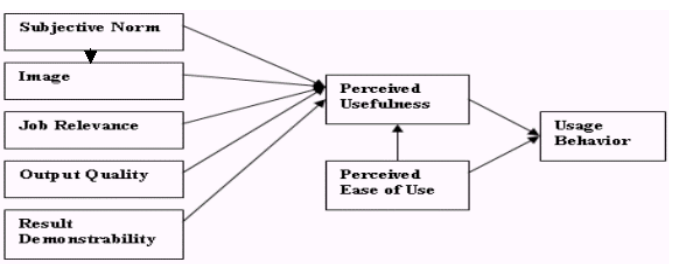
Based on TAM2, there are several factors that may contribute to the perceived usefulness of an information system (Venkatesh & Davis, 2000). These factors are subjective norm, image, job relevance, and output quality and result demonstrability.

Subjective norm and image are two social influences that may affect the perceived usefulness of a system. *Subjective norm* is defined as the individual's perception that most people who are important to him think he or she should or should not do a specific behavior (Fishbein and Ajzen, 1975). The rationale behind this effect is that a person tends to conduct a behavior just because other important contacts (superiors or colleagues) believe s/he should do it even s/he is not favoring doing it. Very limited studies investigated the influence of subjective norm on IS acceptance; one of these studies that found a significant relationship is Taylor and Todd (1995). *Image* is another social factor that affect perceived usefulness. Image is the degree to which an individual believe the use of an innovation will improve one's position in one's social system (Moore & Benbasat, 1991). Thus, an individual may perceive that the use of a specific system is useful because its usage enhances his image. TAM2 also theorizes that subjective norm affect image because if important figures in one's social network believe s/he should conduct a behavior, then conducting it will enhance his/her standing in the social group. Thus, the study hypothesized:

Hypothesis 1: Subjective norm improves perceived usefulness of the discussion forum in the e-learning context.

Hypothesis 2: Image improves perceived usefulness of the discussion forum in the e-learning context.

Figure 2. Study framework



Hypothesis 3: Subjective norm improves image.

TAM2 also theorizes that four "cognitive instrumental" factors determine perceived usefulness; they are job relevance, result demonstrability, output quality and perceived ease of use. Based on TAM2, people perceive the system's usefulness by cognitively comparing system's capabilities with what they need to get done in their job. Job relevance means that the use of a system is relevant to an individual job. Based on task-technology fit research, job relevance is an important influence on the acceptance of a technology (Goodhue, 1995). *Output Quality*, which is the perception of how well the system performs its tasks, affects the perceived usefulness. This effect has been empirically tested and confirmed in the literature (Venkatesh & Davis, 2000). *Result Demonstrability* is the "tangibility of the results of using the innovation" (Moore & Benbasat, 1991). An individual perceives the usefulness of the system if "the covariation between usage and positive results is readily discernable" (Venkatesh & Davis, 2000). *Perceived ease of use* means that the system is simple and effortless for the end user to use. Researchers indicate that perceived ease of use affects usage directly and indirectly through perceived usefulness (Bailey & Pearson, 1983, Venkatesh & Davis, 2000). In the e-learning context, research indicates that ease of use positively affect the system use (Gotthardt et al., 2006), and perceived usefulness (Pituch and Lee, 2006). Thus, the study hypothesized the followings:

Hypothesis 4: Job relevance improves perceived usefulness of the discussion forum in the e-learning context.

Hypothesis 5: Output quality improves perceived usefulness of the discussion forum in the e-learning context.

Hypothesis 6: Result demonstrability improves perceived usefulness of the discussion forum in the e-learning context.

Hypothesis 7: Perceived ease of use improves perceived usefulness of the discussion forum in the e-learning context.

Hypothesis 8: Perceived ease of use improves the discussion forum use in the e-learning context.

Using the system's intention-to-use or actual use to measure the IS acceptance has been debated in the literature (DeLone & McLean, 2002). The intention-to-use is useful in the context where the system use is mandatory. The investigated system use in this study is voluntarily. Thus, measuring the system actual use is more appropriate. In The e-learning context, Pituch and Lee fount that perceived usefulness positively affect the use of e-learning system (2006). Thus, the study hypothesized:

Hypothesis 9: Perceived usefulness improves the discussion forum use in the e-learning context.

STUDY METHODOLOGY

Investigated System and Sample

The study questionnaire was distributed to students in a public academic institution in Oman. The institution is one of the largest universities in the country. The medium of instruction is English in all science fields including commerce where the sample was selected. The university is currently deploying Moodle and WebCT e-learning systems. Instructors may voluntarily use these systems and incorporate them in their teaching. The e-learning systems are used as supplementary tool to support the traditional learning system enrich the learning experience. Some Instructors mandates the students to use the system; others leave its use voluntarily. The study sample is selected from the volunteer use context. One of tool that is utilized by instructors in the e-learning system is the discussion forum. Discussion forums are online discussion groups where people with similar interests engage in discussions, share and debate ideas. Instructors regularly post topics (questions) related to the course subject, and students are allowed to reply, share their ideas and debate others' ideas.

The questionnaire was distributed to about 136 students, but only 92 responded. The sample included about 49% male students and 51% female students. About

54% of student described their English level as average and 36% of them above that. 63% of the students were first and second year student and 37% were major students. About 41% of the students described their computer skills as average, and 40% of them described as above average. All participants had an experience before with the e-learning system. About 32% of students had 1 semester of e-learning experience, 36% had two semesters experience, 23% had three semesters experience and 9% had at least four semesters experience. 24% of the students had used only WebCT e-learning system and 48% of them used only Moodle e-learning system and 28% used both WebCT and Moodle.

Data Collection

Data was collected by a questionnaire. Instructors personally handed the questionnaires to the students. Students were asked to return their completed questionnaires to instructors' mailboxes. The cover letter asked the students to fill out the questionnaire for their use of discussion forum in a specific course. The letter identified the e-learning systems used by the university and the definition of the discussion forum. The questionnaire included some demographic questions and the questions related to the measurements of the study constructs. The measurement scale of constructs was based on 5-point Likert scale: 1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and 5=strongly agree. The questionnaire uses 4 items for usage behavior, 3 for Perceived usefulness, 3 for perceived ease of use, 2 for subjective norm, 2 for Image, 2 for Study-relevance, 2 for Output-quality, and 2 for result demonstrability. The measurements were developed based on Venkatesh and Davis (2000), and adjusted for the use of discussion forum in the e-learning context. For instance, one of the image indicator was "People in my organization who use the system have a high profile" in Venkatesh and Davis (2000). For this study, it is adjusted to "Students who use the discussion forum have a high profile". Two self-reported frequency measurements were also used to measure usage behavior: minutes per week and posts per week.

DATA ANALYSIS

Analysis Methodology

The data was analyzed using the partial least square (PLS) methodology, a structural equation modeling (SEM) based methodology. The study used PLS-Graph Version 3.0 software. With PLS, the rule of thumb suggests that the sample size is to be 5-10 times the larger of the following: (1) the scale with the largest number of formative (i.e., causal) indicators (note that scales for constructs designated with reflective indicators can be ignored), or (2) the largest number of structural paths directed at a particular construct in the structural model (Chin & Newsted, 1999). Reflective indicators are developed based on the assumption that they all measure the same underlying phenomena or construct, hence they all covary. Formative indicators are considered to be uncorrelated; indicators are assumed to be causing rather than being caused by the latent variable. This study investigated the model in reflective mode because it's the most applicable. Thus, a sample size of 30 to 60 is needed to evaluate the investigated model.

Measurement Reliability

The Model in PLS is evaluated based on several statistics. The R-square for dependent latent variables illustrates the predictive relevance of the model. The r-square of perceived usefulness and usage were 0.44 and 0.32 respectively. In PLS, the measurement internal reliability is measured by the composite reliability; the recommended acceptable level is 0.70 (Braclay, Higgins & Thompson, 1995; Hair, Anderson, Tatham & Black, 1998). The construct validity is measured by "Average variance extracted" (AVE) (Braclay et al., 1995). AVE refers to the amount of variance that a latent variable component captures from its indicators; the acceptable level is at least 0.50. *Table 1* shows that all the investigated factors satisfied the reliability and validity standards. PLS also provides the loading of each indicator on their factor, but because of the limited space they are not included here. The correlations among the investigated determinants of perceived usefulness were below 0.50.

Hypotheses Testing

The hypotheses testing were conducted by examining the path coefficients of the independent latent variables and their significance. The path coefficients are used to measure the relationship's importance and the direction of an independent variable and a dependent variable (Hair et al., 1998). *Table 1* shows the t-test results of constructs based on 95% confidence. To test the significance of the PLS estimates, bootstrapping technique was utilized with a re-sampling of 200 as suggested in the PLS-Graph user's guide. The statistical significance of the hypothesized paths was measured by t-values. As indicated in *Table 1*, the significant determinants of perceived usefulness are in order of their b*etas* are Job relevance (0.32), image (0.22), result demonstrability (0.21) and perceived ease of use (0.16). Subjective norm (0.10) and output quality (0.06) are not significant determinants of perceived usefulness. However, subjective norm is a significant determinant on image (0.21). Perceived usefulness (0.48) and perceived ease of use (0.20) have significant effects on the usage of discussion forum. Thus, hypotheses 2, 3, 4, 6, 7, 8 and 9 are supported, while hypotheses 1 and 5 are not supported.

DISCUSSION & CONCLUSION

Review of Findings

The popularity of e-learning systems has been growing in the last few years. The e-learning system offers several tools that can be incorporated to improve the teaching quality and efficiency in academic institutions. One of these tools is the electronic discussion forum. This study aimed to measure the students' acceptance of the discussion forum use in the e-learning system. The study adopted TAM2 model for this evaluation. Based on TAM2, the user acceptance of an information system is measured by perceived usefulness and usage. Perceived usefulness is determined by subjective norm, image, job relevance, output quality, result demonstrability and perceived ease of use. Usage is determined by perceived usefulness and perceived ease of use. However, this study found that perceived usefulness is significantly determined in order of their b*etas* by Job relevance

Table 1. Measurements and t-test statistics

Construct	Total indicators	Reliability	AVE	Beta	t-value	Significance
Usage	4	0.76	0.50	NA	N/A	
Perceived usefulness (H9)	3	0.91	0.78	0.48	6.22	0.005
Perceived ease of use (H7, H8)	3	0.85	0.658	0.16 0.20	1.31 1.90	0.10 0.10
Subjective norm (H1, H3)	2	0.90	0.81	0.10 0.21	1.02 1.79	NS 0.05
Image (H2)	2	0.90	0.82	0.22	2.61	0.01
Job relevance (H4)	2	0.87	0.80	0.32	3.10	0.005
Output quality (H5)	2	0.71	0.59	0.06	0.38	NS
Result demonstrability (H6)	2	0.81	0.68	0.21	1.95	0.05

(0.32), image (0.22), result demonstrability (0.21) and perceived ease of use (0.16). Subjective norm and output quality were not significant on perceived usefulness. Another study on e-learning context also found insignificant relationship between interpersonal influences (subjective norm) on user satisfaction (Roca et al., 2006). However, subjective norm as hypothesized was a significant determinant of image. The insignificance of output quality on perceived usefulness may be traced to the fact that it has a significant correlation with job relevance (0.334) and result demonstrability (0.326). Thus, subjective norm and output quality have indirect effect on perceived usefulness. The perceived usefulness (0.48) and perceived ease of use (0.20) of the discussion forum were significant predictors of discussion forum usage.

Study Limitations and Implications

There are some limitations of the study. First, the sample was selected based on accessibility. A random selection would increase the strength of external validity. Second, this study did not investigate the moderation effect of experience and voluntariness. Future research may test that effect and include more indicators to investigate the study construct, and explore other factors that might be significant to the acceptance of e-learning systems and the benefits of this usage. Third, this study examined only the use of the discussion forum. Other tools in the e-learning system might be also investigated in future studies. Finally, future studies may also have a closer look to the effects of other system characteristics such as reliability, and speed on perceived usefulness.

The study offered useful implications for practice and research. This study provided empirical quantitative evidence of the significance of TAM2 in the e-learning context which is a very limited in the IS research. The study also provided useful insights for the practitioners (Instructors and academic institutions). Instructors should ensure in their course design that the use of e-learning tools should be relevant to the students' studying tasks. They also should constantly encourage the students to use the e-learning system. Developers should ensure that the system provides tangible results that are useful. Some recent research in Oman indicates that one of the challenges of the instructors' adoption of the several tools in the e-learning system in their courses because of the student's attitudes toward this technology and their low acceptance (Ashrafi et al., 2004). This study added initial insights and on the factors that might affect the students' acceptance of this technology specifically in academic institutions in Oman. Because of the growing adoption of the e-learning systems, the findings of this study could assist organizations to have more successful and effective deployment of these systems. Successful deployment of these systems will encourage training organizations to not only use the e-learning systems as a supplementary tool but also use it them to support distance learning. Consequently, this will increase the capacity of these organizations in building human resources.

The Role of Power Distance in Determining the Effectiveness of Educational Technology

Elizabeth Koh, National University of Singapore, 3 Science Drive 2, Singapore 117543; E-mail: elizabethkoh@nus.edu.sg
John Lim, National University of Singapore, 3 Science Drive 2, Singapore 117543; E-mail: jlim@nus.edu.sg

ABSTRACT

Educational technology is being deployed rapidly all over the world. Correspondingly, there is also an increase in student collaboration from different cultural backgrounds through diversified student populations, institutionalized programs and distance learning. The cultural background of students is thus important in IT and education today. This conceptual paper surmises the effectiveness of educational technology, focusing on the dimension of power distance (Hofstede 1980) due to its relevancy to the context. The focus of this paper is on exploring how educational technology affects learning outcomes, and the role of power distance in influencing the effectiveness of educational technology. We postulate that power distance is a moderating influence on the relationship between educational technology and learning outcomes. In particular, the availability of educational technology increases learning outcomes but the effect will be greater on low power distance learners than on high power distance learners. This paper begins with a review of the effectiveness of educational technology, followed by a discourse on power distance. Anchored by the literature review, a research framework is formulated based upon which propositions are raised.

Keywords: Educational Technology, Culture, Power Distance, Effectiveness, Learning Outcomes

1. INTRODUCTION

Educational technology is being deployed rapidly all over the world. Amidst this progress, globalization has boosted international collaboration of student teams. For example, the virtual collaboration between students in the Netherlands and Hong Kong in the three-year HKNET project (Rutkowski et al. 2002). There has also been an increase in culturally diverse student populations such as the jump of more than 4000 international students at the National University of Singapore from 2000 to 2005 (Annual Report 2005; Lee 2000). In addition, educational institutions are increasingly expanding into international markets via setting up new overseas campuses or distance learning (Cronjé 2006).

With the increasing diversification of student populations and cross-cultural collaborations of student teams, the cultural background of learners has been pointed out as crucial in determining educational technology's effectiveness (Leidner & Jarvenpaa 1995; Chang & Lim 2005). Indeed, culture is part of all learners and affects how they think and value learning, as well as how they respond to educational technology. Chen et al. (1999) urge researchers and educators to appreciate the role of culture in education for "a deeper and more valid understanding of the nature of student learning" (p.219).

Culture can be examined from many perspectives, but seminal research on culture by Hofstede (1980, 2001) is more pertinent to learning outcomes (Wang 2006). Hofstede (2001) constructed a taxonomy of cultural dimensions underlining value orientations of people from various national cultures. Power distance, one of these dimensions, is the focus of this paper. Power distance is the extent to which people respond to inequality in power and consider it as normal (Hofstede 2001). In educational contexts, students from large power distance cultures have large power differentials towards instructors and higher status individuals while students from small power distance societies regard other individuals as equal to them. Power distance might affect the usage of educational technology and the ways of learning with it. For instance, students from low power distance cultures participate actively in traditional classrooms and may find it satisfying to participate via educational technology. On the other hand, students from high power distance cultures who rarely speak up in face-to-face classrooms may not feel as comfortable using educational technology. Hence, the use of educational technology may be more effective for different levels of power distance.

In light of these influences, the research questions are: firstly, how does educational technology affect learning outcomes? Secondly, what is the role of power distance in influencing the effectiveness of educational technology? This paper begins with a review of the effectiveness of educational technology followed by a discourse on power distance. Based on the literature review, the research framework and propositions will be presented before the conclusion.

2. THE EFFECTIVENESS OF EDUCATIONAL TECHNOLOGY

Piccoli et al. (2001) found that the performance outcomes are similar to the traditional learning environment although learners using educational technology reported higher computer self-efficacy and had lower satisfaction with their learning experience. Similarly, Curtis and Lawson (2001) acknowledged that the use of educational technology led to comparable collaboration as face-to-face environments. However they noted that factors like student familiarity with the medium and ease of use of the interface are also important moderating factors. Hence, some studies have revealed that educational technology is only as effective as the face-to-face mode of delivery and is commonly known as the "no significant difference" phenomenon (Hiltz et al. 2002).

On the other hand, there are studies that suggest the effectiveness of educational technology. Kulik and Kulik (1991) found that students who learned with educational technology scored higher than students without it, learned faster, enjoyed their classes more and developed more positive attitudes. Alavi (1994) observed that students with educational technology perceived higher levels of skill development, learning, interest, enjoyment, and resulted in better final grades relative to the traditional mode with the same collaborative learning technique. Chang and Lim's (2005) meta-analysis of 68 studies concluded that educational technology helps to increase the cognitive abilities of students. However, the study observed that the degree of effectiveness depends on a combination of the characteristics of the learner, the course and the instructional design. Researchers also propose that for greater student learning outcomes, what is necessary is a change of learning to new constructivist approaches and in applying technology innovatively for learning (Hiltz et al. 2002). Thus, this paper focuses on educational technology based on the constructivist approach, particularly the collaborative learning theory.

Many of these studies surmise that for educational technology to be more effective, there are a number of influencing factors (Piccoli et al. 2001; Chang & Lim 2005). However, it is neither viable nor useful to review each factor. An important aspect pointed out by several researchers' concerns *cultural background* (Leidner & Jarvenpaa 1995; Morse 2003). ***Power distance***, one of Hofstede's (1980) cultural dimensions, has demonstrated a large influence on student learning (Wang 2006). Power distance is a key cultural factor that affects group relationships and the group's performance in collaborative learning (Paulus et al. 2005; Hofstede

2001). The following section highlights power distance's impact on educational technology.

3. CULTURAL DIMENSION OF POWER DISTANCE

While there has been empirical progress on the impact of culture and IT (Leidner & Kayworth 2006), with regard to IT in education, there has been a lacuna of studies that examine the role of national culture on the effectiveness of educational technology. It is well recognized that different cultures display dissimilar behaviors due to unique developments and assumptions in each society (Morse 2003). This paper focuses on the cultural dimension of power distance (Hofstede 1980) owing to its germaneness to the context at hand. Power distance is one of the cultural dimensions constructed by Hofstede (1980, 2001) - the rest being individualism/collectivism, masculinity/femininity, uncertainty avoidance and time-orientation. These dimensions prescribe the behavior of individuals of a certain culture but have been criticized as demonstrating the idiosyncrasies of one particular organization (Gallivan & Srite, 2005) and reducing and simplifying the concept of culture (McSweeney 2002). Nevertheless, these criticisms have mostly been directed at the research methodology and not at the theory (Ford et al. 2003). These dimensions are theoretically sound (Straub et al. 1997) and make known the collective precepts that people of the same culture will value and act on. These dimensions have been independently verified and replicated by other researchers (Smith et al. 1996).

Power distance is the extent to which the less powerful people in society respond to inequality in power and consider it as normal (Hofstede 2001). Power distance has been considered to have a dominant influence on learning outcomes (Wang 2006; Paulus et al. 2005). In educational contexts, power distance is formalized as the student and teacher relationship. Hofstede (1980) observes that students from small power distance societies will have a low tolerance for inequality and hierarchy and hence regard their teachers as peers. They will also be more interactive in class. On the other hand, students from large power distance societies accept status differences and the hierarchy; they respect their teachers as authoritative figures. These students from large power distance societies will be quieter in class and focus more on absorbing knowledge from the teacher. In sum, small power distance cultures have a more student-centered education while larger power distance cultures are more teacher-centered.

Research has yet to fully examine power distance's impact on the learning outcomes of educational technology. As such, results are equivocal. Both small and large power distance learners seem to enjoy using educational technology (Bauer et al. 2000). However, Bauer et al. (2000) also found that small power distance learners were more confident in using technology than large power distance learners. Other studies report that large power distance learners had more difficulties in using technology (Smith et al. 2005), and were unclear with the rules for online behavior (Wang 2006). Additionally, educational technology might not totally meet learning needs of both cultures and students will differ in their level of learning outcomes. Research based on group support systems demonstrates that educational technology increases the participation of both high and low power distance learners and reduces status effects in high power distance cultures (Watson et al. 1994). While this matches the active learning mode of small power distance learners, large power distance learners prefer a different approach to learning which is more passive (Hofstede 1980; Smith et al. 2005). This might have consequences on their learning outcomes.

Another aspect of power distance is its role in impacting the academic performance of student teams (Hofstede 2001). Paulus et al. (2005) found that decision-making processes and methods to resolve disagreements are influenced by the group's power distance. High power distance groups believe in a rigid power structure and may be inflexible in fast-paced and highly coordinated tasks. Swigger et al. (2004) conceded that groups who had high power distance scores performed worst than teams with low power distance scores via computer-supported collaboration. This was exacerbated when teams collaborated on projects which required close coordination and were time-critical (Swigger et al. 2004). Power distance is thus a key factor that determines the effectiveness of educational technology. Different levels of power distance seem to affect the degree of learning outcomes with educational technology. Hence, research on the impact of power distance on learning outcomes should be established. The following section proposes a research framework to investigate the phenomenon.

4. RESEARCH FRAMEWORK AND PROPOSITIONS

This paper examines the availability of educational technology and its impact on learning outcomes. We define learning outcomes to be the satisfaction, self-efficacy, perceived learning and actual academic achievement of learners. Based on the earlier review, the level of power distance influences the degree of learning outcomes. The role of power distance is then posited to moderate the relationship between the availability of educational technology and learning outcomes. We illustrate the framework in Figure 1 while the definitions of the constructs are presented in Table 1.

Based on the earlier review, this paper asserts that the use of educational technology in innovative ways based on the collaborative learning approach enhances learning outcomes. Although some studies have emphasized that educational technology is only as effective as the face-to-face mode of delivery (Curtis & Lawson 2001; Hiltz et al. 2002), other studies have revealed that learning outcomes are enhanced with educational technology compared to the traditional face-to-face mode of learning (Kulik & Kulik 1991; Timmerman & Kruepke 2006). In a recent meta-analysis, Timmerman and Kruepke (2006) found that educational technology significantly increased the performance of college students compared to traditional instruction. Research has also highlighted that the use of educational technology leads to higher affective reactions, perceived learning and final course grades compared to the face-to-face process (Alavi 1994; Chang & Lim 2005). Hence, the paper proposes:

P1: Learning outcomes, in terms of satisfaction, self-efficacy, perceived learning and academic achievement, will be higher with the availability of educational technology than without.

We next visit the interaction between power distance and the learning outcomes of satisfaction, self-efficacy, perceived learning and academic achievement.

4.1 Satisfaction

This paper examines satisfaction as part of the students' desire to learn, whether the availability of educational technology results in students' satisfaction with the end learning result. With the availability of educational technology, mediated communication reduces the barrier in interaction and encourages egalitarian commitment which is in line with small power distance societies. The desire of small power distance learners to connect with others will then be met. In fact, Wang (2006) found that small power distance learners enjoyed using educational technology to connect with others.

Figure 1. Research framework

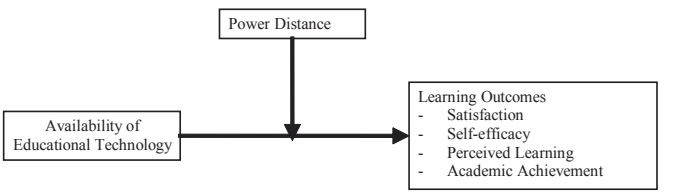

Table 1. Definitions of constructs

Satisfaction	**The extent of fulfillment of a desire or supply of a want (Oxford English Dictionary 1989)**
Self-efficacy	**The degree to which learners feel confident of learning from a given method (Chang & Lim 2005)**
Perceived Learning	**Changes in the learner's perceptions of skill and knowledge levels before and after the learning experience (Alavi et al. 2002)**
Academic Achievement	**Actual cognitive development of learners; related to task performance and typically measured by project or course grades (Chang & Lim 2005)**

On the other hand, although educational technology reduces the barriers for interaction, learners from large power distance cultures do not have the desire to participate in class. The level of status differences perceived by these students is not affected by the medium's affordances. Frank et al. (2004) reported that even when learners from large and small power distance cultures had equal access to educational technology, students from large power distance societies were more likely to use it to socialize with their peers rather than the lecturers and avoided confronting them to prevent conflict over the online medium. Thus we propose:

P2a: The effect of availability of educational technology on satisfaction will be greater on small power distance learners than large power distance learners.

4.2 Self-Efficacy

Bauer et al. (2000) examined student's perceptions of an online course and found that the small power distance group was more confident in using the technology than the large power distance group. The small power distance group also made use of educational technology more while the large power distance students had more difficulties in navigating through the online materials. One explanation could be that the large power distance group lack access to technology. However, Smith et al. (2005) discovered that both groups of students had the same on-campus access to computers and even posted the same number of messages on a bulletin board. The researchers suggest that the predicament of large power distance learners could be due to "a difference in approach to learning" (Smith et al. 2005, p.130).

Due to their higher dependency on the instructor, students from high power distance cultures are less comfortable in independent learning with educational technology and have less self-efficacy than low power distance learners. Large power distance learners on the other hand, have a low dependency on instructors and are familiar with an active mode of learning; educational technology facilitates this and their self-efficacy of learning with it will increase.

P2b: The effect of availability of educational technology on self-efficacy will be greater on small power distance learners than large power distance learners.

4.3 Perceived Learning

Collaborative learning with educational technology stimulates students, encourages participation and the cooperation of students, which increases their perceived learning (Alavi et al. 2002). For example, educational technology allows students to post queries and thoughts at the student's own time and pace. As many high power distance cultures do not speak English as a native language, it supports students who are limited in their English proficiency to give them more time to compose their thoughts (Smith et al. 2005). There is evidence that students from high power distance cultures perceive educational technology to be less inhibiting than face to face classrooms and are more willing to participate using educational technology than in the classroom (Bauer et al. 2000).

However, other studies observe that students from high power distance cultures are constrained by the public nature of the discussions as the rules for online behavior are unclear and the discussions are in full view of the public (Wang 2006). Frank et al. (2004) also found that learners from high power distance cultures were less active in answering questions using educational technology possibly due to anxiety about "lost of face". Additionally, Chang and Lim (2005)'s meta-analysis reported that perceived learning of low power distance learners were larger than high power distance learners. Thus, we postulate:

P2c: The effect of availability of educational technology on perceived learning will be greater on small power distance learners than large power distance learners.

4.4 Academic Achievement

Power distance is a key cultural dimension that impacts the academic performance of teams (Hofstede 2001). For example, decision-making processes and methods to resolve disagreements are influenced by the group's power distance level (Paulus et al. 2005). In a group of high power distance learners, a superior and subordinate relationship may arise because of their desire for hierarchy. Additionally high power distance groups believe in a rigid power structure and may be inflexible in fast-paced and highly coordinated tasks. Swigger et al. (2004) found that computer-supported collaboration of student teams who had high power distance scores performed worst than teams with low power distance scores. This was exacerbated when teams collaborated on projects which required close coordination and were time-critical (Swigger et al. 2004).

On the other hand, low power distance groups have been associated with better academic achievement. Paulus et al. (2005) observed that low power distance learners developed trust to overcome conflicts due to miscommunication, modeled decision-making by consensus, shared in leadership roles and assigned responsibilities based on expertise. This allowed the low power distance group to coordinate their internal processes effectively and produce better solutions. Hence we propose:

P2d: The effect of availability of educational technology on academic achievement will be greater on small power distance learners than large power distance learners.

5. CONCLUSION

The capacity of IT to support the education of students from different cultures is increasingly being relied upon due to globalization and the knowledge economy. At the same time, we are witnessing the collaboration of students of different cultural backgrounds through a diversified student population, institutionalized programs and distance learning. This paper has explored conceptually how educational technology affects learning outcomes and the role power distance can play in influencing the effectiveness of educational technology.

The paper has postulated that power distance is a key moderating linkage between the availability of educational technology and learning outcomes. In particular, the availability of educational technology increases learning outcomes consisting of satisfaction, self-efficacy, perceived learning and academic achievement; but the effect will be greater on low power distance learners than on high power distance learners. Educators, instructional designers, and researchers should not underestimate the significance of power distance in teaching and learning situations. Further work should look into designing and structuring educational technology to become more effective for high power distance learners. Inferences from our propositions would likely stimulate developments in this field. Finally, we advocate future research into other cultural dimensions.

Teaching Systems Analysis and Design Using the Process Game

Charles A. Suscheck, Colorado State University–Pueblo, 2200 Bonforte Blvd., Pueblo, CO 81001, USA; E-mail: chuck.suscheck@colostate-pueblo.edu

ABSTRACT

The teaching of systems analysis and design to students with no background in IS development is notoriously difficult. Most students have great difficulty identifying with both the reasons for a development process and its importance. Many different techniques exist to illustrate both the need for process and the effect of poor process. We propose a fun and simple in-class exercise called "The Process Game", a variation on the popular card game Rummy, which can be used to introduce both of these concepts to students. Experience indicates that students readily grasp the effect of changing specifications and processes on achieving the final goal. A pre-test and post-test experiment is proposed to measure the student subjects' understanding of the concept of process in systems analysis and design, along with the importance of following a defined process.

Keywords: Teaching, systems analysis, process learning, experiential learning.

INTRODUCTION

It is a well known adage that experience is the best teacher. The teaching of systems analysis and design to students with no background in IS development is notoriously difficult. Most students have great difficulty identifying with both the reasons for a development process and why it is important. Adding an experiential component to the teaching of software systems analysis and design is also a difficult task as many of the concepts require an in-depth project, case study, or background.

Individuals attempting to teach systems analysis and design to students at all levels, from secondary school to corporate offices, have faced the same dilemma from the beginning: "How can I introduce this subject to my students in such a way that they grasp both the subject itself and its importance to the success of all types of information systems development projects?" The failure to grasp these facts has been shown to be a major contributor to the poor success rates of these projects (Standish 2004).

This paper proposes a method which uses a game to teach students the importance of one aspect of good analysis and design practice, communication, and shows the effect of less than optimal communication on the achievement of project goals. The balance of this paper consists of a brief review of earlier research on teaching systems analysis and design, an introduction to the game, a research question suggested by the use of the game, a proposed experiment to test the perceived effectiveness of the game, and a discussion of our future research agenda.

BACKGROUND

The struggle to teach the concepts of systems analysis and design (SA&D) to students who find it difficult to internalize either the concepts or the processes has been the subject of extensive scholarship spanning the information era. As early as 1982, Golden (1982) was describing how industry leaders were decrying the poor state of the then-current methodologies for teaching SA&D and the steps educators were taking to address the problems. Later, Olfman and Bostrom (1992) proposed expanding the viewpoint of the role of the analyst taught in the classroom to include facilitation skills and creative thinking skills. They also proposed the addition of experiential learning to the classroom. Larmour (1997) surveyed present and former students seeking to identify those areas where SA&D training was adequate and those areas where improvements could be made.

As the methodologies used in industry to develop information systems applications evolved, the course focus in SA&D also changed. Kendall et al. (1996) made a case for expanding the traditional SA&D to include experiential elements as proposed by Olfman and Bostrom (1992).

The move to the object paradigm in industry should be reflected in a change of focus for modern SA&D courses. Although the evidence about the movement of industry to OO is substantial, there is still an ongoing debate with academia concerning whether to teach traditional structured design or OO (Mahapatra et al. 2005). Since the object paradigm seeks to create a representation of the problem space where object characteristics and behaviors model those of the actual objects, it is imperative that new SA&D students learn to use the object paradigm effectively. Brewer and Lorenz (2003) urged that "educational institutions must also begin educating analysts to create informative models based on OO principles" (54). To fully implement the teaching of object principles in the SA&D classes, many different approaches are being proposed, including Appreciative Inquiry (Avital 2005).

THE PROCESS GAME

As a possible remedy to the problem of students failing to grasp the reason and importance of using a defined process in systems analysis and design, we propose the use of a short, hands-on workshop called "The Process Game" to teach students about the importance of good communication and the consequences of insufficient communication. The game is fun, easy to play, and doesn't require an in-depth project or any type of case study. The entire workshop can be completed in less than an hour. The game uses a variation of a well-known card game - something most students have experience with. In our experience, it has consistently proven to drive the point home about the importance of communication. This workshop has been presented in the classroom at the undergraduate level and at several professional conferences. Each time the game is played, students comment that it helped them to see the importance of communication and how a solid process can assist in situations where communication is difficult.

The basic idea of the process game is to divide the students into a number of groups. Each group has a different communication method. Each participant in the group gets an incomplete set of rules for the card game. A few participants in the group get the remaining rules, but the game is set up so that no one individual (except a 'user') has a complete set of rules. Some groups will have a user who has a complete set of rules and variations of the game. The goal of the groups is to figure out how to communicate and play as many rounds of the card game as possible in 25 minutes. After the game is played, each group will have a representative stand up in front of the class and explain their communication mechanism and the problems they had playing the game. After all of the groups have debriefed the class, the instructor must relate the communication methods to real world applications.

Variations Among Groups

There are 2 dimensions that are varied for each of the groups, communication mechanism and user involvement. The following table describes the mix for each group.

Group	Communication Mechanism	User Involvement
Group 1	Via Email Only	No additional user
Group 2	Via Email Only	Additional user involved
Group 3	Via Telephone Only	No additional user
Group 4	Via Telephone Only	Additional user involved
Group 5	Open Communication	User inserted at last 5 minutes
Group 6	Open Communication	User involved until last 5 minutes

Communication Mechanism Descriptions

Groups designated as "Via Email Only" must communicate only in writing - no hand signals or speaking at all is allowed. One person in the group is selected as the mail server, responsible for routing emails between each player. Players do not hand the emails directly to other players, but hand them to the email server. Emails to more than one person will be routed (passed) by the mail server from one person to the next person. Players must also not email the rules between to other, but can email their interpretation of the rules. Note that students can't see each other's hands, the deck itself, or any discarded cards. This information can only be shared via email, therefore one of the participants in the group must be responsible for managing the cards in the deck.

Groups designated as "Via Telephone Only" can only communicate via telephone (speaking). The group cannot show each other diagrams, papers, write-ups, cards, or use hand signals. The groups can hold conference calls with multiple people. Members of this group cannot just read the rules, but must explain them. As with the Email group, students can't see each other's hands, the deck itself, or any discarded cards. This information can only be shared via telephone, therefore one of the participants in the group must be responsible for managing the cards in the deck.

Groups designated as "Open Communication" have free communication, essentially sharing anything the members have or know. As with the other groups, students in this category can't just read the rules or pass them around, but must explain them.

User Involvement Descriptions

Users get an entire set of rules as well as a section of rules designated as variations. The goal of the user is to introduce a different variation for each round. The variations are not cumulative (only one variation per hand). The user is part of the group and can facilitate or assist in any way he/she would like as long as he/she conforms to the communication mechanism.

The group designated as "Open Communication" with a user involved until the last 5 minutes must not be made aware that the user is going to be pulled from the group at the end, it must be unexpected both on the part of the group *and* the part of the user.

The group designated as "Open Communication" with a user inserted at the last 5 minutes must be told that they have no user - the insertion of the user must be unexpected. In order to accomplish this, a student must be removed from all participation and NOT assigned to any group; keep this in mind when determining the groups. Tell this student that he/she is a user and give the student the entire rule set and the variations. Instruct the student to read the rules and practice if needed. This student will become a relative expert on the game when inserted.

Determining Groups

A group consists of 4 to 6 players. It is important to avoid selecting players who are already in informal social groups as that will effect their communication. Ideally, there should be six groups (24 - 36 students). If there are more than 36 students taking part, repeat the six communication methods - don't create groups larger than six participants. If there are less than 24 students, limit the group communication by eliminating Group 6, Group 5, Group 4, and then Group 3, in that order. The game requires at least two groups (8 participants).

Rule Distribution

The rules for the card game are divided into three segments. There is an incomplete set of rules that is distributed to everyone in the group. There are two sets of additional of rules that are distributed to other players in the group. This ensures that nobody in the group has all of the rules. If there are more than 4 players per group, the two sets of additional rules are copied and distributed to four players in the group. For example, if there are six players, two people will have only basic rules, two people will have the basic rules and the first set of additional rules, and two people will have the basic rules and the second set of additional rules. The game cannot be played without employing all of the rules, so distributing the rules insures that the group must communicate. Although all of the groups are actually playing the same game, it is important to tell the groups that each group may have a different game to play so that the groups don't listen in to another group's game.

Playing the Game

The first step in the game is to distribute the instructions for the process game, but not the rules for the card game. These rules describe each group's communication mechanism and user involvement. The actual rules of the card game will be distributed when play begins. As you distribute the instructions, allow the participants to read them, but don't allow them to discuss the instructions until you give them the signal to start organizing.

The groups are given a signal that they have 3 minutes to organize themselves using any means of communication they'd like. Instruct them to determine who is the group leader (if they want one), who is the user (if applicable), and anything else that they need to decide (mail server, names for mail, scribe, etc).

After 3 minutes, distribute the rules, making sure that everyone gets a copy of the partial rules and the additional sections of the rules are distributed. The user instructions are also distributed. The participants are instructed not to read the rules until the instructor signals. Once all of the rules are distributed to all of the groups, the instructor gives the signal to start the game. Tell the participants that they can spend this time organizing more (within the parameters of the communication mechanism), but at the end of 25 minutes, the game ends and the participants must stop all activities.

After the game is over, each group will spend 2 - 5 minutes talking about what happened. The instructor may have to guide the participants to describe the group's communication mechanism and the problems inherent as well as the effects of a user with ever-changing requirements.

The last step of the process game is for the instructor to relate the communication mechanisms to real world situations. Group 1 and Group 2, where communication is only via email, can be related to a geographically dispersed organization. Email is often used as the primary form of communication when a branch office is located in a country such as Australia or India and the main office is in the United States making organized meetings difficult because of time zone considerations. Group 3 and group 4 use only telephone communication and no written documentation. This type of communication can be likened to agile processes where documentation is marginalized and oral communication is emphasized - i.e. extreme programming. Group 5 and 6 are mainly affected by user involvement, which is typical in many large organizations where the user is in high demand.

RESEARCH QUESTION

The Process Game, as a game, provides a fun-based means of interacting with others in various defined ways. The Process Game, as a teaching tool, is designed to expose students to the importance of having defined processes to follow in seeking to accomplish a task. The use of the game in a SA&D class to accomplish this goal suggests the following research question:

R_0: Does the use of the Process Game have a improve students' understanding of the use of process in systems analysis and design?

The pursuit of an effective means to illustrate to students the importance of using a defined process in SA&D has been the focus of a great deal of reasoned thought and research, as illustrated earlier. Our proposal to use a modification of a familiar game setting to draw students into an experiential learning environment

is a new approach, to the best of our knowledge. After playing the game, they can evaluate the benefits realized by having defined communication process to exchange information.

PROPOSED EXPERIMENT

Research questions themselves are generally not testable. As a consequence, it is necessary to define a hypothesis that can be tested with an experiment. The testable hypothesis for our research question is:

H_0: Playing the Process Game will have a positive impact on the student's perception of the importance of process in systems analysis and design.

The Process Game itself does involve any specific outcomes, the value of which can be used as a construct to represent any change in the students' understanding of the importance of process. It is necessary therefore to design a different type of measure that will generate the necessary construct. We intend to create a short questionnaire to be given to the students before and after participating in the Process Game. The questionnaire will list ten project related tasks, one of which is communication, that the students will assign a value representing its importance to the project. Our test for the hypothesis will be to evaluate the changes in the assigned values pre- and post-test.

CONCLUSION

We are currently conducting pilot tests of the test instrument and the experimental process. If we can secure sufficient numbers for statistical validity, we intend to report the full results of our experiment at the conference. If not, we will report the results of the pilot study.

ABSTRACT

This paper describes the issues in conducting ethical usability testing with children including experiences in developing and testing sign language software on Kindergarten, Prep and Grade five and Grade six children. It considers the unique requirement of researching with children and the process of gaining university approval to conduct research with children. It discusses the difficulties in gaining informed consent from teachers, parents and children, protection of the research subject from harm and the difficulty in empowering children to instigate their right to refuse to participate in the research project. The article also discusses practical issues such as age appropriate practice, the duration of testing and recruitment of participants. Each issue is disused in theory and an example is given from a resent research project Auslan Children.

INTRODUCTION

Auslan Children was a series of research projects that were undertaken to develop high quality software to teach hearing children sign language. There is currently little research specifically in the area of using software to teach young children Sign Language. The target age of children for the first project was four year old children in a kindergarten setting. The target age of the second project was five and six year old children who were in prep at primary school and eleven and twelve year old children who were in grade five and six at primary school. The *Auslan Children* software consisted of direct instruction of Australian Sign Language (Auslan) by three different characters: a female presenter; a super hero and a puppet. The next section of the software had three activities a short story, a song and a game.

In order to develop the best software for learning it was important to take children's preferences into consideration this included researching the most preferred character for presenting new signs, the type of activities that the children liked, the number of sign that children were able to remember in a single session in addition to the differences that age and gender made to the children's preference. The research project ran a number of small scale iterations in order to limit the amount of time spent on non preferred options.

The research was conducted in the context of university research in which researcher was required to meet strict criteria specified by the institutions in order to protect the participants and the credibility of the research and the institution. Private organizations are not subject to the same procedures but should still be considering the following issues in order to protect the best interests of the participating child. It is important to conduct research with children as children can benefit from these activities and the findings from research conducted on adults cannot always be assumed to apply to children. According to the Australian National Statement on Ethical Conduct in Research Involving Humans, "Research is essential to advance knowledge about children's and young peoples' well-being" (2005, p. 4.1). It is by researching children that their voices can be heard and their preferences can be taken into consideration(Burmeister, 2001).. The children that participated in the research were considered valuable to the research as their preferences for learning could be considerably different to adult learners. Hedges states, "Views of children affect the content and process of the education they receive and ways they are researched" (2001, p. 1).

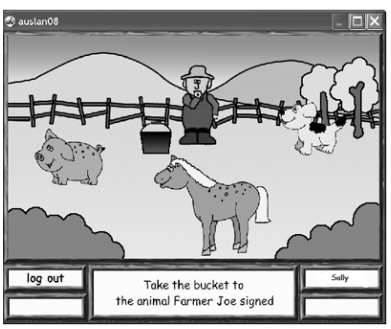
THE COMPLICATIONS PRESENTED BY RESEARCHING CHILDREN

Gaining data from children can be complicated by a number of characteristics that children may exhibit, although not exclusively characteristics of children they are more prevalent in this group. Read and MacFarlane state, "Factors that impact on question answering include developmental effects including language ability, reading age, and motor skills, as well as temperamental effects such as confidence, self-belief and the desire to please" (2006, p. 82). The language and conceptual concepts used in questions is really important to the results for example when children in prep were asked what their most favorite activity and their least favorite activity in *Auslan Children*, eight out of eighteen children (44%) selected the same activity for both showing they either could not make the selection accurately or they did not understand the concepts. False data may be collected if the children can make up answers in order to please the interviewer or if they tell the interviewer what they have been told by adults rather than giving their own opinion (Hedges, 2001). Therefore when it was possible to collect the same data

Figure 1. Direct instruction

Figure 2. Story

Figure 3. Game



from a number of sources this should be instituted. For example when collecting data regarding children's preference for characters between a female presenter, a super hero and a puppet the kindergarten children were able to work for one session with each character, in the fourth session they were able to select the character to take the session, when this preference for character was compared with the character that the children stated was there favorite 4 out of 15 children (26%) changed their preference dependent on the method of asking.

Another reason for using well trained researchers is that young children may have limited ability to express themselves verbally and the accuracy of the data is dependent on the researchers' ability to understand the children (Hedges, 2001). The presence of the researcher can affect the result, especially in the case of children. Read and MacFarlane state, "Even when there is no deliberate intervention the interview has an effect. In one study it was shown that children are likely to give different responses depending on the status of the interviewer" (2006, p. 82). Hedges states "Children behave differently with people they are unfamiliar with" (2001, p. 6). Even the actions of the researcher can effect the willingness of the participants to participate. For example when conducting research at a Kindergarten on using *Auslan Children*, children joined in making the signs with the software when the researcher was just watching, when the researcher had pencil and paper the children behaviour changed and they were less likely to join in at all. Also the presence or absence of a parent or guardian can significantly effect a child's behavior so careful consideration needs to be given to the physical research design.

GAINING UNIVERSITY APPROVAL TO CONDUCT RESEARCH WITH CHILDREN

The process of gaining approval to conduct research on children is quite daunting. At Monash University in Victoria Australia the form that needs to be completed to conduct research on children is twenty one pages, plus a privacy form needs to be completed which is another eight pages. In addition to this explanatory statements and consent forms for the staff, parents and children must be prepared. Written permission must be gained from any organizations involved such as kindergartens. If research is being conducted in schools there is an additional process of gaining permission from the government department of education, and the principle of the school prior to contacting the teachers, parents and students. Filling in the forms is time consuming, and forms need to be sent in three to four weeks before meetings of ethics committees with replies taking and additional two weeks. The main concerns for the Ethics committees seemed only conducting research in the best interest of the children, informed consent from the parents and children, and ensuring that participants are not coerced.

INFORMED CONSENT

The parents or guardians of children are usually required to give informed consent on behalf of the child until the child reaches the age of consent. The parent's or guardian's consent is gained as they are considered more capable of making a decision taking into account all aspects of the research (Hedges, 2001). Field and Behrman state, "informed consent is widely regarded as a cornerstone of ethical research. Because children (with the exception of adolescents under certain conditions) do not have the legal capacity to provide informed consent, the concepts of parental permission and child assent have been developed as standards for ethical research involving children" (2004, p. 7). The Australian National Statement on Ethical Conduct in Research Involving Humans states that consent is required from the "child or young person' whenever he or she has sufficient competence to make this decision" (Commonwealth Government of Australia, 2005, p. 4.2a) and also from the parent or guardian. Parents may only consent if the proposed research is not contrary to the child's best interest.

When research is conducted in schools, the lines of communication between the researcher and the parents are often more complex but acquiring consent from parents must not be compromised. In schools, consent must be obtained from all relevant parties including the child, the parent or guardian, the class teacher, the school principal and the relevant department of education. School staff cannot consent on behalf of students or parents nor can they disclose information for research purposes about any person or group without the prior permission of the individual affected. When sending forms out to children thought a school it is useful to provide a reply paid envelope for the parents to reply directly to the researcher, approximately fifty percent of parents responded in this way when provided with the opportunity.

PROTECTION OF THE RESEARCH SUBJECTS

Designing ethical research is difficult in educational settings as the nature of the experimental process applies different treatments to different groups, which has to disadvantage some groups. Hedges states, "In experiments a researcher ought to verify that children in the control group are not disadvantaged in relation to those in the experimental group who may receive new curricula, new teaching methods or new learning strategies" (2001, p. 8). There are also cases when the control group does not benefit from the treatment and this may be harm by omission (Johnson, 2000). Confidentiality of results can also be an issue as inadvertently revealing a child identity may lead to harm of the child. This may not be releasing a name but having such as small group that the identity can be deduced (Berk, 1997).

Children have the right to expect to be protected from harm in all research conducted on them. The Convention on the Rights of the Child states, "Bearing in mind that, as indicated in the Declaration of the Rights of the Child, "the child, by reason of his physical and mental immaturity, needs special safeguards and care, including appropriate legal protection, before as well as after birth"" (UNICEF, 1989). In addition to this Article 3 of the convention states, "In all actions concerning children….the best interest of the child shall be a primary consideration."

Protection of children in the process of research may not be as obvious as it first seems. If the results of the research is unknown, as is usually the case, then it is necessary to consider the research carefully to predict any harm that may come to children by participating in the research and if there is a possibility of harm then the research should not be conducted (Berk, 1997). For example, harm can be induced in children at different ages in ways that are not relevant to adults (Greenfield, 1984). Older children, for example, are susceptible to harm from procedures that threaten the way they think of themselves (Berk, 1997). People often don't see the value in ethics clearance for Usability testing because it in not medical research but there is unintended harm that can occur if research is not conducted ethically. Children's perceptions of computers could be damaged by participating in research and this could effect their decisions later in life. In addition children should not be made to feel powerless in the process of research so the right to refuse is of critical importance.

Australian National laws governing mandatory reporting of particular issues such as child abuse can pose a dilemma when conducting research. The procedures to be followed in the case of mandatory reporting should be clearly set out so that the researcher knows what their obligations are and the appropriate channels to follow (Newman & Pollnitz, 2002). In order to avoid any issues with this requirement the research on *Auslan Children* was conduced in open areas of the kindergarten and school in order to reduce the likelihood for possible incidence.

REFUSAL TO PARTICIPATE

Voluntary participation is a complex ethical area when working with children. The children may feel coerced into participating in the research if their parent or guardian has given permission even if they do not want to participate in the research. The child's right to refuse to participate in a research project must be respected (Commonwealth Government of Australia, 2005). The language and tone used by the researcher is important as there may be implied coercion when it is not intended. For example, if asking a child to use a computer the researcher could state, "Come and use the computer now" or use a more sensitive statement such as "Would you like to use the computer now". When children elect to participate in research they may change their minds. Hedges states "Children may choose, for example not to answer a question in an interview, or become bored or uninterested" (2001, p. 7). When conducting the Auslan Children research one child refused to take part in the research after the second weeks activity, rather than this being a negative reflection on the research it is a positive outcome that the child felt that they had the right to refuse to participate and was not force to by the researcher. Many children would occasionally refuse to participate because they were currently engaged in another activity the children would then come to the computer when they were ready to have a turn. The right to refuse to participate in a school situation is difficult as students are often not given this option in their normal school situation and may not recognise the right to refuse in a research context.

REPORTING BACK TO THE PARTICIPANTS

Once the research has been completed and analysed the knowledge gained by conducting research with children should then be released to the public (conforming

to the appropriate confidentiality provisions) in order to improve the circumstances of children and thereby justify the conducting of the research (Hedges, 2001). The participants in the research must also be informed of the findings. In the case of children, this should be done in a language that is appropriate to the age of the children involved (Johnson, 2000). The research for these projects was conducted over and extended period and this caused some difficulty in the ability to report back to the participants that were involved. For example when the research was conducted at the kindergarten the children are only involved with the institution for one year and then they move on to school. This makes it difficult to relay the results to the parents and children as to maintain confidentiality the contact details of the children may not be collected so it is not possible to send out the results at a later stage. The best ways to report back may be to make the results available through the organisation for example the kindergarten and also make the results available in a publicly accessible form such as on a web page so that participants and there parents are able to check the results once they have become available.

THE LOCATION OF THE RESEARCH

The location of the research is an important issue: should the researcher go to the children in a home or school setting or should the child come to the researcher? Usability labs offer iterative testing with changes between each test session but the children may not be as comfortable as in the home environment and not as many children can be tested as by testing groups within a school setting. For the experiments on children using the Auslan Software the testing was conducted in the Kindergarten or School. The Kindergarten was selected as it was an environment in which the children were comfortable and they were familiar with using the computer at the kindergarten. The research that was conducted at the school enabled the researcher to work in the environment for which the software was designed to be used in the longer term. It was important to test the likelihood of the software being able to be independently used by the target children in the future. As a result of the research for language learning software the researcher would recommend that any language learning software is loaded onto laptop and controlled by the language teacher to enable consistent control to be maintained over the software by an interested party this means fewer copies of the software could be loaded and maintained well. The three main methods of gathering data are observations, interviews and questionnaires (Hanna, Risden, & Alexander, 1997). One of the advantages with usability testing is that the computer can record some of the data independently such as time on task, response times and selection information in addition to results of testing. Automated data collection may need to be combined with observations is an effective method of collecting data on usability as some duration information may be misinterpreted if only the times are logged.

AGE APPROPRIATE RESEARCH DESIGN

The age of children involved in testing affects the style of testing that is appropriate to gather the required information (Ellis, 2002). Hanna, Risden and Alexander found that "most children younger than 2 ½ years of age are not proficient enough with standard input devices (e.g. Mouse, trackball or keyboard) to interact with the technology and provide useful data" (1997, p. 10). Preschool children should be able to explore the computer independently, however, when conducting usability testing preschool children require extensive adaptation to software because of their limited attention span. In comparison to testing pre-schoolers, elementary school children aged 6 – 10 are relatively easy to test. They can sit and follow directions, are not self conscious of being observed and will answer questions and try new things easily. Six and seven year olds like to be engaged in hands on activities but can be shy (Hanna et al., 1997). When conducting a literature review on two and three year old children the researcher discovered that there was little research on this age group as they are difficult to work with and it is hard to recruit significant numbers for research. This does not mean that research on this group is less important. Working with kindergarten children compared with children of primary school age is much more difficult. It is possible for children in there first year of prep to be shown how to use the software and then work independently, the researcher had to play a much more supportive role with kindergarten children which is time consuming but the competency that this age of child can achieve should not be underestimated.

DURATION OF THE TESTING

Hanna, Risden et al. (Hanna et al., 1997) believe that sessions should not exceed one hour of lab time as preschooler will last thirty minutes and older children will fatigue in an hour. When conducting user testing with children, it is best to select children who can already use a computer. Read and MacFarlane concur stating "Keep it short: Whatever the children are asked to do, make it fit their time span….. For young children, five minutes spent in a written survey is generally long enough, more time can be given, as the children get older" (Read & MacFarlane, 2006). When developing the software Auslan children there were several reasons for developing 10 minute segments such as this is the time that was currently allocated to children to use the kindergartens computer. Also there was concern that kindergarten children would be cognitively overloaded by longer sessions that were introducing new information. The ten minute sessions worked really well; in addition children that were highly engaged had the option of completing more than one session at a time.

RECRUIT OF REPRESENTATIVE CHILDREN

The recruitment of children for research must be considered carefully, as it is quite difficult to not recruit a captive audience through people that are known to the researcher or organisation and who have groups of children of the appropriate age. Hanna, Risden and Alexander (1997) warn against using colleagues' children for usability testing as they are far more exposed to computers than average children and if they don't like the software it can create situation where they feel uncomfortable expressing their true thoughts on the software. A university requirement for conducting research is that both parents and children complete informed consent forms. The explanatory statements for the *Auslan Children* projects were long in order to include all of the information required by the University, these forms are duplicated and combined make quite a thick document. At the start of many of the projects there was less respondents than ideal. Once the project has commenced and peers become aware of the project and want to participate, therefore forms were made available and many more research subjects signed on to participate in the project building a more acceptable number of research subjects.

CONCLUSION

Usability testing with children provides insight into the requirements of software developed for children and the way that they interact with the software however the design of the testing needs to be carefully considered to take into consideration the special requirement of the children. The university approval of research on children is a rigorous process that is designed to protect the best interest of the child and to ensure that the parent and children consenting to participate in research that they are adequately informed about. Careful consideration needs to be given as to the location where the usability testing takes place, the duration of the testing, and how the research participants are recruited. The way that the research is conducted and the language used will effect weather children are able to refuse to participate which is an important right of all research participants. Adequate thought and preparation can ensure that research which children is conducted ethically and provides credible results.

A Usability Framework for the Design of Assistive Technology to Promote Aging in Place

Shirley Ann Becker, Florida Institute of Technology, Melbourne, FL 32901, USA; E-mail: abecker@fit.edu
Frank Webbe, Florida Institute of Technology, Melbourne, FL 32901, USA; E-mail: webbe@fit.edu

ABSTRACT

A usability framework is proposed for designing assistive technology that meets the needs of older adult users. The framework is comprised of both requirements and profile components. The requirements component focuses on requirements specification from the perspective of technology, utility, and usability. The profile component encapsulates user requirements in terms of personal characteristics, normal aging factors, chronic health conditions, and other user characteristics that need to be accounted for in the design of assistive technology.

1. INTRODUCTION

Extraordinary societal changes in the U.S. have taken place in recent decades from both human and technological perspectives. Life expectancy continues to increase due to improvements in both medical care and technology. Older adults, 65 years plus, comprise 12.4% of the U.S. population with about one in every eight Americans being in this age group (U.S. Administration on Aging, 2002). By 2030, the percentage will have increased to 20% of the total population representing twice the number as in 2000. Those 85 years and older represent the fastest growing group (He, et al., 2005).

Information and communication technologies (ICT) have entered a new era of automated support through assistive technologies. The U.S. Administration on Aging (2005) defines assistive technologies as being services or tools that help the elderly or disabled do the activities they have always done but must now do differently. These technologies often determine whether a sixty years or older adult is able to live independently or must move to an institutionalized environment. Many older adults view quality of life as being dependent on aging in place in their own homes (Population Reference Bureau, 2002). This is reflected in 83% of older adults owning their own homes (Gitlin, 2003), even though 58% need help with daily living activities (U.S. Department of Health and Human Services, 2001). Given their stage of life, many seniors are motivated to hold onto a home for as long as possible (Sneeding, et al., 2006).

Research in assistive technologies is needed to promote aging in place with a focus on independent living and control over everyday activities. This includes automated support for managing medication, performing daily tasks, staying socially active, supporting cognitive functions, and maintaining a healthy diet, among others. With these support systems in place, older adults not only have an opportunity to stay in their homes longer but to improve the overall quality of their lives.

Research efforts in assistive technologies have been ongoing for several decades. But, it appears that a lack of commercialization persists in turning research outcomes into viable products. Smart homes, for example, have been studied since the early 1990's. Yet from a practical point of view, it is difficult to assess the benefits of smart homes in achieving aging in place objectives. Hurst et al. (2005) suggest that not only is there resistance in product development but also user resistance. From an older adult perspective, expense, invasiveness, lack of control, complexity, difficulty in operations, and lack of aesthetic appeal impact the acceptance and use of technology. Many older adults have already conceded control over various aspects of their daily living to family, friends, and healthcare personnel. They resist conceding control to technological devices that are viewed as invading privacy and lack perceived personal utility to warrant their use.

An understanding of diversity issues associated with aging is needed in order to develop assistive technologies that are universally accessible. To achieve this, usability factors associated with aging and chronic illnesses need to be accounted for in the design of such technologies. This requires a comprehensive understanding of the targeted user group and technological opportunities as well as constraints.

We present a usability framework that became the basis for designing assistive technology as part of an ongoing research project. The design objective was to account for user diversity associated with aging adults often burdened by caregiving responsibilities.

2. BACKGROUND

There is widespread agreement that assistive technologies offer great potential in dealing with quality of life challenges for an aging population. Older adults face physiological changes that increasingly impact daily living. These changes affect vision, cognition, hearing, and motor skills.[1] Figure 1 shows the degradation of vision due to normal aging illustrating one of the many technology design challenges. In order to produce technologies that meet the needs of older adults, it would be important to integrate aging considerations into the design process. Yet there are few guidelines for designing technologies for older adults with and without chronic health conditions. The U.S. National Institute on Aging (2001) offers guidelines for senior-friendly Web sites, this is a step in the right direction. However, more research is needed to address universal access of assistive technologies for an aging population.

Forty percent of older adults over 70 years of age deal with one or more chronic illnesses that affect daily living (Nehmer et al., 2006). Table 1 shows the percentage of the U.S. aging population suffering from chronic conditions. The significance of this data is that chronic illnesses are relatively pervasive in the aging population; and as such, have to be taken into account during the design of assistive technologies. Arthritis, Fibromyalgia, and other neuromuscular diseases, for example, may affect the use of data entry mechanisms due to degraded finger and hand dexterity. Type II diabetes may affect readability of text presented in a small font size due to

Figure 1. Simulation of the impact of aging vision. (Degradation in visual acuity affects ability to see objects clearly, thickening of lens impacts color perception, and decreased light sensitivity affects adaptation to changes in light levels (American Foundation for the Blind, 2004))

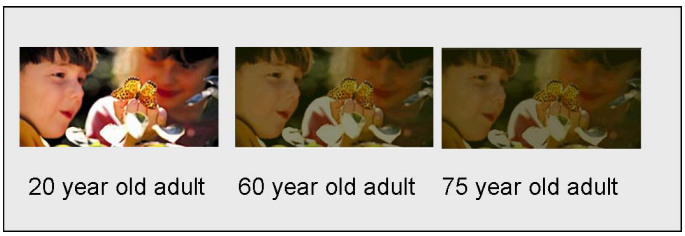

Table 1. U.S. Health and Human Services (2004) statistics on chronic conditions for older adults 65 years plus

Chronic Condition	Percentage
Hypertension	51.9
Arthritis (as diagnosed by doctor)	50.0
Chronic joint systems	46.0
Heart disease	31.8
Cancer	20.7
Diabetes	16.9
Stroke	9.3

lost peripheral vision. Alzheimer's disease[2] may impact cognitive abilities needed for recall of complex tasks associated with using assistive devices.

Figure 2 illustrates two different designs for a PocketPC screen --one of which is a standard user interface. The keyboard design, shown on the left, is part of Microsoft's Windows Mobile 5.0 software system. Data entry on this keyboard requires the use of a small stylus pen with a high level of accuracy in order to successfully tap a targeted key. Due to vision and motor skill degradation, older adults may experience difficulty using this user interface and data entry mechanism. Those older adults suffering from chronic or age-related illnesses with impacts on vision and motor skills may find this keyboard design virtually impossible to use.

The keyboard interface, shown on the right, has been designed as part of our research with input from older adult subjects. The keyboard can be switched to an alphabetical one with even larger key sizes to accommodate vision and physical impairments. (The alphabetized keyboard is not shown in Figure 2.) The senior-friendly design was intended to support the use of finger tip or fat stylus pen to perform a data entry task[3]. Thus, the PocketPC keyboard could be used by older adults to support daily living activities; such as making lists, composing email messages, and setting reminders, among others.

Gregor et al. (2002) have developed the concept of Design for Dynamic Diversity (DDD) when addressing the usability issues associated with the aging population. They suggest that the development of accessible interfaces is unique and a multi-faceted challenge given the diversity of the targeted user group and its ever-changing needs (p. 151). They have developed an informal taxonomy of older adult users that includes: healthy older adults, older adults who are frail due to age-related disability, and disabled older adults who suffer from chronic illnesses. This taxonomy allows for the characterization of user groups based on normal aging factors and the impact of both age-related and chronic diseases. We integrate this taxonomy in a usability framework to support our assistive technology research project.

3. USABILITY FRAMEWORK

The framework proposed in this paper is an expanded version developed by Becker et al. (2000) whereby user and technology characteristics became part of the system requirements. User characteristics, in the original framework, included age, gender, computing experience, education, and typing skills. The technology characteristics included browser type, network access speed, screen size, and specific data entry mechanisms, among others. These characteristics ensured that software applications accounted for hardware and software constraints that if unknown might impede usability by targeted users.

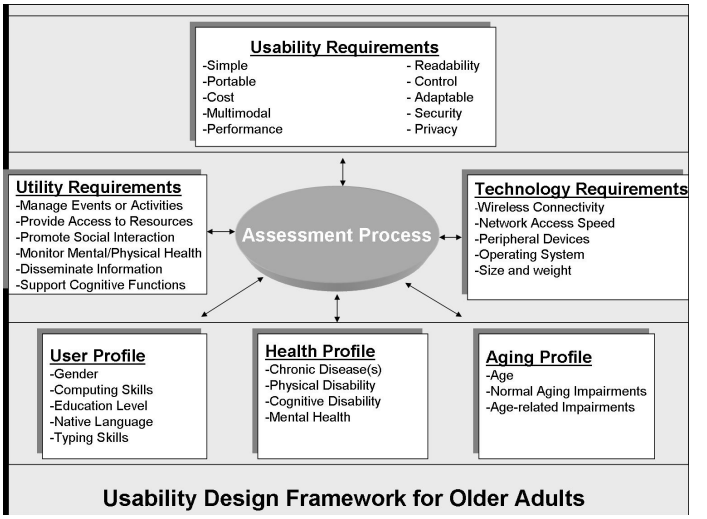
The usability framework includes a comprehensive set of requirements to support the design of software applications as part of our assistive technology research project. These PocketPC applications bundled together are called PocketBuddy; and they target a diverse group of older adult caregivers. The intention is that PocketBuddy, with novel user interface designs, would provide automated support for managing medication, reporting on daily activities, scheduling appointments, monitoring a loved one for whom care is provided, promoting social interaction, and disseminating information.

Framework components were formalized through usability studies involving older adult subjects ranging in age from 65 to 90 years. Feedback from health-care personnel, working closely with older adult subjects, also provided insight regarding factors that might impede or promote usability. Early in the research, it was determined that the framework would encompass the usability needs of older adults who are homebound, isolated, and burdened with caregiving activities in order to promote universal access. It would also capture usability requirements associated with vision, cognition, hearing, and motor skill degradation associated with normal aging; and as much as possible, degradation due to age-related illnesses and health conditions.

Figure 3 shows the framework decomposed into two major components. The requirements component focuses on requirements gathering from the perspective of technology, utility, and usability. The profile component encapsulates user requirements in terms of personal characteristics, normal aging factors, chronic health conditions, and other user characteristics to be accounted for in the design of assistive technologies.

Figure 2. User interface design as part of the assistive technology research project

Figure 3. Proposed usability framework used in the design of PocketBuddy



3.1 Requirements

Usability Requirements

The usability framework shows a set of requirements used in the design of PocketBuddy technology. In our design of a timer application, portability became a usability requirement to promote usage within and external to the home environment. The timer application had a multimodal requirement to ensure events are made known to the older adult as they fire. Audio support, as part of the multimodal requirement, accounted for normal hearing loss associated with aging through the design of appropriate sound frequencies, melody lengths, and volume. A readability requirement accommodated aging vision such that content was highly visible while taking into account screen size. The readability requirement also ensured appropriate use of foreground and background colors to maximize content visibility while accounting for screen glare.

Each of the usability requirements in the framework is further described from a more general perspective.

Simple – This requirement encompasses user recall after initial training and when the technology is not used regularly. The required learning curve must be minimal in order to provide utility to an older adult user. Complex technologies with long learning curves are often not well accepted by adults in later stages of life.

Portable – Portability requirements ensure that technology components are lightweight, readily found when misplaced, and easy to handle if transported by an older adult user. To promote portability, few or no installation or setup requirements are needed when the technology is used in alternate settings.

Cost – Cost requirements ensure that assistive technologies are affordable to those on fixed incomes inclusive of reimbursement potential through federal, state, or private healthcare resources. Affordability and reimbursement requirements would include the cost of licensing, software maintenance and upgrades, and support services.

Multimodal – Multimodal requirements support multiple mechanisms for relaying information to an older adult user. Vision, hearing, cognition, and motor skill degradation associated with both normal aging and chronic conditions would be taken into account. Text-to-speech technology, for example, supplements text display on mobile or handheld devices to account for small screen size, screen glare, and other hardware or software constraints.

Performance – Performance requirements focus on minimizing user discomfort associated with reliability and robustness issues. A usability barrier is encountered, for example, when software or hardware recovery steps must be taken by older adult inexperienced in the use of computing and related technologies. Performance requirements may also be mandated by patient safety and security guidelines put forth by the U.S. Health Insurance Portability and Accountability Act of 1996.

Readability – Readability requirements take into account vision degradation due to normal aging as well as chronic illness and diseases. These requirements ensure that text, buttons, links, and other screen objects are readily visible to the older adult user.

Control – Control requirements take into account normal aging factors and chronic illnesses in the level of control provided to the end user. Control over technology can range from none (invasive) to full (noninvasive). For frail elderly, for example, invasive technologies (e.g., sensing devices) may provide home monitoring capabilities necessary to allow the person to age in place.

Intuitive - These requirements are based on existing user interface (UI) designs that have been traditionally used by older adults (e.g., radio buttons, television remotes). Existing UI designs minimize the learning curve associated with new UI designs. They also promote a high comfort level in using newly developed technologies because they have a familiar look and feel to them. This is especially important to older adults with minimal or no experience in using computing, Web, and communication technologies.

Security – Security requirements ensure personal information is not vulnerable to being stolen or unknowingly shared or sold.

Privacy – Privacy requirements ensure personally identifiable information remains under the control of the individual and is shared only with those who have access rights.

Adaptable – Adaptable requirements promote integration of emerging technologies with existing ones to promote widespread acceptance and use by the targeted user.

Utility Requirements

The utility requirements associated with assistive technologies take into account potential resistance by the targeted user. In particular, the life stage of an older adult may impact tolerance of certain technological designs perceived as complex and invasive with little value added to everyday living.

Manage Events or Activities –Automated support for managing daily events add value to everyday living. Automated medication reminders, for example, promote long-term health and wellness given that such support promotes consistent, correct, and complete adherence to medication management.

Fast Information Dissemination – Fast and transparent information dissemination (e.g., older adult has fallen in the home) promotes longevity of life and aging in place.

Promote Social Interaction - Automated support of social interaction minimizes older adult isolation primarily due to being homebound. Online journals, blogs, email and text messaging, and other interaction-based tools offer a means of remaining virtually connected thus eliminating physical and geographic boundaries.

Monitor Mental or Physical Health –Automated monitoring support for those with chronic and age-related diseases promotes early intervention with the potential for improved quality of life.

Support Cognitive Functions – Memory loss is a normal part of aging. Technologies that support memory recall add value in performing daily tasks. For those with memory loss due to chronic illnesses, memory aids may prolong a move to an institutionalized care setting.

Technology Requirements

The technology requirements component focuses on profiling hardware and software for home use of assistive technologies. Internet access may be required for assistive technologies that transmit data from the home to family or healthcare personnel. Home sensor devices may be connected to existing security systems for continuous monitoring of movement within the home. Other technologies may require personal computers with a particular version of an operating system to utilize software applications. Weight and size may play a role in whether a device is a viable one especially for mobile or handheld technologies.

3.2 Profiles

User Profile

The user profile encompasses personal characteristics that traditionally have been part of usability studies. These characteristics often include age, gender, education, and reading comprehension. They may also include computing experience, Web and mobile technology usage, and typing skills, among others. The user profile provides a means of assessing assistive technologies in terms of ease-of-use, learning curve, memory recall, and other usability factors.

Health Profile

The health profile encompasses characteristics that might impede the use of technology due to chronic illnesses or diseases and the resulting impacts on vision, cognition, motor skills, and hearing. For users suffering from Fibromyalgia, arthritis, or other neuromuscular diseases, for example, typing on a small device may be impossible when designs are not made accessible to those with lost sensitivity in fingertips or lost dexterity in fingers and hands.

Aging Profile

Vision, hearing, motor skills, and cognition are continuously affected by the normal aging process. These impairments can have a profound impact on the use of technology that hasn't been designed with the aging user in mind. Age-related diseases (e.g., cataracts) can compound impairments associated with normal aging. Technologies that are difficult to use by healthy older adults become virtually impossible to use by those with age-related diseases.

4. CONCLUSION AND FUTURE RESEARCH

Assistive technologies offer great potential in supporting daily living activities, improving quality of life, and enhancing social interaction by older adults who are homebound, isolated, disabled, or chronically ill. The need for such technologies will continue to grow with the impending explosion of the aging population and

Table 2. National goals associated with the development of assistive technologies for older adults

Develop creative products to support older adult independence. Research is needed to identify innovative technologies to promote aging in place given the high cost of institutionalized care. These include noninvasive technologies for which the older adult user maintains control over information gathered and disseminated.
Create public awareness of available technologies. A national infrastructure is needed for public awareness of innovative technologies to promote aging in place. This includes the effective dissemination of research outcomes that can be readily expanded into the realm of product development.
Design technology products that assist the broadest range of consumers. Additional research is needed in the area of universal access so that all technologies are made available to those with and without disabilities. The promotion of universal access, at both national and international levels, ensures the broadest range of users have access to technologies.
Assure innovative and competitive leadership of U.S. technology to meet rapidly-increasing global demand for aging-related products and services. With national support, research and innovation infrastructures could be utilized to promote universal access from an international perspective. This would be inclusive of older adults with and without disabilities regardless of geographic location.

its strain on health care personnel, facilities, and other resources. This critical need is being recognized at a national level, as shown by the outcomes of the White House Conference on Aging (2005). Table 2 expands upon several of the national goals.

It became apparent in our compilation of a usability framework that novel interface designs were needed if handheld devices were to be viable as assistive technologies for older adults. As such, research has been initiated on interface designs that focus on universal access by a diverse group of users. A few of the lessons learned are summarized below.

Multimodal Capabilities - The significance of multimodal support became apparent in PocketBuddy usability studies involving older adult subjects. A number of subjects relied on multimodal feedback to ensure a task was completed. Though the button changed color, the subject would listen for a supplemental sound as an indicator that a button had been successfully tapped.

Novel Interface Designs - The design team designed a novel keyboard, as shown in Figure 2, as a means of promoting successful data entry by older adult users. Unfortunately, it was still inaccessible by 14% of the older adult subjects in the usability study. These subjects found the use of the keyboard frustrating given they could not accurately tap on a key. The design team is exploring other novel interface designs to promote usability by all older adult subjects.

Transparent Data Transmission - The usability framework uncovered the need for transparent Internet connectivity for transmission of data gathered on PocketBuddy by an older adult user. In our research, adult caregivers who are seventy years plus comprise a large percentage of targeted users. Many have minimal computing skills and are often consumed with caregiving responsibilities. These caregivers would have little time to learn new technologies and even less time to deal with complex aspects of a user interface.

Future research will study the integration of the usability framework with design space research conducted by Maciuszek et al. (2005). The objective would be a common frame of reference, which maps specific aspects of older adult life to be supported via new or enhanced assistive technologies. The usability framework would provide the means to characterize a user, technology constraints, and usability goals. This would provide a foundation upon which technology could be assessed in terms of user requirements to support aging in place goals.

Critical Success Factors in "Best of Breed" ERP Implementation

Mary Sumner, Southern Illinois University Edwardsville, USA; E-mail: msumner@siue.edu
Joseph Bradley, University of Missouri–Rolla, USA; E-mail: josephb@umr.edu

ABSTRACT

The research on ERP project challenges and critical success factors deals with large-scale ERP implementation using a single, organization-wide ERP package. The integrated nature of ERP software provides an incentive to implement a single ERP solution. However, the "best of breed" approach where the organization picks and chooses ERP modules which best support its business processes from various vendors is an alternative strategy. By examining the experiences of two organizations, this study identifies the critical success factors associated with the "best of breed" approach and the differences between these critical success factors and the critical success factors associated with implementing a single vendor ERP.

Keywords: Enterprise resource planning systems, best-of-breed ERP systems, critical success factors.

INTRODUCTION

The research on ERP critical success factors deals with large-scale ERP implementation using a single, organization-wide ERP package. The "best of breed" approach to ERP implementation is an alternative strategy. One of the significant issues with ERP is the need to re-engineer business processes to "fit" the best practices supported by the software. In the "best of breed," approach, the organization picks and chooses ERP modules which best support its business processes from various vendors. For example, one vendor may provide an optimum solution to HR practices, while another supports production and manufacturing processes better. In the "best of breed" approach, the organization mixes and matches ERP modules to support its business practices most effectively. These companies follow an approach of integrating multiple enterprise systems using a "best of breed" solution.

There is limited research on the "best of breed" approach. Light et al. used a case study approach to compare "best of breed" ERP implementation with single vendor ERP. In their analysis, the "best of breed" approach enabled the organization to support functionality and unique business process requirements (Light, Holland, and Wills, 2001). In their case study of an organization in the entertainment industry, these unique processes included release management, copyright and royalties management, and invoicing. In addition, the "best of breed" approach is less disruptive to organizational processes because it supports existing processes. However, the "best of breed" approach presents a number of difficulties, including the costs of developing interfaces among a suite of applications and higher degrees of maintenance due to complex connections between various components.

Another study indicated that users prefer a "best-of-breed" solution when each department has a unique mission, information transfer among departments is minimal, data translation across systems is easy, and the discount on purchasing the uniform solution is small (Dewan, Seidmann, & Sunderesan, 1995).

RESEARCH QUESTIONS

This paper will provide case studies of two organizations implementing "best of breed" ERP projects and will provide insight into each of these questions based upon their experiences:

1. What are the critical success factors associated with implementing "best of breed" ERP?
2. What are the differences between these critical success factors and the critical success factors associated with implementing a single vendor ERP?

LITERATURE

ERP and IT literature were reviewed using the five functions of management theory as a lens. Possible critical success factors were identified in the areas of planning, organizing, staffing, leading and controlling.

Planning

Integration of business planning and IS planning is a top problem reported by executives and IS managers (Reich & Benbasat, 1996). An A. T. Kearney study indicates that firms that integrate IS plans with business planning outperform other firms (Das, Zahra, & Warkentin, 1991). Most executives do not understand the connection between modern business and technology and "leave technology compartmentalized within the I/T department with disastrous effects (Severance & Passino, 2002)." This literature suggests that the higher the level of integration of ERP planning with business planning the more likely the ERP implementation will be successful.

H1. The level of integration of ERP planning and business planning is positively related to implementation project success.

Organizing

Organizations must deploy resources to attain goals. A common view is that a user must head the project team and it must be a full-time job (Wight, 1974). Another view is that systems knowledge is the least important skill of the project manager (Flosi, 1980).

H2. Organizing the ERP implementation project under the direction of a project manager whose sole responsibilities are the project is positively related to ERP implementation project success.

H3. An organizational structure in which the project manager reports to the business unit's senior manager is positively related to implementation project success.

Staffing

Tasks associated with staffing include recruitment, selection, appraisal and development of employees. Current literature emphasizes the business skills of the project manager. Project leaders must be veterans who have 'earned their stripes' leading projects (Brown & Vessey, 2003) .

H4. Staffing the ERP project manager position with an individual with extensive experience is positively related to project success.

A positive initial experience with a new software package is important to users. A tendency to cut training budgets can result in negative user attitudes (Lassila & Brancheau, 1999).

H5. The quantity and quality of training are positively related to implementation project success.

In most ERP implementations consultants are retained to assist with the project. One practitioner states "the success of the project depends strongly on the capabilities of the consultants…" (Welti, 1999)

H6. Use of an ERP consultant for guidance is positively related to implementation project success.

Leading

Executive support is generally regarded as critical to implementation of management information systems. Senior management communicates direction, allocates resources, delays conflicting projects and deals with organizational resistance (Laughlin, 1999).

H7. CEO involvement in the planning and implementation of ERP systems is positively related to implementation project success.

A champion is critical to new systems. Champions "are more than ordinary leaders…(they) inspire others to transcend self-interest for a higher collective purpose (Burns, 1978). "Successful champions can break down bureaucratic barriers…(Beath, 1991)."

H8. The existence of a champion is positively related to implementation project success.

ERP implementation projects involve change in almost every area of business process. These major changes result in "resistance, confusion, redundancies and errors (Somers, Ragowsky, Nelson, & Stern, 2001)." Change management must be rigorously planned and generously resourced (Brown & Vessey, 2003).

H9. Management's effectiveness in reducing user resistance to change is positively related to implementation success.

Controlling

A process of systematic controls regulates organizational activities. A common method of control in information systems projects is management steering committees. These committees can be viewed as a method to get top management involved, ensure IS/BP planning fit, improve communications and change user attitudes toward IS (Gupta & Raghunathan, 1989). A study of 12 manufacturing firms found that steering committees with executive leadership were a characteristic of projects that stayed on time and on/under budget (Mabert, Soni, & Venkataramanan, 2003).

H10. The use of a steering committee that a.) is headed by the CEO, and b.) meets at least every four weeks is positively related to implementation project success.

Table 1. Case study site characteristics

	Case 1-M-I	Case 2-Boeing
Project start date	1995	1993
Software vendors	Oracle, Datalogix	Manugistics (was Western Digital), Baan, Oracle, Peoplesoft
Revenue	Approx. $1 billion	Approx. $6 billion (defense)
Project cost	$7 million, US only	$16 million, ongoing
Data Source	Multiple interviews and archival data	Multiple interviews (CIO, project leaders)

RESEARCH METHODS

A multiple case study method is used in this research. An open-ended questionnaire was developed. In some cases multiple in-person interviews were conducted, in other cases questionnaires were completed by e-mail with e-mail or phone follow up was used. The validity of the data collected was verified by conducting multiple interviews and by making enhancements to assure completeness and consistency. Interviewees were asked to read case summaries and offer corrections.

CASES

Case 1

M-I Drilling Fluids is a global energy services company. Before the ERP project the company was using home grown information systems on an outsourced IBM platform. The legacy systems were islands of automation. The information provided by these systems was accounting oriented, not operations oriented. Even inventory data was of limited use because of incomplete, inaccurate and late data for receipts and shipments. M-I's aging legacy systems would be very costly to upgrade and would still leave the company with an outdated system The ERP project, begun in 1995, was the company's effort to get up to date and improve the scalability of IT costs, reducing the need for cycles of layoffs and hiring as the economy fluctuated.. The impetus was the foreseeable Y2K problems in the legacy systems. Computer Science Corporation was selected as consultants on the feasibility study and implementation project. The project would be the most significant change effort the company with deeply embedded organizational practices had started.

M-I decided on a "best of breed" solution to their information needs because their drilling mud production required a process manufacturing package. Oracle did not provide a process cost solution at the time the project was begun in 1995, so Datalogix's Global Enterprise Manufacturing System (GEMMS) was selected for purchasing, manufacturing, inventory, cost accounting and sales order entry. The interface software between Oracle and GEMMS was the source of many implementation problems. It is interesting to note that Oracle acquired Datalogix in the midst of the implementation project at M-I. This acquisition actually impeded the project as an exodus of Datalogix employees after the acquisition created a shortage of knowledgeable customer support for the GEMMS software.

The application of the proposed critical success factors to the M-I implementation is now examined.

H1. Business and IT planning. At the time of the ERP adoption decision, IT planning supported business planning at M-I but was not integrated with it. The business plan called for cost control in IT, scalability of IT costs, more transparency of information throughout the organization, and improved financial and operating information. The IS department proposed the ERP system to accomplish these goals.

H2. Full time project manager. Computer Science Corporation was hired as consultants and full time project managers. In addition, two M-I employees, one from the IT department and one from the accounting department, were selected and full time co-managers.

H3. Reporting level of project manager. The project managers did not report to directly to top management at M-I. The project managers reported to the IT director who in turn reported to the CFO.

H4. Project manager skills. The project manager for CSC is described as having excellent project management skills and a good working knowledge of the Oracle financial software, but limited knowledge of the GEMMS manufacturing and distribution software. Also, the CSC project manager had little knowledge of M-I's business process. The M-I co-managers provided the team knowledge in that area.

H5. Training. M-I provided employees primarily keystroke and data entry training. Business process training was not conducted. A major deficiency in training materialized on implementation start-up. On the advice of the consultants, employees were provided with training on the report writer software and were expected to write their own reports. The complexity of the Oracle report writing software proved too much for the average user, so few reports were available in the first few months after implementation.

M-I's IT staff scrambled to design reports for individual users resulting in a proliferation of reports, rather than the fewer multi-purpose reports the company had anticipated.

H6. Consultants. Consultants participated in M-I's ERP feasibility study and implementation project. Consultants drove the project forward, but M-I employees knew the business processes and customer needs. A project co-manager observed that the project really started going well when the company started managing the consultants, rather than the consultants managing them.

H7. CEO role. M-I's CEO did not play an active role in the project, but supported it fully. Top management team members involved in the project were the CFO and VP-Supply Chain Management.

H8. Champion. Project team members identified the two M-I co-managers as the champions for the project. The co-managers worked to reduce user resistance and coordinate the needs of the various functional areas of the business.

H9. User Resistance. Management used an active employee communications program to inform the employees of the importance and progress of the ERP project. The culture at M-I is a top down style of management. Management made it clear to employees that the project was going to succeed so they "might as well get on board." Reduction of user resistance was key to project success. Few M-I employees had any IT sophistication or vision of how a well-designed system could help them do their jobs better.

H10. Controlling the project. The steering committee included the CFO, VP-Supply Chain Management, IT Director, CSC project manager and the IT Director from M-I's majority owner. One member complained that spotty attendance at committee meetings by some functional members contributed to the lack of a broad base consensus to decision making. The finance operation drove the implementation with operations playing a minor role.

MI management considered the implementation successful. The project was completed on time and on budget and met management's expectations of improved transparency, better scalability of IT costs and improved operating efficiency.

Case 2

Boeing is an aerospace-defense industry company with their Integrated Defense Systems (IDS) based in St. Louis. Boeing IDS is a $6 billion division supporting 140 applications provided by 23,000 separate software contracts costing $250 million each year. As background, the systems before ERP were a series of legacy non-integrated mainframe systems. The overall goal in acquiring ERP and commercial off-the-shelf packages (COTS) is to reduce the overall number of systems. For example, Boeing had 16 different procurement systems before acquiring several common procurement systems.

Boeing decided upon a "best of breed" solution because the company did not feel that one ERP system could be used to integrate 140 different applications. They decided to use multiple ERP packages from different vendors. Since Boeing was not willing to change its processes to fit the best practices supported by a package, the company required the software vendor(s) to customize the ERP packages to meet its unique business requirements. Since government contracting entails unique processes, Boeing required its vendors to customize and to maintain specific government contracting modules to meet its needs.

Using the "best of breed" approach, Boeing acquired a variety of commercial off-the-shelf software supporting different applications, including: Procurement/Manufacturing: Manugistics (e.g. was Western Digital); Commercial Procurement: Baan; Financial: Oracle; and HR: Peoplesoft. In each case, Boeing selects large vendors, because they contract with these vendors to customize the software to meet their needs. Every time an upgrade is installed, the software must be customized again. Once a vendor is selected, the partnership can last for as long as ten years.

The overall success strategies for ERP implementation at Boeing were: (1) ERP project leadership by end-users; (2) building capability (e.g. enhancements) into the ERP implementation; and (3) the vendor partnership. As one executive put it, "Boeing is not in the software business, so we have created a partnership with a vendor who can meet our ERP software needs and work with us to modify their package to meet our needs."

The application of the proposed critical success factors to the Boeing implementation of "best of breed" ERP systems is now examined.

H1. Business and IT planning. ERP is a critical strategy to achieve lean manufacturing, and ERP planning is important to achieving these business outcomes. The actual business objective to be achieved was inventory reduction, which is key to lean manufacturing and supply chain management. Management was committed to the value of ERP based upon this business case.

H2. Full time project manager. A customer leads each ERP project. Three ERP project leaders represent core business functions, including Production, Engineering, and Operations. A co-lead from IT handles administration and project management.

H3. Reporting level of project manager. The ERP project leaders were end-user managers at Boeing with extensive experience and business knowledge. The project was continuously reviewed by a Steering Committee, led by the project managers. They reported to senior division management.

Table 2. Findings in "Best of Breed" ERP

	MI	Boeing
H1. IT and business planning integration	IT plan supports the business plan	IT plan supports the business plan
H2. Full time project manager	Consultant served as project manager	ERP project managers are business leaders representing Production, Engineering, and Operations
H3. Reporting level of project manager	Steering committee headed by IT director	Steering committee led by the project managers
H4. Experience of project manager	CSC project leader with excellent project management and software skills	ERP project managers had extensive business knowledge
H5. Training	Limited to keystroke/ data entry	Extensive training on relevant modules
H6. Consultants	Used heavily	Used extensively
H7. CEO Involvement	Limited to approvals, support	Management was committed to the value of ERP based upon the business case
H8. Champions	Two co-managers	ERP project managers were the champions
H9. Management effectiveness in reducing user resistance	Heavy employee communications and top down support	ERP project managers were the change agents. Strategies included education and communications
H10. Steering Committee	Steering committee used, but not headed by CEO.	Steering Committee continuously reviewed the business case for ERP. Steering Committee was headed by the project leaders

H4. Project manager skills. The project managers had extensive business knowledge in Production, Engineering, and Operations.

H5. Training. Software vendors provided training to Super-Users within each business area, and the Super Users became trainers within specific areas. The project managers noted that the importance of training could not be under-estimated. If anything could have been done differently, it would be to provide more extensive training.

H6. Consultants. Some of the team members represented consulting firms, including Ernst and Young and Anderson Consulting. Consultants were active in requirements planning and testing. The change management issues were dealt with by the management team, not by external consultants.

H7. CEO role. Top management drove and communicated the need for change. Management was committed to the value of ERP based upon the business case. Top management said that they could not live with disparate systems and did not see any alternatives to ERP.

H8. Champion. Project leaders were the champions.

H9. User Resistance. The project leaders were the change agents. Management dealt with user resistance through education, continual reviews, and communications. The implicit assumption was that people needed to make the change, or else move on.

H10. Controlling the project. The Steering Committee met regularly to review the business case for the ERP projects, including the business value of the investment. According to one of the project leaders, "the Steering Committee reviews the cost if we don't do the project, and the cost if we do the project." There are ongoing measures of the impact of the project on achieving business results. The major business benefit of the manufacturing ERP project was inventory reduction.

COMMON CRITICAL SUCCESS FACTORS

Several common critical success factors emerged in the "best of breed" projects, and several "new" critical success factors emerged in importance. In each case, ERP was aligned with business objectives, and the ERP projects had full top management support. Top management received briefings on these projects, and the Steering Committees were responsible for closely monitoring these projects. In each case, the project manager(s) were end-user managers with extensive business knowledge, including knowledge of production, manufacturing, and operations management processes. In each case, the champions were the ERP project managers. Steering Committees in both cases continuously reviewed the projects, including the business case.

UNIQUE CRITICAL SUCCESS FACTORS

Boeing and M-I Drilling decided to use the "best of breed" approach because they did not want to change their business practices. Instead, they wanted to select vendor packages that fit their business requirements. The most significant challenge with the "best of breed" approach is the need to integrate ERP modules from different vendors. This requires building interfaces between different ERP modules (e.g. Peoplesoft to Oracle). In addition, if any of the modules are customized, then upgrading to new versions of vendor-supplied modules requires creating new customizations and building new interfaces. The cost implications of the "best of breed" approach are significant and must be continuously justified in terms of business results.

CONCLUSIONS

An analysis of "best of breed" ERP projects, using two case studies, reveals that certain critical success factors in "best of breed" projects are common to vanilla ERP implementations, including alignment with business objectives, effective project management, the role of the champion, and the role of the Steering Committee in monitoring project issues and in measuring project results. In "best of breed" projects, supplier management is magnified in importance because vendors are entrusted with customizing their software to fit the unique business requirements of the customer. Interface management between multiple vendors requires effective vendor management and cost justification—since this approach is more costly to negotiate and more costly to maintain. In Boeing's case, experience with the "best of breed" approach between 1993 and 2006 drove them to justify customization only for "must-have" processes. These customizations were handed over to the vendor, so that the vendor was responsible for building unique modules and for integrating these unique modules with common systems. Leadership by end-user managers assures that only "must have" processes are customized and that these customizations have a business case associated with them.

ABSTRACT

Mobile Data Technologies (MDT) are a natural extension to the traditional office computing environment. It is predicted that more than two thirds of the active workforce will rely heavily on mobile data technologies for business related activities by 2007 (IDC, 2005). However, very little research is available on how MDT adoption decisions are taken by Micro and Small Enterprises (MSEs). In this paper, we present the results of an exploratory study on MDT adoption process in MSEs. The results presented are based on structured interview data collected from MDT adoption decision makers in 33 micro and small business enterprises. The study highlights some major ways in which the MDT adoption process in MSEs can differ significantly from Medium and Large sized organizations.

1. INTRODUCTION

Business use of computing has evolved consistently at a fast pace in the last few decades with the advancements in Information and Communication Technologies. The traditional method of accessing and managing information through a stationary desktop personal computer (PC) is close to obsolescence with an ever-increasing miniaturization of electronic devices and widespread diffusion of advanced wireless standards and technologies. The mobility extended to computing and communication devices by these technologies allows employees the prospect of information exchange anytime/anywhere. From the globe-trotting CEO to the traveling sales representative, *Mobile Data Technologies (*MDT) have radically changed the way employees work. Consequently, MDTs have experienced tremendous growth in the last few years. The market research firm Canalys reported recently that worldwide shipments of smart mobile devices rose 55% year-on-year in Q2 2006 (Canalys, 2006). This growth in MDT adoption has motivated several researchers to study the phenomenon, however, very little research is available on MDT adoption in the context of Micro and Small Enterprises (MSEs) (Riemenschneider *et al*., 2003; Paul *et al*., 1995; Yap *et al*., 1992).

In this paper we explore MDT adoption process in Canadian MSEs. MSEs are a major contributor to any nation's economy. According to a 2006 Statistics Canada's report, 94.5 % of all businesses operating in Canada employed fewer than 50 employees while 73.7 % of all businesses employed fewer than ten employees (Industry Canada, 2006). The problems, opportunities, and management issues encountered by small business are unique (Premkumar, 2003; Kuan & Chau, 2001). MSEs face different challenges in adopting Information Technology (IT) compared to large organizations (Harker & Van-Akkeren, 2002). For example, recruiting and retaining personal could represent a significant resource allocation for MSEs in comparison with medium and large organizations that could have an entire department dedicated to IT (Kuan & Chau, 2001; Dankbaar, 1998). Significant differences in operating conditions and concerns of MSEs prescribe differences in how the decision to adopt an MDT is initiated, evaluated, and approved within MSEs..

We explore the typical activities in the MDT adoption process of MSEs such as *adoption initiation*, *business case development*, *criteria for selection of product,* and *decision to proceed*. The theoretical foundation is based upon the innovation process theory approach wherein we adapt the Markus and Tanis (2000) framework to delineate the MDT adoption process. The next section provides the theoretical background of the study by defining the key concepts used in the study and developing the theoretical framework. Section 3 describes the methodology used in collecting data for the study. Section 4 presents findings and managerial implications and Section 5 presents our conclusions and recommendations for further research.

2. THEORETICAL BACKGROUND

Micro and Small Enterprises

Defining MSEs is not an easy task. Throughout the world, there is no standard or universal definition of MSEs; rather, it is clear that many countries use a variety of different types of criteria to define MSEs (Amboise, 1991). While some criteria are applicable to all industry areas, others are relevant only to certain types of business (Longenecker *et al*., 1998). In Canada, there is no clear guideline or definition for classifying MSEs (Balderson, 2003; Longenecker *et al.*, 1998; Amboise, 1991). For example, legislators may exclude small firms from certain regulations if they fall below a certain number of employees. Statistics Canada usually classifies an organization as a small business when there are fewer than 500 employees, and Revenue Canada uses a minimum profit amount to define small enterprises. Furthermore, a business may arbitrarily be described as "small" when compared to larger firms, but "large" when compared to smaller ones.

There are four commonly used criteria to distinguish the size of an organization (Balderson, 2003; Longenecker *et al.*, 1998; Amboise, 1991). They are: number of employees, total revenue, profit, and type of management-ownership structure. This study will employ the most widely used criterion to size a business: number of employees (Balderson, 2003; Longenecker *et al.*, 1998; Amboise, 1991). This criterion is justified by the abundant adoption studies that have classified enterprises through 'number of employees' (Harker & Van Akkeren, 2003; Fink, 1998; Harrison *et al*., 1997; Igbaris *et al*., 1997; Paul *et al*., 1995; Iacovou *et al*., 1995; Paul *et al*., 1993; Raymond, 1985;). Table 1 illustrates how this paper has defined MSEs.

Mobile Data Technology

Mobile computing and communication devices have radically changed the way organizations conduct their day-to-day business. Increased mobility offers a significant opportunity for businesses, by improving customer service, increasing employee productivity, or allowing for shorter decision approval cycles. In any

Table 1. MSE classifications

Category	Size Definition	Source
Micro Enterprises	1 - 4 employees	(Industry Canada, 2006)
Small Enterprises	5-50 employees	(Industry Canada, 2006; Statistics Canada, 2004; B.-C.-Stats, 2003; Harfield, Driver, & Beukman, 2001; Longenecker et al., 1998; Philp, 1998)

Table 2. Mobile device spectrum

	Price (per month)	Portability (weight in grams and size in centimeters)		Functionality
MDT Basic Basic Cell Phones - a sophisticated radio transceiver used to make phone calls. Basic PDA - a scaled down PC. Basic features include: address book, notepad, appointments diary, calculator and phone list.	$20 - $75	60 – 100 grams	5(w)*10(h)*2(d)	limited
MDT Handhelds Integrated Handhelds - digital wireless devices that can send and receive voice, data and video as well as operate software programs. Able to connect to the internet for e-mail and web access.	$50 - $200	120 – 140 grams	12(w)*7.5(h)*2(d)	Medium
MDT Robust Laptops - a small mobile computer capable of doing the same tasks a desktop computer can do. Tablet PCs - allows the user to write directly on the screen, making it easier for the user to capture, access, and utilize information.	$100 - $500	1.8 – 3.5 kg	30(w)*26(h)*3(d)	High

Table 3. Project chartering phase: Typical activities

Key Activities	
▪ Idea of adopting MDTs surfaced ▪ Business case for investment developed (may be highly informal) ▪ Current state analysis (may be deferred or not done) ▪ Selection of mobile device ▪ Initial plans for how the device will be used, supported, and maintained, upgraded, etc. (may be deferred) ▪ Communication to organization ▪ Organizational changes and/or incentives related to mobile devise and/or organizational performance improvement, if any (may be deferred) ▪ Decision to proceed; approval of MDT adoption plan	**Can you explain how the idea of adopting the MDT was initiated?** ▪ Who initiated it? ▪ Why was it initiated? ▪ When was the idea initiated? **Can you explain how the MDT was evaluated?** ▪ What was the main reason for adopting the MDT? ▪ Was a business case used in the evaluation? ▪ Were any criteria set to help evaluate the device? ▪ What is your level of information technology awareness? ▪ Was the ever changing technological environment evaluated? ▪ Were other additional costs associated with the adoption of the MDT? ▪ Did you test pilot the MDT before the decision was made? ▪ Were plans created to support, train, maintain and upgrade the MDT? ▪ Was there a plan created for how the MDT was going to be rolled out within the organization? ▪ Were the end users consulted about the MDT? ▪ Was there a plan created for how the MDT was going to be communicated to the organization? ▪ When deciding to adopt the MDT's, to what extent would re-engineering have to take place in your work process after the adoption? **Can you explain how the decision to adopt the MDT was approved?** ▪ What was the time period from initiation to evaluation to approval? ▪ How many were involved in making the approval? ▪ Was the MDT approval method the same as other technology acquisitions?

modern business employees routinely require technology to work away from the office and on the move. Leung & Antypas (2001) noted that MDTs can enhance business efficiency by distributing information to the workforce remotely and by offering new channels through which employees can interact with customers and work processes even when they are on the move. Examples could include sales representatives at a client's location or maintenance crews on service calls.

A search through the literature provides only limited results on the definition of Mobile Data Technologies. This is not surprising given the recent emergence of these technologies. Harker & Van Akkeren (2002) describes MDT as being a mobile device, whether it is a mobile phone, PDA, or an integrated handheld that is associated with services. These authors also suggest that MDT 'marries' the two components of mobile phones and e-commerce technologies, hence, helping to eliminate time and distance barriers for organizations. In Computer Associates (2002, p. 2) White Paper mobile devices are defined as "portable electronic components that are used by mobile people to do their work". Schmidt *et al.*(1998, p. 2) defines a handheld computer as "an unobtrusive computing device that is accompanying the user most of the time and provides assistance in different situations and for a wide range of tasks." In this paper we define Mobile Data Technology as an *End user technology which enables the mobility of employees in order to provide functionality for the organization anytime/anywhere.*

An issue that arises in referring to these mobile devices is how to classify the devices into categories. Devices differ in size, weight, performance, storage capacity, display (screen) and input (Keyboard) dimensions, and other so-called cost form-factors (Gebauer & Shaw, 2002). Gebauer & Shaw's propose to position devices along a portability continuum, where portability is determined by the weight and size of a device. We use three evaluation criteria that categorize mobile devices into three groups. The three criteria are as follows: price, portability and functionality. Price is simply defined as the estimated total monthly cost of operating each device. MSEs are price sensitive when adopting new technologies, hence price is our first consideration. Portability is determined by weight and size of the device. Functionality determines the sum of what a product can do for the user (Whatis.com, 2005). Three mobile device categories are thus developed and used in this research are MDT Basic, MDT Handhelds, and MDT Robust. Table 2 highlights how the three evaluation criteria[1] are used to derive the three devices categories.

THEORETICAL FRAMEWORK

The theoretical foundations of this study are based on the process theory approach (Mohr, 1982). Process theories are acclaimed for providing powerful explanations even when strong causal relationships cannot be demonstrated between possible change factors and outcomes. These attributes makes process theories useful to practitioners interested in implementing effective change and to researchers interested in developing comprehensive frameworks of determinants and consequences of innovation adoption.

A common practice in studies using process theory approach is to inductively develop models that identify a set of sequential stages through which organizations pass when implementing change. For example, Soh and Markus (1995) developed a model to explain how investments in information technology, a primary example of discontinuous change, create business value. Their model includes three stages: development, implementation, and ongoing operation. The outcomes of the first stage become the starting conditions for the second stage, and the outcomes of the second stage become the basis for the third stage. Performance in each successive stage is contingent, at least to a degree, on the actions taken in the preceding stage, as well as on the environmental conditions prevailing at the time. Markus and Tanis (2000) extended the Soh and Markus model by adding the fourth stage, dealing with predevelopment activities and by broadening the definition of performance to encompass multiple performance dimensions. We adapt Markus and Tanis's (2000) process theory framework for the purpose of this study and focus on the adoption phase. Markus and Tanis (2000) argue that a business decision to adopt an innovation is not an instantaneous act, rather, it is a process that occurs over time, which can be characterized by key players, typical activities, characteristic problems, appropriate performance metrics, and a range of possible outcomes.

The process model used in this study is a adaptation of the first of four stages (Project Chartering, The Project Configure & Rollout, Shakedown, and Onward and Upward) of Markus and Tanis's (2000) innovation process framework. The focus of this paper is on understanding how MDT adoption decision is initiated, evaluated, and approved in MSEs. Using the typical activities described by Markus and Tanis (2000) in the chartering phase which corresponds to adoption, we illustrate the MDT adoption process as consisting of three prime activities of initiation, evaluation and approval and develop the main investigative questions for this research (Table 3).

3. METHODOLOGY

This paper focuses on empirically exploring the typical activities and issues in the MDT adoption process including *adoption initiation*, *business case development*, *criteria for selection of product,* and *decision to proceed*. Results presented are based on interview data collected from key people responsible for making the MDT

Table 4. Characteristics of respondents (n=33)

	Micro Enterprise	Small Enterprise	*Total*
MDT Basic	6	5	11
MDT Handheld	8	6	14
MDT Robust	3	5	8
Total	17	16	

adoption decision in thirty-three MSEs. Most of the questions asked were open-ended, which helped in soliciting top of the mind concerns and avoiding choice bias. The sample frame used for this study was Canadian MSEs that have already made the decision to adopt an MDT device. The survey instrument was pre-tested with three organizations and did not result in any significant changes.

The respondents represent seven industries. A majority of our respondents (71%) were also the owners of the organization while the rest are at a management level, which is not unusual given the nature of micro organizations. Table 4 describes the characteristics of the survey respondents.

4. FINDINGS AND MANAGEMENT IMPLICATIONS

MDT Adoption Initiation

Adoption initiation is strongly influenced by the expected benefits of technology adoption in medium and large organizations (Kumar *et al.,* 1995). Different organizations may adopt an innovation for entirely different reasons. Recognition of a need or an opportunity may initiate the idea of MDT adoption. In our study respondents were asked about the main reasons which prompted adoption initiation.

Access anywhere/anytime, enhancing productivity, and ability to communicate/online flexibly appeared as the three prime reasons. Access anywhere/anytime was a key driver for more than 63% organizations. Productivity enhancement was an important motivational factor for more than 51% organizations, and more than 30% of the organizations cited ability to communicate and get online as their main reasons (Table 5). Interestingly, about 48% of the MSEs did not consider MDTs they adopted as a productivity increasing technology. Few respondents indicated that they were also motivated by the innovative nature and newness of the devise as a reason for adoption initiation. As one of the respondents commented, "Frankly I went looking for a laptop for productivity enhancement and ended up with a state-of-the-art Tablet PC for innovation. It was also recommended by my niece's husband"

Not surprisingly, 76% owner-managers initiated the idea of MDT adoption. The prime role of owner-manager in making adoption decisions in MSEs has been acknowledged by several studies (Harker & Van Akkeren, 2003; Kumar *et al*., 1995) and we found that the same sentiments were echoed in our study. In most cases, the adoption of an MDT was likely to affect them directly as they were also going to use the MDT and possessed the autonomy to subsequently implement the decision. In other cases the ideas were initiated by end users. Interestingly, the percentage of end user initiated adoptions was less than 25% which may also be a reflection on the centralization of the decision making authority in MSEs with the owner-manager.

There was a large lag between initiation and adoption of devices in many organizations. More than 50% organizations waited 24 months or more before adopting the MDT (Table 6). Some of the respondents attributed this to the reason that some of these devices are expensive to acquire, maintain and support when initially introduced and it made sense for them to wait until the devices were more affordable. The fact that most MSEs have fewer funds for these types of capital purchases than larger organizations may also explain the large time lag. Alternatively, in a few cases, when the owner-managers were interested in reasons like esteem value and innovation they adopted the device in the very first months of its introduction. These owner-managers also indicated a high level of technology awareness.

Table 5. Main reasons for initiating/adopting MDT (n=33)

	Frequency	Percent
Access anywhere/anytime	21	63.6%
Productivity	17	51.5%
Communication/Online	10	30.3%
Innovation and newness	2	6.1%

Table 6. How long ago was the idea initiated before purchased of MDT (n=33)

	Frequency	Percent
In the last 6 months	4	12.1%
More than 6 months and less than 12 months	6	18.2%
More than 12 months and less than 18 months	2	6.1%
More than 18 months and less than 24 months	15	45.5%
More than 24 months and less than 30 months	6	18.2%

MDT Evaluation

Once the idea of MDT adoption is initiated, the next steps in the adoption process are justification, identification of risks, mitigation of risk, evaluation and selection of product, communicating the idea to the organization, and having an initial plan. Markus and Tanis (2000) groups these activities under developing the business case for adoption. Building a business case is the hallmark process in technology adoption decisions of large firms. Business cases are extremely important as they lead to definition of strategic objectives and diagnosis of implementation difficulties. Interestingly, only two (6%) MSEs in our study indicated developing a formal business case for MDT adoption. In most cases (70%), the business case made was informal at best and about 24% of the organizations acknowledged not making a business case at all.

Respondents who prepared an informal business case used a variety of components considered as part of the business case development, which were not documented. More than 53% of the respondents were concerned with the changing technological environment and more than 56% estimated the additional costs associated with the purchase, while the majority of the respondents (76%) consulted the end-users about the adoption.

Some of the components which are common for large organizations were not used by the MSEs. For example, more than 61% of the respondents did not perform a test pilot while about 64% had created no plans to support, maintain, or train their MDT adoption. Almost half of the respondents (48%) had no formal plan to communicate about the MDT adoption to the organization and more than half of the respondents estimated no business re-engineering was required to adopt the MDT. Interestingly, about 35% acknowledged doing some re-engineering post adoption. Major re-engineering was only required in about 14% of the cases.

Most respondents also acknowledged informally evaluating the MDT device. Functionality (70%) and Price (55%) were the most frequently cited criterion for

Table 7. Criteria set to help evaluating the device

	Frequency	Percent
Functionality	20	69.7%
Price	18	54.5%
Portability	9	27.3%
Availability	7	21.2%
Ease of Use	4	12.1%
Quality and Service	4	12.1%
Compatibility with other Devices	2	6.1%

evaluating the mobile device (Table 7). Interestingly, few organizations considered compatibility (6%) with other devices and service quality (12%). This seems to support the view that MSEs are mostly concerned with what a device does and with how much it costs.

Most of the respondents had a high level of IT knowledge. Over 50% of the organizations evaluated the external technology environment and, given that most of the respondents had a high level of IT knowledge, they probably had the capabilities and did this well, even though informally. Although our respondents were not too concerned with test pilots, communications to the organization, maintenance, or roll-out plans, they did make sure that MDT end-users were involved and consulted.

MDT Approval

Project approval was a relatively easy and straightforward exercise, as in more than 44% of the cases one person was involved in the decision-making process. Two people were involved in the approval decision in 27% of the cases, and three or more people were involved in the decision approval in just 29% of the cases.

We asked the respondents about the time lapse between the approval and final purchase. Interestingly, in more than 50% of the cases the final purchase of the device happened within one month of the evaluation (Table 8). One of the owner-managers commented that he is an impulse buyer, and his buying impulse also applies to some of his business technology acquisitions. However, there were an equally large number of cases where the final purchase was delayed due to several reasons. For example, in one case the shipment of the laptops was delayed due to unavailability of the number of pieces required for the model approved. Ultimately, the supplier agreed to provide a higher version at same terms and conditions.

Interestingly, more than 75% of the respondents used the same methodology of approving MDT acquisition as any other types of technology purchases, while only 9% considered this MDT acquisition process more rigorously.

5. CONCLUSIONS

This research is at an exploratory level as not much empirically supported research is available on MDT adoption in MSEs. While it does not produce generalizable results, the reasonably representative sample selected provides valuable insight into the MDT adoption process and documents some critical MDT adoption issues in MSEs. This study bridges the gap in literature with regards to the understanding of MDT adoption in MSEs. The analysis indicated that the adoption process in MSEs is often informal and is significantly influenced in many cases by the owner-manager. The sample studied showed an average time lag of about 24 months or more between when the idea to adopt the device was originated and the adoption decision was made. Evaluation of the adoption decision also was conducted very informally and sometimes not at all. Interestingly, firms did not create a formal business case for adoption which is a regular practice in large organizations.

Business cases are tools that support planning and decision-making (Schmidt, 1999). A good business plan outlines tangible benefits, resources, cost, and risk (Wee, 2000). Respondents did a good job of discussing the MDTs with end-users; this is likely because the organizations were so small that it would be difficult not to discuss the purchase with end-users. Even though the users were contacted, it does not mean that a plan was in place or communicated to support, maintain, and upgrade the MDT post-adoption. The final step, approval, was marked by the lack of a significant time lag, most often taking a month or less. MSEs involved very few people, in most cases two or fewer, in the approval process, and they evaluated this technology acquisition as they would any other.

Table 8. What was the time period from approval to purchase (n=33)

	Frequency	Percent
Right Away	5	15.2 %
Within Two Weeks	8	24.2 %
Within One Month	5	15.2 %
Within Six Months	11	33.3 %
One Year and Greater	4	12.1 %

This study has uncovered a key finding that we feel is pertinent and relevant to the literature: the general absence of a formal business case to evaluate MDTs. This research showed that MSEs generally did not prepare formal business cases and most respondents prepared no businesses case at all.

This research provides a base for further research in focused areas of the adoption process in MSEs. More detailed research can be performed on the need analysis, systems scoping and selection of MDTs, and on the thoroughness of the decision process and its impact on the realization of business benefits. As a high percentage of MSEs are also managed by their owners, we think it would be interesting to explore the affect of ownership structure on MDT adoption in future studies.

ABSTRACT

Data warehouse implementations at the sector levels, especially at the national agricultural level are non-existent. Designing an agricultural data warehouse poses unique and significant challenges because traditionally the collection and dissemination of information have been extremely parochial. Moreover, there has been very little adoption of information technology. Recently the Government of India has embarked on an ambitious project of designing and deploying a data warehouse for the agricultural sector with the intent of using the system for macro level planning decisions. The paper presents some of the design challenges the project has faced and solutions undertaken. It is hoped that the paper will help other such large scale, sector level warehouse designs learn from our experiences.

Keywords: Data warehouse, agriculture, dimensional model, warehouse architecture

INTRODUCTION

Since the 1990s, data warehouses have been an essential information technology strategy component for many medium and large sized, global organizations. Data warehouses provide the basis for management reports, decision support, and sophisticated on-line analytical processing and data mining. A data warehouse is a repository of data that is aggregated and summarized from operational systems to provide decision making support and is subject-oriented, integrated, time-variant, and nonvolatile [7].

Historically, data warehouses have been implemented in banking and financial institutions, retail marketing of consumable and non-consumable goods/services, and telecommunication services. The architectural designs for these types of warehouses are similar with differences usually occurring due to warehouse size and system analysis complexity [9]. A major reason for the similarity in designs of data warehouses across these industries is the ability of each organization to collect data at the finest level of granularity. Another reason for data warehouse similarity is the stability of the organizations and their respective industry sectors.

Data warehouses are often developed to address the business process requirements of a single organization or division. While many unique architectural designs exist across a myriad of companies and industries, these designs all share a common single company or division scope characteristic, and for good reason. Despite the growth in data warehouse development, there is little evidence for warehouses addressing the needs of large holding companies (having multiple organizations) or entire industry sectors and government agencies. Industry sectors and specifically, government agencies have data sources and decision requirements that are significantly different from other firms [6].

The government sector is one area that data warehouse technology can benefit tremendously to support regional, national and global decision making. Of particular interest to this research within the government sector is agriculture. Roughly 70% of the India's population depends on agriculture for its livelihood. Policy decisions within this sector not only directly or indirectly affect its people but also its agri-business industries such as seeds, fertilizers, plant protection, etc. Given the diversity of sources, formats, and subject areas, collecting and integrating such heterogeneous information poses a challenging task for data warehousing. There are few examples of data warehouses at sectoral levels. The earliest development of a sectoral level data warehouse is perhaps by the National Agricultural Statistics Service of the US Department of Agriculture. Their warehouse brought together data from agricultural surveys and census data from ranchers, farmers, agri-businesses, and secondary sources [12]. Another example of a sectoral level data warehouse contains data on pest, pesticides, and meteorological data for the government of Pakistan [13].

While the need for sector level data warehouses for macro economic planning and decision-making has been great, these types of warehouses have been almost non-existent because of the difficulty in coordinating flow and integrating data from the many member organizations. Almost every government sector collects vast quantities of data, but only a fraction of those data are used for planning and decision making. Several factors contribute to this problem; member organizations are often independent, autonomous entities with their own data requirements – namely formats, naming conventions, measurement units, etc. Furthermore, little, if any interaction exists among the different members. Escalating the problems of data integration is that these organizations may collect data at different granular levels. Moreover, many governmental bodies rely on different government, semi-government, non-government and private organizations for data collection, and when the information is collected from one organization's perspective and not from a sector or national perspective, data and systems may exhibit a parochial and protectionist perspective. Therefore, data integration for sector level use becomes a formidable challenge [6].

In this paper we investigate and present the challenges in designing and deploying a data warehouse for the Indian agricultural sector. The observations and classifications made in this research are important at two levels, (1) other sector level organizations may use the information presented to avoid pitfalls when designing data warehouses, and (2) researchers interested in large scale, multi-organizational data warehouses may use the information and actual working data warehouse to direct their research.

AGRICULTURAL SECTOR IN INDIA

Indian agriculture is highly diversified in its climate, soil, horticultural crops, plantation crops, livestock resources, fishery resources, water resources and so on. The diversity of its agricultural sector is a bane and boon to the social, economic, and cultural bases of India's vast population. Moreover, the diversity among resources generates interactions among many different macro and micro factors, and is further complicated with the interdependencies that exist among these. The Indian Council of Agricultural Research, New Delhi under World Bank funded National Agricultural Technology Project has developed a data warehouse for some of these agricultural resources to (1) improve the Indian Council of Agricultural Research's organizational and management system efficiency, (2) enhance scientific research performance and effectiveness to benefit farmers, and (3) encourage farming community participation through innovation and improved technology management. Objectives one and two are being implemented by the Indian Council of Agricultural Research, and objective three is being implemented by the Ministry of Agriculture in 28 districts of seven states. The implementation of the third objective, innovation of information technology, is the impetus for this research, and the Indian Agricultural Statistics Research Institute, New Delhi has been charged with building the data warehouse.

Sources of Information

India is divided into 28 states and six union territories (UT). Each state/UT is further divided into districts (elementary administrative unit) [5]. The district is the basic unit of administration for all purposes. The collection of Indian agricultural information is conducted through multiple organizations throughout the country. There are many national and state level boards and organizations for each agricultural sector. These information collecting agencies operate in the interest of their client organization, often specific to a region or state. Because there are many different data collection agencies and equally diverse resources for which the information is collected, there exists information heterogeneity. This problem is compounded by a lack of common standards applied to data collection. To use the information at the macro planning and decision making level, data must be integrated and aggregated properly [4].

Critical Dimensions

National level planning and decision support processes require access to data on many different resources, such as crops, livestock and fisheries, at varying levels of detail [2]. Information on production (demand and supply), price levels, and population and migration statistics is also expected. Location, Time, and Product are a few of the common dimensions that transcend all warehouse models, but Location and Time pose the biggest problems in integrating data from the varied sources in the agricultural sector. The integration problem may be categorized into one of four common dimensional issues, (1) granularity of Location differs among the different sources, (2) granularity of Time varies among the different sources, (3) several overlapping time domains and (4) aggregation and disaggregation of information at different dimensional hierarchies. These dimensional issues lead to the design the fact table and, therefore, the architecture of the data warehouse.

Location granularity: Similar to sectors such as retail and telecommunications, the agricultural sector uses the Location dimension extensively for its warehouse applications. In the Indian agricultural sector, the Location dimension presents many interesting issues. Location, also known as the Geography dimension, usually has a clearly defined hierarchical structure. In our case this hierarchy is determined by administrative mechanisms and put into effect by the Indian government. Level one is the National level. Level two is State. India is divided into 28 states, often on a linguistic basis. Each State is further divided into Districts (Level three) which may be further divided into Villages (Level four). This level is the lowest that agricultural sector information is collected through agricultural surveys.

Organizations may collect information at any or all levels of the Location hierarchy. Different sample surveys are conducted to acquire production figures of commodities such as fruit crops, plantation crops, etc. at the State level. Statistics of national accounts and different sectors of economy are mostly available at this level. Because each state is somewhat autonomous, the information collected at Level two is very important for state level planning and decision making. Production information is available at the District level for crops, livestock products, fisheries products, land use statistics, etc. Due to its detailed measure of factors, information at this level is very important to planners and decision makers at all levels. The Village level has data such as land use, census data, livestock, and demographic and static parameters such as land ownership and employment. Another Level four attribute is agricultural commodity trades available in Agricultural markets or Mundi (trading place). Price data from many important markets are collected on daily or weekly basis depending on the season of the crop or commodity. Finally, different agro-meteorological stations produce information on climate and weather conditions on a daily basis and form another fourth level hierarchy attribute.

Another challenge presented with the Indian agricultural data warehouse is historical data. Information on production of some commodities is available at the district level, but historical data are only available at the State level. Availability of resources, requisite need for information, and governmental policies present at that time affect the collection at any given level. These resources include human and financial capital and time. The following issues are associated with creation of dimensions in the development of data warehouse:

- The number of levels needed for any location.
- The integration of information coming from different sources (organizations) at different grain levels.
- The definition of fact table for these dimensions.

Aggregation rules to roll up each of the fourth level hierarchy of the Location dimension to the next higher level are different. In the case of villages, it may be a simple aggregation, but in agricultural market where the condition is price, a simple aggregation does not work. Availability of agricultural markets in different states for a commodity depends on its area, production, and consumption.

Integrating information from different sources, especially from various organizational sources, is also a big challenge in the design of the warehouse. Data collection takes place at different levels (e.g. National, State, District) using different methods (e.g. surveys, census, observations) and by different organizations, each with its own formats, procedures, and objectives. Further, definitions, concepts, and purpose are likely to be different for different parameters. Moreover, each source and method contributes to different types of errors. Despite these issues, if information is available at the lower level it is possible to aggregate (roll up) to the higher level. However, when information is only available at a higher level it is very difficult to disaggregate (drill down) to lower level [3, 11]. Most information about agriculture is collected through agricultural surveys or census, which are designed to elicit responses at the National or State level. Regional or lower level estimates can not be obtained from these with reliable precision.

PROTOTYPE

Warehouse Architecture

We propose the use of multiple dimensions to resolve the problems described above. A similar solution is also recommended in click stream data warehouses for enterprise relationship management (eRM) applications [10]. In a click stream data warehouse, the focus is on capturing the mouse clicks, sites and products visited, as well as the time and decisions taken by the consumer. We differ from the click stream warehouse implementation in that we use different fact tables for each type of dimension associated with the Location dimension and its hierarchy. We use the livestock data mart to illustrate our solution.

The data warehouse design employs the Star schema concept in which the central fact table is connected to the dimensions in a star like fashion. The foreign key links from the fact table to the primary keys of the dimension tables yield the star configuration. Each star schema configuration yields a data warehouse cube. Because the software supported only star schema the resulting cubes appear disconnected. Otherwise, they are connected through the respective common dimensions. Integrated livestock surveys are conducted every year for collecting data about the production of livestock products. The Census or complete enumeration for livestock is conducted after every five years. Some of the information in this data mart has been collected only once. Among the data collected, the period over which the data falls differs. Time at which data are collected differ because of the different calendars used. Three calendars, namely Calendar year (January 1 to December 31), agricultural year (July 1 to June 30) or financial year (April 1 to March 31) are employed. Since each time measure is important, it raises the possibility of three independent time hierarchies.

In data warehouse design, fact table grain has to be decided first [8]. In most warehouse designs, the decision is dependent on the level of detail the fact should address, namely, the business process performance measure. Because we do not have all available measures at the lowest level of detail, several fact tables have to be designed. For example, if measures corresponding to the Location dimension are available only at the State level then the grain of the fact table will be fixed at that level. So the granularity of the dimensions will result in many fact tables.

Granularity of Time

Generally, for time dimension in the agricultural sector the lowest grain level is day but many measures are available only at the weekly, monthly, quarterly, and half yearly, or yearly level. Climatic data such as rainfall, humidity, and temperature are available daily. Prices for different commodities and products from different agricultural markets of the country may be available at daily, weekly or monthly for a calendar year. Production measures of food crops, horticultural crops, and plantation crops are always available annually based on the agricultural year. Some of these crops are perennial and others are produced in one, two or three seasons in different parts of the country depending on the climatic, soil and water conditions. Information from human census is available after every ten years while for livestock it is available after every five years. All other socio-economic data are available annually based on the financial year. Keeping in view the above diversified grain level of the time dimension it is a challenging task to develop a data warehouse in

which all these sectors of agriculture are integrated on a common homogeneous platform. The complexity is further raised when availability of information for time levels follows different definitions. In India information about agriculture is available following three definitions of a year as follows:

Calendar Year
Years start from January 1 and ends on December 31. The months are in accord with the Julian calendar months. The first week starts from January 1 irrespective of name of the day and weeks are generated by counting seven days in a week. Last week, 52nd week of the year, consists of eight days to make 365 days in a year. For leap year last week of February consist of eight days.

Agricultural Year
Year starts from July 1 and ends at June 30. The first month of the year is July and the last month of the year is June. Months are assembled similar to the calendar year. The first week of the year will start from July 1 and it will be generated as per the procedure of calendar year. Similarly, first quarter and half year will start from July and generated as per the rule of calendar year.

Financial Year
Year starts from April 1 and ends March 31. The first month of the year is April and last month is March. Months are as per calendar year. The first week of the year will start from April 1 and it will be generated as per the rule of calendar year. Similarly, the first quarter and half year of the year will start from April and generated as per the rule of calendar year.

Because the three types of years have different start and end times, our data warehouse needs three independent hierarchies in the time dimension. The overlapping time periods poses significant difficulties in integrating data from the sources. The following table shows the month number of each year i.e. calendar, agricultural and financial year with respect to the months of calendar year.

Table 1. Time dimension properties

S.No.	Name	Calendar Year Number	Agricultural Year Number	Financial Year Number
1	January	1	7	10
2	February	2	8	11
3	March	3	9	12
4	April	4	10	1
5	May	5	11	2
6	June	6	12	3
7	July	7	1	4
8	August	8	2	5
9	September	9	3	6
10	October	10	4	7
11	November	11	5	8
12	December	12	6	9

Table 2. Time dimension quarterly

S.No.	Starting Month	Ending Month	Calendar year quarter No.	Agricultural Year Quarter No.	Financial year quarter No.
1	January	March	Q1	Q3	Q4
2.	April	June	Q2	Q4	Q1
3.	July	September	Q3	Q1	Q2
4.	October	December	Q4	Q2	Q3

Table 1 shows that integration of the information available at the grain level of months for different year types will not have any problem irrespective of their definitions. Let us consider Table 2 for quarters for each type of year, namely calendar, agricultural and financial year with respect to calendar year:

The integration of the information from different sources at grain level of quarters may not have problems in case of India as the definitions of different year such as calendar, agricultural and financial years are offset from each other by multiples of three months. If the offset is different, as it may be in other countries, it may not be feasible to integrate the information available at the grain levels of quarters for the different year types.

In case the information is available at grain level of half year with respect to any year type, it is possible to integrate the information of the half years of calendar year with half year of the agricultural year because as per the definition, the offset between calendar year and agricultural year is six month. Therefore, the first half year of the calendar year corresponds to the second half of the agricultural year. Any information available at the grain level of half year with respect to financial year may not be integrated with the information of the half year of other two year types.

The information available at the weekly grain level of any type of year may not be integrated between weekly information with any other week of year type. The beginning or the ending of weeks of one-year type does not correspond to the beginning or ending of the weeks of any other year type.

The Current Status of the Project
The data warehouse project was developed with funding from the World Bank and under the National Agricultural Technology Project (NATP) initiative. Several goals and users had been defined for the project. Three types of users were identified for the system. They were (i) research managers, (ii) research scientists, and (iii) general users at IASRI and other research institutes and agencies. At one level, the system was to provide systematic and periodic information about the entire agricultural sector to research scientists, planners, decision makers, and development agencies. At a different level, different users would have the capabilities to use various decision support capabilities through an on-line analytical processing (OLAP) application.

The data warehouse project has been carried out with active collaboration of 13 institutions that operate under Indian Council of Agricultural Research (ICAR), New Delhi. Each of these institutions deals with one or more areas of agriculture. Fifty-nine different databases have been used as source feeds for the data warehouse. The data in these databases are gathered from council and research projects on various agricultural technologies in operation and from published official sources (related agricultural statistics). At a minimum, data from year 1990 onwards, at the district level, are integrated into this system. Many of these databases have statistical information dating to year 1950. In building the central data warehouse, we started by creating subject-oriented data marts and multi-dimensional data cubes. These are published and now available by way of Intranet and Internet access. The validation checks have been put into effect wherever possible.

The data warehouse system also provides spatial analysis of the data with the help of a Geographic Information System (GIS). Data mining and ad-hoc querying are also extended to a small set of users. The web site of the project is already launched (www.inaris.gen.in) and the multidimensional cubes, dynamic reports, GIS maps and information systems are already available to the users.

CONCLUSION

Data warehouses at sector levels are seldom seen. Governments at national and state levels and industry groups and regulatory organizations have begun to realize the potential of integrating data from many sources and using data warehouses to implement such solutions. We have presented here some of the problems that arise in integrating data collected in the Indian agricultural sector. We discuss specific problems associated with granularity of location and time, two key dimensions for an agricultural warehouse. We then present one solution in our prototype using Oracle software.

Towards a Framework of Biometric Exam Authentication in E-Learning Environments

Michelle M. Ramim, Nova Southeastern University, USA, 3301 College Avenue, Fort Lauderdale, FL 33314, USA; E-mail: ramim@nova.edu
Yair Levy, Nova Southeastern University, USA, 3301 College Avenue, Fort Lauderdale, FL 33314, USA; E-mail: levyy@nova.edu

ABSTRACT

In the past fifteen years the use of Internet technologies has been substantially growing for delivery of educational content. E-learning environments have been incorporated in many universities for the delivery of e-learning courses. However, opponents of e-learning claim that a central disadvantage of such teaching medium is the growing unethical conduct in such environments. In particular, opponents of e-learning argue that the inability to authenticate exam takers is a major challenge of e-learning environments. As a result, some institutions proposed to take extreme measures including asking students to take exams in proctor centers or even abandon completely the offering of e-learning courses in their institutions. This paper attempts to address this important problem by proposing a theoretical framework that incorporates available fingerprint biometric authentication technologies in conjunction with e-learning environments to curb unethical conduct during e-learning exam taking. The proposed framework suggests practical solution that can incorporate a random fingerprint biometric user authentication during exam taking in e-learning courses. Doing so is hypothesized to curb exam cheating in e-learning environments. Discussions on future research and possible implications of the proposed theoretical framework for practice are provided.

Keywords: E-learning Environments, Biometric Systems, Unethical Conduct, Academic Misconduct, Online Exam Security, Secured Exam Submission.

1. INTRODUCTION

This paper proposed a theoretical framework for fingerprint biometrics authentication of exam takers in e-learning environments. The following section provides literature review on the increase use of e-learning environments in higher educational institutions. Additionally, the subsequent section provides a review of literature on issues related to unethical conduct in educational settings and in e-learning environments. The subsequent section provides a review of literature related to security issues in e-learning environments, biometric solutions and fingerprints biometric solutions. Subsequent section suggests the theoretical framework combining existing technologies into electronic exams (e-exams). The final section addresses the conclusions with expected contribution of the proposed framework, review of some observed limitations of the proposed theoretical framework, and proposed future research.

2. THEORETICAL BACKGROUND

2.1 E-Learning and E-Learning Environments

Teaching via the Internet has become a popular choice for academic institutions as well as business organizations (Hiltz & Turoff, 2005). Advances in information systems have enabled educational institutions to implement electronic learning (e-learning) systems as a teaching environment (Alavi & Leidner, 2001). Furthermore, e-learning has become a powerful medium for academic institutions and corporate training due to the incorporation of cutting edge technologies. Hiltz and Turoff (2005) have commented that e-learning is "the latest of social technologies that ... has improved distance learning" (p. 59).

The spectacular growth in e-learning in the past decade has been documented in numerous studies. The U.S. National Center for Education Statistics (NCES) reported that "56 percent of all 2-year and 4-year degree-granting institutions offered distance education courses…during 2000–2001 academic year" (US NCES, 2005, p. 3). The dramatic growth in distance and e-learning is evident in the number of institutions that offer e-learning. US NCES reported that "undergraduate level online courses were offered at 48 percent of all institutions while graduate level online courses were at 22 percent of all institutions" (p. 3). Among these institutions, e-learning courses and video technology were the most common kinds of instruction delivery systems. NCES reported that 90% of institutions employed e-learning courses using asynchronous communication systems. While, only 43% of institutions employed synchronous communication systems for the delivery of e-learning courses (US NCES, 2005).

Gunasekaran, McNeil, and Shaul (2002) described the growth in e-learning as the "new dynamic learning models…and is leading the [academic] market to a significant paradigm and cultural change" (p. 45). Courses and entire degree programs are delivered via the Web anywhere at anytime. In addition, e-learning courses are offered by private, public as well as corporate universities. As a result, new resources such as e-books, books on CD-ROMs and e-exams have been adapted to e-learning courses. Students' enrollment in e-learning courses has proliferated reaching more than three million students in the U.S. in 2005 (US NCES, 2005). About 82% of those online students were enrolled in undergraduate level courses during the year 2000-2001 (US NCES, 2005). As a result numerous academic institutions are planning to increase the number of e-learning courses to meet the growth in this demand. However, security issues related to e-learning systems have been raised by several scholars (Ramim & Levy, 2006). Moreover, opponents of e-learning argue that the inability to authenticate exams takers is one of the major challenges of e-learning medium. Although there is a major growth in e-learning programs, some institutions proposed to take extreme measures including asking e-learning students to take exams in proctor centers (Gunasekaran et al., 2002). However, this requirement may not be feasible for e-learning programs with students in remote locations or under various circumstances such as students who are in military service in remote or combat areas, students with severe disabilities, and working professionals. In order to protect the integrity of exams in e-learning environments, solutions for such a significant problem are warranted.

2.2 Unethical Conduct in E-Learning

Given the development of technologies and the demonstrated growth of e-learning usage in academia, students' unethical conduct in e-learning has become a major concern (Kennedy Nowak, Raghuraman, Thomas, & Dacis, 2000). Pillsbury (2004) argues that students' unethical conduct has intensified as a result of the use of technology and the Internet. Most administrators and instructors focus on one type of unethical conduct, namely plagiarism (Naude & Hörne, 2006). However, students' unethical conduct encompasses a wide array of behaviors including technology enabled behaviors such as cheating during an exam by using technology devices (i.e. PDA, calculator, and cellular phone), engaging in online collaboration when it's forbidden (i.e. groupware like Instant Messenger services, chats, forums, and newsgroups), and deceiving (i.e. logging with another student's username/password). These unethical technology enabled conducts are often undetected by instructors in e-learning courses. Moreover, numerous researchers admit that most e-learning programs adopt policies and practices from traditional learning programs and ignore the technology related issues (Kennedy et al., 2000;

McCabe, 2003; Gunasekaran et al., 2002). Pillsbury (2004) noted a number of Web enabled detection mechanisms such as turnitin.com™ that are available to curb plagiarism. Though, extensive body of knowledge is available on plagiarism detections (Decoo, 2002; Hamilton, 2003; Hannabuss, 2001; McLafferty & Foust, 2004), very little attention has been given to providing solutions to other students' unethical conduct such as cheating on exams in e-learning courses. Pillsbury (2004) noted that detection mechanisms for unethical conduct are necessary not only in the initial portal access. Moreover, additional mechanisms are necessary to authenticate users' access in various e-learning course activities (Newton, 2003). For example, instructors attempt to verify that e-exam submission is truly performed by a given student rather than another one.

According to the Center for Academic Integrity (2005), cheating on exams has been reported at an alarming range of 74%. McCabe and Trevino (1996) reported that 70% of students in their study confessed to cheating on multiple exams. A study by Pincus and Schmelkin (2003) compared faculty members' perceptions on various students' unethical conducts seriousness. They concluded that students' unethical conduct related to exam taking perceived by faculty to be one of the most serious unethical behaviors (Pincus & Schmelkin, 2003). Similarly, Dick et al. (2002) also noted that 24% their study participants believed that "advances on technology have lead … to increase cheating" (p. 173). The perceived seriousness of cheating on exams has led numerous academic institutions to reduce their e-learning course offering and in other instances, cease e-learning altogether. In fact, Gunasekaran et al. (2002) admitted that the inadequate technology has led some academic institutions to cease offering e-learning courses due to concerns over the quality of students' assessment and standards. Thus, the central aim of this paper is to propose a conceptual level security solution for this out-braking phenomenon by suggesting a theoretical framework of biometrics authentication to secure e-exams.

2.3 Security in E-Learning

Given the importance of e-learning environments for academic institutions, security related challenges of such environments are capturing the attention of program administrators. Ramim and Levy (2006) discussed a case study of an academic institution that faced a tragic cyber attach to their e-learning environment by an insider intruder. Other scholars have documented related security problems in academic institutions. Yu and Tsao (2003) discussed security challenges of e-learning environments. However, their exploration focused on shielding the technology infrastructure against unauthorized users. Current security practices in e-learning systems relay principally on the utilization of passwords authentication mechanisms. Similarly, Huang, Yen, Lin, and Huang (2004) discussed aspects of security in e-learning systems and suggested attention to two layers when securing e-learning systems. The first layer addresses security of the technology infrastructure used to facilitate e-learning (i.e. hardware, networks, etc.) and the second layer addresses the various applications employed in enabling e-learning (i.e. learning management systems, rich media communication tools, etc.). Huang et al. (2004) criticized existing proprietary e-learning systems for not paying enough attention to the issue of properly authenticating students, in particular during quizzes and exams. Hugl (2005) noted numerous security related technologies that are not currently employed in e-learning. One such solution can include biometric technologies that may potentially become an integral part of e-learning systems.

2.4 Biometric Solutions

According to Tabitha, Pirim, Boswell, Reithel, and Barkhi (2006) *biometric* is defined as "the application of computational methods to biological features, especially with regard to the study of unique biological characteristics of humans" (p. 3). Such unique biological characteristics relies on individual humane identities such as DNA, voice, retinal and iris, fingerprints, facial images, hand prints, or other unique biological characteristics. Tabitha et al. (2006) note that *biometric* is "a method of identification that has been growing in popularity" (p. 2). Moreover, Pons (2006) notes that *biometric devices* are technological devices that utilize an individual's unique physical or behavioral characteristic to identify and authenticate the individual precisely. Essentially, biometric technologies operate by scanning a biological characteristic and matching it with the stored data. Jain, Hong, and Pankanti (2000) note that a biometric system is "essentially a pattern recognition system that makes a personal identification by establishing the authenticity of a specific physiological or behavioral characteristic possessed by the user" (p. 92).

Coventry, De Angeli, and Johnson (2003) discussed the usability aspect of authentication systems and noted that it is a "tradeoff between usability, memorability and security." (p. 153). Additionally, they note that in order to increase security, traditional PINs and password authentication methods are regularly "increasing their length, ensuring they do not form words and ensuring all are different, makes them more difficult to remember and error-prone" (Coventry et al., 2003, p. 153). Similarly to other scholars such as Jain et al. (2000), Pons (2006) and Tabitha et al. (2006), Coventry et al. (2003) maintained that most biometric systems include a digital identifier, a template and a recognition algorithm and they follow similar matching processes. However, they maintained that biometric systems can be separated into physiological biometric (i.e. finger, iris) as well as behavioral biometric (i.e. voice, key board typing behavior). Biometric systems performance can be assessed by employing statistical methods in which accuracy is calculated. Although biometric systems are relatively reliable, Coventry et al. (2003) asserted that system malfunction stems from users' lack of establishing the biometric during the initial stage as well as potential interruptions during transmission of the biometric image in the validation process. Subsequently, they concluded that although the trade off between security and usability aspects remains, biometric systems can facilitate automatic verification for public environments.

Pons (2006) maintained that fingerprints biometric scans are the most commonly used biometric solution as they are less expansive compared with other biometric solutions. According to Jain et al. (2000), a fingerprint is a unique "pattern of ridges and furrows on the surface of a fingertip, the formation of which is determined during the fetal period" (p. 95). Fingerprints are unique for each individual, where even identical twins have different fingerprints (Jain et al., 2000). Several scholars documented the increase popularity of fingerprint biometric-based systems and their decline in costs (Jain et al., 2006; James et al., 2006; Pons, 2006). For example, fingerprints systems are currently used in the Disney® parks and appear to be useful for its high volume traffic and low price authentication. Full hand fingerprint is also used by the U.S. immigration services. Similarly, fingerprints can be used for authenticating students' submissions of exams via the use of biometric devices. Furthermore, Williams (2002) pointed out that fingerprints have been universally acceptable in the legal system worldwide. Fingerprints are a permanent attribute unique to an individual. Fingerprints can be scanned, transmitted and matched with the aid of a simple device. McGinity (2005) pointed out that biometric have been commonly employed in replacing conventional password systems. She cited examples of ISPs that provide fingerprints based biometric for a small monthly fee (i.e. AOL charges $2 per month). Biometric devices enable portable scanning and rapid identification. Thus, finger biometric can be a suitable solution for rapid authentication of users. Using a portable device, users can scan their fingerprints and send a print image via the Internet to the University's network. The network will consist of an authentication server that will house a database of students' fingerprints images. The server will than process the matching of the transmitted print image with a stored copy of the fingerprint (called "template"). Following that, the server will generate a matching result. Thus, McGinity predicted that fingerprints based biometric would become a household activity in the near future.

Yang and Verbauwhede (2003) proposed a secured technique for matching fingerprints in a biometric system. Similarly to McGinity (2005), they argued that biometric systems enhance security far more than the current systems. Biometric systems are more accurate as well as simpler to operate compared with passwords systems. Yang and Verbauwhede (2003) described a fingerprint based biometric system in which the fingerprint template is kept in a server during initiation. Upon scanning the finger, an input device scans a biometric signal and transmits it to a server where it is processed for matching. In an effort to shield the system against security compromises, they recommended processing the matching of fingerprints images in an embedded device rather than the server and only transmitting the results to the servers. Furthermore, they suggested encrypting the fingerprint template prior to storing it on the server. Fingerprints templates can be decrypted whenever a matching process occurs. Yang and Verbauwhede (2003) provided additional solutions useful for building up multiple layers of security in fingerprint based biometric systems.

2.4.1 Fingerprint Biometric Solutions

In the past decade the price of biometric authentication devices has been falling (Pons, 2006). Currently there are low cost solutions for biometrics authentication via fingerprint recognition. For example, Figure 1 provides an image of a biometrics mouse by JayPeetek Inc. called Scan.U.Match™. This devise is part of a package of fingerprint authentication mechanism. The mouse is about the same

Figure 1. JayPeetek Inc.'s Scan.U.Match™ Fingerprint Biometric Authentication Mouse[1]

Figure 2. JayPeetek Inc.'s Biometric Authentication Server, the Authenteon™ Server[2]

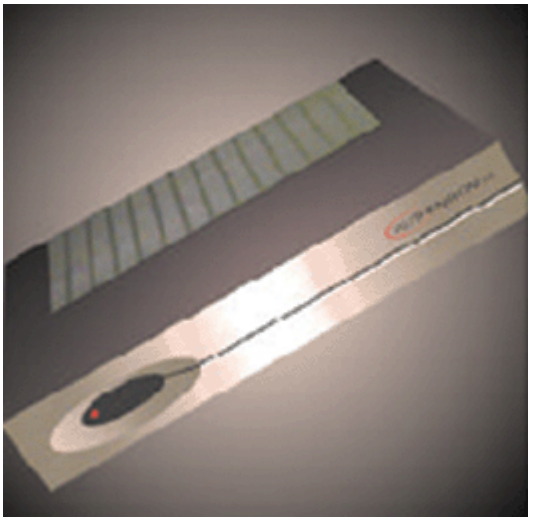

Figure 3. SecuGen®'s Keyboard III™ with fingerprint pad scanners[3]

Figure 4. onClick®'s PCMCIA FingerPrint™ Reader[4]

Figure 5. Sony®'s Puppy® Fingerprint Identity Token by Corp[5]

size as standard mouse, however, it also has an integrated fingerprint scanner that is managed by client side software and controlled by server side software centralized on an authentication server. Figure 2 provides an image of Authenteon™, a biometrics authentication server. JayPeetek Inc. claims that their patented Scan.U.Match™ biometrics mouse solution is unique as it "does not capture the finger image and scrambles the algorithm at the point of scan", rather it "creates a 500 byte secure template that cannot be replicated into a user fingerprint" (JayPeetek Inc.). As such, the Scan.U.Match™ is claimed to be highly reliable with "false rejection rate" that is only 0.01%, or 1 out of 100,000 cases.

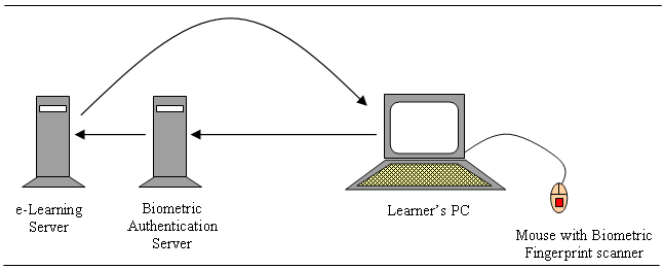
There are numerous other vendors that offer similar solutions in attractive prices. Examples of some of the other vendors include SecuGen® Biometrics Solutions (2005) with their OptiMouse III™, onClick® Corp. (2005) with their VIA™ solution, to name a few.

Aside from the biometrics fingerprint mouse solutions, there are other biometrics fingerprint solutions including keyboard with fingerprint pad scanner (See Figure 3), PCMCIA fingerprint scanner (See Figure 4), and USB fingerprint token scanners (See Figure 5).

3. PROPOSED METHODOLOGY AND DATA COLLECTION

The proposed theoretical framework that this work focuses on is to incorporate biometric fingerprint solutions for user authentication during e-exams. Figure 6 demonstrate the proposed conceptual solution. In standard e-exam, the learner's access is authenticated once by the e-learning server at login for the entire duration of the activity session, while the repeated authentication performed is based on the password cashed in the browser. As such, students are able to login to the e-learning server and have someone else take the e-exam on their behalf. The proposed solution will enhance the current authentication process by adding the fingerprint biometrics solution. For example, in WebCT, during e-exam a random fingerprint authentication can occur to validate the e-exam taker. Although not a foolproof approach, requiring the fingerprint authentication of the learner randomly during

Figure 6. Proposed fingerprint biometric solution for e-exam user's authentication



e-exam with required very short fingerprint scanning response time should provide additional added security. It may discourage learners from having someone else take the e-exam for them. Therefore, the central claim of this proposed approach is that the incorporation of fingerprint biometrics solution in conjunction with e-learning environments will enable a reduction in exam cheating.

5. CONCLUSION AND RECOMMENDATIONS FOR FUTURE RESEARCH

Unethical conduct, in particular cheating in e-exams was documented in literature as a growing concern by many higher educational institutions. The proposed theoretical framework suggested above is unique as it proposed a biometric solution for exam taking in e-learning environments. This theoretical framework may add to the general knowledge of e-learning environments by addressing a major issue of e-exam cheating. Future work in this line of research should incorporate this theoretical approach and conduct a study on the incorporation of biometric solutions in e-exams. One example of a study may include comparison of the same instructor teaching two e-learning sections of the same course, where one section will use regular e-exams and the other section will use the fingerprint biometric approach proposed. The study can propose that:

Proposition 1: Students taking e-exams using the fingerprints biometric solution will have lower grades on the e-exam than their counterparts.

Proposition 2: Students taking e-exams using the fingerprints biometric solution will take longer time to complete their e-exam than their counterparts.

Results of such study can provide initial investigation in an attempt to address the outgrowing phenomena of unethical conduct in e-learning exam taking. If results of this propose study will show that the group of learners who took the exams using the fingerprints biometric solution will have lower grades and take longer time to complete their exam, thus, have a lower cheating rate. Having such results will allow suggesting the proposed framework for higher educational institutions to incorporate it in order to reduce cheating in online exam taking.

Future investigation should be performed by implementing the proposed framework and conducting the experiment proposed above. Additional research can be conducted on the incorporation of biometric solutions to address other academic misconduct behaviors in e-learning environments. However, researchers must be aware of the limitations associated with the theoretical framework proposed here. The first observed limitation deals with the fact that in a remote setting, students may ask to have a subject matter expert seat next to them while they take the exam. The current proposed framework is overlooking this possibility and additional work to address such unethical behavior is warranted. The second observed limitation of the proposed framework is the funding the costs associated with implementing such study in an experimental basis, let alone in a large scale e-learning program. Additional work is needed in exploring the costs and funding sources needed to provide the technological and implementation aspect of this framework. A third observed limitation is related to individual perceptions on the use of biometric systems. For example, Alterman (2003) note several perceived ethical issue with biometric systems, while Tabitha et al. (2006) document a study on the acceptance of such system by individuals. Future research is warranted to further explore issues related to the ethical and acceptance of biometric systems in the context of e-learning.

Examining Instructional Interaction and Student Persistence in Online Education

Steven F. Tello, University of Massachusetts Lowell, One University Ave., Lowell, MA 01854, USA; E-mail: Steven_Tello@uml.edu

ABSTRACT

Student dropout from online courses is often identified as a major problem in higher education. This study examines how online classroom communication factors impact a student's decision to persist in or dropout of an online course. A survey research methodology was used to examine the relationship between instructional interaction and student persistence among adult students in online courses. The results indicate that student perceptions regarding the contribution of asynchronous discussion forum use combined with frequent use of asynchronous discussion account for 26% of the variance in course persistence rates.

INTRODUCTION

As institutions of higher education launch or expand online course offerings, it is important to identify strategies and techniques that promote student participation in online courses and programs. One obstacle to student success in online courses is student dropout, a failure of students to complete a course and/or program of study. Research suggests that online courses have significantly higher dropout rates than face-to-face courses (Levy, 2005; Simpson, 2004). While numerous factors contribute to a student's decision to withdraw from an online course (McGivney, 2004; Simpson, 2003; Willging & Johnson, 2004) researchers have identified student satisfaction as one correlate of dropout in online education (Jun, 2005; Levy, 2005). More recently, researchers have identified a clear relationship between faculty interaction and student perceptions of learning and student satisfaction in online courses (Jiang & Ting, 2000; Roblyer & Wiencke, 2004; Swan, et. al., 2000; Shea, et. al., 2001). This research study examined the relationship between instructional interaction, student satisfaction and student persistence in online courses.

Interaction in Online Education

Instructional interaction between student and teacher is a critical aspect of this study. Moore (1989) identifies three types of interaction in distance education: learner-content, learner-instructor and learner-learner. Kearsley (2000) suggests a distinction must be made between immediate (synchronous) interaction and delayed (asynchronous) interaction. This distinction regarding the method of interaction is important since it affects the provision of feedback to the learner, a concept that many have identified as critical to the learning process (Freedman et. al., 2003; Smith and Dillon, 1999). For the purposes of this study, instructional interaction is defined as directed communication regarding course content and topics between the instructor and students or among students in the online course (Kearsley; Wagner, 1994).

A defining characteristic of online education is computer-mediated communication (CMC). CMC provides students and teacher with two-way communication methods based on the electronic transmission of text, images and more recently, audio and video data. CMC uses email, chat, discussion forums and other computer conferencing systems to facilitate communication between students and teachers and among students (Kearsley, 2000; Turoff & Hiltz, 1995). Communication methods that support synchronous interaction (e.g. text-chat, audio-chat, desktop video conferencing) can provide immediate feedback to learners, a feature that may serve to motivate some learners. Technologies that support asynchronous interaction (e.g., email, discussion forums) can provide the learner with more control over where and when the instructional interaction occurs as well as provide the learner with more time to reflect on and respond to course content and communications (Collison, et. al., 2000; Kearsley, 2000; Salmon, 2000).

Relationship Between Interaction and Persistence

The importance of interaction between students and teacher in supporting positive learner outcomes among face-to-face undergraduate students is well documented. Numerous studies have found that the frequency and content of formal and informal interaction between instructors and undergraduate students in face-to-face courses are correlated to gains in student achievement (Kuh & Hu, 2001; Pascarella & Terenzini, 1991), student persistence (Pascarella & Terenzini) and degree completion (Tinto, 1987). More recently, a number of researchers examining online college students have found a positive relationship between instructor interaction and perceived student learning (Arbaugh, 2005; Shea et. al., 2001), student satisfaction (Arbaugh; Shea et. al.) and student ratings of online course effectiveness (Hay et. al., 2004).

Student persistence addresses a student's commitment to complete a course and program of study. Persistence is considered a positive outcome measure as compared to dropout, which is the negative equivalent outcome (Ormond, 2003). Much of the literature on persistence and dropout draws it theoretical framework from the research conducted by Vincent Tinto. Tinto's model of college student dropout suggests that persistence is an outcome of the student's academic and social integration into that institution's community (Tinto, 1987). While Tinto's research was conducted primarily on undergraduate students in residential four-year colleges and universities, later researchers applied a similar theoretical framework to different student groups including undergraduate commuter students (Pascarella & Chapman, 1983), undergraduate students enrolled in correspondence courses (Sweet, 1986), distance learners enrolled in video-based college courses (Towles, et. al., 1993) and online college students (Willging & Johnson, 2004). These studies suggest that Tinto's model of college student dropout provides a framework for understanding the relationship between student-faculty interaction and student persistence in environments beyond those examined by Tinto.

METHOD

Research Questions

A quantitative research study was conducted which examined the relationship between instructional interaction and student persistence in online education. Specifically, this non-experimental, correlational study asked:

1. Is there a relationship between the frequency of instructional interaction and levels of student persistence in online courses?
2. Is there a relationship between the method of instructional interaction and student persistence in online courses?
3. Do other variables emerge as correlates of persistence among students in online courses?

This study utilized a survey research methodology and records review to investigate the relationship between instructional interaction and student persistence in online courses.

Participants

The online learning program that participated in this study is operated by a public university located in New England. Online programs offered by the university include education, engineering, management, information science, liberal arts and health professions at the undergraduate and graduate level. The online program enrolled 7300 students in 375 course sections during the 2004 – 2005 academic year.

The online program uses a course management system (CMS) for the development and teaching of online courses. The CMS allows faculty to develop course materials that are then accessed by students online via a web browser. All faculty teaching in the online program participate in a training program that introduces online pedagogy and instructs faculty in how to use the CMS to develop and teach an online course. The CMS used by the program supports both asynchronous and synchronous communication methods. These methods include synchronous text-based chat, asynchronous text-based discussion forums and asynchronous email lists.

Sample

The population for this study included 1569 undergraduate and 51 graduate students enrolled in 76 online courses offered in the fall semester by the continuing education division of a public university. The unit of analysis for this study was the individual online course. Criteria for selection included:

1. The instructor agreed to allow presentation of survey tool to all students in the course.
2. The instructor agreed to allow researcher to review course communications.

Participating courses included all of the disciplines offered online by the program at the time of the study.

Response Rates

Survey data was collected at an individual student level, response rates were calculated and the percentage of students completing the survey data for each course ultimately determined whether course-level data was included in the study. A total of 714 student online surveys were returned for the 52 courses that met the participation criteria, representing an overall 64.0% response rate. Courses that met the response rate criteria closely reflected the distribution of disciplines in the overall online program and included four graduate and 48 undergraduate courses.

Instrumentation

This study utilized a survey research methodology to collect data regarding instructional interaction in online courses and student attitudes to their online course experience. An online survey was developed to collect data regarding the online course experience of students who maintained enrollment in their online course through the 14-week semester (http://frontpage.uml.edu/faculty/stello/survey.htm). This 37-item survey collected data regarding: (a) student demographics and characteristics, (b) the frequency of interaction in each online course, (c) the method of interaction in each online course, (d) student attitudes toward interaction, (e) student attitudes toward the courses, and (f) the contribution of interaction methods to the students' course experience.

During the 3-week survey period, students were presented with the option of completing an online survey for each registered online course. Individual student responses were used to create per course measures for each interaction and attitude variable described below. Students could only submit one online survey per registered online course, preventing repeated measures from skewing per course measures. In order to assure that the student reported interaction measures accurately reflected what occurred in each online course, the dataset was validated against the course interaction archives in 10 (20%) of the courses selected to participate in the study. Student reported data regarding the frequency and method of interaction within courses was found to accurately reflect the course interaction archives.

Independent Variable

The independent variable in this study is instructional interaction. This study examined the frequency of instructional interaction and the method of instructional interaction. Frequency of instructional interaction refers to how often students and instructors, and students and students, interact regarding course related materials. Frequency of instructional interaction was measured by two items on the student survey. One item asked students to report how frequently the course instructor used all course communications methods to interact with the students in the course. A second item asked students to report how frequently students used all course communications methods to interact with other students in their respective courses.

Method of instructional interaction refers to whether the interaction within a course occurred using the discussion forum, email lists, or the online chat tool. For each of the three methods of interaction, a series of items asked students to report the frequency of instructor use, the frequency of student use and the duration of student use. Student responses to these items were used to create three Method of Interaction Indexes, which provided interval level measures of the overall interaction in each course by each method of interaction.

Intervening Variables

Four items on the survey examined student attitudes to: timeliness of instructor feedback, utility of instructor feedback, amount of instructor communication, and amount of student communication. A reliability analysis conducted with these four items resulted in a coefficient alpha of .91, with item to total correlations ranging from .55 to .86, suggesting a high degree of reliability. Student responses to these items were summed at the course level and a mean student Attitude to Interaction value was calculated for each course.

Three items on the survey examined student attitudes toward their overall course experience. These items asked students if the course contributed to their knowledge regarding the subject matter, the course met students' expectations, and they would recommend the course to another student. A reliability analysis conducted with these three items resulted in a coefficient alpha of .89, with item to total correlations between .56 to .92, suggesting a high degree of reliability. Student responses to these three items were summed at the course level and a mean Attitude to Course value was calculated for each course.

A third intervening variable, Course Contribution by Method, examined student attitudes toward the use of each method of interaction. These items examined the strength of student agreement with the following statement, "Overall, would you say (method) contributed to your online learning experience?" Student responses for the three Contribution by Method items were grouped at the course level and descriptive statistics were calculated. An initial review of the distribution of per course responses for each item approximated a normal distribution, supporting the use of these items for correlational analysis.

Dependent Variable

Student persistence, the dependent variable in this study, addresses a student's commitment to complete a course and program of study. A persistence rate was constructed for each course by subtracting the number of students who administratively withdrew from a course along with students who failed or took an incomplete in the course from the total enrolled in the course at the end of the two-week Add/Drop period. The resulting difference was then divided by the total enrollment, creating the course persistence rate. The per course persistence rate provided a useful measure of what percentage of students completed each online course. The 52 courses which met the response rate criterion for this study had a mean persistence rate of .80 (SD = .11), meaning 80% of the students enrolled in online courses selected to participate in this study completed the course with a passing grade. Persistence rates among courses ranged from a low of 42% to a high of 100%.

DATA ANALYSIS

Research Question I

The first research question asked if there is "a relationship between the frequency of instructional interaction and levels of student persistence in online courses?" A series of scatterplots were conducted between the dependent variable, Course Persistence Rate and each of the frequency of interaction variables (Instructor, Student, Interaction Index). A review of the scatterplots did not indicate a linear relationship between the Course Persistence Rate and any of the three interaction variables.

This research did identify significant differences between how frequently instructors interacted with students and how frequently students interacted with other students within each online course. Per course Frequency of Instructor Interaction scores ranged from 2.12 to 4.00, with a mean score of 3.10 (SD = .41) while per course Frequency of Student Interaction scores ranged from 1.25 to 3.86, with a mean score of 2.59 (SD = .54). A paired samples t-test was conducted using the mean

Frequency of Instructor Interaction scores and the mean Frequency of Student Interaction scores for each course. The results of this t-test indicated that per course Frequency of Instructor Interaction scores were significantly greater than per course Frequency of Student Interaction scores, t (51) = 9.125, p=.000, with a mean difference of 0.51. This finding indicates that overall, instructors used the online communications tools to interact with students more frequently than students used these tools to communicate with other students within each course.

A strong positive correlation was observed between the frequency of instructor-to-student interaction and the frequency of student-to-student interaction within the online courses participating in this study. A Pearson Product Moment Correlation conducted between the course scores for Frequency of Instructor Interaction and Frequency of Student Interaction confirmed a positive correlation between frequency of instructor-to-student and student-to-student interaction, significant at $r_{50} = .68$, p<.001. The strength of this correlation suggests that as the frequency of instructor-to-student interaction increases in a course, the frequency of student-to-student interaction also increases.

Research Question II

The second research question asked if "there is a relationship between the method of instructional interaction and student persistence in online courses?" Correlational analysis between the method of instructional interaction and persistence required the creation of three method of interaction indexes. These three indexes, the Chat Method Index, Discussion Method Index, and Email Method Index, reflected the overall interaction on the part of instructors and students within each method of interaction per course. A reliability analysis of the three items composing each index revealed coefficient alphas of .92 for the Chat Method Index, .93 for the Discussion Method Index and .77 for the Email Method Index. Once the three Method of Interaction Indexes were calculated, the distribution of course scores and descriptive statistics were reviewed for each index. Table 1 contains the mean and standard deviation for each of the three indexes.

A series of scatterplots were constructed pairing each of the Method of Interaction Indexes to the Course Persistence Rates. An examination of scatterplots comparing persistence with each of the method of interaction indexes did not identify a linear relationship between these variables; however, a review of the mean Method of Interaction scores suggests some differences in how each course used each method of interaction. This difference is explored further below.

Research Question III

Research Question 3 asked if "other variables emerge as correlates of persistence among students in online courses?" The student survey asked respondents to consider how other aspects of interaction contributed to their online course experience. These data, collected at the course level, were used to examine the relationship between persistence and student attitudes to interaction, student attitudes regarding their online course experience, and student perceptions regarding the contribution of a specific interaction method.

Two attitude indexes were created which examined student attitudes to interaction within their online course and to their online course experience. Strong, positive correlations were observed at the course level between Student Attitudes to Interaction and the Frequency of Instructor-to-Student Interaction, $r_{52} = .62$, p<.001, the Discussion Method Index, $r_{52} = .55$, p<.001 and the Email Method Index, $r_{52} = .43$, p<.01. Similar positive correlations were observed at the course level between Student Attitudes to Online Course Experience and the same three variables. These findings suggest a strong, positive relationship between the use of asynchronous methods of interaction by the instructor within a course (i.e., discussion forum, email lists), and positive student attitudes toward that course. A modest, positive correlation was observed between Student Attitudes to Interaction and Course Persistence Rates, $r_{52} = .30$, p<.05.

Table 1. Means and standard deviations for three method of interaction indexes

Index	M	SD
Chat Method Index	8.08	1.66
Discussion Method Index	9.00	2.00
Email Method Index	6.97	1.02

Three course level measures were created to examine students' perceptions regarding the contribution each method of interaction made to their online learning experience. An initial scatterplot of course scores for each of these three items suggested a positive relationship existed between the discussion contribution item and persistence. A Pearson Product Moment Correlation was conducted to examine the strength of these relationships. A strong positive correlation was observed between Course Persistence Rates and the Contribution by Discussion Method scores, $r_{52} = .41$, p<.01.

A multiple regression analysis was conducted to evaluate how well the contribution by method variables and method of interaction indexes predicted persistence. The predictors included the three contribution of method variables and the three method of interaction indexes. The Course Persistence Rate was the criterion variable. A stepwise multiple linear regression analyses was conducted. The Contribution by Discussion Method variable and the Discussion Method Index were significantly related to the Course Persistence Rate, F (2, 48) =8.87, p=.001. The sample multiple correlation coefficient was .51, indicating that approximately 26% of the variance in the persistence rate in the sample can be accounted for by the linear combination of these two measures. The remaining Contribution by Method and Method of Interaction variables did not add to the predictive value of the equation.

CONCLUSION

The data suggest that student attitudes to interaction and student perceptions regarding the usefulness of particular methods of interaction offer the only statistical evidence of a relationship to persistence in this study. In regard to student attitudes to interaction, the data indicate that positive student ratings regarding the timeliness of instructor feedback, appropriateness of instructor feedback and amount of course communications increased in courses as the use of asynchronous methods of interaction increased (i.e., discussion forum, email lists). Likewise, as the frequency of instructor-to-student interaction in a course increased, student attitudes to interaction and to the online course experience improved. This positive correlation to student attitudes was not observed in courses where the primary method of instructor interaction was synchronous chat.

Student perceptions regarding the contribution that the use of discussion forums made to their online course experience were strongly correlated to course persistence rates. This was not observed for student perceptions regarding the contribution the use of chat or the use of email lists made to the students' online course experience.

Given the positive relationship observed between student attitudes to interaction and student persistence; and between student perceptions regarding the use of the discussion forum and student persistence; this study suggests that frequent use of the asynchronous discussion forum by the instructor and students to share course related materials is one factor contributing to student persistence. These findings also reinforce emerging research which identifies a relationship between positive student attitudes toward their online course experience and a student's decision to persist in, or drop out of the course. While an online instructor cannot necessarily control factors outside of the classroom setting, this study suggests instructional interaction strategies that have a positive impact on persistence within the online classroom.

Business Processes Modeling as Social Systems[1]

Joseph Barjis, Georgia Southern University, P.O. Box 8150, Statesboro, GA 30460, USA; E-mail: JBarjis@georgiasouthern.edu

ABSTRACT

Over the past few decades, a number of successful process modeling techniques have been developed. While these modeling techniques are instrumental in process modeling, they seem challenged to capture the deep structure of business process and its social character (commitment, coordination and negotiation). Most of the current modeling methods and techniques are characterized as flowchart-like techniques. Organizations are social systems, where its members communicate and negotiate to carry out different tasks and create results. On the other hand, many of the processes are nested within a super-process that can not be captured by flowchart-like techniques. Another issue of the existing modeling techniques is their semi-formality not lending to model execution (simulation) without further translations. This paper introduces a modeling method and technique that consider organizations and its business processes as a social system. The resulting models are based on the semantics of Petri net, and consequently, the models are fully executable. The proposed method is based on a rather non-traditional concept (the Language Action Perspective), and it adapts graphical notations of traditional modeling formalism (Petri net).

Keywords: social systems, business process modeling, modeling methodology

INTRODUCTION

Business processes have been studied for decades and even longer than that, but the real renaissance of research into business processes started with vanguards of re-engineering revolution such as Davenport, Short, Hammer, Champy (Davenport & Short, 1990; Hammer & Champy, 1993) whose works foregrounded business processes in the mainstream literature. Since then, numerous tools, techniques and methodologies have been developed to study the organizational phenomena and business processes.

A distinctive and important feature of an organization is its social nature –human actors interacting and collaborating to carry out tasks and fulfill the mission of the organization. As such, business process is not merely a sequence or flow of jobs, tasks, or physical materials, but a complex phenomenon involving actors communicating, negotiating, coordinating and agreeing upon certain tasks. As argued by advocates of alternative perspectives for business process study (Winograd & Flores, 1986, Stamper, 1988; Dietz, 1994), the social nature of business process entails a fundamentally different perspective to perceive the reality of an organization and the role (responsibility and authority) of its members. This understanding is difficult to achieve with conventional methods/techniques that are mostly characterized as flowchart-like techniques. One such new perspective was introduced in a framework referred to as the Language Action Perspective, or LAP for short, (Winograd & Flores, 1986). The LAP framework and its philosophical stance inspired emergence of several modeling methodologies and techniques such as SAMPO (Lehtinen & Lyytinen, 1986; Auramäki et al., 1988), Action Workflow model (Medina-Mora et al., 1992), DEMO (Dietz, 1994), BAT (Goldkuhl, 1996), to mention a few. However, since the main emphasis in these methodologies is placed on capturing communication acts and building business process models, their underlying modeling techniques do not lend to further execution or simulation (Rittgen, 2005), which makes it difficult to check the models for dynamic behavior and response to changes. In order to develop executable business process models based on a formalized semantics, this paper introduces a method and technique based on the *business transaction concept* derived from the LAP. The proposed method is further extension of CAP Net developed over the last decade by Dietz (2006), however the modeling technique (graphical notations) introduced is full adherent to the Petri net formal semantics.

Most of the previously introduced Petri net models are dominantly process or workflow oriented rather than business process as a social system. In contrast to prevailing process-oriented and object-oriented models, the introduced method allows not only model processes flow but also take into account the social character of the modeled enterprise such as interacting actors (or actor roles), and the nested structure of activities. This paper further develops the works of (Dietz & Barjis, 1999; Dietz & Barjis, 2000, Barjis & Reichgelt, 2006) on business process modeling deploying the transaction concept supported by Petri net.

In summary, the research finding reported in this paper is hoped to make the following contributions:

1. *Executable models* of business systems based on the *Transaction Concept*. Previous models developed based on this concept are mostly focused on producing well defined and detailed models, so called, *atoms*, *molecules* and *matter* of organizations. Our contribution is to make the resulting models executable to help system designers with model checking and validation, making changes to the model and study the impacts of the changes prior to the intended system development.
2. *Compact models* of complex systems using the transaction concept. Often, in systems modeling designers are either not interested in all the details, or the system under study is too large to be depicted at detailed level, or the designers may spotlight a part of the system while leaving some other parts concealed. In these situations, compact modeling where certain activities are compressed into one well defined component would be of great advantage. Also, when using diagrams, models rapidly get too large to manage.
3. *New knowledge*, generated as a result, contributes to the concepts of Model-Driven System Development, business systems modeling, simulation, modeling methodology, application of modeling and simulation, and advancing the new perspectives of system design and development.

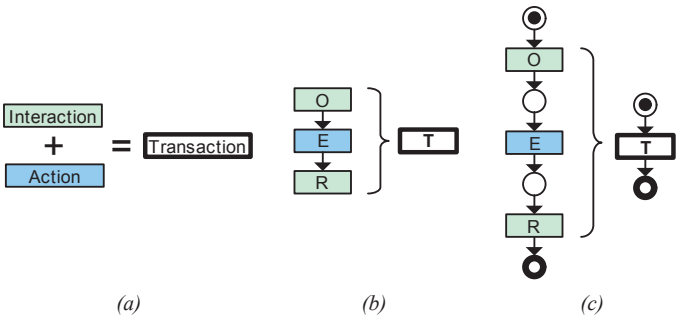
THE TRANSACTION CONCEPT

What follows is an illustrative introduction to the transaction concept using artifacts and constructs adapted by the authors. Readers, interested in more in-depth study about the transaction concept, are referred to the original works by Dietz (1994, 2006). We have adapted the Petri net notations and extended them as modeling constructs. Assuming that readers are familiar with the basic concepts of Petri nets that are widely used in systems analysis and design, we skip their introduction.

Transactions are patterns of interactions and actions, as illustrated in Figure 1a. In the figure, "action" and "interaction" are distinguished by different colors. An *action* is the core of a business transaction and represents an activity that brings about a new result, changing the state of the world. An *interaction* is communicative act involving two actors (actor roles) to coordinate or negotiate. An example of an interaction could be "requesting a new insurance policy", clicking "apply" or "submit" buttons on an electronic form, inserting a debit card into an ATM to withdraw cash, or pushing an elevator's summon button. Replying to the interacting actors and fulfilling their requests is an action, e.g., "issuing a new policy", "dispensing bills", "moving an elevator to the corresponding floor", etc.

Each business transaction is carried out in three distinct phases, the *Order phase*, the *Execution phase*, and the *Result phase*. These phases are abbreviated as O, E and R correspondingly (see Figure 1b), and constitute the OER paradigm (Dietz, 1994). The figure illustrates a business transaction in detailed OER form, and compact transaction form (T). Note that the order (O) and result (R) phases are interactions and the execution (E) phase is an action, therefore they are illustrated using different colors (the Execution phase is represented by a rectangle colored in blue (or gray in grayscale printout)). These three phases are a distinct feature

Figure 1. Transaction: a) pattern of action and interaction; b) sequence of three phases (detailed and compact); c) corresponding Petri net diagram



that entails the discussed method as a business process modeling technique versus just a process modeling. Also, these three phases not only allow for the boundary of an actor (or business unit) to be clearly defined, but also to depict interaction and action as a generic pattern involving (social) actors. Compared to UML, Flowchart, EPC and other conventional modeling methods, the transaction pattern clearly identifies the actors involved as it is discussed below. In other words, in conventional methods, a transaction would be reduced to only one execution phase omitting information about the relevant actors and their role.

Now, we try to introduce the further notions of the transaction concept along with the Petri net notations we adapted. In general, Petri net structure consists of places (graphically illustrated by circles and representing outcome of an activity or process), transitions (graphically illustrated by rectangles and representing an activity or process) and directed arcs (graphically illustrated by arrows and representing flow sequence). Figure 1c depicts a business transaction using the Petri net notations. Again, the figure illustrates a business transaction in detailed OER form, and compact transaction form (T). In the figure, the start and the end places are marked by different circles. These notations will make better sense when a complex process consisting of several related processes is studied and modeled.

Another notion of the transaction concept is the role of actors involved in a transaction. Each business transaction is carried out by exactly two actors (or actor roles), see Figure 2a. The actor that initiates the transaction is called the *initiator* of the transaction, while the actor that executes the transaction is called the *executor* of the transaction. Since the Order (O) and Result (R) phases are interaction between the two actors, their corresponding transitions are positioned between the two actors. The Execution (E) phase is an activity solely carried out by the executor and, therefore, its corresponding transition is positioned within the confines (boundaries) of the executor. In case of multiple actors, they will be conveniently denoted by the letter A and numbered (A1, A2, A#).

A transaction diagram should also represent how the created result (outcome) is recorded. Since each transaction brings about a new result, the Result phase of a transaction is linked to an oval-shaped element representing the new result created (see Figure 2b). For simplicity sake, the depiction of the oval representing a transaction result maybe omitted in the models studied later. If a business transaction is a simple one (not nesting further transactions), it is better to compress its three phases into a compact notation, see Figure 2c. In this case, the transaction is placed within the boundary of the executing actor, while the initiation and ending points are placed within the boundary of the initiating actor.

A distinction is made between simple and composite transactions. Actors' interactions may be arbitrarily complex, nested, extensive and multilayered (hierarchical). A complex collaboration typically consists of numerous transactions that are chained together and nested into each other. *Simple* transactions do not involve, i.e. trigger or cause, other transactions during their execution (like the above figure). In *composite* transactions, on the other hand, one or more phases will trigger further, nested, transactions. For instance, think if actor A1 contacts actor A2 to reserve a hotel room (we denote this request as Transaction 1, or T1). Actor A2 receives the request, checks the room availability, but in order to complete the request, it has to request actor A1 for a payment guarantee (we denote this second request as Transaction 2, or T2). For actor A2 to complete the reservation task, first the payment transaction should be completed. This process is represented in Figure 3a in the form of a nested transaction. Notice that the Execution phase of T1 now has several sub-phases or interactions, where each of the sub-phases is distinguished with a letter of the alphabet attached to the transaction number (e.g., T1a/E denotes "first sub-phase of the Execution phase of Transaction T1"). The process illustrated in the figure starts with the receiving of a reservation request and checking the room availability, then it waits for the payment transaction to get completed, only then the Execution phase gets completed, let say, by conveying a confirmation number to the first actor.

A close look at the reservation process reveals that in fact, the payment transaction, T2, is rather an interaction between the hotel and a credit card company. Thus, the process rather involves three actors (or actor roles): A1 (customer or guest), A2 (hotel receptionist) and A3 (credit card company). The interaction process between the three actors forms a nested transaction structure.

One of the limitations in many modeling techniques is coping with complex real-life systems. Usually models of real systems turn too large using diagrammatic representation. In dealing with this issue, we introduce the "composite" (or nesting) notation graphically represented as a multiple (layered) rectangle. For instance, the model illustrated can be reduced to one composite transaction as shown in 3b. This can be applied to any part of a complex system for the sake of compactness or for spotlighting a specific part of the system while concealing the other parts. The notion of nesting structure is especially helpful in inter-organizational process modeling in which a whole process within an organization or business unit can be reduced to a single composite transaction, thus, keeping the model more manageable.

It should be noted that at any point (phase) an actor may quit the process or decline to proceed or a process is terminated due to internal or external circumstances.

In this manner, any complex process with any number of actors and outcomes can be modeled and illustrated. However, for more complex processes one needs to use the compact notation of a transaction in order to keep the model better managed and controlled. The compact notation is useful for those transactions that are simple (not nesting further transactions). If a compact notation is used, by a convention, the whole transaction is positioned within the confines of the executing actor. Two instances of such a compact modeling are represented in Figure 4a and Figure 4b. In the first case, the two nested transactions are initiated and executed in sequence, and in the second case, the two nested transactions are initiated and executed in parallel.

Another notion, a typical phenomenon in process modeling, is of probability of some activities – optional transactions that may take place depending on some conditions. To indicate that a transaction is an optional one, a small decision symbol (diamond shape) is attached to its initiation (connection) point as illustrated in Figure 5a. In order to transform this optional transaction construct into standard Petri net semantics, a traditional XOR-split that could be modeled by one place that

Figure 2. A process diagram of a business transaction: (a) detailed; (b) with the result; (c) compact

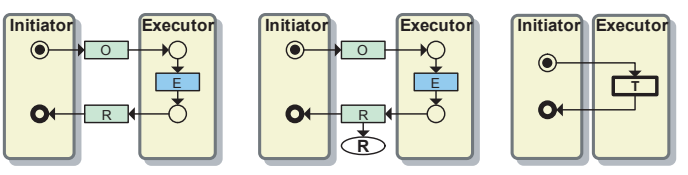


Figure 3. Nested transactions with three actors: (a) detailed; (b) compact

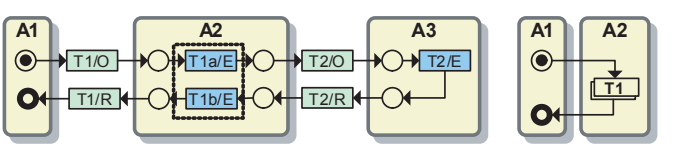

Figure 4. A model with two nested transactions: (a) in sequence; (b) in parallel

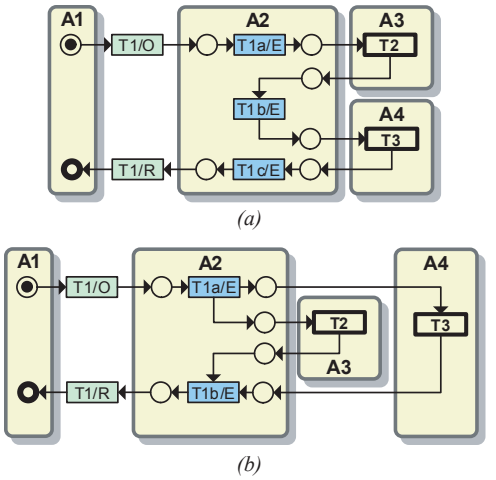

Figure 5. Standard Petri net representation of: (a) an optional transaction; (b) a decision state

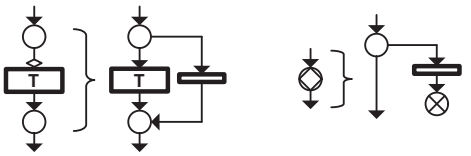


leads to two transitions is used. It requires addition of a skip (or dummy) transition as demonstrated in the figure (notice the tiny rectangle with no labels). A dummy transition is meant that it has zero duration and utilizes no resources.

Finally, there are situations that a process may halt and result in a termination. For example, if there is no room available, then the payment transaction is not initiated at all. This situation is modeled through a place identified as "decision state" graphically represented via a circle with the decision symbol (diamond shape) within it, see Figure 5b. As it is seen, for the transformation of a decision state into standard Petri net semantics, a traditional XOR-split that could be modeled by one place that leads to *proceed* or *stop* is used. Depending on the value of the state, the process either proceeds or terminates as indicated by a place filled with a cross.

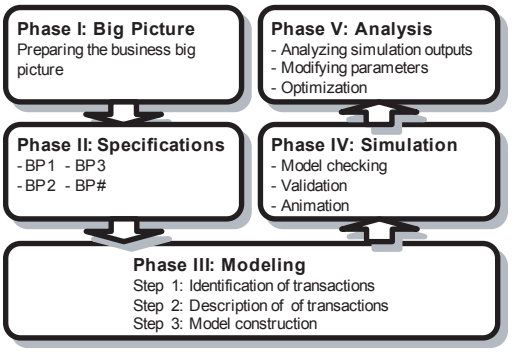
Through these few simplified constructs and mini-models, we aimed to introduce how the proposed method can capture typical situations in business processes, provide sound concept based on communication, and ultimately contribute towards more accurate Business Process Modeling and consequently more adequate IS Design, since the models can be executed several times before it is finalized.

Now that the basic ideas and constructs are introduced, we discuss the underlying framework (guidelines) for deploying the proposed method.

APPLICATION GUIDELINES

Based on practice and application experiments, the following framework (guidelines) was developed. This framework is diagrammatically illustrated in Figure 6, in which both the process flow (block arrows) and feedback loop (circled block arrow) between the phases are depicted. As seen, this is an iterative process where after each simulation and output analysis, the model is refined, some parameters are modified and the experiment is repeated. It may be also required to return to earlier phases (phase I or phase II) for missing pieces of information, if the analysis reveals any flaws or doubts. This is especially important when changes occur for the system under consideration, modifications must be made to the model, and the change impact has to be studied. The entire process consists of the following major phases:

Figure 6. An application framework (guidelines)



Phase I – *Big Picture:* during this phase major processes are identified. Identification of the major processes actually portrays the *"big picture"* of an organization. Also during this phase, scope estimation is conducted – a major process, or focal point, is defined where the main focus will be directed. The perspective taken in this phase considers an organization as a network of business processes (BP). Methods used in this phase are mainly the review of the corporate documents and interview with the business manager if such documentation is lacking or the collected information is vague.

Phase II – *Detailed Picture:* During this phase, each major process of interest is described to fill in the details of the "big picture" previously identified, boundaries of organizational units are defined, and actors and their roles are identified. As a result, an analyst may describe a series of interrelated business processes (BP1, BP2, etc.). Methods used in this phase are mainly based on interviews, observations and review of the documented procedures. However, description can be more articulated so the events, their timelines, and involved actors can be easily distinguished.

Phase III – *Modeling:* For each specific major process of interest:

Step 1: Identification of business transactions using the *transaction concept*.

Step 2: Description of business transactions (actors involved and results created) using the *transaction concept*.

Step 3: Construction of an interaction (process) model using the developed constructs.

Phase IV – *Simulation (Animation, Validation):* In this phase, first the model is checked for absence of semantic flaws and deadlocks. The model is animated for better communication to non-technical users, especially the process manager. Taking the process manager's feedback and input the model is now validated for accuracy and adequacy. Once the model is validated, its behavior is studied through the simulation runs using a discrete-event simulation tools.

Phase V – *Analysis & Improvement:* Finally, the simulation outputs are analyzed for modifications, optimizations, improvements, and comparison of different scenarios. As an objective, at this stage analysts may suggest improvements in the form of redesigning processes, redistributing resources, designing better systems.

This just described framework, and the above discussed modeling method and technique are applied to numerous real world business system. One such a case-study is reported in a separate paper published in these proceedings. Readers interested in the application of the method are referred to the application paper entitled "Business Process Optimization Using Simulation".

CONCLUSION

This paper outlined a modeling method and technique based on the transaction concept and Petri net formalism. This paper studied that the transaction concept derived from the LAP can adequately capture and represent business processes as social systems. The core concept of the transaction concept is its perceiv-

ing of an organization and its business processes as social processes involving interacting actors.

The graphical notations adapted for the transaction concept are based on the formal semantics of Petri nets. This allows modelers to build models that can be directly simulated on computer using Petri net based tools. Simulation of the models benefits in many ways: check the models for deadlocks or flaws; study the model dynamic behavior; analyze and compare different set of model parameters.

However, a few things are not fully investigated. First, we have no evidence how the proposed technique will be understood in comparison with conventional techniques (e.g., UML Activity Diagram). Second, how the resulting models can be mapped into well-known simulation tools (e.g., Arena, Extend). Finally, it is not tested how complex business systems can be dealt with using the proposed method.

As a conclusion, this paper is intended to provide theoretical and practical value for business process analysts, modeling and simulation experts, information system designers, and practitioners of modeling and simulation in general.

ABSTRACT

The IEEE Std.830-1998 was created to standardize the software requirements specification document. The aim of an SRS document is to capture software requirements in an unambiguous manner in order to facilitate communication between stakeholders. The Use-case approach has become a de-facto standard for capturing functional requirements. The IEEE Std.830-1998 provides a structure (template) for documenting the software requirements. But, it does not show how to leverage the information already captured in Use-cases for generating the specification document. In this paper, we present an approach to prepare SRS with Use-cases. We do this by employing classification schemes (Use-case taxonomy) identified to manage the Use-cases. Our method provides additional support to analysts in preparing a standards compliant SRS document by avoiding redundant specification effort and through reduction in the cognitive load. We demonstrate how this taxonomy is used to develop a standards compliant SRS document with the help of a case study.

1. INTRODUCTION

The SRS document described in IEEE Std.830 is divided into a number of recommended sections to ensure that information relevant to stakeholders is captured. This specification document serves as a reference point during the development process and captures requirements that need to be met by the software product. Basic issues addressed in the SRS include functionality, external interfaces, performance requirements, attributes and design constraints. It serves as a contract between the supplier and customer with respect to what the final product would provide and help achieve. Although the IEEE Std. 830-1998 specifies the structure it does not choose one representation for requirements over the other. Neither does it specify what techniques should be used to populate the various sections of the SRS.

The Use-case approach has become the de-facto standard for capturing functional requirements. Many of the sections of the SRS document contain information that would be otherwise collected in UML Use-case artifacts. A significant amount of effort could be spared if the description of functionality captured in these Use-case artifacts is used to populate relevant SRS sections. For large projects, the number of use cases and the amount of related documentation could quickly become unwieldy without the presence of an organization scheme. It is possible to systematically create and populate several of the SRS document sections if Use-cases are documented using appropriate organization schemes. The advantage of systematic translation is avoiding duplicative specification efforts. After all, if time and effort have been expended creating the Use-case artifacts, it makes sense to reuse the results of those efforts when writing the SRS document. It would also lessen the possibility of introducing inconsistencies that arise during duplication.

Presently, there are no concrete techniques to identify and link Use-cases to sections of the SRS. This process is at best ad-hoc, which generates inconsistencies in the final specification document. In this paper we show a systematic way to leverage existing/discovered Use-cases to populate the SRS document. We do this with the help of various schemes for managing and organizing the Use Cases, and by linking specific use case types to related SRS sections. Our method provides additional support to analysts in preparing a standards compliant SRS document by avoiding redundant specification effort and through reduction in the cognitive load. We demonstrate how this taxonomy is used to develop a standards compliant SRS document with the help of case study.

In Section 2 we provide an overview of the various organization schemes used in our method for managing and organizing Use Cases. Section 3 discusses how specific UML artifacts could be linked to the content requested in specific SRS sections. In Section 4 we demonstrate how the organization scheme has been applied in a case study for developing an SRS, and Section 5 concludes our paper with discussion of future work.

2. SRS AND USE CASE TAXONOMY

The Use-case model is an interpretation of the SRS (Spence & Probasco, 2000). For ease of documentation, at times, the Use-case model along with the supplementary specifications document is used as the formal documentation for the project. This may seem like an efficient system but it cannot be substituted for a formal SRS. The need for an SRS document is usually mandated by the management (Spence & Probasco, 2000). Under such circumstances, when an SRS standards document is unavailable, the Use-case model is dissected and the use case descriptions cannibalized in an attempt to populate the SRS. This process tends to be ad-hoc giving rise to inconsistencies in the final document. It also surfaces traceability issues between the Use-case model and sections of the SRS document. Changes in functional requirements in the specification document need to be reflected in the Use-case model and vice-versa. We should also point out that the Use-case model is an abstraction of the system model. It does not capture all the relevant aspects of the system, especially non-functional requirements, which are required for completing the product documentation. An unstructured process for using Use-cases to populate an SRS is inefficient and lacks traceability. The SRS forms the basis for testing plans at a later stage, further boosting its importance in software development process.

There is an incentive to prepare the SRS in accordance to the standards. It ensures readability of the document by other stakeholders who come on board at a later date. The IEEE Std.830 is understood across organizations facilitating communication between disparate organizations. It also makes sense from Information systems maintenance or systems testing perspective, where convention is preferred over unique formats unless extra-ordinary circumstances exist. At the same time there is also an incentive to avoid duplication effort.

Goldman and Song (2005) reviewed four possible schemes, and proposed one of their own, for organizing and managing use cases. The choice of schemes for managing the use cases depends on the context. The five classification schemes presented were:

a. Business Use Case vs. System Use case
b. Essential Use Case vs. Real Use Case
c. Based on Organizational Goals: Core vs. Administrative vs. Routine Use Cases
d. Based on Importance Level: Primary vs. Secondary vs. Optional Use Cases

e. By Function type- 1.Data Entry/Maintenance, 2.Transaction recording, 3.Calculation, 4.Transformation, 5.Communication, 6.Device Control, 7.System Administration.

The schemes could be used either for organizing Use-cases sequentially, like for e.g. table of contents, or for grouping related Use-cases based on shared attributes or behavior. For a detailed discussion on this we would refer readers to Goldman and Song (2005). For our method we employ organization schemes c, d, and e.

What follows is a proposed systematic guide to the translation of software requirements specifications from UML use case models into the IEEE 830 recommended format. The translation makes use of the multiple use case classifications presented earlier in Section 2.

3. SECTIONS OF THE SRS DOCUMENT

Table 1 gives an overview of how to form each SRS document section from the appropriate information captured in the use case artifacts.

3.1 Product Perspective

In Section 5.2.1 of IEEE 830 (Section 2.1 of the SRS), we are told that "this subsection of the SRS should put the product into perspective with other related products. … A block diagram showing the major components of the larger system, interconnections, and external interfaces can be helpful." A use case diagram establishes the system boundary, and should show the use cases that provide functionality to actors outside the system boundary. To some extent this captures the interfaces needed for actors external to the system to interact with the system.

Table 1. Forming the IEEE 830 SRS document from use cases

IEEE 830-1998 Section **2** of the SRS	**UML Use-cases**
Product perspective	Use Case Diagram; Component and Deployment Diagrams
Product functions	Functional requirements use cases organized by the generic type of functionality provided
User characteristics	List each actor Ûse-case pair with brief explanation how that actor interacts with that use case.
Constraints	Non-functional goal-oriented use cases represent soft goals of the actors that justify/ rationalize the need for a specific functional requirement (Lee and Xu, 1999).
Assumptions and dependencies	Interdependencies between use cases, especially between functional and non-functional use cases.
Apportioning of requirements	Use case names categorized by importance (Primary, Secondary, Optional…)
IEEE 830-1998 Section **3** of the SRS	**UML Use-cases**
External interfaces	All UML actor interactions with use cases at the system boundary. Use case descriptions (narratives).
Specific Functional requirements	Functional requirements use cases organized by the generic type of functionality provided. Use case descriptions (narratives).
Performance requirements	Non-functional goal-oriented use cases related to performance
Design constraints	Non-functional goal-oriented use cases related to design
Organization of functional requirements	Use case classification schemes outlined above

Other sub-systems could be represented as agents and the interaction with the system could still be captured just like for a regular actor.

3.2 Product Functions

In Section 5.2.2 of IEEE 830 (Section 2.2 of the SRS), the major functions that the system will perform are described in a summary form. IEEE 830 offers no guidance on how to organize descriptions of the major functions (although several suggestions on organizing the more detailed functional requirements are included).

One of the classifications mentioned above, that of primary vs. secondary vs. optional use cases, can be used to narrow down the field of the possible use cases so that only primary use cases would be described in the major function summary section. The field can further be narrowed by applying the core vs. administrative vs. routine use case classification scheme to eliminate primary administrative and routine use cases. What is left are only the primary core use cases.

3.3 User Characteristics

Section 2.3 of the SRS describes "general characteristics of the intended users of the product…" In the Use Case model an actor is a role. However, IEEE 830 asks for information about the backgrounds of the intended users, including "educational level, experience, and technical expertise," and these have no corresponding collection point within the Use Case, so will have to be added separately. But, mapping roles to users may aid the discovery process.

3.4 Constraints

Constraints, included in Section 2.4 of the SRS, are "items that will limit the developer's options" (IEEE 830). Constraints are also sometimes called non-functional requirements because they are requirements that the system must meet, yet they do not provide or describe functionality that accomplishes the purpose of the system. Examples include regulatory compliance requirements, performance requirements, and compatibility with externally-specified protocols and system interfaces. Representation of non-functional requirements is topic of research but, presently it is included as business rules governing the interaction.

3.5 Assumptions and Dependencies

Assumptions and dependencies (Section 2.5 of the SRS) come from several places in the use case-based specification process. Some assumptions are stated in the preconditions of the functional use cases, particularly when the preconditions refer to things external to the system, whether they are actors or external systems.

3.6 Apportioning of Requirements

Section 2.6 of the SRS document should "identify requirements that may be delayed until future versions of the system." This information is identified by the primary vs. secondary vs. optional use case categorization described in Goldman and Song (2005).

3.7 Specific Requirements

Section 3 of the SRS document contains the heart of the specification of exactly what the system should do and how. Section 3 revisits some of the areas that were addressed in Section 2, but suggests that this is the appropriate place for inclusion of a higher level of detail. Therefore, essential and business use cases are not appropriate for translation into Section 3, only real system use cases are.

3.7.1 External Interfaces

The external interfaces described for inclusion are a more detailed description of the interfaces mentioned in Section 2.1 of the SRS document. The appropriate place to find the corresponding information is in the narrative description of the use case primary and alternative scenarios. These are typically described in a request-and-response format, where an actor action is followed by one or more system responses, followed by further actor actions and system responses, until the completion of the use case and the satisfaction of the requirement. The set of all actor actions, and corresponding system responses, ought to suffice as "a detailed description of all inputs into and outputs from the software system." (IEEE 830, p. 16)

A use case called "Process Sale Transaction and Payment" might include this partial use case description of a request and response in one of its scenarios:

Actor Action	System Response
Cashier scans barcode on product box.	System displays item description and current price on point of sale terminal.

From the use case description, most of the IEEE 830 items may be extracted, and restated in the following corresponding subsections.

a. Name of item: "Cashier scans barcode on product box."
b. Description of purpose: "System displays item description and current price on point of sale terminal."
c. Source of input: Cashier (actor name)
d. Valid range, accuracy, and/or tolerance: as stated in preconditions
e. Units of measure: as stated in use case summary, or in the scenario narrative.
f. Timing: shown by sequence of steps in the use case scenario narrative.
g. Relationship to other inputs/outputs: The most relevant related inputs/outputs will be those that are also involved in the interactions within the same use case. Others may be separately noted.
h. Screen formats/organization: If required, these should be noted as system responses in the use case scenario narratives where appropriate. For example, a requirement for a credit card entry form could be described by this scenario:

Actor Action	System Response
Cashier indicates credit card payment is desired.	System displays empty credit card entry form in window.
Cashier swipes credit card.	System processes credit card.

i. Window formats/organization: If required, these should also be noted as system responses where appropriate.
j. Data formats: These may be noted either in actor actions or in system responses, depending on where the requirement applies. For example: "System displays customer's zip code left justified; hyphen to appear after first five digits if nine digit zip code on file."
k. Command formats:
l. End messages: These should appear as the last system response in the scenario narrative, and/or as described in the use case post-conditions.

3.7.2 Functions

Each functional requirement of a system has an overall description which should appear as the second item in the use case description, after the use case title. More specific information can be mapped from the use case description as follows. The analyst has the choice of whether to include the UML artifacts directly as elements within the IEEE 830 SRS document or whether to abstract from the UML artifacts the necessary information to fill in these sections.

a. Validity checks on the inputs: These should be explained in the "system response" descriptions within the use case description's scenario narrative
b. Exact sequence of operations: The entire scenario narrative for the expected case may be used to describe an exact sequence of operations.
c. Responses to abnormal situations: Alternative scenario narratives will explain how the system must respond to abnormal situations.
d. Effect of parameters: The effect of parameters may be shown through alternative path scenarios.
e. Relationship of outputs to inputs: Use case description scenario narratives also explain the relationship of outputs to inputs since they explain exactly what the system delivers, or how the system state changes, in response to each actor action document.

3.7.3 Performance Requirements

Such requirements can be documented using UML use cases if the UML is extended slightly to accommodate "goal-oriented" use cases. Currently this information has to be captured explicitly during use case development because "goal-oriented" use cases are not a formal representation in UML model.

3.7.4 Logical database requirements

Unfortunately, use cases do not specifically provide for the specification of logical databases when they are used to define system functionality. Other aspects of database requirements called for by IEEE 830, are not documented in the Use Case and have to be supplemented from class diagrams.

3.7.5 Design Constraints and Software System Attributes

Sections 3.4 and 3.5 of the IEEE 830 SRS document external constraints that are imposed on the system's design and implementation. The constraints are therefore documented as requirements. These include standards and regulatory compliance, along with additional non-performance non-functional requirements. The latter include requirements having to do with reliability, availability, security, maintainability, etc.

All of these requirements are non-functional goal-oriented aspects of the system, and have to be documented explicitly as they are not inherently available in the use case.

3.8 Organizing the Specific Requirements

IEEE 830 explicitly concedes that there are many possible ways of organizing the requirements documentation in Section 3 of the SRS. Several possible examples are shown in the appendix.

In the above mappings, an attempt is made to preserve as much information as possible from UML use case descriptions to create the SRS document in IEEE 830 systematically, if not automatically. Most of the example organizations presented in IEEE 830 can be created from these organizational schemes mentioned in Section 2 of this paper. One possible suggestion offered is to organize the requirements by user class, which would translate as actor in the UML use case model. Another is to organize them by feature, which would suggest the use of the proposed seven generic Use-case function types as a classification scheme, although a domain-specific use case classification might also be helpful for more complex systems. Yet another suggestion is to organize requirements by functional hierarchy, for which a UML system level use case diagram ought to suffice.

If all functional requirements have been detailed in use case diagrams and descriptions, non-functional requirements in supplementary specifications, and the use cases have been properly classified by the various attributes describing them, then the analyst will have collected and organized most of the information necessary to create the IEEE 830 SRS document without much further manual intervention.

4. CASE STUDY

The following fictional system's requirements, expressed as a handful of use cases, will be used to illustrate the expressive power of the use case taxonomies. For this case study, we will consider only system use cases, and not business use cases. For simplicity, we will omit consideration of the target's system's interfaces with other information processing systems.

4.1 System Overview

A periodical publisher wishes to implement a computerized information management system to enable it to manage and grow its business. This publisher publishes several magazines, each of which has its own production schedule, advertising rates, and editorial staff. However, the publisher's magazines cover closely related fields of interest, so the subscriber lists of each of the magazines exhibit large overlap with those of the other magazines. One system is required to handle all transaction, subscriber-servicing, accounting, and fulfillment activities. The system is to handle everything that is needed to publish these magazines, except for support of the editorial (content production) processes, which is handled separately.

4.2 Organization and Classification of the Use Cases

Once the use cases have been identified (refer Table: 2, Pg.7) and briefly described, they are classified by applying heuristics (Question-Method) detailed in Goldman and Song (2005). In this case study we use three of the possible classification schemes that would serve us best for preparing the SRS. The deliverable from this exercise is a classification of a use case along three dimensions:

Table 2. Magazine publisher case study use cases and classifications

Use Case	Brief Use Case Description	C/A/R	P/S/O	G.F.T.
1	Add subscriber information: a new subscriber's information is added to the database.	C	P	1
2	Add new subscription: a new subscription is created in the system.	C	P	2
3	Renew existing subscription: an existing subscription is renewed for additional time.	C	P	2
4	Print fulfillment mailing labels: labels to be attached to magazine issues for mailing.	C	P	5
5	Log in: user identifies self with login ID and password.	A	S	7
6	Add advertiser: a new advertiser's information is added to the database.	R	P	1
7	Add advertisement: an advertisement is received from an advertiser.	C	P	1
8	Schedule advertisement (process insertion order): an advertisement is scheduled to appear in one or more magazine issues.	C	P	2
9	Close issue: total the advertising revenue from scheduled ads in this issue and prohibit further advertisement insertions.	R	S	4
10	Back up certain data.	A	O	7
11	Receive payment: payments are recorded for subscriptions or for advertisements.	C	P	2
12	Cancel subscription.	C	S	2
13	Maintain issue publication schedule: record the dates on which tasks such as closing an issue and printing mailing labels must be completed for each magazine issue.	A	S	1
14	Print circulation report: print a summary report of descriptive statistics.	R	S	5
15	The system must be *n*% reliable: This is an example of a non-functional requirement expressed as a goal-oriented use case.	n/a	P	n/a
16	Initialize the system: configure default settings and start the system application.	A	P	7
17	Print loyalty report: print a report showing customers ranked by longevity and number of magazines	R	O	5

a. Is the use case a core, administrative or routine use case?
b. Is the use case a primary, secondary or optional use case?
c. Which generic function type describes the use case functionality?

Table 2 lists the uses cases identified for the case study along assigned. The "C/A/R" column indicates whether the use case is considered "Core," "Administrative," or "Routine." The "P/S/O" column indicates whether the use case is considered "Primary," "Secondary," or "Optional." The "G.F.T." column indicates the use case's classification within the seven generic function types (Section 2). The number in the "G.F.T." column corresponds to the subsection within Section 2.

4.3 SRS Section 3

Based on this classification, we shall arrange the use cases into the "Specific Requirements" Section 3 of the IEEE 830 SRS document. We will use as our major classification the "Core-Administrative-Routine" distinction, followed by the prioritization (Primary/Secondary/Optional). The order of these classifications could be reversed: IEEE 830, Annex A shows that any of a number of hierarchical arrangements is acceptable.

Using this method, the result is an easily produced, yet organized presentation of the use cases, well suited to guiding the design and implementation process.

4.3.1 Magazine Publisher Case Study -- Sample SRS Section 3 Organization

Core

Primary

Data entry / maintenance (4.6.1)

1. Renew existing subscription
7. Add advertisement

Transaction recording (4.6.2)

2. Add new subscription
3. Renew existing subscription
8. Schedule advertisement
11. Receive Payment

Communication (4.6.5)

4. Print fulfillment labels

Secondary

Transaction recording (4.6.2)

12. Cancel subscription

Optional (Note: an Optional Core use case would be rare.)

Administrative

Primary

System administration (4.6.7)

16. Initialize the system

Secondary

Data entry / Maintenance (4.6.1)

13. Maintain issue publication schedule

System administration (4.6.7)

5. Log in

Optional

System administration (4.6.7)

10. Back up certain data

Routine

Primary

Data entry / Maintenance (4.6.1)

6. Add advertiser

Secondary

Transformation (4.6.4)

9. Close issue

Communication (4.6.5):

14. Print circulation report

Optional

Communication (4.6.5)

17. Print loyalty report

Non-functional requirements

Primary

15. The system must be *n*% reliable

5. CONCLUSION

UML provides a language and notations for identifying, documenting, and communicating system requirements. Use-case descriptions and diagrams are most frequently used during the requirements definition stage of a project using UML. The SRS document prepared in compliance with the Std.830-1998 can ensure unambiguous communication between the stakeholders. The Use-case model alone cannot serve as the core piece of documentation as it gives us only an interpretation of the SRS document. But, it can shorten the time required to generate a standard compliant document if existing Use-case description could be re-used in some manner.

To help avoid duplication of effort, a method for systematic translation of UML use case descriptions into the IEEE 830 recommended format has been outlined. In order to increase the comprehensibility of what would otherwise be linear lists of dozens of use cases, we have proposed that use case descriptions be categorized on five different organization schemes.

Finally, we have presented a step-by-step method based on several of the organization schemes for forming each major requirements section of an IEEE 830-based SRS document. This is achieved by using the information captured in UML use case diagrams and use case descriptions. In the absence of systematic techniques for preparing a standards compliant SRS document with Use-cases, our method presents itself as a practical solution. Future work involves determining the efficiency of our technique when compared to traditional ad-hoc approaches for documenting functional requirements. The extent of cognitive load experienced in preparing the SRS document shall serve as another evaluation metric.

Impact of the Use of Communication Technologies on the Work-Life Balance of Executive Employees

Uthpala Senarathne Tennakoon, University of Calgary, 2500 University Dr. NW, Calgary, AB T2N 1N4, Canada;
E-mail: Uthpala.senarathne@haskayne.ucalgary.ca

ABSTRACT

The Internet, email and mobile communication devices are indispensable today. By creating bridges between work and non-work situations, these technologies appear to contribute to blurring of the boundary between work-family domains. This paper presents the results of an exploratory study assessing the usage patterns of these technologies by executive level employees, and the effect of these technologies on their work-life balance.

Communication technologies are an essential life ingredient to the dwellers of today's fast moving global society. The Internet, emails and portable communication devices[1] such as mobile phones, BlackBerries, and PDAs form a technology group that has blended itself well into everyday lives of the global community. Enabled by such technologies, the generic slogan of "anytime, anywhere, and availability at the press of a button" captures the current work culture trend.

Canada, US and UK have reported that managers worked longer hours and experienced a sense of "working high speed" all the time as reported by HRDC (2005), Patel (2002), and Guest (2002) respectively. This appears as a worldwide trend both in developing and developed countries (Bell & Hart, 1999; Black & Lynch, 2001; Guest, 2002; Healy, 2000). While some employees enjoy compensation for the extended work hours and their 24/7 accessibility, for most executives, who are not covered by the overtime legislation (US_Department_of_Labor, 2006), these extra hours are just an extension of their work demands. The *ICT cluster* seems to be adding on to the virtual hours worked.

Extended work hours are reported to have an adverse impact on work-life balance of employees (Chesley, 2005; Gutek et al., 1991; Parasuraman & Simmers, 2001) and on employee health (Sparks et al., 1997). There is a growing concern on the ability of communication technologies to create an "e-leash" on employees (Rothberg, 2006). Addiction to these technologies is considered comparable to drug addiction (McIntyre, 2006). With increasing concerns on the deteriorating quality of home and family life leading to a variety of social problems, the concept of work-life balance has drown the attention of the workforce, employers, and public policy makers. Therefore, it would be important to assess the true impact of the *ICT cluster* on the work-life balance of modern employees.

Recent literature analyzed the usage patterns of mobile devices addressing diverse issues (Arnold, 2003; Chesley, 2005; Churchill & Munro, 2001; Jarvenpaa & Lang, 2005; Perry et al., 2001; Schlosser, 2002). Schlosser (2002) focused on the meanings assigned by employees to mobile devices while the paradoxes of mobile usage were addressed by Jarvenpaa and Lang (2005). Research has also addressed the concepts of "anytime, anywhere" in the context of teleworking (Nath & Chen, 2005; Perry et al., 2001; Venkatesh et al., 2003).

The current paper contributes by responding to a call for a better understanding of the use of technology (Orlikowski, 2000) by presenting an empirical analysis of the usage patterns of a cluster of communication technologies which are critical to modern employees, and their impact on employee work-life balance. The study aims to address following research questions:

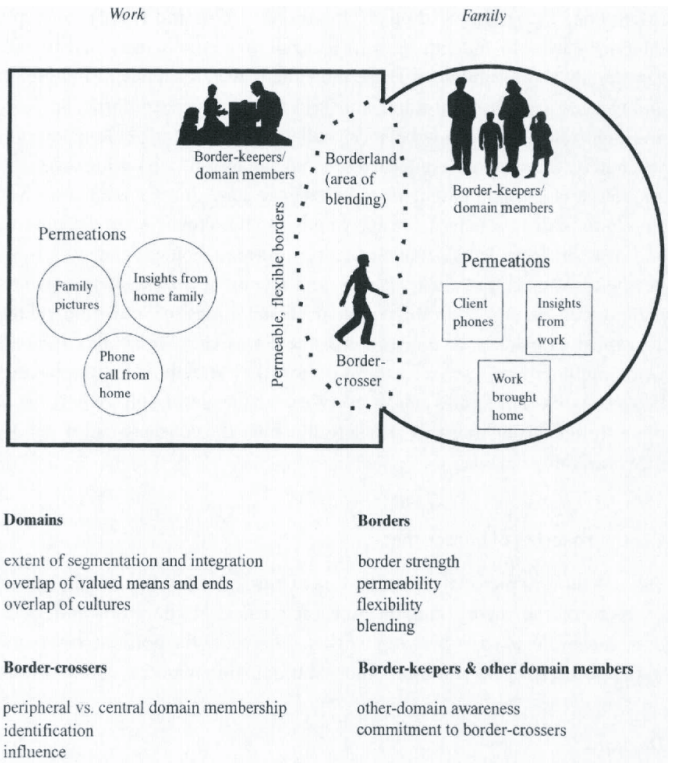
- How do employees actually use the *ICT cluster*? Are there usage differences within the cluster?
- What is the role played by the *ICT cluster* in managing employee work-life balance?
- Do these technologies facilitate a growing blurring of work life and private life, or have employees managed to keep them separate?

THEORETICAL BACKGROUND

The recent explosion of interest in the work-family interface has produced several conceptual frameworks to explain the relationship between these two spheres of life (Greenhaus et al., 2003; Guest, 2002; Gutek et al., 1991; Zedeck & Mosier, 1990). Greenhaus et al. (2003) defined work-family balance as "the extent to which an individual is equally engaged in – and equally satisfied with – his or her work role and family role" (p.513). They proposed three components of work-family balance as time, involvement, and satisfaction, and emphasized the need to have equal weight in work and family roles in each of these components.

In the traditional perspective of work-life balance Zedeck and Mosier (1990) identified five models of representation. *Spillover model* assumes that there are no boundaries in one's behaviour between work and non-work situations and asserts

Figure 1. Work-family border theory: list of central concepts and their characteristics (Clark, 2000, p.754)



that there is similarity between the occurrences in work and family environments. *Compensation model* proposes an inverse relationship between work and family such that work and non-work experiences tend to be antithetical (Staines, 1980). *Segmentation model* hypothesizes that work and non-work are distinct domains of life and individuals can function in each domain without influencing the other. The separation in time, space and function allowed individuals to neatly compartmentalize their lives. *Instrumental model* suggests that activities in one environment will facilitate success in the other. Work outcomes would lead to good family life and life's pleasures. C*onflict model* proposes that the two environments are incompatible with distinct norms, and requirements of one environment entail sacrifices in the other (Zedeck & Mosier, 1990).

Clark (2000) argued that people are daily border-crossers between work and family domains. Although many aspects of work and family are difficult to alter, individuals can shape to some degree the nature of work and home domains and create bridges to attain the desired balance. He provided a pictorial representation of the work-family border theory shown in Figure-1.

The increased usage the *ICT cluster* has enabled location independent working and 24/7 contactability to employees creating 'permeations' across work-family borders. These technologies facilitate border crossings between work and family domains even when the individual is physically in the other domain.

The current research examines the role of the *ICT cluster* as a facilitator for this boundary blurring phenomenon between work and family domains, based on a sample of 26 executive level employees. It also examined how these technologies influenced individuals in achieving their time, involvement and satisfaction balance in work and family roles.

METHOD

The study sample comprised of executive level employees who are usually not covered by overtime legislations and not compensated for additional work time. They would have higher autonomy at work with more cognitive work demands, fulfilling supervisory responsibilities and overseeing the operation of business units or processes. These criteria enable the performance of a portion of job related duties outside work premises and work-time. Initial participants were selected based on available contacts, focusing on the users of the *ICT cluster* and preferably with family commitments. Snowballing technique[2] was used to recruit additional participants for the study. Table-1 summarizes the participant details. The age of participants ranged from 25 to 60 years with 73% of them in the age group 30- 45 years.

Participants were initially contacted through email or telephone. Interviews were held at a location chosen by the interviewees and lasted approximately an hour. Semi-structured interviews were guided by the research questions. The two-way face-to-face communication approach allowed a rich flow of ideas from the participants. Transcribed interviews were coded for common topics which formed the basis of analysis.

Table 1. Participant details

Industries	No of participants	Male	Female
Telecommunication	6	5	1
Railways	1	1	
Manufacturing	1	1	
Banking & Finance	3	2	1
IT/ Software	5	3	2
Legal	1	1	
Education	3	2	1
Consultancy	3	1	2
Chemical Engineering	1		1
Energy	2	2	
TOTAL	26	18	8
Average Age	36.4 years		
Standard Deviation of Age	8.4 years		

THE RESULTS

How Do People Actually Use These Devices?

(a) Emails

Irrespective of the industry all participants highlighted the importance of emails in their work life, identifying it as the main mode of communication at the work place. They used phrases such as, '*indispensable*', '*very crucial*', '*something we cannot live without*', '*my worklife virtually revolves around emails*', '*the work culture in my company is predominantly email driven*', in describing the importance attached to emails at work.

All participants had employer provided email facilities and had remote access to it. However, the majority of the participants maintained separate personal email accounts, and frequently used employer provided Internet facilities in accessing them. Heavy users of emails-at-work claimed to receive over 100 work related emails and spend about 1.5-2.5 hours daily on emails; which amounted to about 15% to 25% of the daily work time. Compared to work-related emails, personal emails were a negligible proportion of 5% to 10%.

(b) The Internet

The use of Internet in work activities mainly depended on the type of occupation. Internet was widely used for research, and participants frequently commented on the *'tremendous time saving ability of the Internet'*. Participants from the software industry highlighted other Internet based technologies such as VOIP (Voice over Internet Protocol) and IM (instant messaging) to be of importance. Many software firms used these services with instant and real-time access to coordinate with overseas partners. Programmes such as MSN Messnger, Skype, and Yahoo Messenger were used to communicate with project teams across the globe and across the room. These IM services performed an important role in maintaining both work and non-work relationships.

Many individuals, who had some form of post graduate studies, highlighted the importance of Internet for education related research as a non-work activity. All individuals had Internet access at home at least through a dial-up facility, but used employer provided Internet access for personal use too. News, sports, banking are some other personal uses of the Internet. Many individuals were not comfortable with using Credit Cards over the Internet.

(c) Mobile Communication Devices (Cellular Phone/ BlackBerry)

Compared to the widespread popularity of cellular phones, BlackBerry use was not prominent. All participants used cellular phones but only two BlackBerry users were in the selected group. In most cases, employers either provided the cellular device, or bore at least portion of the monthly cost. In contrast to the Internet and email technologies, cellular phones played an equally important role in non-working lives of these individuals. They commented:

"I can't even think of a life without a mobile phone. ... Everything is a phone call away from me."

"When you are on such a busy work schedule, how you interlink your family pressures predominantly depends on the mobile phone. By being on the mobile phone you are able to put things together, remotely ... with a schedule of this nature, it is something that you cannot do without."

Participants with a technical background, or in a technology related field tend to use the additional features such as text messaging in a cellular phone. Non-technical and older participants used the devices primarily for voice communication. The users of the additional services appreciated them immensely:

"I think text messaging is a very neat way of not invading into privacy of people. If you don't want to talk but still want to send a message, then just send SMS. Therefore I think SMS really enhance the mobile phone service."

"If you think of MMS (multimedia messaging service), then it is again cool. For example I have a friend with whom I go shopping and we know each other's preferences. So for example when I am in Singapore, I see a nice top, I quickly

take few pictures with prices and send a MMS. She will respond immediately. It is cheaper than a call and we get the work done very satisfactorily".

Many participants exploited ability to be on the phone while on the move, especially in commuting to work:

"I switch on my mobile phone in the morning and would check for any missed calls and send some SMS and make some of the calls while going to office. I do have a driver in the mornings."

"I use the commute time from home to office to make some of the personal calls. I usually drive with a phone conversation or typing a SMS. I don't know if this is good or bad, but I feel it makes me efficient."

"Sometimes while driving to work I would call my support guys to see if there are any issues that need attention, or if I have something in my mind which needs to be looked into. This gives me a head start before I get to the office."

Extended Work Hours: Do These Devices Add to the Work Time?

All participants revealed demanding work schedules requiring them to work beyond the normal 8 hours, to work from home, during weekends and at night. Describing a typical day in their lives, many individuals admitted to checking work emails before going to bed and having the cellular phone on throughout the night to be contactable 24/7.

A divisional manager in a telecommunication company commented:

"My primary task is to provide this infrastructure, and the problem is when there are issues on the system, my staff is the second line of support…. Lately I would say that, thank God I am able to sleep at night. But if I turn back the clock, when I was down the ladder, then I used to be around 24/7 whenever there is an issue. But still I am available over the phone any time of the day."

Another participant commented:

"If you are in the middle of an important project, your might get a call saying that a report has been emailed to you and some feedback is required urgently. So you would just log in to your emails even late at night and see what can be done before you start work next day."

Not all participants agreed on role of technology in extending their work hours. A lawyer commented:

" think the demands of my practice are responsible for that and not the technologies. It would be the same with or without the technologies. But I would view all these technologies as largely positive and since I believe I have a control of them they truly help me in managing my work more efficiently."

Creating Permeable Borders: Work-Family and Family-Work Spillover

Most participants preferred to have a thick border between work and non-work situations. However, work demands have made it difficult to maintain this separation. Research results revealed that the *ICT cluster* played a key role in creating permeable borders between the two domains of work and family. In describing the interactivity of the two domains participants frequently used terms such as *interwoven, overlapping, and interconnected*.

Participants broadly accepted that more work-to-nonwork spillover is present compared to the reverse direction. The main spillover from non-work to work was through cellular phones when it was used in family related matters. This was regarded positively as a means of empowerment since it enabled, for example, the parents to keep track of their children, and attend to household activities through third party intervention. This was described as equipping according to the life style:

"…[cellular phone] is an asset to the lives of people like us. Since we have chosen this life style, we need the necessary equipment to live this life efficiently.

The cases of extended work hours and teleworking described above are classic examples of work-life spilling over to the non-work. However, several individuals considered this as a positive attribute since it allowed them to be present at home while attending to work matters:

"Because of our work assignments, my wife and I live in different locations. So if I start using my laptop when I am with her, then she will definitely complain and grumble. But on the other hand, technology enables me to be with her and work at the same time. And the fact that I have the mobile phone and I can talk to her all the time and she can have access to me anytime is crucial. Without that our lives would have been very difficult."

Described the nature of spillover effect of work and non-work situations, a participant had the following comment to make:

"I work a lot from home and it is possible because I have access to systems through the Internet. This helps me to attend to family matters as and when required. I think my work and family activities are so interwoven and I am almost like a butterfly going from flower to flower- I go from chore to chore, and they could be either family or work related."

Not all were in favour of technology enabled blurred boundaries phenomena. Some participants commented about the invasion of privacy, and the ability of the work life to creep into the family life with the 24/7 accessibility:

"I feel as if I am trapped sometimes and I can't get away and have some peace because of the mobile phone. Yes, I can switch it off, but then, there are situations where you need to have it on."

DISCUSSION AND CONCLUSION

Analyzing the usage patterns of the *ICT cluster* revealed emails to be the most work-centric technology. Although emails may not be critical to all spheres of employment, for the selected executive level employees, emails were the crucial technology in their work life. Cellular phone, the easiest mode for 24/7 connectivity, was recognized as the technology with the strongest association with non-work life. Internet in work and non-work activities depended on each individual and the industry involved.

Providing 24/7 seamless accessibility and ability to attend to work related matters off-worksite and off-working hours, the *ICT cluster* is adding onto work hours of these employees. By blurring the work-family boundary these technologies create spillover in both directions, work-to-family and vise versa. Clark's model (2000) identified these as permeations. Thus, these technologies are facilitating border crossing of individuals between the two domains of work and family.

The study revealed that how people perceived and achieved their work-like balance is very individual-specific and does not necessarily have *equal* distribution of time, involvement and satisfaction in work and family roles. This was in contrast to the definition provided by Greenhaus et al. (2003) in specifying "equal" time, involvement and satisfaction balance. Further, it was observed that an individual could fit into any (one or more) of the five work-life balance models[3] (Zedeck and Mosier (1990) based on their age, industry and individual perception.

Chesley (2005) suggested that cellular phone usage created more spillover compared to computer technology usage. According to the current study, cell phone usage led to more family-to-work spillover. Considering work-to-family spillover, a cellular phone use could act as the sole 'border permeation' or initiate the spillover process with the use of other technologies. For example, an employee could get a call asking him to respond to an urgent email. Although there were only a few users in the study sample, BlackBerry is a device gaining user popularity (Reuteres, 2006). Compared to cellular phones, BlackBerry is equipped to receive emails on the move, anywhere, anytime. Since emails were identified as the most work centric technology by the participants, in the future,

BlackBerry may be recognized as the device creating the greatest amount of spillover in work- family domains.

Convergence of several technologies to miniaturized handheld devices is the current trend (Edur, 2000; Johnson, 2005). However, current research suggests that different functionalities associated with these technologies could have differing impacts on work-life balance. Therefore, future researchers assessing the impact of these convergent technological devices would have to make a distinction among the functionality of these gadgets to correctly ascertain the true impact on individuals. Considering it as a single device may not reveal the intricate details of the impact of each technology within the bundle.

Technology usage varied based on type of industry and the age of participants. Many studies have suggested that women tend to emphasize their family roles more than men (Gutek et al., 1991; Rothausen, 1999; Wharton & Blair-Loy, 2006). Thus it was expected to see a significant gender difference in the usage patterns of these technologies. It was seen that there was a difference in the perceived value towards cellular phone; females perceived it as a security feature compared to men. Other usage patterns didn't highlight any significant differences. This could be due to the increasingly similar roles men and women have in their organizations, resulting in both groups using the technology in a similar manner. On the other hand, the sample of the current study was limited in size, especially in terms of female participation. Therefore, future research could address this issue further. The participants represented a wide range of industries. However, the smaller sample size restricts a wide spread generalization of the results.

Work-life balance of citizens has become an important theoretical, practical, and policy issue. In an era where communication technologies are blurring the boundaries between work and home life, this research provides empirical evidence based on a qualitative assessment of the use of these technologies and their impact on work-life balance of executive level employees. Since different functionalities of the technologies have different implications on the work-life balance issue, the study also suggests that future research should pay attention to these differences rather than simply bundling them together.

Assessing Web Designers' Perception of Web Accessibility

Laura Cook, State University of New York at Geneseo, USA; E-mail: cookl@geneseo.edu
Jack Cook, Rochester Institute of Technology, USA; E-mail: jackcook@hotmail.com

ABSTRACT

People with disabilities continue to be at a disadvantage in terms of opportunities on the Web. Federal laws and state policies help govern website design for federal and state agencies, but their impact thus far is unclear. This paper addresses the issue of web accessibility. A survey was developed and administered to web designers to discover their knowledge, attitudes, and actions taken regarding making pages accessible. The results of these studies are presented in this paper.

INTRODUCTION

The World Wide Web is an integral part of the fabric of our society. Using the Internet has become a way of life for many people around the world, especially in the United States. Prior to being required by law, many buildings were not constructed with handicap access. Today, in the United States, architects must design buildings that are handicap accessible. Just like the buildings of old, most web sites have not been built with user accessibility in mind. Will laws and regulations be needed to force web designers to create accessible web pages? A website is accessible if "anyone using any kind of Web browsing technology is able to visit any site and get a full and complete understanding of the information contained there, as well as have the full and complete ability to interact with the site." (Letourneau, 2003)

According to the 2000 Census, the number of Americans (age five and over) with a disability is 49.7 million, a ratio of nearly one in five people (US Census, 2002). The Internet has had a powerful impact upon the disabled community. According to the National Organization on Disability, the following statement shows the effect the Internet has had on those with disabilities:

"While the Internet has significantly increased the opportunities for social participation for both people with and without disabilities, it has had a much more dramatic impact on quality of life for people with disabilities. 42% of Americans with disabilities online say the Internet has significantly increased their ability to reach out to people who have similar interests and/or experiences, compared to 30% of non-disabled online Americans. And 52% of Americans with disabilities online say the Internet has helped them to be better informed about the world around them, compared to 39% of non-disabled Americans online." (nod.org, 2002)

Anyone can become disabled. Most people experience some temporary or permanent disability -- a broken arm, stroke, hearing loss (to name a few), can render someone disabled. Furthermore, everyday circumstances can mimic a disability, forcing someone to rely on the same solutions used by those with disabilities. For example, if your mouse stops functioning, you must rely on your keyboard – the same way someone who is blind or quadriplegic might. Accessing a web page in a noisy environment increases the importance of audio transcripts or captions just as these transcripts or captions are important to someone with a hearing impairment.

This paper addresses the issue of web accessibility. A survey was developed and administered to web designers to discover their knowledge, attitudes, and actions taken regarding making pages accessible. The results of these studies are presented in this paper and compared against the following hypothesis.

HYPOTHESIS

This research will test the following hypothesis:

Null Hypothesis (H_0): Web designers will ensure their web pages follow the WCAG if there is a policy governing the accessibility of their pages.

Alternative Hypothesis (H_1): Web designers will not ensure their web pages follow the WCAG if there is a policy governing the accessibility of their pages.

Research in this field can lead to improved and more realistic policies and guidelines. This study on accessibility builds awareness and increases the understanding of the magnitude of this problem.

SURVEY OF WEB DESIGNERS

Web designers/developers were anonymously surveyed in April, 2006 to determine their knowledge of issues surrounding web accessibility, the degree to which their organization encourages the design of accessible web pages, and what metrics are in place to ensure that sites are accessible.

Research Methodology

A survey was developed consisting of twenty-two questions to determine perceptions of web accessibility for web designers/developers. The link to this online survey was sent to two mailing lists *(*highedweb-l@geneseo.edu and uwebd@listserver.itd.umich.edu*)* on April 17, 2006. The survey was also sent to a few web designers in Rochester, NY.

Results

There were a total of 161 responses to the survey; 53.42 percent were male, 45.34 percent were female, and 1.24 percent did not answer the gender question. The education level of the respondents was mostly college educated, with 93.79 percent being college graduates, and 32.3 percent of the total with graduate degrees. The age ranges are shown in Figure 1. The respondents were asked what percent of their job was devoted to design and development of web pages. Nearly 30 percent said that 96-100 percent of their job is web design/development. 18.63 percent said that it was 81-95 percent of their job. 16.15 percent responded that it was 61-80 percent of their job. 11.80 percent responded with 41-60 percent of their job, 13.66 percent said it was 21-40 percent of their job, and the remaining 10 percent said it was less than 20 percent of their job. Nearly thirty-seven percent of the respondents have had formal training specifically on web accessibility.

Because of the specific mailing lists that the survey was sent to, not surprisingly, 93.17 percent of the respondents were from educational institutions. When asked whether any websites they design are subject to a web accessibility policy, 49.07 percent responded "yes", 36.65 percent responded "no", 13.66 percent were "not sure" and 1 person did not answer the question. Unfortunately, data was not gathered to determine if the individuals were from public or private schools which would have been a better measure of whether they are subject to state policies on web accessibility, as public universities would be more likely to have to follow state policies.

When asked if their organization had a policy with respect to web accessibility, the responses are shown in Figure 2.

Figure 1. Age ranges of survey respondents

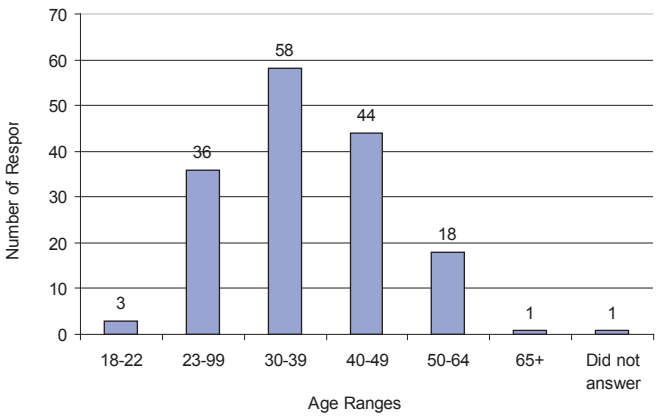

Figure 2. Does your organization have a policy?

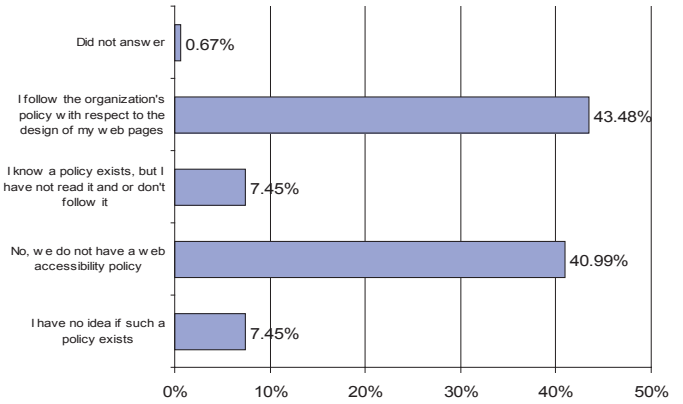

An interesting analysis is comparing those who said their web sites are subject to a web accessibility policy (49.07 percent) with answers to questions related to the actual design of their pages and how important the guidelines are to them. When asked, "How familiar are you with the World Wide Web Consortium's (W3Cs) Web Content Accessibility Guidelines (WCAG)?" the answer choices and percentage of respondents are shown below:

How familiar are respondents with the W3Cs WCAG?

0.62% I've never heard of them
15.53% I have heard of them, but don't really know the particular details
11.18% I'm aware of the guideline specifics but don't use them to guide my website design
47.83% I use them regularly but not consistently to guide my website design
24.84% I always ensure my web pages adhere to the guidelines

In summary from the last two questions analyzed, around 49 percent of the designers/developers surveyed have a policy governing their web pages; yet, only 25 percent always ensure their pages adhere to the Web Content Accessibility Guidelines or their policy.

Respondents were asked which software they used to evaluate their pages for accessibility. The most popular answers were: 62% used Bobby, 51% used browser toolbars, 35% used Lynx, 30% used JAWS, and less than 18% used any other software.

Bobby and the web browser toolbars were by far the most widely used. The browser toolbars are free and easy to use. They give quick feedback to designers because they can be easily docked in the browser window. Bobby is well known and reputable. Nearly eight percent of respondents reported that they have not used any of the software that is available to check for accessibility. When asked *what percentage of their pages* they check with at least one of the programs listed in the previous question, their answers were that only 13.04 percent of respondents check 100 percent of their pages. Roughly 20 percent check between 76-99 percent of their pages. Nearly ten percent of the respondents do not check any of their pages. This number differs from the amount of people that have not used any of the accessibility software which was eight percent.

Questions were asked that do not directly correspond to checking for accessibility, but relate to the topic. These questions related to whether the designers/developers check their pages on multiple browsers, if they check their pages on multiple platforms, and if they use ALT tags with their images. Surprisingly, only 44.10 percent of respondents check 100 percent of their pages on two or more browsers. This might be a result of the volume of pages they are responsible for, or that multiple pages are built on the same basic template or design and/or coding. Almost 30 percent of respondents checked 76-99 percent of their pages with multiple browsers. When asked which browsers they routinely check their pages with, the two most common were Internet Explorer (99 percent of respondents) and Mozilla Firefox (96 percent of respondents). Thirty-two percent of respondents check 100 percent of their pages on multiple platforms (e.g., Windows and Macintosh).

With respect to including ALT tags for images, 47.2 percent use ALT tags with all of their images and nearly 40 percent responded that they use ALT tags with 76-99 percent of their images. As seen in the degradation process, this may be that they do not use ALT tags on images that are used for design only and do not include content.

Question 4 of the survey asked respondents if they had ever viewed any of their web pages using assistive technologies. The results are presented in Figure 3.

When asked what percentage of content of their web pages were displayed requiring browser plug-ins, such as Flash or Shockwave, less than 37 percent of the respondents used these technologies to display any of their content. Only one person responded that 100 percent of their content used these technologies, and one other person said that 76-99 percent of their content used plug-ins. In the same line of questioning, respondents were asked: "What percentage of your pages do you ensure are usable when scripts, applets, or other programmable objects are turned off or not supported?" Only 9.32 percent responded that they do not use these technologies. Twenty-two percent of the respondents checked all of their pages to ensure they are usable without these technologies.

Question 13 asked about their perceptions regarding the importance of ensuring their web pages are accessible according to the W3C's Web Content Accessibility Guidelines, 57.14 responded with the answer "I try to make my pages accessible, but don't always have the time." Full responses to this question are shown in Figure 4.

Figure 3. Assistive technologies used to view Web pages

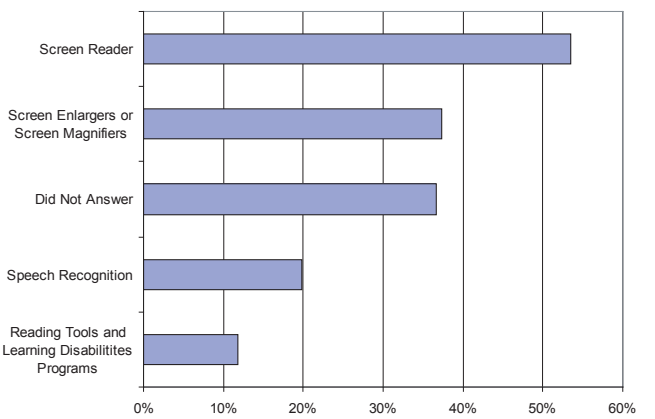

Figure 4. Perceptions about importance of accessible pages

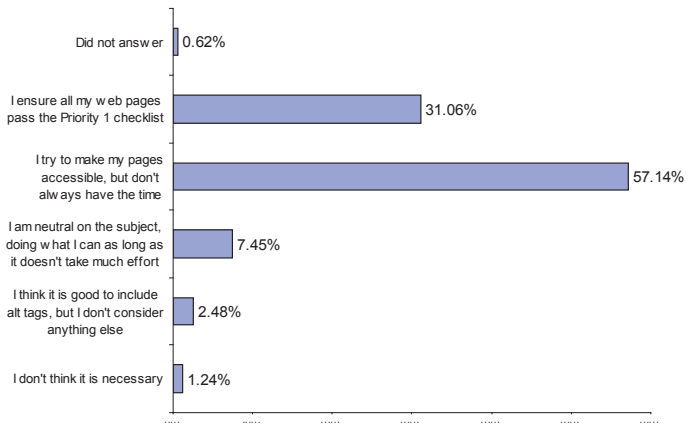

Finally, an important open-ended question was asked: "If you currently don't ensure your web pages are accessible, what factors would influence you to make your web pages accessible?" This question provoked fifty-nine responses. Many people answered that *time* was a major factor influencing whether they make pages accessible or not. Some people pointed out that the checklists are not easy to figure out. One person stated, "Wading through W3C verbosity is a pain." Others stated that organization policies are not in place for this and that customers expect results quickly or they will go elsewhere. There needs to be "an increasing awareness of how important it is for our target audience." Some individuals stated that they have or are moving to a content management system where their template will be developed that is accessible and then the content developers will not have to worry about this issue because it will be built into the template.

Many responses pointed to the fact that there does not seem to be a great development tool that adheres to the standards. They point to, "ease of use, better tools, cheaper tools, ease of checking, better software, additional resources, WYSIWYG editors that build-in fool-proof accessibility," and more. Dreamweaver and other software solutions are moving to build many more accessible standards into the software, like automatically creating a cascading style sheet in the background when using different fonts and font styles. Many features still require users to take the initiative to use them. For example, when inserting a picture in Dreamweaver, there is a box for the developer to add an ALT tag. However, there is not a warning or any action that occurs to alert the user if they do not use one.

Lastly, many people stated that there is not a clear message about web accessibility from their supervisors. They stated that they would put more effort into it if their supervisors told them they had to. One person wrote, "Support from management for making accessibility a priority – having their support is the only way it could happen. Without it, my time will continue to be taken up maintaining the old, less-accessible design. I *want* all my pages to be accessible, but don't have the time."

Accepting/Rejecting the Null Hypothesis

The Null Hypothesis (H_0) was: Web designers will ensure their web pages follow the WCAG if there is a policy governing the accessibility of their pages. The Alternative Hypothesis (H_1) was: Web designers will not ensure their web pages follow the WCAG if there is a policy governing the accessibility of their pages. As stated in the results, almost 49 percent of the web designers surveyed have a policy governing their pages, but only around 25 percent of them always ensure their pages adhere to the guidelines. Therefore, the null hypothesis is rejected.

SUMMARY AND RECOMMENDATIONS

Evidence shows that web pages governed by an organizational or state policy are more likely to be accessible than those that are not. Standards and legislation are having a positive impact on accessibility. However, a policy in no way guarantees that the sites are accessible. Of the web designers surveyed, all of them had heard of the Web Content Accessibility Guidelines (WCAG), but responses varied as to the extent to which they follow them or try to make their pages accessible. Many still feel the tools are inadequate, and the time and resources are insufficient. Based on this research, the following recommendations are suggested for executives in any organization:

- Create a policy for web accessibility and strongly encourage and support designers/developers in making pages accessible
- Regularly assess usability and accessibility of company websites
- Devote adequate resources – time, training, and software tools
- Educate employees, clients, and other stakeholders about this topic

One goal when creating websites should be universal design and access. This will only be achieved through education and increased awareness about this very important issue. If brick-and-mortar companies had signs on their doors stating that only certain people were allowed to enter, this would be apparent to them that this was wrong. The same awareness and understanding needs to be considered on the web.

It is a myth, at best, to believe accessible pages have to be plain or boring. Almost all accessibility guidelines deal with adding to the page, not subtracting (e.g., if you have an image, add an ALT tag). Designers/developers should strive to develop high quality pages visually, with all content intact and usable when viewed in Lynx. In addition, search engines are like blind users. An accessible page may even help a company get to the top of the Google list! Just as we have seen with buildings that have been modified for accessibility, everyone has benefited from elevators, ramps, curb cuts, and other accommodations. There are so many more reasons to create accessible pages. It cannot be stated enough that by making the web more accessible, everyone wins.

ABSTRACT

A use case description (UCD) is used to document detailed behavior of a use case in order to communicate its functionalities to different stakeholders related to the use case. A UCD plays an important role throughout software project's lifecycle. But there is no standard or widely-accepted approach for developing UCDs. They are developed based on the personal preference; both UCD formats and contents vary largely among different documenters. In this paper we present the seven-step use case documentation method. Our method integrates two writing rule sets and the three-level hierarchical use case evaluation method. The two writing rule sets cover syntax style and step rules that guide how to write each step in UCDs. The three-level hierarchical use case evaluation method helps use case developers evaluate UCDs from the overview level, the use case element level, and the sentence level. The recommended techniques of our paper is a synthesis of a thorough comparison of various UCD contents and formats discussed in literatures and our own experiences developed through a graduate Systems Analysis and Design class for many years.

1. INTRODUCTION

A use case approach is widely used to model system functionalities. A use case is a collection of success and failure scenarios in achieving a goal of an actor. A use case model consists of a *use case diagram* and a *use case documentation* (UCD). A use case diagram succinctly summarizes system behaviors from the point of view of actors. A UCD describes use case behaviors and functions in a narrative structured text file [1]. The documentation could be supplemented by diagrams such as activity diagrams and sequence diagrams. These diagrams provide a visualized flow of system interactions. The textual document, however, is the most common and understandable approach for UCDs [7, 8, 15].

A UCD is a communication tool which helps different stakeholders to understand the use case and provides supplementary information for system specification. As a communication channel, readability and understandable is the primary goal for a good UCD. Also since UCDs serve for software system specification, there are extra requirements than the regular text documentation. UCDs should clearly and completely depict system requirements for the specification. Narrative descriptions, however, usually tend to be ambiguous and lack a structure. There must be a set of coherent guidelines to direct documenters in content and structure selection.

A UCD plays an important role throughout software project's lifecycle. But there is no standard or widely-accepted approach for developing UCDs. They are developed based on the personal preference; both UCD formats and contents vary largely among different documenters [1-8, 11, 13-16]. In spite of the important roles of UCDs throughout the project's lifecycle, there have been only few guidelines for producing good UCDs. The lack of accepted guidelines makes both writing and assessing UCDs difficult. It is very difficult to ensure the proper information to be conveyed to all related stakeholders.

In this paper, we present the seven-step method for developing high quality UCD for a given use case diagram. Our method integrates *two writing rule sets* and the *three-level hierarchical use case evaluation method*. The two writing rule sets cover syntax style and step rules that guide how to write each step in UCDs. The three-level hierarchical use case evaluation method helps use case developers evaluate UCDs from the overview level, the use case element level, and the sentence level. The recommended techniques of our paper is a synthesis of a thorough comparison of various UCD contents and formats discussed in fifteen literatures and our own experiences developed through a graduate Systems Analysis and Design class for many years.

The rest of the paper is organized as follows. Section 2 first synthesize the previous work on methodologies for developing UCDs and then give a literature review. Section 3 presents the seven-step UCD development method. Section 4 concludes our paper.

2. A REVIEW OF PRACTICES ON UCDS

Our review on UCDs shows that there is no consensus on the well-accepted methodology for writing UCDs. Based on our reviews on literature as well as our own experiences, we believe that there are two aspects in improving the merits of UCDs as a communication and a specification tool: 1) a need for more concrete writing guidelines for UCD documenters; 2) a need for a methodology for assessing the quality of UCDs and removing mistakes.

2.1 UCD Writing Guidelines

A UCD writing process is no easy task since different writing styles may affect the usability and readability of the UCD. The review of the literature results in only a few simple writing guidelines. One notable guideline is the CREWS (Co-operative Requirements Engineering with Scenarios) Use Case Authoring Guidelines [3]. CREWS consists of eight specific rules. It is believed to be the most complete guideline available till now. But even these rules are quite abstract and hard to remember [4]. To further enhance usability, Cox and Phalp simplified the CREWS to a four step guideline called CP rules [5]. A summary of CREWS and CP rules are shown in Table 1. We will discuss how to remedy the limitations of CREWS and CP rules in Section 3.5.2.

2.2 Literature Review on UCD Evaluation Approaches

UCDs need to be assessed before they are used for system design and implementation. Some experts [6, 2, 7] mentioned that precision and clarity are key

Table 1. A summary of CREWS and CP rules [3, 5]

CREWS rules	CP rules
Style 1: Each sentence in the description should be on a new, numbered line. Alternatives and exceptions should be described in a section below the main description and the sentence numbers should agree. Style 2: Avoid pronouns if there is more than one actor. Style 3: No adverbs or adjectives. Style 4: Avoid negatives. Style 5: Give explanations if necessary. Style 6: All verbs are in present tense format. Style 7: There should be logical coherence throughout the description. Style 8: When an action occurs there should be a meaningful response to that action.	Structure 1: Subject verb object. Structure 2: Subject verb object prepositional phrase. Structure 3: Subject passive. Structure 4: Underline other use case names.

factors for assessment. But they are quite subjective and hard to measure. Most researchers provide simple guidelines on how to write a description. But none of them addressed the issue of evaluating the whole UCDs. More comprehensive criteria are needed to solve this issue. Our review found two types of evaluation methods: *Factor approaches* that address important aspects that a good UCD must meet and C*hecklist approaches* that lists questions for assessing a UCD.

2.2.1 Factor Based Evaluation Approaches

Cox and Phalp [5] proposed a method called 4-independent factors - *Plausibility*, *Readability*, *Consistent structure*, and *Alternative flows*. Later, Cox, Phalp and Shepperd [8] came up with a more concrete 4-C use case heuristics which address the communicability of use cases. The concept of 4-C consists of Coverage, Coherence, Consistency, and Consideration of alternatives. Phalp and Vincent further specified the 4-C heuristics into a 7-C approach [4] based on the empirical study they conducted. In the 7-C heuristics, every criterion consists of several sub-criteria. The 7-C heuristics include:

1. **C**overage: the use case should contain required information in relevant details.
2. **C**ogent: the use case has to be complete, logical path follows the correct order.
3. **C**oherent: the written styles should be coherent to be understood.
4. **C**onsistent Abstraction: use case should follow a consistent level of abstraction.
5. **C**onsistent Structure: alternatives should be separated from the basic flow.
6. **C**onsistent Grammar: Using simple present tense and avoid adverbs, adjectives, pronouns, synonyms and negatives.
7. **C**onsideration of Alternatives: alternatives should contain all the possible paths.

2.2.2 Checklist Based Evaluation Approaches

Though the 7-C approach is quite comprehensive, it lacks the requirements of how much details should be included in the UCD. A checklist based approach assesses UCDs from various users' perspectives: customers, designers and testers [9]. Another checklist approach to address the different users' requirements is 3-C checklists proposed by Copeland [10]. The 3-C represents Complete, Correct and Consistent. This approach is to test 3-Cs of a use case from the point of view of syntax, domain, and traceability:

- Syntax testing is to verify that a UCD contains correct and proper information. Copeland claims that more than half of the use cases failed syntax test in a project he conducted.
- Domain expert testing is to check whether the description meets the domain knowledge requirements.
- The traceability testing is to ensure that all the functional requirements are represented in the UCD and can be traced back.

3. THE SEVEN-STEP USE CASE DOCUMENTATION METHOD

Our review showed that there are only few writing guidelines and inspection methods available. It is necessary to propose a comprehensive and understandable method to documenting and assessing UCDs. In this section, we propose our seven-step UCD method which synthesizes existing rule sets and our own rules. Note that our method focuses on UCDs, rather than use cases themselves. Therefore, our method begins from developed use case diagrams.

Table 2. The outline of our seven step guidelines

Step 1	Understand actors and their goals
Step 2	Write use case goals in one phrase
Step 3	Write an overview description in a few sentences
Step 4	Define the precondition and postcondition
Step 5	Write the sequences of interactions
Step 6	Document non-functional requirements and other optional information
Step 7	Evaluate use case descriptions

We propose the following seven-step use case documentation method. It is a set of coherent guidelines covering UCDs from the very beginning to the end. Especially, our focus is on the Writing Rules and Evaluation method of UCDs. Due to the space limit, we only outline the steps without detailed examples. The seven steps of UCD development guideline are summarized in the Table 2. We discuss them in further details below.

3.1 Understand Actors and Their Goals

The first step in writing a UCD is to understand the actors and their goals. Knowing who the actors are and what their goals are help developers write steps of a UCD. Goals of an actor are high level responsibilities of the actor in the system. A goal should represent "what" of a responsibility, not "how" of the responsibility.

3.2 Write a Use Case Goal in One Phrase for Each Use Case

In this step, a developer states the goal of a use case in one phrase using the format of Verb + Noun phrase. This simple phrase will define the specific goal at a high level term to distinguish one use case from another. For example, if we have a use case named "Process Rents" in a video rental system, the goal phrase could be "To capture rental items along with payment."

3.3 Write an Overview Description for Each Use Case

The next step is to write a short summary of the actor-system interaction [11] in a few sentences. The brief description states an overview of what you are trying to achieve and the scope of the use case. At this step, use only business terms without any technology-oriented terms. For example, the overview description of the above use case could be "A store employee checks out rental items for a customer by calculating due dates and correct charges. The use case also includes checking for any overdue items. The store employee accepts payments for the items and any late payments. A rental slip is issued and kept by the store employee."

3.4 Define the Precondition and Postcondition

Preconditions and postconditons could help developers set up the boundary of the use case. These conditions would limit the sequences of interaction into a clearly starting and ending situation [11]. A use case that was performed earlier could affect the preconditions of the others; some use case is included or extended from others. All these relations will affect the content in a UCD. Before start writing the detailed steps, the documenter must understand the use case suite well and know relationships among the use cases so that relationships among use cases are represented and managed correctly, consistently, and completely. A good precondition is the one set by another use case if one needs to be executed after another.

Postconditions are lists of the conditions that must be true after the use case successfully finishes. Larman suggests that postconditions be documented in a passive and past sentence to represent what already happened [15]. Larman also recommends the following three types of postconditions – (a) objects that need to be created/deleted (b) data that need to be changed, and (c) associations that need to be connected/disconnected.

3.5 Write the Sequences of Interactions

The sequences of interaction are the major part of a UCD. It carries the communication and system design function of the UCD. We will give more focus in this step. There are three types of interactions.

3.5.1 Write the Main Successful Scenario

We begin with the main successful scenario first. It represents the most common and successful path. To identify the main successful scenario, we need to start from the triggering event, proceed step by step till the use case reaches the postconditions depicted before.

3.5.2 Write the Other Successful Scenarios

We then write other successful scenarios that refer to alternative scenarios. They are less frequently executed than the main success scenarios, but still achieve the goal of the actor.

3.5.3 Write Unsuccessful Scenarios

We then write other unsuccessful scenarios that refer to those scenarios that stop before the use case goal is achieved

The Two Writing Rule Sets for Developing UCDs

CREWS and CP rules as we reviewed before focus on the syntactic aspect but miss the specific guidelines such as how to develop each step; what information to record in each step; and what information to avoid. To address these issues, we present synthesized rule sets for writing steps, integrating the ideas of CREWS and CP rules as well as our own experience. We present the guidelines in the form of two writing rule sets as shown in Table 3.

Rule set 1: The Syntax Rules - Describe steps in a precise and unambiguous way

- *Use specific nouns*: Avoid using vague terminology like information, data [11]. Specify the data to be created, deleted, changed or associated [1].
- *Avoid pronouns*: If there is more than one actor involved in the UCD, using pronouns will confuse users on which actor this pronoun is referring to [3].
- *No adverbs or adjectives*: A UCD is to depict the goal fulfillment endeavors, not to write a story. Don't use any adverbs or adjectives like appropriate, required, relevant or sufficient [3, 11]. Using these adjectives make the sentence ambiguous.
- *Use straightforward and specific verb*: Avoid using verbs that have overloaded meanings such as get, keep, have, or do. Try to use specific verbs or associate an overloaded verb with an object as in *find a customer name*.
- *Using present tense*: Write in "present tense" to describe what the system does, rather than what it will do or already done [11].
- *Avoid negatives*: Document use case in affirmative way, don't use "not or no" in the description [3].
- *Using active voice*: Using direct and declarative statements started by an actor or the system [11]. For example: document a step as in "the system validates the amount entered" instead of "the amount entered should be validated by the system".
- *Avoid compound sentences*: Using simpler grammar [13], [4, 6] is recommended to adapt "Subject verb object" or "Subject verb objects prepositional phrase" style when documenting the flow of events.

Rule set 2: The Step Rules - Each step should be only one logical step towards the use case goal

- *Each step must be a goal-driven movement*: Describing the user's step at user interface level is one of the most common mistakes in recording use case steps. For example: "system asks for name, user enters name, system ask for address, user enters address" could be replaced by "user enters name and address" [6].
- *Each action should have a system response*: Any action is users' request sent to the system. Thus it should not occur alone, there must be a system response associated to it [3].
- *Each step must represent only one logical step*: State one logical step at a time. Do not combine two different steps that require a system interaction in one step. For example: "Search products and select the item" are two steps and should be documented in two steps because the system needs to display the output before the second action. [16]
- *Describe your steps in a general tone rather a special case*: The description should be general enough for all the possible variations in this step. For example: "Request one-year subscription" is a special case when applying for a subscription; it should be written as "Select the number of years of subscription." [16].
- *Describe in a right logical order of execution*. Steps should be documented in a logically meaningful order of execution to show step-by-step procession. For example, adding a shipping charge during "Process payment" use case is logically in a wrong order [16].
- *Do not include steps stated in the preconditions*. [16].
- *Do not use ambiguous expressions*. For example, the following are ambiguous steps. "Subscriber enters in demographic information" and "Establish subscription data" [16].

Table 3. A summary of the rule sets

Rule 1: The Syntax Rules	Noun	Use specific nouns
	Verb	Use specific verb; Use present tense; Avoid negatives
	Adverbs	No adverbs
	Adjectives	No adjectives
	Pronouns	Avoid pronouns
	Sentences	Use simple sentences; Use active voice
Rule 2: The Step Rules	Each step must be a goal-driven movement	
	Each step must represent only one logical step	
	Each action should have a system response	
	Describe steps in general tone rather a special case	

3.6 Document Non-Functional Requirements and Other Optional Information

For future references and improving understandability, non-functional requirements can be appended at the end of a UCD. Those non-functional requirements include business rules, performance requirements (response time and throughput), reliability requirements, usability requirements, security requirements, volume and storage requirements, configuration, compatibility requirements, backup and recovery, and any training requirements.

3.7 Evaluation of UCDs

A UCD must be evaluated before actual releasing. The evaluation team should include all the possible stakeholders such as users and designers. We believe that the UCD evaluation process should be an iterative process in which each iteration evaluates different aspects. In this section, we present *the three-level hierarchical use case evaluation method – overall level, use case element level, and sentence level.* Evaluation should begin from the overall level to the use case element level and then to the sentence level.

3.7.1. Check from the Overall Level

This level is to assess the overall structure of a UCD. Issues judged at this level are whether the UCD contains an appropriate level of details and the structure of the use case templates are appropriate. A good UCD should convey all the required information but with no redundancy. There are two major factors that affect the levels of detail:

- Stakeholders' concerns: check if the UCD meets concerns of stakeholders such as end users, developers, and the testers [9].
- Different viewpoints: Depending on whether we adopt an external (black box) or internal (white box) view will affect how much details we need to add to the document and what kind of use case formats we select.

3.7.2. Check from the Use Case Elements Level

The next heuristic goes down to use case element level. It is to test whether the elements included in the UCD are content-wise appropriate and structurally sound. The testing could be conducted using the following 3-C rules [10]:

- Cogent: check the logical paths of the UCD and determine whether it follows a logically correct way.
- Complete: check whether the UCD provides a solution to the problem and check whether the entire possible alternatives are recorded.
- Consistent: check whether the UCD follow the same level of abstraction. The numbering in the main flow and alternatives should also be consistent.

3.7.3. Check from the Sentence Level

After checking the correctness of the use case elements, the next level heuristic goes down to the sentence level. Are the descriptions clear enough for users' to

Table 4. The three hierarchical heuristics of UCDs

Overall	Does the UCD satisfy stakeholders' concerns?
	Is an external or internal viewpoint applied?
Elements	Cogent: Are the logic paths correct?
	Complete: Are all alternative paths included?
	Consistent: Are the levels of abstraction and numbering consistent?
Sentence	Check the syntax rules
	Check the step rules

read and understand? Does each sentence make sense to the readers? The rules we proposed in Section 3.5 could be applied here for evaluation.

The three hierarchical heuristics provide us with a more structured approach which allows users to assess the UCDs from general to specific perspectives. The evaluation from a higher level iteration to a specific level gives assessors priorities in the evaluation process. This could potentially improve the evaluation results and improve the usability of the heuristics.

4. CONCLUSION

In this paper, we have presented guidelines for developing quality UCDs. We have presented the seven step method for writing UCDs for a given use case diagram. Our method incorporates two sets of rules for writing UCDs. Our first rule set, the syntax rules, describes the syntactic guidelines of sentences. Our second rule set, the step rules, shows the guidelines for writing each step specifically in UCDs. Our method also includes the three-level hierarchical use case evaluation approach– from the overview level, the use case element level, and the sentence level. The recommended techniques of our paper is a synthesis of a thorough comparison of various UCD contents and formats discussed in literatures and our own experiences developed through a graduate Systems Analysis and Design class for many years. We believe the methodology we proposed could serve as guidelines for UCD developers and help them to generate higher quality UCDs.

Temporal Categorization for Data Organization

Behrooz Seyed-Abbass, University of North Florida, 4567 St. Johns Bluff Rd S, Jacksonville, FL 32224, USA; E-mail: abbassi@unf.edu
Patrick O. Crews, University of North Florida, 4567 St. Johns Bluff Rd S, Jacksonville, FL 32224, USA; E-mail: gleebix@gmail.com

ABSTRACT

Temporal databases are designed to handle records that are time-oriented. While the additional dimension produces data that is rich in meaning, capturing this history results in large volumes of data that are rarely used. Previous research has found that the additional data can impair system performance when attempting to use temporal databases as operational systems. This paper presents work done in an area that the authors have termed, temporal categorization, which involves a method of data organization that groups records according to their unique temporal semantics. The initial testing on temporal categorization indicates the potential to effectively improve system performance as related to time-oriented data.

Keywords: Temporal Databases, Data Organization, Temporal Categorization, Database Performance

1. INTRODUCTION

While there are many ways of associating time with a fact, most temporal research only considers two time dimensions, valid times and transaction times, to be significant [1]. Valid times capture the history of a real-world object. Systems that handle this dimension of time are known as historical databases. Transaction times capture the history of a fact within the database itself and are handled by rollback databases [2]. Previous research has shown valid and transaction times to be orthogonal [3], but it has also been acknowledged that both of these dimensions are necessary to provide complete temporal functionality. Complete temporal systems are known as bitemporal databases due to their use of both time dimensions [4]. The following example illustrates a fictional, bitemporal employee database.

A company hires a new employee named Bob. He begins work on 1/1/2000 as an Engineer and is entered into the system on 12/30/1999, but is mistakenly listed as a Managing Engineer. This mistake is caught and corrected on 1/5/2000. Six months after being hired, Bob is promoted to the rank of Senior Engineer. Finally, Bob will be automatically promoted to the rank of Supervising Engineer one year after becoming a Senior Engineer.

Table 1 demonstrates how this data would be captured in a bitemporal database. Part A is the initial state of the system. Part B shows the table after Bob's title has been corrected. There are now two records in the system, the erroneous record that has been retired and the corrected record that is now active. Part C is the system after Bob's promotion to Senior Engineer. The Bob/Engineer record that was active in Part B has been retired and an updated version with a definitive Valid_To date inserted into the system. The predictive record of Bob's promotion to Supervising Engineer has also been inserted. It has the same Trans_From time

Table 1. Bitemporal employee database

Part A

Emp_Name	Title	Valid_From	Valid_To	Trans_From	Trans_To
Bob	Managing Engineer	1/1/2000	12/31/9999	12/30/1999	12/31/9999

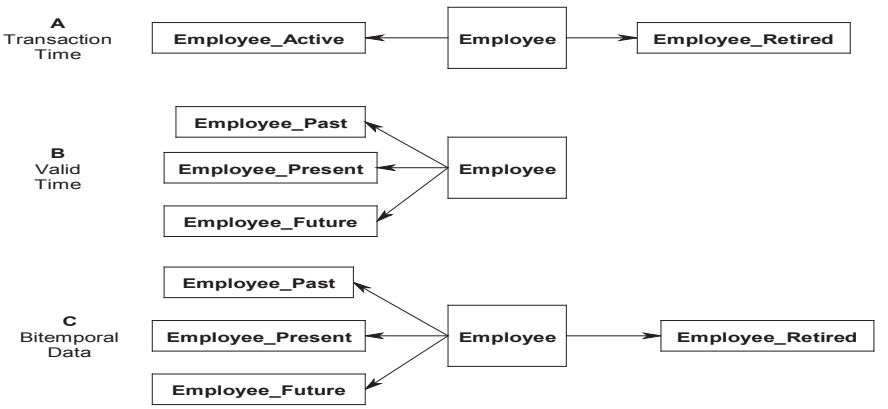
Part B

Emp_Name	Title	Valid_From	Valid_To	Trans_From	Trans_To
Bob	Managing Engineer	1/1/2000	12/31/9999	12/30/1999	1/4/2000
Bob	Engineer	1/1/2000	12/31/9999	1/5/2000	12/31/9999

Part C

Emp_Name	Title	Valid_From	Valid_To	Trans_From	Trans_To
Bob	Managing Engineer	1/1/2000	12/31/9999	12/30/1999	1/4/2000
Bob	Engineer	1/1/2000	12/31/9999	1/5/2000	6/30/2000
Bob	Engineer	1/1/2000	6/30/2000	6/30/2000	12/31/9999
Bob	Senior Engineer	7/1/2000	6/30/2001	7/1/2000	12/31/9999
Bob	Supervising Engineer	7/1/2001	12/31/9999	7/1/2000	12/31/9999

Figure 1. Temporal categorization



as the Bob/Senior Engineer record and both are considered active in the database even though the predictive record has not yet become valid.

The use of bitemporal data clearly adds semantic depth. A user is able to track when a record was entered into the system and when a record was updated or retired, as well as the history of the data in relation to the real world. Unfortunately, this depth comes at a price. The results of the large number of stored records have been shown to negatively impact data retrieval and insertions [5][6][7]. This is particularly true when the database user wishes to focus on records that are currently true in both the real world and the database.

Preceding approaches for dealing with the large number of stored records range from the use of external storage to the implementation of high-performance indexes. One of the first solutions identified the impact of mingling active and retired data in a single system**,** which is comprised of a two-level store to segregate active and retired data [5]. However, the work did not extend to bitemporal systems or to more complicated queries. Another approach focused on using external storage for retired data [8]. While this does allow for the maintenance of active and retired data, it does not permit queries against all data within a system and thus severely limits bitemporal functionality. The use of specialized temporal indexes has also been explored [6]. These high-performance data structures are tailored to the challenges of bitemporal systems, but they also require kernel level changes to the database and are unlikely to be used until they are incorporated into commercial database management systems.

This paper describes a proposed extension to the two-level store where the records are physically separated for categorization according to their temporal semantics by transaction time (active versus retired), valid time (past, present, and future), or a combination of both (sorting active records by valid time and keeping retired records separate from the active ones). The next two sections present an overview of the proposed temporal categorization and considerations related to the database and query processing requirements. Section 4 discusses the initial implementation findings followed by conclusions and recommendations for future work.

2. TEMPORAL CATEGORIZATION

Adding one or more dimensions of time to a database results in increased time for query processing [5][6][7]. This can be attributed to several factors, including the enforcement of temporal constraints and the additional volume of records produced by maintaining historical information in the database [9]. This research work proposes a method, referred to as temporal categorization, of organizing temporal data to alleviate the query processing issues resulting from numerous records. In temporal categorization, the records in a table are physically separated and grouped according to their temporal semantics. The technique involves the creation of separate tables (or storage spaces) for the temporal categories of active and retired in transaction time and valid time.

2.1 Transaction Time

Transaction times are the history of a record within the database. The time values define when a record was entered into the database and when the system stopped regarding it as being true. Therefore, only two semantic categories are defined by transaction times, records that are active and records that are retired. For example, the Employee from Table 1 would be separated into Employee_Active and Employee_Retired. The separation of the records is illustrated in Figure 1 A.

All records are considered true when they are first inserted into the system. This status changes only when a record is updated or deleted. In a transaction time system, a delete operation does not physically remove data from the system. Instead, it is logically deleted [2]. This means that the data remains within the system, but it is marked as inactive and no longer true. The system marks retired data by having a Trans_To value that is less than the current time. Updating a record results in its original form being retired while the newer version of the data becomes what is considered active by the database. An update can be considered to be a combination of a delete transaction and an insert transaction.

2.2 Valid Time

Valid time describes when a fact was true in the real world and creates three possible categories for a record. It was true in the past, it is true in the present, or it will be true in the future [2]. Categorizing records by these semantics is more complicated than using transaction times. This is due to the possibility of present and future records changing their categories. Present records may cease to be true and be moved to the past category. Future records may become true and be moved into the present category.

Figure 1 B presents the categorization of records according to valid times. The records are separated into past, present and future groups. While one cannot truly predict what the future state of an object will be, there are many instances where it is useful to store the predicted state of an object. The inclusion of predictive records is not a requirement for a valid time database, but they do represent a semantic possibility of this time dimension [10]. Therefore, they are included in the proposed valid time categorization.

What makes the valid time changes so challenging is the fact that these recategorizations are not due to user (or system) action alone. They can also result from the passage of time in the real world. The present is always moving and a record that is valid now might not be valid after a few minutes. A database that employed this scheme would need to regularly check future and present records to see if they require a change in category in addition to monitoring the effects of any user updates. There is also the possibility of not having enough records to justify the overhead of categorization. The use of this type of categorization would be decided by how many objects were modeled in the database, how much history (or future) each object had, and how many states were allowed for an object at any point in time.

2.3 Bitemporal Categorization

Figure 1 C presents a possible organization for bitemporal categorization. All active records would be categorized according to their valid time semantics (past, present, or future) and would keep any retired records in a separate group. Further categorization of a bitemporal table's retired records was considered, but it was decided that this might be ineffectual because many queries against a particular state of the database (other than current active data) would fall outside of easily defined temporal categories. Trying to presort the data for every possible temporal query would not be constructive.

3. CONSIDERATIONS FOR CATEGORIZATION

Categorization of temporal data has the potential to improve database performance as related to query processing time and to the complexity of temporal queries. The records in a bitemporal database system throughout time will change by update operations to retired and active records. Over time, the database collects a significant volume of retired records, making the overhead of the temporal categorization process worthwhile. Several possibilities for handling the time-based update and query retrieval have been contemplated.

3.1 Database Categorization

One possibility would be to poll the present and future records at the time of a user query similar to the standard SQL column, shown in Table 2. However, this could severely impact query performance because the system would have to check all of the records for the categorization condition based on the user=s request, particularly when the table grows with retired and valid record over a period of time.

A second possibility would be to maintain the time value of the next shift in categories, such as the earliest Valid_To time in the present group or the earliest Valid_From time in the future group. The system could then reclassify the affected records at the proper time. Unfortunately, any updates, insertions, or deletes would require the system to update its list of update times since these actions could render it inaccurate.

Another option would be for the database to poll the present and future groups at a given time interval, recategorizing as necessary. This approach is highly dependent on the granularity (or level of precision) of the valid time values. If the valid times are only precise to the day, the database could check the tables at the start of each new day. If the valid times were of microsecond granularity, the database would be doing nothing but polling the tables.

3.2 Query Categorization

In practice, if one table is used for holding active and retired data to provide a simple and more optimized query processing, a flag field can be set to mark the retired records. The flag field may be hidden from the users. It is activated and set to retired during the Update and Delete operations according to the semantics. The SQL data manipulation commands would use the flag to access only retired or active records in an optimized approach. To retrieve all the retired records from Employee table as in Table 1 C, a user may execute the following command.

SELECT * FROM Employee WHERE CATEGORY = RETIRED;

CATEGORY may use the options of [RETIRED | ACTIVE] for transaction time to select the correct category of the records from the table.

The active records in the table may be extended into past, present or future categories. In this case, a more comprehensive flag and temporal semantic comparison methodology can be used and the flag can be set to refer to different category domain of past, present or future. To access a particular category domain, the temporal SQL command uses the reserve word CATEGORY with any of the [PAST | PRESENT - CURRENT | FUTURE]. A command could be used to select particular domain as well as search for a conditional semantic value related to date or any other simple or compound condition. Table 2 shows several SQL categorization examples using the fictional Employee table in Table 1 with the query and the SQL that would produce the desired results in a standard system as well as a theoretical database using the proposed temporal categorization.

4. INITIAL IMPLEMENTATION OF TEMPORAL CATEGORIZATION

Physically separating current and historical records to improve system performance across a broad range of temporal queries would be a result of having multiple smaller tables for the system to query rather than one large table. Additionally, having the records separated by temporal semantics eliminates the need for evaluating each record=s timestamps in certain cases. Consider a system where records are categorized by transaction times. If a user wished to search only active records with a Trans_To time of 12/31/9999, the database would not need to test the Trans_To values of each record. It could just run the query against the active data set, ignoring the retired data completely.

To test the possible benefits of this categorization methodology, a simple experimental prototype system with separate tables to support retired and active records was constructed. As records were retired via Update or Delete actions, they were moved into the retired table. The data in these experiments consisted of a single key value coupled with valid and transaction times that tracked an object=s status through a period of time. While this cannot be considered representative of all bitemporal data, it does represent one of the more common applications of temporal databases. Each Insert represents a new state and requires an Update or Delete

Table 2. Comparison of queries across temporal systems

Results	SQL (standard)	SQL (categorized)
All data in the table	SELECT * FROM Employee	SELECT * FROM Employee
All active data in the table	SELECT * FROM Employee WHERE Trans_To = '12/31/9999'	SELECT * FROM Employee WHERE CATEGORY = ACTIVE
All current, active data in the table	SELECT * FROM Employee WHERE Trans_To = '12/31/9999' AND Valid_From < Current Time AND Valid_To > Current Time	SELECT * FROM Employee WHERE CATEGORY = CURRENT AND ACTIVE
All past, active data in the table (interchangeable with future)	Select * FROM Employee WHERE Trans_To = '12/31/9999' AND Valid_To < Current Time	SELECT * FROM Employee WHERE CATEGORY = PAST AND ACTIVE
All active data that was valid within a specified time period (valid for any part of interval)	Select * FROM Employee WHERE Trans_To = '12/31/9999' AND Valid_From < *Start Time* AND Valid_To > *End Time*	SELECT * FROM Employee WHERE CATEGORY = ACTIVE AND Valid_From < *Start Time* AND Valid_To > *End Time*
All data that was valid at a particular point in time for the database	Select * FROM Employee WHERE Trans_From < *Time* AND Trans_To > *Time* AND Valid_From < *Time* AND Valid_To > *Time*	Select * FROM Employee WHERE Trans_From < *Time* AND Trans_To > *Time* AND Valid_From < *Time* AND Valid_To > *Time*

of the current one. The design choice was made to monitor temporal constraint performance as well as query times.

To allow greater flexibility in searching the records, the actual values were also tested in addition to the keyword indicator, such as active or retired, as shown in Figure 1 and Table 2. This provided the capability to test records that were retired after a given date rather than only retired records. The system determines which tables to run against by examining the Trans_To value in the query. If the value matches the placeholder to signify activity, only the active table is searched. If the Trans_To value is something other than that placeholder, it means the record has been retired and only the retired table is used. A single evaluation is performed against the queries Trans_To value, in contrast to the standard system=s need to compare each record=s data against that of the query.

An experimental prototype system was designed to handle the transaction time with active and retired data in combined and separate tables. The performance analysis was focused on transaction time categorization due to its comparative simplicity of result and ease of implementation. Additionally, a combination of Insert/Update/Delete operations were implemented. These operators were built to test the insertion of new versions of real world data and the act of a record's current state becoming real world inactive. A control system was also implemented as the standard system. This system contained all of the functionality of the experimental system minus the categorization. Both systems were built from scratch in an effort to ensure more effective comparisons between systems. They were implemented using the Python programming language.

A collection of queries was designed and run against the standard and experimental systems. The performance data for the queries were collected and averaged. These queries were designed with various business rules and settings for different scenarios that are summarized in following cases. For each case, the queries for the data status involved three levels: all, active after a particular date and active between specified dates.

Case 1: Database records with active status
Case 2: Database records with active status after certain date
Case 3: Database records with active status between date intervals
Case 4: Database records with active and retired status

The performance and results of these queries for different numbers of records were collected and tabulated for both the standard and experimental system, and then averaged. The averaged comparison diagram is shown in Figure 2. It was observed that the categorized experimental system outperformed the standard system in every query category. Figure 2 shows a sample of the average system performance for all different queries used in cases 1-4. The data clearly shows the categorized system's performance to be significantly faster.

Figure 3 shows the insertion times required for various numbers of records in both the standard and experimental system records. The experimental system shows improved performance. It is suspected that this is due to not needing to test whether or not a record is active or retired before testing for any temporal constraints on a table.

Finally, in terms of data storage, there was a constant difference between the systems. The experimental systems showed a difference of approximately 30 additional bytes for any number of records, which appeared to be related entirely to the additional data structure used for holding retired data. The number of records stored did not affect the size difference.

Figure 2. Average query performance comparison

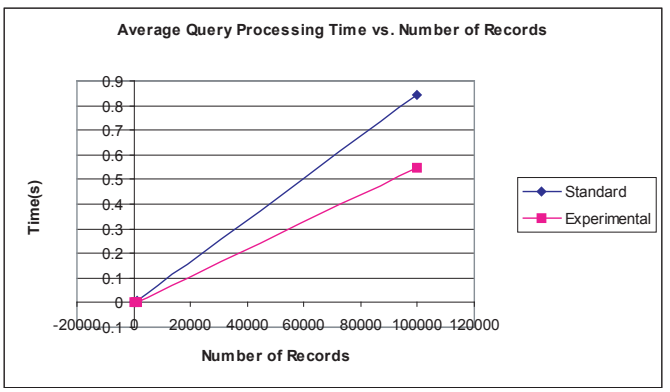


Figure 3. Comparison of record insertion times

5. CONCLUSIONS AND FUTURE WORK

This paper has presented an overview of the authors' current research work on temporal categorization, which was developed as a proposed solution to the problem of how to deal with the large volumes of data that are produced by adding one or more time dimensions to a database. While alternate methods have been suggested, these have typically involved using secondary storage and do not allow for immediate access to the data. By physically separating records according to their temporal semantics, temporal categorization may produce improved query performance due to the smaller volumes of data that must be searched as well as the reduced number of comparisons that must be made in order to find the desired data. This is especially true when dealing with those records that are active and defining the state of objects in the present.

The initial experimental system demonstrated promising performance gains in terms of data retrieval and insertion operations. Even those queries that were expected to show reduced performance were completed more quickly for the categorized system. Additionally, the improved query run times came at the cost of constant storage overhead, which the authors view as a minor cost in comparison to the benefits. In light of these initial findings, temporal categorization can be seen as a viable possibility for temporal data organization. The technique promises improved query processing times and faster data insertion / update transactions for a minor storage cost. The next steps will be to implement this technique in a more robust database system and to explore additional prototypes for temporal semantic categorization.

Future work will consist of evaluating the feasibility and performance of the temporal database categorizations for storage space requirements, insertion and update times, and data retrieval operations for different combinations of temporal criteria. The authors are also interested in seeing how this technique would compare to temporal indexing as a performance enhancement technique. Additionally, it would be worthwhile to examine a wide variety of temporal data sets to better understand how real-world users are storing time-associated records. Finally, the question of valid time categorization must be addressed. This topic will be examined in terms of implementation performance as well as which patterns of database usage will be best suited for these techniques.

ABSTRACT

People usually communicate through multimodal dialogue. Multimodal interaction is in fact flexible and natural because it uses all five senses in parallel. For this reason we need to consider multimodal language definition and processing adopting the techniques and approaches used in Natural Language Processing (NLP). We describe the characteristics of a multimodal language by NLP, considering that the speech mode appears to be the most complete (it is considered the predominant mode). Users communicate and interact through reference to a set of key concepts. These can be expressed with different modes and/or by more than one mode simultaneously. When defining a multimodal language, these key concepts must be extracted. They are then processed using a natural language approach: any concept expressed in any mode can be "translated" into natural language. This implies that speech acts as a "ground layer" that all the modes refer to. We propose a tool to define multimodal languages, which allows the user to define the language in his/her own way to express concepts of a particular domain in the different modes.

Keywords: Multimodality, multimodal language, fusion, ambiguity.

1. INTRODUCTION

The purpose of this paper is to identify characteristics of multimodal languages in order to design a tool that enables the user to define them in some specific contexts. For instance, a possible case is the use of formal graphic models such as Unified Modelling Language (UML) and Entity-Relationship (E-R) diagrams during a project meeting. A second case is the use of tourist maps with which the user can interact to ask for information on restaurants, museums, theatre schedules, transport and so on through multimodal interaction on mobile devices.

A multimodal language is a language that allows people to communicate with a system synergistically through multiple modes (i.e. speech, sketch and writing).

In several contexts, such as those cited above, speech is the most complete (predominant) mode (users tend to explain everything orally, using other modes to support what they say). By predominant mode we mean the mode the system first refers to. It considers other modes only if it needs to solve any ambiguous or incomplete cases.

For this reason we need to consider the definition and processing of multimodal languages according to the techniques and approaches used in Natural Language Processing (NLP).

The study of a synergistic system cannot be separated from the study of the way a machine processes the natural language, i.e. Natural Language Processing (NLP). This presents many problems, the biggest of which is language ambiguity. Oviatt et al [1] explored whether a multimodal architecture can support *mutual disambiguation* (MD) of input signals. Mutual disambiguation enables recovery after unimodal recognition errors, leading to a more stable and robust performance, as it permits the strengths of each mode to overcome weaknesses in the others [2].

Oviatt [3] also highlighted the differences between unimodal and multimodal communication with respect to the structure of spoken language. Sharon Oviatt & Karen Kuhn showed that multimodal language differs from spoken language in its brevity, semantic content, syntactic complexity, word order, disfluency rate, degree of ambiguity, referring expressions, specification of determiners, anaphora, deixis and linguistic indirectness.

Qiaohui Zhang et al [4] handle ambiguity by using gaze information to integrate the user's speech input. If multiple objects are chosen simultaneously due to an ambiguous description, the one closest to the gaze fixation will be the multimodal result.

The ambiguity issue is addressed in [5] by designing a multimodal agent for route construction (MARCO).

This paper discusses both NL disambiguation and multimodal user interfaces. [6] presents studies on the combined use of different input modes. A component-based approach to specify and develop multimodal interfaces using a mode-independent fusion mechanism is described in [7].Michael Johnston [8] describes a multimodal language processing architecture in a unification-based grammar formalism.

Sections 2 and 3 summarise our approach to and problems related with fusion at the multimodal language level and the natural language processing approach in a multimodal environment. Sections 4 and 5 describe the system to define the multimodal language and in section 6 we draw some conclusions.

2. FUSION AT THE LANGUAGE LEVEL AND DEFINITION OF THE MULTIMODAL LANGUAGE

The synergic integration of the system's various input channels can be achieved in several ways. One possibility is to consider the input channels separately and then merge them [12]. An alternative approach is to carry out the integration during the definition of the multimodal language. This requires the capture of its characteristics using natural language and an understanding of the intrinsic nature of natural language; i.e. rebuilding of the language structure and consideration of how the same concept can be expressed by different input types and how implicit references (deictic expressions) can be solved. A deictic expression refers to the personal, temporal, or spatial aspect of an utterance; its meaning therefore depends on the context in which it is used. Examples of deictic expressions are "this", "that", "here" and "there".

When defining a multimodal language some key concepts for a particular domain are extracted. These can be then expressed in different modes, but are processed with a natural language approach. Any concept expressed in any mode can be "translated" into natural language. This implies that natural language acts as a "ground layer" that all the modes refer to, making speech the predominant mode and the key to the fusion of different modes.

Our study therefore involves NLP to understand how to obtain information from a text analysis and exploit it alongside other information conveyed by other modes, thus demonstrating the approach to solve such problems in a multimodal environment.

Through this approach, the definition of the multimodal language can be divided in two phases: the first is parsing-driven, the second oriented to tangible representations of linguistic experiences.

In the first phase some key concepts (expressed according to the various modes) are identified. They are encapsulated in structures (templates), which constitute their "frame" and define the language giving semantic value to what the user says or draws. A template is a syntactic structure consisting of concepts (expressed in the various modes) and syntactic categories, which are assigned with a given semantic value.

Each user action can match one or more templates. However, the multimodal language is not produced from a rules set but from a sentence analysis set - it is deduced from the spoken language. This helps to locate and eliminate syntactic ambiguity, as admissible syntactic structures (at the parsing level) that do not belong to the admitted structures set are not considered.

3. NATURAL LANGUAGE PROCESSING AND MULTIMODALITY

The first step we took was to discover how to pick up information produced by the user from the speech channel.

The study of NLP is important because we use natural language as the basis of our approach to fusion: the speech mode is predominant, while the others are used as a support when needed.

Most human communication is through speech, though in some cases the use of other modes makes it simpler to understand one another and convey concepts: this improves synthesis and precision, especially when relevant concepts need to be communicated.

NLP is thus the starting point for fusion. However, understanding a language involves - among other things - knowing what concepts a word or a sentence stands for and how they are related. The use of other modes therefore plays an important role in helping to solve problems that often arise in natural language comprehension.

In the following section the levels of NL understanding are discussed and some problems related to NLP are described from a multimodal point of view, i.e. with the help of other input channels.

3.1 Levels of Natural Language Understanding

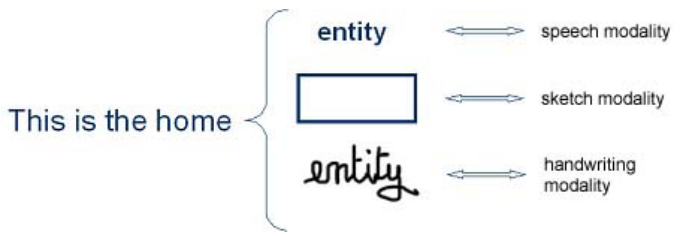
To process natural language a machine has to receive inputs from other modes and have a comprehension of natural language at different levels.

To determine what a user is saying, the system has to analyse an incoming audio signal and recover the exact sequence of words that the user used to produce that signal. This task requires knowledge of phonetics and phonology. The system also has to recognise word variations and contractions (morphology). Furthermore, a syntactic knowledge of the language is necessary to understand which word order makes sense. To this end, we used a statistical lexicalised parser that effectively solves the ambiguity problem. How this is done is explained below.

Understanding the nature of a request requires knowledge of the meaning of the words making up the sentence (lexical semantics) and the ways they can be combined to make a meaningful sentence (compositional semantics).

At this level, we used the information conveyed by the other modes: the key point is that the same concept can be expressed in a number of ways, which must be considered as semantically equivalent. This assigns a semantic value to the user's actions. The semantic side is therefore handled at different levels: first, at the level of each single mode, then at the multimodal level, when the modes are considered synergistically.

Figure 1. Example of the definition of an association in the E-R diagram scenario



The resulting multimodal language consists of these associations among different ways of expressing the same concept. This allows the problem dealt with at the fusion level to be solved at a language level. For example, in Figure 1, the sentence:

"this is the home entity"

has the same meaning as saying:

"this is the home" while drawing a rectangle,

once the entity concept and the rectangle shape have been associated.

A higher level of natural language understanding is founded on pragmatics, i.e. the knowledge of how words are used in everyday life to make conversation easier. This level is dealt with through deictic expression handling.

Some problems which arise in NLP are described below. We will see how the synergistic use of other modes supporting speech can help solve them.

Ambiguity is one of the biggest problems for NLP. First, it increases the range of possible interpretations of NL, and a computer has to find a way to deal with this. There are various types of ambiguity. These include category ambiguity, in which there are a number of grammatical terminal symbols for the same word; for instance, the word "time" can be both a noun and a verb. This can sometimes be resolved by syntactic analysis.

Another type of ambiguity is related to the meaning of a word, which may correspond to only one terminal but a number of different concepts. In fact, many words have more than one meaning; we have to select the meaning that makes the most sense in the context. Temporal observations are essential for this purpose: if a word (speech mode) appears to be ambiguous, it is possible to examine the other modes to rebuild the user's original intention.

A third type of ambiguity is structural, and consists of the existence of more than one parsing of the same sentence. For instance, the sentence "choose between A and B or C" has two possible interpretations:

1. [A] and [B or C]
2. [A and B] or [C]

Referential ambiguity arises when a language does not specify to which word an adjective refers. For instance, the sentence: "pretty little girls' school" can have various interpretations: the school is small, the girls are small, the girls are pretty, the school is pretty.

The use of more than one mode can help to resolve the syntactic and semantic ambiguity in the speech mode: considering speech as predominant, the other modes are called in to clarify the meaning of any ambiguous or incomplete sentences. Any ambiguity in the speech can be disambiguated by examining the information provided by the other modes to obtain the sense of the sentence.

Some types of ambiguity arise at the very moment that other modes are introduced. These are described below:

Ambiguity Caused by Deictic Expressions

Even if deictic expressions (and references in general) can help directly identify what the user is referring to, they can also be a source of ambiguity. When a user pronounces a deictic expression, it is not always clear if s/he is referring to something said previously or something that s/he has drawn or is drawing. The problem gets even more complex in the common situation that the user draws a figure while explaining what s/he is drawing using deictic expressions that do not refer to the figure directly. For instance, if the user says: "And this is the solution to this problem" while drawing a symbol matching a concept, the system has to understand that only the first deictic expression refers to the drawn object, while the second refers only to the discourse, without involving any modes other than speech.

The risk that deictic expressions will create ambiguity in a multimodal system is also related to another factor - their vagueness. In fact, people are not used to specify precisely what a deictic expression refers to, and so the system often has

insufficient information to understand what the user means. The use of temporal windows can be of help: if the user draws an object, the deictic expressions pronounced in a certain temporal interval refer to such object.

Structural Ambiguity

This arises when different multimodal inputs overlap, causing an incorrect interpretation of the user's action.

Let us consider the following example: a user pronounces the sentence "This is the home". Suppose that at this point, the system expects either the concept of entity or that of relation (expressed in any mode). The user may draw the object corresponding to the concept of entity (a rectangle) and at the same time carry on expressing the concept of relation in another mode:

This is the home, *the relation now has to be found.*

If the sketch of the rectangle temporally overlaps the pronunciation of the word "relation", it is not clear if "house" is a relation or an entity.

4. THE SYSTEM ARCHITECTURE

Starting from NLP approaches according to a set of concepts in an application domain, we have designed and implemented a software tool, which provides users with the functions to define a multimodal language.

The system consists of two environments: in the first, the user can define the language in his/her own way to express concepts in the different modes (in our case speech and sketch); in the second, s/he can use the language to interact with the multimodal interface.

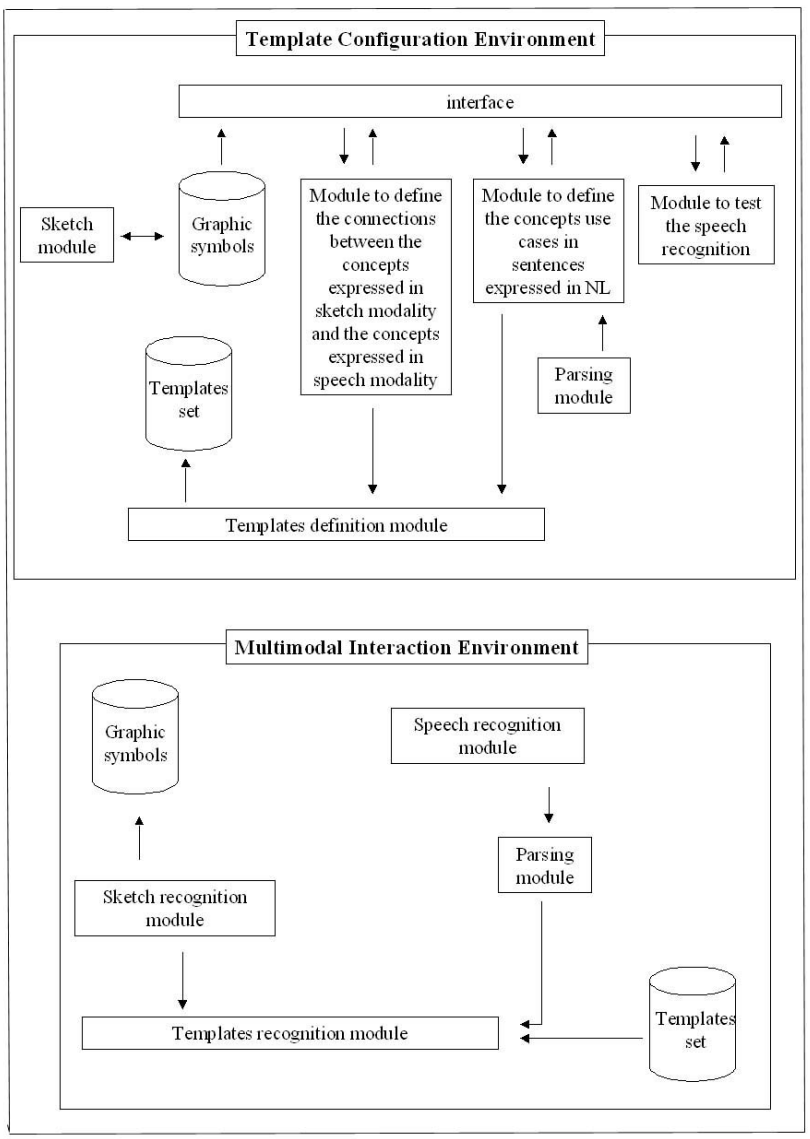
The definition environment is immersed in the fusion system, so that the user can switch from one environment to the other at any time.

The configuration environment has the aim of defining a set of structures - the templates - that enable the multimodal interaction to be processed.

Templates are defined through the following steps:

1. concept definition
   The user locates some concepts s/he thinks are relevant for his/her aim. For example in a E-R diagram definition, the user may locate the concept of entity.
2. correlation of concepts with "signs"
   Once the concepts have been defined, the user provides a sign to represent

Figure 2. The system architecture



these concepts in the speech and sketch modes. For example, the user may connect the concept of entity with the string "entity" (speech mode) and the rectangle (sketch mode).

3. correlation between signs
   The user is required to define a set of use cases (strategy "by example") for the relevant concepts in natural language. For example, the concept of entity is used to create a new entity, the user provides the example "this is the home entity".
4. template learning
   The system generalises the use cases provided in the previous step and builds the template set. It therefore:
   - assigns any deictic expression to the "deictic" category ,
   - replaces the concept with the related signs,
   - replaces any other word with its syntactic category.

In the example, the template obtained will be:

Deictic + VBZ + DT + NN + ("entity" or rectangle)

The template can thus be defined as the syntactic structure of an NL expression of a use case of the relevant concepts. It can then be used to interact with the multimodal system, in which the user can draw and speak at the same time.

A vocal recognition tool writes what the user says on a text editor, while a sketch recognition tool works on the user's drawing. The system makes the fusion between the two signals, recognising any matches between what the user said/drew and the template set. The two input streams are compared on temporally and according to the templates to see if they are complementary or redundant. For example, the multimodal dialogue may contain the following speech:

.....that, well, is now a new entity, the employer (rectangle)

The system architecture is summarised in figure 2: the configuration environment consists of an interface, which communicates with a graphical symbols set and with:

- the module to connect concepts with "signs",
- the module to provide use cases of the concept in NL,
- the module to test the template recognition algorithm.

These modules communicate with:

- the sketch module, which communicates with a graphic symbols library,
- the parsing module [13] which communicates with the module to define the use cases which define the template set,
- the module to define the templates, which communicates with the module to define the connections and the one to define the use cases. This module creates a set of generalisations of the use cases, i.e. a set of templates.

To define the template set, the use cases are provided as input to a natural language parser (in fact use cases are expressed in natural language).

Figure 3. The system

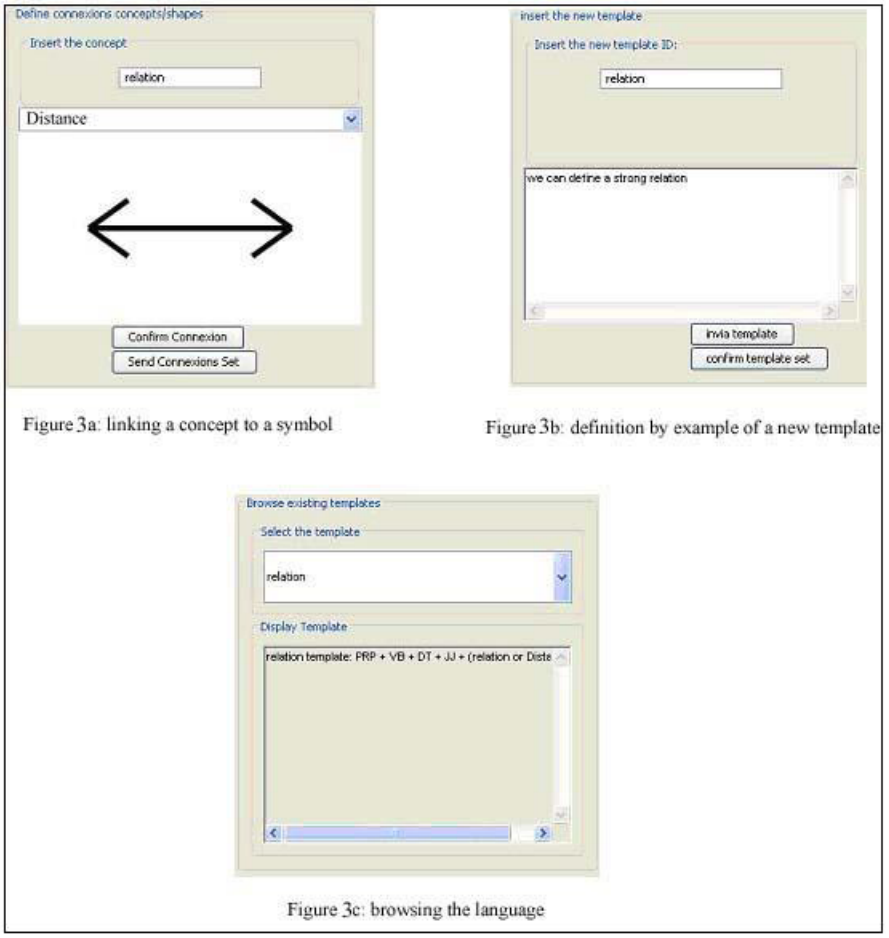


Figure 3a: linking a concept to a symbol

Figure 3b: definition by example of a new template

Figure 3c: browsing the language

The multimodal environment consists of the speech and sketch recognition modules. The sketch recognition module uses a set of graphic symbols, while the speech recognition module uses the parsing module to analyse the user's speech.

The first step in establishing the relationships between the multimodal user dialogue and the template set is the parsing of the user's speech (the parsing step in this environment is similar to the one seen in the configuration environment, except that the system parses the user's speech instead of a set of use cases).

The parser analysis constitutes the input of the template recognition module, which uses the set of templates defined in the configuration environment.

5. THE SYSTEM

The system was developed in Microsoft Windows XP environment, using Java 2 Platform Standard Ed. 5.0 as the programming language.

Figure 3 show the system's focal characteristics. As mentioned above, the language is defined by a set of templates containing a way in which a concept can be expressed.

Some key concepts can be expressed in both speech and sketch modes: the user can associate a word with a symbol (sketch mode) and a word expressed in the speech mode. This is demonstrated in Figure 3a: in this case, the user wants to relate the word "relation" and the symbol "distance" to the concept of relation.

Once the user has defined this relation s/he can define new templates as shown in Figure 3b: templates are defined "by example". That is, the user provides the system with the type of expression having a particular meaning through an example; the system picks the key concepts (in this example, the concept of relation) and lets the user express the rest by any words belonging to the same syntactic categories of the words in the example given. For instance, if s/he says, "we can define a weak relation" the template will be recognised.

Once the language has been defined, the user can browse the template set that makes up the language, as shown in Figure 3c.

Once the template set has been defined, the user can start multimodal communication with the system, thus speaking while drawing. After examining the text related to the user's speech and sketch, the system displays the matches it has found. Deictic expressions are solved by showing the object they point to.

6. CONCLUSIONS

This paper demonstrates the importance of natural language processing in the definition of multimodal languages. It addresses ambiguities by providing a tool for language definition. It shows that multimodal language is built from a template set that encapsulates a syntactic and conceptual structure, where concepts are expressed in the various modes and correspond to a precise semantic value.

The language is defined using a rule-oriented focus in constructing the templates, but is data-oriented in the definition of the overall language. This approach helps to reduce the problem of language ambiguity.

An Optimized Service Oriented Middleware Design for RFID Enabled Solution

Prasenjit Bhadra, IBM India Pvt. Limited, India; E-mail: prbhadra@in.ibm.com

ABSTRACT

Introduction of RFID at the Enterprise level has accelerated the automation of data interchange at various data points across the entire supply chain. The proliferation of RFID tags and readers will require dedicated middleware solutions that manage readers and process the vast amount of captured data. On the other hand, Service oriented architecture (SOA) represents a style of information systems architecture that enables the creation of applications, built by combining loosely coupled and interoperable services [1]. SOA Evolution promises a smooth integration and consolidation of large complex RFID implementation within large enterprise system architecture. The paper aims at the value propositions to the recent practices on such RFID middleware development using the SOA centric design approach and proposes model architecture along with the framework components for such optimization.

I. INTRODUCTION

The recent drift of innovation in an enterprise space is approaching towards two distinct spectrum of technological trends: turning massive amount of data into an operational intelligence by integrating Sensory /classical mobile devices at the edge of the enterprise network and on the other hand, building more adaptive and extensible application environment by addressing need based services with in an enterprise-wide heterogeneous Infrastructure. The essence of the "paradigm shifting" practices reveals that the collaboration of such emerging technology and a handshaking of conceptual abstracts would plot the road map for future solution offerings in an enterprise space. The widespread adoption of RFID requires not only low cost tags and readers, but also the appropriate networking infrastructure [2]. The constant effort of delivering solutions to such emerging areas has brought more focus into developing middleware and frameworks – that promises an application-agnostic offering for a diverse set of requirements. Functionally it manages readers, filters and aggregate captured RFID data and delivers these to the appropriate consumers. The platform also facilitates domain specific/independent integration, adaptation of a chosen set of RFID peripherals, combines the RFID data with application logic, and generates application-level events.

The main involvement of this paper is a middleware design approach delivering open standards along with the solution architecture of such middleware addressing new challenges of Automatic data collection using RFID and seamless integration over SOA platform. The governing idea of such system is primarily built on recent strategies on RFID enablement and extending service delivery approach demanding operational efficiencies within enterprise-wide "On Demand" space.

This paper is organized as follows: Section II focuses on the motivation that drives such design considerations. Section III depicts the principle of a scalable RFID middleware design and the value propositions. Section IV describes the proposed architecture of subsystems within the solution domain and integration methodology. Section V is a brief description of the reference implementation and Section VI illustrates how the service oriented approach addresses the recent challenges on solution design and integration. The paper concludes with a summary of the overall approach and discusses future directions in Section VII.

II. MOTIVATION

The recent pilots and rollouts of RFID implementations reveal that as adoption grows, the realization of benefits and scope of operational areas also grow. In industrial automation and supply chain management domains, RFID technology holds the promise to eliminate many existing business problems by bridging the economically costly gap between the virtual world of IT systems and the real world of products and logistical units [3] .The following points illustrate the objective of an extensible RFID middleware design suitable for wide range of implementations:

Leveraging opportunities provided by RFID to both private and public sectors involve understanding of the potential applications and the different business cases for the technology and its applications, along with their limitations and current challenges, to develop forward-looking policies [4]. Therefore the successful outcome of RFID enablement potentially depends on a set of technology advancement and smooth integration with the effective process change in an enterprise environment. The RFID implementation on top of the existing infrastructure would not highlight much on discrete business process issues and high impact on existing enterprise application architecture.

Item level tracking and asset management using RFID generate enormous amount of data which needs to processed, stored and transferred to an appropriate business system. Studies have been made to baseline the standard practices on data management and application component design to overcome technological challenges from passive RFID based solution. The current practices of solution development should also extend a mind-share on how RFID data can be interpreted in a given business context and turned into the corresponding application events for an optimized service offerings within entire enterprise application domain.

The solution providers have been working on standard set of applications /middleware design to cater most of the requirements evolved from the recent business practices. Such solutions could effectively accomplish the objective of integrating RFID with the operational environment but fails to anticipate the future business problems and collaborating on the solutions for a complex rollout.

SOA has emerged as one of the best alternative to turn the existing and new applications and data sources into an agile IT infrastructure that can help organizations meet changing business needs. This also facilitates reusability of components and services over time. I have tried to propose an architecture of the RFID middleware which extends the bandwidth of solution offerings over SOA centric design. Such optimization promises a wide spectrum of service delivery in a cross platform and cross domain automation where an extensible design not only targets to minimize the concerns as mentioned above but also try to eliminate technology specific constraints.

III. DESIGN RATIONALE AND OPTIMIZATION

Pilots carried out in various industry verticals have potentially extended the expected business values out off such automation. From the Architectural standpoint, an RFID middleware should not target to accomplish a specific goal or project requirements rather facilitate the scope of delivering anything beyond what is featured at the POC/ Pilot phase .

The recent practices and implementations have envisaged an ideal design approach of RFID middleware. The lessons are:

- Realization of early benefits would grow complexity in the incremental RFID enablement as the roll out would embrace more challenges beyond the traditional integration .Therefore a top-Down approach to design will not be well suited in the long run.

- The scalable design of such framework should be holistic to the entire enterprise and embed its capabilities in the overall system architecture.
- A device agonistic abstraction creates a common standard of data exchange protocol for the device service layers.
- Seamless integration of filter events, monitoring/logging and event routing should extend a common standard of event processing capabilities for processing streams of RFID and/or sensory inputs (Data/signals) into business events.
- A generic and scalable enterprise application framework in a multilayered architecture creating distinct service end points would serve data /information interchange and rule checking over the enterprise service bus (ESB).
- The solution framework would opt for a modular approach and well-defined separation of concern for the information interchange and smooth integration with the existing enterprise architecture.

The ongoing development of real-time asset tracking solution has widened the scope of distributed data aggregation and processing over an SOA layer to address the mentioned optimization sentinels.

IV. SOLUTION ARCHITECTURE-APPLICATION COMPONENTS AT VARIOUS LAYERS

The proposed architecture for the middleware design points to different challenges and the corresponding research approach in developing a RFID middleware to provide a seamless environment with in the enterprise network; moving data from the point of transaction to the enterprise systems. An Extensible Event broker model and robust messaging infrastructure constitute the backbone of the solution design. It encapsulates intelligent data processing and routing, interoperable solution components on top of business integration layer and standard communication protocol for data interchange. The multi layered architecture can be customized for specific operational need by configuring services and subsystems as per requirement. The basic design is intend to achieve a reasonable combination of core infrastructure and packaged application features, including device management, integration, data management, and generic business logic .The application layers are broadly structured as follows:

A. The Device Service Provider Domain

The sensory devices are controlled through the processing unit connected at the edge of the enterprise network. The service components primarily provide a device abstraction and logical filtering/aggregation services, supporting the analysis of volumes of data provided by the readers, applying local decision making and intelligence. The group of applications termed as Edgeware or Edgecontroller, are built on a standard framework which can be extended for specific service agent development. The contract between client or consumer and service is interface driven. Discovering and binding for the corresponding implementations are done through the framework layer. Agents are softly coupled and primarily rely on standard messaging protocol over an asynchronous public-subscribe model for information interchange. Thus the runtime components embrace an observer-observable pattern with in the processing environment. There is an external configuration /XML file which contains the declaration of service dependencies with in the runtime environment.

The functional features of the edgeware application environment are as follows:

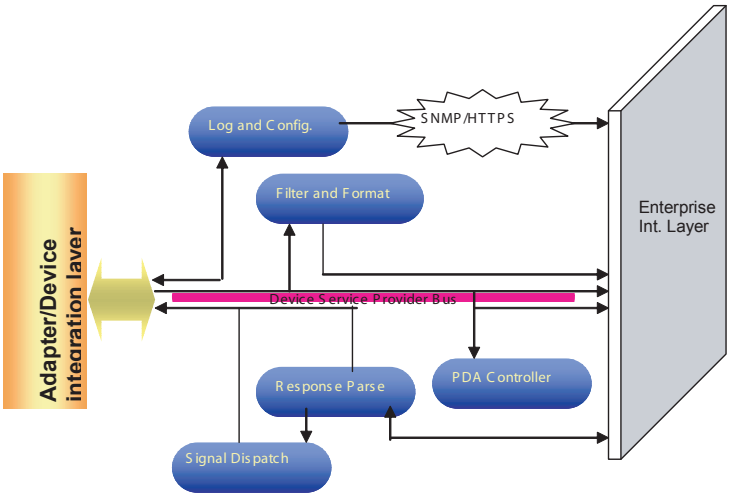
- The Device Integration Layer creates a façade for the transport and device protocol. This layer interprets the incoming signals/ data lists into a common XML format. The application components in this layer are also capable of translating standard commands into device specific instructions. A single interface contains a list of functions to transfer and execute standard read/write, I/O operations and device management command list. As the data/command formats are not yet standardized the implementation of the same adheres the dedicated supports from device/Vendor libraries and APIs in the heterogeneous reader landscape. This is a loosely coupled service agent which can be customized for various readers.[5].
- Depending upon the nature of implementation and volume of data, the notification latency should be configured on top of the data broadcasting layer. For a large scale implementation(i.e. Dock door receiving ,Real-time asset tracking using active tags ,Smart Shelves) a filtering and smoothing service is configured for minimizing the redundancy of the captured raw tag-reads and funneling the unique reads in a predefined format(Text/XML).The service agent additionally performs the checking of the Data format of the incoming raw tags considering either standard specifications(e.g. EPC SGTIN -96 , ISO 15693 , ISO/IEC18000-3) or proprietary data structure as per need .Such optional filter service at the local execution environment mitigates the risk of unwanted injection of bytes from the physical world. Similar filter service would be extended with respect to specific portal/Reader identifiers. Since a single Edge Controller is operational for multiple readers at a particular location , the service can be configured for a specific set of readers or logical grouping which would be considered for a specific application context[6]
- Each edge unit comprises of a Tag-Read- Handler Router -an agent broadcasts the formatted tag list to the centrally located Data aggregation service layers at the enterprise space. The performance of this service layer is optimized through a set of Latency parameters viz. 'paramPublish_Interval', 'param-Purging _Interval' at the enterprise space. On the other hand, relatively simpler application environments or solutions handling low volume of data but need to respond immediately to local interaction with the physical objects (i.e. Data collection using hand-held reader and PDA, WIP tracking, Security monitoring, vehicle tracking and fleet management etc) reduce the overhead of the filter service by eliminating the same within the runtime environment or consider a short notification latency that is comparable to the observation latency and receive immediate notification from the device layer[6].
- The edgeware establishes a common secure message subscription channels with the enterprise layer for data/signal event exchange asynchronously. The router agent publishes the XML messages contain the Event source /Destination ID, Timestamp along with Tag-data elements which are subscribed by the consumers at the enterprise layer to accomplish specific task.
- There is an SNMP [7] agent running on each Edge controller application environment. This service agent is exposed through a secure Web service for the device /infrastructure management. The centrally located Management Information Base with in the enterprise application layer queries for current performance statistics periodically in a systematic fashion using SNMP traps (Synchronous calls). Each Device Agent extends a worker thread which delegates the device/peripheral status to the SNMP agent The Agent persist the details in an XML format, which is forwarded upon request from the management station.
- The response parsing agent carry outs optional service management tasks locally when a notification is received from the other device agents and response/instruction received from the enterprise management base. The operations like Audio visual alarms for any failure, Sensing tagged physical objects in proximity and switch on the reader, maintaining a temporary persistence (using in-memory DB or XML) for the Tag reads if the network is down etc for immediate recovery and faster response at the local site.
- The mobile/handheld devices operational with in the edge domain use an additional GUI based controller (developed on top of standard GUI framework) for data collection trigger, formatting, Manipulation of the data elements and persisting/routing the same with in the application environment.

B. The Enterprise Integration Domain

The enterprise integration is the intermediary between enterprise applications and the Edge Domain. It compiles business sense of RFID read information and enables automatic decision making. The application infrastructure is built upon Service delivery framework defining so called plug-in to the real world. The application tier offers the following features:

- The Enterprise layer persist the configuration details and a logical mapping of the readers /sensory hubs within the business environment data points. The device infrastructure operational need to be registered with the system with respect to such predefined mapping. For an offline mode of operation the same details need to be validated prior to the data aggregation at the enterprise space.
- The Data interchange layer at the top of the enterprise space provides a common gateway for standard publish/subscribe mechanism (centrally Located) handing dataflow across the sensor hubs /handheld terminals and enterprise layer. The unidirectional communication channels are used for subscribing incoming tag lists and other operational inputs. There are standard set of XSDs to validate the data content and format of the incoming Tag-lists. For any non compliance, this service layer generates alert messages as a notification on

Figure 1. Functional components: Device service provider layer



the subscription feedback. The local application can subscribe to the same using the response handler agent to take immediate action (send message via alert console or switching on the Audio-visual alarms).

- The valid Data/Tag-lists subscribed over the enterprise gateway are processed by the data aggregation subsystem analyzing the source/content, are delegated to the respective event generation layer to process the same. The standard XML list contains sensor/RFID event specific inputs is processed as a generic message format and delivered in enterprise application infrastructure. The subscribers consume the message of its interest (RFID event specific to Dock door receiving, choke points, audit details or read counts etc.).Such subscription is structured through a management console considering the reader/sensory hub configuration/mapping and decentralized operations for a specific set of Data elements. A dynamic delegation pattern is incorporated in this layer to bind the message selectors with in the runtime environment. This service is a construct of the Application event emitter framework, which process the incoming messages and check the rules applicable for source of sensory events and specific problem domain.
- The implementation of a rule engine on top of this emitter layer extends an adaptive execution environment for the available service components. The predefined rules act on a set of subscribed data elements to generate Application level events. Such rules are derived from the custom process maps applicable for specific business context. The administrative consoles are available for add/modify the rules applicable at various service layer of the predefined event emitters. Hence the integration layer can be leveraged for numerous distinct process execution and service offerings and provide information directly to "line –of business" applications. The set of rules would be applicable for correlation, precedence checking and complex mapping of the data items from within the event repository. The service layer also facilitates a real-time state transition updation and deletion on the base events.
  The Application Level Events(ALE) generated by such event emitters are persisted in ESB for the consumers interested in specific business operation .The consumers can be any business service, pluggable subsystem which can access these data for raising notification /alert , update backend system and/or constitute an information hub for the business events in an organized report format.
- Reader devices which are part of a secured network are registered and go through a process of device authentication on an ongoing basis to prevent "reader spoofing" (e.g. unplugging a reader and plugging in a (e.g. unplugging a reader and plugging in a laptop which creates a false data stream which is meant to look like it comes from a reader) using a centrally located Administrative and monitoring service[8].The solution architecture is designed such a way that it can protect both stored data as well as data that is in transit. The system should also extend comprehensive management of the readers and other peripherals constitutes RFID enabled infrastructure. .The application component act as an SNMP management station analyzing SNMP traps send form the distributed device infrastructure.
- The centrally located management application service layer includes the product details lookup , rule management, Device infrastructure management , Log details and views ,analytics and other reports/enterprise content solutions

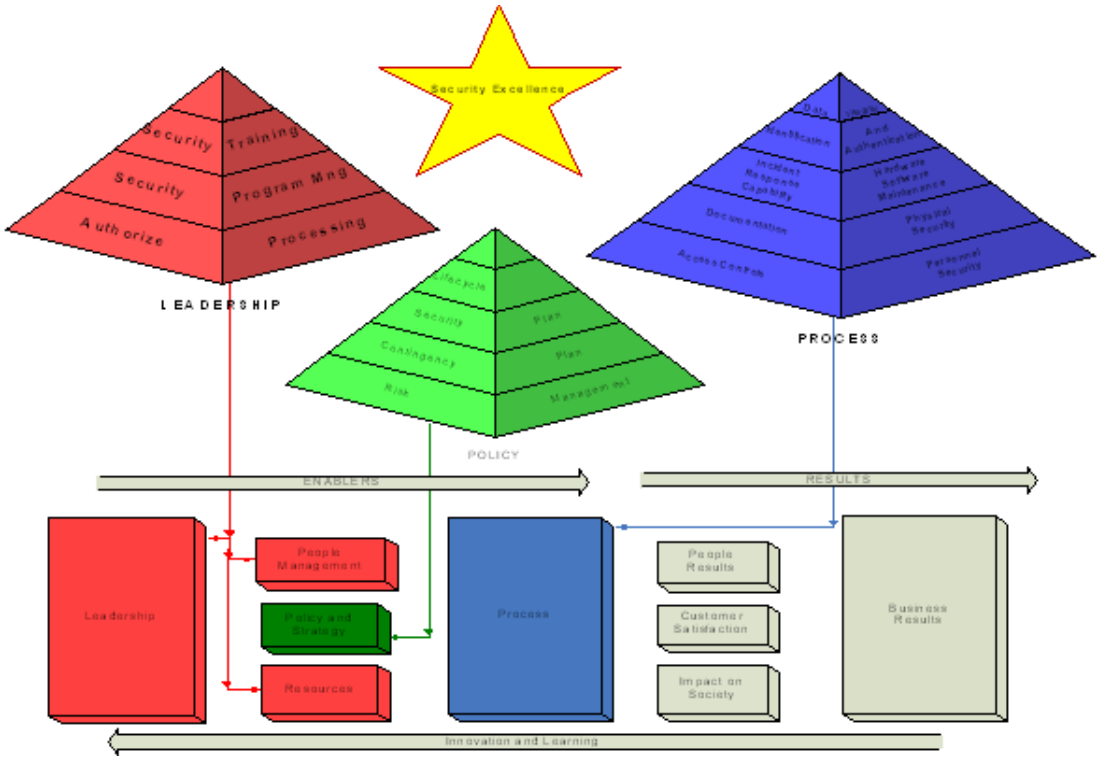
The Object Directory Domain associated with management application services running in the server and other handheld terminals is responsible for user authentication, authorization, and data encryption practices in accordance with a security and privacy management policy.

V. THE REFERANCE IMPLEMENTATION

The proposed design has been realized through an asset development activity in our lab. We have chosen OSGi application framework (SMF on top of IBM J9 environment) to build loosely coupled bundles of the solution .Each bundle exchange signal data over MQ Everyplace messaging infrastructure .The controller uses Message Queue Bridge for store/ forward signal/Data transfer over the network. In offline mode, DB2e is used for local persistence of the tag-lists. The SNMP client bundle updates the network status to the controller to route/persist tag reads. The basic SOA centric design promises a dynamic modularity for the edgeware application environment and accomplish following points of interest:

- The evolving standards/hardware and business requirements demands new generation of devices and sophisticated process automation .with in the enterprise space. The service components thus built on such framework can afford such enhancements following the evolutionary trend and helps to optimize the runtime environment by activating /deactivating services and configuring their service delivery behavior.
- The runtime environment should be integrated with large number of devices viz.; PC, Microcontrollers, OS embedded in the stationary readers, and micro

Figure 2. Functional components: Enterprise integration layer



environment of the handheld devices/PDAs. Therefore the framework components are built on J2ME runtime that supports diverse set of environments.

The server side components are built on WebSphere platform with DB2 as a backend. A service component is built on this platform to receive inbound messages as an MQe Gateway. The application module extends the Jeline event infrastructure and uses pub-sub broker on top of MQ series which exposes a Standard Event Infrastructure and management.

The application services builds on the J2EE layer .They are used for storing devices and other agent configuration along with configuring rules associated with the data aggregation, visualization and correlation. The asynchronous reads and other sensory inputs are parsed by the dedicated event emitter at the event processing layer based on such preconfigured rules and the same is persisted in the ESB layer as ALE.

A configurable supervisor service monitors the ALEs to update, Logs transitions and consumptions of the events in the back end database and sending notification to other systems using Response handler service components.

Some generic application service layers are built to subscribe the events and query the data objects and application level filter to look up the ESB contents for the specific needs.

There are other standard application services built for the health status check using secure SNMP trap, device /user authentication/registration and device agent configuration download over LDAP.

VI. SOA ENABLEMENT- THE VALUE PROPOSITIONS

In order to comply with the typical SOA centric middleware design the proposed framework focuses on three fold approaches:

- The sensory devices constitute the edges in enterprise infrastructure, should promise unique services deliver behavior that transcend the underlying technology for data collection using a common standard event model (XML based) over the network and visualized by enterprise application layer. Such event model is also adaptive to the connectivity of the sensory devices; logging performance is in an assorted device infrastructure and notification through audio/visual alarm and signals.
- The enterprise space extends a managed/scalable environment built on service oriented container/content model. Services comprise of standard event bus, complex calculations and analysis on composite business events using correlation technology and rules engine, which assure potential means of semantically rich communication between systems targeting various business operations. Apart from the data acquisition and translation of the business events, the enterprise application creates a centralized device management service and reduce the on site administration hassles.
- The integration layer relies on synchronization services with the legacy system .The dynamic event generation and logical data aggregation at the enterprise space is accessed through a Hub and spoke model on top of the Synchronization layer. The wrappers built for such synchronization services thus eliminates the hard coded point-to-point interfaces between the middleware layer and multi-platform heterogeneous enterprise IT infrastructure.

The architecture of such focuses beyond a point solution approach, reducing the overhead of replicating information between the Middleware infrastructure and other multitude enterprise systems .smoothen the transition of the events generated at the physical layer to the structured business events. It promises a readily available, reliable scope for real-time asynchronous Event propagation and state-based decision making.The mentioned design approach uses standards-based technologies on an extensible platform to ensure that it's well positioned for the future.

VII. CONCLUSION

Integration of RFID based data collection and automation is a cross functional exercise. Organizations need the freedom to implement RFID in increments and

the flexibility to re-engineer processes that are RFID-dependent. This should also minimize the cost and time to frame a new architecture. The proposed approach targets primarily on Service-oriented architecture (SOA) and features both services and events which could deliver the desired scalability and performance.

The proposed solution architecture is harvested from encouraging experience in designing and implementing RFID solutions for various industries. The optimized middleware design would promise an RFID- technology agnostic and holistic distributed platform for an enterprise wide integration and process automation. It targets to those requirements by exploiting the Service oriented application components, easy-to-use Event Infrastructure for Business process integration seamlessly with wide range of enterprise solutions.

The proposed solution demands continuous supports for integrating new breed of readers as the vendors don't adopt a standard protocol for device –to-application integration. However the recent researches in hardware and firmware development has evolved mature device specification which would have standard implementation for the communication protocol along with some of the built-in services of the device integration .With the advent of such maturity the Edgeware application would be upgraded to more slandered adapter with the evolution of mature specification in future and would be functional as proxy to the enterprise integration layer focusing more on local decision-making services.

At the enterprise space the custom service layers are developed to emit application level events with respect to the applicable rules for various business needs .The current research is targeted on using BPEL for service orchestration or process choreography to design much more flexible service layers and seamless integration.

Therefore considering the potential areas of improvement in the enterprise scale RFID implementation the loosely couple design can be optimized for applications of any size and can be leveraged with the realization of the multi-dimensional impact of the growing need for such automation.

Security Excellence: Fusing Security Metrics into a Business Excellence Model

Clemens Martin, University of Ontario Institute of Technology, Canada; E-mail: Clemens.Martin@uoit.ca
Anasuya Bulkan, University of Ontario Institute of Technology, Canada; E-mail: Anasuya.Bulkan@mycampus.uoit.ca

ABSTRACT

The European Foundation for Quality Management's Excellence Model is a highly recognized business framework that has been implemented in many European countries to achieve Business Excellence. It is a documented approach to determine the overall Total Quality Management (TQM) practices of an organization by assessing nine different criteria. Conversely, the US National Institute of Standards and Technology (NIST) has outlined a set of security metrics that are categorized into managerial, operational and technical controls that can be used to express the security posture of an organization. In this paper, we propose to integrate these two domains to produce a comprehensive security framework based on underlying TQM practices and principles. Hence, we have created security metrics that are more accurate in reflecting the holistic state of a business and all its important aspects including IT security aspects that were not formally considered before.

Keywords: TQM, EFQM, NIST controls, security metrics, business excellence

1. INTRODUCTION

According to the 2006 Computer Security Institute/Federal Bureau of Investigation (CSI/FBI) survey, a total estimated loss of US $52,494,290 was recorded for common types of security attacks. This is indicative of the vital role of security in an IT infrastructure when it comes to thwarting threats and attacks that can result in significant damage. IT security must also be addressed in order to comply with legal stipulations. For example, in the US, there must be compliance with HIPAA, FISMA and Sarbanes-Oxley while on the Canadian side, laws like PIPEDA must be abided by or stiff legal penalties could arise. There are also social and ethical obligations that have to be taken into consideration, surrounding privacy and confidentiality issues. If these considerations are overlooked then loss of reputation can result and a loyal customer base can also be destroyed (Calder, 2005).

A critical review on whether business productivity is facilitated by Information Technology (IT) investments in general has been performed by (Dedrick, Gurbaxani, & Kraemer, 2003), which established that there are indeed higher increases in productivity for both manufacturing and service sectors. Empirical results that were gathered in a production environment also support the claim that there is a payoff for investing in Information Technology (Gurbaxani, Melville, & Kraemer, 1998). In addition, (Martinez-Lorente, Sanchez-Rodriguez, & Dewhurst, 2004) performed an analysis of whether IT has an effect on TQM based on key elements from the European Quality Award- instituted by the European Foundation for Quality Management- and the Malcolm Baldrige Award, which reflect quality management and assurance principles. The analysis revealed that large industrial firms that actively support TQM do recognize that IT plays an important role in achieving the desired results of the TQM implementation.

It is therefore imperative that IT security be addressed as a paramount concern since it contributes to business productivity by ensuring that the IT investments and infrastructures are secure at a level that is acceptable to the business environment. By taking the security domain into account, we are a step closer to our synergistic model of Total Quality Management, which can be viewed as an integral approach for improving an existing framework of processes, where goods and services are delivered to customers based on their expectations and the societal impacts are also considered (Nasierowski, 1997).

IT security mitigates business risks by allowing the smooth functioning of daily activities, resulting in an increased possibility of productivity goals being achieved. It is however, primarily up to top-level management to decide the appropriate security levels for their environments (Michaelsen, Michie, & Boulanger, 1985). If this claim that management should determine the amount of emphasis to be placed on security is correct, then it is worthwhile to determine how much cost should be associated with these security investments.

There have been several proposals for measuring the associated costs which include a Cost Benefit Analysis or Return on Investments (ROI) approach which weighs the risks in relation to the value of assets to produce a quantitative measure (Mercuri, 2003) (Erkan, 2005). It is also a more suitable and relevant approach when it comes to clearly projecting business risks (Jorma & Reijo, 2005). Similarly, a scorecard can be used to model the Return on Investments in order to highlight the benefits of security investments when compared to potential business risks (Banker, Chang, Janakiraman, & Konstans, 2004). It has also been suggested that a Cost Benefit Analysis is an improvement over value-neutral models since it is more persuasive in convincing management that business productivity is facilitated by security investments (Michaelsen et al., 1985) . We agree with this claim and have, therefore, incorporated security metrics into an underlying business framework that already evaluates the return on business investments to determine if a business is successful or not.

By taking this one step further, the security posture of an IT infrastructure is investigated to determine the necessary adjustments that are made to steer the business on the path to excellence. Subsequently, we must have a convergence on what a metric or a measurement should entail: it is Specific, Measurable, Attainable, Repeatable, and Time-dependent (SMART). It is distinguished from a measurement- a single snapshot in time that reflects a certain state- by performing an analysis of the recorded data over time to an accepted baseline (Shirley, 2002). Metrics will be based on IT security goals and objectives and will be, "tools designed to facilitate decision-making and improve performance and accountability through collection, analysis and reporting of relevant performance-related data." (Swanson & Bartol, Nadya et al, 2003). This indicates that the performance-related data is dependent on the specific system and a different combination of the Confidentiality, Integrity and Availability principle will be a security requirement. For instance, governmental and military operations will be more inclined for a higher ratio of confidentiality measures while a commercial enterprise might be more interested in availability principles.

Developing security metrics that accurately produce quantitative results can be a disconcerting task with the level of subjectivity involved. Service Level Agreements had been investigated in the hopes of providing a more quantitative solution to this problem (Henning, 2000). Here, the authors presented different service levels which have distinct, associated cost metrics. In this context, security was investigated to deduce whether it can be represented as a Service Level Agreement by exploring four criteria for metrics: temporal (to be met within a specific time period), performance (tangible delivery of materials), functional (adjustments to systems for normal operations) and process-related (recurring tasks) metrics. However, while this approach to security metrics is important to note, it does not replace assurance methods but instead, defines a set of security-oriented practices for functional operations.

It was further proposed that security metrics should be based on a framework that is already in place or familiar to the organization in order to foster acceptance and widespread understanding of the new security paradigm (Shirley, 2002). As a result, our research aims to progress in this direction by relying on the foundations set, primarily by the European Framework for Quality Management and the US National Institute of Standards and Technology (NIST) in order to capture an

accurate security representation of the state of a business, relative to its existing strategy and goals. We believe that this approach also extends into a broader Total Quality Management solution since the security aspects of an IT infrastructure are also deemed to be important. The EFQM has been chosen based on its wide acceptance and holistic integration of all important business domains while the security controls have been selected based on the US's NIST documents that aim to deduce the security posture of a business.

2. EXISTING MODELS AND STANDARDS

There are numerous existing models that facilitate security evaluation and assurance. The Common Criteria (CC) comprises the ITSEC (*Information technology security evaluation criteria (ITSEC)*1991), TCSEC (Orange Book) and CTCPEC(*Canadian trusted computer product evaluation criteria*1993) while the SSECCM is another important model that can be used throughout the software product lifecycle (Jelen, 2001).

The Orange Book was developed for the Department of Defense in 1985 by the US to apply metrics that determine confidentiality levels of their security systems. On the contrary, the ITSEC was introduced by the UK where a Target of Evaluation has different evaluation levels where there are set security objectives that fit into these levels; the CTCPEC is the Canadian version which provides a guide to evaluate the assurance levels of objects that have certain rights and privileges (Bacic & Robison, 1993). The concerted culmination of these three models into the Common Criteria, focuses on preventing the insecure event from a technical level. In contrast, the Information Security Management System (ISMS) encompasses the BS7799 1995 as a specification and is deemed to be a management model suited for the real world(Brewer, 2005).The ISMS was modified into the ISO/IEC 17799:2000 and later updated as ISO/IEC 17799:2005 where requirements and prescribed roles and responsibilities are better explained. The framework is suited for risk assessment and building management controls (*ISMS standards overview.*2006). In fact, "A mix of aspects such as policies, standards, guidelines, codes-of-practice, technology, human issues, legal and ethical issues constitute an ISMS" (Eloff & Eloff, 2003).

The US National Institute of Standards and Technology is another authority that focuses on the development of security metrics. There are three control areas that are proposed- management, operational and technical controls that contain metrics that can be aggregated into other metric sets as deemed appropriate (Figure 1). This will further be discussed in the following sections. Questionnaires are provided for these critical elements which result in a quantitative measurement being assigned such as a percentage or an average number(Swanson, 2003) .Furthermore, the European Framework for Quality Management is a model that places emphasis on all aspects of a business framework by addressing the non-financial factors- for instance, recognizing the societal impact of its operations(Westlund, 2001) as well as ethical implications (Martín-Castilla, 2002) in the quest for business excellence.

By integrating security metrics into a TQM business model, a solution is created to address business strategy (corporate governance and policy), technology management (utilizing the accepted standards) as well as the management of legal and human-related issues (Eloff & Eloff, 2003). Similarly, Jorma & Reijo (2005) acknowledged the use of business models such as the Malcolm Baldrige model and the EFQM evaluation criteria to measure performance in these areas and noted that IT modeling should be present as well.

3. BUSINESS EXCELLENCE AND THE EFQM

In order for an organization to be a good corporate citizen, it must consider non-financial factors to deliver the required results to customers, the environment and society. In fact, this is increasingly achieved by using a TQM approach (Sciarelli, 2002). Business Excellence (BE) is a holistic concept, also representative of a TQM approach by considering all aspects that have non-financial and/or financial repercussions. Metrics for the non-financial aspects cater for domains that revolve around customers, society and employees. In contrast, financial metrics strive to measure the dollar earnings for the business relative to production goals (Westlund, 2001). On this note, we propose that security excellence is an extension of business excellence by blending the existing requirements of a business- whether being financial, legal or ethical domains- with the necessary security mechanisms to protect critical business information, resources and operations. It is not an add-on feature and should not be isolated from a business framework. Thus, with respect to its integration into the EFQM, there are proposed levels of fusion that can occur at the nine different domains of the EFQM model and these can be assessed or measured at periodic intervals. The **Enablers** in turn produce **Results** which are measured according to a set evaluation process (European Framework for Quality Management, 2003) (Figure 2). It should be noted that these assessments do not replace Risk assessments but instead include them as subset of the metric control sets that will be used in the evaluation process. Refer to the NIST controls which include Risk Assessments as a control set in Figure 1.

The EFQM is a highly recognized model that was formed in 1988 and has grown over the years with applications across a wide variety of sectors including health care (Perides, 2002) and educational settings (Saraiva, Rosa, & Orey, 2003). As a case in point, it was adopted by a University Medical Centre in the Netherlands after an initial implementation of an ISO 9000 system failed to meet their needs. Over time, the system was unable to cope with the integration of all aspects of the University setting in a holistic manner. As a result, the move was made to adopt the EFQM, one of the reasons being the inclusion of a continuous improvement process in its TQM principles (Geraedts, Montenarie, & van Rijk, 2001). As a result, the EFQM model has been chosen as a foundation for our Business Excellence extension because of its inherent feedback process that allows continuous innovation and improvements, which contribute to the business being sustainable and competitive over time. In addition, it encompasses a systemic integration of all business aspects that we also consider to be significant. It however, lacks a security component and this may be due to the period of time in which it was formed since security concerns were not a top priority in the business operations as compared to the shift in focus that they are currently experiencing. We firmly believe that security is an integral component that needs to be included and a security excellence paradigm is obtainable by transcending one step further to include this domain.

4. SECURITY EXCELLENCE

We will use the US National Institute of Standards and Technology's metric sets, which are used to evaluate the security of a business to perform an integrative assessment of the Business excellence aspects. As a result of the different EFQM domains that are present, the NIST metrics have been categorized under **Policy**, **Leadership** and **Process** metric sets to demonstrate their appropriate assessments and integration into the EFQM framework. The NIST metrics have been grouped into the appropriate categories based on their inherent characteristics and dominant factors. For instance, the **Risk management control** forms part

Figure 1. Puzzle of NIST controls hat can be aggregated into different metric sets

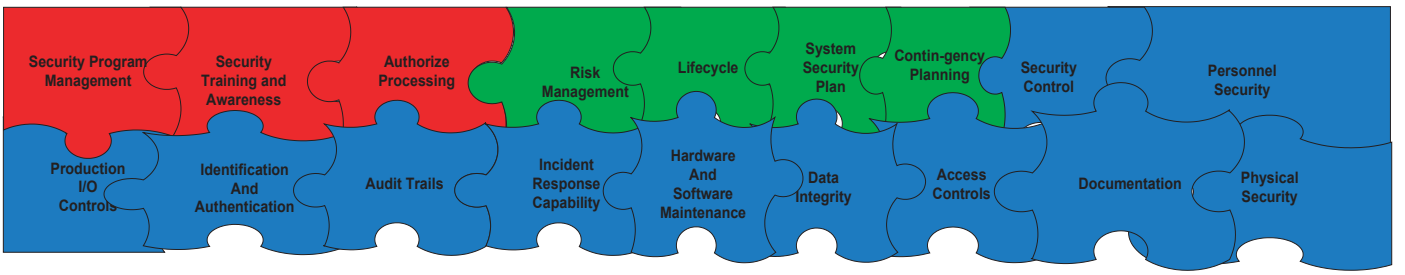

Figure 2. Integration of the NIST controls in the EFQM model

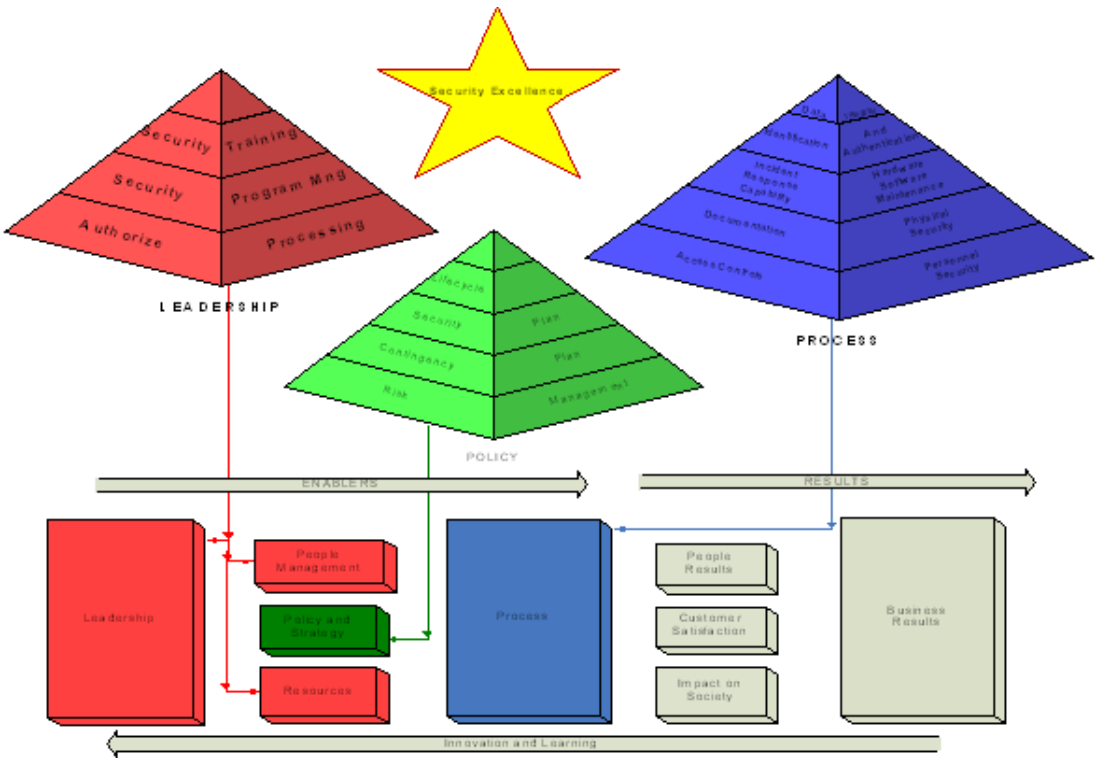

of the **Policy** metric set since it needs to be established firstly, in the Security Policy for it to flow across the remaining TQM structure (Figure 3). All of the remaining NIST controls will be further grouped into their appropriate categories in the following section.

Risk management, in the security context, is a process that encompasses identification and assessment of risks as well as mitigation, monitoring, reporting and prediction of security risks. After these phases have been completed satisfactorily to the expectations of the risk analysts, the appropriate procedures and guidelines are compiled into a Risk management document. The documented procedures will complement the Security Policy of the business which is integrated with the EFQM's corresponding **Strategy and Policy** domain; it represents a merger between both business and security policies. The top-down TQM structure becomes evident as the **Resources** are then tailored to deal with the results of the Risk management assessment as well as any contingency plans and guidelines in the Security/Business Policy. The **Leadership** criterion then comes into focus by communicating the contents of the Policy to all levels of the organizational structure. In addition, the Leadership skills must support and promote these Risk management assessments. **People** are then trained through aggressive security programs and awareness campaigns to carry out the guidelines of the Policy. Finally, the **Processes** are carried out as expected after having made the necessary changes that resulted from the security risk assessment.

The above is a description of how a specific control flows along the TQM structure and integrates with all the relevant business domains but it is however, performed from a security perspective. The obvious integration cannot be dismissed and as depicted in Figure 2, the synergy of these two domains is explicitly shown as the NIST metric sets are fused with their corresponding counterparts in the EFQM. Each specific control in each of the metric sets follows a similar TQM structure as explained above with the Risk management control (Figure 3). In essence, after the control is placed in the appropriate metric set by determining where it has a stronger impact, it is then related to all the other business domains in the EFQM. This relation or interaction of the metric sets produces a more integrated and accurate result for the individual security metric. This is due to the fact that there is an evident interaction of the security metric to the goals of the different business domains and the metric, thus, needs to be applied to all of the other EFQM criteria as well. This therefore, contributes to a more accurate result of the state of the business' performance level when it comes to that particular area or control, as defined by NIST.

As another example, the **Security Training control** can be considered as more of a driving force as part of the Leadership domain since it is an appropriate metric to determine how supportive management is toward training sessions. If management has the right approach and support for training sessions, then the **People** will be motivated to be security-conscious and will be educated on how to use the **Resources** effectively so that the **Processes** can then function as expected. This same sort of analysis has been performed for each metric to determine the category in which it is assigned to and a TQM approach is then followed to establish its relationships to the other domains, as explained above with the **Security Training** control.

After a control has been placed in either of the **Policy**, **Leadership** or **Process** categories (or pyramids), it is grouped along with other similar controls that collectively, will reflect the overall measurement or state of that category. We have therefore, classified similar controls in their respective categories which are depicted as pyramids in Figure 2. Each metric set has been represented as a pyramid due to the fact that all the stages of a pyramid converge to a common apex. The common apex is representative of precise goals and objectives that are shared by all the elements or controls of that metric set. For instance, all controls of the **Policy** pyramid should converge to the same security requirements that are reflected in the Security policy. If all layers have satisfactorily produced desirable results, then the pinnacle of the pyramid is reached in terms of there being an "excellent" Policy framework in place. The same is applicable to the other Process and Leadership pyramids or metric sets.

Furthermore, when the goals have been achieved in each pyramid, there is an alignment of their summits to the desired concept of **Security Excellence**. However, only if each pyramid has produced the required results then this can

Figure 3. Top-down TQM approach to formulating risk management security control

be achieved. Otherwise, it will not be a total security solution if one pyramid has been positioned correctly while its counterparts are dangling in a precarious or insecure position.Each metric set can now be immersed into their corresponding components in the EFQM framework. For instance, the **Policy** pyramid is fused with the evaluation criteria of the **Policy and Strategy** criterion of the EFQM. The same integration is also performed for the other pyramids as depicted in Figure 2. Tables 1 and 2 depict an integration of the **Policy** and **Leadership** security metrics into the EFQM's **Leadership and Policy** criteria.

4.1 NIST Pyramid for Policy Metric Set

The **Policy** metric set is representative of all the controls that measure the effectiveness of a Security Policy. They may be interlinked with each other at varying degrees and are as follows:

- **Lifecycle**- Deals with the implementation of security to any new process or even existing methodologies that have already been implemented.
- **Security Plan**- A plan should be implemented depending on the system requirements and defined roles to personnel should be allocated. The plan should be periodically assessed and should conform to an ISMS policy, such as ISO/IEC 17799.
- **Contingency Plan**- In the event of a catastrophe, a back up plan must be in place based on potential risks. Responsibilities and prescribed actions should be clearly outlined to avoid confusion and to restrict further damage.
- **Risk Management**- Risks should be eliminated or controlled to an acceptable level. The outcomes are mostly projected on an economic basis and can also be consequences that result from failing to comply with regulations. Even past experiences that have been recorded could be taken into account to provide a more comprehensive risk analysis. Also, linkages to other systems must be documented and those arising risks should be dealt with accordingly (Calder & Watkins, 2005).

Table 1. Integration of leadership metric

Enablers- Leadership				
1.1Leadership-10%(Inspire, Support, Promote)	Checklist Questions	Policy (Docs/records)	Process (actual procedure)	Tested and Improved (continual assessment)
"Visible demonstration of TQM"-Zink [30]	1.1.1 Do managers participate in regular meetings?			
	1.1.2 Do managers take initiative and train new employees?			
	1.1.3 Are they available to answer questions via email or other means?			
	1.1.4 Do they participate in training courses or make new courses available?			
	1.1.5 Do they share their knowledge that they may have learnt from training courses/conferences themselves?			
	1.1.6 Do they regularly remind and keep the security culture alive in meetings?			
	1.1.7 Are they present at all levels of meetings whether personally or by distributing memos?			
	1.1.8 Do they make use of other media such as bulletin boards, posters, letters, videos to communicate concepts?			
	1.1.9 Do they explicitly inform employees and stakeholders about the current state/level achieved in terms of security?			
	1.2.0 Do they effectively communicate the steps that need to be taken to reach the company's ideal security target or state?			
"Support of TQ through provision of appropriate resources and assistance"[30]	1.2.1Is management available when defining security issues in improvement activities?			
	1.2.2 Is there a security budget or emergency security fund?			
	1.2.3 Is there active support for moderating workshops or executing training activities?			
	1.2.4 Are resources made available for training sessions e.g. fully equipped room or releasing staff for training sessions?			
	1.2.5 Is support available for those actively taking improvement activities and suggestions taken into account?			
"Involvement with clients, external customers, external organizations" [30]	1.2.6 Are security links to other branches, divisions, conglomerates protected?			
	1.2.7 Are clients' privacy concerns ranked as a high priority and systems are in place to protect this?			
	1.2.8 Does the company software facilitate the adherence to legal and social implications?			
"Recognition and appreciation of the efforts and achievements of people"	1.2.9 Is there a system in place to provide recognition for departments or divisions that provide innovative security-related solutions?			
	1.3.0 Is there recognition and support for those teams/individuals that have effective security solutions?			
	1.3.1 Are the evaluations constructive in motivating persons to reflect on their strengths and weaknesses?			

Table 2. Integration of risk management metric

2. Enabler-Policy and Strategy	2.1.1 Is there a documented risk policy included in the security policy?
2.1 Risk Mgmt-NIST control	2.1.2 Is there current documentation available about the state of each system/entity?
	2.1.3 Are risks outlined regarding CIA principle?
	2.1.4 Are natural/manmade disasters taken into account as well as expected guidelines?
	2.1.5 Are other links to systems documented?
	2.1.6 Is there an acceptable level of risk defined and communicated throughout the organization?
2.2 "Policy based on info that is relevant and comprehensive" –{{391 Calder, Alan 2005; }}	2.2.1 Are social, political and legal scenarios covered?
	2.2.2 Do employees agree based on feedback that it is comprehensive?
	2.2.3 Compared to other best in class companies, are the security measures comparable or inferior to theirs?
	2.2.4 Is there an annual evaluation to address and update the security policy?
2.3 "How policy and strategy are developed" and " How the policy and strategy are regularly updated and improved"	2.3.1 Are the corporate goals fused with the security policy in the employee handbook?
	2.3.2 Are customer and other concerns updated in the policy as they occur?
	2.3.3 Are there regular internal and/or external assessments of the policy?
	2.3.4 Are the results incorporated into an annual strategy review and then adapted?
	2.3.5 Are less time-consuming, regular assessments done at least fortnightly?

4.2 Process Pyramid Metric Set

The **Process** metric set forms the core of the IT infrastructure and appropriate metrics that facilitate the smooth functioning of the Security

Policy is categorized here under the process-oriented view. The corresponding controls are:

- Data Integrity
- Identification and Authentication
- Incident Response Capability
- Documentation
- Access Controls
- Hardware and Software Maintenance
- Physical Security
- Personnel Security

4.3 The Leadership Pyramid Metric Set

The **Leadership** pyramid represents leadership skills that are applied in a more cutting-edge, integrative management style that is integrates best security practices. The metric set is dependent on the Policy being carefully crafted and being used in a way that is understood and engrained in those who are involved in the process. To achieve this aggressive security training and a security management program should be enforced. The metric set also evaluates how enthusiastic and supportive management is toward training sessions and if they themselves serve as reminders and enforcers of the Policy. In addition, management should make provisions to assign key roles and responsibilities to the right personnel.

The Leadership metrics measure:

- Security Training
- Security Program Management
- Authorize Processing

5. FUTURE WORK

The next stage of the project involves producing the actual quantitative security metrics that will represent the EFQM structure since the TQM relationships have been determined for the NIST metrics. The metrics will be applied to an environment that already utilizes a TQM approach in the form of a case study. We envision that a software prototype can then be built which encompasses a fusion of Security and Management principles and supports an evaluation process that encompasses both Business and Security Excellence.

6. CONCLUSION

TQM has been widely adopted because its value has been understood in supporting the corporation in its on-going efforts to satisfy its business objectives while at the same time paying attention to other non-financial aspects as well. IT Security, therefore, needs to be considered as a part of any Business Excellence effort. We presented an approach on how such an integration can be achieved by complementing an existing business excellence framework in order to maintain the competitive advantage and to be sustainable over time. In addition, the accompanying metrics to measure the effective merger of these two domains are not done in isolation since the security goals also support the business goals and therefore, can be measured in an integrated fashion.

ABSTRACT

A survey conducted to determine the information needs of physicians revealed that medical guidelines are regarded as a vital instrument of quality management. Since many physicians lack adequate guideline knowledge, we advocate a process-oriented approach towards the implementation of medical guidelines. We argue that a successful implementation requires the embedding of guideline content into medical and clinical information systems. Thereby, physicians would more likely consider guideline information since they were readily available as part of their familiar information systems. Furthermore, relevant data stored in information systems can be used to tailor the presentation of guideline content to the physicians' actual needs. Additionally, the proposed integration of guidelines within information systems facilitates a guideline-compliant medical documentation. This paper investigates and discusses various integration methods to recommend a holistic approach for the deployment of medical guidelines in clinical information systems.

1. INTRODUCTION

As quality management has become an urgent issue within the healthcare market, the demand for additional information is increasing. Subsequently, new sources of information have arisen from this need (e.g. professional journals, medical knowledge data bases, discussion forums, etc.). Physicians, who have to catch up on aspects of quality assurance and management, are facing a vast amount of information with different levels of usefulness, significance and quality. In addition to simply providing information, the challenge is to make this information available appropriately. Only then, information regarding the process of quality management will become useful and in turn be used by physicians.

During a survey we asked about 2500 German physicians about their information demands and their handling of information [1]. It turned out, that physicians are interested in medical guidelines, which are elaborated and detailed documents on quality issues. The Institute of Medicine defines guidelines as "systematically developed statements to assist practitioner and patients decisions about appropriate health care for specific clinical circumstances" [2]. Several studies [3-5] report that despite physicians regarding medical guidelines as important, they often lack adequate guideline knowledge that would enable them to improve the quality of treatment.

We conducted interviews with physicians in order to learn about their difficulties when trying to implement guidelines into their daily practice. Based on the results of our survey, on the analysis of international Web portals providing guideline information, on the examination of different solution approaches towards the implementation of guidelines and adapted from the statements of the interviewed physicians, we developed a concept and a prototype for a work-process oriented implementation of medical guidelines [6]. Although, the system meets the requirements of physicians with respect to their information needs, it is restricted to address issues of information supply and advanced training. It doesn't support, however, the documentation of a patient's treatment according to medical guidelines and it doesn't provide pro-active information supply without explicit request from the physician.

This paper reports on current approaches of computer-based implementations of medical guidelines. We stress the importance of identifying workable and effective paradigms for guideline use, before developing formal models and designing applications. This is followed by a brief introduction of our prototype of a work-process oriented application of medical guidelines. After that, we discuss several possibilities to integrate our solution within clinical information systems. Finally, we briefly expose our future work.

2. COMPUTER-BASED IMPLEMENTATION OF MEDICAL GUIDELINES

Having recognizing that physicians don't automatically familiarize themselves with written medical guidelines and apply them appropriately, the provision of guideline information at the point of care is of growing interest. Possible applications focus not only on precisely tailored information supply but also on clinical decision support and reminder functions.

A well-structured formal model is a precondition for guidelines to become machine-interpretable and to integrate them into information systems. In our review, we considered several existing approaches [7-8]. Some of them require the modelling of detailed workflows, others, e.g. the SAGE guideline model [9-10] provide decision support based on existing clinical workflows. In contrast to the other approaches, the SAGE guideline model takes infrastructural standards such as Health Level Seven's Version 3 (HL7 v3) Reference Information Model (RIM) [11] and part of the SNOMED Clinical Terms [12] into account. The Fraunhofer Institute for Applied Information Technology currently works on a similar approach that is based on the Guideline Interchange Format (GLIF) [13-14] and also supports HL7 messaging standards to communicate with the patient's record repository [15].

It will depend on the integration strategy whether a guideline model including its own workflow description or being based on existing workflows would be useful. If physicians would like to document treatment processes closely according to specific medical guidelines, a guideline model extended with control flow specifications should be chosen. Otherwise, many physicians and hospitals define their own workflows (e.g. by clinical protocols or pathways); that's why the guideline model should not control the host systems' workflow management. Therefore, the identification of settings and applications in which medical guidelines can be most helpful, least obtrusive and demanding to workflow constraints is essential for developing a guideline model. Actually, there is little agreement on the most effective applications for computer-based guidelines. Consequently, it is not clear which functional requirements, and thus what conceptual guideline models offer the most likely chances of success. This problem is reflected by the variety of modelling approaches. In [16], Wears and Berg criticize current technology-driven approaches towards advancing clinical decision support systems for not adequately addressing the needs of physicians. They claim that any solution will not be effective with respect to yielding high-quality care, if it isn't tailored to the actual users and their specific environment.

3. SOLUTION APPROACH TOWARDS THE IMPLEMENTATION OF MEDICAL GUIDELINES

Our Web-based approach towards the implementation of medical guidelines focuses on two main features. The first one helps physicians to select appropriate guidelines, whereas the second feature adjusts the content and the layout of guidelines to the current task of a physician.

1. Assistance when searching for relevant guidelines
   In response to physicians reporting difficulties in identifying the appropriate medical guideline, particularly before the exact diagnosis is known, our solution makes it possible to select guidelines regarding the patient's symptomatology. By specifying main symptoms, it is possible to confine the number of diagnoses related to indication-specific guidelines. Furthermore, physicians get an overview of the complete symptomatology that is characteristic of a specific disease according to the guideline.
2. Process-oriented supply of relevant guideline information
   Physicians use medical guidelines for different reasons: E.g. they need specific guideline information during a patient's examination or they would like to deepen their knowledge about the treatment of a particular disease. In order to meet these requirements we developed two solution alternatives to visualize guidelines:
   - Due to the fact, that physicians don't want to adapt their daily routine to medical guidelines, it is necessary, to determine the activities that are typically part of the treatment process. By this means, we developed a simple process model consisting of the activities "Anamnesis", "Diagnosis", "Make Diagnosis", and "Therapy" and adjusted structure and content of medical guidelines to these activities. Thus, it is possible to provide guideline information on a cross-guideline applicable level. Therefore, physicians can find relevant information more easily, independent of the particular guideline and without having to adapt general treatment processes. This model is intended to be used, e.g. during doctor-patient talks.
   - In order to assist physicians who would like to get known a medical guideline in more detail, we also provide an indication-specific process model. This model is not adapted to physicians' treatment processes but describes the course of treatment recommended by the medical guideline.

4. INTEGRATION OF MEDICAL GUIDELINES INTO INFORMATION SYSTEMS

Although the feedback received from primary care physicians who tested our stand-alone application has been very positive, we would have preferred our solution to be integrated within existing information systems for many reasons. Our current prototypical Web-based application offers low-level context oriented access, because only the current activity is taken into account. But there are other aspects, like e.g. the available amount of time, the physician's specialization, risk factors etc., which must be considered before it is possible to provide adequate guideline information. These context data could be made available by clinical information systems. Furthermore, our solution would be more valuable, if it's integrated in systems that physicians are accustomed to using, since they should not have to interrupt their current task to switch between different applications. Some physicians are also suspicious in terms of data protection and network security; that's why they don't like to access the internet from a computer on which patients' health records are stored. Besides, medical guidelines are supposed to gain importance as proof of quality assurance. Therefore, physicians would like to have documented evidence that patient's treatment conforms to guideline recommendations.

4.1 Objectives of Guideline Integration

Guideline integration seems to be a valuable improvement of our solution approach, because it provides the possibility of a tighter interconnection between guideline content and data stored in information systems. The objectives of guideline integration into information systems can be described as follows:

- Context-oriented information supply: Medical information systems contain data, e.g. patients' medical histories, that can be used to determine the current physician's needs in terms of guideline information. E.g., references to prophylactic measures should correspond to patients' health profiles and the comprehensiveness of the information supplied, should depend on the amount of time that a physician has available. Thus, it would be possible to regard a more extended set of context information instead of just the current activity.
- Continually education: By integrating medical guidelines into existing information systems, physicians constantly get in touch with guideline information. Such a "learning-by-doing"-strategy promotes the effective implementation of guidelines in everyday work life.
- Effective risk management: In the future, medical guidelines could gain importance in cases of legal disputes. If physicians can document patients' treatment according to guidelines, they are enabled to verify that healthcare was compliant to evidence-based medicine.
- Marketing instrument: The increasing competition in the healthcare market prompts hospitals to assure that their medical treatment meets high quality standards. Therefore, an effective integration of medical guidelines into physicians' daily practice could lead to a competitive advantage.

We identified several levels of guideline integration that differ from each other regarding the possibility of achieving the objectives mentioned above.

4.2 Web-based Information Supply

The easiest way of integrating guideline content within information systems is by providing access to Web applications resembling our prototype. The disadvantage of this approach is that the possibilities of information exchange between information system and web application are very restricted. It is possible to pass context parameters from the information system to the web-application. Thus, the guideline information that a physician is interested in, with respect to the current context, could be more precisely defined. Though, Web applications usually serve the purposes of information supply, due to data protection and limits regarding the interoperability with client systems, a comprehensive and integrated documentation of treatment processes is not possible. Furthermore, physicians have to use an additional tool; that could reduce acceptance and thus, the implementation success. Therefore, a full integration of medical guidelines requires more complex solution methods.

4.3 Assistance by Selecting Appropriate Guidelines

In order to prompt physicians to use medical guidelines, the system should indicate the existence of appropriate guideline information as soon as possible. Those hints can be made available automatically or on request. The system can identify potentially useful guidelines at two different points of time:

- The physician enters a diagnosis according to a well known classification standard, e.g. ICD-10 [17].
- The system compares the data, entered by the physician, with guideline information, e.g. typical symptoms, lab values etc. This requires the integration of comprehensive medical thesauri, e.g. SNOMED-CT [12].

Classification standards like ICD-10 are widely diffused and already integrated by most of the information systems. Therefore, it is only necessary to determine which medical guidelines correspond to which ICD-10 codes. The disadvantage of this approach is that most of the diagnostic measurements are already made. Therefore, physicians probably won't get guideline support during differential diagnostics. Furthermore, the amount of data that can be used to identify an appropriate guideline, like symptoms, risk factors, test results etc., is reduced to simple diagnosis codes. That's why this approach causes loss of data, that would be useful for purposes of information retrieval.

Standardized terminologies used for medical documentation and data exchange improve the semantic interoperability between different systems and applications. Physicians document clinical pictures and therapeutic procedures, which will be automatically enhanced with additional medical terms. Further on, these terms are used to improve the potential of information retrieval tools. Thus, the integration of medical thesauri is a promising way to identify relevant guidelines during the course of medical treatment.

4.4 Context-Oriented Information Supply

Since medical thesauri facilitate semantic interoperability, they could not only contribute to support the identification of appropriate guidelines, but also to provide guideline information regarding the context of treatment processes. As mentioned before, our prototypical Web application only considers the current activity of a physician to determine the required information. If the context of a treatment process is described by standardized medical terms in more detail, the filtering rules applied to guideline content will work more precisely.

Besides the current activity and a patient's symptomatology, there are other aspects that have an impact on what content is meaningful to be delivered. E.g. the

physicians' specialization, the available time slot, and patient information (age, sex, medication, etc.) are among these aspects.

In order to support context-oriented information supply, the parameters influencing the relevance of specific parts of guideline information must be defined. The resulting context model can be used in combination with knowledge tools, such as decision support systems. In this respect, the SAGE approach [9-10] describes a guideline model, that defines so called "context nodes". These context nodes correspond to preconditions whose fulfilment will trigger the presentation of specific guideline information, serving purposes of decision support.

4.5 Automatic Controlling of Guideline Compliance

Medical thesauri and context data could be used not only to select relevant guideline information but to implement control functions. These functions are aimed at assuring physicians that their treatment is guideline-compliant. Both, diagnostic measures and therapeutic procedures can be taken into account. The information system derives the activities, done by the physician, from the medical documentation or the underlying workflow management system. Thus, it is able to compare these activities with the recommendations of medical guidelines. Based on the results of the comparison it informs the physician about differences.

For instance, a patient is suspected of having early rheumatic arthritis. Therefore, the physician accomplishes the necessary laboratory tests and enters the resulting values into the system. Then, the activities of the physician are automatically compared with the guideline recommendations. After the data matching, it suggests to make an additional examination, e.g. the test for the rheumatoid factor is missing.

The advantage of this approach is that there is no need for changing user interfaces. Physicians can use their information systems as before. But now, they get the possibility to check if they provide healthcare according to medical guidelines. The control functions could be activated manually or automatically. In the latter case, the trigger events, e.g. the documentation of a diagnosis, that cause the execution of control functions must be specified.

The disadvantage is that the system doesn't actively support treatment processes. The compliance to the guideline is only determined after the treatment. Therefore, unnecessary examinations can't be avoided. As physicians treat patients as before and can only check the guideline compliance with hindsight, it is not possible to achieve the positive effects of a "learning-by-doing"-strategy.

4.6 Guideline-Compliant Documentation Based on Common Practices

If we succeed in making guidelines part of common documentation strategies of physicians, their implementation would be most effective. Therefore, the objective is to modify standard documentation processes as less as possible. E.g. existing documentation forms could be extended by adding a guideline information bar (see Figure 1). Physicians choose whether they use this bar or not. Since the forms don't change, the documentation process remains the same.

As illustrated in Figure 1, we integrated the bar into a documentation form for anamnestic examinations of an existing information system. By combining the bar with the functionality described in 4.3, the system presents relevant guidelines regarding the symptomatology. Additionally, the bar could contain more information, e.g. special notes with respect to drug dosages. Physicians can fill in the form as normal; after that, they can decide if they would like to access the next documentation form and proceed with the next treatment step as recommended by the guideline (by using the NEXT button). Therefore, forms must be connected to each other, according to the medical guideline. Only if the guideline describes activities that aren't covered by existing forms, new forms are necessary. Other functionalities might be included, e.g. physicians can access the relevant passage of the original medical guideline by using the INFO button.

Thus, it is possible to document the treatment process according to medical guidelines, based on common documentation practices. The advantages are, that physicians don't have to adapt their documentation strategy and suppliers of information systems don't have to adjust documentation forms completely, in order to support process-oriented guideline compliant medical documentation. But, as process orientation becomes more and more an important issue in healthcare (e.g. clinical pathways), the systems will have to support process-oriented documentation strategies anyway, in the future. However, this solution approach could contribute to smooth the transition from the current medical documentation, that mainly considers aspects of reimbursement, to a documentation strategy, that allows to follow the treatment process that led to specific medical decisions more easily. Additionally, a history function could be implemented, that stores the sequence, in which a physician filled in documentation forms. Thus, it is possible, to check the compliance of the treatment with guideline recommendations with hindsight, as described in chapter 4.5.

4.7 Process-Oriented Documentation According to Medical Guidelines

The objective of medical guidelines is to influence physicians' decisions and practices. For acceptance purposes, in 4.5 and 4.6 we described strategies that can assure a guideline-compliant treatment and documentation without fundamentally changing treatment processes. With respect to educational purposes, it should be possible to adjust treatment processes to guidelines. This requires developing a

Figure 1. Guideline information bar to support guideline compliant treatment

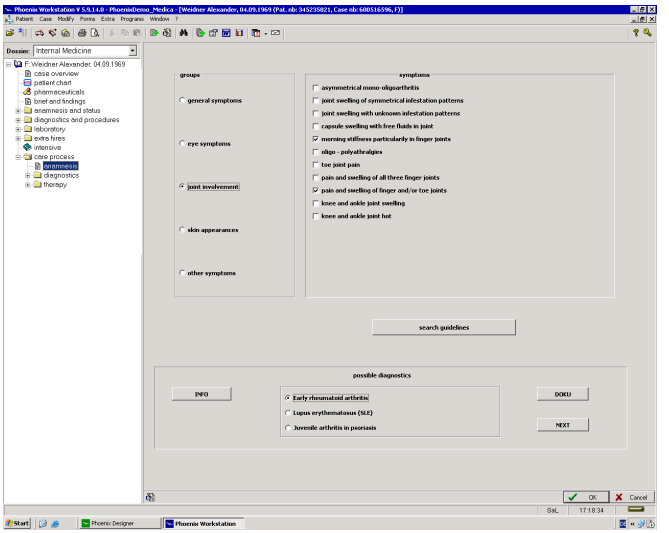

Figure 2. Process model of the medical guideline "Treatment of early rheumatic arthritis"

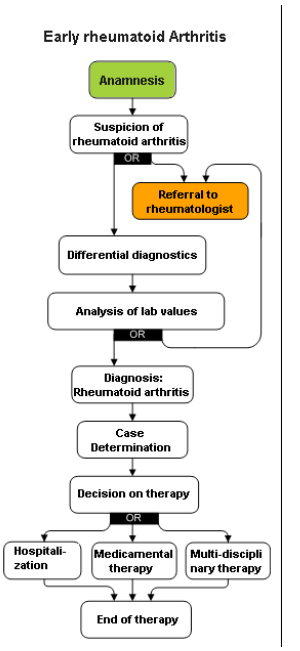

detailed process model of every guideline. Figure 2 shows an exemplary process model of a German medical guideline about the treatment of early rheumatic arthritis. We developed this model for our prototypical Web application.

The suppliers of information systems have to create documentation forms related to these process steps. E.g. if the physician confirms the activity "Referral to rheumatologist", the activity has to be registered as done and optionally a corresponding referral form should be issued automatically. Additionally, active decision support based on guideline information and patient's data, should be realized. If the physician confirmed the diagnosis and has to decide on therapy, the system could indicate which therapy appears to be most appropriate according to the patient's health status and medical preconditions. This requires the implementation of the functionality described in 4.4. Thus, this integration method would fulfil all the objectives mentioned in 4.1. The disadvantage of this approach is that treatment processes differ from guideline to guideline and therefore, physicians have to reconsider medical documentation depending on the current diagnosis.

5. CONCLUSIONS AND FUTURE WORK

Medical guidelines define recommended strategies for managing health care in order to improve quality, to reduce variations in practice and to help control costs. Since studies have shown that physicians lack adequate guideline knowledge, there is a growing interest in finding effective ways of integrating guidelines within information systems in order to deliver patient-specific recommendations at the point of care. Regarding the variety of formal guideline models and experiences with clinical decision support systems, it is essential to identify promising clinical settings and to determine the functional requirements in terms of practice-oriented guideline implementation.

Therefore, our fist step was a detailed analysis of the physicians' needs. After that, we developed a solution concept towards a process-oriented implementation of medical guidelines. Based on this concept, we developed approaches to directly implement guideline content into information systems. It turned out, that the full implementation of some features previously requires the implementation of other features. For example, in order to document treatment processes according to a specific guideline, first of all, the relevant guideline has to be identified. Furthermore, if systems should provide relevant guideline information in order to support physicians' decisions, it must be possible to determine the context parameters of the current treatment.

In cooperation with a number of German physicians and a commercial supplier of information systems, it is planned to develop a prototype that evaluates the integration options as described in chapter 4 with respect to a specific clinical setting. Thus, it will be possible to give recommendations on appropriate guideline modelling.

INTRODUCTION

As the use of Web technologies has increased tremendously, the web business is getting attentions from business organizations. Originated from artificial intelligence (AI) tradition, the syllogism based Semantic Web has a great deal of hype. To introduce the semantic web, this paper is the initial effort to conceptualize the promises of the semantic web in the context of information and communication technologies. Especially, this paper emphasizes the science aspect of the semantic web, introducing theoretical approach on its meaning.

A promising and ambitious statement can be found from the inventor of Web technology and the director of W3 Consortium, Tim Berners-Lee (1998), that "One of the major obstacles to this has been the fact that most information on the Web is designed for human consumption…the Semantic Web approach instead develops languages for expressing information in a machine processable form." As we all can perceive, data on the Web is not in a processable form for any application. Thus, what the semantic web seeks is data in a reprocessable form from the the web. XML and web service have been in the same track of this idea. Even combined with XML and web services, the semantic web intends to serve more intelligently who use the web technologies.

Through the theoretical conceptualization in this paper, the merits of the semantic web are revisited in terms of web science.

THE SEMANTIC WEB

The semantic web is "a web of actionable information – information derived from data through a semantic theory for interpreting the symbols" (Shadbolt et al., 2006). The semantic theory explains "meaning" to which the logical connection of terms establishes interoperability between systems. The aim of the semantic web is to provide services based on the machine-understandable web resources so that the business integration through machine internetworking and communication is facilitated. To effectively communicate through the semantic web, there needs to be a common conceptualization, called *ontologies*. Ontology is defined as the science or study of being. In the artificial-intelligence and Web science, however, it refers to the specification of a conceptualization, which defines terms and their relationships in a formal manner (Hendler, 2001). That is, ontology in the web science is a document or file that formally defines the relations among terms including taxonomy and a set of inference rules (Berners-Lee et al., 2001).

Ontologies, the basis for the semantic web, consist of various forms of knowledge such as entity-relationship (ER) models, unifying modeling languages (UML), data warehouses, XML schemas and documents, and other metadata repositories (Frankel et al., 2004). ER diagram and UML, based on the theory of sets and relations, advocate standardization on conceptualization. On the contrary, there is no single ontology for the semantic web. The semantic web rather diversifies ontologies because of its flexibility in semantic expression.

IS VIEW OF THE SEMANTIC WEB

According to the proponents of the semantic web, the conventional web is ill suited for automated information processing due to the unavailabilty of semantics for machines to infer. Building semantics on the Web brings the meaning to the web data and its relations. Proponents of semantic web, therefore, propose "the use of markup language to annotate data with semantic labels so that machines can identify content meaning and use rules for manipulating semantic information appropriately" (Flake et al., 2003). To do this, the semantic web uses ontologies. Though there is no standard ontology elected, ontologies in the semantic web have deep and shallow structure (Shadbolt et al., 2001). Often discovered in science and engineering, deep ontologies involve building and developing conceptual specifications toclassify complex sets of properties of objects. Shallow ontologies, on the contrary, explain the basic relations in terms of geospatial information. Shallow ontologies consist of a relatively small number of unchanging terms that help organize a large amount of data. The examples include the terms like customer, account number, etc.

However, these two views of ontologies are not enough to understand all forms web business. This classification of the semantic web does not provide conceptual framework which can help to build the semantic web. Therefore, we introduce the theory of deep structure from the field of linguistics because it can append the meaning of the semantic web in information and communication aspects. This theory was pioneered by Noam Chomsky in linguistics, and was introduced in IS by Wand and Weber (1995). The theory of deep structure consists of three structures: deep, surface, and physical structures (Truex and Baskerville, 1998). Table 1 summaries the relationships between the terms of structure, definition, and meanings. In addition to this theory, we interpret three structures into core, concept, and framework (Table 1).

A core is a central and often foundational part usually distinct from the enveloping part by a difference in nature. Deep structure defines the intention of information systems to be modeled by real world systems. It implicitly means value, beliefs, and norms that are important to organization and IS. Thus, deep structure has rules that govern individual behavior and interactions. We will use the term 'core' in

Table 1. Conceptualizations of IS: Core, concept, and framework

Conceptualization	Structure	Definition	Meaning
Core	Deep Structure	Intention	Rules, Values, Beliefs, Norms
Concept	Surface Structure	Institution	Mind, Thought, Notion, Abstract
Framework	Physical Structure	Interaction	Categories, Terms, Practices

this study with the same meaning of deep structure to view IS. Second, a concept is something conceived in the mind, thought, notion, or an abstract or generic idea generalized from particular instances. Instantiation occurs from interactions between actors. In the context of IS, actors interact with IS. Thus, institutions built by actors through interactions can be formalized to concepts. The second structure, surface structure, explains this nature of concept. Surface structure can be explained as an interface between the IS and its users' organizational environments. Third, a framework is a basic conceptual structure (as of ideas) and a skeletal, openwork, or structural frame. The third structure, physical structure, belongs here. It refers to the technologies used to implement information systems. Thus, it determines the protocols that apply to the perceptions of social interaction as collectives by observers. Information system provides such categories and terms to be used in actual work places.

World Wide Web (W3) Consortium defines the semantic web as follows:

The Semantic Web provides a common framework that allows data to be shared and reused across application, enterprise, and community boundaries. It is a collaborative effort led by W3C with participation from a large number of researchers and industrial partners. It is based on the Resource Description Framework (RDF).

The core of the semantic web is well established as appeared in the W3 Consortium statement. This is a definition of semantic web in which semantics is represented in XML and Resource Description Framework (RDF) using URIs. Thus, URIs, XML, and RDF represent the deep structure of semantic web. There is less ambiguity in this structure because it is clearly defined in general terms. Framework, however, raises difficulties in a rationalization of actual data-sharing practice. It determines the physical structure of semantic web, interaction between the semantic webs in actual practice. In other words, ontologies, inferences, and logics of semantic web explain what physical structure of semantic web is about. Until now, the use of ontolgies is limited to the interested community meaning that there will be multiple ontologies of different fields of web businesses. The hardest conceptualization of semantic web is surface structure. What concepts can be drawn from semantic web? For core and framework in Table 2, it is relatively easy to picture what semantic web is and what it does. However, surface structure directly points institutions of semantic web. What institutions can we possible expect? Can different ontologies share same institutions? As we listed in Table 2, partial understanding explains the evolution of semantic web from large scale to medium scale systems while transformability applies to the situation from small scale to medium scale. Intertwingling basically pinpoints the concept of "self-organized web" (Flake et al, 2003). However, to develop the governing concept of the semantic web that describes different ontologeis in a big picture, we will envision the surface structure of semantic web more rigorously in the following section.

RECURSIVE SELF-ORGANIZING ARCHITECTURE

One of the anticipated benefits of the semantic web is that direct machine-to-machine communication can replace the human end-user interaction as with the current web applications, increasing the efficiency of systems. As the current web enables users to connect to applications, the web agent architecture enables applications to connect to other applications. The semantic web, therefore, is a key technology in enabling business models to move from B2B to more intelligent B2B.

Internet technology has evolved from a primitive information exchange to a complex information communication and even can be extended to knowledge management. Traditional client/server architecture, the backbone of the Internet technology, was mainly applied to exchange information through World Wide Web, connecting clients and servers. The Internet technology, however, has been limited to documents to documents based on hyper linkable relations. With the introduction of the semantic web, the processes of applications are combined in the self-organizing nature. The conventional web is based on the Internet as 'inter-networking'. The semantic web, however, view the Internet as 'meta-networking', where it is named as the recursive self-organizing architecture while the conventional web uses client/server architecture. The conventional client/server architecture consists of direct connections between client and server. However, the semantic web is emphasizing the logical structure using semantics, **recursive self-organizing architecture**. Recursive self-organizing architecture is a new design paradigm that explains there is no need for a direct relation between machines. Instead, a machine may establish a connection to the recursive self-organizing network. Thus, the recursive self-organizing architecture appends the collective inferences of all networks' processes, data, information, and knowledge on the semantic webs. In other words, institutions are structured in semantic web and can be hosted, as established on recursive self-organizing network. It is also recursive because of its inference engine.

As discussed earlier, the relation structure has a different meaning in the semantic web compared to the conventional web. In the conventional web, hyper links implicitly infer TCP/IP protocol that is shown to the users as logical addresses for the connection between client and server. The relation between the links is static as the link between web pages embedded in html files. In the semantic web, the relation between web pages is not explained by hyper links; rather it is abstracted as "instantiation" between machines. Not like hyper links, instantiation infer freedom of connection to any other ontologies.

Table 3 summarizes the design paradigms of the conventional web and the semantic web.

Table 2. Conceptualizations of the Semantic Web

Conceptualization	Structure	Definition	Examples
Core	Deep Structure	Intention	• URIs • XML • RDF
Concept	Surface Structure	Institution	• Partial understanding • Transformability • Intertwingling
Framework	Physical Structure	Interaction	• Ontologies • Inferences • Logic

IMPLICATIONS

Back in the 1990's companies like SAP AG, Oracle, Baan, PeopleSoft and J. D. Edwards created a multi-billion dollar business with ERP technology that automated and connected what had once been disparate parts of corporations – human resources, manufacturing processes, inventory supply and financial planning. These companies rode the wave of the corporate BPR (business process re-engineering) trend that gained steam in the middle of the decade. Along the way, the ERP industry began to get saturated and view its growth struggle due to its focus on internalization. The main reasons for this were the Internet revolution and the surprising speed with which e-business began to change the way business was done, i.e., externalization of enterprise. Almost immediately, businesses have started to become Web centric.

In technical tradition, three solutions are accepted in current externalization efforts. First, process integration solutions have become commonplace in today's market, but the current vendor emphasis is on proprietary offerings, not standards. Process integration is critically important to the automation of both internal and enterprise systems, so both vendors and users will come under increasing pressure to standardize process models and protocols as relational database model became a de facto. The second important integration model is the "Web Services" framework model, promising a dynamic approach to application integration. The idea behind the autonomous distributed integration pattern is that integration can occur dynamically by combining Internet-accessible services at run-time according to a predefined pattern. Finally, an internet-based, hosted integration service is emerging as a cost-effective way for mid-market companies to participate in integration. These services join trading partners by employing integration hubs with transformation, routing and message management services. Lease/rental and per-transaction payment models provide an alternative to software purchase and enable smaller players to participate in value chains with much larger partners.

Although the integration market has been characterized by many small innovative start-ups, the essential e-business integration problem is an enterprise-level problem. Companies that started out adopting EAI technology to connect ERP systems with a few other systems, or synchronizing databases or a data warehouse, are quickly moving toward e-business solutions. E-Business infrastructures are complex, big-ticket items. Large organizations are more comfortable partnering with large vendors that can provide full solutions. IBM is considered a leader in this space, even though the components of its solution are not yet fully integrated. Other vendors making end-to-end integration include BEA, NEON (New Era of Networks), STC, TIBCO and Mercator.

To implement e-business technically means to determine how to implement in the three areas as discussed previously, integrations of processes, applications, and communications. To move this topic to the organization level, components of organizations must by re-visited and re-structured in the lights of modern IT-enabled organizations. Organizations have been collection of people with same goals and their relationships. With enterprise externalization of modern IT-enabled organizations equipped with advanced information and communications technologies, it adds one more values on integrations in processes, applications, and communications. E-business, in many cases, not just extends existing business practices but also include new perspective of how to integrate different levels of processes, services, and communications. Thus, the use of e-business imposes different roles in relations.

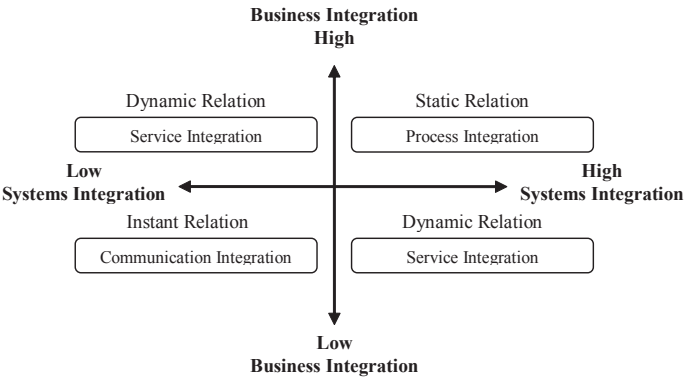
Now, it is possible that all organization contents can be stored, manipulated, and exchanged in any form of information systems. Examples are any relational database systems, ERP systems, and more recently web stores. Any part of organizational contents including business processes can be separated and digitized into information systems. Even, these systems can be related with other systems. These relationships, however, had been established only among humans. Thus, integrated processes are still static. Due to advance networking and the Internet, businesses information systems can be connected through communications networks. But, wait. What happened to the human members of organizations? In traditional settings, organizations used to be all about members and their relations. This at present is very tough to define due to the rapid changing environment but it alternately puts into two directions human roles in IT organizations. The first direction is rather negative effects on the importance of human roles. The traditional roles of humans are digitized into the IT systems. Thus, valuable assets, relations, which have an ontological meaning of members in their organizations are drastically diminished. Dramatic effects were many incidents of lay-offs in the late 1990s and early 2000s. This changes can reflected in dynamic relation in service integration structure. The second direction is now being gradually discovered in the field, establishing the new types of relations to systems instead of the ones using humans. Traditional strong cohesive bondage with other members is now shifting to information systems because organizational contents are abstracted into the systems and those can be communicated with others. This new trend builds new type of communication, communication instantiation (machine-to-machine instantiations).

Business integration in terms of processes, applications, and communications is touted to add considerable value to companies (Figure 1). In particular, recent development in e-business allows companies to enjoy the benefits of integration both by extending existing business practices and by adopting new perspective to the roles of business partners. The basic premise of the business integration through information technology is that any part of business including business processes and content can be digitized and embedded into information systems.

Figure 2 shows a graphical illustration of two different dimensions; business integration and systems integration. Business integration occurs when two parties coordinate their businesses while systems integration means the level of configuration to adjust systems. It also shows the nature of relation between systems; static, dynamic, and instant. Technically speaking, this shift has already begun from late 90's when eXtensible Markup Language (XML) gained popularity.

There are organizational impacts from business integration. Because the traditional human roles are digitized into the information systems, process integration, such

Figure 2. Business integration topology



as ERP or EAI, has been reflected in many incidents of lay-offs in the late 1990s and early 2000s. As a result, new relations built in process integration replace the traditional strong cohesive bondage between humans with the role-based modular integration. Toward service and communication integration, companies have hard time to find business implications till now. Service integration is promising but it has a drawback that it needs manual adjustment to coordinate run-time services. The proponents of the semantic web claim that communication integration can solve the problem of service integration.

CONCLUSION

The use of the Web is evolving, even it is self-evolved. Without semantic web, it is also possible to write a scenario that envisions Web algorithms which are intelligent enough to infer semantics from the current Web structure. However, it would also highly increase the complexity of Web business, making business integration heterogeneous. As shown in the enterprise externalization, communication instantiation movement shares the same idea, machine-to-machine instantiation, by the recursive self-organizing architecture. In other words, semantic web has strong business implications. For future study, the semantic web conceptual model we developed here can be mapped to the physical model, discussing recursive self-organizing architecture.

Web science is described as "a science that seeks to develop, deploy, and understand distributed information systems, systems of humans and machines, operating on a global scale" (Shadbolt et al., 2006). This paper discusses the conceptualization, dynamics, and topology of the semantic web in web business. This is an initial step to analyze the essence of practical technologies using the lens of science in business context.

CIO's Perspectives of Critical Issues in ERP Upgrade

Fan Zhao, Florida Gulf Coast University, 10501 FGCU Blvd. S., Fort Myers, FL 33965; USA; E-mail: fzhao@fgcu.edu

INTRODUCTION

Enterprise systems have spread rapidly among organizations. According to AMR research (2005), ERP market size was $47.88 Billion in 2004. Although ERP systems offer a great deal, implementation success is far from assured. Statistics show that more than 70% of ERP implementations fail to achieve their corporate goals (Standish Group, 2004) and the number of horror stories about failed or out-of-control projects is growing (Olson, 2004). To deeply understand ERP systems, many researchers are working on this topic and hundreds of ERP research was published in last eight years. However, recent review (Botta-Genoulaz et al., 2005) suggests that most existing ERP research focuses on selection and implementation, not on ERP's post-implementation impacts.

Selection and implementation are critical areas, and numerous valuable insights have been studied by many researchers (Quiescenti, et al., 2006; and Wang, et al., 2006). According to Staehr et al. (2002), the ultimate impacts of ERP on the organization – once the system has been implemented and has been "shaken down" – are not as thoroughly researched. Therefore, understanding post-implementation of ERP will help organizations succeed longer after the ERP implementation. ERP upgrade is one of the major activities in the post-implementation stage of ERP implementation (Nah et al. 2001). Every three years, a major ERP upgrade and several small upgrades are typically needed to keep the system running smoothly. Organizations will spend a significant amount of money on each ERP upgrade project. Without comprehensive understanding of ERP upgrade concepts in the organizational environment may lead to terrible nightmares, and even result in irretrievable disaster. Therefore, the aim of this research focuses on what factors are associated with ERP upgrade success.

There are several reasons why this study is important. First, each ERP upgrade project costs a significant amount of money. For example, a Midwest university spent over $2 million on a recent ERP upgrade project. While the initial ERP implementation happens only once, ERP upgrades will happen many times after the first ERP implementation (probably once every three years). Therefore, the cost of ERP upgrade is continuous along with the usage of the ERP system in the organization.

Second, according to our literature review through over forty IS top journals in last decade, relatively little research attention has been given to ERP software upgrade. One possible reason could be that upgrade is perceived a smaller project (compared to first time ERP implementation), and another reason could be that little theory has been developed regarding the topic of ERP upgrade. However, ERP upgrade is one of the important activities in the ERP software lifecycle, and an effective and efficient implementation of ERP upgrade has a tremendous impact on an organization's continuous business process improvement.

Third, little progress has been made in identifying relative importance of success factors in each ERP upgrade stage. Understanding the relative importance of success factors in each stage can help IT managers emphasize on dominant issues during the ERP upgrade projects. Especially when there are needs to make decisions about trade-offs among different upgrade activities, IT managers can focus on the most important factors other than less important factors in each upgrade stage.

ERP UPGRADE

ERP upgrades are mainly intended to take advantage of new technologies and business strategies to ensure that the organization keeps up with the latest business development trends. Therefore, the decision to upgrade ERP is usually not driven by code deterioration or anticipated reduction in maintenance costs alone, but by different purposes. According to an AMR study (Swanton, 2004), 55% of upgrades were voluntary business improvements triggered by the need for new functionality, expansion or consolidation of systems; 24% of upgrades were triggered by technology stack changes; 15% of upgrades were forced by de-support of the running version of software to avoid vendor support termination (Craig, 1999); and 6% of upgrades were triggered by bug fixes or statutory changes.

The cost of ERP upgrades is high (Montgomery, 2004). Swanton (2004) mentioned that the cost of each upgrade includes: 50% of the original software license fee and 20% of the original implementation cost per user, which means over 6 million dollars for a 5,000-user system. Typically, each ERP upgrade requires eight to nine months of effort with a team the equivalent of one full-time employee per 35 business users. The ERP-adopting organization does not have to develop and re-write the ERP system itself but rather it replaces (or upgrades) the old version with a readily available new version from the ERP vendor. However, a lack of experience may cause the costs and length of the upgrade project to approach or even exceed those of the original ERP implementation effort. Collins (1999) listed some general benefits for organizations from ERP upgrades:

- Eligibility for Help Desk Support: Most of ERP software vendors stop providing technical support 12 to 18 months after the next version becomes available. Therefore, keeping upgrade with the pace of ERP vendors will guarantee the support for the system from the vendors.
- Solutions for Outstanding "Bugs" or Design Weaknesses: It is impossible to guarantee spotless and error-free ERP systems after the implementations even though vendors will conduct many different testing processes to eliminate the happenings of errors in the system before the leasing time. "The majority of software bugs are resolved and delivered either fix-by-fix, or all-at-once as part of the next release version of the ERP package." In this case, upgrades will be beneficial to the organizations in problem solving.
- New, Expanded, or Improved Features: ERP software provides organizations with the knowledge and strength (i.e. best practices) from the vendors. ERP upgrades provide organizations future enhancement from the vendors to give the organizations better opportunities to catch up the current business development, improve their processes and build more efficient business models with new functions, new features and new processing styles provided in the upgraded ERP versions.

This study seeks to provide a comprehensive understanding of ERP upgrade by interviewing CIOs in different organizations according to their experiences from their organizations' ERP upgrade projects.

METHOD AND ANALYSIS

This study uses an in-depth semi-structured interview technique to examine the success factors in ERP upgrade. This method allows a more spontaneous, informal and broader examination into the specific experiences of the interviewees in relation to the topic, which can be useful in identifying factors of influence that previously have not been examined (Taylor and Bogdan, 1984).

To ensure better results, we used only those companies who reported that their organization's ERP upgrade was completed the previous year or this year. By excluding organizations who completed ERP upgrade over two years, 15 CIOs were interviewed. A wide variety of industries were represented in the responses. Characteristics of the organizations are shown in Table 1. The purpose of this study is to gain an initial understanding of key factors in ERP upgrades.

Semi-structured interviews were audio-taped and later transcribed verbatim in preparation for analysis. In analyzing the data, Miles and Huberman's (1994)

Table 1. Sample demographics

Organization	Industry Sector	Annual Gross Revenue	Number of employees	ERP Vendor
A	Industrial Manufacturing	9 Billion	60,000	JD Edwards
B	Public Sector	1 Billion	3,000	JD Edwards
C	Consumer Products	3 Billion	6,500	Oracle
D	High Technology	1.1 Billion	2,000	Oracle
E	Agriculture	100 Million	200	Oracle
F	Education	500 Million	6,000	PeopleSoft
G	Healthcare	850 Million	6,000	PeopleSoft
H	Education	800 Million	11,000	SAP
I	Industrial Manufacturing	2.6 Billion	24,400	SAP
J	Industrial Manufacturing	19 Billion	84,000	SAP
K	High Technology	200 Million	200	SAP
L	Utilities	200 Million	1,100	SAP
M	Bank	1 Billion	86,000	SAP
N	Distillery	2.7 Billion	3,400	SAP
O	Industrial Manufacturing	100 Million	100	Syspro

method was followed. That is, two researchers coded data independently. In the first phase, each coder read the transcripts to identify the key factors using qualitative classification. In the second phase, subcategories were identified to further the understanding of the layers of factors within each category. In the last phase, each factor was weighed by counting the number of respondents who provided the same or similar answers or emphasized similar themes.

Several strategies were used to ensure the reliability and validity of the analyses. The use of two independent coders ensured convergence in interpretation. Member checks as proposed by Maxwell (1996) were used by sending research findings to all participants. All of the participants concurred with the interpretation of the data gathered from their own interview.

RESULTS

Eight themes emerged from the coding and analysis of the qualitative interview data: Business vision, communications, consultants, customization, project management, top management support, training and education, and user involvement.

Business Vision

It is important that the organization has a clear sense of whom and what it is before implementing an ERP project (Cotteleer & Bendoly, 2006). Business vision concerns project goals clarification and their congruence with the organizational mission, business objectives and management expectations of the IT project. All the CIOs believe that "ERP upgrade should have a clearly defined business vision/mission to serve as a blueprint for organizations' success." It is a common knowledge that the first phase of an IT project starts with a conceptualization of goals (Mandal & Gunasekaran, 2003). Further more, the CIO from organization A mentioned that "careful deliberation of success measurement as well as management of expectation by the project manager of IT projects is important factor influencing the success of the project."

ERP projects could suffer a huge disaster without a clear business direction (Cotteleer & Bendoly, 2006). This can be approved by past ERP project failures resulted by inadequately defined business visions (Ehie & Madsen, 2005). A clear business vision remains important through all stages of the implementation life cycle (Loh & Koh, 2004). The vision should provide a direction and general objective, and no details are required (Al-Mudimigh et al. 2001).

Communication

One major purpose of communication is to inform every level in the organization about the expectations or goals of the change (Huang et al., 2004). Communication involves messages about why change was needed, what the "to be" environment will look like, and what will happen if change does not occur. All the CIOs described positive perspectives about communications. The CIO from organization F emphasized that "Building a complete and convenient communication system for employees was found to be the best way to avoid various communication failures in the organization." Researchers have identified communication as a critical success factor influencing organizational projects (Holsapple & Sena, 2005). Poor communication among reengineering team members and outside organizational members could cause a failure result of project implementations (Belout & Gauvreau, 2004).

Communication should not occur only within a small group of project team members. Frequent interlocking discussions between different functional teams should also be scheduled (Tsai et al., 2005). Given an example, the CIO from organization J mentioned that "We offered employees a good e-mail system, and also created many telephone and face-to-face opportunities for all employees to gain information about ERP changes. So users can share and exchange their education, knowledge, and information quickly and conveniently."

Consultants

Due to the complexities of ERP projects, most organizations will hire consultants. Consultants may have experience in specific industries, comprehensive knowledge about certain ERP packages or modules, and may be able to help organizations make best decisions in different situation during the implementation of ERP projects (Ehie & Madsen, 2005).

Most of the CIOs mentioned that the cost of hiring consultants can consume more than 30 percent of the overall budget for their ERP upgrade projects. The CIO from organization B displayed a positive perspective on consultants, "I think the success of an ERP upgrade project depends on the capabilities of consultants based on their knowledge of the ERP system. We delayed our upgrade project for 4 months because of the consultants. We replaced our consults three times and that's a nightmare for us during the ERP upgrade." Therefore, organizations should manage and monitor it very carefully by determining the number, how and where to use external consultants appropriate to the ERP projects needs (Botta-Genoulaz et al., 2005).

Customization

Even with today's state of the art technology, organizations find that not all their requirements are provided by the ERP systems they adopt. One of the major challenge an adopting organization faces while configuring an ERP system is that software does not fit all their demands (Kumar et al., 2003).

In ERP projects, customization includes two types of activities: configuration and modification. Configuration is a customization that organizations make decisions on all the functional choices designed by ERP vendors in the ERP packages. Modification is a customization that organizations try to modify the ERP vendors' code to build new functions in the ERP packages.

Since customizations are usually associated with increased information systems costs, longer implementation time, and the inability to benefit from vendor software maintenance and upgrades (Loh & Koh, 2004), customization should only be requested when essential or when the competitive advantage derived from using non-standard processing can be clearly demonstrated (Light, 2005). The CIO from organization C declared that "Organizations should try to adopt the processes and options built into the ERP, rather than seek to modify the ERP to fit the particular business practices."

Project Management

Project management is a key to the success of any large project (Kumar et al., 2003). 15 CIOs mentioned project management 37 times during the interviews. Proper management of scope is critical to avoid schedule delays and cost overruns (Tsai et al., 2005).

The vast combination of hardware and software and the myriad of organizational, human and political issues make many ERP projects huge and inherently complex, requiring new project management skills (Ryan, 1999). According to the CIO from organization D, "a better project management can ensure a better upgrade plan and lead you to the right direction in the next couples of months during the upgrade. One of the reasons we delayed our ERP upgrade for two and half months and spent a half more millions dollars is because we underestimated the importance of project management."

Top Management Support

The commitment of top management to the diffusion of innovations throughout an organization has been well documented (Mabert et al., 2003). In particular, early in a project's life, no single factor is as predictive of its success as the support of top management (Sun et al., 2005). The support of the top management will help focus efforts toward the realization of organizational benefits and lend credibility to functional managers responsible for its implementation and use (Tsai et al., 2005).

All the CIOs emphasized that top management support is critical. The CIO from organization H stated that "it empowered IT team to be flexible in upgrading." Research on project failures also shows that project cancellations occur when senior management delegates progress monitoring and decisions at critical junctures of the project to technical experts (Tchokogue et al., 2005).

Training & Education

The lack of user training and education has been one of the significant determinants of many ERP systems failure (Gupta, 2000). End users will become frustrated and refuse to use the system if they do not know exactly what happens in the processes (Tsai et al., 2005). To describe the problems his team faced during the ERP upgrade, the CIO from organization M mentioned that "training was a problem. It was a logistic problem in terms of getting enough classroom space and balancing the number of instructors and classroom space versus when we were going to take the system live. Some of the earlier classes had empty seats and some of the late classes had demand that exceeded our capacity. In a perfect world we would have had more training, especially when we went live, or perhaps even try to break up the go live."

ERP implementation requires a critical mass of knowledge to enable people to solve problems within the framework of the system. If the employees do not understand how a system works, they will invent their own processes using those parts of the system they are able to manipulate (Al-Mashari et al., 2003; Mabert et al., 2003; Dowlatshahi, 2005).

User Involvement

User involvement refers to participation in the system development and implementation processes by representatives of the target user groups. System implementation represents a threat to users' perceptions of control over their work and a period of transition during which users must cope with differences between old and new work systems (Wu & Wang, 2006). According to the CIO from organization I, "user involvement is effective because it restores or enhances perceived control trough participating the whole project plan. The organization should have an implementation process that strives for a high level of user acceptance early on through the use of constant presumptive end user consultations."

CONCLUSIONS

ERP upgrade projects have grown in importance, as vendors are seeking to generate revenue through improved systems. The reticence of vendors to support old systems was noted by multiple organizations in this study. (The value of improved functionality was also noted.) Upgrade projects seem to be much more controllable than initial ERP installation projects. This should be expected due to the experience organizations gain with their original systems.

This study aims to improve understanding of ERP upgrade. 15 CIOs from a wide variety of industries were interviewed. Qualitative data were analyzed and themes were developed from the data. In essence, the paper recognizes a series of critical issues that must be carefully considered to ensure successful implementation of an ERP upgrade project. These factors, business vision, communication, customization, external support, project management, top management support, training and education, and user involvement, are teamed together to build a complete picture of ERP upgrade. This picture makes a worthwhile contribution since it has clearly identified factors that are influencing ERP upgrade and gives important implications to those CIOs and IT manager who are implementing or will implement ERP upgrade projects. With knowledge of these eight factors, CIOs and IT managers can avoid underestimating or overestimating some factors during their ERP upgrade.

Further more, adhering to the various levels of application of ERP systems will ensure that organizations can derive maximum benefits from ERP systems after upgrading, and that the decision-making process and the flow of information happen in a seamless, corporate-wide perspective.

Since this research is a qualitative study, it is recommended that future studies apply quantitative methods to evaluate the results from this study.

The Impact of Transactional E-Commerce on CPAs' Perception of Audit Risk: Preliminary Results

Steven T. Breslawski, State University of New York, College at Brockport, 350 New Campus Drive, Brockport, NY 14420, USA; E-mail: sbreslaw@brockport.edu

ABSTRACT

In this paper, we report results from a preliminary study designed to understand 1) the level, if any, at which transactional e-commerce systems are viewed as sufficiently substantive to have a material impact on audit risk, and 2) how the presence of a material transactional e-commerce system impacts auditors' perceptions of audit risk. The results provide motivation for a more extensive and detailed study that investigates how a material e-commerce presence impacts the individual components of audit risk specified in SAS 55 (AICPA, 1988).

INTRODUCTION

It is well understood that the development of computerized information systems has long spawned challenges for accounting professionals charged with auditing financial statements. In particular, numerous authors and texts have discussed the problem of "auditing around the computer." The problem, in essence, occurs when information systems are either sufficiently complex or opaque as to render it impossible for auditors to efficiently and effectively conduct an audit. In these situations, there may be an increase in audit risk.

Audit risk is the risk that the auditor will fail to detect one or more material errors in the financial statements. Audit risk is espoused to have thee components: Inherent Risk, Control Risk, and Detection Risk. The basic audit risk model framed in *Statement on Auditing Standards 55* (SAS 55) is as follows:

Audit Risk = Inherent Risk * Control Risk * Detection Risk

Inherent Risk is the risk that an assertion made in a financial statement contains a material misstatement, assuming the absence of controls that might detect the misstatement. Inherent risk varies by financial statement assertion, type of business, and complexity of the business environment. *Control Risk* is the likelihood that controls established by a business fail to prevent, detect, and correct a misstatement. Inherent and control risk are assessed by the auditor, but are not directly under their control (although the auditor might make recommendations that will influence future levels of control risk). *Detection Risk* is the risk that an auditor fails to detect a material misstatement in the financial statements that has evaded detection by internal controls. Detection risk is controllable by the auditor and is a function of nature, timing, and extent of audit procedures applied.

As information technology has become more complex and ubiquitous, the challenge facing auditors has grown correspondingly. The accounting profession has responded with more guidance to auditors (embedded in professional standards), automated auditing software, better educated and more technically savvy audit professionals, and the use of information technology specialist on audit teams. However, despite the responsiveness of the accounting profession, the exponential growth in the scope and sophistication of new information systems technologies threatens to outpace and overwhelm the responses of the auditing profession, almost like a fire that is growing faster than firefighters can extinguish it.

While the information technology (IT) environment continues to challenge auditors' ability to effectively and efficiently test information systems controls or verify the integrity of transactions, recent changes in regulations and professional standards, most notably the Sarbanes-Oxley act of 2002 (henceforth SOX) (SEC, 2002) and SAS 94 (AICPA, 2001), compel auditors to be more aggressive, thorough, and efficient in this regard. The overarching consequence of SAS 94 and SOX is that managers and auditors can no longer simply assess control risk at its maximum level and assert that the effectiveness of IT controls can not be assessed. They are now compelled to develop a detailed understanding of the controls and the associated control risk.

Specifically, section 404 of the Sarbanes-Oxley act (SOX) requires the senior management of publicly traded companies to establish and maintain adequate internal controls for financial reporting as well as annually assess the effectiveness of said controls. The law also establishes attestation requirements auditors to assess management's certification of the effectiveness of its internal controls over financial reporting. Section 404 went into effect in November 2004; see Geiger and Taylor (2003) for a review of section 404.

SAS 94, *The Effect of Information Technology on the Auditor's Consideration of Internal Control in a Financial Statement Audit* requires the auditor to test the automated IT controls embedded in computer programs by using computer-assisted audit techniques. Auditors are obliged to respond in this fashion when the IT environment is complex and it is not practical to reduce detection risk to acceptable levels through the use of substantive tests alone. Further, SAS 94 requires tests of both the design and operation of controls in order to reduce the assessed level of control risk. While SAS 94 focuses on the control risk component of audit risk, threats to inherent risk are implied as well. SAS 94 identifies various IT-related threats that render certain asset classes inherently more risky. These include reliance on systems that incorrectly process data, the processing of inaccurate data, unauthorized access to data, destruction or modification of data resulting from unauthorized access, recording of unauthorized or nonexistent transactions, unauthorized changes to systems and programs, and unauthorized manual intervention. A number of authors have discussed the correlation between control and inherent risk; see for example Cushings and Loebbeck (1983) and Waller (1993).

The issues addressed in SAS 94 are not entirely new to auditors, as SAS 94 amends on guidance provided earlier in other professional standards, including SAS 47 (Audit Risk and Materiality), SAS 55 (Internal Control in a Financial Statement Audit), SAS 73 (Using the Work of a Specialist) SAS 78 (Internal Control: An Amendment to SAS 55), SAS 80 (Electronic Evidence). SAS 94 does not, however, change the basic audit risk model described above and specified in SAS 55.

RESEARCH QUESTIONS AND FOCUS

SAS 94 and SOX both compel auditors to pursue enhanced vigilance in the face of existing and emerging IT environments. Two general questions for researchers are:

1. To what degree, if any, do auditors perceive that various IT environments and technologies change audit risk and, therefore, audit practice?
2. At what scope of adoption do various IT environments become a material concern in the assessment of audit risk?

While these questions can be asked for many of the exciting IT technologies embraced by business in recent years, our focus in this paper will be transactional e-commerce. We define transactional e-commerce as *the process of conducting*

transactions, including buying, selling, purchasing, and payment using the internet or other computer networks connecting two or more organizations. Transactional e-commerce (TEC) has had a profound impact on business practice and the degree to which TEC has become ubiquitous suggests that its impact on audit risk is relevant to many in the audit profession. Further, transactions are perhaps the most fundamental inputs to the financial reporting process and are therefore key to the consideration of how technology impacts audit risk.

A priori, it is difficult to predict how a material transactional e-commerce presence impacts audit risk. Traditionally, transactional e-commerce has taken the form of highly structured electronic data interchange (EDI) transactions supported (and recorded) by a third party value added network (VAN) using dedicated, private, and secure communications links. EDI has evolved into a highly structured and mature technology, benefiting from international standards such as EDIFACT and ANSI X12 (see, for example, OECD, 1995). It can be argued, for example, that traditional EDI systems lend themselves to perpetual auditing approaches and would therefore result in a corresponding reduction in audit risk; see, for example, Helms (2002) and Write (2002). Because there are substantial costs involved, EDI has been adopted primarily by large organizations that often have highly trained IT staff and internal audit staff, also suggesting reduced audit risk.

Compared to traditional EDI, web-based TEC is much less mature as a technology and much less standardized. Consider, for example, that web-based TEC has grown from virtually zero in 1995, in terms of number of companies impacted and volume of sales, to billions of dollars in sales and thousands of companies involved. Traditional EDI is rapidly being replaced or augmented by internet-based solutions that are often less secure, standardized, and robust in their designs than traditional EDI implementations. Adopters of web-based transactional e-commerce include smaller firms with more modest IT and internal audit staffs. In this new environment, we might expect audit risk to increase.

Consider also that e-commerce technologies have facilitated accelerated fracturing of the business value chain. As companies outsource nearly everything except their core competencies, it becomes more and more difficult for auditors to confirm the existence of management and software application controls; it is not unusual for those controls to reside with other companies. As paper trails, legacy systems, and programming staff are replaced with vendor-based and outsourced IT solutions, institutional knowledge of the details underlying software controls becomes increasingly scarce. See Pathak and Lind (2003) for a good discussion of possible ways that IT might impact audit risk.

This paper represents the initial stages of inquiry regarding the relationship between a transactional e-commerce presence and audit risk. Our long-term goal is to develop a detailed understanding of whether changes in perceived overall audit risk, related to the IT environment, are directly related to changes in the auditor's perception of inherent, control, and detection risk as suggested by the SAS 55 audit risk model. However, we first begin by determining whether audit professionals can even respond to questions concerning the impact that transactional e-commerce has on audit risk. As such, our immediate goal in this study is to explore the following questions:

1. From an auditor's point of view, what is a material e-commerce presence? That is, at what point does a transactional e-commerce presence become enough of an issue as to impact perception of audit risk and, therefore, the conduct of an audit?
2. How does a material e-commerce presence impact audit risk and, consequently, audit costs?
3. Are the components of audit risk (inherent, control, and detection risk) impacted by a material e-commerce presence?
4. Does the amount of experience of the auditor, in the e-commerce environment, impact perceptions of changes in audit risk?

While some, most notably Pathak and Lind (2003), have discussed the relationship between audit risk, audit practice, and IT, we are unaware of any research that seeks to solicit the perception of auditors on these issues.

SURVEY INSTRUMENT AND RESULTS

This inquiry is based on analysis of responses of fifty CPAs who agreed to complete a brief survey. The fifty participants, identified from the American Institute of Certified Public Accountants (AICPA) database, worked for large firms and indicated auditing as an area of interest. We hoped to identify individuals who had experience auditing in a TEC environment as well as individuals who had little or no experience, in order to understand how perceptions between the two groups differed.

Prior to administration of the survey to the target population, a pilot survey was administered to 12 local CPAs for the purpose of investigating clarity in the wording of survey instructions and questions. Survey questions are prefaced by instructions, to participants, that include a brief description of the audit risk model and the definitions of inherent, control, and detection risk. A definition of the phrase *transactional e-commerce* is also provided.

Results - Question 1: What is a material transactional e-commerce presence? Participants were asked to define a material transactional e-commerce presence in terms of percent of total sales and percent of total purchases. Results appear in Exhibit 1.

Exhibit 1. Material transactional e-commerce presence defined in terms of sales and purchases

A material transactional e-commerce presence is defined as….			
Sales		**Purchases**	
Response	**% of Respondents**	**Response**	**% of Respondents**
Sales exceed 10%	34%	Purchases Exceed 10%	24%
Sales exceed 20%	52%	Purchases Exceed 20%	70%
Sales Exceed 30%	14%	Purchases Exceed 30%	6%
More than 40%	0%	More than 40%	0%

Exhibit 2. Impact of material transactional e-commerce on audit risk and costs

A material transactional e-commerce presence results in….		
Response	**Impact on Audit Risk**	**Impact on Audit Cost**
Increases significantly	46%	22%
Increases, but not significantly	54%	62%
Does not increase/decrease	0%	16%
Decreases, but not significantly	0%	0%
Decreases significantly	0	0

Exhibit 3. Impact of material transactional e-commerce on audit risk components

What is the impact of a material e-commerce presence on…			
	Inherent Risk	Control Risk	Detection Risk
Significant Decrease	0%	0%	0%
Moderate Decrease	0%	4%	0%
No Meaningful Impact	12%	22%	14%
Moderate Increase	74%	40%	70%
Significant Increase	14%	34%	16%

The results suggest that a fairly modest e-commerce presence is considered to be material with regard to audit planning and risk.

Results - Question 2: How does a material transactional e-commerce presence impact audit risk and, consequently audit costs. Responses appear in Exhibit 2.

The auditors uniformly perceived an increase in overall audit risk, with about one-half perceiving a significant increase in risk. Interestingly, only about twenty-five percent thought that the increased risk would result in significant increases in audit costs while the remainder predicted little or no impact on costs. Ninety-four percent believed that increased costs would *not* be passed along to the client.

Results - Question 3: Are the components of audit risk (inherent, control, and detection risk) impacted by a material e-commerce presence? We asked auditors to provide "overall and general[1]" perceptions concerning the impact of a material e-commerce presence on inherent risk, control risk, and detection risk. Results appear in Exhibit 3 below.

Only two of the fifty participants suggested a decrease in any of the risk components (control risk). Auditors are most concerned with significant increases in control risk, consistent with the focus of SAS 94.

The results suggest that the perceived change in overall audit risk, shown in Exhibit 2, is associated with changes in the components of the SAS 55 model. However, since we measured the changes in a qualitative rather than quantitative fashion, the exact nature of the relationship AR = IR * CR * DR cannot be explored. In future research, we will determine whether CPAs are able to articulate percentage increases/decreases so that the relationship can be explored more completely.

Results - Question 4: Lastly, we were interested in whether the amount of experience one has in auditing in an e-commerce environment would influence perceptions of changes in audit risk. Of the fifty participants, thirty-two percent claimed "substantial" experience auditing in an e-commerce environment, thirty-six percent claimed "moderate" experience, twenty-six percent claimed "little" experience and six percent claimed "none". We organized our subjects into two groups, whose experience was "substantial or moderate" and "little or none". Utilizing the categories shown in Exhibits 2 above, a chi-squared test of independence revealed no statistically significant difference (α=.05) in the responses of the two groups with regard to perception of changes in audit risk. As such, we conclude that perception is independent of level of experience.

SUMMARY AND CONCLUSIONS

Our goal was to begin an investigation of how an important type of information technology, specifically transactional e-commerce, is perceived by CPAs to impact audit risk and practice. A survey was used to determine whether auditors have salient opinions that can be expressed concerning the relationship between transactional e-commerce and audit risk. Not only were auditors able to express opinions on the relationship, the opinions were uniform in suggesting an increase in overall audit risk and in the individual components of risk. The results motivate further detailed study to see if the relationship between the components of audit risk, as specified in the SAS 55 model, can be substantiated, perhaps by asking auditors to express perceived changes in risk in numeric terms and at the account and management assertion level. A larger sample will facilitate the inclusion and analysis of additional control variables. For example, the differences in responses pertaining to traditional EDI systems and non-EDI web-based systems might be explored.

A majority of auditors suggested that some increase in audit costs would occur, suggesting (as anticipated) a change in audit practice. A more detailed analysis of changes in audit practice, resulting from the perceived increase in audit risk, could be pursued. This includes understanding whether increased costs are due to changes in procedures, changes in scope, changes in timing of procedures, or some combination.

ENDNOTE

[1] The qualifier "overall and general" is required because these risk factors should be assessed for each account classification (e.g. accounts receivable) on the financial statements and for each management assertion made for the account. Under SAS 55, the assertions are completeness, existence, ownership, valuation, and disclosure.

Examining Data Cleansing Software Tools for Engineering Asset Management

Vivek Chanana, University of South Australia, Adelaide, SA 5001, Australia; E-mail: Vivek.Chanana@unisa.edu.au
Andy Koronios, University of South Australia, Adelaide, SA 5001, Australia; E-mail: Andy.Koronios@unisa.edu.au

ABSTRACT

To be more cost effective and efficient, organizations are relying on improved operations and maintenance strategies for their engineering assets. Even after having done huge investment in operations and maintenance systems, they are not able to reap proportional benefits. It is mainly attributed to the quality of data present in these systems and lack of integration between diverse systems used in the organizations. The paper presents uniqueness of data encountered in engineering asset management (EAM) setup and the quality problems in such data. It reviews the suitability of commercially available data cleansing software tools for EAM environment, provides a comparative evaluation of features of tools and points to the areas that need improvement to effectively handle EAM data.

Keywords: Engineering asset management, data cleansing, data quality, data cleansing tools.

1. INTRODUCTION

Striving for success in today's global economy has put manufacturing and utilities organizations under intensive pressure. They are trying to achieve this through increasing production efficiency, reducing inventory carrying costs through just-in-time strategies, while ensuring that their products meet customer satisfaction. Unfortunately, organizations have not done equally well on the asset management front. To achieve maximum possible up-time for their assets, organizations are now trying to turn towards asset management as an optimization strategy to improve their process efficiency, reduce maintenance cost, and improve their returns over time on assets (Eerens, 2003). The objective of effective engineering asset management (EAM) is to reduce total cost of ownership of assets, ensure the optimum level of reliable and uninterrupted delivery of quality service, minimize the need for new assets, and continuously align assets with organizational needs (IPWEA, 2002).

Engineering asset management involves acquiring, maintaining, and disposing of assets and is a serious business. Staggering investments are made in engineering assets. The cost of maintenance and replacement of these assets represents a major share of their operating costs. According to a study conducted by ARC Advisory Group (Snitkin, 2003), nearly 40 percent of manufacturing revenues are budgeted for maintenance. The potential for savings from proper management of assets is immense. Obviously, a little improvement can result into significant savings through reduction in maintenance cost. Enhancing quality of data stored in various information systems supporting EAM through data cleansing can reduce the operational and maintenance cost in organizations and contribute significantly to their bottom line.

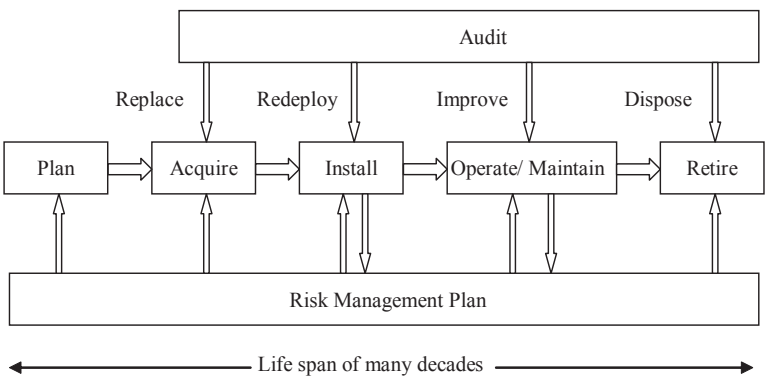
In this paper, the authors discuss the results of a study done to evaluate commercially available data cleansing software tools for EAM environment. The paper is organized as follows. Section 2 discusses how data encountered in EAM is different from data found in business applications. Section 3 defines the concept of data quality and highlights the quality problems in such data. Section 4 then provides a solution to improve data quality through data cleansing. Section 5 provides a list of commercially available data cleansing tools that were investigated and also provides a comparative evaluation of features of these tools and points to the areas that need improvement to effectively handle EAM data.

2. EAM ENVIRONMENT

Engineering asset management deals with the effective management of broad range of physical assets like machinery, production equipment, and fleets belonging to engineering organizations. Engineering assets exhibit unique characteristics in many ways. They are generally complex, expensive and operate for continuous periods of time. They need care so that they can provide service without failure for an extended useful lifetime. They need to be managed through best practice methodologies and business processes for getting maximum benefit from them (Blanchard, 2006). The process of asset management is sophisticated and involves the whole asset lifecycle that generally spans over many decades as shown in Figure 1.

Maintenance strategies for engineering assets, once *run-to-failure* now are becoming *condition-based*. Condition-based maintenance used in strategies like Reliability

Figure 1. Engineering asset lifecycle stages



Centered Maintenance (RCM) constantly monitor the health of assets and collect lots of data pertaining to asset conditions. In addition to this, data related to asset operations are also collected. The analysis of collected data provides knowledge about the current and future condition of assets and helps to schedule and plan future maintenance activities.

Data typical of asset management environment can be both structured and unstructured. The structured data could be related to physical characteristics of assets like its type, size, ratings, specifications, bill of materials (BOM) of parts and spares etc. The unstructured data could in the form of notes, inspection reports, sketches, work instructions, safety data sheets etc. Data can be captured both automatically through sensors and field devices, and manually through human operators and technicians in a variety of formats. The automatically captured data can be periodic or continuous process-centric streaming real-time data. Data could also be sourced from a variety of databases and disparate operation and maintenance systems.

Data types can typically include: inventory data, condition data, performance data, criticality data, lifecycle data, financial data, risk data, reliability data, technical data, physical data, GPS data, etc. EAM environment contains many information systems used at various life cycle stages and these systems store data in their propriety formats. Some of the systems used in typical EAM environment are:

- CAD: Computer Aided Design
- CMMS: Computerized Maintenance Management System
- DMS: Document Management System
- ERP: Enterprise Resource Planning
- GIS: Geographic Information System
- LIMS: Laboratory Information Management System
- PAM: Plant Asset Management
- PDM: Product Data Management
- PLM: Product Life Cycle Management
- SCADA: Supervisory Control and Data Acquisition
- SRM: Supplier Relationship Management
- WMS: Warehouse Management System

3. DATA QUALITY ISSUES

Data quality has become an important topic of investigation in research and industry however, so far there is no single agreed definition of data quality (Maletic and Marcus, 2000). We define high-quality data as data that are *fit for use* by data consumers—a widely adopted criteria (Strong et al, 1997). Data quality is regarded as multidimensional concept in the literature and there is no general agreement on a firm set of data quality dimensions (Wand and Wang, 1996; Wang et al, 1995). Frequently mentioned dimensions are:

(i) accuracy (degree of correctness and precision with which real world data of interest to an application domain are represented in a system),
(ii) completeness (degree to which all data relevant to an application domain have been recorded in a system),
(iii) consistency (degree to which the data managed in an information system satisfy specified constraints and business rules), and
(iv) timeliness (degree to which the recorded data are up-to-date).

Data used in EAM organizations can have a wide range of errors, inaccuracies and inconsistencies, such as wrong data, missing data, inconsistent use of abbreviations, misspellings during data entry, outdated or invalid data etc. in single or multiple data sources. Also EAM organizations generally have a significant portion of their data stored in legacy systems that constitutes lots of unstructured data. These organizations face many problems in mapping field names while migrating from legacy systems to enterprise asset management applications.

As discussed in the last section, EAM organizations use plethora of information systems that deal with asset data. Data in these information systems have great diversity in formats and semantics (Friedman, 2006). These organizations cannot deliver attractive return on investment unless they are underpinned by clean and consistent data. As systems grow in complexity and the volume of data increases, the level of data quality becomes more critical to success. The effectiveness of decision-making is limited to the quality of the data. A number of organizations worldwide have suffered large financial losses due to inaccurate, incomplete or wrong data in their data repositories (English, 1999).

4. DATA CLEANSING

Data cleansing deals with detecting and removing errors and inconsistencies from data in order to improve their quality (Muller and Freitag, 2003; Rahm and Do, 2000). Data cleansing also called data cleaning or scrubbing has caught on in a big way as a crucial first step in organizations dealing with applications like data warehousing, data mining and knowledge discovery where data forms their core asset.

As mentioned in section 2, asset management is characterized by a range of diverse data sources most often from multiple vendors and at times with some proprietary data formats. Data cleaning becomes especially important in such situations when multiple data sources need to be integrated. On the lower end of the problem, it could be a case of simple redundant data that can be handled easily. On the other end, semantically same data having different representations in heterogeneous sources will result into redundant data. In order to have a single view and access to accurate and consistent data, consolidation of different data representations and elimination of duplicate information becomes very necessary. This problem has been referred to in literature as merge/purge problem (Hernandez and Stolfo, 1998).

While most practitioners of data quality are aware of the problems with their data quality issues, only recently there has been an emphasis on the systematic detection and removal of data quality problems (Dasu and Johnson, 2003). A data cleansing approach detects and then removes all major errors and inconsistencies both in individual data sources and when multiple data sources are integrated. Therefore, data cleansing should not be performed in isolation but together with schema-related data transformations based on comprehensive metadata.

5. DATA CLEANSING TOOLS

5.1 Commercially Available Data Cleansing Tools

In recent years there has been a significant growth of data quality tools in the market. This is the result of organizations realizing the importance of good quality data and the harm poor quality data can do to their effectiveness. The organizations are considering data quality as a strategic issue and are actively seeking solutions for its improvement. They are relying on technology for improving data quality which has led to a strong interest in data quality tool market. Although data quality tools market is still modest in size compared to many other software markets, there is a likelihood of it growing in future. This is evident by the tumultuous movement in the market and the interest it has evoked in small and large vendors. There have been mergers and high profile acquisitions by large vendors like Business Objects, IBM and Pitney Bowes.

The authors investigated the suitability of some commercially available data cleansing software tools in the market for the cleansing of asset management data. Our analysis is based on our appraisal of the available literature found on vendor's homepages, their product specifications, and independent industry survey reports from consulting firms. The limitation of this research at this stage is that the comparison of the cleansing tool is not based on any testing of installed software with real data. The reason for not doing this is that the cleansing software tools are very expensive and hence it was not practically possible and financially feasible to investigate all software installations. In future research activities we plan to interview the vendors so that we can get information that is not freely available. Later on, with the identification of industry partners of our University who have used these software tools, we plan to have even more in-depth viewpoint and feedback about the respective advantages and features of these tools. Although every attempt was made to include major vendors in this study, it is possible to have missed some major vendor in this area and/ or not adequately covered some specification of their tools that they might support.

Following is the list (in alphabetical order) of commercially available tools that we reviewed:

- Athanor - Similarity Software (IMC, 2006)
- DataSight - Group 1 Software - Pitney Bowes (G1S, 2006)
- dfPower Studio - DataFlux SAS (DFC, 2006)
- i/Lytics - Innovative Systems Inc (ISI, 2006)
- Information Quality Suite - First Logic - Business Objects (FLI, 2006)
- PowerCenter - Informatica (IMC, 2006)
- Trillium Software System - Harte-Hanks Trillium Software (HTS, 2006)
- WebSphere QualityStage - Enterprise Edition IBM (IBM, 2006)

Table 1. Comparison of data cleansing software tools

Features	Athanor 3.0	DataSight	dfPowerStudio	i/Lytics	IQ8	PowerCentre	Trillium Software System	WebSphere QualityStage
Vendor	Similarity Systems (Informatica)	Group1 Software (Pitney Bowes)	DataFlux SAS	Innovative Systems	First Logic (Business Objects)	Informatica	Harte-Hanks Trillium Software	IBM

Support for Unicode	Basic	Very good	Basic		Good		Good	
Client Server platform	Good	Basic	Good		Good		Very good	
User Interface		Intuitive	Graphical workflow GUI		Intuitive	Effective		Easy to use
Scalable		Good			Very good		Good	

In addition to the above mentioned data cleansing tools, we also investigated some more commercially available tools as well as tools developed as an outcome of academic research, like: AJAX (INRIA, France), Arktos (National Technical University, Athens), DataLever Enterprise Suite (DataLever Corporation), dn: Clean (Datanomic), Intelliclean (National University of Singapore), Porter's Wheel (University of California, Berkeley), and WinPure (WinPure Inc). These tools are not included in the comparison shown in Table 1, as they did not offer an exhaustive range of data cleansing features.

5.2 Comparison of Data Cleansing Tools

The data cleansing software tool vendors are offering a wide range of data quality functionality like data profiling, data parsing/ correction, data matching/ de-duplication, enrichment, integration, and data monitoring (Howard, 2004). They are either offering various data quality components as a separate product, with some degree of integration between them or a suite of functions covering full spectrum of capabilities. It becomes convenient for organizations to deploy a single-vendor solution for enterprise-wide data quality requirement. Table 1 provides a comparison of eight major data cleansing tools we investigated in detail. The three levels of rating: 'basic', 'good' and 'very good' are assigned based on the degree of support for a feature by the vendor. Cells in a column are left blank where sufficient information about the respective features is not available from the vendor.

5.3 Analysis of Data Cleansing Tools

The initial impetus to commercial data quality tools was given by customer data management problem. The customer data (i.e. the name and address of customers) that support Customer Relationship Management (CRM) related activities is the most volatile field in corporate databases. The quality of this type of data quickly degenerates over time. Therefore, most of the pioneering data quality tools focused initially on cleaning up customer data only; even today majority of data quality functionality is aimed at this type of data. But at the same time the present day data quality tools have expanded well beyond such capabilities and the vendors are including other data domains like product data and financial data to their list. Master data management (MDM) initiatives are driving the product data whereas financial data is being driven by corporate accountability and regulatory pressures from governance initiatives like Sarbanes-Oxley, and HIPAA compliance.

Lots of applications are driven by today's powerful database technologies. The data cleansing tools are offering fast access to and from relational databases like: Oracle, SQL Server, DB2 and others. They are also supporting Windows ODBC connectivity, and traditional delimited files. In addition to conventional data quality functions, the tools provide a scope for connectivity to databases, integration with enterprise systems like Enterprise Resource Planning (ERP) and data warehousing tools like Extract transform Load (ETL).

Text processing systems worldwide are increasingly supporting Unicode to have a consistent way of encoding multilingual text and to exchange text files internationally. As enterprises expand their reach to global locales and clients, more and more companies are moving their business data to Unicode. Majority of vendors we reviewed are providing support for Unicode framework, allowing users to read and write data from a wide variety of Unicode and non-Unicode pages. Some vendors are supporting Geocoding and are able to enrich data by adding value to the captured data. This feature is very importance for assets that are installed in remote areas and for those assets that are in transit.

Adoption of Web services and service-oriented architecture (SOA) for achieving agility and ease of adapting to changing business requirement by organizations is at an increase. This is very well matched by the data cleansing tool vendors who are providing support for SOA. They are supporting industry Web Services standards like SOAP, XML, WSDL, UDDI, and HTTP through the SOA framework. SOA is an ideal implementation methodology for centralizing data quality processing across the enterprise and is quick to implement and easy to maintain. The tools should reach out with Web Services integration for popular IBM WebSphere, BEA WebLogic, and Microsoft .NET platforms.

6. MORE NEEDS TO BE DONE TO SUPPORT EAM DATA

The functionality of commercially available data cleansing software tools has improved over the years. The tools can adequately address the data quality problems of transaction based data that usually reside in tables of relational databases. But more needs to be done towards the improvement of specifications and feature of these tools enabling them to cater for the peculiar and unique data that are typical of asset management environment.

Some asset data may not be available in structured tables; it may reside on flat files. Though data cleansing tools have started to broaden their range by adding more data types like non-name product data and financial data under the structured data category, they are far from handling typical asset data that might include parts list and condition monitoring data under structured data types, and specifications, inspection reports, instructions etc. under unstructured data types.

The earlier versions of data cleansing tools worked on flat files in batch mode. The present data cleansing tools are supporting hybrid client/server architectures that allow validation, standardization, and matching done in real-time across a LAN or WAN (Lee et al, 1999). Support for real-time functions is very important in an asset management setting where control and monitoring data can be in real-time and streaming and it is expected to cleanse data before it is saved onto a database or data repository, or used for triggering or actuating some action linked to the status of data.

In asset management environment, annotations are often done by engineers and technicians during regular installation, operation and maintenance of assets and while carrying out modifications and improvements to the existing process or assets. This generates a lot of very useful metadata that calls for adequate handling. The future tools need to enhance their capabilities from syntactical to semantic. They not only need to merely recognise the structure of data but also understand the meaning of data through extensive use of metadata. The tools based on metadata-driven design will enable enterprises to move beyond defect inspection to solving data defects through root-cause analysis and building in data quality from the outset as a core function of any application design. The vendors like Trillium Software and Firstlogic have developed tools that make use of some data matching and cleansing business rules (Galhardas, 2001) but tools need to have centralised set of common business rules that can drive all the various data quality components like profiling, matching, cleansing, validation, standardization and enrichment.

7. CONCLUSIONS

By having an effective asset management in place, EAM organization can reduce total cost of ownership of their assets, get the most out of their assets, minimize the need for new assets, and continuously align capital assets with organizational needs. The organizations rely on a number of disparate information systems to improve operations and maintenance strategies for their engineering assets. Through these systems, they collect structured and unstructured data in various formats. Bad quality data in data repositories and lack of integration between diverse systems does not allow the organization to have a comprehensive view of all the data they own and severely impacts the quality of their decision making process.

Data cleansing software tools can provide help in improving data quality. But sadly, as shown above, data cleansing tools that are commercially available from vendors fall short of cleansing some nuances of engineering asset data. The vendors need to enhance their features to cater for the burgeoning need for cleansing asset management data.

This paper discusses how data cleansing tools can improve the quality of dirty data; though it should not be considered as the only way to improve the quality of data. Moreover data cleansing through tools should not be seen as a standalone activity. The real and more effective solution lies in establishing a well defined data quality methodology that controls the business process and does not allow the bad data to enter information systems in the first place.

Low Budget E-Commerce Solution for a Dental Supply Company

David Gadish, California State University Los Angeles, USA; E-mail: dgadish@calstatela.edu

ABSTRACT

This case presents an overview of an e-commerce solution for a dental supply company that provides dentists with over 16,000 different dental products from alloys, to dental instruments to x-ray products. Using the e-commerce solution of ENG Dental Supply, dental offices are able to order products online. This is a more efficient approach to the traditional catalog order method where dentists would call in or fax their orders. The process and challenges of implementing this low budget e-commerce solution are discussed.

INTRODUCTION

ENG Dental Supply is a family owned and operated dental supply company serving the community of dentists of Southern California. The company was founded in the 1940's and currently serves approximately 1,000 clients and offers over 16,000 different products from over 200 manufacturers. ENG Dental Supply was a labor-intensive company where traditional methods were still used for most of the company's operations. ENG was relying on the fax machine and most processes were completed manually. Management did not have the vision to keep up with technology. Management did not consider the importance of technological solutions that other firms have implemented to increase efficiency and cut costs. The company's processes were considered to be so straight forward by the management that little attention was paid to changing the way business was conducted. A decision to modernize came as revenues started falling and existing clients started ordering dental supplies from competitors.

The organization consists of the following units:

- The executive team oversees the organization, maintains relationships with key clients, and with top suppliers.
- The accounting department is responsible for accounts receivable and accounts payable, as well as financial reporting.
- The warehouse operations department receives products from over 200 manufacturers of dental products and equipment. Employees unpack merchandise, arrange merchandise on shelves in the warehouse, and enter incoming inventory into the computer system. They also collect merchandise from shelves and pack into boxes for shipment to dentist offices, and load on trucks for daily delivery.
- The purchasing department monitors inventory levels, and purchases the appropriate merchandise ensuring sufficient levels exist in the warehouse.
- Customer services department employees answer client phone calls to take orders, and provide product information / prices. They record orders in the computer system. They also process faxed orders sent by sales people or clients.
- Sales Department employees visit client dental offices to provide product information, and take orders. They then fax these orders to the customer service department for entry into the computer system and fulfillment. They also visit prospective clients, and work to convert them to clients.

THE DENTAL SUPPLY INDUSTRY

The North American market size in 2005 was estimated to be $5.6 billion (Patterson D.S., 2006). Two main players in the market are Patterson with 32% and Sullivan-Schein with 30% market share. Market growth is estimated to be 7-9% annually. Consumables growth is estimated to be 5%-7%, whereas equipment growth is estimated to be 10%-12%.

Benco (Benco, 2006) and Pearson Dental Supplies (Pearson, 2006) are two mid sized companies. The other players in the Dental Supply Industry include but are not limited to AccuBite Dental Supply, Atlanta Dental, Applied Dental, Burkhart Dental, Conger Dental Supply Company, Darby Dental Supply, Discus Dental, and Eastern Dental Supply.

The North American dental market consists of about 156,000 U.S dentists and around 18,000 Canadian dentists (Pearson D.S., 2006). 65%-70% are sole practitioners. There are over135,000 dental practices. The average revenue per dentists stands on $550,000 per annum. Dentists spend $0.05 – $0.07 revenue per dollar on consumables supplies, which means $25,000 to $35,000 of revenues per annum.

STAYING COMPETITIVE WITH E-COMMERCE (EC)

The Internet, the World Wide Web and other developments of the information revolution will redefine patient care, referral relationships, practice management, quality, professional organizations and competition (Bauer, J.C., Brown, W.T., 2001). The Web offers the advantages of both centralization of information and coordination (Marks, R.G. (2004). To survive, ENG needed to increase revenues, reduce operating costs by automating business processes through the implementation of their website and e-commerce solution, and build on the ENG Dental Supply brand name. By achieving these goals ENG will then provide customers with information online, allow them to place orders online, and reach out to their prospects using the internet. ENG will become more accessible to their clients and prospects.

ENG will use their website to further inform its customers of new dental supplies and sell dental supplies to its customers. The ENG website will ultimately consist of four systems:

- Product system: will include product search and an online catalog system
- Customer system: will include a customer accounts systems, authentication system and links to order and product systems
- Order system: will include customer orders and delivery systems
- Supplier system: will tie the products and inventory levels to suppliers for automated reordering

The website was designed to integrate the first three areas of commerce. The systems mentioned above were implemented using web technologies. Databases, web servers, web applications and other computer technology were used to get the website up and running.

After performing some preliminary research on websites of major dental supply companies an effort was undertaken to implement some of their strategies for success in our own website. The goal is to deliver a complete set of services for our customers that is easy to use and navigate. These services include:

- Customer accounts systems: customers will be issued a personal account, which will include past purchases and current purchases. They will also be able to customize their home page for easy shopping, by defining their preferences.
- Online catalog systems: customers will have access to an organized list of products where he or she can browse and click through to the product detail level.
- Products search systems: customers will have the convenience of a product search engine whereby a keyword is entered to retrieve a "like" product.
- Order/order tracking systems: customers will be able to track their purchases from the time they place an order until it arrives at their offices.
- Inventory and procurement system: inventory levels will be updated daily for customers convenience

The implementation would be based on expanding our website capabilities. Ways that the company can utilize to sell its products to customers were determined. This information was conceptualized on how the website would look compared to accessibility of the content.

EC Planning Phase

In creating the E-commerce solution for ENG Dental Supply, the Systems Development Life Cycle process was utilized. It consists of seven phases. The planning phase covered project scope and budget.

Determine Project Scope - ENG needed to catch up with their competitors almost immediately if they wanted to remain a viable dental supply company. In order to do so, ENG needed to provide its customers with an online product catalog that would have electronic commerce capabilities so the customers could compare products and place orders.

Determine Budget - The client allocated $45,000 for the initial implementation, and so the question facing the team was how to implement the maximum possible for the tight budget. To achieve that, the activities were prioritized and implemented selectivity.

EC Analysis Phase

The e-commerce site needed to be easy to use and maintain. An analysis study of the company's business processes was performed in order to identify ENG's requirements. Information about employees and their duties was collected, and a course of actions was formulated based on the analysis of the findings.

Research Competition - Portals differed in many characteristics, such as the number of services, product pricing, discussion forum activity, navigability, reaction time in response to questions and site responsiveness (Schleyer T, Spallek H., 2002). The online presence of the dental supply competitors including their e-commerce capabilities was analyzed. These companies included: Patterson Dental Company, Sullivan-Schein Company, Burkhart Dental, Inc., Darby Dental Supply and Benco Dental, Inc.

Analyze Employees and Client Requirements – Meetings with management covered the employee and client requirements. The customer service department, and the outside sales people, were then utilized to determine their requirements for such a system. They were asked to review competitors systems, and recommend ways in which the ENG System could be designed to achieve their needs and be better then the competition.

Research ISP's - The information of the company's Internet Service Provider was gathered. The company hosting the website relied on older technology and the ISP features did not allow for the usage of dynamic information. Several ISP's were studied for reliability, connectivity and service to support the new website. A company by the name of 1and1 met all the requirements for the solution.

Research E-Commerce - Several e-commerce packages were tested before making a final purchasing decision. X-cart Gold was selected to drive the new e-commerce site. The price was also very competitive compared to other vendors. The main reasons why this package was chosen are listed in Table 1.

EC Design Phase

The design phase consisted of designing an e-commerce site look and functionality, creation of the process to update prices, creation of the process to add/remove/modify products and the planning for marketing campaigns.

Design E-Commerce Site Look/Functionality - Two main actions were taken with respect to ENG's website, to improve its performance and usability:

- **Minimize** dynamic content; with careful performance analysis, it was determined that the usage of dynamic content on the site would decrease server performance. Budget constraints impeded the company to afford a high-end dedicated hosting server. Therefore, in order to improve performance on the website, dynamic content use would be minimized as much as possible.
- **Increase** the appeal of ENG's website. The main page of every website is critical in capturing the visitor's attention. Generally only five seconds are required to captivate the audience's attention. If the content does not convey the right message, the potential customer may be lost. The company's original website did not attract visitors.

The site was not sophisticated enough and e-commerce was non-existent. A survey of 250 clients was performed in order to determine what needed to be changed. The results were very clear. The recipients agreed that the website needed to be thoroughly revised. Hence, the website was redesigned, to maximize its appeal and functionality.

Create Process to Update Prices - Product prices were updated daily on the existing DMS environment. This was a manual process based on market prices of products offered by the competition. A new e-commerce solution meant that prices would need to be updated twice, creating possible inconsistencies between online and offline ordering prices due to human data entry errors. To resolve this, a batch process would be created to copy all price changes from the DMS to a Microsoft Access document twice each month. This document would be manually imported into the new e-commerce environment, then updating the prices quickly and consistently.

Create Process to Add/Remove/Modify Products - A list of products added, removed or modified would be downloaded from the DMS environment twice per month. The changes to product descriptions, added products or removal records would then need to be manually recorded into the system by an operator.

Plan Marketing Campaigns - A plan and a schedule were created outlining the traditional and online marketing efforts that would take place to promote the e-commerce website. Some activities were planned for the pre-launch period, others for the initial operational period and for ongoing activities.

EC Build Phase

E-commerce software was purchased, customized and tested.

Purchase/Configure Test Computer - A dedicated computer was purchased in order to perform testing of the website by the company's staff. The computer was setup as a dedicated machine to perform intensive tests and identify any

Table 1

Free customer support for X-cart customers. Whereas most vendors provide technical support for their products at a cost, X-cart has free customer support with the purchase of the software.	Personal order history log gives ENG' customers the ability to view how much and what they have ordered in the past.
Ability to print transactions.	Clients can search products by title, description and category.
The option to use discount coupon codes and gift certificates.	Full inventory control.
"Out of Stock" notifications.	Quantity discounts.
Retail and wholesale pricing.	Allow customers to choose delivery methods.
Ability to process credit cards using different known transaction companies.	Export sales and customer data for use in a spreadsheet.
Printable shipping labels.	Personalized greetings of regular customers.
Real-time order tracking for registered customers.	Encryption protection for secure transaction and customer data transmission.

Figure 1. Screenshot of ENG's homepage

Figure 2. Screenshot of ENG e-commerce storefront page

possible design errors. The investment of this system was a few hundred dollars.

Purchase E-Commerce Package - The software package chosen for the design and implementation of the e-commerce site is called X-cart Gold and was purchased from X-cart solutions (X-Cart). The basic package offered system capabilities such as querying, ordering and processing.

Create E-Commerce Website - The graphical user interface was customized for a more aesthetically appealing look. Features such as product search and thumbnail display were added (see Figure 1 and Figure 2).

Test E-Commerce Website - A limited data set of product records and clients was entered into the system. Testing was performed to ensure online ordering, transaction recording, and reporting of other key functions worked flawlessly.

Data Build Phase

The current database contained in the DMS was updated with detailed product descriptions and placed into a hierarchy in accordance with industry norms.

Extract Product Data from DMS - A script to extract all DMS data was created, tested and executed. Data was extracted into an MS Access file.

Figure 3. Screenshot of ENG's product categories

Identify Products to List Online - The organization's purchasing manager reviewed each product item in the Microsoft Access file. Over 5,000 products were identified as being discontinued or no longer sold by the company. Records were uploaded into the e-commerce package and tested to ensure the system reflected the appropriate values.

Product Data Cleanup - Focus was placed into making sure that all products had full description including prices and tags. The data was extracted into Microsoft Excel.

Classify Products - The DMS environment used only by ENG staff did not classify products in categories. Dental offices would require these to facilitate a more user friendly search. A list of ENG product categories was created by analyzing the categories of products available on competitor's websites (see Figure 3). These categories were subdivided into 638 subcategories to allow users to further refine their search of dental products.

Load Data - The e-commerce website uses MySQL to store the extracted records provided by the vendor in charge of retrieving the mainframe's information. The MS Access data was exported into a common separated value (CSV) file that would be recognized by the e-commerce package. These records were then carefully imported into MySQL to ensure data integrity (see Figure 4).

Collect Product Images – The image collection process caused major time delays due to difficulties entailed in obtaining the images from product supplier and manufacturers. ENG's suppliers and manufacturers were contacted in order

Figure 4. Screenshot of ENG's product listings

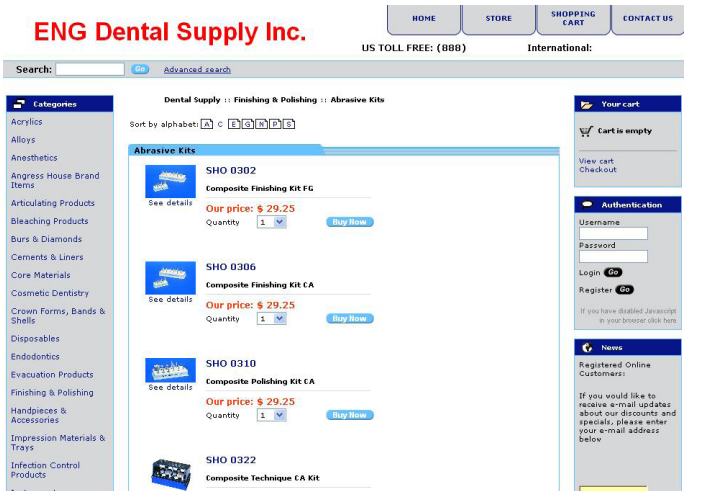

Figure 5. Screenshot of a dental product image

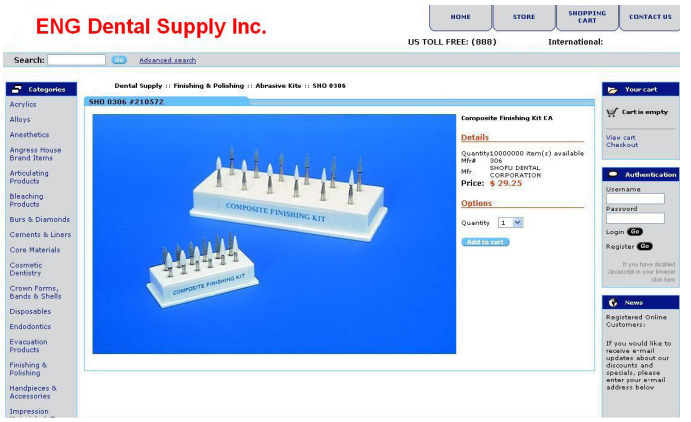

to provide their images for the e-commerce environment. Manufacturers provided diskettes or CDs with the product data. These images were converted to low-resolution format using Advanced JPEG compression version 4.8 software. The images were named according to the ENG product codes. Images are in the JPG format, which is a standard format supported by the X-cart package.

Populate Images into E-Commerce Website - This manual process involved importing one image for the directory of images into the corresponding data record in the e-commerce environment (see Figure 5).

Test E-Commerce Website/Data Focus - Testing was performed for a period of one week. All departments of the organization were involved in the thorough testing of the new site. Feedback was provided for minor adjustments of the e-commerce environment. A full time person was assigned to search for the most popular products to ensure their descriptions would help locating them online. A second week of testing involved ten ENG clients. They were provided with written instructions and telephone support to help them register, and use the system to purchase dental products online.

EC Deployment Phase

Deployment consisted of creating training materials, training employees, moving the website to the production environment, and then training ENG's customers.

Create Training Materials - Two training programs were offered to ENG: one for its employees and another for its clients. Separate training materials were prepared to train customer service staff and employees supporting the system. The documentation included:

- A document specifying the system's different features and capabilities; product search features, registering to the website, etc.
- A document containing an overview of the architecture of the system, instructions of how to maintain and add basic features to the system.
- A document containing a site map and information regarding product so as to assist customer service staff in supporting customers remotely.

Train Employees - The ENG customer service and sales department employees were trained on registering to the system, searching for products, reviewing transactions and extracting transactions from the DMS environment for order fulfillment.

Move site from Test to Production Environment - The new website had to be uploaded and promoted from testing to production once the required tests were performed.

Train Clients Online - Two main options for client training support were offered:

- Phone support by the customer service department staff for those clients encountering difficulties ordering or searching products through the system.
- Personal visit by sales representatives - in extreme cases where phone support didn't resolve the clients' problems or for VIP customers.

Customers were trained to register online, to search for products, to order products, to change orders and to review the order history.

EC Operations Phase

Ongoing operations of the e-commerce environment include price updates, adding, removing or modifying product information, marketing the e-commerce website, and supporting the site and the data.

Update Prices - The customer service support department employees were trained in the process outlined earlier. The ongoing was then implemented.

Add/Remove/Modify Products - The customer support department employees were trained in the process to add, remove and modify product information as outlined earlier. The ongoing process was then implemented.

Market E-Commerce Website - Both online and traditional marketing materials were created to maximize the exposure of the new program. ENG was provided with creative solutions to help increase its website exposure through website optimization, search engines and cross linking to dental websites frequented by prospective customers. The website was developed and optimized to attract search engine spiders. Online Marketing has been an ongoing activity since outside forces (such as updated content of other websites and other organizations' online presence) impact ENG' position in the major search engines such as Google, Yahoo, AOL and MSN. Search engines assist leading interested visitors to any page in the updated website.

The online marketing campaign was marketed directly to:

- Existing clients not currently buying online.
- As clients started purchasing online, clients were targeted to purchase more.
- Existing clients online that should be buying more.
- Lost clients – in order to regain their business by offering purchasing in a more convenient environment.
- New clients:
  - Established dental offices
  - Newly graduated from dental school

The following are examples of the online marketing activities that ENG had to adopt after the implementation of their e-commerce site:

- Setting up website cross linking with other organizations. Cross-linking was done with organizations in the same sector and related areas to increase traffic.
- Publishing articles in other dental organizations' online newsletters, announcing the launch of ENG' website as a way to increase exposure.
- Promoting ENG site on search engines to increase traffic to the website. The primary engines were Google, Yahoo, MSN, AOL Search, and AskJeeves.
- Creating a store on E-bay to expand the sale of the goods through other means. The reasons for recommending this approach were:
  - To sell products
  - To channel more traffic from e-bay to the e-commerce website.
  - To enhance the ENG brand.
- Linking to portals (vertical portals of the dental industry)

Targeted traditional marketing of new capabilities was accomplished as follows:

- Sales persons contacted selected clients to inform them of the new capabilities of the system. These clients were invited to a special launch event where the new system was presented. In order to provide incentives, discounts were offered for those clients ordering products using the new system.
- Other existing clients of ENG were contacted by sales persons to inform them of the new capabilities and its advantages.
- Flyers were distributed in major dentistry schools in California in order to expose ENG' products to recent dental school graduates.
- Stickers were placed on dental shipments showcasing the new e-commerce website URL.
- Letters were mailed with each client's invoice, informing them of the benefits of the searching for and ordering products online.

The key to this e-commerce implementation solution is to measure our website's functionality. To ensure a successful implementation the following activities will take place:

- Monitor number of membership forms submitted through the company website.
- Measure how many potential clients sign up for the company newsletters through the website.
- Monitor the number of reported emails and requests.
- Monitor the increase of business as the website is enhanced.
- Create online surveys on our website and partner website to gather information about customer service satisfaction levels and customer suggestions.
- Collect customer feedback and customer complaints to measure the satisfaction levels and identify our weaknesses.

Support E-Commerce Website - The ENG customer service department would be responsible for fielding client calls about the usage of the new e-commerce environment, about recommendations for changes or enhancements to the environment, as well as product search assistance to clients that cannot find the products they need. A list of proposed enhancements would be created to be incorporated into the planning on the next release of the site. Any data errors identified would be resolved within one business day.

SUMMARY

A decision was made to implement a shopping portal for dental practitioners that serves as a gateway for accessing over 16,000 products offered by ENG over the web. The objective of the portal was to: (1) Lower the cost of operations for ENG, (2) Improve efficiency, (3) Increase revenues. The ability to capture demographic information, shopping habits and other vital information was also implemented. Several kinds of reports were created through data mining to perform effective target marketing.

The dental portal currently allows visitors to access all the products offered by ENG through a single-secured sign in.

The number of customers quadrupled and revenues more than tripled over a two-year period since the installation of the system.

Towards a Design Theory of Autopoietic Knowledge Management Support Systems

El-Sayed Abou-Zeid, Concordia University, 1455 de Maisonneuve Blvd. W., Montreal, Canada, H3G 1M8; E-mail: el-sayed@jmsb.concordia.ca

ABSTRACT

The theory of autopoiesis, as a system-grounded way of thinking with biological foundations together with its extension into social domain, is used as a kernel theory for developing a design theory for knowledge management support systems. The "design product" aspects, meta-requirements and meta-design, are defined. Design methods are also suggested.

INTRODUCTION

As the awareness of the importance of managing organizational knowledge grows, the issue of how to build information and communication technology (ICT)-based systems to support knowledge management activities has been raised. However, as argued by Malhotra (Malhotra 2002), the underlying premises guiding the development of ICT-based knowledge management support systems (KMSS) increase the possibility of their failure. In fact, knowledge and its manipulating activities, by their very nature, are socio-technical phenomena in which social and technical factors interweave the ways in which people work (Alavi et al. 1999; Nidumolu et al. 2001; Pan et al. 1999). Therefore, a new "design theory" is needed to address the salient features of KMSS (Hahn et al. 2000). A "design theory", as explicated by Walls et al. (Walls et al. 1992a), must have two aspects - one dealing with the system (design product) and the other dealing with the procedures of designing the system (design process). In addition, these two aspects have to be grounded on theories from natural or social sciences, i.e., kernel theories.

The search for kernel theories requires a closer look at the system theories that go beyond the traditional system theory that is based, among other things, on Cartesian dualism, i.e., mind/body or cognition/action, and on a model of cognition as the processing of representational information (Mingers 2001). One of the candidate theories is the theory of autopoiesis, which can be best viewed as a system-grounded way of thinking with biological foundations, together with its extension into social domain.

To this end the objective of this work is to explore the potential of theory of autopoiesis as one of the kernel theories for dealing with both "product" and "process" aspects of autopoietic KMSS (AKMSS) design theory.

The remainder of this paper is organized as follows. In the next section, the issue of why a new approach for designing KMSS is need will be addressed. In the following sections the autopoiesis theory and autopoietic view of organizational knowledge are discussed. Then the autopoiesis theory will be used to derive a design theory for knowledge management support systems. The paper concludes by discussing the implications of the proposed approach.

WHY A NEW APPROACH IS NEEDED

In order to develop a design theory for KMSSs, the work to be supported by them has first to be described. This work can generally be described in terms of the characteristics of three elements: *organizational knowledge*, *the knowledge manipulating processes to be supported*, and *users and their work context* (Markus et al. 2002). The first element, *organizational knowledge*, has the following distinctive features:

- *Action-orientation*: According to Collins (Collins 1974), knowledge is a capability and thus creates the capacity to do something. Therefore, organizational knowledge is always anchored to business things toward which thought or action is directed or is communicated by the members of the firm (Hislop et al. 2000) and is constantly produced and re-produced through its business application (Augier et al. 1999) in order to create business value. One of the implications of the action-orientedness is its *indeterminacy*: As the business environment is in the state of continuous change and as organizational knowledge whatever its type is engrained in business activities, it is difficult to determine a-priori what knowledge will be requested, who will request it, who will supply it, and when and how the knowledge will be used (Abou-Zeid 2002; Markus et al. 2002).
- *Distributedness:* Organizational knowledge is spatially and temporally distributed as it is generated, owned and used by *autonomous* members of the organization, e.g., individuals and groups, and mobilized among them (Boland et al. 1996; Bonifacio et al. 2002). Moreover, the actions of organization members and their interpretation of symbolic representation of knowledge (explicit knowledge or information) are grounded in their *collective* tacit knowledge which has been formed in the course of past socialization and has become basic assumptions (Polanyi 1983; Tsoukas 1996).
- *Situatedness*: Knowledge cannot be disembodied from the people who carry it or from the situations in which they engage (Sierhuis et al. 1997). Therefore, using knowledge depends on the situation and people involved rather than on absolute truth or hard facts. Even the effective re-use of knowledge representations requires its re-creation to suit the local conditions (Boland et al. 1995; Collins 1993; von Krogh et al. 2000).

The aforementioned distinctive features of organizational knowledge require that *K- manipulating processes*, the second element, to be *social* and *contingent*. First, since organizational knowledge is distributed and context-dependent, most K- manipulating processes involve social interactions among organization members. Moreover, knowing and learning are inherently situated and distributed phenomena, residing in a series of non-localizable associations between social and material elements (Araujo 1998; Nidumolu et al. 2001). Second, as organizational knowledge is action-oriented and situated the type of its manipulating processes and the patterns of their execution are contingent upon these factors.

These characteristics of organizational knowledge and its manipulating processes call for re-conceptualizing *users of KMSS*, the third element, as *active social actors*. First, the use of knowledge and the interpretation/re-interpretation of explicit knowledge (or symbolic knowledge representations) cannot be disembodied from the user. Therefore, *the users of KMSS have to be considered as constituents of such systems who play specific roles in their operations*. Second, because of the distributed nature of organizational knowledge and the sociality of its manipulating processes, i.e., involve social interactions among organization members, the concept of the KMSS user is best described as a social actor - defined as "an organizational entity whose interactions are simultaneously enabled and constrained by the socio-technical affiliations and environments of the firm, its members, and its industry" (Lamb et al. 2003), p. 218) .

The distinctive features of organizational knowledge and its manipulating processes, together with the concept of active social actor suggest that the dominant capture/codify/store approaches (Hildreth et al. 2002) for developing KMSS are ineffective (Malhotra 2002; Swan et al. 2000). First, these approaches are based on the conceptualization of an ICT-based system as a representation of another pre-given "real world" system that enables its users, through its processing functions, to obtain information about a certain domain without having to observe it (Wand et al. 1995). Central to this conceptualization is the notion of "representability", i.e., the capability of representing the knowledge about the pre-given and objective things that exist in the real world using static structures such as entities and objects. Underlying this notion is the assumption that knowledge exists independently of human knowers (Hirschheim et al. 1995) and consequently

can be publicly owned by the organization (Wasko 1999). However, knowledge representations, which are static and context-independent structures, cannot be equated with knowledge, which is dynamic and context dependent (Malhotra 2002). Second, these approaches treat the user as an atomic individual capable of articulating her/his knowledge requirements well (Hahn et al. 2000; Lamb et al. 2003). Moreover, they consider users as external entities who have no major role in manipulating knowledge, i.e., *disembodiment assumption*.

OVERVIEW OF THEORY OF AUTOPOIESIS

In order to conceive of living systems in terms of the processes that realized them, rather in terms of their relationships with an environment, Maturana and Varela (Maturana et al. 1980) coined the word *autopoiesis* (αυτοσ = self, ποιενιν = creation, production) to denote the central feature of their organization, which is "autonomy". The meaning of this word coveys the very nature of living systems as systems that maintain their *identity* through their own operations of continuous self-renewal. Moreover, these systems could only be characterized with *reference to themselve*s and whatever takes place in them, takes place as necessarily and constitutively determined in relation to themselves, i.e., *self-referentiality*.

One of the key concepts of autopoiesis is the distinction between *organization* and *structure*. On one hand, *organization* is the capability of a system to re-produce its identity by referring constantly to itself, through the alternate re-production of its components together with the component-producing processes, i.e., the capability of a recursive self-reproduction. On the other hand, *structure* is the realization of a system's organization through the presence and interplay of its components in a specific realization space. While *organization* is necessary to establish system unity and identity, *structure* is necessary because different spaces of its actualization impose different constraints on system's components (Maturana et al. 1980). By rough analogy, an algorithm for solving certain problem can be viewed as a description of the system's organization whereas the corresponding computer program can be viewed as the realization of this organization (structure) in a certain space (programming language).

Autopoietic Systems

An autopoietic system is defined by Maturana and Varela as "a network of processes of production, transformation and destruction of components. These components constitute the system as a distinct unity in the space of its actualization and they continuously regenerate and realize, through their interactions and transformations, the network of processes that produce them." (Maturana et al. 1980), p.135)

Among the distinct characteristics of the autopoietic systems, the most relevant ones are:

- **The simultaneous openness and closure.** Autopoietic systems are *open* with respect to structural interaction with the environment, i.e. *structural openness*, which is unavoidable consequence of the fact that system elements must satisfy the particular requirements of the physical domain in which they occur, while they are *closed* with respect to their own organization, i.e. *organizational closure*. The recognition of *the simultaneous openness and closure* of autopoietic systems is in opposition to the tradition for which a system is one or the other but not both. This interpretation is possible only because of the clear distinction between organization and structure (Bednarz 1988).
- **Structural determination**. The state transition a system undergoes in response to environmental perturbations is entirely determined by its structure at that time. Moreover, a system specifies which environmental perturbations may trigger which structural changes. In other words, the environmental perturbations could trigger the system's structural changes but can never determine or direct these changes. Moreover, a system specifies which environmental perturbations may trigger which structural changes. Over time, through ongoing interactions with the environment, an autopoietic system will experience what Maturana and Varela (Maturana et al. 1992) describe as a *structural drift*, or a gradual change to their structure. The nature of this change is determined by previous system's history of structural changes, i.e., its *ontogeny.*

Higher-Order Autopoietic Systems

Two (or more) lower-order autopoietic systems can be "structurally coupled" to form higher-order autopoietic system. S*tructural coupling* is the ongoing process of the congruent structural changes between two (or more) systems that results from recurrent interactions between (among) them. Therefore, structural coupling has connotations of coordination and co-evolution. Moreover, following structural determination principle, two structurally coupled systems means that each of them selects from its possible structural changes those which are compatible with those in the other system and, at the same time, are suitable for the maintenance of its identity.

Social systems, such as enterprises, are constituted through the process of third-order structural coupling, or *social coupling*, the one that occurs between (or among) two (or more) second-order autopoietic systems. However, the unique feature of any human social system, such as an enterprise, is that the social coupling among its constituents occurs through "*language in the network of conservations which language generates and which, through their closure, constitute the unity of a particular human society*" (Maturana et al. 1992), p. 196). From this perspective, language is viewed as an example of social structural coupling that generates the self and creates *meaning* through interactions with others. Moreover, language represents what Maturana and Varela would describe as a *consensual domain*, which is defined as "the domain of interlocked conducts that results from ontogenetic structural coupling between structurally plastic organisms" (Mingers 1995), p. 78). Within a consensual domain, two autopoietic systems would be able to observe the attribution of meaning to common events and undertake coordinated actions.

THE AUTOPOIETIC PERSPECTIVE OF ORGANIZATIONAL KNOWLEDGE

The underlying premise of the dominant perspective on cognition is that effective action is explainable in terms of manipulating formal and static representations of the objective and pre-given reality (Mingers 2001). In contrast, according to theory of autopoiesis, perception is neither objectivist nor purely constructivist (Varela 1992), p. 254). Rather, it is co-determined by the linking of the structure of the perceiver and the local situations in which it has to act to maintain its identity. This is the basis of *enactive (embodied) cognition* which implies that the autopoietic system's activities condition *what can be perceived* in an environment, and these perceptions, in turn, condition future actions. In this view, "A cognitive system is a system whose organization defines a domain of interactions in which it can act with relevance to the maintenance of itself, and the process of cognition is the actual (inductive) acting or behaving in this domain." (Maturana et al. 1980), p. 13). In addition, cognitive domain of an autopoietic system is defined as the domain of all the interactions in which it can enter without loss of identity (Maturana et al. 1980), p. 119). Therefore, knowledge is not an object that may be captured, packaged, processed and distributed. Rather, it is an embodied notion.

Moreover, the concepts of structural coupling and consensual domains provide the bridge between the cognition of the individual and the patterned behaviors that are often described as 'organizational knowledge' (Kay et al. 2005)..

As discussed in the previous section language is viewed as an example of social structural coupling that generates the self and creates *meaning* through interactions with others. According to theory of autopoiesis "it is by languaging that the act of knowing, in the behavioral coordination which is language, [which] brings forth a world" (Maturana et al. 1992)(p. 234). In other words, meaning arises as pattern of relationships among the linguistic distinctions done by firm's members through the process of languaging.

In this context "languaging" refers to "the process in which language is not only maintained but is constantly being developed based on previous language" (von Krogh et al. 1994), p. 61). Organizational languaging, therefore, means *word choice in usage*, the process by which meaning emerges as a relationship between and among the various linguistic descriptions (distinctions) that actually used by members of the organization during their interaction with themselves or with external entities. Moreover, organizational languaging covers two domains: writing and conversations (von Krogh et al. 1995).

A PRELIMINARLY DESIGN THEORY FOR AUTOPOIETIC KMSS (AKMSS)

Table (1) summarizes the components of an information system design theory (ISDT).

AKMSS Meta-Requirements

One of the implications of theory of autopoiesis is that organizational knowledge

Table 1. Components of an information system design theory (ISDT) (Walls et al. 1992b)

Design Product	
1. Meta-requirements	*Describes the class of goals to which the theory applies.*
2. Meta-design	*Describes a class of artifacts hypothesized to meet the meta requirements.*
3. Kernel theories	*Theories from natural or social sciences governing design requirements.*
4. Testable design product hypotheses	*Used to test whether the meta-design satisfies the meta-requirements hypotheses.*
Design Process	
1. Design method	*A description of procedure(s) for artifact construction.*
2. Kernel theories	*Theories from natural or social sciences governing design process itself.*
3. Testable design process	*Used to verify whether the design method results in an artifact which hypotheses is consistent with the meta-design.*

is an embodied (enactive) notion and it cannot be treated as an object. Furthermore, it indicates the crucial role played by languaging in creating and sharing new knowledge. This perspective implies that KMSS can be best conceptualized as "an additional medium through which interlocking behaviors may converge and the congruities of context, that give rise to consensual domains" (Kay et al. 2005). Therefore, the meta-requirements of autopoietic KMSS can be stated as follows:

- An AKMSS should support organizational knowledge evolution and sharing through organizational languaging.
- An AKMSS should support the two aspects of organizational languaging: writing and conversations.

AKMSS Meta-Design

One of the implications of autopoietic "structural determination" principle is that the same environmental stimuli are perceived differently by different firm's members. Therefore, each member develops a repository of tacit personalized knowledge that allows him/her to make sense of reality. Such personalized knowledge can be *partially* described in terms of a "personal ontology". According to Gruber (Gruber 1993) an ontology is *an explicit specification of a conceptualization of a domain*. Therefore, changes to any of the three elements in the definition can cause changes in an ontology: (1) changes in the domain, (2) changes in conceptualization, or (3) changes in the explicit specification (Noy et al. 2002). Furthermore, such changes (ontology evolution) frequently occur in a distributed environment through interactions among different firm's members over different contexts (Bouquet et al. 2003). Therefore, the class of artifacts that meet the meta- requirements of AKMSS is:

- A set of firm's members (stakeholders) evolving personal ontologies.

AKMSS Design Method

Beside the evolution of firm's members (stakeholders) personal ontologies caused by their interactions, these interactions can result in merging or aligned personal ontologies. In merging, a single ontology that is a merged version of the original ontologies is created. Often, the original ontologies cover similar or overlapping domains. In alignment, the two original ontologies persist, with links established between them.1 Alignment usually is performed when the ontologies cover domains that are complementary to each other (Noy et al. 1999). Therefore, the design methods of AKMSS are:

- Personal ontologies creation, evolution, merging and alignments methods.

CONCLUSIONS

We contend that the theory of autopoiesis, as a system-grounded way of thinking with biological foundations, can be useful as one of the kernel theories for both of "design product" and "design process" aspects of KMSS's design theory. There are several implications for the KMSS development process deriving from our theoretical orientation. First, organizational knowledge is an embodied (enactive) notion and it cannot be treated as an object which can be captured, packaged and processed. From this perspective, organizational knowledge is nothing but a "purposeful coordination of action" while what is called explicit knowledge (symbolic knowledge representations or information) is the symbolic description of action (Zeleny 2005). Second, the role of "languaging" in creating new knowledge is emphasized. Third, the conceptualization of KMSS as the medium in which the organizational languaging can be realized is introduced.

Metacognition and Its Role in the Development of Team Competencies

Rozz Albon, Curtin University of Technology, Perth – Western Australia, Australia; E-mail: r.albon@curtin.edu.au
Tony Jewels, Queensland University of Technology, Brisbane – Queensland, Australia; E-mail: t.jewels@qut.edu.au

ABSTRACT

When graduates now enter the professional workplace, their ability to work as effective team members will contribute much to their immediate levels of productivity. Various types of group work are already being incorporated into higher education pedagogies with the stated intention of preparing students for modern workplace environments. Yet preparing for such an important vocational skill is not always so enthusiastically embraced by students. Many students openly state that they do not like working in groups because they believe that they can achieve better outcomes on their own. We investigate in this paper the metacognitive processes that students might engage in to help explain why group activities in an academic environment may be so unpopular.

Keywords: Team work, metacognition, pedagogy, team-learning

INTRODUCTION

There has never been a greater need for mastering team learning in organizations, as team learning will be a critical step in building learning organizations:

"Team learning is vital because teams, not individuals are the fundamental learning unit in modern organizations", (Senge, 1992, p10*).*

Within institutes of higher education, the incorporation of various types of group work into pedagogies is already widespread, yet many examples fail to embrace a rationale for, or the potential benefits of, multiple contributor environments essential in a knowledge intensive society. While perhaps being an ideal candidate to capitalise on the benefits of knowledge sharing behaviours, higher education has generally not realised its potential. The teaching of team learning extends beyond commonly used approaches merely requiring students to produce a report in which they can adopt a jig-saw approach (Biggs 2003) where each individual places their piece in the final task or puzzle.

One high performing post-graduate student recently summarised the apparent view of many when he commented in an email on 3 October 2006:

"My honest opinion is that the way in which we as students are encouraged to work in teams has little or no relevance to the 'real world' (whatever that is) that this university is preparing us for."

It would appear that collaborative learning as a group approach, as distinct from cooperative learning, continues to monopolise the intention of teaching students to learn to work with others, a goal synonymous with team learning. The emergence of newer online learning approaches such as 'intergroup collaboration' still emphasises knowledge access as distinct from knowledge sharing (Palloff & Pratt 1999), dependant on the co-production of knowledge, which itself is dependant on particular contexts or environments in which learning is socially situated (Brown, Collins, & Duguid 1989).

Group work does have a place in learning as one strategy which develops particular skills such as communication, and providing avenues to practise small and discrete skills. In contrast, however, team learning is a significant approach to knowledge sharing which harnesses the synergy of collective knowledge.

Data collected recently from students undertaking various IT degree courses indicated that they were aware of individual qualities that might contribute to team competencies, ably nominating several (Jewels & Ford 2006). However, their ability to apply those qualities was questionable, with many claiming they did not really understand how to be a successful contributor to sustain a team outcome, and particularly how to function in a high performance team. This not only applies to students, it reflects the real world as noted by Katzenbach & Smith (1993).

Knowing what students know about themselves when functioning in the social-cognitive context of teams, and how they monitor this, provides insight into the development of a theory of team learning and a significant contribution to taxonomy of team competencies.

A better understanding of how individuals function in teams, and how teams can learn together would appear to have some important practical benefits.

"Until we have some theory of what happens when teams learn (as opposed to individuals in teams learning) ... Until there are reliable methods for building teams that can learn together, its occurrence will remain a product of happenstance", (Senge, 1992, p238).

While others have described ideal team practices and how team building can be encouraged, as yet no-one has developed a theory. To advance the teaching of team learning and its inherent shared knowledge, a conceptual framework is required; one that will embrace the synergy and energy created when individuals aspire to excellence and are intrinsically motivated to accept challenge in dealing with conflict, in order to arrive at new knowledge.

Extending on previous works by Jewels & Albon (2006, 2007), this paper specifically examines the contribution of metacognition in identifying the basis for a theory of acquiring team competencies, beginning with the identification of the metacognitive processes students employ to function either in working groups or higher performing teams. The authors believe that information provided to the following question will assist to advance a theory: What metacognitive strategies do students use to know how to work competently in teams?

Senge (1992) describes the types of teams that we are discussing:

"...where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning how to learn together", (p3).

Working in a team for students may be seen merely as working in a group, a situation in which they use familiar habits of doing things at the expense of being metacognitive about functioning differently. It may be that because the context involves planning and committing effort to receive a mark and eventually a grade for the unit/subject, in difference to the real world of projects, that theories of motivation are also needed in developing a theory of team learning.

There are many examples of group work currently being conducted within institutes of higher education that appears not to reflect team work at all, but is only characteristic of the poorest of the five levels of group/team performances that is described by Katzenbach & Smith (1993), where effective knowledge management practices are unlikely to occur. A taxonomy, synthesising works

Table 1. Taxonomy for the assessment of team competency maturity (Jewels & Albon, 2006)

Levels of Group/ Team Maturity	Examples of Competency		
	Individual	Team	Organisational
Working Groups	Individuals are only nominally a group coming together to report on individual progress.	Members help each other at a peripheral level in the belief that each member can best perform for the group by working individually.	The organisation only expects group members to provide individual inputs. Tendency to reward individual not group performance.
Pseudo Teams	Psychologically members know they must contribute to team output but cannot see beyond their own view & perspective.	Members know their contribution must interact in the final product and so are prepared to assist each other. Effort is made to listen to and respond to each other.	Explicit acknowledgement of value of teams but no resources or incentives given for team output.
Potential Teams	Members recognise their individual responsibilities but yet to recognise team responsibility.	Members recognize personal skills and those of others; are aware how these can contribute to the success of the team project; have nominated strategies but lack collective accountability.	Support given for overall team performance but lack of acknowledgement of the individual's team responsibilities.
Real Teams	Prepared to up-skill and do additional work as part of accountability to team.	Members hold themselves mutually accountable for the projects direction, development and outcome.	Support and resources given to teams and the individuals in them for current work.
High Performance Teams	Members recognise each others strengths and weaknesses and how the final project can be shaped by these factors.	Members all deeply committed to each others personal growth and success. Contribute so member's contributions are optimised for the collective good.	Support provided to teams and individuals for personal growth that is focussed towards current and future work.

from Katzenbach and Smith, Barnett, and Frame, developed by Jewels & Albon (2006), (Table 1) enables group or team work to be defined and in turn enables educators to set criteria for assessments in accordance with the expectations of each team description or level.

METACOGNITION

Metacognition, a term originally associated with John Flavell (1979), is often referred to as '*thinking about thinking*'.

"Metacognition refers to one's knowledge concerning one's own cognitive processes or anything related to them, e.g., the learning-relevant properties of information or data", (Flavell, 1979, p232).

Metacognition and its inherent internal monitoring of thinking, 'cognitive processes, knowledge, cognitive and affective states, and the ability to consciously and deliberately monitor and regulate' (McCaslin 2004, p279), has a significant role to play in the development of team competencies and their successful application in challenging and complex assessments in higher education contexts.

Most of the research on metacognition has focussed on cognitive factors with little to no studies conducted on social influences on learning (McCaslin, 2004). Flavell (1971) recognised that knowledge of others influenced an individual's thought processes and behaviour. He identified that one monitors one's behaviour in response to differing social contexts. A clear example is the control of people's language in differing social groups or situations: with mates, with the Vice Chancellor, parents or the court room.

Levine, Resnick, & Higgins (1993) have called for more research in understanding cognition in the real world in which *'emotions, social meanings, social intentions and social residues'*, (p64) are inter-related with cognitive activity. Functioning successfully in teams is one such activity which demands we teach students how to understand and monitor themselves, if they are to participate productively in the future world of work, either through implicit structures and behaviours or through direct instruction. Being better informed about what students understand about team performance and its inherent competencies, and also how students might adapt to working in teams, will contribute to enhancing the taxonomy of team competencies originated by Jewels & Albon (2006, 2007).

In contrast to the typical metacognitive instruction used by learners to help them monitor and control effectiveness in learning and problem solving behaviour, this research extrapolates ideas and principles from Lin, Schwartz, & Hatano (2005) and their adaptive metacognition (AM) developed for teachers. AM *'involves both the adaptation of oneself and one's environment in response to a wide range of [classroom] variability'*, (p245). In a similar way to the action of teaching, in which new and novel problems and situations present themselves, interacting successfully in teams as an integral member also requires individuals to move beyond habit and routine and take on adaptive behaviour. This is in contrast to existing and usual research which has focussed only on individualistic approaches to metacognitive thinking, where problems or needs are clearly defined, environments are stable, and learners are responsive. AM posits that the teaching environment and therefore this current research on the individuals who make up teams that *'problems are ill-defined, and involve a variety of values that may not be in complete harmony'*, (p247). The team member handles *'many interacting factors simultaneously that often cannot be neatly decomposed and treated one at a time',* Lin et al. (2005, p248), and *'reflects on their values and the consistency between their own values and those of other members…to guide them towards an acceptable solution'*, (p248).

CONTRIBUTION FROM MOTIVATIONAL THEORIES

Self-determination theory (Reeve, Deci & Ryan 2004) raises the issue of the sociocultural forces that support autonomy, competence, and relatedness. Do students perceive the learning environments of universities to value collectivist ideas and solutions? Team allegiance and team cohesion is fundamental to high performance teams but what is the thinking related to achieving this outcome by students? What is the baseline of thinking and behaviour from whence change

will come? Student's behaviour in a team will be affected by the way they think they are expected to behave, or need to perform as a team member. Students perceive themselves to have a defined role – that of the student as established by institutions. When placed in teams, this familiar role is challenged, leaving them unsure how to behave so as to maximize outcomes for the team and develop an 'egoless' team (Weinberg 1971). To realise the potential of teams, academics need to articulate and maintain a strong performance ethic within the university context, such as providing for flexible learning, being available for consultation through various means, providing flexible consultation perhaps through online programs, reviewing timetables, providing meeting rooms or spaces and facilities as well as developing a mind set of teams (Figure 1).

McClelland (1961) cited in Maehr & McInerney (2004) suggested that achievement behaviour was comprised of four distinct but related elements:

- competition with a standard of excellence,
- affective concern for goal attainment,
- an evaluation of performance, and
- some standard for the attainment of a long-term goal.

It is assumed these same four elements also apply to teams, because it is the team who is now motivated to function and work as one. Functioning in this way would also appear to challenge notions of the self, and the self as student who aspires to passing the unit/course. It is further assumed, as noted by Katzenbach & Smith (1993), that if companies with strong performance standards spawned real teams (Table 1), then team members must think about standards, leading to the following questions:

- How do students determine themselves to be self-competent and valuable contributors in team work assessments?
- What is their criteria, and how do they measure and monitor their personal performance?
- Do students think about their behaviour and its impact on the success or failure of the group to achieve shared goals? If so, what questions or attributions do they make?

When we know more about students' thinking, we can take positive steps to assist them acquire self-competence. Davidson, Jaccard, Triandis, Morales, & Diaz-Guerrero (1976), with their etic-emic personal investment model, cited in McInerney & Van Etten (2004), highlighted the conflict an individual has between behaving through habit (adaptive behaviour) and behaving through conscious intent. Teams take the risks associated with conflict and team members deal with the conflict – but how? Intent is affected by larger macro-environment of the institution, lecturer expectations, team member expectations and perceived value of these to the behaviour. The student's normative beliefs affect their intent to behave in the group environment, but again, how are these applied and when?

Goal theory (Schunk 2000), identifies why students want to be successful and translates to why and how students intend to be successful in team work. Identifying metacognitive strategies associated with ability orientations, task orientations or social orientations will assist in developing a taxonomy of competencies for each of the team levels (Table 1). That is, if students metacognitive thoughts focus on gaining social approval, respect or recognition from their team peers, then they are making an effort to conform with social norms. Alternatively a lack of effort may be felt by disapproval and rejection from other team members. Identification of these normed behaviours and how they are established will assist in focusssing teaching on students' acquisition of team competencies associated with group dynamics and successful interaction behaviour. In contrast, if students' metacognition reflects attention to demonstrating competence in the team, this may be at the expense of contributing quality work to achieve team outcomes, further contributing to the competences required for each level of the taxonomy. This is also supported by the self-worth theory of Covington (2004) and human motivation theory of Maslow (1954), cited in Schunk (2000), which state the need and focus on approval and acceptance by others is dependent on how competent one is perceived in the eyes of others.

The sociocultural framework of motivation espoused by McCaslin (2004), provides insight into investigating and interpreting the metacognitive thoughts by students engaged in tasks reflecting the levels of team performance. McCaslin contends that, as tasks become more difficult (higher team levels), they *'require and challenge the integration and enhancement of the affective and the intellectual in the mediation of goal-directed behaviour'*, (p9). Further, *'a focus on peers, shifts attention from the social origins of emergent identity…to a notion of continuous coregulation of activity and consciousness'*, (p9). Obtaining metacognitive thinking about how team member's function in groups or teams should provide insight into understanding the nature of the skills or competencies that concern students.

PEDAGOGICAL IMPLICATIONS

In addition to motivational theories, a teaching model which enables learning in teams, should be selected. Maker & Nielson's (1995) teaching model appears philosophically aligned with the principle of team competencies described by Gilson, Pratt, Roberts, & Weymes 2000; Katzenbach & Smith, 1993; Senge, 1992, providing the initial structure for acknowledging the implicit and intangible features of teams. This model is characterised by four broad non-mutually exclusive categories:

- content,
- learning environment,
- product, and
- process.

The model has numerous specific features, such as complexity, abstractness, mobility, openness and variety which suggest that learning opportunities should be created by centering on complex and abstract content so as to deepen students' understanding of ideas/concepts. This lends itself readily to the management of knowledge where learning is continuous, knowledge is generated and the tolerance and encouragement of initiative is considered significant in students' development of team competency skills. The development of a team-centred approach through this model has the potential to mobilise the efforts of each member to share knowledge, develop shared goals and operate as an effective team.

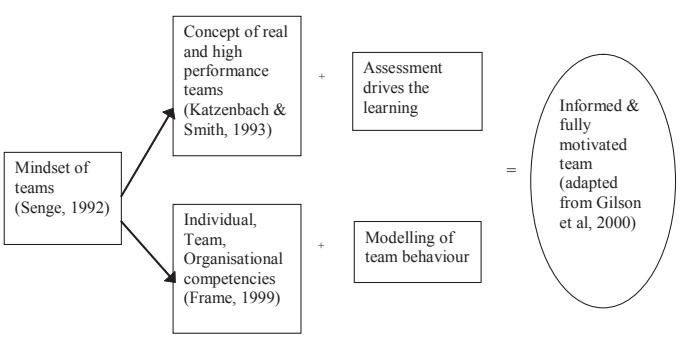
The model also highlights the impact of an open rather than closed approach to learning, necessary when teams search for solutions to problems. The use of acceptance and evaluation in preference to judgement alone further aligns this model to one suitable for the development of team competencies where responding to ideas critically and constructively is essential. The diversity and differences of team members are accepted as the team sharpens its focus on shared purposeful activities, and opportunities for students to learn with non-traditional classroom pedagogies and spaces is nothing short of essential to the development of team competencies for future managers of knowledge. An emphasis on real-audience and real product is central to the new propounded team-centred approach as this culminates the team's synergy, shared knowledge and aspirations for success.

It appears that Maker & Nielson's teaching model complements both the teaching of team competencies and team competency values. We offer it as a framework for educators to create opportunities to teach team competencies within specific curriculum.

A model proposed by Jewels & Albon (2007), (Table 1) highlights three key factors:

- Mindset of teams – real and high performance teams & individual, team and organisation competency,
- Modelling of team behaviour,
- Assessment drives the learning: complex, challenging assessment tasks.

Figure 1. Multi dimensional team competency teaching model



Optimal function of the taxonomy, that is, its eventual use in teaching team competencies at each of the identified levels, is dependent on its expansion, which we argue is obtained through an investigation using metacognition. An analysis of skills will enable categories to be identified and aligned with each level of team.

Although the authors are cognisant of explicit teaching, they value implicit and powerful approaches such as modelling. Following the identification of the social and interpersonal cues, and interpersonal effectiveness to make effective team interactions academics can assist in sensitising all members to achieving and contributing to high performance teams. Of note is the need for students to see the team as accountable for success and equally, failure. It is no longer relevant to be accountable as individuals, but at the same time individuals cannot be loafers. Identifying, through an analysis of student's metacognition, how students monitor their own and others behaviour to arrive at their behaviour in team accountability is important in the development of the team competency taxonomy.

SUMMARY

Traditionally, higher education has predominantly focused at the individual level, even though inroads have been made into student-centred learning and its related group approach. We propose that in order to align more with real-world environments it is also necessary to take into account team competencies in which those individuals operate and to explicitly teach how these team competencies can be realised.

By employing deliberate strategies and making students aware of their conscious behaviour and intent, team competencies may be more readily and consistently acquired. The concept of subordination of the individual goal to that of the team encapsulates the ethos which must underpin the teaching of teams in the higher education contexts, aptly termed team-centred learning as distinguished from teacher-directed or student-centred learning.

University students require more than being physically placed into teams to complete team assessments; they need to learn how to share knowledge. Complex, rich and meaningful assessments force students to draw on the knowledge, attitudes, beliefs of each of its members, and in turn, engage them in the process of learning to be team members and acquire specific team competencies. Performance is the primary objective and the team becomes the means to the end (Katzenbach & Smith, 1993). The discomfort students might feel when they recognise they do not work well in groups is described by Takeuchi & Nonaka (2004):

"New knowledge can also pose a threat to self-image. In order to accommodate new knowledge, people must make changes in themselves – existential changes (Polanyi, 1958) ..... He or she may have to accommodate new routines and technical requirements associated with another line of work. For most of us such a change in work and profession involves a major shift in who we are. Indeed, what we know – and how that affects what we do – is often at the root of personal identity. Because knowledge is so intimately tied to self-image, people often resist anything new. Breaking away from known habits can feel very risky", (p129).

Katzenbach & Smith (1993) state that, *'A demanding performance challenge tends to create a team',* (p3). They note that the drive and need to perform and take up this challenge outweighs other rewards and incentives, and that often potential teams fail to become a team due to the lack of challenge. Academics should therefore set a complex and challenging task beyond the ability of one person to complete if the value of working in teams is to be truly recognised by students.

There are compelling reasons why students need to be equipped to be multi-contributors in the kind of teams required in the future world of work. The research supporting the increased performance when students are explicitly taught how to think using comparisons and reflections paves the way for teaching team competencies in order for students to aspire to and become high performance teams. It is anticipated that problem solving and decision making behaviour would become transparent in addition to instilling a degree of confidence in students. Understanding the metacognitive strategies students use when in any role, particularly those identified by Belbin (1981) will further the development of the competencies for the taxonomy and lay the foundations for a theory on team learning.

The Power of Informal Networks: A Perspective of Two Studies

Irena M. Ali, Defence Systems Analysis Division, Defence Science and Technology Organisation, Department of Defence, Canberra, Australia; E-mail: irena.ali@dsto.defence.gov.au

INTRODUCTION

The terms 'dissemination of information', 'information needs', 'information seeking', and 'information sharing' are usually connected with library science. However, these concepts go beyond the field of librarianship. These concepts are now considered elements of 'information behaviour'. Information behaviour has been defined as "the totality of human behaviour in relation to sources and channels of information, including both active and passive information seeking, and information use. Thus, it includes face-to-face communication with others, as well as the passive reception of information" (Wilson 2000: 49). Many organizations provide value for customers by facilitating the dissemination of information. They do so by strategically utilising their knowledge about customers' information seeking and needs, and information and communication technology in support of networks of self-organizing employee teams.

During the 1990s, a number of companies attained dramatic competitive advantage by creating comprehensive, complex communication and information networks. The increasing efficiencies and speed of information and communication technology (ICT) enabled these companies to remain flexible and adaptable to change, and also to make accurate predictions and minimise risk. Tucker, Meyer, and Westerman (1996) explain that the impact of technology on such business organizations has resulted in them being referred to by various names such as "modular", "cluster", "perpetual matrix" or "network" organizations.

In the military, Network Centric Warfare (NCW) is an attempt to translate this business concept of the 1990s into military practice. The NCW has emerged as the umbrella under which the implications of information and communication technologies and the connectivity they enable for military operations and organization, are argued and assessed (Army, 2003). One of the tenets of NCW is that a robustly networked force leads to increased information sharing (Directorate of Future Warfighting 2004). In this paradigm, the focus seems to be on hardware, bandwidth, and electronics, and yet the human, and his or her behaviour within the networked environment, is a crucial element. An important, yet often overlooked aspect, of NCW-related behaviour is information seeking.

The sharing of information lies at the core of NCW[1] — shared information leads to improved quality of information, which in turn leads to enhanced shared situational understanding[2]. The role of information behaviour in NCW is, therefore, paramount. Atkinson and Moffat (2005) state that the sharing of information is based on trust developed through social interaction, and shared values and beliefs. In line with Wilson's (2000) definition of information behaviour, the human, not technology, is the node in such interactions, and this node is more than just a link; it is a bond between the players that has developed from mutual trust. Therefore, a significant component of a person's information environment is the relationships he or she can tap into for various informational needs.

This paper focuses on how people gather and share information in environments characterised by high levels of uncertainty and high tempo. It will draw on the research outcomes of two separate, yet interrelated, studies that highlight the role of informal networks as a crucial source of information. In this sense, the paper looks at information behaviour in the context of the military organization. The understanding of factors impacting on human information behaviour is of particular importance to the military where the speed and quality of decision making in operational situations determines mission effectiveness.

The first study, which investigated Social Learning within the Australian Defence Organisation (ADO), was conducted during 1999 through to 2002 by a research team of the Defence Science and Technology Organisation (DSTO) in Australia. The immediate aim of that research was to understand the issues inherent in building learning, adaptive, and sustainable organizations. The long-term objective, however, was to develop frameworks that would support the development of information systems to guide and enhance organizational learning and facilitate knowledge management. In the context of that study, social learning was defined as learning occurring within a group, an organization, or any cultural cluster and it includes:

- the procedures that facilitate generative learning – learning that enhances the enterprise's ability to adjust to dynamic and unexpected situations and to react creatively to them; and
- the processes and procedures by which knowledge and practice are transmitted across posting cycles, across different work situations and across time (Warne, Ali, and Pascoe 2003).

This paper will refer specifically to the processes and procedures by which knowledge and practice are transmitted as they directly relate to human information behaviour.

The second research project conducted by this same DSTO research team[3], during 2003 through to 2006, focused on the human dimension of future warfighting (HDoFW) and examined broad psychosocial issues that need to be considered to fully exploit NCW and other future operating concepts. Interviews were conducted with one hundred Australian Defence Force (ADF) personnel returned from deployment to the Middle Eastern Area of Operation (MEAO)[4] (HDoFW Research Team 2006).

In both studies predominantly qualitative research methods (semi structured interviews) were used to collect data. In the social learning study, the interviews and ethnographic observations were supplemented by a quantitative survey to collect data and to validate qualitative findings (for full details of the research methodology see Warne, Ali, and Pascoe 2003; HDoFW Research Team 2006). The data was analysed using qualitative software NVivo and Leximancer.

In drawing out the outcomes of these two research projects, this paper focuses on a predominant theme that emerged from our data—that people continue to use social sources as a primary means of gathering and sharing information in high uncertainty and high tempo environments.

INFORMATION SEEKING AND SHARING: FINDINGS OF THE TWO STUDIES

Given the role of information in military organizations and military operations, it is interesting to note that very little research appears to have been conducted on information behaviour in the military[5]. A quick Google search[6] of various terms highlights this point:

Search terms	Results
"Information systems" and "military operations"	5,030, 000
"Information use" and "military operations"	78 600
"Information seeking" and "military operations"	41,400
"Information behaviour" and "Information behavior" and "military operations"	32

These results are especially interesting in light of what information behaviour actually is: "the totality of human behaviour in relation to sources and channels of information" (Wilson 2000: 49).

Given the lure of technology and the current fervour about what it can achieve, a noteworthy point was made by Kruse and Adkins (2005:1) that almost every worthwhile achievement or development is the result of group effort because, after all, humans are born collaborators and social animals. Furthermore, despite the opportunities provided by technology, key elements for innovation and advancement are the sharing of information and knowledge and the willingness to cooperate. In this respect, warfare is no different from other endeavours.

The findings from both of our research studies clearly point to relationships playing a key role in people's behaviours, and it is the quality of their networks of interconnected relationships that determines opportunities for sharing information, or places constraints on information seeking. There are numerous factors that underpin these relationships and, in turn, underpin people's information-seeking and information-sharing behaviours. There are three factors that repeatedly emerged from the research findings: trust, informal networks, and the development of common identity, as shaping human information behaviour. This paper will focus on these factors.

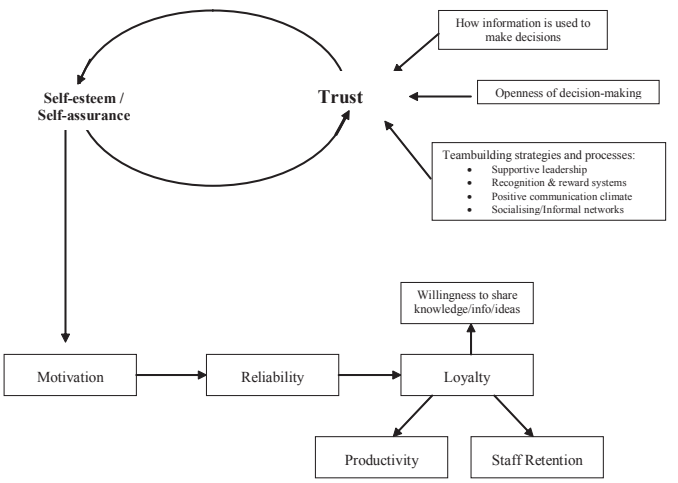
TRUST

Effective and efficient exchange of information underpins the success of military activities because accomplishing military goals, particularly in operational contexts, requires collective action and cooperation. However, in the warfighting context, where information can be highly sensitive and when the potential recipient is largely unknown, individuals are not always willing to provide requested information, or to volunteer information. As might be expected, therefore, trust building was seen by most study participants, in both of our research projects, as an essential activity for information sharing.

The term 'trust' generally refers to positive expectations held by one party (individual or group) about the actions or intent of another when there is some degree of risk involved. For example, Mayer, Davis, and Schoorman (1995:712) define trust as "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party".

In other words, we trust another person to the extent that we believe they will act beneficially (or at least not detrimentally) towards us if we choose to engage them in some form of cooperation and when cooperating involves some degree of risk (see Gambetta 1988; Mayer, Mollering, Bachmann, and Lee 2004). Thus, trust is especially relevant when there is uncertainty or ignorance as to the motives and actions of others. When these can be predicted with absolute certainty, trust is not required. When they cannot, as in most 'real world' circumstances, a degree of trust is necessary to make human action and interaction possible (Simmel 1964; Costigan, Ilter, and Berman 1998; see also Ali et al 2004).

Figure 1. The role of trust in organizations



In both of research studies, our participants identified trust as critical to Australian-US/coalition cooperation and jointness within the ADF. In fact, trust was one of the most frequently mentioned factors in the HDoFW study. People spoke about trust as the glue that kept human networks and interconnections aligned and it was also seen as an underlying foundation for collaboration:

... if you can build up a rapport very quickly and get to know them and they get to trust you and you trust them, it becomes a lot easier...

The findings of our research into social learning revealed that employees who were feeling assured about themselves and their value to the organization were more likely to be motivated, reliable, and to have loyalty to the organization. Of importance here is that our interviews and observations clearly highlighted that the willingness to share information, knowledge and ideas with others is precipitated from this loyalty (as is higher productivity and higher staff retention). These relationships are depicted in Figure 1 below (Ali et. al, 2002).

COMMON IDENTITY

Studies into the impact of information sharing on various aspects of organizational life suggest that information sharing promotes common identity and mutual trust (eg, Schein 1993 and Phillips 1997). Interestingly, our study findings into social learning in military organizations (Ali et al. 2002; Warne, et al. 2003) indicate that it is common identity and trust that foster willingness to seek and share information. In line with systems thinking (Senge, 1992), common identity requires a shift from seeing ourselves as separate to seeing ourselves as connected to, and part of, an organization or its sub-units.

For NCW, developing common identity is an important issue because the core effort of NCW is to develop and distribute superior situational awareness, common understanding of the commander's intent, and common identity to synchronise operations and activities (Ahvenainen 2003). In the HDoFW study the extent to which developing a common identity impacted on information sharing was well illustrated by looking at the role of embedded, liaison or exchange officers (HDoFW Research Team 2006). Our interviewees frequently spoke of the critical role played by liaison, exchange, or embedded personnel. Whilst the presence of these personnel was vital in many ways, most important was their role in the provision of information and the development of situational awareness. For example, many of our interviewees spoke of how ADF personnel embedded in US Headquarters became critical nodes in the ADF's understanding of US plans and activities.

Likewise, having US personnel embedded in ADF Headquarters paid similar dividends in terms of information behaviour and, in turn, interoperability. The following account of the value added of having an American officer embedded within a RAAF unit illustrates this point:

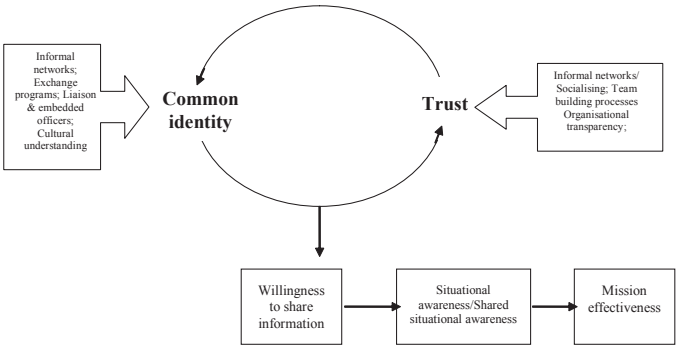
He knew our system. He knew what we didn't know about working with an American wing in combat. So he was kind of critical to helping the guys through the labyrinth of what's different...the exchange positions are absolutely critical to your interoperability.

As common identity grew, through fostering of informal networks by exchange or embedded personnel, the access to information and other resources became more available:

...our American officer ... was working hand in hand with us all day, every day, and he literally became part of the Australian team – [these] personal relationships that allowed us to get pretty much what we needed.

Specifically, achieving 'seamless' interoperability necessitated a more sophisticated form of interaction. In describing this, one of the interviewed officers drew a sharp distinction between 'liaison' and 'embedded' personnel:

Figure 2. The role of trust and common identity for mission effectiveness



…the value of having not liaison officers, but embedded staff officers in an international headquarters…[is that they] develop an intimate knowledge of the American and British planning processes, the way they execute an operation. And having that knowledge meant that we could integrate directly into their team…as opposed to being someone who sat in the back of the office and answered questions.

These examples clearly show that developing common identity, relationships, and trust paves the way for information and other resource sharing. This is particularly important in operational or disaster situations where information is critical to decision making and actions that follow.

Figure 2 provides a diagrammatic representation on the relationship between trust and common identity (which our data suggests is a recursive one), and the impact on willingness to share information via the development of common understanding. Figure 2 also depicts that information and knowledge sharing enhances shared situational awareness, which in turn impacts on decision making and ultimately on mission effectiveness.

INFORMAL NETWORKS

The HDoFW interview data clearly indicates that in addition to the formal networks provided by exchange or embedded officers programs, the informal networks that people established were crucial in the development of trust and common identity. They also provided a further set of conduits for information seeking and sharing (HDoFW Research Team 2006).

i. The Role of Socialising in Building Informal Networks

In both our studies, almost all the interviewees said that establishing a personal connection was crucial for a productive working relationship and for trust building. Scholars use the term *social capital* to refer to human relationships that make organzations work effectively. They explain that healthy social relationships in organizations build trust, make people learn faster and be more productive and creative (Prusak et al 2001; Ehin 2004). Of importance here is that our interviewees reported that the sharing of information was sometimes impeded by a lack of trust arising from barriers associated with rank, position, service or force affiliation, and the perceived expectations that go with those barriers. Therefore, discovering non-work related commonalities allowed them to relate to each other on more than an instrumental basis. Socialising was perceived as a vehicle for developing wider networks, and therefore it enabled people to get to know each other.

...even with the little bit of rapport that we had, the results were astounding … The socialisation did contribute a lot to the success of our mission.

In the social learning study, the majority of respondents indicated that work-related social activities lead to a greater sense of team spirit and thereby positively contributed to the willingness of information exchange. These social activities were not seen as frivolous functions but as core activities that are ultimately task-oriented. As one of the respondents put it:

…it is important and we do, we have time out where we go for coffee and to chat, it's team building and getting to know each other, and I think that's really important because you need to get to know the personalities on your team….We talk about work things when we're having coffee, but it's joking and fun.

Informal social gatherings were seen by both studies' participants as an opportunity to get to know each other, build trust and stronger relationships and, more importantly, share knowledge. Many interviewees told us that during such informal social gatherings they learn more about what is happening in other areas of the organization than though formal channels, and they increase their matrix of informal connections, as illustrated by the following quote:

…social gatherings are necessary because they provide an opportunity for face-to-face talking and to find out what are the important issues on people's minds at the moment….If you didn't have those social gatherings, you would just see the range of issues that they were dealing with, but you wouldn't really know what was important to them or what they were particularly worried about…

The participants in both of our studies pointed out that developing these connections and networks paid dividends in promoting interpersonal trust and paved the way for subsequent information and resource sharing:

So I'd go up and have a chat with them and then I'd find out more of what they did. So when the boss would come up and say, "Look, you know, we need to know about this and this",[so I'd say]"Yeah, I know this guy …

ii. The Role of Informal Networks in Managing Handovers

In the military, frequent changes in postings and job rotation are natural occurrences. How quickly and effectively a new person assimilates into a new job is, to a large degree, determined by the quality of the handover. Our interviewees said that during handovers they were not after 'procedural things' as these are fairly standard; instead they were after

…getting to know and getting to feel what the organisation is, who the personalities are, and really getting a feel for the culture in the organisation…

When personnel were asked what they look for during a handover, the frequent answer was a list of contacts that one officer can pass to another. This 'invisible college' provided a trusted source of information for things which do not appear in organizational charts or in formal policies and procedures. These informal networks cut through formal reporting procedures and could jump start many initiatives. Additionally, they were seen as essential for day-to-day business and for information and knowledge sharing. Those who did not get the chance for a handover relied heavily on informal networks and contacts for pre-deployment information gathering and to find out as much as possible about their posting and what might lie ahead.

…from an informal process. A friend of mine - I was taking over from a friend of mine, who was already there, so I rang him over there to find out exactly what was going on…

The results of both our studies clearly indicate that tasks were accomplished more efficiently as a result of the informal networks of relationships that were formed across functional groups, multinational forces and agencies. Furthermore, these informal networks enhanced the quality and timelines of shared information which, in turn, contributed to overall mission effectiveness.

CONCLUSIONS

Military operational environments and emergency management require that critical and timely information comes from known and trusted sources. Information seeking, therefore, is a prominent and crucial activity in any military operation and more so in a NCW environment because of the reliance on timely and relevant

information for individual and team situational awareness. Although technical developments in information and communication technology facilitate speedier and wider sharing of information, they do not reflect the information seeking behaviour that people engage in.

The results of our studies demonstrate that information sharing and people's willingness to disclose information is shaped by the building of trust and the development of common identity that occurs through informal networks and relationships. This research points to the informal networks being a precursor for development of trust and common identity. In addition, analysis of numerous disasters that occurred in the last few years demonstrate that quality of response depends not so much on quality of planning or even equipment, but on the quality of human networks that are formed to provide relief (Denning 2006).

The effectiveness of military operations, or for that matter management of any emergency situation, requires collaboration between many players. A shift from co-existence to cooperation cannot occur without informal networks since it is through these networks that trust and common identity are cultivated. And the result is not only more coordinated planning, but also a greater pool of knowledge to draw upon. Therefore, the power behind informal networks and the significance of human interaction for information sharing and gathering must be taken in account in the planning of communication strategies in military settings. More research into this area is still needed to fully understand why typical 'command-and-control' approaches and technological solutions do not always provide the desired result.

Although the research subjects and settings are military, the study findings have much wider applications. Organizations that need to quickly respond to a changing environment need to harness the knowledge of many diverse players and in doing so must not underestimate the power of informal networks for information and other resource sharing. There is a need to better understand what gives rise to such networks and how to facilitate their functioning without sabotaging formal plans and decisions. Furthermore, the implications of this research for any organization are that it is essential to understand human information behaviour first and how people use technology before investing into technological solutions.

ABSTRACT

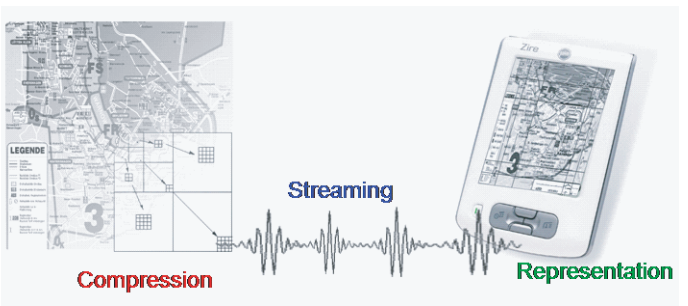
Imagery must be adequately processed and adapted to be used in mobile environments. This contribution shows that this can be reached by a rigorous combination of all stages of the image communication pipeline to a single task-aligned system. To achieve this, the modern imaging standard JPEG2000 serves as a foundation for image compression and streaming. Founded on the concept of Regions of Interest and Levels of Detail to describe current demands at client side, powerful generic strategies for the content handling are proposed. The pre-defined task is represented by one of 3 common problems in mobile environments – image browsing, viewer guidance, and content exchange. Beside new ideas to accomplish these tasks on application level, in focus is the strong decrease in the demands for device capabilities by an appropriate image handling. The achieved results show that many resources are saved by an appropriate image communication using JPEG2000.

1. INTRODUCTION

The enthusiasm for mobile computing is still unbroken. With the ability to access information every time and everywhere, the mobile freedom allows for completely new commercial applications. Due to its form factors and the application environment, however, mobile devices are still restricted by *low computing power* and *bandwidth*. As imagery is one of the most important but also most demanding information carriers it must be adequately processed and adapted to be used in such environments (Rosenbaum et al., 2006). How to achieve this by efficient image communication strategies designed to solve a task at hand is shown in this publication. Thereby, the focus is on the achieved results rather than the technological background. However, the required basic technology is briefly explained.

A meaningful image communication strategy consists of the stages *compression, streaming*, and *visual representation* (cf. Figure 1). Although numerous different techniques for each stage have been proposed, an arbitrary combination does usually not lead to an appropriate result. A high performing system can only be guarantied if all stages of the whole communication pipeline are tightly coupled (Rosenbaum & Schumann, 2005). Founded on an appropriate visual representation at the mobile client, this basically means that *only data contributing to the current representation is processed and transmitted*. Although, similar ideas have already been proposed, they are either based on proprietary solutions (Owen et al., 2001) or discuss a specific task only (Deshpande & Zeng, 2001; Ortiz et al., 2004). The ideas proposed in this publication are fully compliant to the international standard JPEG2000 (ISO, 2002), which allows an easy migration of the introduced strategies into existing systems, and due to the generic description of the current demands by Regions of Interest (RoI) and Levels of Detail (LoD) for a broad applicability. To avoid the redundant data transfer in case these demands change during interaction, the principle of a progressive refinement is adopted.

Figure 1. The image communication pipeline



Although the applicability of the proposed JPEG2000-based compression and streaming technology extends far beyond the discussed tasks, this publication focuses on 3 common problems in mobile environments: *Image browsing, Viewer guidance,* and *Content exchange*. Beside the proposal of new ideas for appropriate visual representations and the underlying data handling, of main interest within this publication is their coupling to an appropriate communication system.

This contribution gives an overview about the proposed ideas and achieved results for each single communication stage. Section 2 reviews the idea of RoIs and LoDs and introduces different options for their flexible access within an JPEG2000-compressed image. Section 3 is concerned with a demand-driven streaming of the data based on dynamic RoIs. Section 4 is dedicated to introduce new ideas for the visual representation of the image data depending on the previously mentioned tasks and shows the results of an appropriate image communication. The publication closes with conclusions in Section 5.

2. FLEXIBLE COMPRESSION WITH JPEG2000

Image compression is the foundation for an effective and efficient data handling. Although there are numerous approaches, the JPEG2000 standard represents the current state-of-art and combines a superb compression performance with numerous features. The main important properties regarding a flexible image communication are the modular structure of the data and the ability to support dynamic RoIs.

An RoI is basically a closed pixel area within the image. To determine the current interest, to every RoI is assigned an LoD. Although, there are many approaches to support RoIs within JPEG2000, they usually lack of flexibility to change RoI position or LoD during a running transmission. To achieve this, the concept of dynamic RoIs has been introduced and modeled for JPEG2000 (Rosenbaum & Schumann, 2002). It is based on the encapsulation of the encoded data in independent data containers and supports beside the general options to de- and refine RoIs dynamically, many LoD levels (e.g. gradual resolution, quality, and color). To increase the applicability and performance, different additional concepts, e.g. Limited Spatial Access (LSA) on the data-streams, may be applied (Rosenbaum & Schumann, 2004).

Although JPEG2000 is more complex than its predecessor JPEG, it has been revealed that the strong reduction in the amount of data by the RoI feature heavily decreases this drawback. This can be ensured by producing highly flexible data-streams during encoding.

Result: The result of the compression stage is an appropriately partitioned JPEG2000 image consisting of *modular data containers* able to support the independent reconstruction of single RoIs at the desired LoD. The RoI feature can heavily *decrease the need for computing power and bandwidth*.

3. IMAGE STREAMING WITH DYNAMIC ROIS

Progressive data streaming is an indivisible part of modern image communication. It handles the transfer of the data to the mobile device and basically consists of 3

stages*: Calculation, Sequencing,* and *Signalization* of the compressed data. The following sections discuss the different options for each of these points.

3.1 Calculation

Contrary to pixel domain, the calculation of data parts belonging to a RoI is more complex. As during compression the image is transferred into a scalable representation (ISO, 2002), the content of a pixel region is usually included in multiple data containers. Different approaches to accomplish their calculation have been proposed (Deshpande & Zeng, 2001; Ortiz et al., 2004). However, usually only the spatial dimension of the RoI and less its reconstruction at a reduced LoD is considered. Due to the known structure of the encoded image, this criterion can be fulfilled by a successive selection of RoI containers for each LoD dimension up to the desired LoD (Rosenbaum & Schumann, 2002; Rosenbaum, 2006). By reducing the number of transmitted containers, further bandwidth is saved.

3.2 Sequencing

The goal of sequencing is an interest ordered data transfer by changing the position of data containers within the transmission sequence. This can be achieved by either *global* or *local prioritization*. The global strategy is based on the prioritization between RoIs and thus, allows for a much more flexible adaptability of the streaming process. The basic idea is the assignment of a prioritization value to each RoI (Rauschenbach, 1999). RoIs with values n have an advantage of $(n\text{-}m)$ transmission steps before data of a RoI with prioritization value m $(n>m)$ is included in the sequence. If data from multiple RoIs is to be transmitted, it is interleaved.

The local R-D optimized strategy prioritizes containers belonging to a single RoI. As each element contributes to a pixel region, there might be elements which are truncated at the borders of the RoI. Thus, they do not contribute in the same extent to the refinement of the RoI as fully covered elements. Dependent on the respective overlap, to these elements is internally assigned a smaller priority (Taubman & Rosenbaum, 2003) to achieve a faster quality refinement at client side (cf. Figure 2).

Figure 2. Visual comparison of the reconstruction of a RoI at 6.4kB from the original (left) and R-D optimized sequencing (right).

3.3 Signalization

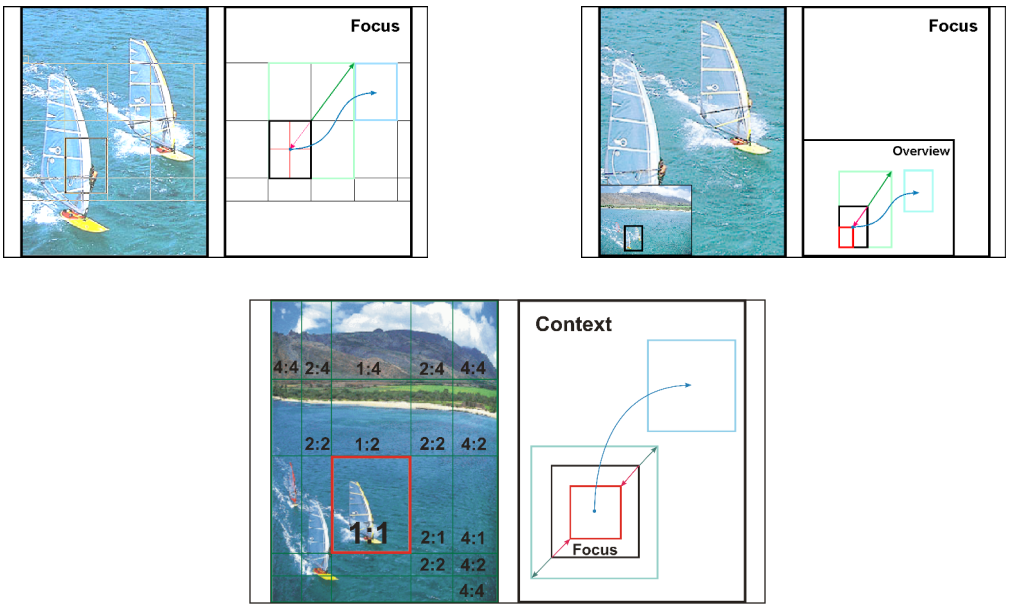
The goal of an appropriate signalization strategy is the proper identification of the transferred data at client side. Due to the reason within *external signalization* to each data chunk is assigned a unique ID, the required bandwidth might significantly increase (cf. to ISO, 2004). Contrary *inherent signalization* identifies each received data element from a predefined progression order. Although inherent in the JPEG2000 codec, the principle must be enhanced to deal with arbitrary container orders as outcome of the sequencing stage. Rosenbaum & Schumann (2002) accomplish this by the un-complex inclusion of new containers within the resulting data-stream. As this also increases the amount of data a strategy for *synchronized signalization* has been proposed by Rosenbaum (2006). Due to the reason server and client running synchronously during transmission, no additional data must be included into the transferred data and much bandwidth can be saved.

Result: A successful streaming of the image delivers the data containers provided by the compression stage in the currently most *appropriate order* to the mobile client. Thereby, the client is able to recognize each container and to process the included information. No more containers than required to reconstruct each RoI at its currently assigned LoD are transferred leading to the effect that much *less processing power and bandwidth* are required.

4. VISUAL REPRESENTATION

Before shown to the user, the received data is usually processed and converted to an appropriate visual representation. This process strongly depends on the respective task and the users needs. The creation of representations used by the 3 interactive tasks: *Mobile image browsing, Viewer guidance*, and *Content exchange*, however,

Figure 3. The image represented by different browsing techniques: Grid-based Zoom&Pan (top/left), largeDetail-View (top/right), and the rectangular FishEye-View with selected RoI scaling values (bottom). Each technique provides different means for interaction (blue: panning, red: zoom in, green: zoom out).



requires strong computing power. In the following, it is shown that the beneficial features of JPEG2000 can be exploited to significantly reduce these needs.

4.1 Mobile Image Browsing

The small screen space of mobile devices imposes a significant usability problem if large imagery is to be displayed. The aim of image browsing is to ease the comprehension of the content by an appropriate representation and means for interaction. Although there are different approaches to achieve this, especially for the strongly limited mobile clients new developments are required. In the next sections, a sophisticated browsing technique for each of the approaches – *Zoom&Pan (ZP)*, *Detail&Overview (DO)*, and *Focus&Context (FC)* – is reviewed and its resource requirements within an image communication system using the introduced streaming technology are discussed. The general approach for any representation is to partition the image in RoIs and to assign well-defined LoD and prioritization values. RoIs which are interesting are assigned a high LoD, RoIs which are not shown the lowest LoD. The prioritization strongly depends on the respective technique and expected behavior. A general taxonomy for image browsing techniques in conjunction with guidelines for their appropriate streaming can be found in (Rosenbaum & Schumann, 2005).

4.1.1 Grid-Based Zoom&Pan (GbZP)

The main disadvantage of many ZP-based techniques is that no context to the shown image part is provided. This is overcome within GbZP by a navigation grid showing information to the currently displayed region and the whole image (cf. Figure 3). This grid also serves as a means for interaction - another drawback of ZP-based techniques. The traditional slider paradigm and menu-based zooming is replaced by intuitive grid interaction. Each grid cell represents a different image region and corresponds in its dimensions to the displayed region. The grid outline represents the whole image. The information seeking mantra of Shneiderman (1996) -*Overview first, zoom and filter, then details-on-demand*- can be accomplished by 3 fast interactions only. More details to GbZP and the design of the belonging image communication system can be found in (Rosenbaum & Schumann, 2005).

Results: As only a certain image region is shown, creating a GbZP representation is *un-complex*. Furthermore, only data for the currently shown region is transferred. Consequentially, bandwidth requirements strongly correlate with the ratio between this region and the whole image. The *save of bandwidth* for a representation requiring 10% of the space consumed by the full-detail image is *approximately 90%.*

4.1.2 The largeDetail-View (lDV)

To display relevant micro and macro information at the same time, the large-Detail-View provides in additional overview to the whole image (cf. Figure 3). Although, the DO principle is well-known in the area of Information Visualization, it can also be applied for image browsing (Karstens et al., 2004; Rosenbaum, 2006). Within the overview, a viewfinder shows the currently displayed region with regard to the whole image. To concentrate the means for interaction to a particular structure, all browsing tasks are accomplished by a modification of the viewfinder. Though, the effective exploration requires many cognitive switches between the two views, the permanently shown overview eases the orientation within the image significantly. To explore contents covered by the overview, it may be displaced or hidden. An image communication system tailored to the lDV is described by Rosenbaum (2006).

Results: Due to the additional scaling operations needed to create the additional overview, the lDV requires *slightly more computing power* than ZP-based techniques. The same applies for the transmitted data. Due to the very low detailed overview, however, the *additional amount of data is little* and might be even negligible if content covered by the overview is omitted during transmission.

4.1.3 The rectangular FishEye-View (rFEV)

The rectangular FishEye-View has been introduced by Rauschenbach (1999). It is founded on the lens metaphor, and as shown by Karstens et al. (2004) allows for an intuitive user interaction . The consistent embedding of the focus is achieved by a complex belt partition of the background (cf. Figure 3). Belts close to the focus are less scaled than belts at the image borders. Thereby, a single belt is formed by many RoIs with different scaling values. Such a configuration is high-demanding for an appropriate image communication, but can still be handled by the introduced technology. More details to the design of the belonging communication system can be found (Taubman & Rosenbaum, 2003).

Results: The rFEV is very intuitive, but also *much more complex* during the creation of the belonging visual representation than other techniques. Much scaling operations are required to smoothly embed the focus. Regarding the requirements for bandwidth *more resources are required* as for GbZP or lDV. However, there is still much data which can be omitted during data transfer. If the ratio between the image dimensions and the available screen space is 4:1, approximately 70% of the data is negligible.

4.2 Viewer Guidance for Raster Imagery

To quickly extract relevant information from large images is difficult. The aim of viewer guidance is to intuitively direct the attention of the viewer to this information. Contrary to image browsing the image is represented in its full dimensions, but usually enriched with additional contents as frames or annotations. Due to the fact, these structures are usually permanently combined with the content, however, this has the significant drawback that the highlighted region may not be changed. To overcome this, two paradigms from Information Visualization - *Depth of Field* and *Tool glasses* - have been adopted to raster imagery.

4.2.1 Depth of Field

The effect aroused by embedding a highly detailed focus region into a blurred background is called Depth of Field (DoF) (cf. Figure 4/left). As humans do

Figure 4. The depth of field effect (left) and tool glass approach (right) applied to still imagery by blurring the background or removing texture from the current focus

not like to look at blurred objects, it is a very effective means of guiding the attention of the user to the focus. However, the demands of DoF representations often exceed the abilities of a mobile device. Due to this, new ideas for their creation and transmission have been introduced by the authors (2006). They are mainly based on the Discrete Wavelet Transform (DWT) as integral part of the JPEG2000 codec. As the DWT inherently separates detail and approximation of the image, the later can be used for blurring. Thereby, the modular structure of the data-stream allows the removal of the details without to decode the image. This also applies for an additional decrease in the quality of the reconstructed signal to advance the blurring effect. Even such complex image processing operations can be supported by an appropriate image handling (Rosenbaum & Schumann, 2006; Rosenbaum, 2006).

Results: All operations required to create a DoF representation of the content are accomplished in compression domain. Thus, the implementation is more than *5 times faster* compared to traditional pixel based processing. As the blurring of the large background regions is accomplished by removing data containers, the coupling with the proposed streaming technology leads to a *tremendous save of bandwidth*,. In case the focus covers 1/10th of the image, almost *90% of all available data can be skipped* during transmission.

4.2.2 Tool Glasses

The main idea of tool glasses is to reduce the content shown within the focus. Due to the resulting inconsistencies, the embedded focus immediately attracts attention. The reduction of presented information within edge or detail glasses, however, is also a great means for content exploration. In any event, the extraction of details requires much computing power. To extent the application area for such tools to mobile environments, new ideas are required. To achieve this, Rosenbaum & Schumann (2006) again take advantage of properties of the DWT. To all contents belonging to the focus, the approximation of the image is removed and replaced by more suitable data without to decode the image. This leads to a representation as shown in Figure 4/right, and is an proceeding can be fully supported by an appropriate communication system (see also (Rosenbaum, 2006)).

Results: Working in compression domain is *un-complex*. The proposed texture removal strategy is up to *20 times faster* compared to pixel-based techniques, and thus, is rather appropriate for mobile devices. During interactive exploration, the *modification* of the new focus region can be achieved *in real-time* on current mobile hardware. Due to the fact, the large background regions are shown in full detail, the *save of bandwidth is little.*

4.3 Content Exchange Between Imagery

The exchange of content between two or multiple images in consequence of modifications is a frequent task in mobile environments. Especially the often changing data in commercial information systems requires efficient mechanisms for remote content updates as achieved by non-interactive image editing functionality. As moving imagery also helps creative, editorial and business professionals to create powerful communications, the relevance of Motion-JPEG2000 for commercial applications is similar. However, data exchange is easy to accomplish in pixel domain, but requires much resources if the content is only be available in compressed representation. To overcome this, the content might directly be processed in this form. Rosenbaum & Taubman (2003) and Rosenbaum (2006) present a scheme for an exchange of JPEG2000-compressed content. After briefly describing the underlying idea, two of its main applications are explained in more detail.

4.3.1 Content Exchange in JPEG2000 Domain

Content exchange in compression domain requires the access of all encoded data contributing to the reconstruction of a closed image region directly on the data-stream. The crucial challenge here is the multi-resolution representation of the content. This is considered by the introduced Limited Spatial Access (cf. Section 2) leading to an appropriate partition of the image during compression. If this principle is applied to a source and a destination image, corresponding data containers can simply be exchanged without to violate the compliance of the resulting data-stream (cf. Figure 5/left). By taking advantage of the multi-resolution property, it is even possible to reduce the source contents in their spatial dimensions (cf. Figure 5/right). The decoding of the modified data-stream leads to a reconstructed image with contents from both images. If a remote scenario with frequent content changes at server side is considered, this idea can easily be applied for an efficient data streaming. Instead of transferring the whole modified image, only data belonging to the altered regions is transmitted and merged at client side with static contents.

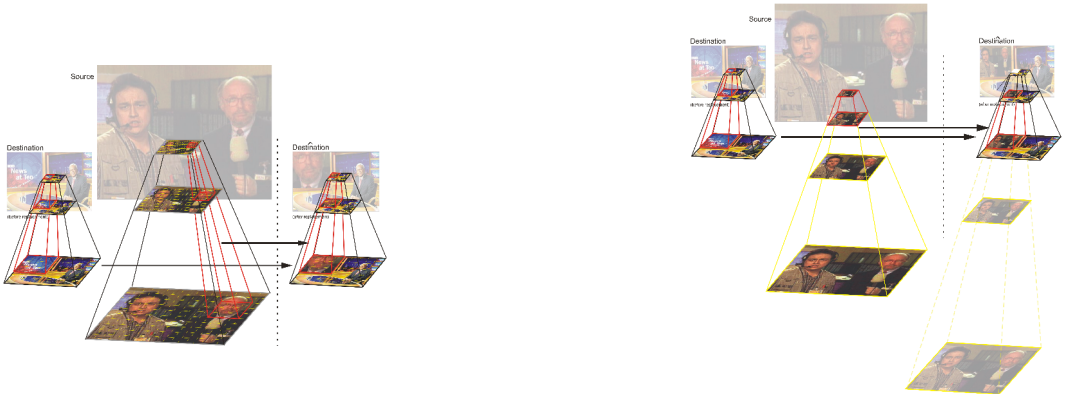
Results: Working in JPEG2000 domain *strongly decreases the complexity* of the exchange task for encoded imagery. As no decoding is required, the proposed strategy is *9 times faster* than pixel based processing. The performance gain even increases if the result has to be in encoded form for transmission or storage. The save of bandwidth strongly correlates with the ratio between the modified region and the whole image. If it covers a 1/10th of the image, 90% of all available data may be neglected.

4.3.2 An Image Editing Framework

Although content exchange in JPEG2000 domain is un-complex, all data containers involved in the exchange procedure must exactly fit to their respective counterparts. This is not always granted and limits the applicability of the approach. To overcome this, an editing framework has been proposed by Rosenbaum (2006). It is shown that the probability of a perfect fit increases with a subsequent un-do of the encoding procedure, and the recursive application of the exchange procedure based on different container types always leads to the desired result.

Results: The evaluation of the proposed framework has revealed that its performance is never slower than a full pixel-based exchange, but *in average much faster*. This means that by a universal applicability, *much less computing power* is required for content exchange at client side. As approximately the same amount of data is transferred in both cases, there is no significant difference in the use of bandwidth compared to the general exchange scheme.

Figure 5. The basic scheme for content exchange in JPEG2000-domain (left) can also be enhanced to inherently reduce the spatial dimensions of the included image region (right)



4.3.3 Motion-JPEG2000

Although Motion-JPEG2000 offers a number of very desirable features for digital video processing, its compression performance is not as high compared to other codecs. This is mostly due to the neglect of interframe redundancies. This is considered by a strategy designed to advance the compression performance of Motion-JPEG2000 video (Rosenbaum, 2006). By detecting and omitting data belonging to regions which are static with regard to two subsequent frames, much data is removed from the original data-stream. The original frame can easily be reconstructed by re-including this data from the previous frame whenever required. Due to the fact that each single frame within a compliant Motion-JPEG2000-video is encoded with JPEG2000, the proposed ideas for static or remote context exchange in JPEG2000 domain can be applied without limitations.

Results: Due to the foundation on the described basic scheme, detection, removal and reconstruction are *little demanding regarding computing power*. All stages are accomplished on encoded data and no decoding is required. Thereby, this procedure is also applicable to video streaming. By transmitting only the dynamic parts of each frame and reconstructing the whole frame at client side usually *much bandwidth is saved*.

5. CONCLUSIONS

By focusing on the results achieved by the design of appropriate communication systems, this publication has shown the potential of image communication using JPEG2000. To reduce the impact of *limited computing power* and *bandwidth* in mobile environments, all stages of the image communication pipeline have been tightly coupled. Based on the generic concepts for a *demand-driven streaming* based on *dynamic RoIs and JPEG2000*, the three major tasks in mobile environments – *Image browsing, Viewer guidance* and *Content exchange* could been implemented very efficiently. The respective communication systems *significantly reduce the need for computing power* (DoF-80%, content exchange-89%, Tool glasses-95%) *and bandwidth* (often 90%). Overall, the achieved results confirm the authors' assertion that such a system can *greatly increase the performance* in mobile environments. The rigorous compliance of the proposed technology allows for an easy migration in existing systems.

ABSTRACT

The current dynamic and turbulent business environment has forced companies that are competing in global markets to change their traditional methods of conducting business. Recent developments in applying Information Technology (IT) offer the most exciting business opportunities in the marketplace. Organizations must re-evaluate every aspect of their strategies and quickly move to a working mode where the electronic commerce is essential for their success. One of tools that can be used for measuring the diffusion rate of IT is e-readiness assessment. Small and Medium Enterprises (SMEs) are critical to the economies of all countries, including developing ones. They cannot be left behind and many are already demonstrating their entrepreneurship strength by grasping opportunities offered by IT. The concept of e-readiness assessment for SMEs has received limited attention in the literature. This paper first studies e-readiness assessment models proposed for countries and then develops a model for measuring the e-readiness of SMEs (ESME) by an exploratory study using Delphi technique.

Keywords: E-readiness Assessment, Small and Medium Enterprise, Information Technology, Delphi technique, Iran.

INTRODUCTION

E-readiness can mean different things to different people, in different contexts, and for different purposes [1]. Thus, it is important to define e-readiness in the context of this paper. E-readiness of a Small and Medium Enterprise(SME) is defined here as the ability of an SME to successfully adopt, use and benefit from information technologies (IT) such as e-commerce.

Information technology (IT) is a term that generally covers the harnessing of electronic technology for the information needs of a business at all levels. It utilizes computer-based systems as well as telecommunication technologies for the storage, processing and communication [2,3]. While an information system (IS) is a group of formal processes that together collect, retrieve, process, store and disseminate information for the purpose of facilitating, planning, control, coordination and decision-making in organizations, IT on the other hand provides the technical solutions identified in the IS, including the networks, hardware and software [4]. IT today is basically electronics and is based on integrated circuits or silicon chips. Hanson and Narula further identified two major forms of IT as Telematics (meaning 'big media') and Ethnotronic (meaning 'small media'). Telematics are to be identified with such technologies as computers, telephone, satellites, television, radio, video and those that rely on large-scale infrastructure. Ethnotronics include technologies such as typewriters, audio cassette recorders, fax machines, paper copiers, calculators, digital watches and other more personal types of technology [5].

While providing insight into the overall e-readiness of countries on the macro level, few studies have attempted to evaluate e-readiness from a micro perspective. In particular, a small number of studies have undertaken as assessment of the adoption e-commerce in small and medium enterprises (SMEs) in the United States, Australia, some European and Asian countries [24]. The objective of the research is to present a model that assesses the e-readiness of SMEs, particularly their preparedness for adoption of electronic commerce.

E-READINESS MODELS AND CONCEPTS

Over the last years, a number of models for e-readiness assessment of countries on the macro level have been developed by different organizations. On the surface, each model gauges how ready a society or economy is to benefit from information technology and electronic commerce. On closer examination, the models use widely varying definitions for e-readiness and different methods for measurement. These models mainly are in four categories as follows:

1. Ready-to-use tools: There are few ready-to-use tools freely available on the web.
2. Case studies: There are numerous case studies assessing specific countries' e-readiness, and many of these could be used as bases for e-readiness tools.
3. Third party surveys and reports: These reports aim to rank and rate countries on various measures held to indicate e-readiness.
4. Other e-readiness assessment models: In addition to the formal tools and surveys described above, there is a range of other frameworks such as digital divide reports and position papers that can be similarly used for e-readiness assessment.

The above mentioned models can be divided into two main categories, first those that focus on basic infrastructure or a nation's readiness for business or economic growth, which are e-economy models and second, those that focus on the ability of the overall society to benefit from IT which are "e-society" models. These two categories of models also have different assessment methodologies such as questionnaires, Statistical methods, best practices, historical analyses [27,28]. Table 1 shows detail of some important e-readiness assessment models.

There are several definitions for e-readiness. The CSPP model defines an 'e-ready' community as one that has high-speed access in a competitive market; with constant access and application of ICTs in schools, government offices, businesses, healthcare facilities and homes; user privacy and online security; and government policies which are favorable to promoting connectedness and use of the network [26]. The Asian Pacific Economic Cooperation (APEC) group defines a country as e-ready that is 'ready' for e-commerce, has free trade, industry self-regulation, ease of exports, and compliance with international standards and trade agreements [6]. McConnell International defines e-readiness as the capacity of nations to participate in the digital economy[7] and finally, the Center for International Development at Harvard University the most acclaimed institution in e-readiness research defines an 'e-ready' society is one that has the necessary physical infrastructure (high bandwidth, reliability, and affordable prices); integrated current

Table 1. Some of important e-readiness assessment models

Model Name	Author	Reference	Focus
Apec	The Asian Pacific Economic Cooperation (APEC) Electronic Commerce Steering Group	[6]	E-Commerce Readiness
CSPP	Computer Systems Policy Project	[26]	Existing Infrastructure
CID's	The Center for International Development at Harvard and IBM.	[8,9]	Society
McConnell International	McConnell International prepared this report in collaboration with World Information Technology and Services Alliance (WITSA)	[7]	Infrastructure, Digital Economy, Education and Government

USAID	U.S. Agency for International Development	[20,21]	Access, Government, People

ICTs throughout businesses (e-commerce, local ICT sector), communities (local content, many organizations online, ICTs used in everyday life, ICTs taught in schools), and the government (e-government); strong telecommunications competition; independent regulation with a commitment to universal access; and no limits on trade or foreign investment[8,9].

While the above mentioned tools focus on assessing readiness of countries, governments and policies for adopting information technologies, some others e.g. IQ Net Readiness Scorecard [22] assess the readiness to adopt other different concepts. IQ Net Readiness Scorecard was developed by CISCO and is a Web-based application that assesses an organization's ability to migrate to an Internet Business model. It is based on the book Net Ready [43], which gauges the readiness of IT service providers.

E-READINESS OF SMALL AND MEDIUM ENTERPRISES

There are a number of definitions of what constitutes a small to medium enterprise (SME). Some of these definitions are based on quantitative measures such as staffing levels, turnover or assets, while others employ a qualitative approach [23]. Some researchers suggests that any description or definition must include a quantitative component that takes into account staff levels, turnover, assets together with financial and non-financial measurements, but the description must also include a qualitative component that reflects how the business is organized and how it operates[23].

In our view, SMEs' e-readiness is the ability of an SME to successfully adopt, use and benefit from information technologies (IT) such as e-commerce. It is related to the level of IT acquisition or adoption (especially e-commerce) by them. Many other studies have attempted to describe the factors influencing IT adoption in SMEs. For example, Iacovou et al. [44] studied factors influencing the adoption of electronic data interchange (EDI) by seven SMEs in different industries, they included perceived benefits, organizational readiness, and external pressure. To measure perceived benefits they used awareness of both direct and indirect benefits. Variables measuring organizational readiness were the financial and technological resources. In order to measure external pressure, they considered competitive pressure and its imposition by partners. The results suggested that a major reason that small firms become EDI-capable is due to external pressure (trading partners). The adoption of the internet was also studied by Mehrtens et al.[45].

Other studies have shown that many of the barriers reported in the late 1990's by Lawrence and Hadjimanolis are still current in today's SMEs. Tambini (1999)[29] and Eid et al (2002) [30] found that SME managers are still not convinced that e-commerce fits the products or services that their businesses offer. Studies by Bakos and Brynjolfsson (2000) [31], Sawhney and Zabin (2002) [32], and Merhtens et al (2001)[33] have found that there is still a reluctance for SME managers to adjust their businesses to the requirements and demands placed on it by e-commerce participation. Some of these barriers are summarized in table 2.

E-readiness of SMEs (ESME) is related to the level of IT acquisition or adoption especially e-commerce by them. SMEs for achieving to a good level of e-readiness must remove the above mentioned barriers and also pay attention to the factors influencing IT adoption. Therefore, assessment model of ESME should be determined with regarding these barriers and also the factors affect IT adoption in SMEs. We consider the mentioned barriers and the factors influencing IT adoption in SMEs in seven groups which are, Telecommunication and technical infrastructure, Legal environment, Competitive pressure, Human resources and cultural infrastructure, Management and organizational policy, Communication with environment and finally, Information technology security.

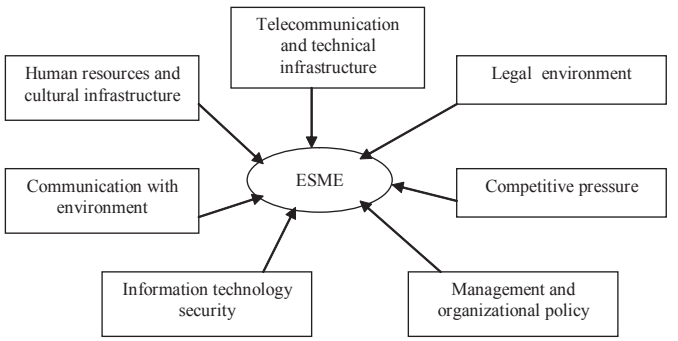
In this paper, we propose an assessment preliminary model of ESME with regarding the seven mentioned dimensions which are as follows (as shown in figure 1):

a. Telecommunication and technical infrastructure which determines the status of telecommunication and technical infrastructure in SMEs.
b. Legal environment which determines the required legal conditions for IT adoption in SMEs.

Table 2. Some barriers to e-commerce adoption in SMEs

Barriers	Ref.
E-commerce doesn't fit with products/services	Eid et al [30] , Kendall et al [34] Tambini [29], Hadjimanolis [27]
E-commerce doesn't fit with the way we do business	Sawhney & Zabin [32],Mehrtens et al [33] Bakos & Brynjolfsson [31], Farhoomand et al [35],Poon & Swatman [36]
E-commerce doesn't fit the way our customers work	Bakos & Brynjolfsson [31],Hadjimanolis [27]
We don't see the advantages of using E-commerce	Lee & Runge [39],Chau & Hui [40] Purao & Campbell [38],Lawrence [28] Hadjimanolis [27]
Lack of technical know how	Mirchandani & Motwani [43], Hadjimanolis [27] Farhoomand et al [35], Purao & Campbell [38]
Security risks	Oxley & Yeung [42], Reimenschneider & McKinney [37] Purao & Campbell [38], Hadjimanolis [27]
Cost too high	Reimenschneider & McKinney [37] Ratnasingam [41] , Hadjimanolis [27] Purao & Campbell [38],Lawrence [28]
Not sure what hardware/software to choose	Farhoomand et al [35], Hadjimanolis [27]

Figure 1. Proposed model for assessment of ESME



c. Human resources and cultural infrastructure that is related to the quality and quantity of IT workers and cultural circumstance for IT adoption in SMEs.
d. Management and organizational policy which determines status of organizational plans and management commitment for IT adoption in SMEs.
e. Communication with environment which determines the status of electronic communications with SME's stackholders.
f. Information technology security which determines the status of IT security in SMEs.
g. Competitive pressure which influencing IT adoption in SMEs.

RESEARCH METHODOLOGY

In the previous sections, the concept of e-readiness and its assessment models for countries on the macro level was introduced. In addition, we proposed an e-readiness assessment model for SMEs based on study of barriers and factors influencing IT adoption in SMEs.

In this research for validating the model, we use an exploratory Delphi study. The Delphi technique, which was developed by the Rand Corporation in the 1950s, is a data collection approach that is designed to structure group opinion [50]. A two-round Delphi technique was used to implement this research. Delphi panel members were selected amongst researchers and academics with experience in the use of IT and e-commerce applications within SMEs. A total of 100 members were identified as eligible for panel membership, and were mailed electronically invitation letter soliciting their participation in the research. A total 45 members volunteered to participate in two data collection rounds.

We use a Likert-type scale for analyzing the questions, where 1=strongly unimportant, 2=unimportant, 3= neutral, 4=important, 5= strongly important. In addition, for calculating weight of the indicators in comparison with each other, Eigenvector algorithm is used [51]. Figure 2 shows the frame structure of this research.

The rating used to assess each dimension or indicator (item) is ranked according to the table 3. Also, one sample t-test is performed to test the value of population mean (μ) for determining rating of each dimension or indicator as follows:

a. First, all of items are tested with "$\mu \geq 4$". According to the table 3, accepted items receive strong rating (+++).
b. We will perform two tests " $3 \leq \mu$ "and "$\mu < 4$" on unaccepted items in part a, the passed items receive medium rating (++).
c. Finally, remained unaccepted items in part b, will be tested with "$\mu < 3$". Accepted items receive weak rating (+). All items are tested at alpha = 0.05.

Table 3. Rating used to assess dimensions or indicators

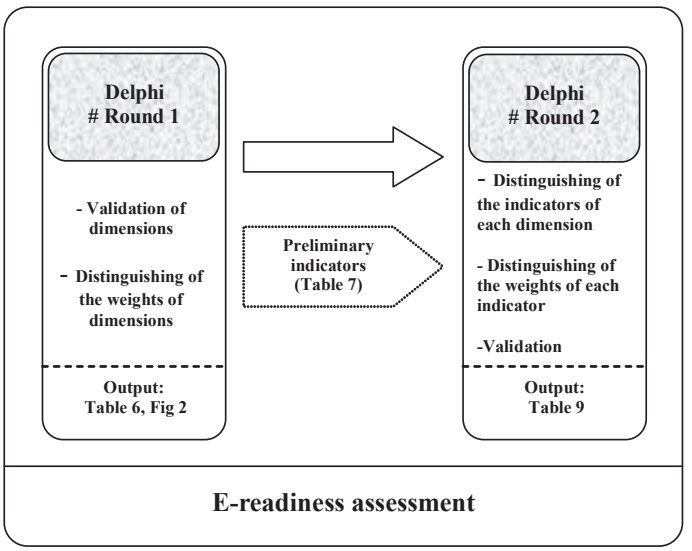
	Criteria	Assigned Rating
1	If the amount of the population mean is greater than or equal to 4, dimension or indicator has a strong effect.	+++
2	If the amount of the population mean is greater than or equal to 3 and less than 4, (3≤ mean <4) dimension or indicator has a medium effect	++
3	If the amount of the population mean is less than 3, dimension or indicator has a weak effect.	+

The dimensions or indicators that receive strong or medium rating are accepted as effective factors for assessment of ESME.(To analyze data the statistic package Minitab for Windows Software is used.)

RESEARCH RESULTS

As indicated in Table 4, the average of importance assessment (mean) for the seven proposed dimensions ranged from 2.77 to 4.31. This table also shows that six dimensions receive strong or medium rating (mean ≥ 3) and one dimension receives weak rating. Therefore, the accepted dimensions include: Telecommunication and technical infrastructure, Legal environment, Human resources and cultural infrastructure, Management and organizational policy, Communication with environment and finally, Information technology security. Validated model for assessment of ESME will be according to figure 3.

Figure 2. Research structure



As before mentioned, most of e-readiness assessment models are in national level and they mainly assess a country readiness for participation in the digital world. Some dimensions of the validated model have been considered for e-readiness assessment in macro level models according to table 5.

Table 6, shows another result of Round 1 that is related to calculating weight for dimensions of the validated model with using eigenvector algorithm. First, we make preference matrix. It is a reciprocal matrix which is made based on pairwise comparisons between pair of dimensions. Each element of the matrix is in the form $\frac{n_{ij}}{n_{ji}}$, n_{ij} is the number of experts that believe dimension ith is more important than dimension jth, and n_{ji} is the number of experts that believe dimension jth is more important than dimension i_{th}. The weight of dimensions is calculated by eigenvector of the matrix [76]. (The sum of weights is equal to one)

On the other hand, the main objective of the Round 2 was to identify validated indicators for the validated dimensions of the model. Table 7, shows the proposed preliminary indicators for assessing the validated dimensions. In this table, T1 to T9 are preliminary indicators for assessing telecommunication and technical infrastructure, L1 and L2 are preliminary indicators for assessing legal environment, C1 to C11 are preliminary indicators for assessing communication with environment, HC1 to HC4 are preliminary indicators for assessing human resources and cultural infrastructure, MO1 to MO5 are preliminary indicators for assessing management and organizational policy, and finally, I1 and I2 are preliminary indicators for assessing information technology security.

As indicated in Table 8, the average of importance assessment (mean) for the proposed indicators ranged from 2.2 to 4.91. This table also shows that seven indicators receive weak rating (+) include C1, C9, T2, T4, MO1, HC3, HC4 and the others that are validated indicators, receive strong or medium rating. Table 9, shows another result of Round 2, is related to calculating weight for validated indicators of the dimensions with using eigenvector algorithm that explained before.

The model can be used for the assessment and comparison of e-readiness of the considered SMEs with measurement of the indicators (qualitative or quantitative) and applying their weights and also dimensions' weights. For achieving more exact results, it must be further examined especially for different categories of SMEs.

Table 4. Validation findings for dimensions of the proposed model (n=45)

Dimensions of the proposed model	mean	stdev	p.value	rating
Telecommunication and technical infrastructure	4.31	1.30634	.069	+++
Legal environment	3.77	0.76541	1, 0.971	++
Human resources and cultural Infrastructure	4.20	1.33463	0.173	+++
Management and organizational policy	4.20	1.28793	0.141	+++
Communication with environment	3.75	0.98062	1, 0.949	++
Information technology security	3.88	0.76739	1, 0.849	++
Competitive pressure	2.77	1.16496	0.086	+

Table 5. The relation between the validated model and macro level models

Dimensions of the proposed model	E-readiness assessment models for countries (macro level models)
Telecommunication and technical infrastructure	APEC, CID, CSPP, EIU, NRI, UNDP, USAID, SIBIS, SIDA, MI, IDC, Mosaic
Legal environment	CID, APEC, ITU, USAID, SIDA, MI, CIDCM, EIU, NRI

Table 7. Preliminary indicators for assessing the validated dimensions

Indicator	Indicator Description
T1	Percentage of organizational parts that connected to the computer network
T2	Bandwidth of access to the local network
T3	Bandwidth of access to the internet
T4	Number of phone lines
T5	Number of computers
T6	Number of computers that connected to the internet
T7	The quality of supporting telecommunication and technical services
T8	The quality of hardware equipment of the network such as servers, modems, etc
T9	The reliability in access to computer services
L1	The adherence rate to the laws related to information technology such as: copyright law, intellectual property right, e-commerce act, etc.
L2	The adherence rate to the ethical issues in using computer services
C1	Percentage of electronic customers of enterprise
C2	Percentage of electronic communication with customers
C3	The quality of electronic communication with customers
C4	The quality of electronic communication with partners
C5	Percentage of electronic communication with partners
C6	The quality of electronic communication with suppliers
C7	Percentage of electronic communication with suppliers
C8	The rate of communication with the IT developer organizations(consultants, developers of websites, etc)
C9	Percent of organizational revenue which related to the electronic customers
C10	Possibility of electronic communication with outside organizations (the whole of business process such as negotiation, order, deliver, etc.)
C11	The quality of information systems and electronic information exchange in the organization (e-government of the organization)
HC1	The level of information literacy of managers (level of computer skills)
HC2	The level of information literacy of employees (level of computer skills)
HC3	The level of information technology skilled literacy of employees such as percentage of employees that have high degrees in information technology related courses
HC4	The level of IT pubic acceptance (organizational environment)
MO1	Existence of organizational unit that is liable for IT development
MO2	Amount of investment by organization related to the IT development
MO3	Commitment and seriousness of management related to the IT development
MO4	Existence of strategy for IT development in the organization
MO5	Existence of clear plan and policy for IT development
I1	Existence of hardware and software infrastructure of information security in the organization such as firewall system, VPN, etc.
I2	Using of security mechanisms in the organization such as authentication, integrity, privacy, access control, etc.

Table 8. Validation findings for preliminary indicators (n=45)

Indicator	mean	Stdev	p.value	Rating
C1	2.9556	0.36739	0.650	+
C2	4.2444	0.90843	0.961	+++

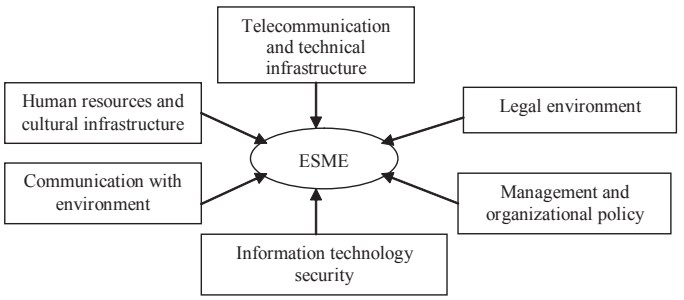
Figure 3. Validated model for assessment of ESME



CONCLUSION

E-readiness of a small and medium enterprises is defined here as the ability of an SME to successfully adopt, use and benefit from information technologies (IT) such as e-commerce. In this paper, we proposed an assessment preliminary model of ESME with regarding to study of barriers and factors influencing IT adoption in SMEs and used an exploratory Delphi study for validating it. The study findings, showed the major six dimensions for assessing of ESME consequently are telecommunication and technical infrastructure, human resources and cultural infrastructure, management and organizational policy, information technology security, communication with environment and finally, legal environment.

The validated model can be used for the assessment and comparison of e-readiness of the considered SMEs with measurement of the validated indicators and applying their weights and also dimensions' weights.

MIS Textbook Selection Using Analytic Hierarchy Process

Farrokh Mamaghani, St. John Fisher College, 3690 East Avenue, Rochester, NY 14618; E-mail: fmamaghani@sjfc.edu

ABSTRACT

Many business schools and individual faculty members are faced with decisions regarding the evaluation and selection of a MIS textbook for their courses due to the availability of many choices on the market. This evaluation and selection requires a multiple criteria decision-making method. The purpose of this paper is to apply the Analytic Hierarchy Process (AHP), a well-known multiple criteria decision making method, designed for decisions that require the integration of quantitative and qualitative data, to evaluating and selecting a MIS textbook.

1. INTRODUCTION

In today's classroom, textbooks serve as a tool, tutor, guidebook, and gauge (Association for Supervision and Curriculum Development, 1997). Teachers throughout the world base approximately 50 percent of their weekly teaching time on textbooks (Schmidt, McKnight, & Raizen, 1996). Therefore, selecting a proper textbook for a course has been one of the most important tasks for faculty. In order to help teachers select the proper textbooks, much research has been done to evaluate different textbooks at grade schools (Cohen, 2005; Dove, 1998). However, very little research is devoted to evaluating the textbooks used at the college level. Thus, it is no surprise that there is not much research done in regards to the evaluation and selection of textbooks for courses in the MIS field. While there is no indication of patterns of how MIS instructors select textbooks and the exact role the textbooks play in the classroom, which needs further study, at least one thing is certain— a majority of the instructors teaching MIS courses would like to have a textbook that would best meet their students' needs and become a good resource for other class activities such as case study analysis and discussion. A study of nearly eighty syllabi posted on the World Wide Web reveals that the majority of MIS instructors depend heavily on a textbook as a teaching tool in their courses. The proliferation of syllabi on the Web presents for the first time the possibility of gaining a comprehensive picture of how MIS survey courses are taught and how textbooks are used in them.

2. DETERMINING STUDY PARTICIPANTS

Textbooks may not be able to be rewritten or revised periodically, but the selection of textbooks can be done on a periodical basis. Therefore, instructors of MIS courses should evaluate available MIS textbooks frequently and select a textbook that meets their course objectives and incorporates the "voices" of all involved parties into consideration.

There are many factors that enter into the textbook evaluation and selection process and we will not attempt to be exhaustive in listing several general factors that may be involved. In the following sections, we will identify the parties that will either directly (faculty and students) or indirectly (employers) be affected by the choice of a textbook.

2.1 Instructors' Input

Decisions regarding textbook selection can only be made in the context of the particular learning situation in which they will be used and are influenced by a variety of factors. Besides the personal preference of an instructor, the evaluation and selection decision may be affected by factors such as content, availability of assessment tools and ancillary materials, a Web site, and price. As we mentioned earlier, this is not a complete list of factors that influence the choice of a textbook. However, we choose these factors to demonstrate our selection methodology.

2.2. Students' Input

Some of the students, whose needs are not met by a textbook, will lose interest and complain that they spent too much money on the textbook(s). Modern constructivist theories therefore believe that learning really takes place when the student can construct the new information into his/her original cognitive system (Jarvinen, 2001). In other words, students' needs have to be met in order to reach the goal of meaningful learning. Therefore, it is sensible to incorporate students' desires when considering the selection of textbook(s) in order to meet their needs.

To solicit students' inputs we conducted a survey in four sections of a 300-level Information Systems course, Information Technology Management, consisting of 106 students, as the sample for this study. This course is required for accounting and management majors in the AACSB accredited Business School, since it provides a comprehensive overview of the field of information technology management. The survey solicited students' feedback regarding various aspects of the textbook that was use during the course.

2.3. Employers' Input

Besides instructors' and students' needs, there is another equally important consideration for the selection of a MIS textbook. Since the information technology field is ever changing, teaching MIS courses requires instructors to equip themselves with the most up-to-date knowledge and technology. Therefore, one of the qualities of MIS textbooks that teachers should be looking for is adaptability. The textbook should not only be adaptable to new organizational developments, but also to the needs of local employers, based on the fact that most MIS graduates find jobs locally. However, most MIS textbooks are written in the view of being used nationwide. Therefore, they may not necessarily parallel the needs of local employers. Consequently, identifying local employers' needs and incorporating them into the process of selecting MIS textbooks is also important.

2.3.1 Employer Participant Selection

In order to select local employers to participate in this study, we asked the College's Career Services to identify the top 20 local employers of our accounting and management majors for the past five years. Following the approach used by and (Watson, 2000) each employer was initially contacted to identify the individual(s) in charge of hiring new graduates. Then each individual was asked about his or her willingness to participate in the study and twelve were selected. An important objective of the participant selection process was to solicit a diverse and well-informed viewpoints.

2.3.2. Data Collection

Telephone interviews were conducted to gather employers' feedback. The interviews were 20-30 minutes in length, including the introduction, and were comprised of the five questions. These questions were selected based on the review of AACSB requirements and 10 appropriate and current MIS textbooks on the market. At the end of the interviews the participants received a transcript of the telephone interview and were asked to review it for accuracy and add comments where appropriate.

3. METHODOLOGY

To incorporate all the voices, it is necessary to find a helpful methodology which provides for inclusion of quantitative as well as qualitative data. Analytical

Hierarchy Process (AHP) is an extremely useful methodology in this case. AHP has been known as a very useful multi-criteria decision making methodology to help decision makers select the best alternative among several available choices (Al-Subhi & Kamal, 2001; Bayazit, 2005; Lari, 2004).

Therefore, this paper attempts to demonstrate how AHP can help instructors to evaluate and select an appropriate MIS textbook for their courses with the inclusion of quantitative and qualitative factors from instructors, students and future employers, in the decision process.

4. AN OVERVIEW OF ANALYTIC HIERARCHY PROCESS

Saaty's Analytic Hierarchy Process (Saaty, 1995) has three major components:

1. Problem structuring – the formation of levels in a hierarchy,
2. Preference Assessment –prioritization, and
3. Synthesis

The AHP is unique in that it allows the quantification of intangibles through the construction of the problem in a visual hierarchical manner. This permits relationships between the ultimate goal, the criteria of choice and the alternatives to be clearly delineated in the decision-making process. This in turn functions as an aid to breaking the communication barrier that may exist between decision makers due to their different backgrounds, training and motivation. The hierarchy serves to create priority structures relevant to a specific decision problem. In deriving these priorities a distinction is made between local priorities that reflect the importance of an element at a lower level, those at a level higher in the hierarchy, and global priorities that reflect the importance of a criteria element with in relation to the focus of the problem. The basic AHP procedure consists of the comparison of pairs of factors within a set of reciprocal matrices.

The values in the matrix so formed indicate the strength by which one element dominates over another with respect to specific criterion by which they are being compared. Such a matrix is of the type:

$$A = \begin{Bmatrix} W_1 & w_1/w_2 & w_1/w_3 \ldots\ldots\ldots\ldots\ldots\ldots w_1/w_n \\ W_2/w_1 & & \\ \ldots\ldots & & \\ w_n/w_1 & & w_n/w_n \end{Bmatrix}$$

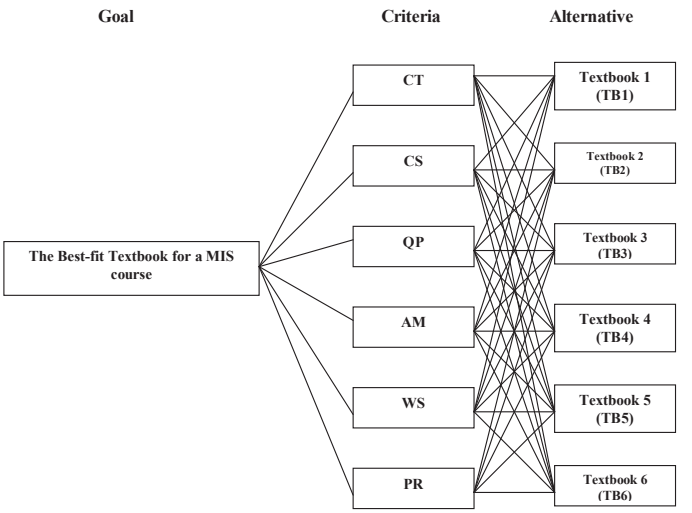
where every element wi/wj is representative of the a_{ij} comparison. Obviously if the i^{th} element is compared to the j^{th}, a comparison is also being made of the j^{th} with the i^{th} element (w_i/w_j, a_{ji}) causing the matrix to be a reciprocal matrix satisfying the criterion

$$a_{ij} = 1/a_{ji}$$

Since the comparisons may be qualitative, a scale capable of eliciting judgments from people in a consistent manner is needed, which also presents the flexibility to make judgments based on experience and personal expertise rather than on an absolute numerical value. Saaty uses a scale 1-9 based on the finding that an individual is incapable of simultaneously comparing more than seven alternatives (plus or minus two) (Miller, 1956, Saaty, 1977).

In this study we used scale 1 for equal importance (two factors contribute equally to objective), scale 3 for weak importance of one over another (experience and judgment slightly favor one factor over other), scale 5 essential or strong importance (experience and judgment strongly favor one factor over other), scale 7 for demonstrated importance (one factor is strongly favored and its dominance is demonstrated in practice), scale 9 for absolute importance (the evidence favoring one factor over another is of the highest possible order), and scales 2,4,6,8 as intermediate values. If factor i has one of the above non-zero numbers assigned to it when compared with factor j, then factor j has the reciprocal value when compared with i.

Figure 1. Decision hierarchy



5. USING AHP TO EVALUATE AND SELECT A MIS TEXTBOOK

5.1. Problem Structuring

In this study, a small group of evaluators comprised of three faculty members in charge of teaching MIS courses in an undergraduate accounting and management program discussed and brainstormed to generate evaluation criteria and identify alternatives. After initial deliberation, members of the evaluation team prepared a short survey to solicit inputs from students as well as several potential employers. After analyzing the results of these surveys, the evaluation team identified the following six evaluation criteria and six widely used MIS textbooks currently available in the market as the selection alternatives. These evaluation criteria were:

1. Content (**CT**)
2. Real World Case Studies (**CS**)
3. End of Chapter Questions and Problems (**QP**)
4. Ancillary Materials (**AM**)
5. Web Site (**WS**)
6. Price (**PR**)

Figure 1 shows the decision hierarchy.

5.2. Weighting the Criteria

After construction of the decision hierarchy, the second step was to assess the relative importance of criteria. An AHP evaluation is based on the decision maker's judgments about the relative importance of each criterion in terms of its contribution to the overall goal as well as preferences for the alternatives relative to each criterion. Therefore, in this example the evaluation team needs to specify their judgments about the relative importance of each of the six criteria.

Establishing priorities among criteria was based on pair-wise comparisons. A meeting with members of the evaluation team was scheduled to make pair-wise comparisons among criteria and available textbooks.

Table 1 shows the comparison matrix, which indicated the results when evaluating the relative importance of the criteria in a pair-wise fashion. The entries in the matrix consist of one's on the main diagonal and reciprocals of the ratings in the cells below the diagonal. The assignment of one's to the main diagonal is based upon the fact that when we compare any criterion against itself, the judgment must be that they equally preferred. The elements below the diagonal are reciprocals of those above because if, for example, content (CT) is eight times more preferred than case studies (CS), then (CS) must be one-eighth as preferable as (CT).

Table 1. Criteria comparison matrix

Criteria	CT	CS	QP	AM	WS	PR	Average
CT	1	8	5	8	8	9	.496
CS	1/8	1	1/3	4	5	5	.129
QP	1/5	3	1	7	7	7	.225
WS	1/8	1/4	1/7	1	1/3	1/5	.029
AM	1/8	1/5	1/7	3	1	1/3	.046
PR	1/9	1/5	1/7	5	3	1	.076

Table 2. Pair-wise comparison of how the selected textbooks address the content criterion

	TB1	TB2	TB3	TB4	TB5	TB6	
TB1	1	1/3	1/2	1/2	3	3	.124
TB2	3	1	3	3	5	5	.376
TB3	2	1/3	1	3	5	5	.247
TB4	2	1/3	1/3	1	3	3	.148
TB5	1/3	1/5	1/5	1/3	1	1	.052
TB6	1/3	1/5	1/5	1/3	1	1	.052

5.2.1. Calculating the Relative Weights(Priorities) of Criteria

While the AHP is an easy-to-understand methodology, the mathematical calculations required to derive priorities from pair-wise comparisons involve what are known as *eigenvalues* and *eigenvectors* and may turn out to be difficult and time consuming without a computer program. Although the Expert Choice software (http://www.ExpertChoice.com) easily performs these calculations, however these calculations can be carried out using a spreadsheet software, to obtain an approximation of the priorities.

The row averages of .496, .129, .225, .029, .046, and .076 in Table 1 provide an approximation to the priorities of the evaluation and selection criteria. Based on these priorities, content (CT) is the most important (preferred) criterion followed in importance by end of chapter questions and problems (QP), real world case studies(CS), price(PR), ancillary materials (AM), and Web site(WS).

5.2.2. Pair-wise Comparisons of Textbooks with Respect to Each Criterion

Tables 2 show the comparison matrix indicating the pair-wise evaluation on how the selected textbooks address Content (CT) criterion.

Similar tables should be constructed for CS, QP, WS, AM, and PR criteria.

Table 3 provides the relative importance of the textbooks by criterion type. For example, using the textbook comparison matrix for the content criteria (CT), the normalized eigenvector is calculated; it is shown in the CT column. Larger values of the eigenvector indicate a greater importance of textbook with respect to the criterion. Thus, TB2 best addresses the content criterion, followed in decreasing order by TB3, TB4, TB1, TB5, and TB6. This process of calculating the normalized eigenvector is repeated using the textbook comparison matrices for content (CT), case studies (CS), end of chapter questions and problems (QP), ancillary materials (AM), Web site (WS) and price (PR). Results of these calculations are provided under their respective columns. The results indicate that TB2 is the best-fit textbook alternative when considering the content criteria, TB3 is the best textbook when examining the Web site criteria, and TB2 is the best alternative when considering real world case study criteria.

The normalized eigenvector of the criteria comparison matrix is also shown in Table 3. It indicates the relative importance of the criteria based on the evaluation team members' data. The computational results yield the following: content(CT) is the most important, followed in importance by end of chapter questions/ problems(QP), real world case studies(CS), price(PR), ancillary materials(AM), and Web site(WS).

Table 3. Relative importance (normalized Eigenvectors)

	CT	CS	QP	WS	AM	PR
Criteria Relative Priority	.496	.129	.225	.029	.046	.075
TB1	.124	.030	.029	.104	.054	.130
TB2	.376	.446	.466	.278	.202	.150
TB3	.247	.268	.287	.278	.299	.308
TB4	.148	.032	.052	.156	.178	.114
TB5	.052	.078	.083	.156	.178	.237
TB6	.052	.145	.083	.027	.089	.060

Table 4. Composite prioritization

	CT	CS	QP	WS	AM	PR	
TB1	.496*.124 +	.129*.030 +	.225*.029 +	.029*.104 +	.046*.054 +	.075*.130 =	.087
TB2	.496*.376 +	.129*.446 +	.225*.446 +	.029*.278 +	.046*.202 +	.075*.150 =	.378
TB3	.496*.247 +	.129*.268 +	.225*.287 +	.029*.278 +	.046*.299 +	.075*.308 =	.267
TB4	.496*.148 +	.129*.032 +	.225*.052 +	.029*.156 +	.046*.178 +	.075*.114 =	.111
TB5	.496*.052 +	.129*.078 +	.225*.083 +	.029*.156 +	.046*.178 +	.075*.237 =	.085
TB6	.496*.052 +	.129*.145 +	.225*.083 +	.029*.027 +	.046*.089 +	.075*.060 =	.073

Table 4 illustrates the final overall prioritization of the six textbook alternatives. From this, the order of prioritization would be TB2, TB3, TB4, TB1, TB5, and TB6.

6. CONCLUSIONS

The purpose of this paper is to present a structured and systematic methodology, the Analytical Hierarchy Process (AHP), for the evaluation and selection of a MIS textbook. The methodology performs multiple criteria evaluation through a pair-wise weighting process for all criteria. This methodology allows a decision maker to incorporate qualitative as well as quantitative data in the decision process and offers a rigorous model on which a complex decision problem can be dealt with effectively. The evaluator does not have to reach an overall judgment in a single phase. Instead, the evaluator can (1) determine the relative significance (or importance) of the criteria through a relatively simple pair-wise comparison of two criteria, one at a time, then (2) evaluate textbooks under each criterion through a pair-wise comparison of each two textbooks one at a time, and (3) the AHP model will automatically present the solutions in terms of the evaluation of each textbook based on all criteria as well as on each single criterion.

In this paper six MIS textbooks were evaluated based on content, real world case studies, end of chapter questions and problems, ancillary materials, Web site, and price as the decision criteria. While the application described in this paper was carried out using a spreadsheet, an interactive commercial computer program (Expert Choice) is available that computes the priority vectors. Major conclusions from similar applications of the AHP were that it was found to be valid, flexible, and easy to apply and did not overlook any significant factor.

ABSTRACT

In this paper we address issues related to delegation of responsibilities and their importance in increasing the flexibility and the effectiveness of business processes. Organizations usually establish a set of business rules regulating the way business processes are managed. For example, they specify which user should perform a given work in a given situation. In a changing and highly dynamic environment, rules can not be planned in advance in a fine-grained level. What's more, in actual circumstances users may delegate work assigned to them; indeed, it is not always possible to account for every responsibility required in a moving environment. These delegation activities should be controlled. In addition, unforeseen circumstances like absence could take place. That is, we introduce a delegation model in order to allow the predefined rules to be less exhaustive and the decision-taking mechanism to be decentralized, to control the delegation activities between actors and to take into account unforeseen circumstances.

1. INTRODUCTION

In current distributed and dynamic environments, the goal of companies is to well and quickly meet with customers' requirements. In some cases, developing complete rules specifying exhaustively how actors will proceed is inaccurate, because this limits their autonomy and efficiency when changes make some predefined conditions inapplicable.

Instead of developing fully business policies, we propose to provide the ability of delegation provided that it is controlled by an effective model. There are many requirements that may drive to provide delegation capabilities:

- Making easier process management by decentralizing the control and the decision-making and allowing actors to be more autonomous and confident.
- Collaborative work in human organizations requires the use of delegation as natural and useful way to cooperate. Actors could wish to cooperate in a project.
- Responsibilities may conflict, and specific policies may require that an actor delegate some of his duties in order to separate conflicting duties.
- An actor may lack resources (e.g. time, equipment) essential for achieving his responsibilities.
- Unforeseen circumstances, such as unplanned absences (illness, leaves), may require to change actors.
- Substitution: in some situations like business mission, the employee needs to delegate the achievement of the responsibility he ensures to another employee.

To deal with these requirements, we introduce a multi-level delegation in order to make business rules less complex and flexible, processes more efficient, and management and control more flexible.

In this paper, we address issues related to delegation of pieces of responsibilities and their importance in increasing flexibility of business processes. Selecting some parts of responsibilities gives the delegator great flexibility in choosing which work he/she wants to delegate.

By granting autonomy to actors and allowing them to delegate and to decide which parts of responsibilities they want to delegate, the development of the business rules by the manager is greatly simplified. In fact, the decision-making and the process control will be distributed between him/her and the other actors of the organization. Thus, the process manager has to define significant rules on a coarse-grained level without seeing details whereas actors that are allowed to delegate define exhaustively how tasks should be achieved and by whom. Therefore, this approach satisfies the process manager requirements as well as ones of the participating actors. The process manager will have less complex rules to handle (this fact is time-saving) and actors will be more autonomous and confident.

The paper is organized as follows: in section 2 we discuss related work and present our contributions. In section 3, we introduce a delegation model for flexible business process modeling, we provide a meta-model and we illustrate our model with a case study. Section 4 concludes the paper.

2. BACKGROUND AND MOTIVATION

The literature provides a considerable work dealing with various aspects of delegation. Delegation can take many forms. Gasser and McDermott [5] address user-to-machine delegation; they define it as "the process whereby a user in a distributed environment authorizes a system to access remote resources on his behalf". Henry and Gladny [7] deal with machine to machine delegation; they consider requirements for a digital library that emulates massive collections of physical media for clerical, engineering, and cultural applications. Nagaratnam and Lea [9] discuss process-to-process delegation in the distributed object environment. Sandhu et al. [11] address delegation among the role administrators. Delegation addressed in [2], [6], [7], [8], [9] and [11] is related to rights in a security context. Schaad and Moffett [1] address delegation of obligation and authorizations. Becker et al. [3] deal with delegation in distributed software process management allowing a client in interorganizational development processes to delegate parts of net-based process models to contractors.

Delegation addressed in most common work is unconstrained and without any conditions, that is not convenient and may cause frustration. In addition, delegation is often defined as a substitution mechanism of all or a subset of actor's roles to one or more other actors such as in [2], or the ability of a user to delegate to another user some permissions related to a role [2] or single tasks [4].

Nevertheless, in some cases an actor needs to delegate only some functions held by his/her role. Furthermore, in some cases, role-based delegation is required. For instance, if the "loan manager" is absent, loan manager's responsibilities can be delegated to other employees based on their capabilities (roles) rather than their identities (individual actors). For instance, "Offer_preparing" can be delegated to the role "loan manager's assistant".
