UML modeling has attracted significant research attention (Agarwal, 2003; Burton Jones and Meso, 2006; Evermann and Wand, 2005; Fedorowicz and Villeneuve, 1999; Siau and Cao, 2001; Siau and Loo, 2006). While much has been said about expected benefits of Use Case modeling (Jacobson et. al., 1999; Kobryn, 1999), little empirical research has been directed at these claims. Dobing and Parsons (2006), for example, found little empirical research on the effectiveness of Use Case modeling.

The UML approach is genrally accepted, however, it has critics. Douglass (1998) argued UML is large and overly complex. Halpin and Bloesch (1999) suggested UML models are designed for software engineering and are less suitable for validation of conceptual models. Dori (2003) has suggested that UML has difficulty in integrating structural and process elements of system designs. Dobing and Parsons (2006) suggested Use Case modeling faces two significant challenges. One challenge is that Use Cases tend to isolate stakeholders from object class models. This results in a lack of information on classifications and categories within the system. They argue that information in the Class Diagram is valuable in developing understanding and is not provided by Use Cases. A second challenge is the lack of formalism, which allows Use Cases to mix conceptual, design and implementation details in the same description. This mixture of design and conceptual elements may cause confusion for stakeholders and reduce the effectiveness of the stakeholder/analyst communication.

Separating Conceptual Modeling from Requirements Engineering

To understand how uses cases can be used, it is important to outline the system development process. The information system development process can be viewed as a series of increasingly formal representations ending in machine executable code (Wand and Weber, 1993).

Three generic roles in this development process include stakeholders, analysts and developers. The least formal representations of the system are the concepts held by stakeholders. In a standard development process, analysts interact with stakeholders to develop more formal representations of the system, often called conceptual models (Wand and Weber, 2002). These conceptual models are shown to stakeholders to validate analysts' perceptions of the system.

Conceptual models are a foundation for the development of formal functional requirements. Analysts develop functional requirements primarily to communicate system details with developers. In an ideal world, developers could use the formalized functional requirements to develop the eventual machine code for the systems (the system artefact).
Throughout the development process, the system representation grows increasingly formal and precise. The role of the analyst is to communicate system details in such a way as to develop a common understanding of the system between developers and stakeholders.

Analysts are involved in two distinct processes. The first involves interacting with stakeholders to develop an understanding of the system. This process is defined as conceptual modeling (CM) (Everman, 2005; Wand and Weber, 2002). It involves eliciting requirements, representing them, and having stakeholders interpret and validate these requirements. The second process formalizes this conceptual understanding into a set of functional requirements. This second process is defined as requirements engineering (RE). CM and RE are related processes that facilitate the common objective to reason and communicate about a domain. Because they are related, the same techniques are often touted for use in both

CM and RE, though the audience for the processes may be different. Use cases have often been suggested as useful tools for interacting with stakeholders, but use cases can also inform developers about process issues.

3. THEORETICAL FOUNDATIONS

Conceptual modeling involves the capture of domain information to develop understanding and support communication. Developing understanding of a system and its components is, therefore, a process of learning (Gemino and Wand, 2003). This is true for the person developing the model as well as the person viewing it. The design of conceptual modeling techniques may be informed, therefore, by theories of how humans develop understanding from the graphics and words they are presented with. Mayer (2001) suggests two contrasting views of learning –information acquisition and knowledge construction. These views are discussed briefly below.

Information Acquisition

Learning as information acquisition implies that learning is a process of adding to long-term memory. The model viewer receives information and stores it in memory. The responsibility for learning rests on the model creator to deliver appropriate information. The goal is to deliver required information efficiently. In this view, the conceptual model is a standard vehicle for efficient information delivery to the model viewer.

Knowledge Construction

An alternative view is knowledge construction. This view suggests knowledge is personally constructed. Two model viewers presented with the same conceptual model may come away with different learned outcomes. This occurs because the model viewers attempt to make sense of the information presented and integrate this information into a coherent mental representation. Knowledge construction suggests the model viewer is an active sense maker rather than a passive receiver of information.

A Model of Conceptual Modeling as Knowledge Construction

As a framework for reasoning about conceptual modeling, we use the model of knowledge construction (Gemino and Wand, 2003; 2005). In this model, the model viewer is constructing knowledge by actively organizing and integrating information with previous experiences. Three antecedents of the process are suggested: (1) content, (2) presentation method, and (3) model viewer characteristics. The content represents the domain information to be communicated. The presentation method is the way in which content is presented to the viewer. Viewer characteristics are attributes prior to viewing the content. These characteristics include knowledge and experience with the domain and with the modeling methods used to present information.

The construction process is where the sense making activity is hypothesized to occur. The results of knowledge construction are encoded into the long-term memory. The learning outcome modifies the model viewer's characteristics. Learning outcomes can then be observed, only indirectly, through learning performance tasks.

Cognitive Theory of Multimedia Learning

Messages that combine graphics and words are defined by Mayer (2001) as "multimedia messages". The Cognitive Theory of Multimedia Learning (CTML) provides a theoretical perspective on the level of understanding developed by a person viewing explanative material, such as an analysis diagram in requirements validation. The theory is based on work by Baddeley (1992) and Paivio (1986) and has been developed through a decade of empirical work (Mayer, 1989; Mayer, 2001).

The theory is focused on the interaction between a person and the information presented to him or her. The CTML suggests there are two pathways in cognition, verbal and visual. While independent, these channels communicate in working memory. When a person views presented material, relevant information from the verbal and visual channels is selected. This information is organized to create separate visual and verbal models. These two models then interact and are subsequently integrated with prior knowledge in long-term memory to develop new knowledge. An overview is provided in Figure 1.

In the CTML, an understanding of verbal and visual information is developed through three stages of memory. In the first stage, *sensory memory*, information is selected into one of the two dual coding pathways. The selected information is then developed into visual and verbal models in *working memory*. In the final stage, the verbal and visual models from working memory are integrated with *long-term memory* to create understanding. This describes the process of knowledge construction.

Learning Outcomes and Performance

The CTML has enabled Mayer to develop principles relating to the effective design of multimedia messages. He suggests the most effective communication occurs when verbal and visual pathways are utilized simultaneously. Mayer suggests three outcomes when presenting explanative material to people: 1) no learning, 2) rote learning and 3) meaningful learning. These outcomes are based on measures of two variables: retention and problem solving. Retention is the comprehension of material being presented. Problem solving is the ability to use knowledge gained to answer related problems not directly answerable from presented material. For example, if presented with an explanation of how a car's brake system works, a retention question might be "*List the components of a braking system*," but a problem solving question would be "*What could be done to make brakes more reliable?*" These problem solving task have been used by Bodart et. al (2001); Burton-Jones and Meso (2006) and Gemino (1999; 2004).

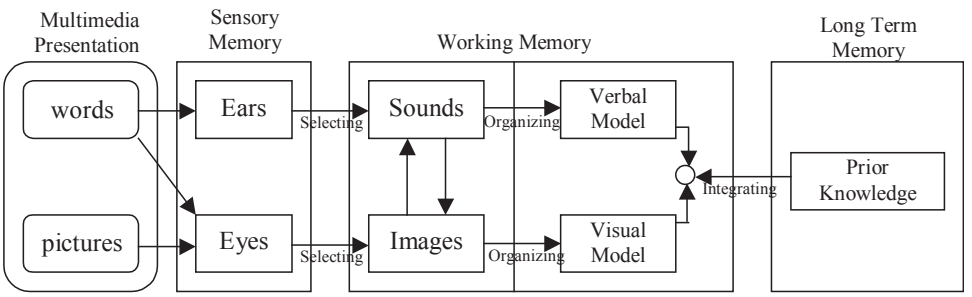
No learning occurs were retention and problem solving are low. Rote learning occurs where retention is high; however, problem solving measures are low. This indicates that although the material has been received, material has not been well integrated with prior knowledge. Meaningful learning occurs where retention and problem solving are high.

4. EXPERIMENTAL DESIGN AND HYPOTHESIS

Overview of Experimental Design

Three dependent variables (comprehension, retention and problem solving) will be measured. Other variables measured include prior knowledge of the domain,

Figure 1. The cognitive theory of multimedia learning (adapted from Mayer, 2001, p. 59)



knowledge of the modeling method, and participant demographics. Two treatment groups were compared using a single case. The first treatment was provided with a set of use cases describing a system. The second treatment was provided the same set of use cases along with a one-page use case diagram. The single page diagram shows the interaction between use cases and actors in the system as well as any interaction between use cases in the system. The following statement provides the underlying logic for conducting this experiment: If a participant is presented with a) a set of use cases and b) a set of use cases and a diagram relating these use cases, then the participant will gather a significantly higher level of understanding of the domain being presented with b) than with a).

Hypothesis

Mayer's (2001) multimedia principle suggests a potential for higher levels of understanding from use cases associated with diagram than use cases alone. The multimedia principle therefore enables us to suggest the following hypothesis:

H1: *According to the multimedia principle from the CTML, participants viewing a set of use cases with an associated use case diagram will develop a higher level of understanding of the domain than participants viewing use cases alone.*

5. METHOD

An empirical procedure was developed to test the hypothesis above. The procedure was based on Mayer (1989, 2001), and used for system analysis by Bodart et. al (2001), Burton-Jones and Meso (2006), Gemino (1999, 2004), Gemino and Wand (2005).

Participants

Forty-nine upper level business students took part in the study. All students had taken a system analysis course and had basic familiarity with use case models. Females accounted for 20 of the 49 participants (41%) of participants. Participation was voluntary. An incentive of $15 was provided for the top four performers. The average time to complete the study was 45 minutes. All participants were at an introductory level in business process design, and had no particular experience with object oriented analysis. A pre-test was given to measure experience with system analysis and the business domain used in the analysis as well as other demographic variables.

Materials

One case including five use cases and one use case diagram was used in the experiment[1]. The use cases and use case diagram were created using an approach described in Dennis and Wixom (2000). The text description was provided by the Voyager Bus company case in Bodart et. al. (2001).

Procedure

Participants were randomly assigned into two treatment groups. An envelope was given to each participant containing a pre-test, five use cases (plus diagrams if necessary), experimental tasks (comprehension, retention and problem solving) and a posttest. Participants worked independently and first completed the pre-test followed by the three experimental tasks and finally the post-test.

The first task was a twelve question multiple choice comprehension task (True, False, Uncertain). After the comprehension task, participants were instructed to put away the use cases and diagram (if provided). Participants were than given 6 minutes to complete a retention task, which asked participants to write down everything they knew about the processes in the use cases. This task was followed by four problem solving questions used by Bodart et. al. (2001). Participants were given 2 minutes to write as many answers as possible to each problem solving question.

Measures

Learning performance was measured using three variables: comprehension, retention and problem solving. Comprehension was the number of correct answers out of a possible of 12 questions. Retention and problem solving scores were coded by two individuals. The retention score was created by giving one mark for each complete and correct idea statement expressed by the participant. There was a maximum of 20 idea statements identified in the use cases. The problem solving score was created by giving participants one point for each acceptable response to the problem solving questions. The Pearson correlation between coders for retention was 0.88 and for problem solving questions 0.90. Differences between independent ratings were then discussed, and a final score for retention and problem solving was established.

6. RESULTS

Preliminary Tests

Since the sample size was relatively small, it is important to establish the homogeneity of variances before ANOVA analysis. Levene statistics for each of the dependent measures indicate that the hypothesis of equal variances is not rejected across any of the variables at the 0.05 level.

Domain and modeling experience were collected in the pre-test and used as covariates in an ANCOVA analyses. Both domain and modeling method experience were found to have insignificant influences on the dependent variables. This result may be due to the uniformly low levels of experience held by participants. While it seems likely prior domain experience and modeling method experience are related to the dependent measures, the factors, as measured in this study, had no significant effect in this study and were excluded in further analysis.

Results

The means and standard deviations of the dependent measures (comprehension, retention and problem solving) across the two treatment groups are provided in

Table 1. Means and Std. Dev. across treatments for dependent measures

Dependent Measure	Case: Voyager Bus			
	Treatment Groups			
	Without Diagram n=25 Means (SD)	With Diagram n=24 Means (SD)	Difference between means (With-Without)	Sig.
Comprehension	7.627 (.321)	8.139 (.328)	.0512	0.271
Retention	7.877 (.541)	9.670 (.552)	1.793	0.025*
Problem solving	12.174 (.824)	14.568 (.841)	2.394	0.045*

** significant at the 0.05 level*

Table 1 below. The results show little difference across treatment groups for comprehension measures. Note that participants had full access to use cases during the comprehension test. Since the information was available in either treatment, the diagram had little effect in basic comprehension.

Retention and problem solving measures showed differences in the anticipated direction. The size of the effects was approximately 20%. This is measured by dividing the difference between the "with" and "without" diagram scores and then dividing the result by the score for the without diagram group.

An ANOVA was applied to test the significance of these differences. Results, provided in the final column of Table 1, suggests significant differences for both problem solving and retention measures at $\alpha = 0.05$ level. This result provides evidence to support hypothesis H_1. These results suggest that although the content across treatments was the same, the organization provided by the use case diagram enabled participants with access to the diagram to build a more sophisticated mental model. Note that although the sample size is relatively small, the effect size is relatively large.

These results suggest that diagrams, even simple diagrams such as the use case diagram provided in this experiment, have measurable effects on viewer understanding.

7. CONCLUSIONS

Mayer's Cognitive Theory of Multimedia Learning has been used to demonstrate that humans process both text and pictorial images together to develop a deeper understanding than either media alone. Text descriptions often accompany drawings, but little formal research has been done to clarify the potential effect of exhibits. This paper describes an experiment which evaluates the level of domain understanding for subjects when drawings are used to support use cases compared to the use cases alone. The results support the hypothesis that a use case diagram has a significant positive effect of the level of understanding developed by a person viewing use cases.

Future research can be directed more closely on what diagram elements are most effective in supporting use cases. In addition, more empirical evidence is required to understand the effectiveness of use case modeling. While the text based approach has some excellent features and has appealed to practitioners, it is clear that diagrams are an important component for communication. More needs to be understood about this relationship if we are to make use case modeling an even more effective communication tool for stakeholders and developers.

ACKNOWLEDGMENT

The authors wish to thank Liliana Petrescu for her work in collecting and coding experimental data. This research was supported by the National Science and Engineering Research Council of Canada.

ABSTRACT

Modern enterprise information systems are distributed systems usually built on multi-tiered client server architectures and can be defined using well-established frameworks such as the Zachman framework or the Open Distributed Processing Reference Model (RM-ODP). Both frameworks identify views regarding the system designer's viewpoint, but they do not suggest a methodology for view creation. A consistent framework for enterprise information system engineering, compatible with both the Zachman framework and RM-ODP is proposed by the authors. It consists of a metamodel describing alternative system views, a corresponding methodology comprising discrete stages performed either by the system designer or software tools and a UML 2.0 profile for view representation. In this paper, a case study where the proposed framework was applied is discussed, focusing on the features provided to the system designer using the UML 2.0 profile. The profile is implemented by extending the Rational Software Modeler functionality.

1. INTRODUCTION

When building an enterprise information system (EIS), the desired properties of the system should be defined, such as its structure and behavior, while the role of the system in the environment should also be considered. Many different stakeholders may be involved in this process, as defined in the Zachman framework (Zachman, 1999). Each of these stakeholders focuses on certain concerns and considers these concerns at a certain level of detail. A *viewpoint* defines the way the system is conceived by a stakeholder according to his concerns (Boer, 2004). The conception of the system according to a certain viewpoint is described as a system *view*, thus one or more views correspond to a certain viewpoint. Each view may be formally defined by a *model*, while it is communicated to the stakeholder by a *representation model*, which is a concrete representation of the system view on some medium (e.g. paper or computer program). A consistent representation of the systems implies that each view is not examined in isolation but interrelations between views are formally defined. We argue that the way system views are related must be fully and typically defined in the corresponding models. In order to formally define a viewpoint, one should define a metamodel describing the supported views independently of the modeling language used for system representation and then define the representation model. In this way, a view may be represented using different languages (e.g. UML), in a common manner, facilitating the transformation between representation modeling languages.

Having adopted this viewpoint-oriented description of information systems, we defined for the system enginnering viewpoint three complementary views, namely *Functional, Logical* and *Physical.* Some of them may be further decomposed into subviews emphasizing specific entities into a greater level of detail. These views are part of a framework introduced in (Nikolaidou et al., 2006) which offers a consistent framework for information system engineering. More specifically our framework comprises:

- A metamodel describing different views and the relations between them (EIS metamodel). These relations are strictly defined using constraints.
- A methodology for EIS engineering based on the proposed views. The methodology consists of discrete stages performed by system designer, software tools or a combination of both. Taking advantage of the formal definition of relations identified between views, system engineering stages may be invoked automatically, as a result of the metamodel constraint validation.
- A UML representation for all defined views. A UML 2.0 profile is defined for this purpose (EIS engineering profile).

The overall framework is briefly presented in section 2, emphasizing the supported views and the corresponding UML 2.0 profile. In section 3, a case study where the proposed framework was applied is discussed, focusing on the features provided to the system designer using the UML 2.0 profile. A Rational Software Modeler plug-in has been implemented to support the additional functionality of the profile.

2. EIS ENGINEERING FRAMEWORK

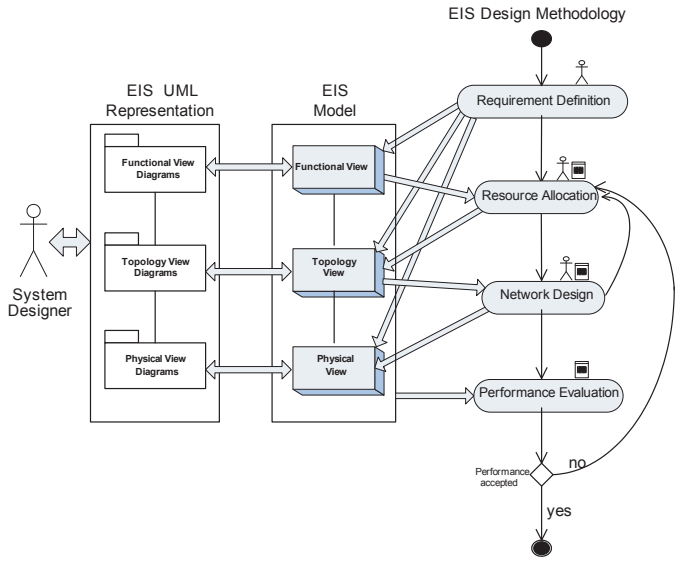
The framework is based on three complementary views:

Functional View is used to describe functional specifications such as system architecture, user behavior and application requirements. System architecture refers to the architectural model adopted. In case of our framework, multi-tiered client-server models are described. Services provided by each application tier (called module) are also defined. User behavior is modeled through user profiles describing the behavior of different user groups and their performance requirements. Application requirements are described in terms of quality of service (QoS) requirements imposed to the network infrastructure, e.g. amount of data processed, transferred or stored. Each service is described in a greater level of detail through the *service description* subview.

Topology View facilitates the definition of system access points and the resource allocation and replication. To characterize any location (i.e. a building, an office, etc.), the term *site* is used. As such, a site is a composite entity which can be further analyzed into subsites, forming thus a hierarchical structure. Functional and Topology views are interrelated. Resources (e.g. processes and files) correspond to services and data described through Functional view and are located into sites.

Physical View refers to the aggregate network. Network *nodes* are either *workstations* allocated to users or *server* stations running server processes. Topology and Physical views are interrelated. Both are decomposed to the same hierarchical levels of detail. At the lowest level, network nodes are related to processes/data replicas.

Figure 1. EIS engineering framework



2.1 EIS Engineering Methodology and Metamodel

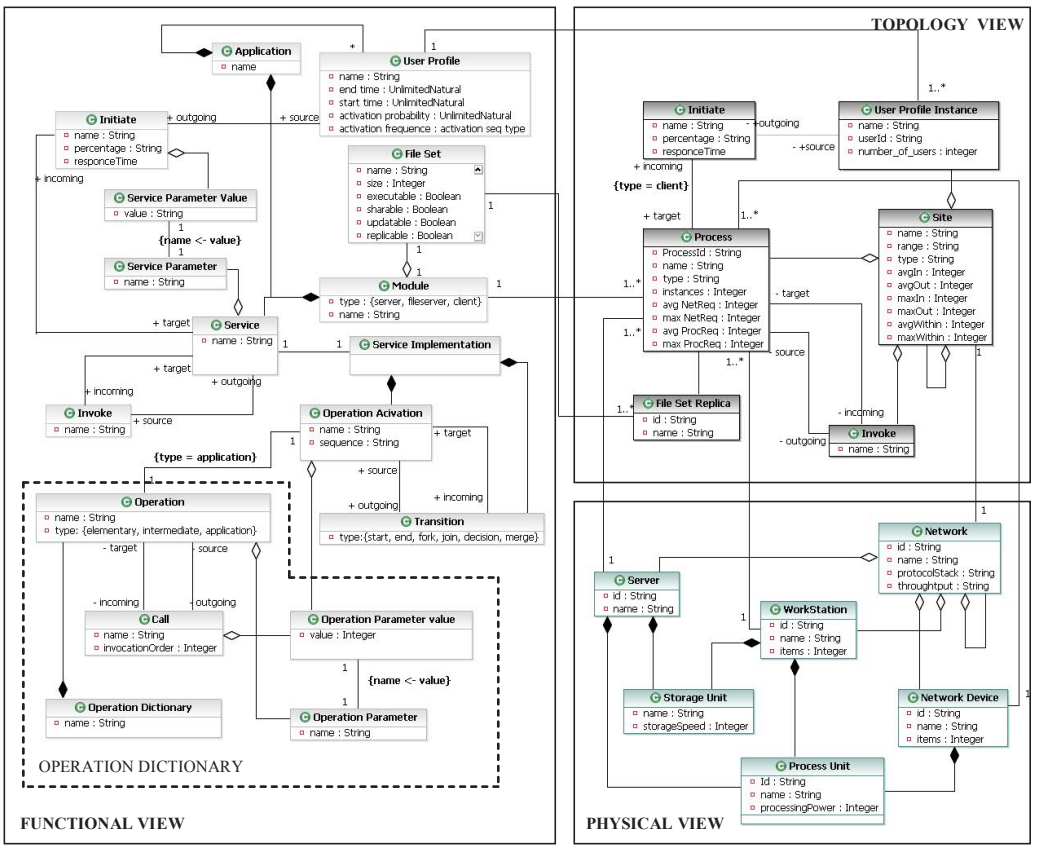
The proposed methodology includes the following discrete stages of the system engineering process:

1. System requirements definition.
2. Resource (process/data) allocation and replication policy definition.
3. Network architecture design.
4. Performance evaluation of the proposed solution (prior to implementation). Although it is not a necessity, it is certainly useful.

As resource allocation and network design problems cannot be independently solved, stages (2) and (3) are repeatedly invoked for different abstraction levels until an acceptable solution is reached. Both resource allocation and network architecture problems are usually supported by automated or semi-automated tools using mathematics, heuristics or a combination of both. These tools may be repeatedly invoked for different abstraction levels (Graupner et. al, 2001) and (Nezlek et. al, 1999). The system designer may perform or partially perform these tasks on his own, thus both options must be supported. To evaluate system performance, a simulation tool as the one described in (Nikolaidou et al., 2003) can be used. The simulator uses as input the overall system model and produces performance results. Since each of these tools supports its own representation metamodel (for example queuing networks, Petri-nets, objects), there is a need to properly create and instantiate the "internal" system model prior to invoking the tool.

The proposed methodology stages along with the EIS model consisting of the predefined views are presented in figure 1. Discrete stages receive/modify information from/to specific system views, as depicted by the arrows between them. The relation between views and between stages is also depicted in the figure. Requirements definition is the initial stage and corresponds to the definition of system architecture and application requirements (Functional View), the system access points (Topology View) and, if any, the existing network architecture (Physical View). Each view is represented by one or more UML diagrams properly extended. All the required extensions are grouped into a UML 2.0 profile which also describes the relations between views.

Figure 2. EIS engineering metamodel



As already mentioned the models created follow a formal metamodel which itself contains relationships and restrictions inflicted between system entities belonging to the same or different views, which may lead to a specific stage invocation (e.g. if the network hierarchy in Physical View is modified, this modification must be depicted in Topology View as well). Embedding restrictions within the metamodel facilitates the management of the EIS engineering, as the overall system model is taken into account and not a specific system view corresponding to a discrete stage. Thus, the overall process becomes more effective, since discrete stage (and corresponding tool) dependencies are depicted within the model as view dependencies and consequently they are easily identified. Furthermore, it becomes more efficient to integrate autonomous software tools at different levels of detail, as each of them is independently invoked without knowing the existence of others.

All the entities of the metamodel along with their interdependencies are presented in figure 2. As shown in figure 2, despite the fact that views concentrate on different aspects and thus include different model elements, there are however correspondences between them indicated in the diagram by the lines that cross view boundaries.

2.2 EIS Engineering UML 2.0 Profile

The defined UML 2.0 (OMG 2004a; OMG 2004b) profile comprises a number of stereotypes. Essentially, the concepts of the metamodel are reflected onto the stereotype attributes and constraints. Attributes convey the information required to describe the EIS metamodel entities (e.g. *throughput, activationFrequency, processingPower* etc.). Constraints, which are extensively used within the profile, represent relationships and restrictions between metamodel entities maintaining model consistency. Constraints mainly facilitate:

1. automatic computation of specific attribute values.
2. limiting attribute value range.
3. relating attribute values of specific elements to attribute values of other entities belonging to the same or other UML diagrams (implementing thus the linkage between different models).
4. model validation in view and overall model level.

Attributes and constraints for each stereotype are analytically introduced in (Alexopoulou et al, 2006). Following, the UML diagrams selected for each view are briefly presented. Stereotypes are listed in Figure 2 along with the EIS metamodel entity they correspond to. The relative icons are also included, so that the reader can understand the figures presented in the case study of section 4. Functional view is represented through UML component diagram, since component diagrams are eligible for depicting system functionality at a logical level. Concerning service description subview, it is represented through activity diagram, as it involves flow of operations. UML communication diagrams, which depict interaction between entities, are suitable for the representation of Operation Dictionary, since the latter involves interactions between operations showing in particular invocation order and parameter passing between them. Physical View, which comprises the network infrastructure, is illustrated through UML deployment diagrams, which are commonly used to represent network architectures (Kaehkipuro, 2001). Lastly, the representation of Topology View is based on UML component diagrams.

3. CASE STUDY

The proposed framework has been applied for the engineering of a typical banking system. In this case, resource allocation and network design stages were performed by IDIS software tool (Nikolaidou, 1999), that supports the representation and exploration of resource allocation and network topology design through algorithms combining mathematics and rules of thumb. To evaluate distributed system performance, the discrete event simulation tool described in (Nikolaidou, 2003) was used. Requirements definition was performed by the system designer using the EIS engineering UML 2.0 profile, implemented in Rational Modeler (IBM Co, 2005).

An appropriate UML modeling tool for EIS engineering UML 2.0 profile implementation must fulfill the following requirements: a) it must be UML 2.0 compatible, b) it must facilitate mechanisms to extend the provided functionality (e.g. by importing profiles) and c) it must export models in XML based on existing UML classes and profile-specific stereotypes. After serious considerations regarding various UML 2.0 tools, we decided to implement the profile in the Rational

Figure 3. Stereotypes of the EIS engineering profile

Software Modeler environment (IBM Co, 2005). The extensibility features of the Rational Software Modeler are based on the open-source Eclipse platform. Eclipse provides useful APIs, frameworks (e.g. Workbench, Workspace, Help, etc.) and plug-ins that facilitate the development of new tools. EIS models are stored in an XML format in accordance with XMI (OMG 2005) to ensure interoperability. Before using a specific tool, the partial transformation of EIS model into the tool-specific internal model is realized. Using this transformation, the invocation and initialization of any tool can be automatically performed. The case study focuses on requirements definition and aims at demonstrating the use and implementation of EIS engineering profile through Rational Modeler. However, hits on the overall framework functionality are provided.

The Bank supports 38 discrete teller transactions. The amount of transactions/day varies according to branch size, while the average amount of teller transactions in large branches is over 10.000 per day. The required response time is 15-18 sec for most transactions. The system architecture relies on server-based computing. A central database is installed in headquarters, while transaction logs are maintained in local databases of each branch. Transactions are coordinated by a transaction monitoring system – TMS (Tuxido), also installed in headquarters. Transactions are composed by 24 discrete atomic transactions initiated by TMS. Each transaction consists of 3 to 7 atomic ones. All atomic transactions are implemented by stored procedures running in the central database. To enhance security and ensure a single authentication point, all user programs run on a dedicated execution server (CITRIX), while in user terminals only the corresponding client (CITRIX client) is installed.

FUNCTIONAL VIEW

Functional view facilitates the system designer to a) define the EIS architecture (client and server modules) and b) define the functionality provided by its modules and the requirements imposed by them and the interaction between them to the network infrastructure.

EIS modules identified were the following: *File Server*, *CentralDB, LocalDB*, *TMS* and *Citrix*. Since *LocalDB* represents logging, only a simple *insert* service was implemented for recording the log. *CentralDB* supports 33 stored procedures, represented as a different service. *TMS* Module includes 24 services corresponding to discrete atomic transactions. *Citrix* Module includes 38 services corresponding to discrete teller transactions. They involve the invocation and processing of forms, the activation of atomic transactions through *TMS* and log recording. Tellers are modeled as User Profiles initiating *CITRIX Client* modules corresponding to each teller transaction. In the following, we focus on teller transaction to demonstrate real-world system representation capabilities of the proposed framework.

Figure 4. Fraction of functional view: Transactions trx31600 and trx2000

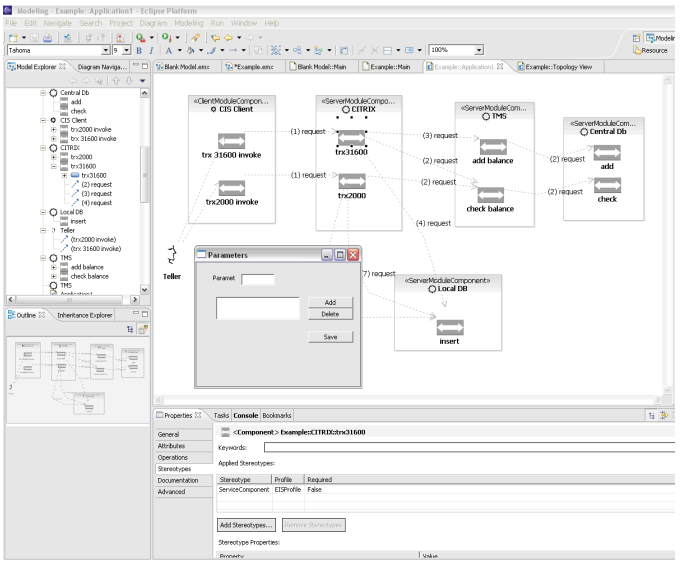

Figure 4 represents a fraction of Functional view, implemented as a Component diagram in Rational Modeler, emphasizing services needed for the representation of transactions trx31600 (i.e. cash deposit) and trx2000 (i.e. request business loan). As depicted in the figure, services are represented as component stereotypes and modules as package stereotypes. The *trx31600* service of the *Citrix* Service Module is selected in the figure. Additional stereotype attributes are stored in the corresponding fields supported within Rational Modeler platform (bottom right part of figure 4). Input parameters of each service are added by system designer through a custom menu created using Rational Modeler Eclipse API. In this case (*trx31600*), only the *module* attribute is filled, since the service has no input parameters (*inputParameterList* attribute is empty). On the left part of Rational Modeler's screen in figure 4, it is shown that *trx31600* service component is further decomposed into other entities.

Trx31600 service is described by the corresponding activity diagram, implemented as a subdiagram of the Functional view component diagram. It is represented in figure 5. As shown in the figure, trx31600 includes the activation of the appropriate forms (operation action 1), the activation of the central database through the TMS (operation action 2 and 3) and local database update (operation action 4). Each discrete step is represented by an action instantiating a predefined operation included in the Operation Dictionary. Operations represent requirements imposed to system resources (network, processing nodes, etc). When defining an action, all input parameter values of the corresponding operation must be filled. They must be either constant or already defined as trx31600 service input parameters. As shown in figure 5, all operation input parameters must be constant, since trx31600 service has no *inputParameterList*. The corresponding validation constraint is implemented as a custom script initiated by Rational Modeler's *Run Validate* default menu appearing when right-clicking on any UML diagram entity. Some of the actions, as *request* (selected in figure 5), result in the invocation of other services.

A constraint automatically adds the corresponding invoke entity between the relative service components of Functional View (figure 4). The invoke entity has the same name as the action.

OPERATION DICTIONARY

Figure 6 represents a fragment of the operation dictionary. All operations are decomposed into elementary ones (processing, storing, transferring), representing processing, storing and network requirements. The system designer may add new operations in the dictionary, to enhance operation expression.

In figure 6, the addition of *form_access* operation is presented. Three steps should be accomplished: parameter definition, definition of dependencies to existing operations and validation performance. A related constraint checks if all the parameters defined for an operation are passed as values to called operations used for its execution. Parameter and dependency definition is performed through pop-up forms. *Form_access* operation parameters are *FileServer, form_name* and *processing. Form_access* operation "uses" two other operations in order to be executed: *processing* and *write*. First, calls *processing* (which is elementary operation) and

Figure 5. Trx31600 activity diagram

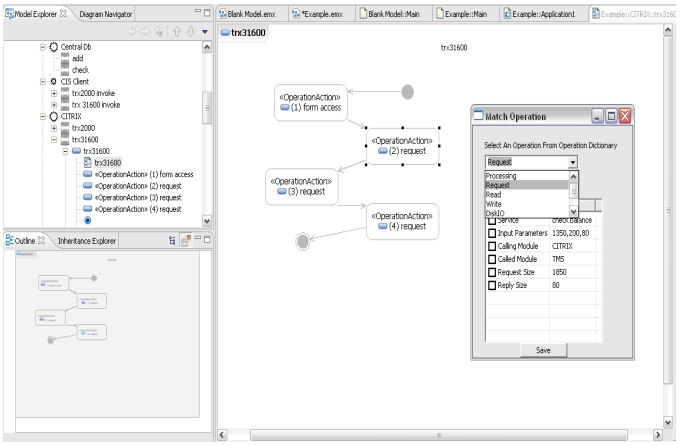

Figure 6. Operation dictionary fragment

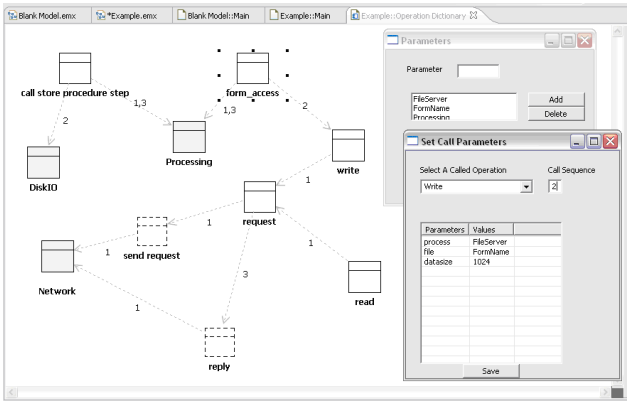

then *write* and then again *processing*. Parameter values of the called operation must be defined. The pop-up window entitled *Set Call Parameters* depicts *write* operation parameter definition.

TOPOLOGY AND PHYSICAL VIEWS

The Topology View facilitates process and user profile allocation to sites. Allocation is performed by the designer through Rational Modeler interface. Alternative, the designer may invoke *IDIS* to perform the allocation of processes or data. Three different types of branches are supported: large, medium and small. Large branches have more than 30 tellers stationed at two different floors. The upper floor is dedicated to business transactions (10 tellers), while all others are served in the main hall. The corresponding fraction of Topology View is depicted in figure 7. Each hall is represented as a subsite of a branch site (both represented as *Site Packages*). Headquarters is also presented as a site.

Figure 7. Fraction of topology view

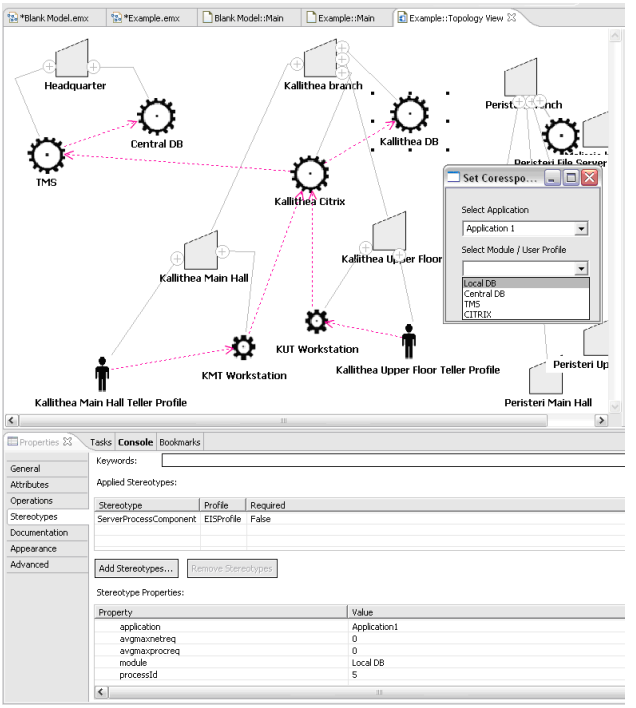

Figure 8. Fraction of physical view

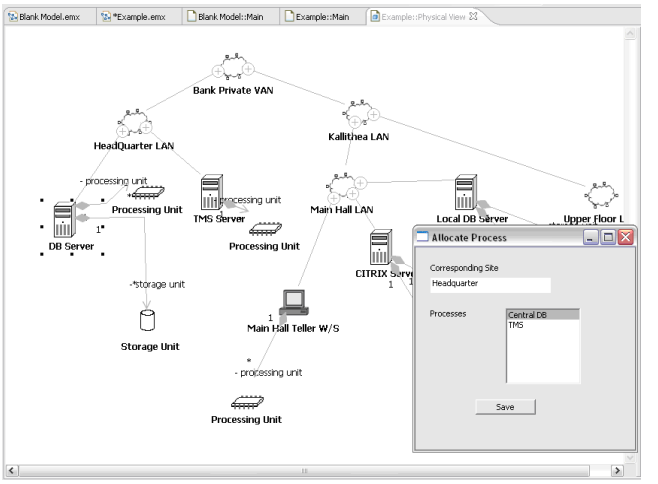

Tellers, modeled as *users*, are placed in *Main Hall* and *Upper Floor* sites, along with corresponding *Citrix client* processes. Since the system relies on server-based computing, most server processes are placed only in headquarters, while no replication is employed simplifying the overall architecture. Furthermore, since there was a request to maintain log data in local branch databases, a local database server replica is placed in each branch. The only issue to be explored was the placement of *CITRIX Server*. Although the system designer placed a *CITRIX Server* process in each branch, the logical configuration tool removed the processes from medium and small branches and placed one in Headquarters to minimize communication cost. This is codified in the EIS model stored in XML. When this model is loaded again in the UML tool, Topology View appears automatically updated.

Processes and users appearing in Topology View must correspond to EIS modules and user profiles represented in Functional View. As shown in figure 7, when defining process replicas, a shortcut menu containing two drop-down lists appears. The first one corresponds to the application (described by a discrete Functional View) and the other one to the module (defined within the Functional View). Furthermore, the corresponding relationships between processes and modules must be defined in both diagrams. The properties of server process stereotype are shown at the bottom part of Rational Modeler Screen. In figure 7, the property values of *Kallithea DB* server component are shown. A related constraint is activated by the *Run Validation* menu option.

Physical View is rather trivial. It facilitates network design and is performed by the designer through Rational Modeler interface. Alternative, the designer may invoke *IDIS* to perform this task. A fraction of it is presented in figure 8. The overall network is TCP/IP based. Branches are connected to headquarters using leased lines, forming a private WAN. The connection speed is indicated as the name of membership relation between node devices and site packages. As indicated in the figure, branches are internally supported by switched 100BaseT Ethernet. The structure of Physical View in the banking system (network architecture) was predefined. As shown in the figure, the system designer may define the processes running on a node through a pop-up window. The candidate processes for a server node must belong to the corresponding site and be server processes. Network hierarchy must correspond to site hierarchy and vice versa. Thus, when validating the model presenting in figure 8, an additional site (corresponding to the Bank Private WAN) should be automatically added in Topology View of figure 7.

4. CONCLUSIONS

A consistent framework for EIS engineering was introduced. It consists of a metamodel describing alternative system views and the relations between them, a corresponding methodology comprising discrete stages performed by the system designer or software tools and a UML 2.0 profile for view representation. The main advantage of the proposed framework is the formal definition of views and their consistent UML 2.0 representation. This is accomplished using constraints

in both the metamodel and the UML profile. As proven by the presented case study, constraints play an important role in the consistent representation of the system under study, since they impose the necessary restrictions and relationships between entities participating in different views. The proposed framework is currently tested in terms of completeness and expressiveness, using large-scale EIS architectures as test cases.

5. ACKNOWLEDGMENT

This research was supported in part by Pythagoras program (MIS 89198) co-funded by the Greek Government (25%) and the European Union (75%).

A Framework for Performance Evaluation of Intelligent Search Agents

Nurul I. Sarkar, Auckland University of Technology, Auckland 1142, New Zealand; E-mail: nurul.sarkar@aut.ac.nz
Naveed Iqbal, Auckland University of Technology, Auckland 1142, New Zealand

ABSTRACT

Because of the intelligent search agents (ISAs) can automate the process of searching through and evaluating reams of information on the Web, these agents are becoming increasingly popular in applications such as e-commerce and online businesses worldwide. While efforts have been made recently to develop various ISAs and multi-agents systems, very little is understood and known about the performance evaluation of such agents. A robust framework is required to assist efficient performance evaluation of ISAs. In this paper, we propose a framework for performance evaluation and comparison of ISAs. The proposed framework allows experimentation in which search agents can be evaluated based on a performance metric. This paper provides an in-depth performance evaluation of five selected ISAs to verify the robustness of the framework. The proposed framework is simple and can easily be adapted to applications requiring performance evaluation of similar intelligent agents.

Keywords: Intelligent search agents, performance evaluation, World Wide Web

INTRODUCTION

The competitive business environment and the growing complexity of work and personal lives create demands for performing many (often simultaneous) tasks more efficiently and promptly. To support these imperatives, new sophisticated and powerful intelligent software tools are developed. One such emerging software tool is the notion of an ISA (Boudriga & Obaidat, 2004).

ISAs are becoming increasingly popular in applications such as e-commerce and online businesses worldwide. This popularity results from the availability of various sophisticated and powerful intelligent agents that can automate the process of searching through and evaluating reams of information on the Web. For example, an ISA can be used to search on the Web to find a car matching a list of criteria, as tracking down the best price for purchasing grey Toyota Camry 2006.

A detailed discussion of intelligent agents, in general, can be found in (Boudriga & Obaidat, 2004; Dragan, 1998). Although many sophisticated and powerful intelligent agents and multi-agents systems have been developed in recently years, the performance evaluation of such agents is still an unexplored area in the field of agent technology (Saracevic, 1995; Srinivasan, Menczer, & Pantt, 2003).

This paper emphasizes that a good framework is required to assist efficient performance evaluation and comparison of ISAs. In summary, the main contributions of this paper are:

- We present a framework for performance evaluation and comparison of ISAs.
- We introduce a new performance metric called "search speed" for a better performance evaluation of ISAs.
- We provide an in-depth performance evaluation of five selected ISAs to verify the robustness of the proposed framework.

This research is exploratory in the sense that there was very limited prior research in the area of performance evaluation of ISAs to guide this research endeavour. Therefore, we adopted an empirical investigation methodology for the performance evaluation of ISAs (Dora, 2004; Serenko, 2006). The following research question was proposed:

How to select an ISA from a pool of search agents for a particular application?

The remainder of this paper is organized as follows. We first review past research on intelligent agents. We then introduce a framework for performance evaluation and comparison of ISAs. The experiment details and the performance evaluation of five selected ISAs are described. Experimental results are presented, and a brief conclusion ends the paper.

LITERATURE REVIEW

A number of recent studies demonstrate the usefulness and viability of using agent-based technologies in various applications; for example, in manufacturing automation (Heragu, Graves, Byung-In, & St Onge, 2002; Weiming, 2002), managing relational database (Rudowsky, Kulyba, Kunin, Ogarodnikov, & Raphan, 2005), network payment security (Hui-Zhang & Ji-di, 2004), e-business (Zi-Ming, Bo, & Yuan-Yuan, 2005), knowledge management (Houari & Far, 2004), fault diagnose system (Bo, Changhong, & Xiue, 2006), education (Pan & Hawrysiewycz, 2006), and web content filtering (Salter & Antonopoulos, 2006). In this section, we summarize previous work on performance evaluation of intelligent agents.

Mawlood-Yunis et al. (2004) experimented using two mobile agents and analyzed their platform's performance behaviour in distributed search. An interesting finding from their research is that in small networks multi agents systems do not provide any advantages and the associated overhead is high.

Camacho et al. (2002) evaluated various agent platforms (e.g., JADE, ZEUS, and SKELETON AGENT) based on the following metrics: number of agents used; number of requested documents; request time; and number of articles retrieved. Qi and Sun (2004) identified the operators that may increase the performance of a multi-agent system.

Lau and Zhang (2004) investigated how agents in a multi-agent system cooperate with each other. Results show that partial cooperation between agents is better than the fully cooperation of agents. Mao et al. (2004) point out that the coordination amongst the agents in a multi-agent system effects the performance of the system.

Samaras et al. (1999) stress the importance of performance benchmarking in the case of multi-agent distributed systems. O'Malley et al. (2000) examined the performance of static agents versus mobile multi-agent systems. The experiment involved searching for documents using static and multi-agent systems on a number of machines and then calculated the transmission control protocol/internet protocol (TCP/IP) traffic generated by the agents.

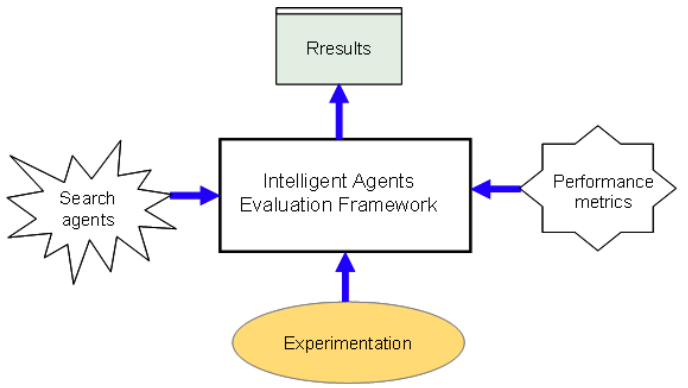
In summary, the proposed framework is almost alone in its goals and capabilities. The framework is described next.

THE PROPOSED FRAMEWORK

Figure 1 shows a simple framework for the performance evaluation of ISAs.

As seen in Fig. 1, the proposed framework allows experimentation in which search agents can be evaluated based on a performance metric. It is important to use an appropriate metric for the performance evaluation of ISAs. Once a performance metric is identified, the experiments can be conducted and results can be obtained using the proposed framework (Fig. 1).

Figure 1. The proposed framework



While various metrics for the performance evaluation of intelligent agents are reported in the software engineering literature, we briefly describe the following commonly used performance metrics:

Accuracy: In information retrieval, accuracy is measured in terms of recall and precision, where recall is relevance of the results obtained and precision is the cleanliness of the results (Kaki, 2004). This metric is not considered in our study since we did not have any human participants in the study who could rank the results obtained for accuracy measurement.

Throughput: This metric is commonly used for the performance measurement of communication networks. Throughput can be measured in bytes per second or packets per second or bits per second (bps). We ran all the experiments for the evaluation of ISAs under a control environment and measured the network throughput for every iteration performed, ensuring that the network throughput was not affecting the performance measures.

Round trip time: The round trip time (RTT) is the time required by a process to complete a task. For example, RTT is measured from the moment a query is placed on the source machine until the last packet arrives. The RTT can be affected by the size of a query.

Memory consumed: To measure the amount of computer memory consumed by a search agent, the MS Windows® default task manager utility can be used. This utility measures the memory usage dynamically when an application or process runs on the system.

Results returned: This parameter gives us the total number of results returned by an ISA per search.

Both "RTT" and "Results returned" can be used independently for performance comparison of ISAs. However, for simplicity and better performance comparison, it is useful to be able to compare the ISAs based on a single metric. Therefore, we define a new metric called "search speed" by combining both Results returned and RTT. The search speed (S_{speed}) is defined as

$$S_{speed} = \frac{N_{srr}}{T_{rtt}} \quad (1)$$

Where, N_{srr} is the total number of results returned in one search; and T_{rtt} is the round trip time (in seconds).

The search speed tells us about the capacity of an ISA (i.e., how many results returned by an ISA per second per query). An agent is said to be more powerful compared to another agent if it has a higher search speed.

EXPERIMENT DETAILS

The experimental setup consists of a desktop PC (Intel Pentium 4, 2.8 GHz; 512 MB RAM; 60 GB Hard disk; MS Windows XP Professional) and an ADSL modem (upload and download at 128 Kbps and 2 Mbps, respectively) linked to the Internet as shown in Fig. 2.

To measure the RTT and throughput, an open source software tool called Ethereal (www.ethereal.com) was used to captured packets from the live network and save them in a log for analysis.

Figure 2. Experimental setup

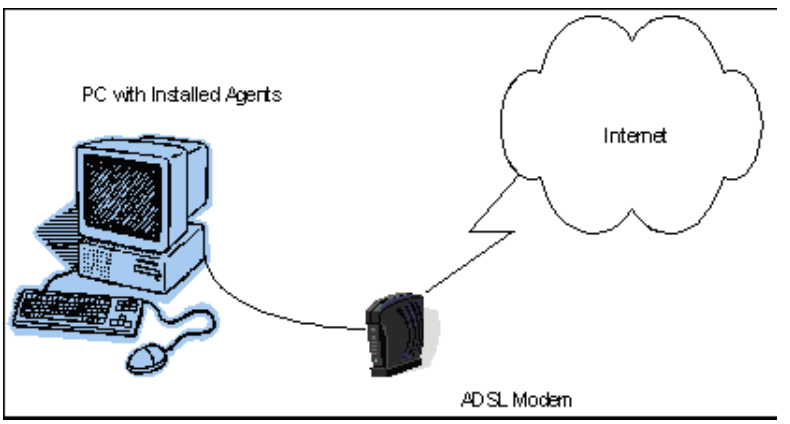


Table 1. Queries used in the experiments

Number of terms	Query
4	nicotine level smokeless tobacco
3	attention deficit disorder
2	dog crate

The selection of queries was very crucial in our experimentation. According to Jansen (2000) most of the web queries are only of two terms. A term can be a word, number, symbols, or even a URL. A query also contains one or more search terms and logical operators. In the experiments, we have used queries with 2, 3, and 4 terms as shown in Table 1 (Jansen, 2000).

Selection of ISAs

The selection of ISAs was a multifaceted and complex task since there were very limited number of ISAs available at free of costs for download and experiment in a control environment. The following five ISAs were selected for experimentation to test the robustness of the proposed framework:

FirstStop WebSearch™: This search agent provides a comprehensive search results and run under MS Windows. It can search on multiple search engines and websites concurrently.

WebSeeker™ 5.0: This agent has an indexer built into the program that keeps track of the browsed pages and monitors for new information. It has the ability to check whether the results can be reachable or not.

WebFoil 2.1: This agent provides multiple search sources at a time and search results provided through a detailed report.

Copernic Agent: This search agent can search multiple resources, combine the results, and stores the search history for later use.

WebFerret 5.0: This agent searches multiple sources, and sorts the results.

To facilitate an accurate data collection, it was vital to eliminate all the extraneous differences among the ISAs. Therefore, the advanced options provided by the ISAs were not selected in our experiments and only the default settings were used. To obtain an accurate and unbiased result, each query was submitted 10 times to each of the five ISAs in turn and all the measurements were recorded. This process was repeated at three different times of the day (at 0900, 1600, and 2100 hrs) for each of the five ISAs. In summary, we took the mean value for 30 observations per query. The experimental results are presented next.

RESULTS AND DISCUSSION

The experimental results for the performance comparison of five selected ISAs are summarized in Table 2. The ISAs are shown in the first column. The mean results returned by each ISA, and the corresponding mean RTT (in seconds) are shown in column 2 and 3, respectively. In column 4, we present mean throughput (bytes/second) which was measured for all iteration performed during experimentation. The mean search speed and the standard deviation are shown in the column 5 and 6, respectively. The 95% confidence interval (C.I) of the mean search speed is shown in the brackets.

As seen in Table 2, Copernic performs better (in terms of search speed) than the other four agents. The standard deviation of search speed varies significantly from its mean. We observe that the mean throughput performance of the ISAs differs slightly (from one another), but this variation is not very significant and does not affect the search speed.

We also found that as the complexity of the queries increases, ISAs tend to lose their search speed. For example, in the case when we used a quotation in the first query "nicotine level smokeless tobacco" to match the exact phrase, almost all five ISAs performed very low (results are not shown here due to the space limitation).

The mean search speeds of the ISAs are compared to see whether they differ significantly. The one-way ANOVA (also called F test) was carried out for the analysis of variance for the five ISAs under study. The F value after the ANOVA test was found to be 20.99, which is the ratio of the two variances: (1) the mean square between agents; and (2) the mean square within the agents. The degree of freedom was 4, which is the variation between the agents.

Figure 3 shows the difference (in magnitude) among the search speeds of the five ISAs (A = Copernic Agent, B = FirstStop, C = WebFerret, D = WebFoil, and E = WebSeeker). As seen in Fig. 3, Copernic has the highest search speed while the WebFoil has lowest.

LIMITATIONS OF THE STUDY

Firstly, a very limited number of ISAs was available (free of costs) for download and install on a local machine for experimentation. Due to the budget constraint we could not get hold of commercial agents to be included in our study. Another limitation was the time constraint as we had to complete the project within the given time frame.

CONCLUSION AND FUTURE WORK

In this paper, we proposed a framework for performance evaluation and comparison of intelligent search agents (ISAs). The framework allows experimentation in which search agents can be evaluated based on a performance metric. For a

Figure 3. Variation of search speed (magnitude) among the five ISAs

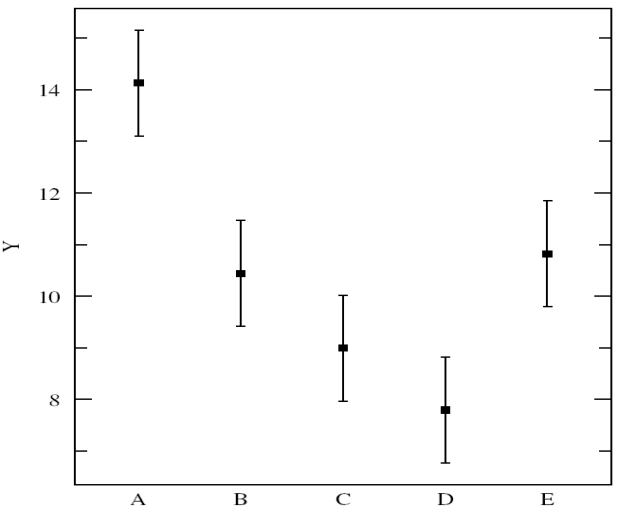

Table 2. Performance comparison of ISAs

Search agents	Mean results returned	Mean RTT (second)	Mean Throughput (bytes/second)	Search speed (results returned/second/query)	
				Mean (95% C.I)	Standard deviation
FirstStop	229.05	19.11	136190.83	10.40(9.41,11.46)	4.95
WebSeeker	218.62	19.40	125482.32	10.80(9.80,11.85)	6.11
WebFoil	166.22	21.07	128475.43	7.79(6.77,8.82)	4.35
Copernic	237.05	16.50	129326.87	14.10(13.10,15.15)	7.74
WebFerret	172.97	18.55	121421.73	8.99(7.97,10.02)	4.75

better performance comparison of ISAs, we introduced a new metric "search speed" by combing the number of results returned and the RTT. Through various experiments and measurements under a control environment, we gained an insight into the performance comparison of the ISAs by using search speed as one of the performance metrics.

We found that not all the five ISAs can perform equally well in terms of their search speed. For example, among the five ISAs evaluated, Copernic is up to 36.2% ($\frac{4.1-8.9}{4.1}\times 100\%$ faster than the WebFoil.

The proposed framework is simple, easy to implement and can be used for performance evaluation of similar intelligent agents from other domains, such as online shopping. We have tested the framework and found to be robust.

This study can be further extended by using a case study in evaluating the performance of similar ISAs. Further research on the impact of query length and complexity (e.g., more terms using Boolean operators) on the performance of ISAs is suggested. The performance of search agents under different data types, such as text, images, and multimedia data is also planned as an extension of the present study.

ABSTRACT

The development of successful IS practices relies on the existence of well documented, formal work system practices and the existence of cross-functionally integrated of work teams. In manufacturing firms, formal work system practices serve as a public repository of organizational knowledge, including key manufacturing policies, procedures, and definitions. Cross-functional work teams provide the vehicle by which new work system practices may be quickly created and implemented throughout the firm. Study results indicate that firms with high levels of manufacturing work system formalization and integration have higher levels of IS strategic planning effectiveness, IS responsiveness to organizational computing demands, and IS end-user training effectiveness. Perceptions of IS performance were also higher for firms with greater work system formalization. Data were collected from 265 senior manufacturing managers who were selected because their perspective of IS performance was desired and because manufacturing units are an important user of the services. ANOVA was used to test our hypotheses.

Keywords: Information System Development, Work System Formalization, Work System Integration, IS Strategic Planning Effectiveness, IS Responsiveness, End-User Training, IS Performance

1.0. INTRODUCTION

Today's global manufacturing environment has significantly impacted the basis of competition for U.S. firms (Nam et al., 2004). Many U.S. manufacturers have sought to improve the effectiveness of production processes and capabilities through the implementation of IT-reliant work systems. A work system is defined as "a system in which human participants and/or machines perform work using information, technology, and other resources to produce products and/or services for internal and external customers" (Alter, 2003). Thus, an IT-reliant work system must capture key organizational knowledge for its information-based technologies and systems to improve the speed and quality of decision processes.

In the case of manufacturing firms, the purpose of information-based technologies and systems is therefore to support the activities of the production work system. While the boundary between a firm's work systems and its information systems may overlap and blur with time, the development of successful IS practices remains a critical outcome the IS function must achieve in support of this requirement. An important prerequisite for the development of successful IS practices is the existence of well-documented, formal work system practices (Alter, 2003).

Formal work system practices provide a vital reference, serving as a public repository of organizational knowledge (i.e., key manufacturing policies, procedures, definitions, etc.), which are necessary to develop supportive IS practices (Lee & Choi, 2003). Cross-functional work teams provide the integration mechanism by which new work system practices may be more quickly created, disseminated, and then implemented throughout the firm (Bailey, et al. 2001). The integration of the work system provides a basis for employees to resolve differences related to the common meaning and definition of manufacturing work system practices, thus accelerating this process (Rondeau et al., 2000).

The central tenet of this study is therefore that firms demonstrating both high work system formalization and integration will provide a consistent and stable basis upon which to build effective IS practices. Such firms should be perceived to have higher levels of IS strategic planning effectiveness, IS responsiveness to organizational computing demands, and IS end-user training effectiveness. Perceptions of IS performance are also expected to be higher. For this study, data were collected from 265 senior manufacturing managers who were selected because their broad perspective of their firm's work system and IS practices of interest was desired. Ultimately, their perceptions matter most because they may choose to pay for IS services or to outsource, downsize, or replace their IS function's services. The ANOVA procedure is used to test our research hypotheses.

2.0. RESEARCH MODEL, LITERATURE REVIEW, AND HYPOTHESES DEVELOPMENT

This research proposes IS practices will be higher for firms demonstrating more formal work system practices and greater work system integration. The matrix given in Figure 1 shows that firms may be classified into one of four cells by level of work system formalization (i.e., low or high) and level of work system integration (i.e., low or high). Manufacturing firms classified within ***Cell 1*** (i.e., low IS function success) possess low levels of both work system formalization and integration. They may have less need for information processing and therefore have a lower IS requirement. In contrast, firms classified within ***Cell 4*** (i.e., high IS function success) possess high levels of both work system formalization and integration characteristic of a post-industrial environment. These firms should have an information-rich, internal environment that is capable of flexible resource deployment.

Firms in ***Cells 2*** and ***3*** should demonstrate moderate levels of IS function success. These firms will possess either a high level of work system formalization and low

Figure 1. Research model

Work System Formalization (FO) \ Work System Integration (IN)	Low	High
High	**Moderate IS Performance (Cell 2)**	**High IS Performance (Cell 4)**
Low	**Low IS Performance (Cell 1)**	**Moderate IS Performance (Cell 3)**

work system integration (i.e., Cell 2) or a low level of work system formalization and high work system integration (i.e., Cell 3). Those demonstrating high formalization and low integration may require standard information products and services requiring little or no customization. Those demonstrating low formalization and high integration may require non-standard information products and services requiring extensive customization. These firms are therefore expected to exhibit moderate levels of perceived IS effectiveness.

2.1. Work System Formalization

Formalization may take the shape of written operating procedures, quality improvement methods, employee handbooks, and other documents that direct employee action towards customer requirements (Price & Mueller, 1986). Without documentation, standard operating procedures and work methods are subject to misinterpretation. Over time, organizations may forget their purpose, including the reasons why they were developed. When formalized, the full meaning and benefits of the written documentation can be shared freely between departments, across plants, and throughout the firm (Argotte & Epple, 1990; Levitt & March, 1988).

2.2. Work System Integration

Integration is the process of blending elements of the organization into a united whole. When organizations face a complex and uncertain environment, they are more likely to use integrative devices such as task forces, committees, or liaisons to increase their chances for success (Germain et al., 1994; Miller and Droge, 1986). As management struggles to gather and process more information and make increasingly complex decisions, they delegate decision-making to lower-level work groups. The increased interdependence of workers that results gradually diminishes existing job and work group boundaries, increases individual task meaningfulness, and expands information exchange (Romme, 1997; Susman & Dean, 1992).

2.3. IS Strategic Planning Effectiveness

Senior management assessments of IS strategic planning effectiveness should accommodate: 1) senior managers' preference to discuss IS strategy in ways that more generally relate IS strategy to business strategy (Hirschheim & Sabherwal, 2001) and 2) their need to relate IS strategy to its impact on customers and the marketplace in general (Henderson & Venkatraman, 1999). The final IS plan must therefore project a clear vision of the IS organization's role, IS goals and objectives, and the ways the firm's information technologies and systems should operate to be effective in a manner understood by senior management (Rockart & Hofman, 1992; Teng et al., 1994).

High work system formalization is critical for more effective IS strategic planning because potential misinterpretation of work system support requirements (and risk) is decreased due to specific, well-defined, and widely distributed work system documentation (Palmer & Dunford, 2002; Segars & Grover, 1999). High work-system integration is also critical in that it helps firms understand the relationship between existing and emerging work practices (Suchman, 2002). Effective IS planning requires the existence of formal knowledge to insure IS plans incorporate critical work practices in proposed solutions. It also allows the politics and personalities of the enterprise to be considered in these solutions (Hodge, 1989). Thus, we hypothesize:

H1: *Firms scoring high in both Work System Formalization and Integration (i.e., Cell 4) will score higher in IS Strategic Planning Effectiveness than firms scoring low in both Work System Formalization and Integration (i.e., Cell 1).*

2.4. IS Responsiveness to Organizational Computing Demands

A lack of responsiveness to user issues, questions, and concerns by the IS function is commonly cited as one of the primary reasons behind IS downsizing and outsourcing initiatives. Many users experience frustration when their IS function fails to properly prioritize requirements and deliver useful results on time and within budget. As such, these IS functions are often the focus of intense user dissatisfaction and the target of poor user performance evaluations (Doll & Doll, 1992; Due, 1992; Powell, 1993; Rowley & Smiley, 1993).

An IS function within firms with high work system formalization and integration should be perceived to be more responsive to users. High work system formalization establishes a well-documented, stable work environment. This better supports the development of more efficient, standardized computing support services. High work system integration enables the rapid prioritization of work system goals and objectives, clarifying the importance of related IS support requests. This better supports the development of a more appropriate IS response, based on the relative importance of organizational computing needs, to be generated. Thus, we hypothesize:

H2: *Firms scoring high in both Work System Formalization and Integration (i.e., Cell 4) will score higher in IS Responsiveness to Organizational Computing Demands than firms scoring low in both Work System Formalization and Integration (i.e., Cell 1).*

2.5. IS Effectiveness in End-User Training

Effective end-user education and training involves teaching general problem solving approaches, including abstract reasoning and specific technical skills (Nelson, 1991). Attaining this is critical in an IS environment where cognitive skills, that are necessary for continued learning, vary greatly among participants and may, on-the-average, be less than desired (Harrison & Rainer, 1992). Effective end-user education and training can enable the rapid acceptance of new technologies and software, empower users to experiment more freely, and motivate them to deploy new technologies more quickly (Kappleman & Guynes, 1995).

High work system formalization enables the definition of specific worker skills and abilities required to perform business processes. This specificity better supports the identification of key information technologies, including the IT user training solutions required for workers to use these technologies effectively. High work system integration allows for common agreement on the content of business processes and type of IT user training that may be needed. This better supports the definition of both formal coursework and on-the-job learning experiences. Thus, we hypothesize:

H3: *Firms scoring high in both Work System Formalization and Integration (i.e., Cell 4) will score higher in End-User Training Effectiveness than firms scoring low in both Work System Formalization and Integration (i.e., Cell 1).*

2.6. IS Performance

Management's satisfaction with IS performance depends on the ability of IS to facilitate better decision-making (Raghunathan & Raghunathan, 1996). End-users recognize the benefits of the services provided by IS, especially how these services lead to faster and better decisions in highly competitive situations (Rondeau et al., 2003). The challenge faced by the IS function is to develop clear, objective measures of IS performance (Costea, 1990). High work system formalization can create a more predictable user environment, enabling IS managers to be more effective in anticipating users' IS product and service needs. High work system integration allows users to work out their differences related to business requirements before attempting to translate them to IS requirements. Thus, we hypothesize:

H4: *Firms scoring high in both Work System Formalization and Integration (i.e., Cell 4) will score higher in IS Performance than firms scoring low in both Work System Formalization and Integration (i.e., Cell 1).*

3.0. INSTRUMENT DEVELOPMENT AND DATA COLLECTION

Work system formalization (FO) and integration (IN) items were developed based upon a review of the manufacturing literature. Items designed to measure IS strategic planning effectiveness (SP), IS responsiveness to organizational computing demands (RD), and end-user training effectiveness (UT) were developed from a review of the appropriate IS literature. Items designed to measure IS performance (IP) were adapted from an instrument by Ragunathan & Ragunathan (1996). All items are measured on a five point Likert scale. Structured interviews were conducted, a pre-pilot test done, a pilot study done, and a large-scale study that targeted executive-level manufacturing managers. These steps were taken to

ensure the content validity, reliability, and brevity of the instruments as well as internal and external validity.

Data were obtained as part of a mail survey designed to capture both IS and manufacturing data. All firms selected had at least 250 employees within US SIC codes 25 and 34 to 38 (see Table 1). The mailing yielded 265 responses: an effective response rate of 4.3%. While less than desired, the makeup of the respondent pool was considered adequate. 44.9% of the respondents reported a job title of president, CEO, vice president, or general manager. 30.6% said that they were plant managers, directors, or senior managers. 20.4% were managers and 4.1% did not provide job title information. Tests of non-response bias indicated no statistically significant difference between the firms on the mailing list and the responding firms for either SIC code or firm size (number of employees).

4.0. STUDY RESULTS

4.1. Results of the Measurement Model

The items for all work system and IS dimensions were submitted to exploratory factor analysis. Principal component was selected for the extraction procedure with varimax factor rotation. Results are given in Table 2. Most factor loadings were 0.60 or 0.70 or better with two manufacturing work system formalization items being 0.50 or better. While formalization items F03 and F06 factor loadings were less than desired, they were considered important to this research and were thus retained. Factor loads below 0.40 are not shown with no significant cross loads, implying convergent and discriminant validity. All of the factors were composed of a single dimension. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy was 0.92.

Table 2. Statistical attributes of the factors

	Scale	# of Items	Mean	Standard Deviation	Reliability
FO	Work System Formalization	6	3.93	0.86	0.92
IN	Work System Integration	7	3.96	0.79	0.85
SP	IS Strategic Planning Effectiveness	5	3.14	0.99	0.92

Note: IS construct means for firms classified within each FO and IN, low or high cell combination are provided in the left side of this table. Overall IS construct means are shown in Table 2.

Table 3 gives the means, standard deviations, and reliability estimates (Cronbach, 1951) for the IS dimensions. All factor reliabilities are above 0.80 or 0.90 except for end-user training effectiveness, which is 0.77. The final instruments are short and easy to use. Each scale has seven or fewer items, and the total number of items across all scales is only thirty. Due to manuscript space limitations, the instruments have not been included but are available from the authors. The instruments meet generally accepted validity and reliability standards for exploratory research.

Figure 2. Respondents classified by cell

Note: A total of 265 respondents were split into High or Low cells by FO and IN factor means.

Work System Formalization (FO) \ Work System Integration (IN)	Low	High
High	45 (17%) (Cell 2)	114 (43%) (Cell 4)
Low	55 (21%) (Cell 1)	51 (19%) (Cell 3)

4.2. Approach to Hypothesis Testing

The division of the sample into the cells shown in Figure 1 depends on the calculation of overall construct means for FO and IN, which are given in Table 3. Individual responses were then classified into the four cells shown in Figure 1 by comparing them to these overall means. If a respondent's FO and IN score was above the construct mean, it would be considered to be above average in terms of its formalization or integration. If a respondent's FO and IN score was below the construct mean, it would be considered to be below average in terms of its formalization or integration. SPSS was then used to conduct analysis of variance (ANOVA) tests to determine whether the dimensions of the IS environment varied significantly among the four cells. Figure 2 shows the final classification of respondents into four cells.

4.3. Results of Hypothesis Testing

The results shown in Table 3 support hypotheses 1, 2, and 3 as discussed earlier as well as the corollaries to these hypotheses. Firms that are high in both FO and IN have higher levels of the SP, RD, and UT than firms that are low in both FO and IN. The *F* values for the main effects for SP, RD, and UT indicates statistically significant differences in the group means at the $p<0.01$ level. Hypothesis 4 was only partially supported with firms having high FO also having higher levels of IP than firms that are low in FO. The *F* value for FO effects for IP indicates statistically significant differences at the $p<0.01$ level while the *F* value for IN effects for IP indicates no statistically significant differences. Therefore, hypothesis 4 was not supported relative to IN effects on high or low levels of IP.

There were no significant interaction effects found in the analyses. This result indicates general support for the argument that manufacturing firms with highly formalized and integrated work systems tend to have high levels of these information systems variables, including IS performance. These results are statistically significant at $p<0.01$ or $p<0.05$ in all cases except IS Performance. In this case, FO generates a significant difference at the $p<0.05$, but IN does not.

One explanation for this may be that manufacturing IS users may view information technologies as tools to assist them in performing standardized work. What may be most important is how closely the IS function replicates and supports formalized work system practices. Senior manufacturing managers may simply view the IS function as a tool builder/provider and not a participant in work system integration efforts intended to improve these practices. Thus, their perceptions of IS performance may be more closely associated the IS functions ability to replicate formalized work system practices than with its involvement in work system integration efforts.

A second explanation is that a relationship does exist between manufacturing work system integration and IS performance, but it may be indirect in nature. Work system integration may directly impact other manufacturing or IS related variables which may in turn directly impact IS performance. For example, IS strategic planning effectiveness, IS responsiveness to organizational computing demands, and end-user training effectiveness have all been hypothesized to impact IS performance in the IS downsizing, IS outsourcing, IS satisfaction, and end-user training literatures.

5.0 CONCLUSION, LIMITATIONS, AND FUTURE RESEARCH

This study explores the contingent nature of a firm's IS environmental variables in the context of work system formalization and integration. Study results indicate that more formal work system knowledge is needed to develop more effective IS practices. Greater work system integration complements and supports the development of formal work system knowledge. Firms exhibiting both greater work system formalization and integration aide their IS functions in maximizing their effectiveness.

One important implication of these findings is that manufacturing user departments should create formal policies, procedures, instruction manuals, and other forms of documentation to reduce the ambiguity of their IS support requirements. A second implication is that manufacturing user departments should seek to become more cross-functionally integrated to insure that IS support requirements reflect common organizational needs and definitions. Doing both should increase the speed at which IS support requirements may be defined and implemented in support of manufacturing work system requirements. Study results lend support for the assertion that IS departments located in firms with low work system formalization and low work system integration may be predisposed to poor perceptions of IS performance.

These IS departments may find help in the form of modern knowledge management technologies (KMT). KMTs allow work system practices to be captured, cataloged, organized, saved, and retrieved much more easily. They also allow users to share work system knowledge and contribute to its ongoing development on a real-time basis. Thus, IS functions located within manufacturing firms characterized by low work system formalization and/or integration may find benefit through the introduction of such technologies.

5.1. Limitations

The results of any research study and its generalizability have to consider limitations. Though precautions have been taken to avoid obvious limitations, it is impossible to avoid all such concerns. Both the dependent and independent variables in this study have been measured through a single respondent, which may introduce response bias. The assumption is that senior manufacturing managers have knowledge of their firms FO, IN, and IS practices.

The amount of data captured in this study and the need to collect data from top managers have created a low response rate. To ensure that response/non-response bias is not an issue, tests were done to compare attributes of these groups. The IS variables measured in this research are not exhaustive. In addition, they focus mainly on the internal aspects of the organization and not on the external links with suppliers and customers. Finally, one factor, end-user training effectiveness has only two items, which casts doubt on the reliability of this measure.

5.2 Future Research

Clearly, future research can attempt to address each of the procedural problems identified in the limitations section. Furthermore, the inclusion of additional work system or IS variables that focus on the relationship between an organization and its IS function could be important. For example, such studies could examine the impact of work system variables on other IS-related practices not addressed here such as IS development approaches or end-user computing practices. Other studies could further address the impact knowledge management software could have on improving work system formalization and its subsequent impact on IS development practices.

ABSTRACT
We claim that mail Spam and Phishing can become an operational tool in the hands of terrorists, to perform more than just simple recruiting and fund raising activities. We show that by using spam methods terrorists can reach the heart of society, and succeed in getting some of its fringes to act on their behalf. This "outsourcing" of terrorist activity to own members of the attacked society may adversely affect law enforcement ability to use profiling in the war against terror. We describe a system that combines standard spamming techniques with standard and adapted security mechanisms, and which provides the functionality needed to target, recruit, and operate terrorist cells and opportunistic accomplices.

1. INTRODUCTION
If you are like most Internet users, your mailbox has been routinely flooded with "spam". Spam are email messages that try to tempt the recipient into buying something, and spammers typically send millions of identical unsolicited messages in order to get only a few buyers – altogether it estimated that spammers send 12 billion messages daily, or more than half of all email messages[Spam Filter Review, 2004].

Whereas today, spam is used primarily by commercial companies who want to increase their sales, we are already seeing cyber criminals who start using spam-based "phishing".

Phishing is a form of criminal activity using social engineering mainly to access private and secret information. Phishing today is mainly being used to extract secret codes and other information for fraudulent financial transactions [Phishing report 2004]. According to a recent survey, 43% of US adults have been targeted by phishing attempts [First Data *Phishing Survey, 2005]*.

This Article reveals a new possible method that terrorists can easly take advantage of when carrying out there terror activities, and exposes the absence of current technology from tackling such terrorists activity

The article will show how terrorists can use spam and phishing methods not only to recruit members and raise funds, but also to influence other people to carry out attacks on their behalf. We will also show that through the use of spam terror, terrorists can create fear and terrorize the public, even without taking any action.

Clearly, however, the most dangerous prospect is that terror spam can be used to draft agnostic individuals and units, from within the inner parts of the attacked society, who will commit terror attacks on behalf of, and under the guidance of terrorists. When the enemy could be almost anyone and anywhere, law enforcement will find it very difficult to use profiling techniques in its war against terror.

2. CURRENT USE OF CYBER MEDIA BY TERRORIST GROUPS
The Internet today contains endless information, tools and opportunities. Terrorist use the Internet today to satisfy their own needs. Much has been said about terrorists seeking to enlarge their power and capabilities taking advantage this important tool. Listed down are some of the main ways in which terrorists are using the Internet today.

- Mass-Communication Tool.
- Planning and coordination of terror attacks.
- Intelligence gathering.
- Fund raising.
- Recruitment.
- Psychological Warfare.
- Cyber Attacks.
- Providing Instructions to Potential Attackers.

Is Spam the Next Ultimate Tool in the Hands of Terrorists?
In this article, we claim that spam may become the important tool in the war against terrorism. Clearly spam can serve as a useful tool to spread terrorist's messages and knowledge, and to raise funds for terrorist's organizations. More interestingly, we claim that Spam can also serve as a tool for terrorists to influence individuals to act on their behalf or at least serving their purpose.

3. SPAM AND SPAMMING METHODS
The Spam Phenomenon
Spam refers to one or more **unsolicited** messages, sent or posted as part of a larger collection of messages, all having **substantially identical content**. It usually manifests itself as an email campaign that targets millions of email accounts around the world, in an unsolicited fashion *[Monkeys]*. Experts estimate as many as 12 billion spam messages daily, making for over 75% of all email traffic *[Spam Filter Review, 2004*

Spam proved itself as an easy way to reach a large audience, and an effective sales tool that works well despite the low apriority success rate of each individual email message.

Phishing
Whereas most spam is commercially motivated, "phishing" is a relatively new form of spam that is probably closest to the terror spam that we introduce next. Phishing is spam, used by fraudsters to get access to the passwords and other private or financial information of unsuspecting users. *[Drake, Jonathan & Eugene 2004]*

4. TERROR SPAM
We believe that spam can become attractive to terrorist groups, not merely as a tool to spread their messages, but also to raise funds and recruiting members. More importantly, we speculate that spam can be used by terrorists to influence non-members to carry out attacks that coincide with the terrorist's goals and plans, and to coordinate activities of a dispersed heterogeneously motivated network of activists. Whereas today, it is commonly assumed that some Islamic terrorist organizations will only recruit staunch believers to carry out attacks (especially suicide attacks), we believe that in the future they may use "outsourcing" techniques, and will find the right justification to doing so. The trigger may be lack of resources, or the clear logistical and operationally benefits of "outsourced" activity, but in any event this may result in higher quality attacks.

The main features that make terror spam and phishing attractive to terrorists are:

1. Anonymity and difficulty of tracing;
2. Low cost to reach a large audience and hence the ability to engage a large number of (low probability) initiatives;
3. Leverage in reaching new and otherwise inaccessible audiences
4. Ability to recruit operatives from within the attacked society
5. Ability to spread fear, even without any action being taken

Usage
Terrorists can clearly use spam as a means to achieve there goals. Especially by focusing on direct needs to carry out attacks such as:

- Communications.
- Funding.
- Recruitment.
- Influencing individuals on taking extreme actions.

5. HOW TERROR SPAM MAY WORK

In this section, we describe how terror spam may work. We start by reviewing potential target audiences for terror spam, and the chances of response/success. We then discuss various technical modifications to traditional spam, which may be required to facilitate terror spam.

Target Audiences

In this section, we present terror as a "product" to be spammed. Like any other product, the terror spammer needs to consider the target audience(s), so that the campaign reaches the intended recipients, and so that the campaign is structured to appeal to the respective audiences. While it is true that the direct cost of spamming is very low, terror spammers may still want to avoid indiscriminant campaigns. First, spamming indiscriminately requires more resources, and will also reduce the time-to-block time frame, i.e., the time it would take law authorities to stop the spam and to block the next step of making contact with a collaborating receiver. Second, and more importantly, it may be important for terror spammers to craft different messages that will appeal to specific audiences.

We consider the following groups as primary targets for terror spammers:

- **Affinity religious, ethnic, and national groups**.
- **Sympathizers.**
- **Disadvantaged and disgruntled groups**.
- **Teens**.

Terrorists group can benefit from almost any outcome such a spam campaign will bring.

By throwing spam campaign terrorists will be able to achieve physical damage in some cases and advertisement that can lead to public panic in other cases, in both cases terror organization will benefit.

A spam campaign can be used to coordinate an attack among a number of people

This type of coordination can be achieved due to the high level of control that the technology environment provides i.e. giving guide to many people that are located in distance places. Exact orders can be given to all executers telling them precisely what to do in a specific time period or place, additional guidelines can be given via SMS. More over a special secured forum or chat room can be opened and enable the attackers to exchange information between themselves.

If at the same day a number of American symbols such as restaurants, entertainment chains etc…will be attacked the media effect will be very large.

The spam campaign can simply empower "Traditional" cyber terror actions

By encouraging users to DDOS web sites email addresses and other web based services of governments and private companies such as banks, e-com web site etc…and by that disrupt public services.

In some cases the potential users will prefer not to take an active role in terror actions but will be willing to volunteer critical information. Security leaks of critical infrastructure, governmental offices and public places can give a meaningful added value to the terror organizations. Terrorists can tempt users to "help" by offering money to any sensitive information that will be delivered to them.

In Some cases the spread of fear and instability is far more damaging then the physical act of terror itself.

If up until now we thought that a terrorist must come from a certain part of the world or alternative believe in certain things at this point we will have a problem of defining a terrorists due to the fact that it can be the next door neighbor that doesn't believe in anything suspicious and revenge is the only thing that guides him.

6. TECHNICAL IMPLEMENTATION OF TERROR SPAM CAMPAIGN

We propose an implementation blueprint for a Terror Spam System (TSS) that uses available spam technology, and simple modifications thereof that provide the additional security services that terrorists may need.

System Overview

The TSS is designed to enable terrorists to initially contact a wide target audience, and to then continue to communicate with respondents safely until and after the terror act is actually committed.

In the initial phase, the TSS enables the terrorist groups to reach as many potential agents (prospects) as possible. Some prospects may share the terrorist's motivations, whereas others may simply want to leverage the terrorist's capabilities and resources in order to achieve their own goals (which may partially coincide with the sponsoring terrorists). In this phase, the TSS provides some mechanisms that would reduce the risk of detection, and others that would help segregate communication channels.

Once the first responses are received, The TSS provides additional security mechanisms, and various controls on the communication with different prospects, including mechanisms designed to segregate communication channels, and to reduce the risks posed by informants and ingenuine respondents, as well as the risk of exposure of genuine respondents.

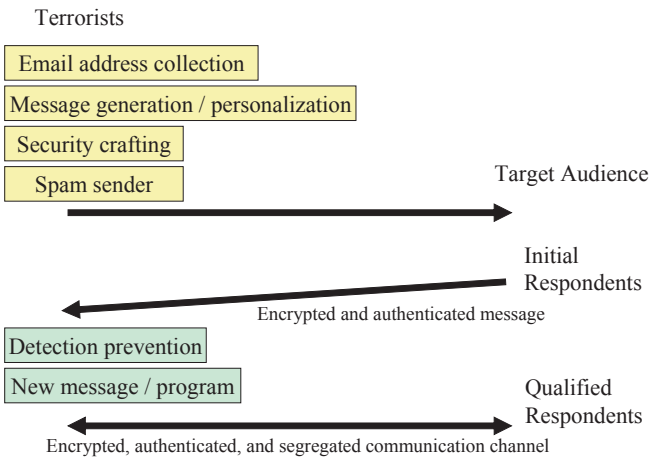
Figure 1 shows an overview of the TSS system and the flow of information and processing.

Just like in a marketing spam campaign, the goal of the first phase is to mass mail to prospective "agents". The first step in this phase is to acquire lists of email addresses of potential prospects, based on a specified set of target audience criteria. This is done by the "**Email address collection**" component.

Next, the TSS "**Message generation and personalization**" component shall construct/design a message (or select one from a number of pre-designed alternatives) to match each of the targeted prospects. The goal here is to personalize a message that is likely to draw the attention and response of targets. Thus, different messages can be mapped to different target audiences.

Subsequently, each message shall be enhanced with security mechanisms using the "**Security crafting**" component. For example, we propose that messages contain a script, and recipients are requested to reply through this script rather than by clicking "Reply" and using the regular SMTP reply. This script may, for example, encrypt the reply using a public-key scheme. The security mechanisms shall make it more difficult for the ISP to record and track the response, and shall make it difficult for an eavedropper to interpret the actual message. The script may also collect some information about the recipient's machine, using spyware-like technologies. This information, together with the message unique ID, and a time

Figure 1. Overview of TSS system



stamp indicating when the message was sent, may later be used to authenticate the respondent and to detect possible "mischief". Finally, different batches of outgoing messages shall be designed to respond to different email addresses (collection points), for segregation reasons.

The next step is of course to send the messages, using the "**Spam Sender**" component. This component will use standard spamming techniques to distribute the email messages to the target addresses. As an example, to avoid detection, the Spam Sender may distribute the messages into several batches which will be sent through several mail servers and at different times.

This completes the first phase of mass mailing.

The expectation is that a small fraction of recipients will respond to the initial email campaign. The secured script that is embedded in the message will use the identifier, time stamp, and the unique public-key that is provided for this message to encrypt this communication. The reply will be sent to one of several receiving email addresses, per the above mentioned segregation policies. The receiving program will then use the "**Detection prevention**" component to review the responses for authenticity and for various tell-tales of possible risks. Replies in which there is a mismatch between the unique identifier and the address to which the original message was sent, and the address from which the response was received will be ignored. It is also possible to ignore responses that are not received within a certain time window from their time stamp, as ones that may have been tampered with, e.g., the received may have contacted law enforcement authorities. (of course this may result in some loss of genuine respondents). Filtered messages will be sent to human operators, who will then use a separate communication channel with each respondent.

In the beginning of this "second level communication", the prospect would be provided with software components that would enable the implementation of additional security mechanisms, e.g.

- confidentiality – through encryption using public and/or symmetric key schemes for the communications, as well as for communication traces and data stored locally on the prospect computer
- authentication – using cryptographic means, and also physical and OS identification of the prospect computer
- segregation – using a unique channel and communication address for each prospect
- detection avoidance – by frequent changing email addresses and other "meeting locations"
- detection of mischief – through a spyware component that would monitor the activities of the prospect, and his/her other communications

Description of Specific System Components

In this section, we provide a more granular description and discussion of each of the TSS components.

1. Email addresses collection
   The role of this component (which will likely be implemented as a set of specific systems and procedures) is to acquire email lists according to the characterization of the target audience. Spammers are implementing similar systems, which use a variety of automatic and manual methods, e.g.,
   - extracting email addresses from mailing lists, directories, chat rooms, and discussion forums
   - automated harvesting of email addresses from web pages, who-is contact lists, etc.;
   - guessing email addresses for a specific domain, e.g., as a combination of first and last name;
   - using social engineering methods to obtain email addresses and other personal information;
   - legitimate purchase, and/or bribing for, and/or breaking into consumer databases
2. **Message generation/personalization**
   Mail messages should attract prospects to open and read, and if possible entice prospects to respond/act. In general, messages should be short and to the point. As indicated, the message shall also collect necessary information and initiate second-level contact.
   A possible implementation may start with a number of pre-composed message templates in several languages that will support localization, and then select and fill out the template that best fits each targeted recipient. A matching function shall be constructed to maximize the match between the features of the message and those of the prospective recipient. Dynamically adapting matching functions may be programmed to learn from past response rates.
3. Security crafting
   This component adds a security response script to each message. The script shall support automated encryption of the response, and targeting of the response directly to one of the collection centers. The script shall also verify that response does not exceed the valid time window. In addition, the script shall collect and send back some identifiers from the user's machine like the user and machine names, MAC, and IP address. The script may also collect more subtle information such as email correspondence, browsing information, bookmarks, etc, and may even install a spyware component (or even a trojan) that will continue monitoring the activity on the machine.
4. Spam Sender
   The spam sender is fed with a list of email addresses and the message templates that were selected for each. Before sending, the spam sender attaches a time stamp to each message, to start its validity window. The main challenge of the spam sender is to avoid its detection and the blocking of its messages. Spammers have specialized in this, and use methods such as:
   - use many and frequently changing IP addresses, as well as use of spoofed addresses;
   - use third-party outgoing mail relays that were left open
   - sending smaller batches from each outgoing mail server;
   - adapt the templates messages to a form that would be less detectable by filtering programs (this shall probably be done in the messages database itself, rather than in the sender, but we bring it here because it is one of the ways to avoid detection)
   - use HTML messages with Java script-encrypted frame tags that launch the body text only at the email client
   - use web beacons, and deceptive opt-out links to verify which addresses are active (again, this shall probably be fed back into the email addresses database)
   - use Trojans on some of the recipients to send more messages from *their* machines
5. Detection prevention
   The role of the receiver is to detect responses from law enforcement and other impersonators. Responses that are not well encrypted with the originally provided keys (in the script) will be rejected. Several rules in the detection prevention component shall seek suspicious information in the machine-specific data returned from script. This data shall also be stored and compared to future communication with same prospect. In case of serious suspicion, the receiver may abandon the entire communication associated with this email collection center, assuming it was compromised.

7. SOME RECOMMENDATIONS

In order to prevent and/or minimize terrorist's success in achieving their goals by using spam we'll suggest a few actions that could be taken.

1. Create a "Terror Spam Tracing Center" that will monitor all terror transportation.
   This center will gather data from all ISP's and publish domains, ISP', IP's etc…of mails that are suspected to be from terror organizations and publish them to all ISP's. The ISP's will be obliged to block all mails from the terrorists list.
2. Send a follow up email to every address that receives a "spam-terror" email saying that you just received an email from a terror organization, please delete it, Indicating that cooperating with terror organizations is a felony, letting the recipient understand that is actions are being watched and he's will be better off if he stops the contact with terrorist organization.
3. Create a unit that will detect and follow the traces of terror spam, in order to reach the perpetrators. Detectives in this unit shall respond to terror spam, and shall create contact where possible (under cover of course) with the relevant cells, with the goal of gathering intelligence and making arrests
4. Shut down servers that were used to send terror spam using either legal or semi-legal means depending on the location of those servers.
5. Some thought should be taken in order to protect the mobile phone industry from SMS terror Spam.

8. CONCLUSION

There is evidence today that religions terror organizations are linking with other terror organization in order to join forces against common enemies. For example Al Qaeda and far right groups such as neo-nazis and skinheads in Europe, these links are suspected to be both on the financial and action carrying levels. If terror organization will decide to further extend there links to individuals whom not necessarily believe in their organization ideology but are willing to take actions that might serve it than Spam email might serve as a perfect tool to achieve those links. By using this simple tool we showed how terror organizations can easily cause more violent incidents and increase the terror level world wide. Spam can reach civilians inside a target population that want to harm their own population provides a perfect communication tool. The spam will allow individuals to contribute both silently and actively to terror organizations dependent on each individual's preference. We showed that spam is hard to stop and detect, although the industry is taking more meaningful and aggressive approaches verse spam still spam is difficult to detect and many spam emails reach the users mailbox at the end of the day. By using spam terror organization will spread the knowledge of creating dangerous weapons, as technology is getting better and better the task of creating explosives is getting to be unbelievably simple in a way that teenagers can easily build explosives and activate them, Moreover spam can help coordinate between people who do not interact directly and by that increase the level of the terror actions and the public insecurity and fear. Finally we showed a few actions that can be taken in order to fight the phenomena of spam terror.

The Use of Information Technology by Government in Combatting Disasters: Lessons from Katrina

Laura Lally, Hofstra University, Hempstead, NY 11549; E-mail: acslhl@hofstra.edu

ABSTRACT

In August, 2005, Hurricane Katrina caused a massive loss of life and destruction of property on the Gulf Coast of the United States. This paper examines the role Information Technology can play in predicting disasters, and in mitigating the impacts of those that do occur. The analysis indicates that available IT resources were not used to their fullest potential in the case of Hurricane Katrina.

Keywords: Crisis Management, Information Technology, Post 9/11.

INTRODUCTION: USING TECHNOLOGY TO COMBAT DISASTERS

The Post 9/11 environment has been characterized by an increased emphasis on disaster planning on the part of national and local governments. Government funding for new technologies aimed at combating terrorist attacks has resulted in a wide range of new initiatives. Additionally, there has been an increased public awareness of the potential for disasters, not only from terrorist attacks, but from accidental failures such as blackouts, and natural disasters such as hurricanes. This paper will argue that many of the evolving technologies for countering terrorism can also be used to help inform and protect citizens from large scale accidents and natural disasters as well. Information technology can provide governments with a means of: 1) educating their citizens about the likelihood of the occurrence of a potential disaster, 2) disseminating up to the minute information about any disasters that are immediately threatening, 3) mitigating the impact of disasters through evacuation planning, health care availability, and emergency food and water supplies and 4) recovering from and rebuilding after the disaster has happened.

In August 2005, Hurricane Katrina hit the Gulf Coast of the United States, causing over 1500 lives to be lost and irreparable damage to many homes, businesses, and unique historical landmarks. This paper will provide an analysis of this devastating event and analyze how information technology could have been used to mitigate the impact of this disaster, and to prevent future hurricanes from having as severe an impact. A disturbing revelation in the aftermath of Katrina was that many of the IT based strategies that were available were not used, or were used and the results not acted upon. Local, state and federal government did not respond as citizens of a highly technologically advanced society would have expected them to.

The results of the analysis will indicate IT based strategies for predicting future natural disasters, informing the public about their likelihood and the most appropriate response, mitigating their impact, and helping urban environments recover and rebuild.

LEARNING FROM HURRICANE PAM

Unlike terrorist attacks, which rely on surprise, hurricanes and most natural disasters can be predicted before they occur and tracked with enough lead time to allow evacuation. In the case of terrorist plots, information gathering on suspects must be balanced against civil rights violations. Natural disasters do not need their privacy protected. Therefore, IT based information gathering can be used to the fullest extent possible. IT based radar systems can illuminate developing storms, and IT based simulation models can give managers and government leaders experience with "virtual disasters" that can help them prepare for real ones. Evacuation routines can be designed to ensure that everyone has the time and means to reach safety. Supply chain management systems can be tailored to help relief agencies provide emergency assistance. Supply chain alliances with private sector organizations and individuals to provide emergency relief can be established before emergencies occur.

In the case of New Orleans, simulation models had already predicted that the levees protecting the city would not withstand a Class 3 hurricane and weather experts had predicted that a hurricane of such force was well within the realm of possibility. National Geographic magazine in October, 2004 published an article called, "Gone with the Water," which included the following warning (Bourne, 2004, p. 100):

...The doomsday scenario is not far-fetched. The Federal Emergency Management Agency lists a hurricane strike on New Orleans as one of the most dire threats to the nation, up there with a large earthquake in California or a terrorist attack in New York City. Even the Red Cross no longer opens hurricane shelters in the city, claiming the risk to its workers is too great.

Also in 2004, a computer simulation of a hurricane, called Hurricane Pam, was developed as an exercise for dealing with a major hurricane in New Orleans. The result was widespread devastation (Brinkley, 2005, p. 18):

270 officials from all levels of government did participate in a FEMA-funded week long simulation of a Category 3 Hurricane striking New Orleans, a fake but very realistic storm called Hurricane Pam based on extensive models developed at Louisiana State University. The primary assumption of the Hurricane Pam exercise was that "Greater New Orleans is inundated with ten feet of water within the levee systems as a result of a Category 3 or greater hurricane." The attendees learned that it would not be just water, in fact, but a "HAZMAT gumbo." They heard that the total number of people left stranded in the toxic water "may approach 500,000" if residents didn't evacuate. And they were further informed that a monstrous storm such as Pam would leave 30 million cubic yards of debris—not counting human remains—spread out over 13 parishes in Southern Louisiana.

Local government leaders and relief agencies were told to prepare accordingly, but the recommendations resulting from the model were not implemented. "Having lived through Pam for a week, the 270 officials just went home (Brinkley, 2005, p. 19).

For three days prior to Katrina reaching New Orleans, radar models showed the storm approaching and measured its strength. "Surge warriors," such as Ivor van Heerden, had developed sophisticated ADCIRC (advanced circulation) computer models to predict the impact of hurricanes in the gulf. Thirty hours before landfall, experts predicted that there was a strong likelihood of a major disaster, yet a mandatory evacuation was not called for. When major flooding was indicated, van Heerden "forwarded the results to every official at every level of government I could think of " saying a worst case scenario had developed and that mandatory evacuation was necessary (van Heerden, 2006, 41). Only a voluntary evacuation was called for. By the time the evacuation was mandated a day later, there was not enough time to have it implemented.

PREPARE RELIEF EFFORTS BEFORE THE DISASTER OCCURS

On the positive side, private sector organizations, such as Wal-Mart, predicted the seriousness of the storm and began planning the delivery of emergency supplies to areas they feared would suffer the greatest damage. After the initial hit of Katrina, Wal-Mart provided the greatest share of water, food and equipment to stricken areas (Brinkley, 2006, p. 251).

Wal-Mart, the world's largest retailer and America's biggest private employer, stepped up to the plate by offering vast warehouses full of essential supplies to those stricken by the Great Deluge. Under the lighting quick leadership of CEO Lee Scott, Wal-Mart used its muscle to meet the needs of the victims in the three ravaged Gulf States, donating emergency supplies ranging from Strawberry Pop Tarts to Hanes underwear…"Wal-Mart was our FEMA," said Warren Riley of the New Orleans Police department.

Partnerships between local governments and private sector organizations that specialize in supplying customers with the necessities, should be forged before emergencies occur. Supply chain management software, widely used by these large chains, could be modified to help streamline relief efforts should an emergency occur. Volunteering to assist in local emergencies should win large chain stores a great deal of good public relations in their surrounding communities.

Likewise, a number of heroic individuals emerged from Katrina. Individuals within New Orleans with private boats rescued their neighbors. "Far flung American communities galloped to do all they could (Brinkley, 2006, p. 250)", but FEMA denied permission to enter until a chain of command could be established. A database of certified volunteer first responders should be developed so that these individuals can be contacted, transported to disaster areas, and deployed effectively. Good Samaritan legislation needs to be developed to protect volunteers from lawsuits, should their best attempts have negative consequences.

Additionally, private sector initiatives from Amtrak, Marriott, Continental Airlines, and a number of faith based groups were also refused or delayed. Offers of medical support from Cuba, airdropped military rations from Germany, and cash and oil supplies from Kuwait were also refused. Even FEMA subcontractors were put on hold (Brinkley, 2006, p. 250).

Cool Express, an ice company in Blue River, Wisconsin had a standing contract for ice deliveries in disaster situations. Yet the company didn't receive permission to send trucks to the region until 4 p.m. on Monday. By that time, the ice wouldn't even reach the staging area in Dallas until late Tuesday. After that, it would be another eight-hour drive to southern Louisiana.

Disaster recovery alliances with the private sector other countries need to be developed and designed before hand. Simulation modeling of future disasters should include members of these alternative sources of relief.

BECOME FAMILIAR WITH THE LOCAL ENVIRONMENT AND LOCAL CUSTOMS

Rescue efforts in New Orleans were also hindered because rescuers were not familiar with local street names or the location of key relief centers (Brinkley, 2006, p. 258).

The problem the U.S. Coastguard had with FEMA was that FEMA didn't know the local geography or place names or wards of New Orleans. They couldn't pronounce Tchoupitoulas (choppa-too-liss) Street, let alone spell it. They couldn't cross over the Crescent City Connection bridge because they thought it was a shuttle service to Houston.

GPS systems should be developed and used before a disaster to help relief workers navigate an area and reach important destinations effectively. Alternative routes can also be developed if part of an area is under water, or otherwise inaccessible. Simulation models need to be tailored to the social and cultural environment of the disaster.

An enhanced knowledge of local customs and language would also aid rescue workers. An economically and culturally diverse urban area, such as New Orleans or New York consists of a number of different subcultures. Differences in language and attitudes toward authority figures such as police and government officials made rescue efforts in New Orleans more difficult. Government officials need to be aware of the various languages spoken in an urban area so that warnings can be issued in appropriate languages. Internet access must be available to all citizens so that emerging threats can be delivered on a timely basis. Rescuers need to be aware of social customs regarding approaching strangers in a non-threatening manner. Language translation software and simulation modeling of social interactions developed for soldiers in Iraq, needs to be tailored for first responders confronting diverse social groups in their own country.

DIRECTIONS FOR FUTURE RESEARCH

This analysis will be extended and enhanced by including a wider range of sources about the disaster, and more concrete descriptions of IT based tools that can be used to predict, prevent and prevail over future disasters. Post Katrina initiatives will also be examined and evaluated.

Degrees of Delight: A Model of Consumer Value Generated by E-Commerce

Laura Lally, Hofstra University, Hempstead, NY 11549; E-mail: acslhl@hofstra.edu

ABSTRACT

This study proposes a model of Web applications to guide designers of the next generation of Web based businesses. This study will draw upon the Theory of Consumer Involvement, exploring the implications of consumer involvement in designing appropriate applications. The theory will be extended to create a four part Consumer Value Model—based on four different kinds of value a site can deliver. Implications for Web site development and design, Critical Success Factors for sites delivering each form of consumer value, and the appropriate business model for making each type of site profitable will result.

Keywords: Consumer Involvement theory, Critical Success Factors, Consumer Value Model, E-Commerce, High Engagement, High Product Involvement, High Purchase Involvement, Low Engagement, Web site design.

THE NECESSITY OF PROVIDING CONSUMER VALUE

After an exciting and tumultuous first decade, E-Commerce has experienced a wide range of successes and failures. Designers of next generation Web based businesses need to know which applications will provide value to customers and profits to the businesses that create them.

This paper proposes a new perspective, the Consumer Value Model **(CVM),** that distinguishes the *types of value to the consumer* provided by an E-Commerce application, and argues that it is only by providing one of these types of value to customers that an E-Commerce site can *generate business value* to the creators of the Web based business.

This study will draw upon the Theory of Consumer Involvement from the field of Consumer Behavior in Marketing and develop a Consumer Value Model **(CVM)** based upon the type of underlying involvement with the product or service offered by the Web site. This approach is in contrast to earlier studies that focused on the consumers' involvement with Web use in and of itself. The result of the analysis will be a four-part model of consumer value that will have implications for the Critical Success Factors of Web site development and design, and the appropriate business model for making the site profitable.

This paper will argue that a *consumer value* oriented approach to technological development will provide valuable insights. Allen (2003) argues that the search for applications that provide value to users can be more important than technological innovations.

Furthermore, a given user may interact with a computer in a number of different roles and contexts, giving web designers alternative means of providing value to the same consumer. Users may learn the details of a player trade on their favorite sports team, seek important information for buying a home, conduct routine transactions like bill paying, or pass time playing a game, through the same computer. Roussos, Peterson, and Patel (2003) argue that each user assumes a number of identities when interacting with a computer and that each identity must be managed.

THEORETICAL PERSPECTIVE: INVOLVEMENT THEORY

This study will draw on *Involvement Theory* from Consumer Behavior research to inform the analysis. A consumer's involvement with a product can be defined in terms of, 'the degree of personal relevance that the product holds for the consumer. Under this definition, high involvement purchases are those that are very important to the consumer and thus provoke extensive information processing' (Schiffman & Kanuk, 1999, p. 186). Consumer behavior further distinguishes between *product involvement,* which occurs when the consumer finds the product inherently meaningful and enjoyable, and *purchase involvement*, which occurs when a consumer takes an interest in the details of a product because he or she is making an expensive or risky purchase. *Low involvement* products tend to be commodities which consumers find neither fascinating nor risky. Although a number of studies (Venkatesh, 1999, Agarwal & Karahanna, 2000, Novak & Hoffman, 2000) addressed user's involvement with computer use and Internet surfing per se, Lally (2003, 2004) first addressed the idea of studying users' involvement with the underlying product or service as a determinant of Web site success. Lally (2003,2004) argued that the typical Internet user doesn't surf the Internet because they find computers or the Internet inherently fascinating but because the Internet: 1) allows them to interact with something they do find fascinating, 2) helps them gather information for important purchases or other major decisions, or 3) allows them to conduct routine transactions in a convenient and efficient manner. Her results indicated that users seeking serious information versus entertainment require fewer of the immersive features provided by multimedia, but require more timely, accurate content.

HIGH PRODUCT INVOLVEMENT: PROVIDE HEDONIC VALUE

Goods for which consumers develop high degrees of product involvement include high end stereo equipment, automobiles, music, art, and movies. Celebrities and sports teams can also generate high levels of involvement among their fans. Customers become educated about the product and enjoy discussing it with others. They find visiting retail outlets for these products inherently enjoyable, even if they are not planning an immediate purchase. This intrinsic pleasure in shopping is called *hedonic value.* Customers willingly devote time and attention to learning about the details of the product and develop sophisticated levels of knowledge. When they do make purchases, customers are willing to pay a premium for products whose characteristics suit their personalities and satisfy their tastes.

High product involvement goods are typically sold in retail outlets where they are displayed in an attractive and involving manner to increase hedonic value. Sales representatives need to be well informed about product features. Educating potential customers and interacting with already knowledgeable customers is part of their job. Because these products tend to have a strong visceral component, customers are often given the opportunity to interact physically with the product before making a purchase.

In E-Commerce, Web sites targeting consumers with high product involvement must confront the limitations of the on-line shopping experience. Consumers cannot physically experience the products as completely as when they are in a retail outlet. As bandwidth limitations become less of a constraining factor, however, Web designers can use multimedia to compensate for the lack of physical presence. Lui, Arnett, and Litechy (2000) suggest that Web designers should aim to create hedonic value for users by making sites playful and engaging. High quality graphics, sound, and animations can provide virtual experiences that consumers find inherently enjoyable. On-line experts can provide advice about products. User groups can provide the enjoyable experience of discussing the products with others. High end auction houses have found, for example, that customers will purchase very expensive works of art over the Web if they can view details of the artwork through high quality graphics, and interact with art experts to become more informed about their potential purchase.

Because High Product Involvement addresses an enduring personal interest on the part of consumers, a *subscription revenue model* is most likely to be successful.

Users are likely to return to sites over and over again, just as they look forward to new issues of magazines on their favorite subjects. Therefore, content must be continually refreshed to provide new experiences with the desired product.

HIGH PURCHASE INVOLVEMENT: INFORM RATHER THAN ENTERTAIN

Unlike consumers with high product involvement, consumers with high purchase involvement do not find their product inherently enjoyable. Instead they invest time and attention because the product is important, expensive and/or risky. High purchase involvement goods include information about buying a home, medical information when they or a loved one need medical help, and financial investments.

When shopping for high purchase involvement goods, consumers want access to essential facts to help them make important or risky decisions. They willingly engage in extensive information processing to help them make the right decision. For managers of Web sites for these products, involvement theory suggests that the emphasis be put on informing, rather than entertaining the consumer.

For consumers making one time important purchases such as buying a home, a fee for content business model would most likely be the most successful. Unlike the case with High Product Involvement, High Purchase Involvement does not represent an enduring interest in a product, so users would be less likely to want to subscribe on a long term basis.

LOW INVOLVEMENT PRODUCTS: MAKE IT QUICK AND SIMPLE

Low involvement products, in contrast, do not personally engage the user. Cash from automatic teller machines, soda from vending machines, and office supplies are examples of products that customers seek out of necessity, not because they find the shopping experience inherently enjoyable. Customers prefer 'limited information processing when the purchase is of low personal relevance' (Schiffman & Kanuk, 1999, p. 186). Involvement theory suggests that an efficient purchasing process is the quality most valued for these products. Kaufmann and Lally (1994) found, for example, that for automatic teller machines, easy access dominated design features in attracting customers.

A fee for transaction business model would be most appropriate. Users with heavy demands on their time and attention are frequently willing to pay a premium to minimize the time and effort required of them to conduct routine tasks. Usability testing upfront is critical, but once the site is well designed frequent changes and updates are likely to confuse, rather than provide value, to the customer.

Table 1 summarizes the design consequences and business models suggested by the theory of consumer involvement for E-Commerce applications.

The three categories can be characterized as:

- High Product Involvement: High Intrinsic Interest, High Importance.
- High Purchase Involvement: Low Intrinsic Interest, High Importance.
- Low Involvement: Low Intrinsic Interest, Low Importance.

PASSIONS VERSUS PASTIMES: EXTENDING THE MODEL

An examination of the growing proliferation of casual entertainment E-Commerce applications, such as computer gaming and downloading TV shows for iPods, indicates that there exists a fourth category of applications. *These applications provide high intrinsic interest to the consumer, but are not of enduring personal importance*. Consumer based applications aimed at killing time in a pleasant and engaging matter attract a significant number of consumers. This analysis proposes to extend the theory of consumer involvement to include applications that provide this form of value and substitute the terms High Engagement and Low Engagement for the Low Involvement category suggested by involvement theory:

- High Engagement: High Personal Interest, Low Importance.
- Low Engagement: Low Personal Interest, Low Importance.

These sites should charge for the service they provide consumers with a pleasant means of passing the time, either though connect time or usage. As new, more exciting forms of High Engagement applications become available, customers are likely to switch to them, hence the need for constant innovation. Because the degree of personal relevancy of a particular product is low, customer loyalty is likely to be fleeting.

Table 2 extends the categories suggested by the theory of consumer involvement to include High Engagement sites.

Table 1.

	Critical Success Factors	Business Model
High Product Involvement	Media rich immersive interfaces	Subscription
High Purchase Involvement	Timely, accurate information	One time fee for individuals. Subscriptions for business.
Low Involvement	Quick efficient transactions	Fee for Transaction

Table 2.

	Critical Success Factors	Business Model
High Product Involvement	Media rich immersive interfaces—high quality information conveyed through a range of media—fascinate user continually over long periods of time.	Subscription
High Purchase Involvement	Timely, accurate information, facts conveyed clearly—inform users for important decisions.	One time fee for individuals. Subsciptions for business.
High Engagement	Media rich interfaces to hold users attention over immediate time period.	Fee for Connect Time
Low Engagement	Quick Efficient transactions simple interfaces—minimize users transaction costs.	Fee for Time Used.

CONCLUSION

This paper has presented a model of consumer value, for understanding the motivations behind consumer adoption of E-Commerce applications, what features are most appropriate and what business models apply. Empirical studies will follow to address the applications of the model to next generation Web Applications.

Pervasive Computing: The Cause for Including Mobile Application Development in Undergraduate IS Curriculum

Kathryn A. Marold, Metropolitan State College of Denver, Campus Box 45, P.O. Box 173362, Denver, CO 80212, USA; E-mail: maroldk@mscd.edu

INTRODUCTION

Computing for the end user has changed dramatically with the shrinkage of the personal computer and the availability of wireless connections. Not only is the Web ubiquitous and the Internet universally available, but the saturation and the size of the hardware used for personal computing has changed as well. What is commonly referred to as mobile computing has changed application development. Users have moved from cabinet-sized desktop computers to laptops and notebook computers, to personal digital devices, Palm Pilots, Blackberries, Pocket PCs, and finally to smart phones. Cell phones with Internet access and various software applications in addition to established telephony software are now common. The situation of ever-present computing power in all aspects of our lives has become known as *pervasive computing* (Bergeron, 2001.)

The importance of teaching our IS majors with modern GUI software programming tools that use new Java and .NET programming languages is well-recognized in most American computer information systems departments granting undergraduate degrees. However, teaching IS majors programming that can be ported to smart devices and interfaces with Web services that are accessed wirelessly is relatively new. The importance of new IS graduates knowing how to develop appropriate mobile computing applications should not be ignored. IS curriculum for the undergraduate should include programming for mobile devices. This gives our new graduates more competitive employment opportunities: entry level IT positions remain competitive, despite slight improvements in the job market (Bureau of Labor Statistics, 2006.)

The required programming course(s) in most undergraduate IS programs has always concentrated on the basic logic and programming techniques needed for entry level positions in industry. And that is still true: there is no substitute for basic problem solving methodology, design tools, logic of basic constructs, and rudimentary coding skills. Yet when employers advertise available positions, they almost universally request specific skills. Academics know that keeping current in IT curricula is a constant struggle, but one with definite paybacks. Keeping programming language curricula current has never been easier, or more rewarding. It *is* possible to teach mobile computing applications in our programming courses, and thus give our students experience in programming for a pervasive computing environment.

When GUI tools and IDE's (integrated development environments) became common, the old command-line instruction and heavy emphasis on syntax gave way to teaching modern fourth and fifth generation programming languages that were object oriented. *Cobol* was replaced by *C*, then *JAVA* and/or *Visual Basic*, and *C++* . Building console applications with a *C* compiler within *UNIX* often was replaced with building *Windows* applications within microcomputer operating platforms. Attention to user interface and connecting to data sources for database file processing and more robust transaction processing systems became a reality within undergraduate programming courses. The RAD (rapid application development) tools available provided an environment where students could do more in-depth programs within a semester time-frame. Next, development of Web-based transaction processing systems as well as *Windows* applications was possible when programming suites were introduced. The same opportunity now exists for students to develop Web services and applications for Smart Mobile Devices such as Pocket PCs and cell phones, using the emulators built into programming suites. Students in an existing programming class at Metropolitan State College of Denver used Pocket PCs with wireless access to develop smart device mobile applications while learning to program in *C#.NET*. The response was positive, the programs were relevant and immediately useful, and the experience obtained with WI-FI (wireless fidelity) and mobile devices were true resume builders.

DISTINCTIONS WITH MOBILE COMPUTING APPLICATIONS

The interface of modern programs is vastly different from the command-line interface of the mainframe and early microcomputer days. Text-based systems are scarce today, and are foreign to most computer users –even those in the IT industry. The early GUI appearance of application programs has evolved into a Web-like interface. Ample RAM, high resolution devices, and faster processors have given us the luxury of highly sophisticated multimedia interfaces. The smart device programs that students learn to program must take into consideration the audience using them; they are culturally, occupationally, and geographically dispersed. Blom, Chipchase and Lehikoinen conducted extensive research on contextual and cultural challenges for Nokia, Inc. (2005.) They studied the length of typical smart device use, the cultural idiosyncrasies, the personal nature of the use, the privacy and security concerns of users, the use of smart devices while commuting, walking, sitting in meetings, on public transportation—even use while driving or cycling. In 1997 Page developed a model of requirements for *Windows* mobile-based products (2005). There is a profile for the typical smart device user.

Nokia was a pioneer of smart mobile device applications. The designers of their third party application software deemed the most important aspect of the design was to provide the user with feedback. The use of cell phones and smart mobile devices by a younger population drove the user requirement for a very visual application. The proliferation of ring tones, IM (instant messaging), text messaging, and the exchange of digital photos and video by cell phone users confirm Kangas and Kinnumen's multimedia recommendations (2005.)

Sprint, Inc. holds that previously there were two basic consumer screens: the TV and the PC. In 1999 they set out to develop a third—the mobile phone screen (Balaji, 2005.) Done correctly, it would evolve into the most used personal screen, since users would use the same device—a variety of the smart phone—to communicate, to access the Web, to view TV and movies, and to compute. One device would be used individually for all computing and communicating uses; it would be small and mobile. The PCN (personal communications network) that was advocated in the late 1980s would be common by 2010 (Marold, 1996.)

THEORETICAL UNDERPINNINGS OF TEACHING MOBILE APPLICATIONS

As Roger Schank points out, scholars from Aristotle, to Galileo, to Dewey, to Einstein have concurred that real learning is by doing (2001a). We learn when we need to use the concept, and we understand when we physically perform the steps toward mastery (Schank, 2001b). Learning by doing with mobile devices is nearly impossible to implement in a traditional college computer lab setting.

However, when a disconnected practice environment is provided, when each student is responsible for his/her own server and Pocket PC, when the student has enough exposure for a comfort level, application development for mobile devices can be successful. Mobile devices and wireless connectivity are integral to the learning process. Bergeron notes that the majority of mobile technologies simply fit into the process of everyday business and personal life. If they do not fail unexpectedly, they fade out of conscious existence (2001).

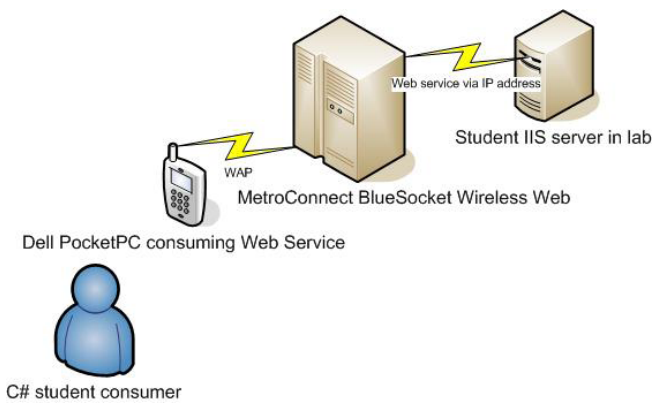
Adapting for programming instruction in mobile smart device applications requires some adjustments and some capital outlay for the institution. A special needs lab for information systems majors at Metropolitan State College of Denver was completed five years ago (Fustos, 2004). Once the lab was in operation, the potential for teaching mobile applications and Web services was evident. The programming software, the IIS (Internet Information Services) server software, and development stations were already there. All types of hand-held devices, from Palms and PDAs, to Blackberries, to cell phones have become less expensive (Tam, 2005). The prototype applications students build can give IS majors a "feel" for what modern programs they will be designing for the industry.

DETAILS OF PROGRAMMING FOR MOBILE DEVICES

Using computer labs to teach programming classes is recognized as an optimal setting—provided that the environment can be controlled. Metro's special needs lab has twenty stations in the lab, giving students plenty of room to work. There is an instructor station with display equipment and "smart classroom" touch pads that are easy to use. The instructor station controls all student client stations with *SynchronEyes* software. This allows the instructor to lock stations, broadcast the instructor monitor to all stations, and display any student client machine at any time—either to the whole class, or individually and privately. Students can work along with the instructor in interactive sessions, or easily follow an instructor demonstration or *PowerPoint* presentation on their monitors.

The added expense for this class was the purchase of twenty Dell Pocket PCs with WI-FI capability, so that the Pocket PC could serve as a client and wirelessly access the student desktop computer station as its server. Development for all applications, whether Web applications or not, was on the desktop station using the *Visual Studio.NET 2003 Professional* software. The installation of *ActiveSync* software allowed students to move their applications to the Pocket PCs from their server computers using a USB (universal serial bus) connection—a simple drag and drop operation. The special needs lab computers have an additional removable hard drive where students have all privileges and may develop Web applications using IIS (Internet Information Services). The students programmed their Web applications to use the IP (Internet Protocol) address of their own servers for the Web reference, allowing them to wirelessly consume a Web service. (Although there is a Pocket PC Emulator built into the *Visual Studio.NET Professional*, the value of being able to port programs to individual mobile devices and use WI-FI 802.11.B technology to access servers cannot be underestimated.) The class could experiment with wireless technology—WI-FI, infrared beaming, and Bluetooth short distance FTP, all of which were included on the Dell Pocket PCs. The exposure to pervasive computing included projects that were developed within the semester-long class: there were independent smart applications, mobile Web pages, and creating and consuming Web services. Figure 1 shows how this was done.

Figure 1. Using WI-FI to consume Web services with pocket PCs



DISCUSSION

The existence of the campus wireless BlueSocket Web site simplified the process of using the Pocket PCs to connect to the student lab servers. In 2004 Metro installed Wireless Access Points(WAPs) on campus. BlueSocket is heavily used by students with laptops. Therefore, students in the C# class could simply login to the BlueSocket site with their Pocket PCs, and then connect to their individual lab servers via the IP address. The simplicity of the hardware connections allowed them to concentrate on the software—the programming content of the course. Aside from the security of their assigned lab servers and their vulnerability to modifications or removal of their programs (backups were constantly stressed), student implementation was optimal. Students were responsible for programming their own applications and maintaining their own Pocket PCs. They were kept in a locked cabinet in the lab, and checked out as needed. After the instructor corrected student programs and assigned grades for them, the Pocket PCs were returned and reset for reuse. The servers are on removable drives in the lab. They are re-imaged every semester, so there is a fresh start with the desktop computers as well. The use of WI-FI and Pocket PCs for the course allowed students to learn programming using the C# programming language in a three-tier architecture. It also exposed them to three popular wireless methodologies.

CONCLUSION

Incorporating mobile computing into the information systems curriculum at Metropolitan State College of Denver has received accolades from instructors, students, administration, and potential employers. Pervasive computing that has become the *modus operandi* of our society dictates an adjustment in how we educate our future information technology workers. Experience with wireless application development with smart mobile devices is another step toward keeping information systems curriculum current.

Round-Tripping Biblical Hebrew Linguisitic Data

Jan H. Kroeze, University of Pretoria, Pretoria, 0002 South Africa; E-mail: jan.kroeze@up.ac.za

1. INTRODUCTION

In processing language electronically, one can either concentrate on the digital simulation of human understanding and language production, or on the most appropriate way of storing and using existing knowledge. Both are valid and important. This paper falls in the second category, by assuming that it is useful to capture the results of linguistic analyses in well-designed, exploitable, electronic databanks. The paper focuses on the conversion of linguistic data of Genesis 1 between an XML data cube and a multidimensional array structure in Visual Basic 6 in order to facilitate data access and manipulation.

2. RELATIONAL DATABASE TECHNOLOGY VS. XML TECHNOLOGY

If the linguistic data of Genesis 1 were to be captured in a typical relational database, organised according to clauses as records in rows, and according to linguistic categories as logical attributes in columns, the word order of the elements in the clauses would be lost. One could, of course, store the positions of the words or phrases in a separate table and use a system of primary keys, foreign keys and joins to reassemble the original text, but this would cause much overhead (cf. Bourret, 2003).

Since the tables in traditional two-dimensional relational databases consist of rows and columns implying a maximum depth of two levels (Jeong & Yoon, 2001), one could only capture information of one linguistic module in a row without losing coherence. However, even if only the analysis of one linguistic module were captured in a table, it would be sparsely populated. One would therefore need multidimensional data storage facilities in order to find a better solution.

This paper, therefore, investigates XML technology to mark up free text, because it allows the hierarchical and multidimensional organisation of data. This data can be transformed into a three-dimensional array, processed by a computer program and saved back to XML for storage or transfer. Furthermore, XML was chosen because it is itself text-based and intuitively provides a suitable means to capture linguistic, textual data. It is very simple to use and does not require a high level of programming skills. An XML file is also platform independent and can be used by various programming languages and other software packages.

3. THE STRUCTURE OF THE DATABANK

3.1 The Structure of the Databank in XML

An XML document comprising of the text and markup of Genesis 1 may be regarded as a native XML database while a VB6 program that manipulates the data may be regarded as a content management system (cf. Bourret, 2003). The structure of the databank in XML for this project is built on the hierarchy as shown in Figure 1.

A complete discussion of the use of XML to build the Genesis 1 linguistic data cube may be found in Kroeze (2006a).

3.2 The Structure of the Databank in VB6

Although a lot of processing, such as indexing and searching, can be done directly on XML documents, one often needs a program to do more ambitious analyses (cf. Burnard, 2004). Visual Basic 6 (VB6) was chosen to perform this role with a view to this project, because XML is essentially a hierarchical system which fits the three-dimensional array data structure facilitated by VB6 perfectly.

Figure 1. Hierarchy underlying the XML databank containing linguistic data of Genesis 1

Hebrew Bible	- not used in this study
Bible Book	- not used in this study
Chapter	- root element in this study: <Genesis1>
Clause	- each clause represented by one table: <clause>
Clause Number	- each clause's ID: <clauseno>
Table Headers	- headings for each column: <headers><header>
Language Levels 1-5	- the various modules of analysis: <level1> ...
Level Description	- description of module per row: <leveldesc>
Phrases 1-5	- the word groups in a clause: <phrase1> ...

When converted into VB6, the databank module consists of a multidimensional array data structure. Multi-array data storage is one of the two main ways of implementing data warehouses (Wang & Dong, 2001). Typical data warehousing processing that may be performed on the clause cube using arrays and loops has been discussed in Kroeze (2004b). A multidimensional array structure is very suitable for a limited data set, such as the data in this project, due to its built-in indexing. Multidimensional online analytical products (MOLAP) "typically run faster than other approaches, primarily because it's possible to index directly into the data cube's structure to collect subsets of data" (Kay, 2004). The VB6 program discussed in this paper may be regarded as a simple MOLAP tool.

The three-dimensional array in VB6 contains records of 108 clauses. Each clause has five or less phrases. Each phrase potentially has five levels of analysis. One

Figure 2. The first unit in the three-dimensional array populated with linguistic data from the first clause in Genesis 1

```
Option Explicit
Public Clause(1 To 108, 1 To 5, 1 To 6) As String
Sub Main()
Clause(1, 1, 1) = "Gen01v01a"
Clause(1, 1, 2) = "bre$it"
Clause(1, 1, 3) = "in the beginning"
Clause(1, 1, 4) = "PP"
Clause(1, 1, 5) = "Adjunct"
Clause(1, 1, 6) = "Time"
Clause(1, 2, 1) = "-"
Clause(1, 2, 2) = "bara"
Clause(1, 2, 3) = "he created"
Clause(1, 2, 4) = "VP"
Clause(1, 2, 5) = "Main verb"
Clause(1, 2, 6) = "Action"
Clause(1, 3, 1) = "-"
Clause(1, 3, 2) = "elohim"
Clause(1, 3, 3) = "God"
Clause(1, 3, 4) = "NP"
Clause(1, 3, 5) = "Subject"
Clause(1, 3, 6) = "Agent"
Clause(1, 4, 1) = "-"
Clause(1, 4, 2) = "et ha$amayim ve'et ha'arets"
Clause(1, 4, 3) = "the heaven and the earth"
Clause(1, 4, 4) = "NP"
Clause(1, 4, 5) = "Object"
Clause(1, 4, 6) = "Patient"
End Sub
```

level of analysis is added to record the verse number as primary key for reference and searching purposes. An array of 108 x 5 x 6 is used to implement this data structure. If manually populated with data, the first clause could be coded as shown in Figure 2.

A complete discussion of this structure may be found in Kroeze (2004a). The same structure is used in this project to convert the data captured in the XML document into the VB6 array.

4. CONVERSION BETWEEN VB6 AND XML (ROUND-TRIPPING)

One of the advantages of an XML databank is the separation of the data and the manipulation thereof. The same data can be used for various purposes. An XML document in itself is not very reader-friendly. Therefore, one needs other software to efficiently process the data in such a repository (Kumar et al., 2005). Conversion is often necessary to make the data accessible for algorithms that implement efficient retrieval and human-friendly interfaces (cf. Ramsay, n.d.; cf. Witt, 2005).

If data is represented in a different format, it should first be parsed by an application. In our experiment, the data should be represented in an interlinear format which is easier to read. This necessitates that the VB6 program reads the data into an array in order to be printed as a series of linear tables on the screen. Removal of the XML tags restores the original text so that the layers of analysis become more comprehensible.

The conversion to and from XML format is called round-tripping. Round-tripping is the circular process of storing document data in a (XML) database and recreating the document from the database, a process which could result in a different version of the original document (Bourret, 2003). In this experiment round-tripping refers to the process of converting the Genesis 1 XML document to the three-dimensional array structure in VB6 and saving it again in XML format. If no changes are made while the data resides in the array, the resulting XML document should be an exact copy of the original (*ideal* round-tripping - Smiljanić, Blanken, Van Keulen, & Jonker, 2002). However, the array phase should facilitate updates to be made, which should also be reflected in the resulting XML document. Due to the limited scope and length of this paper, no program code is presented here.

4.1 From XML to VB6

All data in an XML document is text. The markup itself is also text only (Huitfeldt, 2004). For a linguistic database this creates no problem, since it also contains text data only. Therefore, in VB6 all the variables of the three-dimensional array are also of type *string* only. The limitation of arrays that all the elements should be of the same type (string, integer, boolean, etc.) therefore poses no problem. To strip the XML code from its tags, much string processing is performed (cf. Petroustos, 1999).

The easiest way to convert the Genesis 1 data would be to ensure that empty elements (e.g. where a clause has less than five noun phrases) are represented by a dash (-).The loop that reads the data cube elements into the three-dimensional array can then simply assume that the next line in the XML document will be the next element in the data structure. Not all phrases have syntactic or semantic functions and these missing elements may also be rendered by a dash. This simple implementation is used in this experiment, because it also ensures that the XML document is an exact copy of the original document after ideal round-tripping.

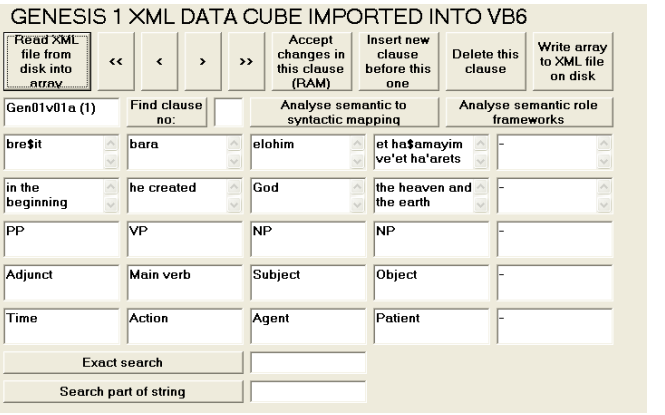
Although validation is usually done by means of a schema, it could also be performed here during the conversion process. In a subroutine the tags are first stripped and the remaining data tested against a standardised list of valid entries (e.g. syntactic and semantic functions) before it is transferred to the array. To show the contents of the array, the elements of each clause are displayed in a series of textboxes. When the program is run, the interface looks as shown in Figure 3.

Advanced data mining may now be performed on linguistic data stored in the three-dimensional array. Compare, for example, Kroeze (2006b) for a study of the semantic role frameworks extracted from Genesis 1.

4.2 From VB6 to XML

The conversion of the content of the three-dimensional array in VB6 to XML is more or less the reversal of the above process. While it is not necessary to perform validation again, string processing is used to convert the variables to lines of text

Figure 3. Interface used to render, process and round-trip linguistic data stored in a three-dimensional array and XML data cube



wrapped in applicable XML tags. The structure of the XML schema must be strictly adhered to in order to create a file that can again be read into VB6. In order to keep the test data intact, the current date and time could be added to the name of the output file so that a different XML file is created each time the button "Write array to XML file on disk" is pressed. If one wants the output file to have the same name as the input file (as in ideal round-tripping) that part of the code should be changed by replacing the name of the output file with the name of the input file.

5. CONCLUSION

This project proposed a database solution for the capturing and use of linguistic data. The paper focused on the conversion of linguistic data between an XML document and an array structure in VB6. After referring to the data structures in both XML and VB6, a method was discussed to round-trip the linguistic data between these software formats. One may conclude that these technologies are suitable for the efficient storage, transfer and processing of linguistic data.

Towards a Meta-Model for Socio-Instrumental Pragmatism

Peter Rittgen, University College of Borås, 501 90 Borås, Sweden; E-mail:
Diego Armando Obeso Trejo, Tecnológico de Monterrey, 801 00 Culiacán, Mexico; E-mail:

ABSTRACT

We claim that a general conceptual framework for the IS field should provide some kind of common upper-level ontology to describe and explain artifact-mediated social interaction. Such an ontology, Socio-Instrumental Pragmatism (SIP), has been suggested. Our aim is to refine and formalize this ontology by providing a meta-model in the form of a UML class diagram. We discuss the implications of such a model as well as its relation to other ontologies.

1. INTRODUCTION

The rise in the use of information systems (IS) is undeniable, and every day IS become a more important part of organizations. But far from being perfect, the design and implementation of IS in organizations is still a very problematic task that is often fraught with failure (Ågerfalk et al., 2006). There is a need for a better understanding of IS, organizations, and their relation to come up with a framework capable of integrating these two concepts. For the past two decades, theories of communication have been imported into the IS field, and the Language Action Perspective (LAP) has been proposed as a way to understand IS and organizations based on communication (Winograd and Flores, 1986; Goldkuhl and Lyytinen, 1982). Later on an ontology to capture the social world was proposed and described in Goldkuhl (2001), Goldkuhl, Röstlinger and Braf (2001), Goldkuhl (2005), and Goldkuhl and Ågerfalk (2002). This ontology was named "Socio-Instrumental Pragmatism" since it aims toward human actions which are supported by the use of instruments and performed within the social world (Goldkuhl, 2002). Socio-Instrumental Pragmatism (SIP) presents a generic framework which allows for the analysis of the social world. Within this world there are six ontological categories:

1. Humans
2. Human inner worlds
3. Human Actions
4. Signs
5. Artifacts
6. Natural objects

Since SIP was intended as a generic framework which can serve as a base to analyze the social world it is not aimed exclusively at the IS field. We think that a meta-model based on the SIP ontology but with a focus on the IS field is needed. This meta-model has its foundations in both LAP and SIP, and presents a model that will allow us to view organizations and IS together with a focus on actions.

The model consists of the basic categories: actors, objects and actions. In addition to this we also consider other important aspects of organizations that are related to their functioning.

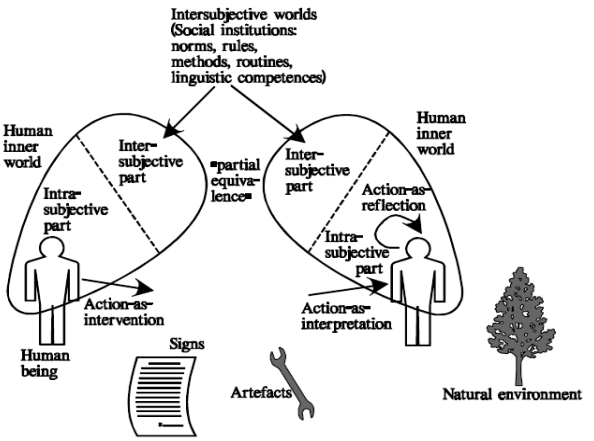
2. TOWARDS A NEW META-MODEL

2.1. Socio-Instrumental Pragmatism

As mentioned before, there is a need for a framework that allows us to describe social systems in a clearer and more thorough way. Our work is based on the SIP ontology. Within the SIP ontology there are six ontological categories (Goldkuhl, 2002):

- **Humans** are the most important participants in the social world described by the SIP ontology; they act in the world based on meanings and perceptions.

Figure 1.



- **Human inner world** represents the knowledge that a human being has acquired over time about themselves and the external world; this inner world is intended to be seen as part of the human being.
- **Human actions** also form a part of the human being; they can be overt, which means that the actions are intended to intervene in the external world, and they can be covert, when they are aimed to change some human being's inner world; covert actions try to change knowledge that is present in the human inner world.
- **Signs** are the result of communicative actions; for instance, when someone writes a note saying, "I will be at the store", the writing of the note is by itself a communicative action but the note created is a sign which will mean something to the person that will read it.
- **Artifacts** are things which are not symbolic and not natural but which are material and artificially created. Examples of artifacts are cars, clothes, a knife, etc. The difference between signs and artifacts is that while signs are intended to mean something to someone (symbolic), artifacts perform material actions. For instance, a human might use a knife (artifact) to cut some carrots, i.e. artifacts are needed to perform material actions.

Natural environment are the objects present in the environment that are not artificially created by humans (e.g. trees).

Figure 1 shows the different realms of the world according to the SIP ontology.

2.2. Meta-Model

Our model is divided into three main categories:

- Actors
- Objects
- Actions

Although we do not see Agent as a category; we do acknowledge the importance of agency and describe it as a special element in the model.

2.2.1. Actors

Actors are the main entities in our model, and they can perform either as locutor or addressee within a communicative context. When actors perform actions directed towards another actor we speak of social actions. They can be performed either in a human-human relation or in a human-artifact-human relation. When performing as locutor the actor is trying to change some aspect of the world by means of his/her actions. For instance, when a person pays the phone bill he/she is trying to avoid the interruption of his/her phone service. When performing as addressee the actor receives and interprets an action directed to him and can act as a consequence of that action. Taking our example the addressee will be the phone company, which at the moment of receiving the payment will not make any attempt to interrupt the customer's phone service.

Besides locutor and addressee we can distinguish between organizational actors and human actors. The former is an actor that performs as an agent on behalf of the organization; the latter performs an action on behalf of his/herself.

2.2.2. Objects

An object may be physical or conceptual and it may be formed by other objects or related to them, but every object is unique (Embley, Kurts and Woodfield, 1994). Under the object category we have artificial and natural objects. Artificial are those created by human beings, while natural objects are those created by nature and found in the environment. Among artificial objects we have artifacts (material objects) and signs (material or immaterial). Artifacts are created to extend actors' capabilities and are seen as tools. Signs on the other hand are not tools but messages in a static phase waiting to be interpreted by actors or artifacts. A message can take either a physical form (a written text) or a non-physical form (an utterance) (Goldkuhl, 2002).

We can distinguish between 4 different types of artifacts: static, dynamic, automated and multi-level. Static artifacts are those that cannot perform any operation by themselves, e.g. a stone or an axe. Dynamic objects are those capable of performing some operations by themselves but they need constant control by a human being to function properly, for example a car or a driller. Automated artifacts are those that can operate entirely by themselves and only need to be started by an actor. Here we can mention a washing machine as an example. (Goldkuhl and Ågerfalk, 2005).

Multi-level artifacts are those that have a mix of capabilities and can perform either as static, dynamic or automated artifacts depending on the circumstances. They have an important property which is the capability of creating and interpreting signs, they lack consciousness and are ruled by a pre-defined set of instructions that serve as a guide to perform the pre-defined actions they do. IT systems are an example of multi-level artifacts. Signs can be created either by human beings or artifacts, and every sign can be interpreted by human beings only, by artifacts only, or by both (Goldkuhl, 2005). A written note is a sign, an utterance performed by an actor is another example of a sign as well as a ticket printed by a system in an electronic store.

2.2.3. Actions

The objective of human actions is to change something in the world. Actions can be communicative or material. The main difference between these two types of actions lies in the fact that communicative actions are intended to change knowledge. Knowledge is implicitly meaningful to someone; and knowledge handling is an exclusive characteristic of actors within an IS. On the other hand, material actions are aimed at material conditions and aspects of the world which are meaningful to someone. They are intended to change something physical among the external world. Winograd and Flores (1986) stated that language is prior to consciousness, and we might add that consciousness is prior to actions performed by actors. As a human characteristic, knowledge can be learned through actions, either communicative actions (e.g. a conversation) or material actions (e.g. when studying an object). Knowledge is the result of the actor's interpretation of both communicative and material actions, and it can be acquired in a social context from other actors transferring knowledge (e.g. in a classroom) or in a non-social context (a person reading a book on his/her own) (Goldkuhl, 2001).

We can divide actions into i-actions (intervening actions) and r-actions (receiving actions). I-actions are those intended to make a change in the external world. For instance, the action of opening a window is intended to change a particular aspect of the external world (the window will move from close to open). R-actions are those executed covertly, for example when two people are going out and person A tells B "It's cold outside" (communicative i-action). Person B listens and interprets the message (r-action) and maybe after that person B will take a jacket on the way out (material i-action) (Goldkuhl, 2001). Among i-actions and r-actions we have indefinite and predefined actions. Indefinite actions are those performed by humans and we call them indefinite since it is not certain how they will be performed by the actor. The same action can vary from actor to actor. When two employees are ordered to clean a shelf, they will both do it but not in the same way, one can do it better or faster than the other one. Indefinite actions can be either r-actions or i-actions. A person that executes indefinite actions has the capability of performing both, i-actions and r-actions. For example, cleaning the shelf is clearly an i-action, the person is modifying something external, something physical. However, we can also find indefinite actions that execute covertly, for example, the person interpreted the order (covertly) and then started to clean the shelf.

We also have pre-defined actions which are performed by artifacts. These actions will always be performed in the same way following previously programmed instructions (Goldkuhl, 2005). Pre-defined actions are i-actions, since they are intended to change an aspect of the external world. Among indefinite actions we can find both, communicative and material actions, and among pre-defined actions we will always have material actions, sometimes with communicative intentions. Table 1 shows how pre-defined and indefinite actions can be either material or communicative. Let us take the example of printing a sales ticket. This action is performed by an IT system, it is a pre-defined i-action with communicative intentions. The objective of printing the sales ticket is to give information to the customer, who will interpret the ticket (r-action) in a communicative manner.

Organizational actions can be either internal or external, and material or communicative. Although human beings perform the actions within organizations, we can say that an organization can act. An organizational action has human origins and purposes and is done through humans, by humans or by artifacts that act on behalf of the organization (Goldkuhl, Röstlinger and Braf, 2001). We will consider

Table 1. Pre-defined and indefinite actions

Example	*Performer*	*Type of action*	*Nature of action*	*Intention*
Printing of a sales ticket	IT-system	Pre-defined	Material with Communicative intentions	i-action
Reading of a sales ticket	Customer	Indefinite	Communicative	r-action
Cleaning a shelf	Employee	Indefinite	Material	i-action
Change of the inventory when performing a sale	IT-system	Pre-defined	Material	i-action
E-procurement of goods transaction	IT-systems	Pre-defined	Material	i-action from the buyer, r-action from the seller

that organizational actions constitute an interaction of two or more elements from the organization (actors or artifacts) within an organizational context. A worker at a clothes factory using a sewing machine to manufacture clothes is performing an organizational action. He is acting to perform an organizational objective (to produce clothes). But a man on a farm that goes to the forest to chop wood using an axe, although using an artifact to perform the action, is not performing an organizational action since there is no organizational purpose if he merely burns the wood to warm up his house.

When performing actions by means or with the help of IT systems we can distinguish between three different types of actions: interactive, automatic and consequential actions. Interactive actions are supported by and performed through IS and they consist of one or more elementary interactions. Elementary interactions (e-actions) consist of three phases: a user action, an IT system action and a user interpretation (Goldkuhl, 2001). Let us take the example of an online bank transfer done by a user online. The user will initially introduce his username and password to access the bank system (Phase 1), after this the IT system will check in the database if the information is correct and if it is it will grant access to the user and display a welcome screen (Phase 2). The welcome screen is interpreted, and the user now knows that he can start his transaction. This is the end of the elementary interaction. Later on the user inputs the data to make the bank transfer, such as account number, amount to be transferred, etc. (Phase 1 of a second e-interaction), and so on.

Automatic actions are performed by IT systems that produce messages for the actors or other systems. They are done entirely without human intervention. Taking the bank system again: After logging on a message pops up telling the customer that the due date for the credit card payment is very close. The system will execute this operation by itself and present it to the user.

Consequential actions are those performed as a consequence of a message. In the bank example , when the customer sees that his payment is due he might proceed to execute the payment, or he might decide not to do it and wait for the final day.

Based on these types of IS actions, IS are seen as Information Action Systems. This perspective is called actability. Actability is supposed to reinforce the concept of usability within the IS framework and focuses on action and communication. IS actability is the information system's ability to perform actions, and to permit, promote and facilitate the performance of actions by users, either by means of the system or based on information provided by it in a business context (Sjöström and Goldkuhl, 2002).

The components of the IS are the IT system, the actor and the e-action. IT systems are social systems that are technically implemented and have an action memory which stores the past and future actions. Actors can play the role of communicator, performer or interpreter in the IS.

2.2.4. Agents

Agents are a special type of object; we can position agents between objects and actors. They are created by actors, and perform actions to help them complete their tasks. They can be seen as servants of actors, but they have a level of communicative capabilities that allow them to act as communicative mediators. They are also capable of creating signs for the actors or other agents to interpret. Agents have a transformative capability, a property that human beings have as well. The difference between agents and human beings lies in the fact that human beings can perform both socially aware (such as a conversation) and non-socially aware actions (such as a blink) while agents can only execute the latter (Rose and Jones, 2004).

IT systems can perform as agents. They can be seen as static artifacts, automated artifacts or dynamic artifacts (Goldkuhl and Ågerfalk, 2005). In all three cases the common denominator is communication. Communication is seen as a kind of action that IT systems can perform and by doing so they become communication mediators. IT systems as well as actors have the capability to create signs and to process them. Actors can also interpret them (Goldkuhl, 2001). The relation between the signs and their interpreters is called pragmatics. Within IS pragmatics, actions are divided into those that occur within the sign transfer and consequential actions that are performed in response to the transferred sign (Goldkuhl and Ågerfalk, 2002).

2.2.5. Organizational Actions

Roughly we can say that within an organization every actor acts to fulfill organizational objectives, hence they are agents helping to accomplish organizational actions. In Example 1, we provide an example of how our meta-model can be applied. Let us take the case of an electronics store.

Example 1.

A customer (C) comes into the store and the following dialog with the salesperson (S) develops.

(S): "May I help you?"
(C): "Yes, I would like to buy some batteries."
(S): "Which type of batteries do you want?"
(C): "Rechargeable AA batteries please."
(S): "We have X and Y brands."
(C): "I would like X."
(S) passes the batteries over the bar code reader and says: "10 dollars, please."
(C) pays.
(S) completes the sale in the system and hands the receipt to the customer.

Table 2. Sales process for an electronic store

Actor	*Action*	*Type of action*	*Details*
S	Utterance: May I help you?	Communicative i-action	
C	Utterance: Yes, I would like to buy some batteries.	R-action → communicative i-action	C interprets utterance by S and responds
S	Utterance: Which type of batteries?	R-action → communicative i-action	Dto. (switched roles)
C	Utterance: Rechargeable AA batteries, please.	R-action → communicative i-action	Dto. (switched roles)
S	Takes the batteries and passes them trough the bar code reader.	R-action → interactive i-action	S interprets utterance by C and performs interactive action
IS (Agent)	Reads bar code and gets product information from the database.	Automatic action	IT system performs automatic action and displays product details on screen
S	Reads product information and informs C.	R-action → consequential i-action	S interprets message on screen and passes info to C
C	Pays for the batteries.	R-action → material action	C interprets utterance of S and pays
S	Receives payment and hands C the receipt.	R-action → interactive i-action → automatic action → material action	S receives payment, S closes sale in IT system, IT system modifies inventory and prints receipt, S hands receipt to C

When we analyze this business interaction according to our meta-model we arrive at the results shown in Table 2. We will see organizational actions as those actions performed to fulfill an organizational objective. In Table 2, the objective is to sell batteries. We can also notice that many of the actions are multi-functional, i.e. one "surface" action corresponds to a number of implied, "hidden" actions. When the salesperson asks for the type of batteries, he performs an implicit r-action by correctly interpreting the request "I would like to buy some batteries." At the same time he also responds appropriately by performing the i-action of asking for the type of batteries.

3. OTHER ONTOLOGIES

In the literature we can find a number of competing ontologies that are also potential candidates for a general conceptual framework for the IS field. Social roles, for example, were introduced by Masolo et al. (2004). They characterize social entities only partially and do not cover the issue of actions which is central in the social realm. Intentional collectives (Bottazzi et al., 2006) introduce actions but mainly in the form of plans and tasks. In this model action objects are not seen as an important issue. Nevertheless, this theory has a very detailed description of social concepts based on social roles.

The Actor Network Theory (ANT) (Tatnall and Gilding, 1999) argues for the symmetry of the elements in the social world (i.e., the network of social actors). This means that both actors and action objects are viewed as so-called actants. This implies that we cannot distinguish between the different roles that these elements have in social action (McLean and Hassard, 2004). For the ANT theorists, the elements of the network relay and prolong collective actions, and no element is considered as the source of the actions. Therefore, instead of being actions, they are seen as events. Events are described in the same way as being collective actions that have no source but are performed by the actants of the network (McLean, and Hassard, 2004).

As a result of the contemplations in the previous sections we have developed a meta-model (see Figure 2) that covers the most important aspects of Socio-Instrumental Pragmatism as discussed in the relevant literature. Technically the meta-model takes the form of a UML class diagram with generalization / specialization and association.

4. CONCLUSIONS

We started our paper with the assumption that Socio-Instrumental Pragmatism might contribute towards the development of a general conceptual framework for the IS field. We then set out to capture both the breadth and depth of the SIP literature with a suitable meta-model. This process consisted of uncovering the central concepts and their (often implicit) relations and making them explicit in a clear and concise way. We did this with the help of a UML class diagram, a modeling language which is well established and documented and can therefore be expected to support the communication of and about the meta-model among a large group of IS researchers.

We are well aware of the fact that such a meta-model is not, and cannot be, the ultimate solution to a general conceptual framework for the IS field. However, we think that our model can stimulate a fruitful discussion about the vital components of such a framework. We do not know of any other meta-models that cover the breadth of IT-mediated social action with similar stringency.

Forecasting Trading Rule Performance Using Simulation

Paul Lajbcygier, Monash University, Australia; E-mail: Paul.Lajbcygier@infotech.monash.edu.au

ABSTRACT

We create a generic trading rule and simulate its performance characteristics. By understanding that a specific trading rule which belongs to this generic rule shares the same performance characteristics in the long run, we can decide if the trading rule will achieve our trading goals and therefore, if it should be included in our trading system.

1. INTRODUCTION

A company devoted to trading financial markets for profit, such as a hedge fund, should have explicit trading goals. A hedge fund's trading system should be constructed so that it achieves these goals.

To optimize its value, a hedge fund must: survive for as long as possible; produce the best performance possible; and, grow assets under management.

So, an important trading goal is to grow assets under management. Historically we may find that to achieve optimal asset growth maximum draw-downs must be less than 30%, and the annual return must be greater than 10%. This means that the hedge fund must be confident that its trading system should meet these conditions; else, the company will not achieve its goals.

How do we know if a specific trading rule can achieve certain trading goals without testing it thoroughly on every market? Using the methodology described in this work we can predict what performance characteristics a trading rule will have in the long run, irrespective of the market on which it is traded.

The key is that we use a combination of a generic trading rule and simulated data for trade generation. For a generic trading rule, simulation can provide accurate estimates for any performance characteristics of interest irrespective of the market traded.

This insight is very powerful: it means that once we classify a trading rule as belonging to the generic class, we know what performance characteristics it must have. This power is obtained through the use of simulated data. Since our data is not market specific, nor are our estimated performance characteristics.

The performance characteristic of a real trading rule tested on the real market data will converge to the simulated performance characteristics in the long run. Thus we can decide if the trading rule will achieve our trading goals and if it should be included in our trading system.

There is virtually no literature in this area.

2. TRADING RULE MODEL

We begin with a discussion of the generic trading rule. The assumptions for our model are that:

1. The components of position management, transaction costs, risk management, and position sizing completely specify a trading rule and its performance.
2. Given a sequence of trades, the result of the next trade is unknown. It is random.
3. Each trade result is independent from previous trades and no serial correlation exists in any sequence of trade results.
4. A trading rule can have only one entry. It has at least one exit.

The first assumption is straightforward; if we knew of other components that were a part of the trading rule, they would be included.

Assumptions 2 and 3 are justified by a simple argument. If either assumption were untrue, we would have additional information that would improve the success of the trading rule. Any rational trader would use this additional information to improve their returns. Therefore, these assumptions hold.

Assumption 4 may appear to be an oversimplification. The assumption allows us to understand a simple trading rule. We can then build on that knowledge to understand increasingly complex systems.

The equations that describe our simulation are:

$$e_i = e_{i-1} + \Delta_i$$

$$\Delta_i = r_i \cdot p_i - c_i$$

$$c_i = k * p_i$$

$$p_i = R_i / R$$

$$R_i = y * e_{i-1}$$

$$e_0 = \text{initial capital}$$

$$r_i \sim D$$

where i,=1…N is the trade number; r_i, trade return for time i; p_i, position size of trade i; e_i, equity after trade i is complete; e_0, initial equity; y, percentage of equity at risk; R_i, total equity at risk; R, stop loss at a percentage of entry price.

D, is the distribution of trade returns. Historically, this has been performed utilising trade returns from tests of a particular trading rule implementation against market data. Instead we use the structure of the trading rule (its entry and exits) to define shape of D.

2.1 Deriving the Distribution of Trade Returns

In this section we create D, the distribution of trade returns, using the structure of the trading rule.

We know that D is a conditional distribution function; it is conditional on the entry signal. Once a trade is open, we have to exit.

We start by looking at D for a simple trading rule that has only two possible exits, a stop gain and a stop loss. We will call this class of trading rules, 'dual stop trading rules'.

A dual stop trading rule has a distribution function that two step functions at the stop gain/loss points. If we set the value of a stop loss to be –R (a percentage of entry) and the stop gain to be at mR where m=1,2 or 3.

-R is the stop loss, which is the maximum acceptable loss, it is clear that R is related to the risk management calculation. In fact, R is the loss on a single security, whereas R_i is the total acceptable loss on a trade. Therefore, $R = R_i / n$, where n is the number of securities (e.g. shares) taken in the trade. We get n from the position size divided by the cost of a security.

Rather than involve market prices we will set R in this work during the simulation.

What then is m? It is the size of a winning trade compared to the size of a loss. We call m the winning trade size from herein.

There is an implicit assumption in the model, that the distribution is static over time.

Table 1. Values used in simulation

	Variable	Values Tested
R	Stop loss	1%, 5%, 9%
y	Risk Management	1%, 1.5%, 2%
k	Transaction Costs	1%, 1.5%, 2%
m	Multiple	1-3 steps 1
	Probability of win	20% - 90% steps 10%

2.2 Simulation Details

We test dual step trading rules in our simulation. For each trade, only two values are possible in the trade return distribution: stop win or stop loss. Also required are the probabilities for each value.

For this m will be set to range from 1 to 3 and the probability of a winning trade will be range from 20% to 90%. Only combinations that have positive expectancy are simulated.

As we iterate through each value of m, we will calculate the position size using the current equity for each trade and the percentage risk model of money management.

The initial equity, e_0, is set to 1000. Each simulation run will consist of 50 trades. This approximates one trade per week (about one year) or once per month (about 5 years). For each trading rule combination, 50 simulation runs are performed. With multiple simulation run, we have a distribution of results for each performance metric.

Each unique combination of parameters is a defined to be a trading rule. That is, a generic trading rule can be defined by specifying various simulation values: a stop loss of 5%; a fixed risk management of 2%; transaction costs of 2%; a multiple of 3; and a probability of winning of 50%. In reality, there may be many (or none) actual trading rules that correspond to this generic system.

3. PERFORMANCE METRICS

In our analysis of simulated trading rule performance, we consider three performance metrics: maximum drawdown, time below the high water mark, and expected net profit per trade.

During the course of a series of trades, a trader's equity goes up and down depending on the result of each trade. Each high (peak) in equity has a low point (valley) that follows it before the next peak. The difference between a peak and its subsequent valley is the peak-to-valley drawdown (**Figure** 1, left hand figure**)**. The maximum of all peak-to-valley drawdowns in any sequence of trades is the maximum drawdown. It gives a measure of the largest loss that a trading rule underwent due to a sequence of trades. Maximum drawdown is a percentage of the peak equity. The lower the maximum drawdown the better; it represents a smaller loss.

The high water mark is the highest equity value that a trading rule has produced to date in a sequence of trades. It never decreases. Measured as a percentage of overall trading time, time spent below the high water mark is a loss, even when the trading rule is profitable overall, as it is a lost opportunity to earn a return elsewhere (Figure 1, right hand figure).

The expected net profit per trade is the average profit per trade, measured using the profit net of transaction costs.

4. SIMULATION ANALYSIS

In this section we consider each performance measure in turn.

4.1 Average Profit per Trade

The median average profit per trade for all systems tested was $548 and the mean $1,486 and it ranged from a minimum of -$1,852 to a maximum of $29,470.

From Figure 2, the median average profit per trade grows exponentially with an increase in the stop loss. The inter-quartile range grows at the same rate and both the first and third quartiles increase.

Median average profit per trade shows a linear decline as transactions cost increase. Since costs reduce profits, this is expected. The inter-quartile range does not change, but the first and third quartiles decrease at the same linear rate as the median.

From Figure 2, we can see that the median average profit per trade increases linearly as risk increases and the change is statistically significant. The inter-quartile range increases but the third quartiles increase at a larger growth rate than the decline in the first quartile. Thus, as we increase risk, we increase the probability of a low average profit per trade, but at slower rate than we increase the probability of a higher average profit per trade. Interestingly, even with risk at its lowest value (1%), the first quartile is below zero, which gives a 25% chance of having a negative average profit per trade.

As the probability of winning increases, the median average profit per trade increases exponentially. There is an anomalous result at a winning probability of 50%. Addition of trading rules with a winning trade size of at least two is the cause of this anomaly. At a winning probability of 30%, inter-quartile range is totally below zero; which means there is a 75% chance of losing within the overall systems tested.

Increasing the winning trade size also has an exponential growth affect on the median average profit per trade. The inter-quartile range increases with the increase in winning trade size, the third quartile is increasing exponentially, the first quartile linearly.

For a trader wanting to improve their average profit per trade, it means improving their probability of a winning trade or increasing the size of a winning trade. If neither of those is feasible, they can increase their risk, but the rate of improvement is only linear compared with the exponential benefit of increasing the winning probability or the size of a winning trade.

Figure 1. A pictorial representation of draw-downs (on the LHS) and time under water (on the RHS)

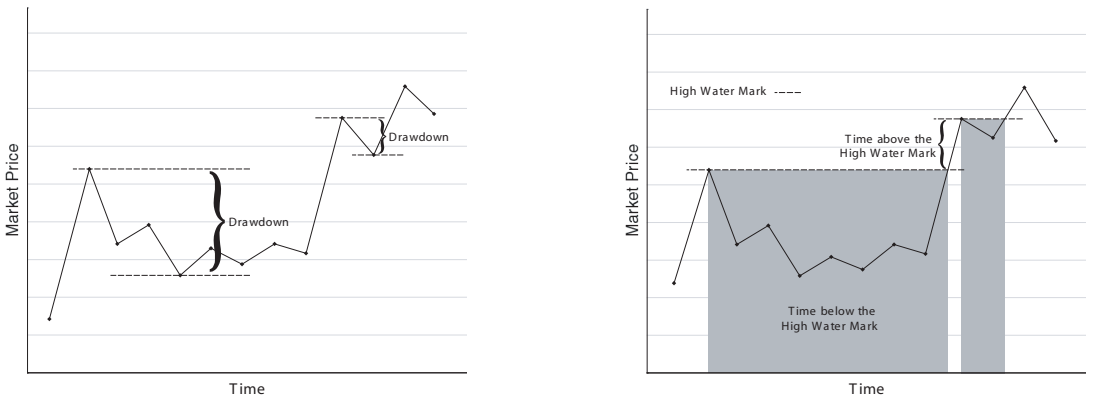

Figure 2. Box plots of transaction costs and stop loss against average profit per trade Box plots of risk, probability of a winning trade and winning trade size against the average profit per trade

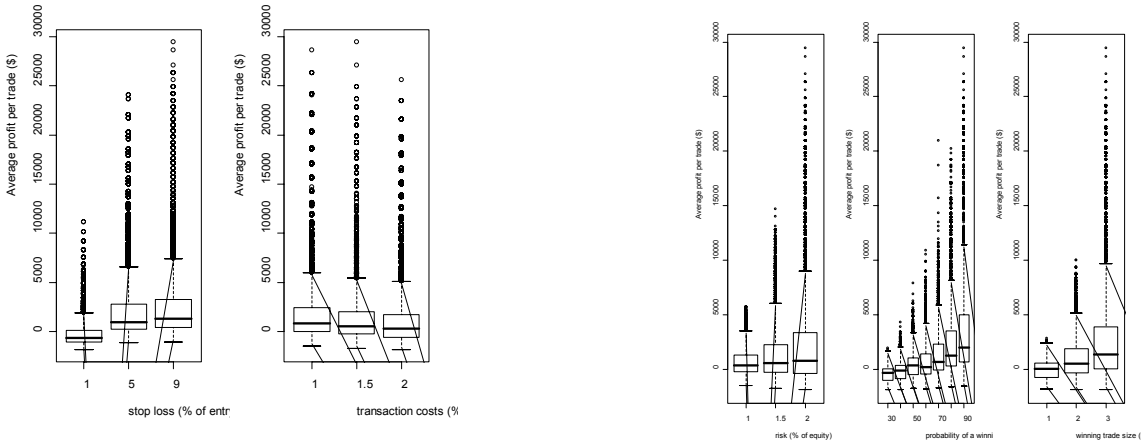

The stop-loss can be increased but it has a diminishing affect on average profit per trade after 5%.

4.2 Maximum Drawdown

Maximum drawdown, across all systems simulated, ranged from a minimum of 0% to a maximum of 92.6%, with a mean of 17.33% and a median of 8.597%.

In Figure 3, increases in the stop loss show an exponential decline in the median maximum drawdown. Inter-quartile range decreases at the same rate as the stop loss increases. Increasing stop loss to reduce maximum drawdown is an exercise in diminishing returns.

There is linear growth in the median maximum drawdown and the first quartile as transaction costs are increased. The change in median is significant. The inter-quartile range and the third quartile increase exponentially. For a trader, this means increasing transaction costs, exponentially increase the uncertainty in the maximum drawdown, but the increase in the median is less dramatic.

Since traders avoid drawdowns where possible, transaction cost management is valuable in reducing both the probable maximum drawdown and the uncertainty around the maximum drawdown.

Looking at Figure 3, median maximum drawdown increases as risk increases. It decreases exponentially as winning probability increases. Both relationships are statistically significant. For both risk and winning probability, the inter-quartile range changes at the same rate.

Winning trade size has no significant impact on median maximum drawdown.

As risk increases, the impact of a loss increases and hence the median maximum drawdown increases. The inter-quartile range increases as risk increases and moves upwards. This means that as risk is increased the levels of maximum drawdown at the first and third quartiles increase; our chances for worse drawdowns increases.

Conversely, as the probability of winning increases, fewer losses are likely and the median maximum drawdown decreases. The inter-quartile range decreases, lowering the spread of the maximum drawdown. Both the first and third quartiles decrease and our chance of lower maximum drawdowns increases.

Increasing the winning trade size has no significant impact on the median, nor does the first quartile move but the third quartile diminishes exponentially. This means the probability of a low drawdown (below the median value) does not change but the probability of high drawdowns (above the median) decreases. As winning trade size increases, expectancy increases. This has the positive effect of reducing the maximum drawdown as the system is profitable and spends less time in a drawdown. This is visible in Figure 3.

4.3 Time Below the High Water Mark

Time below the high water mark, for all systems tested, has a mean of 62.01% and a median of 66.0% and ranged from 0% to 100%.

Figure 3. Box plots of stop loss and transaction costs against maximum drawdown and Box plots of risk, winning trade size and probability of a winning trade against maximum drawdown

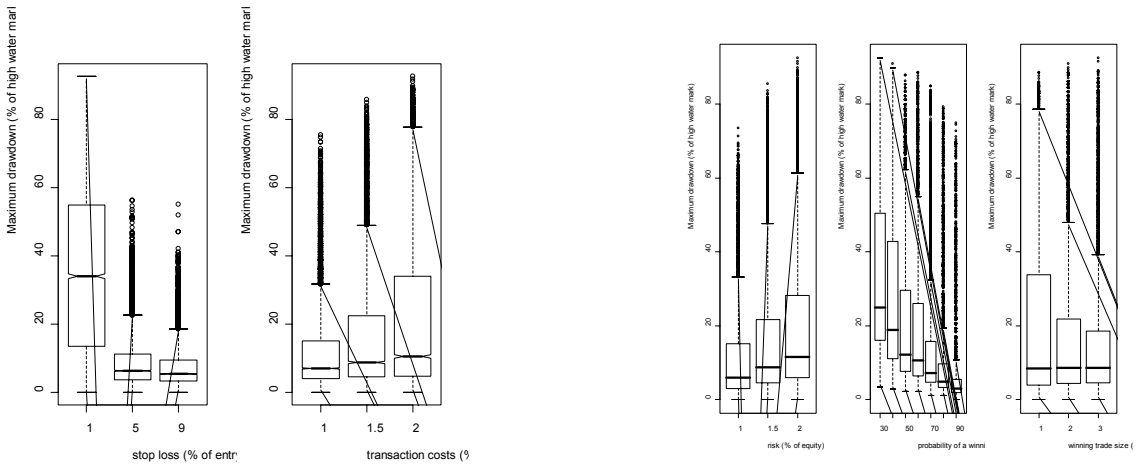

Figure 4. Box-plots of stop-loss, transaction costs, risk, probability of winning trade and time below high water mark

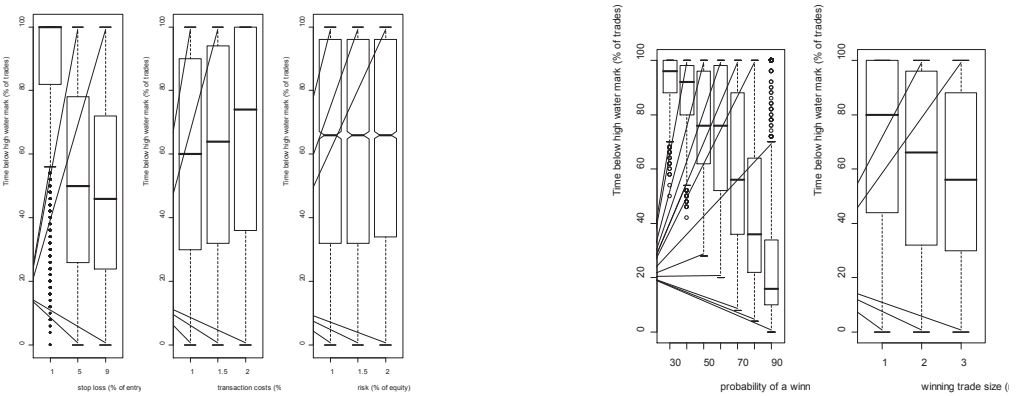

Change	Effect
Increase probability of a win	• Increases median return on assets • Decreases median maximum drawdown • Increases median average profit per trade • Decreases median time below the high water mark • Decreases median length of the longest losing streak
Increase risk	• Increases median return on assets • Increases median maximum drawdown • Increases median average profit per trade
Increase the size of a winning trade	• Increases median return on assets • Increases median average profit per trade • Decreases median time below the high water mark
Increase transaction costs	• Decreases median return on assets • Increases median maximum drawdown • Decreases median average profit per trade • Increases median time below the high water mark
Increase stop loss	• Increases median return on assets • Decreases median maximum drawdown • Increases median average profit per trade • Decreases median time below the high water mark

From, **Figure 4** there is an exponentially decreasing relationship between time below the high water mark and stop loss. As the stop loss increases, trading rules spend less time below the high water mark. This is due to the interaction between the stop loss and winning trade size.

Increasing transaction costs has an exponential affect on the median time below the high water mark, another good reason for traders to control costs. The inter-quartile range is constant for increasing transaction costs.

From **Figure 4, c**hanging the risk had no significant affect on the median time below the high water mark. Nor did it have an impact on the inter-quartile range. It may seem counter-intuitive that increasing risk has no impact. Recall, however, that under the percentage risk model, increasing risk will decrease the size of the position.

Let us look next at the probability of a winning trade and the winning trade size against time below the high water mark (see **Figure 4**). Most apparent is the decline in the median time below the high water mark as the probability of a winning trade increases; yet the range of values for time below high water mark increases at first and then decrease once probability of winning exceeds 60. As the time below the high water mark metric is bounded by minimum and maximum values of zero and 100% respectively, this is to be expected.

What is unexpected, is the increase in the median at a probability of winning of 60% and the inter-quartile range increase at the same point. Interaction with another component might be the cause this effect. For a winning trade size of one and a stop loss of 1%, all winning probabilities returned a 100% time below the high water mark value. Interesting, but why does this happen? When the stop-loss is 1% and the winning trade size is one, transaction costs equal or exceed the size of a win. The separation of transaction costs clearly identifies that, in this instance, transaction costs are making a profitable system, unprofitable. For this type of system, transaction costs must be less than the size of the stop loss.

There is an exponential decline in the median time below the high water mark (see **Figure 4)** and the winning trade size; inter-quartile range does not change with an increase in winning trade size.

As indicated earlier, we only recorded results for trading rules with a positive expectancy. When the winning trade size is equal to one (winning and losing trades are the same percentage size), it takes until the probability of winning exceeds 50% before there is a positive expectancy. In this case, it is likely that a large portion of time is spent below the high water mark, due to the losses incurred. As this multiple increases, the impact of a single loss is smaller than the impact of a win and so the time below the high water mark decreases.

5. CONCLUSION

The aim of this paper was to forecast the performance characteristics of a trading rule. To do this we built a model for trading rule simulation, modelled the class of dual step trading rules, and analysed the data from simulating the model. The analysis identified clear guidelines for traders to improve performance.

ABSTRACT

Process assets library (PAL) is a repository of software process-related documents, necessary to implement technologically infrastructures in support of organizational process. This paper offers a review of the literature related to PAL and exposes some questions for solving in Software Process Engineering.

Keywords: Software Process Improvement, CMMI, Process Support Technology, Software Process Assets.

1. INTRODUCTION

The objective of this paper is to present the current situation on software process asset libraries, which are repositories that store information about software process of an organization, allowing that accumulated experience could be used in future software projects.

PAL concept is included nowadays in the CMMI model as a way to achieve the software process definition. This repository is composed generally by a great quantity of no structured information that makes difficult search and reuse of software process assets.

Planning, design and building of a PAL is a task that still is in an initial research phase; therefore, this paper presents a summary of the main studies, advances and questions found in the research of this kind of libraries.

The paper is organized as followed. Second section presents a body of knowledge of the main areas that delimit the concept of PAL. Third section reviews works related to PAL. Fourth section shows a summary of dissertations related. Fifth section discusses issues for solving. Concluding remarks are given in the last section.

2. BODY OF KNOWLEDGE

2.1. Main Areas of Knowledge

Due to the great quantity of meanings that exist in software process engineering domain, a conceptual definition is necessary to avoid serious confusions on having use the PAL term in the area of Software Engineering. This conceptual definition is showed in Figure 1.

- *Software Engineering*: The application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software; that is, the application of engineering to software.
- *Software Process*: A set of partially ordered process steps, with sets of related artifacts, human and computerized resources, organizational structures and constraints, intended to produce and maintain the requested software deliverables.
- *Software Process Management:* This area is concerned with the management of the technical aspects of the software development process. It includes knowledge about software process elements: activities, methods, and practice that people use to develop software.
- *Software Process Engineering:* It deals with methodologies, tools, and techniques for the design and implementation of software processes. It includes knowledge about representing the important characteristics of a process as a coherent, integrated set of well-defined software engineering and management processes for organizations, teams, and individuals.
- *Software Process Improvement (SPI):* It is a systematic procedure to improve the performance of an existing process system by changing the current processes or adding new processes for correction or avoidance of the problems identified in the old system by process assessment.

2.2. SPI Models

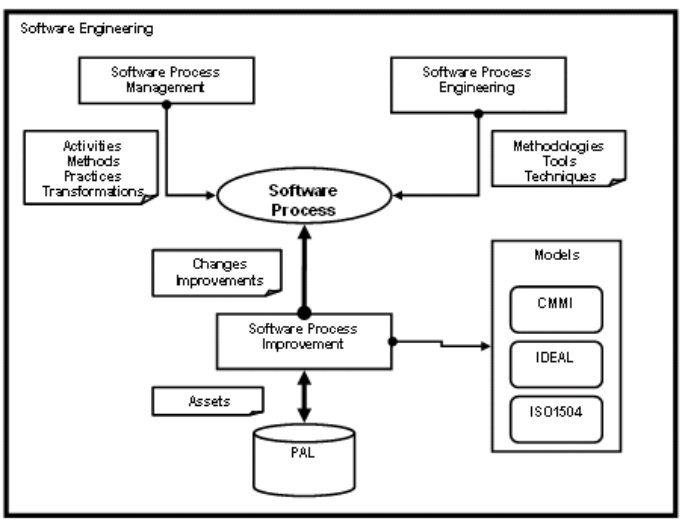
To achieve a successful SPI, the industry has developed models that assess the reached maturity and to identify improvement strategies.

One of the most known proposals is Capability Maturity Model Integration (CMMI) developed for Software Engineering Institute (SEI). CMMI consists of best practices that address the development and maintenance of products and services covering the product life cycle from conception through delivery.

Other models related to SPI are:

- IDEAL: Describes a model defining the main phases and stages to introduce SPI in an organization and to establish supporting infrastructure.

Figure 1. Areas of knowledge



- ISO 15504: It is an international standard, which specifies a reference model with two dimensions: a process dimension and a capability dimension.

2.3. Process Asset Library: PAL

The documentation of software processes to obtain a CMMI certification contains information related to organization's process assets (knowledge about how the organization realizes its processes). The documentation must be available by a repository named PAL. The use of a PAL is a required practice for achieving CMMI Level 3 and achieving a defined process.

PAL belongs to software process support technologies allowing the integration of production and management technologies and supporting for storage and retrieval of organization's process information.

PAL is an organized, well-indexed, searchable repository of process assets that is easily accessible by anyone who needs process guidance information like examples, data, templates, or other process support materials [12]. Some main purposes of a PAL are:

- Provide a central knowledge base for acquiring, defining, and disseminating guidance about processes related to the organization's tasks.
- Provide mechanisms for sharing knowledge about the organization's process assets and how they are used.

Another useful applications of PAL are to assemble sub-processes in constructive fashion y/o derive modified processes by replacing and/or modifying constituent sub-processes.

3. RELATED WORKS

PAL concept is related to many efforts found in the literature about software process improvement: Software Process Reuse, Process Libraries, PSEE, Experience Library, STARS Program, Zahran's Proposal and other proposals (Figure 2). These works incorporate some technical infrastructures and solutions in organizational process.

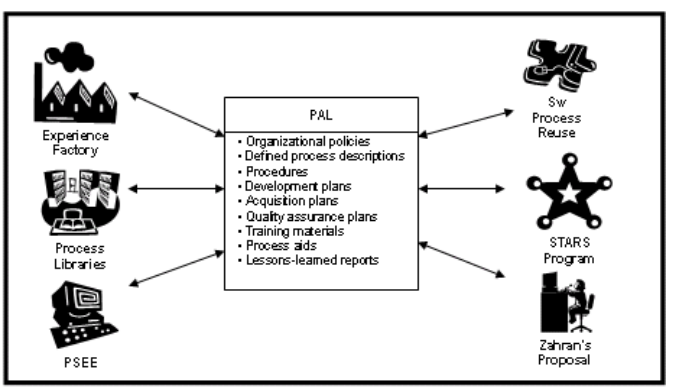
3.1. Software Process Reuse

CMMI indicates that the organization is expected to have one or more approved software life cycles. Individual projects are expected to follow established guidelines and criteria for: selecting the most appropriate of the approved life cycles, tailoring and elaborating the selected life cycle and the organization's standard software process, to fit the needs and particulars of that project [19].

Some studies about software process reuse are:

- Gertrude [29] is a model to re-use software processes, based on object-oriented methods.
- In [25] the characteristics of process components are indicated, allowing projects the freedom to define their own life cycles.
- GPM [17] is a web-based software process management and monitoring tool, providing a mechanism for a software process model to be defined, modified, tracked and measured by a GUI.

Figure 2. Related works



- Case-based reasoning approach has been used on: APSEE [27] a system to identify the similarity between the problem with previous situations stored in the case base and CABS [11] a system that uses a formal notation allowing the user to sketch new processes or adapt template processes, in a matching process which identifies and suggest the reuse of similar processes and process components stored in a library.
- Reuse Architectures: Process Reuse Architecture [10] that uses facets, reuse guidelines and process patterns taxonomy, and Open Architecture for Software Process Asset Reuse [5] through the identification of architectural elements and the specification of element interfaces.
- In [16] a set of process notations and methods for defining processes and tailoring reusable processes is described.
- GUIDE [14] is a rule-based system, for which specific projects are tailored through decision trees used at an arbitrary level of project detail.

3.2. Process Libraries

Process libraries supports reuse capabilities for processes, including the creation, update, deletion, measurement, and management of process assets [33].

A set of works related to building of process libraries is outlined:

- SPLib [24] organizes a process collection constituting a multilevel knowledge base.
- Process Evolution Dynamics Framework [26] is based on an experience-based categorization of process evolution-related activities.
- QUEST [1] is a collection of tools when it highlights a repository, which is a knowledge-based software process model.
- PROGEN [20] is a knowledge-based system for process model tailoring and reuse.

3.3. PSEE

Process-centered Software Engineering Environments (PSEE) can be considered a new generation of software development environments with possibility of adapting to every specific software project, providing a better automated support.

A PSEE interacts with a process model developed by Process Modeling Language and a Process Engine can then enact the process model. The process engine has three components [8]:

- An interpreter that executes the process model.
- A user interaction environment (UIE).
- A repository that stores the artifacts produced during the process. This repository can offer some attributes and purposes of a PAL

3.4. Experience Library

Other proposals to capture critical knowledge from software projects are experience-based approaches and organizational learning, named Experience Library or Repository of Experience [4].

These approaches consist in apply past knowledge to current projects while software practitioners engaging in knowledge creation processes. BORE [15] is a tool that supports this experience-based approach, which collects and disseminates project experiences as "cases" representing emerging knowledge of development practices in an organization.

3.5. STARS Program

The mission of DARPA's Software Technology for Adaptable, Reliable Systems (STARS) program is stimulate the productivity from process reuse technologies. Key constituents of the model are: a PAL, process definition, process enactment, process measurement, and process evolution [13]. PAL provides reusable process assets from public repositories over broad-area networks.

3.6. Zahran's Proposal

Zahran [30] provides a framework for establishing an environment for SPI. The framework has two infrastructures:

- Organizational and management: with roles and responsibilities to manage SPI activities.
- Technology and tools: with facilities and tools for automating process activities and supporting the various process improvement roles and responsibilities.

3.7. Others Proposals

Other ideas related to development of software process information repositories are:

- DAGAR [21] is a repeatable and documented process with accompanying language and is based on a domain architecture process.
- Collaborative Parallel Enactment (COPE) Process Architecture [28] has basic capabilities for specifying process elements, their characteristics and interconnections.

4. RELATED DISSERTATIONS

There are several dissertations related to repositories for Software Process Engineering. Some of them are outlined as followed.

- A Software Process Asset Management and Deployment System is developed in [18] that captures the existing processes, as well as the improvements and changes to these processes into a set of assets that can be reused in future process instances.
- A Workflow Reuse Management System is developed in [22] to unify efforts in PSEEs and Workflow.
- In [7] a study is realized on Process Support Systems that generally are slightly flexible when unexpected situations arise during process execution, producing deviations and inconsistencies. A framework to formalize the concepts of deviation and inconsistency is proposed.

Some studies have been developed in Alabama University about Software Process Engineering to support projects related to *NASA's Flight Software Group at the Marshall Space Flight Center*. One project is Standards Advisor Project, a software system designed to improve the quality and productivity of space systems development by making it easier to find and use standards and other information that guide system development. Some works developed are:

- A Web portal is developed in [23] for delivery information related to process and capturing experience.
- The use of metadata is proposed in [2] to storage standards.

5. ISSUES FOR SOLVING

In spite of the quantity of published results, a lot of questions for solving related to SPI and PAL still continue.

Issues as questions with regard to process model languages, which must be tolerant and allow for informal and partial specification that facilitates their adoption for the practitioners.

Also there are similar questions in PSEEs, since many systems have been developed without a wide acceptance and use, because mainly to their lack of flexibility.

Issues relating to software processes expect to be clarified [9]: requirements for process modeling notations and formalisms, representing global process constraints, granularity, integrating product models, process capture, process-centered environment, enforcement and process automation. There is little information about: what kinds of processes to capture, what processes to ignore, and the need to consider different representations of these processes and other materials for the different roles to be played and the different purposes for which it will be used [6].

Some aspects to consider in future researches are [27]: separation of details in process modeling, level of detail, abstraction mechanisms, search criteria for process elements, mechanisms to ensure the correct reuse of retrieved elements.

Atkinson [3] exposes characteristics that a software library must include: nature of the asset, scope of the library, query representation, asset representation, storage structure, navigation schema, and relevant criterion. Also he defines issues of technical design for software libraries that must be considered: assets definition, assets modeling, definition of relationship between assets, and definition of insertion, removal, update and access policies.

All these issues presented about PAL wait to be faced and solved in future works.

6. CONCLUSIONS

To create a PAL that achieves to standardize and reuse a software process, it is necessary: to describe the process; to store it in a suitable format; to identify the desired process in a database and to retrieve it; and to adapt it to organizational needs [29].

The bibliographical review has discovered that the researchers have carried out many efforts in the first aspect (process description) leaving aside other aspects that even have not been solved.

Models for software process improvement as CMMI indicate the need to build and manage this kind of repositories. Nevertheless CMMI does not specify what technical characteristics are needed to implement a PAL successfully. For which, it is an obligatory requirement that already has begun to obtain results, with the emergence of research proposals that try to address the problem of defining infrastructures for supporting software process assets (standardized and integrated in the future) to create, to organize, to access and to reuse information concerning software process improving.

ACKNOWLEDGMENT

This work on PAL was supported by GPS – Software Process Management Platform: Modeling, Reuse and Measurement (TIN-2004-07083) of the Spanish National Research Program.

Smooth ERP Migration by Using Next Generation Distributed ERP Systems*

Lars Frank, Copenhagen Business School, Howitzvej 60, DK-2000 Frederiksberg, Denmark; E-mail: frank@cbs.dk

ABSTRACT

In a distributed ERP (Enterprise Resource Planning) system, the different local ERP systems are integrated in such a way that each local system can use the resources/stocks managed by the other local ERP systems. Businesses with branch offices may benefit greatly from such systems. In this paper, we will describe how a distributed ERP system can be used to convert/migrate to a new ERP system in a smooth way. The smooth migration property is a consequence of the distributed ERP systems ability to allow different ERP systems to operate on the same stock table. That is, the distributed ERP system can use the stock file from the old ERP system while customers over time are converted to the new distributed ERP system. As this type of converting does not need to take place overnight, it may reduce the risk and peak load for manpower in the converting period.

Keywords: ERP migration, converting risks, converting time, distributed ERP systems.

1. INTRODUCTION

Converting to a new ERP system is normally done overnight for the following reasons:

- Most major companies can only live a short time without an ERP system or the old legacy systems.
- It is not possible to run the new and the old ERP system in parallel as product stocks normally cannot be updated from both systems in a smooth way.

Converting overnight may be risky as the new system cannot be tested in a full scale production environment because the employees rarely have time to use both systems in the test period. A distributed ERP system may reduce the converting risk as such a system will make it possible to update the stock table from both the new and the old ERP systems. This makes it possible to do the converting over time.

A distributed ERP system used for converting must be able to update heterogeneous databases, which will present a problem with the ACID properties. The extended transaction model used in this paper implement the global atomicity property by using compensatable, pivot and retriable subtransactions in that order as described in e.g. Frank and Zahle [2].

The global consistency property is not implemented but it is the responsibility of the application designers to use countermeasures against the isolation anomalies in such a way that the database always will converge towards a consistent state.

The paper is organized as follows: First, we will describe the replication designs we recommend for distributed ERP systems that make it possible for different ERP systems to operate in parallel. Next, we will describe the architecture of a distributed ERP system as such a system is used in the new converting method. Finally, we will describe the method for smoothly converting to a new ERP system.

Related Research: The different replication designs used in this paper are described and evaluated in [4]. The extended transaction model used in this paper is *The Countermeasure Transaction Model* [2]. This transaction model owes many of its properties to e.g. [4], [5], [6] and [7].

2. THE MOST IMPORTANT REPLICATION DESIGNS

In general, replication methods involve n copies of some data where n must be greater than 1. The basic replication designs storing n different copies of some data are defined to be n-safe, 2-safe, 1-safe or 0-safe, respectively, when n, 2, 1 or 0 of the n copies are consistent and up-to-date at normal operation. In autonomous databases, it is normally only possible to use the 1-safe or 0-safe replication designs and, therefore, only these designs are used in this paper.

In general, it is not possible to select one of the replication designs as the best because all the designs have very different properties. However, if one knows the requirements of application, it is possible to select the most inexpensive design fulfilling those needs. This is illustrated by Frank [3].

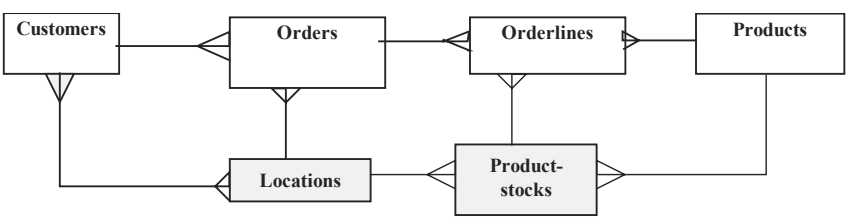
3. ARCHITECTURE OF A DISTRIBUTED ERP SYSTEM

In the following, we will describe in broad outline the table design of some of the most important tables in a distributed ERP system. In a distributed ERP system each local ERP system must have local autonomy to operate in disconnected mode. In the following design, we have also tried to optimize performance, availability and possibility of recovery.

The Product table is vital in all locations. We recommend that the Product table is replicated by using the basic 1-safe design with a central primary copy and secondary copies in all the other locations. We do not think it is necessary to use the n-safe, 0-safe, or expensive versions of the 1-safe designs, because normally the file is only updated from the central location when product prices are changed or new products are introduced. Therefore, updates can be executed in advance with an operation date. This means that in case of failure, it is possible to defer all updates of the Product table until the failure has been repaired, i.e. no lost transactions will occur. In other words, no risks are taken by using the inexpensive basic 1-safe design.

We will recommend that the Customer records for customers who deal with more than one branch office are fragmented and 0-safe with primary copy commit in the central location. The secondary copies will be stored in all the locations where a

Figure 1. Entity-relationship diagram for a distributed ERP system



customer has placed orders previously. The balance of a customer must be updated each time an Order is invoiced, and, therefore, the balance is first updated in the local Customer record. Later, the updating should be committed globally at the central primary copy. The other involved remote branch offices will (sooner or later) receive the updates committed globally by the update of the central primary copy. We will recommend that the Customer records for local customers are fragmented and 1-safe with commutative updates. The primary copies are stored in the locations that deal with the local customers and the secondary copies are stored in the central location.

We will recommend that the Order table is fragmented with the basic 1-safe design as an Order record is normally used only in the location where the corresponding sale took place. However, for backup and data warehousing a secondary copy can be stored in the central location.

Suppose the Product-stock table has a record that includes the quantity of each product in stock at each store location. We recommend that the Product-stock table has the no-replication design, as it may be too expensive to replicate the data on-line. The table is also fragmented in such a way that each store location has its own Product-stock records. (A snapshot copy of the local Product-stock tables should be stored for backup in the central location).

We recommend that the Orderline table is fragmented and 0-safe with primary copy commit in the store location and a secondary copy stored in the location that created the order. In other words, first the Orderline should be created in the database of the order location and later it should be confirmed in a store location where a primary copy of the Orderline is created if the quantity ordered is in stock.

4. CONVERTING TO THE NEW ERP SYSTEM

An overnight conversion may be risky as the new system cannot be tested in a full scale production environment because the employees rarely have time to use both systems in the test period. A distributed ERP system may reduce the conversion risk as such a system will make it possible to update the stock table from both the new and the old ERP systems. This makes it possible to do the conversion over time.

The idea is to run the distributed ERP system in the same location as the ERP system that is going to be converted. All the replicated tables described in example of the previous section are created in the new distributed ERP system except the stock table. By using a special interface, it should be possible to access the stock table in the old ERP system through the new distributed ERP system.

It is possible to create a test department with customers in the distributed ERP system and test how to sell and restore the stocks in a production environment. At the same time, it is possible to use the old ERP system as usual. After a test period, it is possible to convert the sales departments one by one. When all sales departments have been converted to the distributed ERP system, the Stock file may be converted too. Now, the sale module of the old system can be deleted. Other ERP modules may be converted in the same way, but it is important not to delete old tables before all modules that use the old tables have been converted. If the company does not need a distributed version of the ERP system when the conversion has been completed, a non distributed version of the new ERP system can use the converted ERP database of the distributed ERP system. The conversion method described above is not simple. Therefore, the method is only recommended if the overnight conversion is too risky or costly compared to the new method. Another problem with the new conversion method is that special software is needed if the old and new ERP systems are heterogeneous. The special software is necessary to access the old stock file from the distributed ERP system. Special software is also needed for the different replication methods as the replication methods of the distributed ERP system only can be used between homogeneous ERP systems. On the other hand, a great deal of the replication programming has to be done anyway as the tables from the old ERP system must be converted to the new ERP system.

Does Economic Freedom Enhance the Impact of Technology on Global Productivity?

Koffi N'Da, Rochester Institute of Technology, New York, USA; E-mail: kxnbbu@rit.edu

ABSTRACT

This paper assesses the joint effects of economic freedom and technology on productivity. Using regression analysis we examined a sample of more than 100 countries from 1990 to 2000. The results indicate that countries with greater economic freedom have an increased association between technology and productivity.

INTRODUCTION

Productivity is considered a key indicator of national success. Consequently, much effort has been expended in the economics literature to determine factors influencing it. Our concern is with a subset of this literature pertaining to the effect of technological investments on productivity. This literature generally finds that technology is associated with productivity and economic growth.

But technology cannot be considered in isolation. Other factors may affect or modify the relationship between technology and productivity. In this study, we consider one such factor, economic freedom. The objective of this paper is to assess the joint effects of economic freedom and technology on productivity. The existing literature tends to treat these two factors as separate and our contribution is to consider the joint effects. We argue that technology has a greater effect on productivity when coupled with economic freedom. We test this hypothesis using a sample of more than 100 countries and find supportive evidence.

BACKGROUND AND LITERATURE REVIEW

Technology and Economic Performance

Many studies have investigated the relationship between Information Technology (IT) investment, productivity, and economic growth. Dedrick, Gurbaxani and Kraemer (2003) categorize these studies based on the aggregation level of data: firm-level, industry-level, and country-level. The initial debate in the literature centered on whether IT produced economic growth or productivity. Early tests did not indicate a relationship, but tests using data from the 1990s indicate that IT influences productivity.

While most of the studies were conducted using firm-level data, many studies also used country-level data. These studies are of recent vintage (mid-1990s onward) and use univariate tests associating IT investments with economic growth and productivity. The greatest impact of IT is found in developed countries (Yoo 2003). The link between IT and economic performance is not robust in developing countries (Dewan and Kraemer 2000).

The lack of an IT impact in developing nations is further explored by Indjikian and Siegel (2005). These authors review existing evidence and conclude that IT investments by themselves cannot solve the travails of developing nations. This raises the possibility of moderating factors affecting the link between IT and productivity.

Economic Freedom and Productivity

Economic freedom, as distinguished from civil and political freedoms, refers to the degree in which a market economy exists and provides an environment favoring voluntary exchange, free competition, property rights, and a limited degree of interventionism in the form of government ownership, regulations, and taxes (Gwartney and Lawson 2002). Most but not all studies indicate that economic freedom is positively and significantly correlated to productivity. Focusing specifically on developing countries, there has consistently been empirical evidence that economic freedom is one of the most important factors that affect economic performance. Countries that better protect economic rights tend to grow faster (Goldsmith 1997). According to Wu and Davis (1999), the establishment of free a market is essential to a developing country's economic growth. Other studies have demonstrated that economic freedom combined with other factors such as political freedom, civil freedom, and democracy has a positive effect on the economic performance of developing countries (Nelson and Singh 1998; Vega-Gordillo and Alvarez-Arce 2003).

Contribution of this Study

The notion that IT investments and diffusion need to be supported by complementary investments and environmental conditions (Green, Melnyk and Powers 2002; Lee, Gholami and Tong 2005) is an important one and lies at the heart of our study. At the firm-level such complementary investments may include items such as workforce training. At the national level too, there are many environmental variables affecting the impact of IT. In this paper, we consider economic freedom to be a complementary variable.

Our study is perhaps most closely related to Meso, Datta, and Marika (2005). These authors examined the modifying effects of governance variables on the relationship between economic growth and IT. They found an interaction effect for certain variables. For instance, they found that Voice, Accountability, and Rule of Law interact with IT to further economic growth. However, they also find IT to be negatively related to economic growth contrary to much of the literature. Our study uses different dependent and independent variables and measures in different time periods. More importantly, our focus is on economic freedom and not governance.

DATA AND METHODOLOGY

Productivity

The dependent variable in our study is Gross Domestic Product (GDP) per worker adjusted for purchasing power parity and expressed in US currency. We collected values for this variable for the years 1990 and 2000 from the Global Market Information Database issued by Euromonitor International. The database covers 205 nations from 1977 to 2006.

Technological Capability

Our independent variables are technology and economic freedom. We measure technology through the Indicator of Technological Capabilities for Developed and Developing Countries. The indicator was complied by Archibugi and Coco (2004). We use this index because it is one of the most widely used and detailed indexes.

Economic Freedom

Our economic freedom variable is the Economic Freedom of the World (EFW) indicator by **Gwartney** and **Lawson** (2002). It is measured on a ten point scale with 10 denoting the highest level of economic freedom. EFW contains the following five areas: 1) size of government, 2) legal structure and property rights, 3) sound money, 4) openness of markets, and 5) regulation of credit, labor and business.

The EFW measure is also one of the most widely recognized and detailed indexes of economic freedom. We focus on economic freedom rather than political freedom because we are more interested in the policies that directly effect economic productivity. The index has been stable over time and has been used in several published papers (e.g., Vega-Gordillo and Alvarez-Arce 2003). The index has been compiled since 1970 and is publicly available at www.freetheworld.com.

Regression Models

Throughout the tables as well as in the text, we use the variable names mentioned above. We estimate the following models:

- Model A: $Prod2000 = \beta_0 + \beta_1 Tech2000$
- Model B: $Prod2000 = \beta_0 + \beta_1 Free2000$
- Model C: $Prod2000 = \beta_0 + \beta_1 Tech2000 + \beta_2 Free2000$
- Model D: $Prod2000 = \beta_0 + \beta_1 Tech2000 + \beta_2 Free2000 + \beta_3 Tech2000*Free$

Where:

- Prod2000 = GDP per worker in 2000
- Tech2000 = Indicator of Technology Capabilities for Developed and Developing Countries in 2000
- Free2000 = Economic Freedom of the World indicator in 2000
- Free = dummy variable equaling 1 when Free2000 is median or higher

RESULTS

Descriptive Statistics

Table 1 reports descriptive statistics on the three key variables: technology, freedom, and productivity. Tech2000 ranges from 0.028 to 0.867 and has a mean and median of 0.329 and 0.313 respectively. Free2000 ranges from 3.5 to 8.7 and has a mean and median of 6.399 and 6.5 respectively. Prod2000 ranges in value from 183 to 105,064 and has a mean and median of 13,273 and 3,978 respectively.

We also calculate correlations. Consistent with the literature on the effects of technology and freedom on productivity, we note significant correlations between technology and productivity as well as between freedom and productivity.

Regression Analysis and Models of Productivity

Model A is a regression of Prod2000 on Tech2000. Consistent with results reported in the literature, we find high R-squares (0.6416) as well as a significant coefficient for Tech2000. We also find strong results with Model B that uses Free2000 as the independent variable. Comparing the R-squares for models A and B, we note a stronger explanatory role for Tech2000. This is confirmed by model C which uses both Tech2000 and Free2000 as explanatory variables. While both variables have significant coefficients we note that the R-square for model C is only slightly higher than R-square for model A.

A key contribution of our study is an understanding of how freedom modifies the effect of technology. Model D adds the interaction variable indicating how freedom modifies the effect of technology on productivity. This variable has a significantly positive coefficient of 26,254 with a t-statistic of 2.71. This indicates that countries with higher levels of freedom have a greater link between technology and productivity. This is consistent with McNair (1998) who argues that there is synergy between IT and economic freedom.

Adj. R^2		.6416	.4821	.6762	.6933

SUMMARY

Using a sample of more than 100 countries, we assess the joint impact of technology and economic freedom on productivity. We use two samples, one containing 1990 data and the other containing 2000 data. We find consistent results indicating that both technology and economic freedom are influential variables. We also find indications that technology is the more important variable and the impact of economic freedom is primarily through its modifying effect on technology. Thus, countries with greater economic freedom have a greater link between technology and productivity.

We caution readers about the suggestive nature of these results. Because we rely on cross-sectional associations, we cannot make strong statements about causality. Further, we may be detecting spurious correlations by not properly specifying all relevant variables. In particular, our research design could be subject to the problem of correlated omitted variables. Nevertheless, our results are reasonable and consistent with expectations. Thus our study is a valuable complement to the large literature on IT effectiveness.

Deployment of Electronic Commerce Tools in the Business-to-Business Services Context

Jari Salo, University of Oulu, P.O. Box 4600, 90014, Finland; E-mail: jari.salo@oulu.fi
Heikki Karjaluoto, University of Oulu, P.O. Box 4600, 90014, Finland; E-mail: heikki.karjaluoto@oulu.fi

ABSTRACT

The aim of this paper is to show how electronic commerce (EC) tools are deployed to manage business-to-business services. The case study reports on usage of various EC tools including the internet, the email, and ERP system to speed up and eliminate some manual administrative work in business-to-business service processes. For managers this paper shows how processes between companies and interfacing processes in a business-to-business service context can be done in a more cost-effective manner. For academics this study provides some ideas for further and consistent empirical research on the impact of EC tools on business services.

INTRODUCTION

It has been suggested in the literature (Vargo and Lusch, 2004) that markets must move away from economics based dominant logic of marketing into a revised logic focused on intangible resources, the co-creation of value, and relationships. In here, we focus on services and the co-creation of value between the service suppliers and the clients and relationships between the suppliers and clients.

The emergence of EC in forms of interconnected computers, the internet and mobile phones has enabled radically new and innovative services to be offered to customers via digital channels. Digital channels have appeared and been adopted very rapidly (see Poon and Joseph 2000; Cho and Park, 2003).

EC have changed the place and characteristics of service setting. In business-to-business setting companies are using novel EC tools such as the extranet to interact within and between organizations digitally (Vlosky et al., 2000). Businesses can use EC tools to re-engineered business processes (Aldin et al., 2004) and those also enable many novel channel and communication solutions (Agnihotri et al., 2002). The basic aim of the paper is to understand, explain and describe how EC based tools can be deployed in the business-to-business service industry. A detailed review of different types of EC tools that can be deployed also in service industry setting is provided by Salo (2006).

First, we present a review of the services literature. Second, we present the methodology section of the paper. A case study elaborates on the use of EC in a business-to-business service organization. Finally, we conclude with a discussion of future research areas for business-to-business services conducted with EC.

BUSINESS-TO-BUSINESS SERVICES

After the invention of the internet companies started to utilize it for various marketing purposes including providing a variety of services ranging from buying airline tickets to monitoring thermal power plants. As practitioners continued to add different kinds of services and products to the information highway academics only pondered the possible consequences of this new phenomenon. Until recently Zeithaml, Parasuraman and Malhotra (2002) and Parasuraman and Zinkhan (2002) among others have provided insights into the changes occurring in the service industry sector. Digital delivery of services has altered some features of service quality as well as made service consumption more convenient to customers (see Ruyter et al., 2001). It should be noted that the internet and mobile phones are just channel additions that need to be managed accordingly.

METHODOLOGY

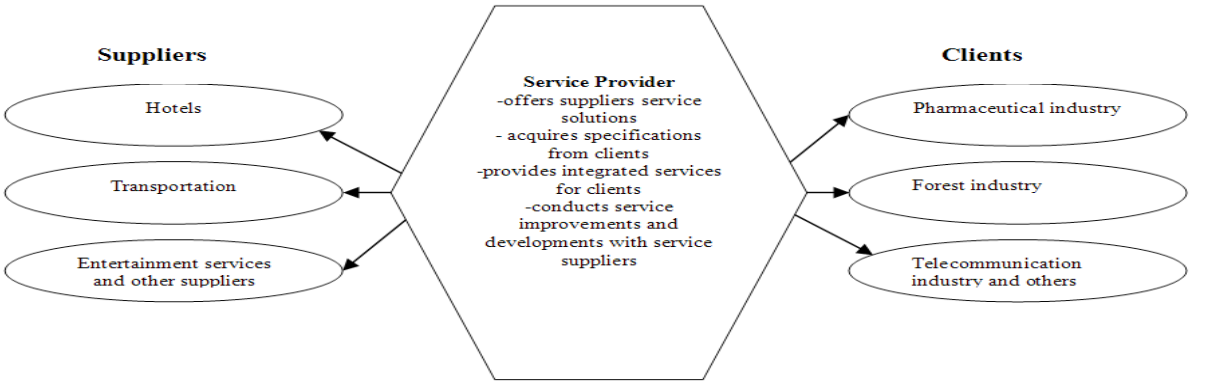
Due to the novel nature of this phenomenon in which the researcher has only little or no control at all over events occurring in a real-life context, a case study is the most appropriate method (Yin, 1994). The case company was selected based on the idea that it should represent the problem of the study. Besides the interview the empirical part of this study consists of various kinds of data. The objective of data collection was to get rich primary data from the studied phenomenon. The semi-structured interview formed the main data source from which the issues were identified and the framework was completed.

USAGE OF EC TOOLS IN B2B CONTEXT

The company studied is a relatively large Finnish service industry company providing mainly B2B customers with a wide range of entertainment and catering services, including transportation and accommodation. The Service Provider has faced rapid growth since its establishment in 2000. The Service Provider has been successful in offering various services to its clients. Clients are usually large pharmaceutical companies developing different types of medicines, forest industry companies providing paper and wood based solutions to end-customers and telecommunication industry clients such as mobile phone manufacturers and developers. The Service Provider has over 100 established business relationships with its clients. Service suppliers are hotels, transportation services providers, and entertainment service providers. Currently, the Service Provider has close relationships with a large number of service suppliers and even more loosely structured connections with other service suppliers. These suppliers provide the means for the Service Provider to solve their client's problems. For example, many large pharmaceutical companies need an excellent location and entertainment services to present new solutions to medical doctors; businesses in the forest industry need ways to reward excellent work conducted by their employees, for example by having an unofficial get together or party. The growth in demand partly stems from the fact that the CEO has personally created and maintained many of the relationships with clients and suppliers. The company has a special role in the value-chain as it facilitates transactions with help of its competence in collecting a wide array of services into one commodity offering as presented in Figure 1.

Figure 1 shows in detail the central role of the Service Provider between its large clients and relatively small service suppliers. Locally, suppliers are large but on a global scale, and when compared to the Service Provider's clients, the suppliers are relatively small. The Service Provider combines multiple business organizations that offer different kinds of services ranging from hotel services to fly fishing activities into an integrated service which is targeted to their clients. Since the Service Provider offers routine services and some tailored services to its clients it is heavily dependent on the collaborative supplier network. This co-operation is possible because before the establishment of the Service Provider company the CEO operated a catering firm and collaborative networks of organizations emerged in early 1996. She was conducting business with many organizations and simultaneously created a wide personal contact base. The collaborative network at that time consisted of the Service Providers' future clients but also future collaborative network suppliers. The relationships and partnerships developed during that time were important for the rise of the Service Provider company.

Figure 1. Central role of the service provider



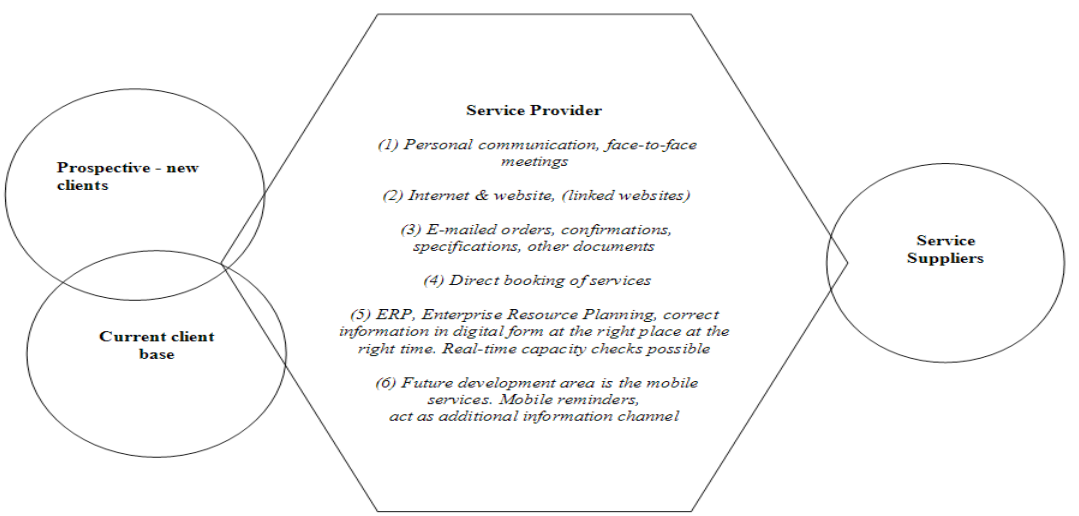
Besides offering routine services to clients the Service Provider also develops new services in interaction with its suppliers. Basically the Service Provider develops services based on each client's specifications. In practice, the new service development is conducted together with several service suppliers in joint meetings. After a new service concept is developed it is offered to many customers. For example, a small theatrical play performed in a restaurant or pub context is one of the newly developed service concepts. The co-creation of services would not be possible if the Service Provider was not acting as a middle man between the service suppliers and clients.

In addition to developing new service concepts, the Service Provider and service suppliers have established several means to communicate digitally. According to the CEO, 90 percent of sales come from B2B clients and 70 percent of sales are initiated with the help of EC tools such as e-mail or the internet. The CEO explained that older customers contact the Service Provider directly by e-mail while the internet is a very attractive channel for new customer acquisition. Moreover, digital interaction is used in routine communications and to handle administrative issues. Clients of the Service Provider can also interact digitally with the company. Companies can order hotel rooms and book tables in restaurants in advance digitally. This frees the time of salespeople and their assistants for other more productive work. The room and table reservation system was developed by a local software house. The newest digital addition is a real time ERP system that enables both the clients and suppliers to interact digitally with each other. It helps with communication and streamlines the decision making process as well as driving down extra costs related to booking services. The Service Provider is also creating loyal client electronic mailing lists to develop even more trustful service relationships. The CEO is also very interested in developing mobile services especially for B2C customers and adds that without the internet it would be almost impossible to operate so effectively. The future challenge is to develop a coherent computer based service system that serves B2B and B2C customers equally. Figure 2 depicts the eminent role of EC tools in the service network created by the Service Provider.

CONCLUSION

We have illustrated how a service industry company serving business clients and providing service development to its service suppliers used different types of EC tools to improve the value gained by both clients and suppliers. Based on the case study it can be proposed that the digital infrastructure development is an antecedent for successfully digital service delivery. In addition, the selection of proper EC tools to be used in service development and delivery are the second step while pilot testing serves as third phase of the EC tool adoption in service setting. After successful adoption of an EC tool further service re-engineering and automation as well as digitization possibilities are analyzed and planned. For managers this paper has provided several interesting insights into the EC tool adoption in business-to-business service setting. The paper discussed sequential adoption of EC

Figure 2. Role of the EC tools in the interaction between the actors



tools and also highlighted the pertinent role of social communication especially in a new service development setting. These future contributions could be done with the help of longitudinal case studies or surveys. It should be noted by the managers that the amount of EC tools used to deliver service is dependent on customer acceptance (see Ruyter et al., 2001). Thus, under what conditions and in what service settings deployment of EC tools is useful might be an interesting future study area (see Cho and Park, 2003).

A Multi-Criteria Decision Support System for Selecting Cell Phone Services

INTRODUCTION

Cell phones have achieved high levels of market penetration in a relatively short time. According to the Canadian Wireless Telecommunications Association (CWTA, 2006), more than half of all Canadians are cell phone customers and 47% of all phone connections in Canada are wireless. For many organizations, equipping their employees with cell phones is an accepted operational cost. The industry-analyst firm Yankee Group estimates that businesses now spend a quarter of their telecommunications budgets on cell phone expenses (Allianceone, 2006). In Massachusetts, over 10% of cell phone bills are paid by employers (Cummings & Smith, 2005).

Most areas have multiple cell phone service providers, and each typically provides a wide variety of plans with different cost structures. One Canadian company claims that most companies are actually spending 20-50% more than they need to (Allianceone, 2006). There are several reasons for this. First, finding the most cost-effective plan from among so many choices is complex and time-consuming. Second, each employee can have a different calling pattern in terms of total minutes, where the calls are originating from or going to, and when the calls are placed. Often there is no single plan that is best for everyone. Third, cost is not the only factor to consider; service quality varies as well. Moreover, plan costs, calling patterns and service quality are constantly changing. While larger organizations can use specialized consulting companies and have the volume to get special discounts, smaller businesses are often very much on their own to determine which plan(s) is best for them.

The goal of this research is to develop a Multi-Criteria Decision Support System (MCDSS) to help organizations, particularly small businesses, determine the best cell phone plans for their employees. Finding the lowest cost plan is relatively straightforward using a computer-based system; each calling pattern can be compared over all plan cost structures. To incorporate non-cost factors, a survey was conducted among small businesses to determine which they considered to be most important. These factors were then integrated into the MCDSS using the Analytic Hierarchy Process (AHP). The system allows decision makers to have different preferences for the importance of non-cost factors, different rankings for how each service provider performs on these factors, and different weightings between cost and non-cost factors overall.

CELL PHONE INDUSTRY

This research was conducted in a small city (population under 100,000) in Canada in 2006. At that time, there were four major cell phone providers, two owned by the same company, offering a total of ninety business plans with different rates. The rates have a similar structure across different plans. The main elements are a fixed monthly cost, per minute rates and additional options. The fixed monthly cost covers service fees (including system access and 911 emergency services) and often includes an allotment of "free" minutes. Once these have been exhausted, per minute rates come into effect.

Per minute rates are based on when the call is placed and its origin and destination. Canadian cell phone service providers usually divide location into three categories: local, long distance within Canada and from Canada to the U.S., and long distance from the U.S. to Canada. Within each category, the minutes can be classified by time as weekday, evening, and weekend. Each plan can provide different free minute allotments and different per minute rates for each of the nine combinations of location and time. However, each provider currently has identical weekend and evening rates so there are actually only seven call types to consider.

Some plans offer additional options that customers can select according to their needs and usage patterns (e.g., caller ID). Some affect costs, such as special rates when calling other cell phones from the same provider and business pooling plans that allow a group to share unused free minutes.

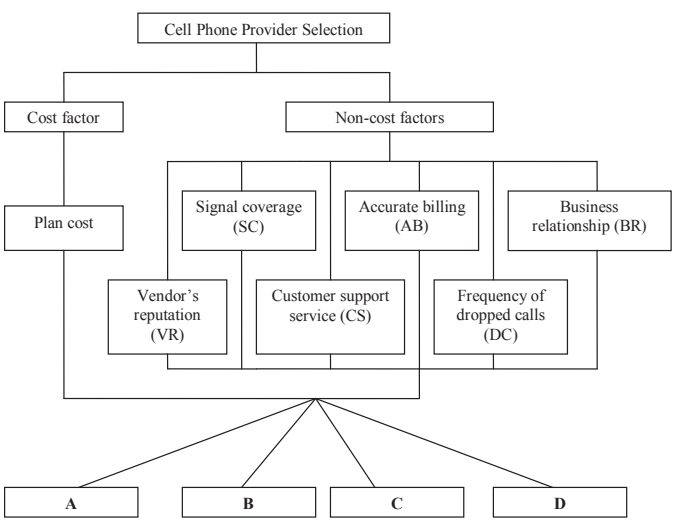
CUSTOMER SURVEY

Finding the best provider of a product or service is a common task that typically involves multiple criteria. The lowest cost plan is not necessarily the best plan. Non-cost factors can significantly affect a user's experience with any supplier, and cell phone service customers are starting to focus more on factors such as billing accuracy, provider reputation, and service quality (Cummings & Smith, 2005; Mao, Srite, Thatcher, & Yaprak, 2005; Navarro, 2005; Totten, Lipscomb, Cook, & Lesch, 2005; Woo & Fock, 1999). We selected 13 of these criteria (Table 1) for consideration.

A survey was constructed using a five-point Likert scale to measure the importance of each criterion. In addition, some demographic data were collected to help understand the characteristics of local business cell phone use. After constructing the questions, 10 academic researchers with backgrounds in the cell phone industry examined the clarity of the questions, the accuracy of the language, and the structure of the questionnaire. The questionnaire was refined and finalized after incorporating their feedback.

The survey was mailed to a random sample of 140 businesses, identified using the local Yellow Pages telephone directory. Most of them were in construction,

Figure 1. A four-level AHP hierarchy for selecting cell phone service vendors



transportation, and automotive retailing. Two response methods (regular mail or Web-based) were provided. A 29.2% response rate was obtained within four weeks. The six most important non-cost criteria (with 5.0 being the highest possible rating) were signal coverage (4.53), customer support service (4.53), accurate billing (4.47), frequency of dropped calls (4.45), provider's attitude and willingness to maintain the business relationship (4.37), and vendor's reputation 4.26. The two most important cost factors, ranked fifth and seventh, were the fixed cost of the plan(s) (4.37) and the per minute rate (4.21). Respondents were given the opportunity to include additional factors not included in the survey. Contract handling and warranty coverage were among them, but none of the entries occurred frequently enough to be included in the system.

Most respondents reported that their cell phone bills are less than $2,000, and none were responsible for cell phone bills for over 50 employees. The average monthly cost for each user is estimated at $64.71.

SYSTEM DESIGN

The goal of this research was to build a Decision Support System (DSS) to help small businesses find the right cell phone plan for their needs. The system was designed using a standard framework (Sprague, 1980), where the key component parts are a database, model base, and dialogue generator (or user interface).

Database

The database typically requires external and internal data. In this case, the external data are the cost structures for each plan. These were retrieved from provider web sites on February 2, 2006. The internal data is based on 500 different simulated employee calling patterns, which are generally consistent with local calling patterns. The database was stored using Microsoft Access.

Model Base

The model base has three main parts, which analyze cost and non-cost factors and then integrate them to provide a final decision (Figure 1). The Analytic Hierarchy Process (Saaty, 1980), a multi-criteria decision making technique which permits the inclusion of subjective factors in arriving at a recommendation, was used to assess the criteria because it can handle both quantitative and qualitative criteria. For that reason, a large number of DSS covering many types of products and services have been developed using the AHP (Vaidya & Kumar, 2006; Vargas, 1990).

The AHP facilitates decision making among a number of alternatives and criteria by formulating priorities. The process requires that the decision maker provide judgments about the relative importance of each criterion (e.g., signal coverage, customer service support, etc.) and then specify preferences for each decision alternative (cell phone provider) on each criterion. The output of AHP is a prioritized ranking, indicating the overall preference for each of the decision alternatives (Saaty, 1980, 1990). Expert Choice™ a commonly used software package to perform AHP computations, is used in this system.

Non-Cost Factors

Non-cost criteria are attributes of the four cell phone service providers, not the 90 individual plans. In order to determine the weight of each of the top six non-cost criteria (Figure 1), 15 entries are required for the pairwise comparison matrix. Table 1 provides an arbitrary set of example ratio judgments. These would normally vary among decision makers. Similarly, the ratio preferences of alternatives (providers) with respect to each criterion were entered into pairwise comparison matrices. Based on an example set of ratio preferences, the relative priorities of the providers with respect to the set of criteria are computed by Expert Choice™ (Table 2). The missing entries, excluding the main diagonal of the matrix, can be determined using the reciprocal. For example, if Signal Coverage (SC) has a priority of 2 over Customer Support (CS), then CS has a priority of 0.5 over SC.

Finally, the aggregate relative priorities (combining the criteria weights in Table 1 with the relative priorities of the providers in Table 2) were generated using Expert Choice. These priorities (p_i^{NC}) range from 0.323 (A), the best choice when cost is not a consideration, to 0.269 (B), 0.215 (C), and 0.193 (D).

Cost Factors

The lowest cost cell phone plan for an employee can be found by simply computing the cost of every plan for that employee's calling pattern (i.e., number of minutes for each of the seven calling types) and selecting the minimum. For this system, a Search Decision Rule (SDR) approach was used based on Taubert (1968) who proposed this method for the aggregate scheduling problem.

The search algorithm for this system seeks the minimum cost with respect to different calling patterns. In the search loop phase, the minimum cost for the seven different call types (based on call time and locations) for a calling pattern are obtained within the inner search loops, and the total minimum cost is determined through an outer search loop. In both loops, comparisons are made between the

Table 1. Pairwise comparisons of criteria

Criteria	SC	CS	DC	AB	BR	VR	Weights
SC			3.0			2.0	0.136
CS	2.0		4.0	1.0	2.0	2.0	0.258
DC							0.065
AB	3.0		3.0		2.0	2.0	0.270
BR	2.0		2.0			2.0	0.168
VR			2.0				0.105

Note. SC: Signal coverage; CS: Customer support service; DC: Frequency of dropped calls; AB: Accurate billing; BR: Provider's attitude and willingness for business relationship; VR: Vendor's reputation

Table 2. Relative priorities of providers with respect to each criterion

	Criteria					
Providers	SC	CS	DC	AB	BR	VR
A	0.232	0.200	0.205	0.167	0.167	0.232
B	0.140	0.200	0.169	0.333	0.333	0.395
C	0.232	0.400	0.288	0.333	0.333	0.232
D	0.395	0.200	0.338	0.167	0.167	0.140

currently achieved cost and its previous optimal cost. If the current cost is less than previous optimal one, minimum cost becomes the current cost. Otherwise, the existing minimum cost is retained.

This can be expressed more clearly as follows. Let U_{ik} be the projected usage time for calling type k (below) for the i^{th} employee. Based on plans offered by local cell phone providers, seven different calling types are included:

- Local daytime usage (k = 1)
- Local weekend usage (k = 2)
- Local evening time usage (k = 3)
- Long distance daytime usage within Canada or from Canada to the U.S. (k = 4)
- Long distance weekend/evening usage within Canada or from Canada to the U.S. (k = 5)
- Long distance daytime usage within the U.S. or from the U.S. to Canada (k = 6)
- Long distance weekend/evening usage within the U.S. or from the U.S. to Canada (k = 7)

A particular cell phone service provider P may have N_p plans available. Every provider has different costs for each calling type for each service plan. Each plan has a basic service charge and allots a maximum amount of free time (which could be 0) for each calling type. When an employee's usage exceeds these amounts, the organization is charged for additional use at various rates. Even for the same provider, these rates vary from plan to plan and this cost is denoted by $C_{ik}^{\ j}$ and will be calculated whenever applicable by the function $f^j(U_{ik})$ for a particular vendor as follows:

$$C_{ik}^{\ j} = f^j(U_{ik}) \quad (j = 1, .., N_p)$$

where $C_{ik}^{\ j}$ is cost of the k^{th} calling type under the j^{th} service plan for the i^{th} employee. Note that $f^j(U_{ik})$ calculates the cost for additional time beyond the free allotment and therefore $C_{ik}^{\ j}$ is equal to zero if the time used is at or below that free allotment.

The total cost for the i^{th} employee under a given plan j is given by

$$C_i^j = B_i^j + \sum_{k=1}^{T} C_k^j \quad (j = 1, .., N_p)$$

where:

C_i^j = the total cost for the i^{th} employee under the j^{th} plan

B_i^j = the basic service (fixed) cost for the i^{th} employee under the j^{th} plan

T = number of calling types (T=7)

$C_i^{j_i^*}$ is the minimum of all plan costs for the i^{th} employee for the plan j_i^* among all N_p plans, where:

$$C_i^{j_i^*} = \min\left\{C_i^j, j \in N_P\right\}$$

For a group of N employees, the total minimum cost is:

$$C^* = \sum_{i=1}^{N} C_i^{j_i^*}$$

Using the simulated user calling patterns, the minimum cost when using a single provider is the sum of these minimum costs, which are $29,058.69 (D), $36,869.57 (B), $47,377.18 (A) and $52,466.97 (C).

To determine the relative priorities of the providers with respect to cost, a pairwise comparison matrix was generated. The lower the cost, the more preferred it is. For example, selecting B is 1.423 (52,466.97/36,869.57) times preferred compared to C. As for non-cost factors, the preference of C compared to B can be determined using reciprocity (i.e., $a_{ji} = 1/a_{ij}$ for i^{th} and j^{th} providers). The relative priorities of each provider with respect to cost (p_i^C), generated using Expert Choice™, are 0.208 (A), 0.267 (B), 0.187 (C), and 0.338 (D).

Integrating Cost and Non-Cost Priorities

Finally, both cost and non-cost priorities for the providers need to be integrated to produce the overall final ranking (Sarker & Zahir, 2006). Let p_i^C and p_i^{NC} be the relative priorities of i_{th} provider for cost and non-cost factors, and w_1 and w_2 be weights of the factors, respectively (subject to $w_1 + w_2 = 1$). The overall aggregate relative priority A_i for the i_{th} provider is:

$$A_i = w_1 \times p_i^C + w_2 \times p_i^{NC}.$$

The decision maker can choose different weights in accordance with the goal of the organization, and finally determine which provider, and associated minimum cost plans, is optimal for an organization.

As shown in Table 3, A outperforms the rest of the providers when the cost weight is less than 46% while D is the best choice for higher cost weightings.

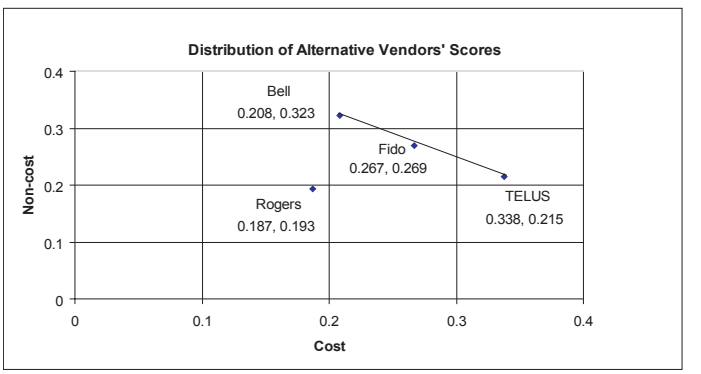
Figure 2 provides a graphical view showing that only A or D can be the optimal solution.

Table 3. Aggregate relative priorities of providers for different cost and non-cost weights

Cost Weight (w_1)	A	B	C	D
0%	**0.323**	0.269	0.193	0.215
10%	**0.312**	0.269	0.192	0.227
20%	**0.300**	0.269	0.192	0.240
30%	**0.289**	0.268	0.191	0.252
40%	**0.277**	0.268	0.191	0.264
46%	**0.270**	0.268	0.190	**0.272**
50%	0.266	0.268	0.190	**0.277**
60%	0.254	0.268	0.189	**0.289**
70%	0.243	0.268	0.189	**0.301**
80%	0.231	0.267	0.188	**0.313**
90%	0.220	0.267	0.188	**0.326**
100%	0.208	0.267	0.187	**0.338**

Note. $w_1 + w_2 = 1$ (w_2 is non-cost weight)

Figure 2. Providers' relative priorities with respect to cost and non-cost factors



CONCLUSIONS

Selection of cell phone service providers can be solved as multi-criteria problem involving both quantitative and qualitative factors. An integrated DSS was constructed to help organizations select the best cell phone provider(s). The method is a significant improvement compared with existing methods that are cost-oriented only. Both the literature review and the results of the survey indicate that several non-cost criteria play important roles in determining the optimal cell phone service provider. Signal coverage was considered most critical, and this may be particularly important to organizations that not only serve the city they are in but also a large surrounding rural area.

The AHP-based analysis of potential providers makes it possible to include multiple non-cost criteria. The factors relevant to the cell phone provider selection can be manipulated in accordance with the user's preferences. Moreover, not only are non-cost factors included but the results of the analysis can be used to demonstrate how and why these factors are influencing a decision.

Utility Computing and Its Applications

Sri Madhisetty, University of Technology Sydney, Australia; E-mail: sri@it.uts.edu.au

ABSTRACT

Utility Computing (UC) is an on demand delivery of enterprise applications and business process in a shared, secured and scalable standards based environment over the Internet. Though many service oriented architectures have failed before to deliver on their promises of remote delivery of IT services, the ubiquitous nature of computing which is now present is the motivating factor for computing to be seen in a "Utility model". This paper also elaborates on how we could accommodate such a system using a mobile interface.

1. INTRODUCTION

As service oriented model is becoming more popular Utility Computing (UC) is becoming more acceptable. Many businesses are not aware about the productivity it could increase by using this model. However some business has already adopted this model partly, by using services provided by an external vendor to augment their existing Information Technology (IT) infrastructure.

The problem currently the industry is facing is that there is no established framework about how to adopt these changes strategically for the organization to effectively utilize its IT services. Many organizations are moving away from the current licensing model to use software IT services, provided by an external vendor to suit their specific business needs, and focus on their core business. The chief benefit from moving away from the licensing model gives the company more flexibility in the way it can use the software upon its need not because they have to buy everything what a software vendor pushes the user to buy. Most people would not imagine having a cow in their back yard for a cup of milk. It is easier to go to the super market to buy a specific quantity for consumption. The electricity is another example of how we pay for what we use, and not buy in bulk. Computing has become ubiquitous in nature by which if there was a remote device that could deliver services through a network to any device which could access it could become very popular.

Utility Computing is going to impact on the IT-Infrastructure of any organization and how IT services will be delivered in the future. In most business services are provided by specific components for example to support a Unix application, a UNIX based server has to be installed. These components by themselves may not be compatible with each other leading to data inconsistencies or IT resource duplication. The creation of many independent data centers, all of them running on same hardware and for the most part running similar software has imposed several penalties on many firms[1], which could lead to problems in integration, and compatibility of the software with the hardware are some issues organizations face today. Regular updates are to be made at regular intervals to support the applications organizations use. The update software is not tested for every individual application on board, which may lead to unreliable systems. Such a fragmented system may not provide good use of the existing infrastructure. Though the present systems are profitable in a vendor's perspectives such that the vendor can push the new hardware technology on to the consumers. This leads to Organizations over investing in their IT resources; this trend may not provide sustainable growth in the IT industry.

The advances in the network technology are enabling it to extend and reach out to other business across the supply chain and in many instances, directly to the consumer [2]. According to the recent Gartner study, the Application Service Model (ASP) goes beyond savings on technology, and includes savings associated with hiring, and rapid implementation of projects, and the ability to scale up the system and benefits related to business process enhancement [5]. Thus the concept of providing IT resources from a remote location is becoming more acceptable. Early forms of UC are already happening as some companies have outsourced their backup and recovery process to corporations like IBM and HP. These remote data centers could be maintained remotely by expert organizations that have the skills and resources to be able to look after stored corporate data. This is now becoming very acceptable; this demonstrates that very complicated network intensive applications like backup of data could be implemented using the Utility model.

2. ADOPTION OF UTILITY COMPUTING BY ORGANISATIONS

Organizations are actively investigating cost of effective alternatives such as IT outsourcing and the use of application services delivered over the Internet by external providers. Utility computing is software on demand service and is likely to have a major impact by providing IT solutions to the end user organizations.

It could be debated about how such a model could be established using an existing IT infrastructure and study the impact of Utility computing architecture in many small to medium organizations. I have chosen a mobile architecture, because it can easily demonstrate the ubiquitous nature of today's computing environment.

It could support my argument for adopting UC in a grand scale by enhancing specific hardware and software technologies. Most mobile devices like mobile phones are able to access the Internet remotely and use many day-to-day applications remotely through the device, usually a mobile phone.

IT vendors are eager to establish partnerships with the organizations to deliver service-oriented model such as the UC model to deliver IT services. Delivery of such services is possible because of the advancement of Internet technologies like broadband i.e. 3g network from Telstra and dedicated VPN. The granularity of the service depends on which model is being adopted. Application Service Model " ASM " provides applications to organizations remotely. The "Business Process outsourcing model" is responsible for providing parts of the IT services remotely.

The impact on productivity is limited by the amount of expert resources required to configure, install and operate enterprise applications and the fast rate of technology change, which require periodic maintenance. [4] From the service consumers point of view it is a challenge how to integrate different services provided by multiple organizations, another issue is what architecture model to follow to allow such an integrated scalable of IT services customized to different users in the same organization. One could only imagine the complications in customizing applications remotely to serve one particular person in an organization. It is also debatable on what architecture to be followed in order for business to use Utility Computing model.

As most current available software has proprietary architectures it makes it difficult to integrate with other applications. In order to provide interoperability among applications, it is vital to allow different applications to share date and business process. The question then is how to adopt an architecture which addresses the needs from a end user perspective and how to make them compatible with the clients view of effectively managing IT resources which needs to be addressed.

An attempt is made by me to integrate a mobile architecture to suit the Utility model.

3. UNIQUE MOBILE ARCHITECTURE TO SUPPORT UTILITY COMPUTING

Mobile computing is becoming popular because it provides data and voice access remotely. A mobile device needs to interact with several heterogeneous components in order to fulfill its task. XML standards exist to make data non-platform specific. For example the World Wide Web can serve as a best resource in locating the best price for any product. It is very difficult to catalog and send contents in the public domain, in order to provide a semantic access to the data. However agents

independent of the browser application do the task of locating the best price for a product. The problem quickly becomes multifaceted when a combination of contents and catalogs has to be transmitted and received from various sources from the web in order to provide dynamic access to the data.

Here we can clearly see that the UC based applications are only feasible if many different heterogeneous entities cooperate with each other as a federated system.

The Utility approach could bring about a scalable implementation maximizing its use of hardware and software resources. The current ongoing development of SOAP (Simple Object Access Protocol), WSDL (Web Service Description language) and others promises to provide substantial advantages to problems in software integration [6].

However in order to support multiple data sources which can deliver customized information to many end users using a utility model requires a semantic integration of data sources. However Semantic Web has much broader implications upon data access. The semantic solution is to provide descriptions of information on the Web to allow, "Machine understanding" of information. This could allow intelligent agents to automate many information-processing tasks [7]. This also enables dynamic service discovery and composition for a Utility Based Model (UBM). Therefore the service provider is transparent to the end user.

An optimal infrastructure to best suite the Utility Computing paradigm is a server which has integrated components such as a Web Server, a business logic layer and a database to support Ansi Sql query standards. This database could be used to facilitate storage and retrieval of large files with media content. (Unstructured data) In addition to the existing layers an added layer which could support semantic data integration which can communicate with the mobile device is ideal to generate personalized content remotely from an integrated server approach to support Utility Computing model.

CONCLUSION

Utility Computing is a new paradigm shift in the way computing could be done in the future. As computing is becoming ubiquitous in nature, soon people would see that there is no rational in adding more hardware to increase productivity. The advancement in network infrastructure and the power of the internet are the impetus for developing a model, which treats computing power as a form of utility, such that an organization can pay only for what it uses, and not what the vendor wants to sell. Organizations like IBM would become powerhouses which would enable smooth and efficient use hardware technology and provide scalable IT-Services to its end users.

Multimedia and Virtual Reality Technologies in Architecture Education

Nicoletta Sala, Università della Svizzera italiana, Mendrisio, Canton Ticino 6850, Switzerland; E-mail: nsala@arch.unisi.ch

ABSTRACT

The evolution of multimedia and Virtual Reality (VR) technologies can open new educational opportunities in architecture education. This paper describes an example in this educational field.

Keywords: Hypertext, Multimedia, Hypermedia, Virtual Reality, Education, Architecture.

1. INTRODUCTION

Multimedia is the use of several different media (e.g. text, graphics, animation, audio, video, and interactivity) to convey information. With increases in performance and decreases in price of the hardware, multimedia is now commonplace. Therefore, this technology could offer new opportunities in educational environment, for example integrating different media in the teaching path.

Virtual Reality (VR) is another technology which could have great potential in the school of the next future. It is an environment that is simulated by a computer. The origin of the term "virtual reality" is uncertain though. It has been credited to *The Judas Mandala*, a 1982 novel by Damien Broderick where the context of use is somewhat different from that defined now. As a medium, VR has three defining characteristics [1]. It is interactive (users can interactive with models), spatial (models are represented in three spatial dimensions), and real-time (feedback from actions is given without noticeable pause). VR can be classified according to its methods of display; we have immersive VR (which involves a high degree of interactivity and high cost peripheral devices, for example the head mounted displays), and non-immersive VR in the form of a windows into a virtual world displayed on a computer's monitor [2]. A virtual reality system has the following three primary requirements [3]: immersion (which permits to the user the physical involvement, capturing exclusive visual attention and responding to three-dimensional input. For example, through a head-tracker, 3D mouse, data glove, or fully instrumented body suit); interaction (through the three-dimensional control device to "navigate" in the virtual environment); and visual realism (which is a representation of the virtual world using computer graphics techniques). This paper describes an application of multimedia and virtual reality in a faculty of architecture, where these technologies are used in the teaching paths in different courses.

2. MULTIMEDIA AND VIRTUAL REALITY IN ARCHITECTURE EDUCATION

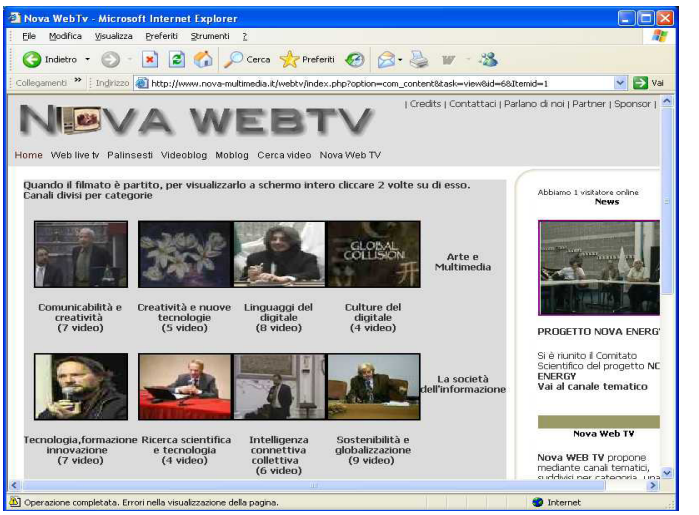
Multimedia are modifying the ways in which we share information. In particular, it is affecting methods of teaching and learning [4, 5]. We analysed the teaching impact of multimedia technologies in a faculty of architecture, in particular in two courses: one of mathematics and the other dedicated to the computer science. The investigations followed the question: "How to organize some academic courses using multimedia solutions and virtual objects integrated in the teaching path?" To answer it, two courses, specifically conceived for the Faculty of Architecture at University of Lugano (Mendrisio, Switzerland), have been organized starting from 2000 [6]. In these courses, the traditional lectures were integrated by the use multimedia as a teaching strategy. First course, named "Mathematical thought", was inserted in the first year of the studies until 2004 (5 credits ECTS, European Credit Transfer and Accumulation System). It introduced basic facets of mathematical thought connected to the arts and to the architecture (e.g., the symmetry, the proportions, the golden ratio, the curves and the surfaces, the fractal geometry and the complexity in the study of the urban grown). The second course, named "New media for the architecture" (third year, 5 credits ECTS), is actually in the curriculum of the faculty. This course proposes how new media and the graphics solutions can create new architectural shapes, for example hypersurfaces, and a new kind of architecture (for example, cyberarchitecture transarchitecture, and hyperarchitecture).

The traditional lectures were integrated by the use multimedia, because 60% of students today are visual learners [7, 8]. This category of learners may benefit most from multimedia presentations, which combine words with pictures and audio can help to redefine the teaching methods [4, 7, 9].

The lectures were organized using hypertexts and multimedia presentations, didactic CD-ROM, animations in Java language, scientific documentaries, data streaming, dedicated to the information and communication technologies. Figure 1 shows the home page of Nova Web TV (http://www.nova-multimedia.it/webtv/) that is a section of the portal Nova Multimedia (http//www.nova-multimedia.it), which collects interviews, "media book", and scientific data streaming dedicated to the connections between arts, new media and computer science. "Media Book", available on line in pdf format, collects the theoretic contributes of famous contemporary scientists coming from the international academic and scientific panorama. We used some interesting "media book" and the interviews, present in the section Nova Web TV, integrating their in the teaching path. The lecture hall was provided with the technological structures which was allowing to use different media in the lessons. Their contents were integrated in the teaching path.

Other technological tool integrated in the teaching path was the Virtual Reality (VR). In recent years, VR has emerged as a revolutionary human/computer interface, challenging everything to which individuals are accustomed. Research institutes around the world have demonstrated the potential of VR systems as a visualization tool and, as technology continues to improve, it is proposed that VR systems will become increasingly pervasive as tools for education [10, 11]. Thus, inside our educational environment, the virtual reality have been used in two ways. One is to insert this technology in the process of teaching. For example, to

Figure 1. Home page of Nova Web TV (http://www.nova-multimedia.it/webtv/)



explain the 3D surfaces some 3D virtual objects have been created, using VRML (Virtual Reality Modelling Language). The virtual objects can be observed in the theoretical lessons and it is possible interact with their during the laboratory activities [6]. The students manipulated the polyhedrons, observing them from different points of view. They also analysed the connection between virtual polyhedrons, the nature and the architecture (for instance, looking for an analogy between the polyhedron forms, the forms of Radiolaria, a kind of protozoa, and the geodesic domes). They studied the crystals' shapes and their symmetry, with virtual crystal created using VRML, and they came in virtual buildings to observe their geometrical components and their analogy with natural shapes.

Second way is to integrate virtual reality in the design process, for example to realize virtual models of buildings. It has been developed in the laboratory activities of the course of "New media for the architecture", where the students use the virtual reality technology, and they present their architectural projects using hypermedia presentations and "virtual tours" inside them. This educational approach is begun in 2001 and it continues everything today. During these five years, the students evaluated the teaching process through multiple choices tests. During the exams, we evaluated the quality of the teaching method analysing the students' school profit. Important deductive considerations are shown.

In brief:

1. multimedia assists the teaching process (in fact, different communication codes in a lecture make more incisive the explanation);
2. the lectures are now more interactive (for example, in the laboratory activities the students can create virtual objects and they can navigate in didactic hypermedia); and
3. the students got good grades in the exams.

Some of the possible benefits of VR on the design process and practice of architecture could be:

- the ability to test ideas in "real time" in a "three-dimensional" space during the design process;
- communication of ideas, and the power to illustrate the projects;
- the elimination of much of the guesswork in design;
- braver and better designs; and
- the integration of the design process.

These deductive considerations are in agreement with recent studies which have recognized that virtual reality offers benefits, and it can support the education and the design project [1, 10, 11, 12, 13, 14, 15]. In particular, in the faculties of architecture where the design is affected by the medium used [1, 16]. Henderson (1999) notes that: "Young designers trained on graphics software are developing a new visual culture tied to computer-graphics practise, that will influence the way they see and will be different from the visual culture of the paper world" [17, p. 57]. Architects who have grown up with digital media and virtual reality will be expert users of interactive, spatial, real-time environments [1, 18]. These designers will solve problems using representations that do not emulate paper-based media.

3. CONCLUSIONS AND FUTURE TRENDS

Educators and researchers look for more efficient ways of teaching and learning. Furthermore, it is proposed that different media assists in the teaching processes. Kozma (1991) argues that media which promotes cognitively relevant characteristics such as symbol systems and processing capabilities, enables students to process information more effectively and understand it more fully [4]. Bagui (1998) has observed that, because multimedia allows guided discovery, students involvement in learning is increased, understanding is greater, and the intrinsic features of the computer (e.g., immediate feedback, animation, and individualization) are more likely to motivate students to learn [19].

We are proposing that multimedia and virtual reality can assist the teaching process, in agreement with other researchers [4, 12, 13, 14, 15, 19, 20, 21, 22]. Therefore, all subjects of our courses have been organized implementing multimedia solutions [6, 23]. In fact, the use of multimedia technologies in the traditional lectures have promoted the following pedagogies including:

- an in depth study of the platonic solids
- application of the perspective
- to observe the fractal forms
- to manipulate some virtual object in 3D (e.g, virtual geodesic domes, or virtual crystals).

We observed that the hypertexts facilitate human learning. Recent researches show that a more tree-like or hierarchical text structure limits navigational difficulties as compared to a purely heterarchical structure [21, 22]. During the laboratory activities we noted that in the students' navigation in hypertext some students can only interact with pages passively, by reading and clinking the links. For this reason, it is important that in the laboratory activities the presence of the professorial assistants, it is important because their facilitation can illustrate the correct and active navigation inside the document organized as hypertext [23].

In order to effectively apply VR as an educational tool in architecture, and in other technical areas, a number of simulation difficulties have to be identified and solved. For example, to maintain high frame rates on personal computers and the low resolution of inexpensive viewing devices. One of the main aims of VR is to create virtual worlds and virtual environments in which humans can interact together. The problem of the interaction with other users and with virtual objects will raise in the next future. The realism presumably will play a major role in the programs' success and likely will prove positive in the future. How to create the virtual worlds? Some virtual worlds will be oriented certainly to the educational field and other for training, works or fun. Architects will potentially help to make the virtual world a pleasant and stimulating place to work and live in, with a good quality of life. This will require people who understand the psychological effects of the spaces, generated by the computer, on people inside them, and the architects have to prepare themselves to this new work opportunity. Architects as designers of Virtual Worlds will be required to make these environments interesting, rich, and engaging places. Therefore, it is important to prepare a correct training on the use of VR in the faculties of architecture [1, 16, 24]. Some architectural theorists are looking at VR as such an inhabitable alternative reality. Whyte (2002) affirms: "they describe objects in interactive, spatial, real-time media as though they existed in a new form of space, rather than in spatial representations and look at Novak (1996) terms the vitality of architecture after territory" [1, p. 46]. VR is also connected to the cyberspace. Novak argues that: "Cyberspace as a whole, and networked virtual environments in particular, allow us to not only theorize about potential architectures informed by the best of current thought, but to actually construct such spaces for human inhabitation in a completely new kind of public realm" [25]. For the architectural education, virtual reality will become the place to go to do things that you could not normally do in architect-designed buildings.

The educational approach presented is only a small step towards locating a correct fit, or the integration between new media, and traditional media in the teaching process [26]. It also uses Virtual Reality. As such it can promote more interesting and interactive the lessons, instead of the traditional educational methods [26]. It is also proposed that this approach will accommodate different learning styles, favouring the visual learners. This paper is a set of suggestions emerging from our teaching activities. With them we hope to give an aid to the teachers that want to use multimedia and virtual reality technology in their work.

Structuring the Market for E-Collaboration Systems: A Study Based on Cluster Analysis

Kai Riemer, European Research Center for Information Systems (ERCIS), Leonardo-Campus 3, D-48149 Münster, Germany; E-mail: kai.riemer@ercis.de

ABSTRACT

Software systems for supporting communication, coordination and cooperation processes in groups have become the backbone infrastructure to support knowledge work in a globalized economy where virtual work has become the prevalent modus operandi. Fuelled by recent technology trends numerous new E-Collaboration systems have appeared in the marketplace. In this paper a study that aims to shed light on the market for E-Collaboration systems is presented. A sample of 66 E-Collaboration systems was characterized in terms of their feature sets using a classification approach. Cluster analysis was used to uncover patterns in the resulting data. Four systems classes and a range of sub classes were identified each of which is briefly described. The results, being a reflection of the existing market complexity, should be equally helpful for researchers who deal with E-Collaboration systems as their objects of interest, as well as for business executives, who need to gather information to support buying decisions.

INTRODUCTION

E-Collaboration systems are an increasingly important class of information systems. For many people work arrangements with colleagues from different companies in spatially distributed teams have become the new reality in contemporary organizations (Bélanger *et al.*, 2003). Increasingly, virtual teams are used to organize knowledge-intensive work in projects where the best experts are distributed across the globe (Lavin Colky *et al.*, 2002). Consequently, E-Collaboration systems have become a key technology and indispensable infrastructure for many enterprises. Fueled by recent trends such as the emergence of new communication media numerous new E-Collaboration systems have appeared in the marketplace. Hence today, an almost incomprehensible number of systems exists that often support a wide range of features.

In this paper a study is presented that aims to shed light on this market by structuring the range of available systems in meaningful classes. Such a classification is equally desirable from a management point-of-view having to deal with the selection of systems, as well as for researchers who focus on E-Collaboration systems as their objects of interest. Researching the application and the impact of E-Collaboration systems on individuals and organizations is only possible, if one has a good understanding for the typical features of these systems and available alternatives.

SYSTEMS CLASSIFICATION AND CLUSTER ANALYSIS

Previous attempts to the classification of E-Collaboration systems were mainly conceptual and based on single features; systems were divided in classes such as E-Mail, Conferencing, Calendars and the like (e.g. Munkvold, 2003). Today, most E-Collaboration systems would fall in two or more of these categories. With the diversification and the expansion of the available range of features such a classification seems no longer suitable. Rather, this study follows an empirical approach that explores systems classes in the marketplace by means of cluster analysis. Only those systems were included in the study that support direct inter-personal interactions in terms of group communication, coordination, and collaboration. According to this definition no systems were considered that only support human-computer or computer-to-computer interactions like electronic data interchange (EDI) applications.

An initial Internet search resulted in a list of 212 software systems that comply with this definition. Based on a catalogue of classification criteria a sample of 66 systems was classified[1]; the sample was made up of all systems about which enough information was available on the Internet to carry out the classification. The resulting sample turned out to be quite diverse so that it provides a good representation of the entire market.

Classification Criteria

Since the aim of our study was to distinguish systems from a user perspective and in regards to the support of E-Collaboration processes and not their technical background, characteristics like systems architecture were not considered.

Table 1. Catalogue of classification criteria

Group process	Communication			Coordination			Collaboration		
Types of communication	Text			Audio			Video		
	synch.	asynch.		synch.	asynch.		synch.	asynch.	
Shared resources and features	Discussion forum	Black board		Document spaces	Surveys		Online presentation	Application sharing	
	Address book	Group calender		Task list	Project plan		Resource management	Project controlling	
	Document distribution list		Workflow			Protocol			Whiteboard
System use	Continuous					Situational			
Role for group	Primary					Secondary			
Awareness	Informal Awareness		Group structural Awareness			Social Awareness			Workspace Awareness

The following list gives a brief introduction of the classification criteria; table 1 provides a detailed summary[2]:

- *Group processes supported by the system*: Group processes can be distinguished according to their level of interdependency: Communication describes the process of inter-personal information exchange by means of various types of media. Coordination refers to aligning group activities in regards to joint activities, and collaboration describes the joint work on shared objects where people are jointly responsible for the outcome.
- *Types of communication*: Communication can take different forms and be distinguished by media type and temporal distribution. Depending on temporal distribution the three media types *text*, *audio,* and *video* can be differentiated in synchronous and asynchronous communication.
- *Shared resources and features*: Besides access to communication media most E-Collaboration systems provide a range of shared resources or features that support group processes such as electronic forums, blackboards, document spaces, application sharing facilities, group calendars, project plans etc.
- *Typical use of system*: E-Collaboration systems can further be distinguished by their typical use within the group, whether they are typically used continuously in a day-to-day fashion to support ongoing activities or whether the system is used only situational to support a specific activity.
- *Role for the group*: Systems that provide functions for the support of basic group processes are regarded as primary systems; they support the group members with all essential functions like for example e-mail communication or calendar functionality. Secondary systems provide additional functions that complement primary systems.
- *Awareness features supporting shared perceptions*: Compared with traditional workplaces distributed collaboration has several deficits in relation to the perception of shared activities (Jang *et al.*, 2000). To this end, E-Collaboration systems offer functionality to create what is called *group awareness* in order to bridge these deficits: „Awareness is an understanding of the activities of others, which provides a context for your own activities" (Dourish and Bellotti, 1992, 117). Four types of awareness can be distinguished (acc. to Greenberg *et al.*, 1996): 1) *Informal awareness* refers to the knowledge of the location and availability of group members. 2) *Group structural awareness* indicates the structural properties of the group. 3) *Social awareness* refers to the perception of others in a shared work environment. 4) *Workspace awareness* describes the knowledge of actions of others in relation to shared documents.

Cluster Analysis

Based on the criteria catalogue a sample of 66 E-Collaboration systems was classified. The resulting data was used to perform a cluster analysis using the statistical software package SPSS in order to uncover patterns of similarity between systems in the data set. A cluster analysis is an explorative analysis that typically involves an iterative process of applying different algorithms and interpreting the results in order to come to a result that is found meaningful with regards to the criteria. In doing so, the *Ward* method was used as the main algorithm with other procedures to corroborate the results. According to Everitt the *Ward* algorithm is a versatile method that in most cases promises interpretable results (1993). The method tends to the formation of clusters that are relatively homogeneous and in most cases signals the correct number of clusters (Everitt, 1993). Euclidean Squared Distance was used as the proximity measure, since it is suitable for binary data and also recommend in combination with the *Ward* algorithm.

A cluster analysis is deemed successful if the researcher, who is familiar with the data, can sensibly interpret the resulting clusters (Everitt, 1993). A good set of clusters shows homogeneous and clearly separable clusters. To identify the clusters dendrograms were used in combination with rearranging the classification matrix according to the set of clusters found in each of the analysis runs.[3] The first turn of applying Ward already delivered a well interpretable and almost satisfactory result. However, the resulting clusters contained some allocations that did not quite fit. It quickly became clear that all wrongly allocated systems where smaller tools that only provided a limited set of features. Hence, a total of 17 systems were separated from the rest of the sample to become the class of "specialized tools". Processing the remaining 49 systems using *Ward* then delivered a clear and unequivocal result. The dendrogram (see appendix A) shows three clearly separated clusters.[4]

RESULTING E-COLLABORATION SYSTEMS CLASSES

According to the cluster results the market for E-Collaboration systems can be divided into four systems classes. Since these classes are still quite large and contain a range of systems further sub classes were identified.[5] In the following, the classes are described using typical characteristics; for details and examples please refer to the resulting classification in appendix B.

Everyday Systems

Everyday systems are continuously used by the group as primary systems to support everyday activities. To this end, the systems provide basic features to support all three group processes - communication, coordination and collaboration. Everyday systems focus on asynchronous text-based communication; all systems offer e-mail as the primary type of communication; most systems also provide discussion forums. Other typical features are calendars, address books, task lists, and document spaces. The only supported form of awareness is workspace awareness in relation to documents in shared spaces. The class holds a total of 23 systems in five sub classes:

- *Client server groupware systems* have a long history in the market. Most systems descend from traditional e-mail systems offering typical functions such as calendars, address books, task lists. These systems are directed at middle sized to large enterprises because of considerable setup costs.
- *Web-based team rooms* follow a different philosophy. Access to the system is provided via an Internet browser. The core idea is to provide a shared online workspace. In addition to the typical features provided by Client server groupware they also provide discussion forums and black boards. The systems are suited for smaller enterprises; some providers offer ad hoc workspaces that can be rented by teams for the duration of a project.
- Although being similar to web-based team rooms in terms of features *Intranet systems* differ in their focus in that they are intended for enterprise-internal use. They supply typical Intranet features such as discussion forums and black boards. In addition, some systems support enterprise-internal processes by providing document distribution lists.
- *Document-oriented systems* have their origin in document management systems. Their main focus is on asynchronous collaboration on shared documents. To this end, the systems support document versioning as well as mechanisms for the structured storage and retrieval of knowledge objects.
- *Real-time systems* are a rather small sub class[6]. Beside the support of asynchronous group processes these systems also provide means of synchronous real time communication via Instant messenger as well as audio and video conferencing. A central feature is the presence information of the team members for the purposes of creating informal awareness.

Coordination Systems

This class comprises 13 systems that focus on group coordination processes. The systems are typically used continuously by the group members albeit as secondary system to complement everyday systems; typically they do not support the most basic group processes such as E-Mail communication. Typical features are document archives, group calendars, task lists, project and resources plans, project controlling, as well as document distribution lists and workflows. Most systems support group structural awareness that gives team members an overview of group structures, roles and competences in order to further support coordination. Three sub classes were identified:

- *Process coordination systems* focus on the planning, modeling, execution, and coordination of processes in teams and organizations. The systems are mainly specialized workflow tools but systems like Actionworks also offer a broader range of resources to support team coordination besides workflow support.
- *Project coordination systems* focus on the project as the main entity. In addition to project planning features, project coordination is further supported by project controlling features (i.e. to capture times and project expenses) and shared calendars, document spaces, and sometimes document distribution lists.
- *Task coordination systems* are used for day-to-day coordination mainly within enterprises, e.g. with the focus on field service coordination. The systems feature shared calendars to coordinate meetings, appointments, or client visits. The systems also offer a rudimentary project support by means of task lists or documents distribution lists.

Table 2. Characteristics of systems classes

Criteria	Everyday systems	Coordination systems	Meeting systems
Group processes	Communication Coordination Collaboration	Coordination Collaboration	Communication Collaboration
Type of communication	Text asynchronous and synchronous	Text asynchronous	Text, Audio, Video synchronous
Shared resources and features	Group calender Address book Task list Document spaces Discussion forum	Group calender, Task list Project plan Ressource management, Project controlling Workflow Dokument spaces	Whiteboard Application sharing Presentations Surveys Protocols Document spaces
Use of syste,	Continuous	Continuous	Situational
Role for the group	Primary	Secondary	Secondary
Awareness	Workspace	Group structural	Informal, social, workspace

Session and Meeting Systems

Meeting systems comprise 13 systems that support online sessions and video conferences; they are used situational and as secondary systems. Online meetings are typically used for decision making or simultaneous work on shared documents. The systems are based on extensive synchronous communication such as audio and video communication. Other typical features are application sharing and whiteboards. Surveys can be administered to support ad hoc decisions and online presentations can be held to conduct online seminars. Awareness is supported to a significant degree in the informal, social, and workspace dimensions. Three sub classes were identified:

- Two of the systems in this class can be described as *Ad hoc meeting systems*. These are smaller tools that allow for the quick and uncomplicated initiation of conferences.
- *Standard meeting systems* offer all functions described above and thus support shared meeting sessions. Sessions and meetings can be planned using a scheduler.
- In addition to the standard features of meeting systems *systems with seminar capabilities* offer services for the planning and realization of online seminars and entire e-learning curricula. These seminars can be given by tutors or be recorded and provided for asynchronous use.

Specialized Tools

This class summarizes the group of 17 systems that only implement limited features to support computer-aided group work. Since this group is quite heterogeneous no common characteristics can be identified that are shared by all systems. Nevertheless, the following sub classes can be described:

- *E-mail systems* provide server functionality that allows enterprises to setup their own e-mail infrastructure.
- *Forum servers* support the setup of discussion forums, text chat or voice conferences. Enterprises can use these systems to open up communication channels for teams in an intranet environment.
- *Social software* describes a novel type of Internet systems that provide new ways of text-based collaboration. Popular examples are Blogs or Wikis. These technologies can be used in teams to facilitate discussions or joint work on text documents.
- *Team calendars* are web-based tools that provide group calendars to coordinate and schedule team meetings and project work.
- *Instant Messaging and A/V chat systems* offer synchronous text, audio and sometimes video communication. These are small software tools that hold a list of contacts (the buddylist), provide presence information, and facilitate the ad hoc initiation of conference calls.
- *Group editors* support concurrent work on text documents. The spectrum reaches from simple text editors to server software that enables the synchronous use of modern office programs.

CONCLUSION AND OUTLOOK

The market study has produced four systems classes and a range of sub classes that provide an overview of the fast growing E-Collaboration market. The systems were characterized using typical features and characteristics. The study provides practitioners with an overview of available systems classes and their respective focus in order to support investment decisions. Researchers who are interested in the development, use, and adoption of E-Collaboration systems can use the typology as guidance to structure their domain and as support in selecting suitable systems as research objects.

While the study illustrates the status quo of the market, two interesting trends emerged from our inquiries that are likely to shape future market developments. First, drawing from recent media reports, it becomes clear that there is a tendency towards integrating richer sets of communication media. This trend is fueled both by the popularity of Instant Messaging as well as voice-over-IP telephony. Today, with *real-time systems* already showing up as a sub class in this study it can be assumed that the trend towards real-time communication (RTC) systems will gain momentum. RTC systems are based on instant synchronous communication and presence awareness information and aim at improving availability and coordination in distributed work processes (Riemer and Frößler, 2006). Second, there is a tendency towards systems integration and convergence. On the one hand, a convergence of different market segments can be observed. A good example is the fusion of the markets for document management systems with traditional groupware; the *document-oriented systems* are a result of this trend. On the other hand, software enterprises like IBM, Microsoft or Oracle pursue strategies of systems integration which creates comprehensive E-Collaboration Suites. IBM for example is at the moment integrating its Workplace suite with its Lotus Domino products in order to create an integrated collaboration infrastructure that features characteristics of more than one of the systems classes described in this study.

Hence, a replication of this study in a few years time is likely to paint a slightly different picture with more synchronous media support and a range of integrated systems likely to show up in the cluster analysis. The proliferation of new types of integrated systems will create new research opportunities for researchers in the E-Collaboration domain.

ENDNOTES

[1] The systems classification was carried out by three experts independently. A few deviations arose during the process of classifying; these were discussed and led to a more precise specification of the criteria.

[2] For detailed information on the classification criteria, background information on the study and additional material such as classification tables and dendrograms please visit our web site online at http://collaborate.uni-muenster.de/market-study.

[3] See appendix A for the final dendrogram and appendix B for a rearranged matrix for the final result.

[4] Two more procedures (average linkage and complete linkage) successfully corroborated these results. The resulting dendrograms were omitted due to space restrictions.

[5] Please note that the sub classes are not based on the cluster analysis and do not correspond with the dendrogram shown in appendix A; internally, the three clusters are too homogenous for the algorithms to come up with sensible sub classes. Rather, they were identified by the researchers using the classification criteria as well as other information such as the history and market positioning of the systems.

[6] Oracle Collaboration Suite qualifies both as documents-oriented and a real-time system (see classification in appendix B).

Quality Aspects in Ontology-Based Information Retrieval

Darijus Strasunskas, Norwegian University of Science and Technology, NO-7491, Trondheim, Norway; E-mail: dstrasun@idi.ntnu.no
Stein L. Tomassen, Norwegian University of Science and Technology, NO-7491, Trondheim, Norway; E-mail: steint@idi.ntnu.no

ABSTRACT

Ontologies are increasingly used in various applications (e.g., semantic interoperability, data integration). One of the reasons is that ontologies are seen as a means to improve qualitative characteristics of applications. In particular, there is an intensive on-going research on ontology-based information retrieval. Typically, ontology usage in information retrieval adds another level of complexity; therefore we propose a holistic method for evaluation of ontology-based information retrieval systems as well as define a set of essential features for ontology-based information retrieval tools.

INTRODUCTION

In this article we investigate the application of ontology to enhance Information Retrieval (IR). Since information quality is critical for organizations, ontologies have been used in a number of information retrieval systems (Aitken & Reid, 2000; Brasethvik, 2004; Ciorascu et al., 2003; Nagypal, 2005; Suomela & Kekalainen, 2005; Vallet et al., 2005) in order to improve their performance.

There are sparse evaluations of ontology-based information retrieval (ObIR) tools (e.g., Aitken & Reid, 2000; Brasethvik, 2004; Suomela & Kekalainen, 2005; Vallet et al., 2005), and they report improvement compared to a traditional IR systems. However, it is not clear whether this improvement is optimal, i.e. how could ontology properties enhance IR.

Furthermore, IR evaluation methods are mainly based on relevance of retrieved information. However, additional sophistication of ObIR tools adds complexity on user interaction to reach improved results. Therefore, standard IR metrics as recall and precision are not feasible to measure user satisfaction because of complexity and effort needed to use the ObIR systems. Furthermore, evaluation methods based on recall and precision do not indicate the causes for variation in different retrieval results (Alemayehu, 2003). There are other factors that influence the performance of ontology-based information retrieval, such as query quality, ontology quality, complexity of user interaction, etc.

We investigate quality aspects essential for improvement of information retrieval. This paper tries to answer two following questions. How can we enhance ObIR performance? How should an ObIR system be evaluated?

Related work comes from several areas. Consequently, in next section we first take a look at ontology-based IR systems and then we proceed with an overview of IR systems and ontology evaluation methods and metrics. Then we discuss essential features of ObIR systems relating these features to users' experience and present a holistic evaluation model for ObIR quality assessment. In last section we conclude the paper and outline future work.

RELATED WORK

First, we summarize ontology-based information retrieval (ObIR) approaches, classifying them according complexity of user interaction. Second, we survey the IR evaluation methods and metrics, pointing out their weakness in analyzing the cause of variation in results. Third, we take a look at ontology evaluation, as ontology plays one of the central roles in ObIR systems.

Ontology-based Information Retrieval

An increasing number of recent information retrieval systems make use of ontologies to help the users clarify their information needs and come up with semantic representations of documents. While general assumption of ObIR is as follows. If a person is interested in information about *B*, its likely that she will find information about *A* interesting, with a condition that *A* and *B* are closely related terms/concepts in the ontology. Then user provided query is expanded by hypernyms (superclasses) or hyponyms (subclasses) or other related concepts (sibling concepts or other neighborhood concepts).

Furthermore, approaches to ontology-based information retrieval can further be categorized according to the complexity of required user interaction: a) simple keywords based entry into text field; b) multi-optional specification of search parameters; c) advance interaction through a specific ontology query language. Approaches belonging to the first category allow user to enter keywords in a simple text field. The provided query is expanded using an ontology without any further interaction from the user (e.g., Ciorascu et al., 2003). The second category of ObIR systems spans more diverse range of approaches. The approaches here require more interaction by the user. Nagypal (2005) uses ontology to disambiguate queries. Simple text search is run on the concepts' labels and users are asked to choose the proper term interpretation. Tomassen and Strasunskas (2006) discuss four abstraction levels of query terms, where users are allowed to specify the granularity of information needed. Other approaches let users to browse the provided ontology and select relevant concepts (e.g., Suomela & Kekalainen, 2005). Approaches in the latter category typically adopt knowledge base approach to interact with the information using reasoning mechanism and ontological query languages (e.g., SPARQL, RDQL, OWL-QL) to retrieve instances. Documents are treated either as instances or are annotated using ontology instances (Ciorascu et al., 2003; Kiryakov et al., 2005; Rocha et al., 2004; Vallet et al., 2005). These approaches require advanced knowledge of ontology query languages and target professional users.

Information Retrieval Evaluation

When evaluating information retrieval systems retrieved information is typically assessed by its relevance or non-relevance to the users' information needs. Then IR systems are compared based on their ability to retrieve and rank relevant information. Evaluation methods in information retrieval are focused on precision and recall metrics (Baeza-Yates & Ribeiro-Neto, 1999). Furthermore, there are a number of other similar metrics derived from the precision and recall metrics such as *novelty*, *coverage*, *the E measure*, *Harmonic mean* (a.k.a. *F – measure*) (Baeza-Yates & Ribeiro-Neto, 1999). Korfhage (1993) discussed *satisfaction* and *frustration* metrics, where satisfaction metric takes into account only relevant documents, while frustration – non relevant documents.

Important information that indicates the causes for variation of different retrieval results remains hidden under the average recall and precision figures (Alemayehu, 2003). Gao et al. (2004) argue that there are other factors than IR system that needs to be considered in the evaluation. These factors are as follows (Gao et al., 2004): indexing and searching methods; difficulty of a searching topic with respect to retrieval; and quality of a query. The detail analysis on how these factors and their interactions affect a retrieval process can help to dramatically improve retrieval methods or processes. In fact, it is widely acknowledged that factors external to an IR system can affect retrieval result significantly and examination of these factors is essential to the improvement of IR systems (Alemayehu, 2003; Gao et al., 2004; Jansen & Pooch, 2001; Kim & Allen, 2002; Zins, 2000).

Ontology Evaluation

The ontology's ability to capture the content of the universe of discourse at the appropriate level of granularity and precision and offer the application understandable correct information are important features that are addressed in many

ontology/model quality frameworks (e.g., Burton-Jones et al., 2005; Gangemi et al., 2005; Lindland et al., 1994; Tartir et al., 2005). Most of them are generic quality evaluation frameworks, which do not take into account ontology applications (i.e. metrics are not defined for task specific usage of ontology). For instance, Ontometric (Lozano-Tello & Gomez-Perez, 2004) methodology defines Reference Ontology that consists of metrics to evaluate ontology, methodology, language and a tool used to develop ontology.

Brak et al. (2004) summarize main perspectives of ontology evaluation. Below we comment applicability of the evaluation perspectives for ontology evaluation in ObIR.

- *Lexical, vocabulary, or data layer*. Checks the vocabulary used to represent concepts. Ontology best fits to a particular domain when its vocabulary corresponds to the vocabulary used by a user and terminology in a document collection.
- *Hierarchical or taxonomical relations vs. other semantic relations*. Some methods evaluate the ratio of IsA relationships and other semantic relationships in ontologies, where the presence of various semantic relationships identifies the richness of an ontology. This perspective is important for ObIR systems, since higher richness (i.e. more diverse relationships) allows better matching of the provided query in a form of triples, which results in better performance.
- *Context and application level*. Here it is evaluated how the results of an application are affected by the use of an ontology. However, in the case of ObIR, adding an ontology into a system changes its architecture and the way of interacting with the system. As well it is difficult to create an experimental environment where no other factors but the ontology influence the performance of the application.
- *Syntactic level*. Since ontologies are created in particular languages, the ontology specification needs to match the required syntax of the language. This ontology quality is a precondition for any ontology usage, including ObIR.
- *Structure, architecture, design*. Ontologies need to meet certain predefined design principles. Parts of a domain may be badly specified therefore the ontology may need maintenance.

Figure 1. Essential features of ObIR systems depending on users' experience

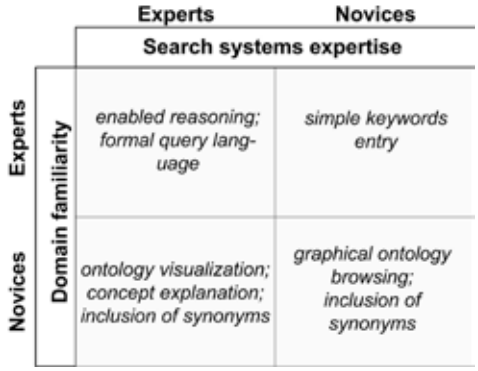

Figure 2. Holistic evaluation model for ontology-based information retrieval system

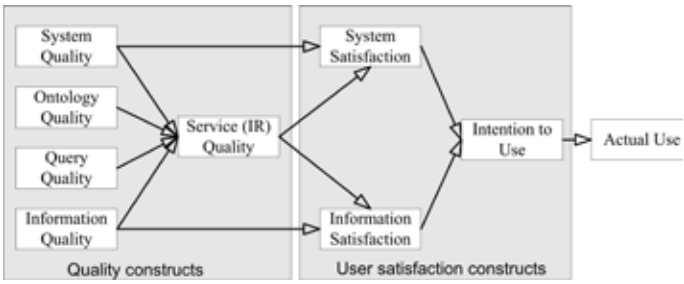

EVALUATION MODEL FOR ONTOLOGY-BASED INFORMATION RETRIEVAL

An important factor in search is the experience of the users. Expertise in this area is often considered along two dimensions, namely, domain expertise and search expertise (Jenkins et al., 2003). The former subjects are knowledgeable about a particular domain, while the latter have experience in using search engines and tools. Domain experts evaluate search results more closely as well as web search experts investigate results deeply, while search novices use breadth-first search strategy (Jenkins et al., 2003). Surprisingly enough, even the experienced users (computer specialists) are using 3 words on average in query to specify their information needs (Fox et al., 2005), and that seems to be valid for web search in general (Gulla et al., 2002). This important aspect demonstrates a certain need for query expansion by certain means.

Choice of search strategies depends on the level of experience as well as level of sophisticated interaction with ontology-based information retrieval systems (see Figure 1). Evaluation of some ObIR systems indicates that ontology based IR systems perform better for more generic queries (Brasethvik, 2004; Suomela & Kekalainen, 2005). Inexperienced users find ontologies helpful in comprehending domains by familiarizing themselves with the terminology and formulating queries (Brasethvik, 2004; Suomela & Kekalainen, 2005). Therefore, in these cases a graphical visualization of the ontology is a certain quality. In addition, it was found that linguistic enhancements (inclusion of synonyms) close the gap between ontology concepts and documents, and enable ObIR to perform better for queries that are required to find only a small number of documents (Aitken & Reid, 2000; Brasethvik, 2004). Furthermore, inclusion of synonyms facilitates mapping between user's query and ontology concepts (i.e. it eases query processing in ObIR). However, domain experts prefer to specify terms/concepts directly in a search field, instead of browsing an ontology (Suomela & Kekalainen, 2005).

However, the complete quality of the ontology-based information retrieval system needs to be seen as a composition of various qualities, where all these qualities contribute to final user satisfaction. We define a holistic evaluation model for the ontology-based information retrieval systems (see Figure 2). The model is inspired by Technology Acceptance Model (Davis, 1989) - a model for explaining and predicting user acceptance of information technology. The arrows in the figure depict dependency between the model constructs.

The constructs of the holistic ObIR evaluation model are defined as follows. *System Quality* concerns indexing, ranking and user interface implementation qualities. Some value-adding aspects of user interaction with an ObIR system are presented in Figure 1. *Ontology Quality* aspects have been discussed above; though need to be elaborated further and related to a particular ontology usage scenario in an ObIR tool. *Query Quality* really depends on the users' experience in the domain and information seeking per se. Figure 1 deploys ways to help to specify more precise information needs. *Information Quality* is external to an ObIR system, and can be partially compensated by good ranking algorithms. Furthermore, information quality is a research topic itself and for more details the reader is referred, for instance, to Eppler (2006). Quality of these four components directly impacts *Service Quality* that can be measured using traditional (i.e. recall and precision based) methods.

System Satisfaction denotes the degree to which a user perceives the use of a system being effortless. *Information Satisfaction* is the degree to which a user believes that retrieved information would be useful. System and information satisfactions are determined by quality of corresponding components of an ObIR system and a service quality. *Intention to Use* is the degree to which a user intends to use a system and that depends on both, system and information satisfaction. Intention to use determines *Actual Use* that can be observed in longer period of time.

CONCLUSIONS AND FUTURE WORK

In this paper we have focused on quality aspects of ontology-based information retrieval (ObIR). We have argued about added complexity to interaction with information retrieval systems by employing ontologies. Consequently, we have related a set of vital features of ObIR depending on users' experience.

Furthermore, we have argued inadequacy of traditional information retrieval evaluation methods to assess ObIR quality and potential adoption by the users. We have

presented a holistic evaluation model for ObIR tools. We will need to conduct a series of empirical evaluation of ObIR systems in order to test our holistic evaluation model and reconfirm dependencies between constructs defined there.

Ontology quality aspects have been overviewed; though need to be elaborated further, since the value of specific ontology properties depends on the actual use of the ontology in these systems. Therefore, major future work is to define specific application scenarios of ontology in IR and accordingly relate required ontology properties.

ACKNOWLEDGMENT

INTRODUCTION

The application of Radio Frequency Identification (RFID) to patient care in hospitals and healthcare facilities has become more widely accepted in recent years. RFID and other wireless technologies are the next evolutionary step in patient/object/asset identification and tracking. RFID can potentially deliver many benefits to the healthcare industry. The appropriate application of RFID technologies can reduce many manual operations performed in patient care. When RFID is applied to existing workflow models of patient care, the number of manual steps involved in checking and processing patients can be reduced. RFID can automate the admitting, screening and treating processes for patients, enhance communications between caregivers and support teams, and reduce medical errors (Wicks, Visich, and Li, 2006). In addition, to reduce the number of medical errors, some hospitals have started to use RFID chips on wristbands that can be embedded with data and scanned with a reader to identify patients and what surgical procedure is needed (Hancox, 2006).

However, despite the promised benefits, over 90% of the hospitals in the U.S. still have not adopted the technology (BearingPoint, 2006). As such, this paper examines the current information process used to process patients from admission to discharge, and then it considers where RFID can be applied in a hospital setting to improve patient care and hospital operations. Next the paper investigates the challenges associated with deploying RFID technology in a hospital environment. It is expected that the results of this study will be useful to hospital administrators contemplating RFID deployment in identifying challenges and opportunities.

OVERVIEW OF RFID

RFID is a communication mechanism utilizing radio energy to enable a remote device to communicate with the base station. RFID relies on storing and retrieving data using devices called RFID tags. A tag contains writable memory, which can store data for transfer to various RFID readers some distance away. An RFID system may consist of several components: tags, tag readers, edge servers, middleware, and application software. The purpose of an RFID system is to enable data to be transmitted by a tag which is read by an RFID reader and processed according to the needs of a particular application. The tag contains a transponder with a digital memory chip that has a unique electronic identifier. The interrogator (i.e., reader), which consists of an antenna packaged with a transceiver and decoder, emits a signal activating the tag so the interrogator can read from and/or write to it. Automatic tag reading allows vast amounts of data to be stored and transmitted at once, streamlines and speeds up operations while improving accuracy and productivity. Automatic tag reading also does not require direct contact or line of sight between RFID tags and readers.

Active RFID tags contain their own power source, usually an on-board battery. *Passive* tags obtain power from the signal of an external reader. *Semi-passive* tags are a variant of passive tags where a battery is included with the tag, but the tag must be excited by a reader in order to transmit data (RedPrairie, 2005). See Table 1.

Table 1. Comparison of different RFID systems (RedPrairie, 2005)

Characteristics	Active	Semi-Passive	Passive
Power Source	Battery	Inductive	Inductive
Memory	Up to 288 bytes	Variable	Up to 288 bytes
Read Range	<1500 ft.	<100 ft.	<15 to 30 ft.
Class	Read only Write once, read many Multi read/write	Write once, read many	Read only
Frequency	125KHz, 134KHz, 13.56MHz, 868-930MHz, 2.4GHz	915MHz, 2.4GHz	303MHz, 433MHz

RFID IN HOSPITALS

In the context of hospitals, hospitals offer a wide range of services and functions. This study proposes identifying where RFID can be applied from the perspective of the patient. Specifically, the different stages of the patient life cycle—from admission to discharge—are identified, and where RFID may be applied to improve operations is explored.

Patient Life Cycle: From Admission to Discharge

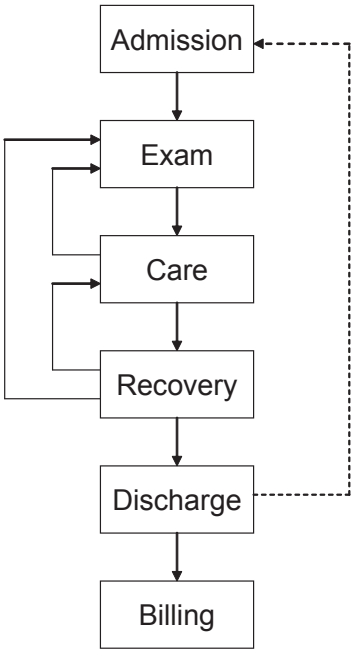
Many hospitals track their patients using manual systems. These systems are typically paper driven utilizing everything from whiteboards, cards, and charts to self-adhesive notes. One useful tool to examine where opportunities of improvement may lie is the patient life cycle. The cycle has six stages (see Figure 1):

Admission: Admission to a hospital usually involves paperwork being filled out by the patient and hospital staff. The information recorded includes: insurer/ability to pay, patient name/contact information, and reason for admittance. Once this information is obtained, the patient is assigned an identification (ID) number that is written on the chart and a wristband which is then attached to the patient.

Examination: After formal admission, the patient is delivered to the appropriate department for diagnostics and treatment. As the patient is treated by the medical staff, the wristband, orders, and charts are visually inspected to confirm procedures, medications, transportation, and later the ultimately discharge from the hospital. This process is performed to assure the correct patient is being treated.

When a patient is first treated, a visual inspection of the patient is performed. If a visual inspection does not provide the cause of the problem, additional tests are performed. Test results are reviewed to determine possible causes. If enough information is obtained, the treatment is started, otherwise, more tests are performed until enough information can be evaluated to provide care. At this point, the patient is either discharged or assigned to additional care.

Figure 1. Patient life cycle



Patient Care: When it is determined that a patient needs further care, he or she is assigned a bed and transported to his or her room by an orderly. On regular intervals the following procedures are carried out:

- Blood work is drawn and analyzed (by phlebotomist).
- Blood pressure, pulse, temperature, and O_2 saturation are recorded.
- IV fluid levels are recorded and replaced as needed.
- Other evaluations of the patient are recorded (e.g., pupils, motor skills, awareness, pain sensations).
- Other specimens are obtained and sent to labs.

As needed, the patient is removed from his or her room and transported to departments where procedures, treatments, tests and examinations are performed. To document the treatments, caregivers record actions taken and results on the patient's chart.

Recovery: As the patient improves, he or she is encouraged to walk around for exercise. The patient's movements are recorded of when they left and returned. Meals, medical supplies, and medications consumed by the patient are continuously recorded.

Discharge: Hopefully, the patient reaches a point where the physician determines that hospital care is complete. At this stage, the patient is issued post-hospital care instructions, and the patient is processed for discharge from hospital. When leaving the hospital, the patient is typically transported on a wheelchair to the curbside or transported back home using a non-emergency medical transport service.

Billing: Billing information is processed and statements sent to appropriate parties (e.g., insurer) for payment.

Benefits of Using RFID

Given that less than 10% of hospitals in the U.S. have adopted RFID (BearingPoint, 2006) and that hospitals still predominantly use paperwork, there should be many opportunities of using RFID to improve operational processes in hospitals. In many hospitals, records and charts are recorded in paper form with some information entered into computer terminals to be printed out and placed in the chart. Procedures, inventory control of assets and consumables, and billing information are all still recorded manually and later entered into a computer.

In an environment where RFID is integrated into the hospital information system, a patient can be tracked from the time they enter the hospital to the time they leave. This process starts when a patient is issued an RFID wristband (during *admission*). Once tagged, the patient can be monitored as they enter and exit rooms. As care is provided to the patient, handheld scanners and terminals with wireless capabilities may be used to input information about procedures performed and the condition of a patient. For example, an emergency room (ER) staff scans the patient as he or she is admitted and all materials used in the care of the patient (during *examination*). Medicines and materials would be associated with a patient and recorded automatically. The collected data enable other medical staff in the next shift to review what was administered to treat the patient. By automating these systems, harmful drug interactions can be identified automatically and notification sent to the physicians.

When properly integrated into an existing medical system as part of a systems solution, RFID can be used in conjunction with automation to check for errors and perform routine record keeping. When scanners are connected to the network using wireless networking and docked networking, a caregiver can update a patient's chart in real time to provide hospital staff with the most current information (during *care*). Vital signs, test results, and procedures can be viewed and checked instantly by medical staffs or by automated routines. If a patient were to be administered a drug, real time tracking could show what medication was dispensed and when it was delivered and taken by the patient. At any time during this physical process, software can check for errors and notify hospital staff if the wrong medicine was dispensed or administered to a patient (Wicks, Visich, and Li, 2006).

With all this information recorded centrally, it makes sense to utilize existing network technologies to allow closer monitoring of the patient by medical staff (during *care*). This would allow nurses to use workstations to record and look up patient information in real-time. Doctors and nurses could look up patient records using handheld devices, wireless notebook computers, or even cell phones. If a patient's condition worsens or improves, physicians can be notified automatically by event triggers written into the patient tracking software. No longer would the doctor need to see the patient or the printed chart to assist the patient. Doctors could quickly identify a patient, retrieve comprehensive medical records, review patient's recovery status, and check past medical logs which have been recorded by nurses via RFID terminals.

As the patient recovers, he or she is frequently encouraged to exercise and walk around the hospital (during *recovery*). As a patient moves about, his or her movements can be tracked by RFID readers scattered throughout the facility. Such information can be logged and can give the tending physician an idea of how much physical activity the patient has engaged in. In addition, when the patient becomes well enough to leave the hospital, the discharge process can be streamlined (during *discharge*) since most information related to his or her care has already been captured using RFID. Moreover, a record of the entire care process captured by RFID is also useful if the patient ever returns for additional care. If the patient returns, his or her medical history could be retrieved to view past diagnosis and treatment. If RFID were extended to a hospital-issued card (e.g., a tagged hospital card or subcutaneous implant) to be kept with the patient, such a card can expedite the subsequent admission process.

While the patient was being cared for at the hospital, equipment and consumables can be tracked and recorded as they are issued or used on a patient. Such tracking is necessary for inventory and billing needs (for *billing*). With fully recorded information, the hospital can automate billing generation for patients and insurance companies. The medical care industry is cost driven where cost recovery determines the profitability of a hospital. By more closely tracking the consumables using RFID, hospitals will be able to avoid excess inventory, reduce out-of-stock periods, and improve the efficiency of medical service supply chain. With a more complete care history, it will also be easier to identify billing fraud.

CHALLENGES OF ADOPTING RFID IN HOSPITALS

RF Interference with RFID Tags

As with any wireless technology, there is the possibility of interference from external sources. Solutions include (1) suppressing interference sources and (2) requiring closer proximity between the RFID tag and the scanner. In any case, there may be situations where it is not practical to scan RFID tags because of the environment. An example of this would be the MRI scanner in the radiology department. The electromagnetic (EM) fields present in the bore of the magnet are significant and would block most RF communications. There is also the issue

that one would not want ferrous materials near such a device for safety concerns. This problem can be solved by scanning the patient as they enter the room before being placed on the scanner table.

Partial Implementation

Given that RFID cannot be ubiquitously deployed in a hospital overnight, many hospitals are considering partial implementations of RFID. A partial implementation first requires a careful analysis of the workflow of a hospital to determine what activities are compartmentalized. The best areas to implement RFID would be where activities are compartmentalized from the rest of the hospital. For example, if a patient is given a wristband that is dual use or tri-use (i.e., containing bar code, RFID tag, and printed text), then the wristband would allow other departments to perform their work regardless of whether or not those departments have RFID scanners.

RFID Security and Privacy

RFID is secure in that tags are extremely difficult to counterfeit and impossible to read without a reader. In fact, some consider the tags physically tamper-proof (Finkenzeller, 2003). However, a common security concern lies with the radio transmission of the tag when it is interrogated by a reader. Since tags emit omnidirectionally, those with specialized high-gain antennas can intercept tags' radio transmissions over a long distance. An example is where an individual sits in the parking lot and uses a high-gain antenna to listen for radio transmissions of RFID tags in a building (Anteniese, Camenisch, and de Bedeiros, 2005).

One solution is to reduce the transmit power of the tag so that transmission distance is only a few inches. But if an operator is required to be so close to the tag to read it, then the process becomes no different from that of bar coding, and the advantages offered by RFID are negated. The long-term solution is to encrypt the data on the tags. It is possible to read/write tags to store encrypted data on the tags, thus making the data intercepted by third parties difficult to use. This solution still makes it possible for a third party to read what is stored on the tag, but it does require the third party to have additional knowledge to make use of the information.

In addition, there is also the issue of the tag remaining active after it is no longer needed by the hospital. If a patient were to walk out of the hospital with his or her wristband on, the tag in the wristband would continue to transmit data when interrogated by a reader. The solution to this would be to deactivate the tag once it is no longer needed (Juels, Rivest, and Szydlo, 2003).

Operational Issues

The development of RFID as a viable alternative to bar codes is a challenge. Range and accuracy are two technical challenges that RFID must overcome to achieve expected benefits. The effective read/write range of passive RFID readers is quite short, and readers must be within a few feet of the object to accurately read the tag or write to it. Active tags allow for longer ranges. The proximity of reads can be an issue if there are multiple objects too close together making it difficult to read tags. The materials on which the tag is affixed may also affect readability. However, as RFID technology improves, the issues of range and accuracy will be solved. For example, the new-generation Gen2 tags provide greater performance, even when used on containers with liquid and metals, and result in more simultaneous reads (Symbol Technologies, 2006).

CONCLUSION

When implemented properly, RFID can significantly aid the medical staff in performing their duties. This paper first presents an overview of RFID technology, then it examines the patient life cycle from admission to discharge. Based on the patient life cycle, it considers where RFID can be applied in a hospital setting to improve patient care and hospital operations. It is found that RFID offers the ability to reduce manual entry of records, increase security for the patient and hospital, reduce errors in administering medication, assist staff by reducing manual labors involved in tracking materials, and serve as a component of an automatic audit system. In addition, RFID enables a fully automated solution for information delivery at the patient bedside, thus reducing the potential for human error. Finally, the challenges associated with deploying RFID technology in a hospital environment are also presented.

ABSTRACT

The Office of Online Learning at Walsh College takes responsibility for delivering high-quality online programs at undergraduate and graduate levels. The department has adopted a project-management-centered (PMC) approach to knowledge management that has shown demonstrable efficiencies in the amount of resources required and the total time to complete implementations, while realizing gains in overall satisfaction and quality. This paper explores the PMC approach and the advantages realized to Walsh College.

INTRODUCTION

When you are in the business of providing high-quality education to your student body, managing the distribution of knowledge is critical. At the Walsh College School of Accountancy and Business Administration, our motto is "from the boardroom to the classroom," so we constantly need to find ways to make knowledge *flow* from the boardroom to the classroom – whether that classroom is an actual classroom or a virtual classroom delivered through a Learning Management System (LMS).

As Walsh College's Office of Online Learning, our department takes responsibility for delivering the high-quality online programs offered by Walsh College. Within this sphere of responsibility, the department is commissioned with rolling out new degree programs designed to provide our graduates with the tools they need in a competitive job market while continuing to evolve existing programs in lock-step with the current business climate. These two tasks alone involve managing many changes to our knowledge base; courses are being updated on a constant basis. Further, there is a business need to incorporate the most effective online learning pedagogies and technologies available in everything we deliver so that our courses are not only relevant, but effective and of the highest quality.

A final challenge is that there is constant pressure to "do more with the resources at hand," which is a pressure that exists almost everywhere in the current business climate. Tandem with this challenge is speed at which courses are requested to be developed and updated. A recently published article by Eric Park focuses on the decrease in development time for courses and maintains that the rate of course development has already moved from two to four months to one to two months. Utilizing a development process that includes steps for rapid course development and updating is critical (Park, December 2006). Additionally, a study released by Bersin and Associates in 2004 states, "There's a new training category emerging, which we call 'Rapid E-Learning.' It is a whole new approach to Internet-based training - one that changes the development model, leverages new tools, and dramatically changes the economics of content development" (DeVries, 2004). So, the approach used for distributing knowledge to our students needs to be an efficient one that makes maximum use of the resources at hand.

The challenges faced by Walsh College are not unique; there is often a need for businesses to manage the distribution of knowledge that is ever-evolving in such a way that it is relevant and timely to their employees. Often, the question is not "*What* knowledge are we going to deliver?" but "*How* are we going to deliver this knowledge?" Following a project-management-centered (PMC) knowledge management approach has helped the Office of Online Learning deal with this challenge in a systematic way.

What is a PMC Knowledge Management approach? It is an approach that treats knowledge management in such a way that it has a lifecycle similar to a software development lifecycle. That is, PMC Knowledge Management has several *phases* that closely resemble phases used to develop complicated pieces of software. Specifically, the PMC Knowledge Management can be described as having the following phases:

1. Gathering knowledge from a subject matter expert (SME)
2. Defining outcomes for the knowledge
3. Specifying the methods by which knowledge will be delivered
4. Ensuring that methods are consistent with outcomes
5. Development of the knowledge for distribution
6. Review of the materials by the instructional designer and the SME
7. Training the SME in how to maintain and update developed knowledge
8. Maintenance of the knowledge
9. Archival\Re-Use\Destruction of knowledge

All phases of the PMC Knowledge Management approach are managed in a similar way to a client-vendor-customer relationship. In such an approach, a client asks a vendor to solve a particular problem *on behalf* of the customer. In many cases the client knows *what* problem needs to be addressed by the vendor, but not *how* to solve the problem. However, the client and the vendor are both responsible for making sure that the customer is ultimately satisfied.

PMC Knowledge Management in the educational sector works in a fashion where instructors are considered to be "clients," students are "customers", leaving agents of the institution responsible for implementation of knowledge management to be the "vendor." As such, each aspect of a particular knowledge management implementation (in this case course development) needs to be managed in a similar fashion to how a project manager manages a software implementation. One person or team is ultimately responsible for all aspects of the process of delivering a particular implementation, and that person or team is that primary point of contact with the "client" (the instructor). At Walsh College, the team charged with this responsibility is a team of Instructional Designers.

THE INSTRUCTIONAL DESIGNER ROLE IN PMC KNOWLEDGE MANAGEMENT

It is important to understand how the instructional designer working in a PMC Knowledge Management environment is different than that of a traditional instructional designer. Traditionally in education, the instructional designer's role is that of a *guide* who recommends effective teaching and assessment strategies to faculty. In PMC knowledge management, their role is expanded so that they *manage the flow of knowledge* throughout the entire implementation. The instructional designer is involved in *every phase* of a knowledge management implementation; they drive the process from start to finish, building solid instructional design into

every phase of the final product. A more detailed exploration of the instructional designer's role in every phase of the implementation is as follows:

Phase 1: Gathering Knowledge from a SME

During this phase, the instructional designer works with the SME to set timelines for turnover of "raw" content and sets up a framework for how that content will be delivered throughout the knowledge management implementation. Each SME is contacted by an instructional designer, who sets clear expectations for what the SME needs to provide, a timeline for material delivery, and how the instructional designer works with them throughout the entire process. Instructional terminology such as outcomes and objectives is also discussed. This has the effect of immediately giving a SME a clear understanding of what their involvement will be throughout the implementation. The relationship between SME and the instructional designer is approached as a *partnership* where the SME is responsible for developing outcomes, course materials, and assessments. The instructional designer's role is to serve as their primary point of communication and material refinement within the Office of Online Learning. Together, the SME and the instructional designer guide the direction of the implementation through its development.

Phase 2: Defining Outcomes for the Knowledge

It may seem counter-intuitive to determine outcomes for knowledge *after* knowledge is gathered, but in the academic arena, a SME will often have a textbook and publisher supplied ancillary material (PowerPoints, glossaries, test banks, videos, etc.) in hand that needs to be looked at critically and its usefulness determined. The instructional designer works with the SME to *prioritize* what things they want their students to know, develop outcomes based on those priorities, and then (more often that not) go back to phase 1 in order to reconcile any gaps between what has been delivered and what the outcomes are.

Phase 3: Specifying the Methods by which Knowledge will be Delivered

Once the SME and the instructional designer have determined that there is enough delivered knowledge to meet the specified outcomes for the implementation, they work together to build a roadmap (syllabus) of *how* that knowledge will be delivered. The instructional designer assists the SME in breaking up knowledge into manageable "chunks" that address the learning styles of many different types of learners. Best practices and the most effective learning pedagogies are employed in this phase, ensuring that the knowledge is delivered in ways that are accessible to learners in their optimal learning style.

Phase 4: Ensuring that Methods are consistent with Outcomes

A critical review by the instructional designer and the SME is done in this phase that serves as a "reality check" that ensures all outcomes are effectively being met before the actual development of content for delivery begins. The instructional designer and the SME review each "chunk" of knowledge certify that knowledge is consistently and clearly mapped back to predetermined outcomes for the implementation. Failure in completing this step often leads to knowledge that is diluted and unclear, which produces an unsatisfactory learning result.

Phase 5: Development of the Knowledge for Distribution

At this point in the process, the knowledge is ready to be developed for delivery. The instructional designer's role in this step is not so much the actual development, but ensuring that the development team has a clear understanding of how to develop the implementation.

Half of this responsibility involves establishing clear communication of what is to be developed. For this, tools can be employed to help manage the interaction between instructional designers and developers. It is critical that these tools serve as a platform for clear communication of the work that needs to be done for the implementation. It is equally important that these tools allow the instructional designer and the developer to consistently track which pieces of work are being done by whom, so that where an implementation stands is never in question.

The other half of this equation involves setting standards that establish what is appropriate and inappropriate for the implementation. For example, a particular color combination may be inappropriate for people with color blindness. Or, the use of certain animations may be distracting to the learner. Clear documentation of these standards eliminates any confusion in this regard. It is absolutely critical that these factors are established ahead of time so that consistent delivery of knowledge is assured, particularly when multiple developers are working on a particular implementation.

Phase 6: Review of the Materials by the Instructional Designer and the SME

As knowledge is developed and delivered, the instructional designer and the SME go through what has been delivered to ensure it is consistent with what was planned. Developed materials that do not meet expectations are sent back for redevelopment and re-checked when they are once again ready for review. At this point in the process, a knowledge management implementation reaches a stage where it is considered "feature complete". The materials, ancillary materials, videos, etc. are all in an organized and presentable state that is ready for the learner.

Phase 7: Training the SME in How to Maintain and Update Developed Knowledge

Although the knowledge management implementation is "feature complete" at this point, the SME needs to learn how to maintain the knowledge. In academia, it is common for textbook editions to change, or have textbooks that contain old or inaccurate knowledge. The SME needs to be able to update the knowledge as needed.

The instructional designers take on the role of showing instructor how to manage their own knowledge, walking them through the mechanics of how to make their changes. More importantly, they instill a "value set" in the SME that allows them to make good decisions on how to approach making changes. For example, adding an entirely new knowledge topic to an implementation may require the setting of new objectives or obsolescing old objectives.

Phase 8: Maintenance of the Knowledge

At times, it becomes necessary for the instructional designer to work with the SME and evaluate how the knowledge is being maintained and delivered. Two critical evaluations of the knowledge are performed at this point.

The first evaluation involves ensuring that knowledge is still mapping to current outcomes and that currency of presented knowledge is assured. As knowledge is maintained over a period of time, there is a tendency for an implementation to creep beyond its original stated objectives. This will result in knowledge and objectives not being consistently aligned. Further, there is a valid tendency of the SME to never completely discard knowledge that is obsolete, which can create a "clutter" problem throughout the implementation. The instructional designer works with the SME to ensure such issues are resolved.

The second evaluation involves taking a fresh look at the implementation for ways to improve it. For example, there might be a new compression utility available for videos that delivers a higher quality result. Additionally, it is possible that the SME wants to completely alter the way they teach a concept in such a way that the learning becomes more interactive. The instructional designer works with the SME in much the same way as they work in phase 3 of the process to determine the most effective ways to deliver the new ideas for the existing knowledge.

Phase 9: Archival\Re-Use\Destruction of Knowledge

Finally, there will always come a point where knowledge reaches the end of its useful life. The instructional designer works with the SME to determine which pieces of knowledge should be reused in another implementation, archived for further reference, or destroyed entirely. Items that are to be reused or archived are ultimately placed into a library for easy retrieval and have their contents catalogued.

From the more detailed overview of the phases in PMC knowledge management, it is evident that the instructional designer is more than just a "guide" to instructors. Rather, they serve in much the same fashion as project managers do for projects. They manage the whole knowledge management implementation from start to finish, providing critical guidance to the SME and the developers through each phase of an implementation.

Further, the phases outlined in PMC Knowledge Management create a framework for managing change. Knowledge does not often remain static, so establishing an effective and clear framework for managing the changes to knowledge is an

integral part of how quality and consistency are achieved in knowledge management implementations over time.

THE BENEFITS OF PMC KNOWLEDGE MANAGEMENT

The benefits of PMC Knowledge Management realized to Walsh College's Office of Online Learning have been enormous. We are truly able to deliver "more with the resources at hand" consistently and effectively with a relatively small team of highly-motivated people, which is reflective of how market conditions exist today. Further, PMC Knowledge Management has allowed our department to deliver more effectively on our promise to deliver knowledge "from the boardroom to the classroom" at quality levels we had never been able to achieve before, all at a lower cost. This may seem counterintuitive, as a nine-phase process can look unwieldy and expensive at first glance. In reality, however, our instructional designers are finding that they are able to handle several knowledge management implementations at one time by setting clear expectations up front, establishing open channels of communication with each SME, and staying on top of the flow of knowledge into the department.

To further demonstrate the benefits of the PMC Knowledge Management approach, here are some key benefits realized to Walsh College within one year of implementation:

1. Increasing the number of knowledge management implementations (course development) the department is able to handle at one time *five-fold* from 3 – 4 implementations to 15 – 20, with no increase in staff.
2. There has been a drastic reduction in the number of support problems associated with new courses from both new faculty and students.
3. Complete remediation to newer and more effective online learning pedagogies for over 50 existing online courses has taken place.
4. The Office of Online Learning has been able to manage double-digit growth in both the number of courses offered each semester and the number of students taking courses online.
5. Ensuring that student satisfaction with online courses is consistently high across all programs.
6. Increasing overall student satisfaction by an average of 14% for courses running for the first time that are facilitated by a SME who is actively engaged throughout all phases of course development.
7. The Office of Online Learning has created and fostered a culture when change is planned for and managed on a consistent basis.
8. Consistently receiving high levels of satisfaction with the end product from each SME developing new or updating existing courses. This has encouraged many who were skeptical about online learning to delve into creating their own online courses.

CONCLUSION

A PMC Knowledge Management approach can be a very effective tool for managing a large number of simultaneous knowledge management implementations. PMC Knowledge Management can set up a framework for dealing with change consistently and effectively. Finally, PMC Knowledge Management can help manage large knowledge management implementations with greater efficiency than can be achieved without having them in place.

Put together, these factors can create highly successful teams that are charged with managing all phases of knowledge management and create a culture of innovation that pervades an entire program.

ABSTRACT

Software Process Improvement is one of the main software development challenges. Unfortunately, process descriptions generally do not correspond to the processes actually performed during software development projects. They just represent high-level plans and do not contain the information necessary in a software project. This lack of alignment between the process and project is caused by processes that are unrelated to project activities and failure in detecting project changes to improve the process. Process and project alignment is essential to really find out how process management is important to achieve an organization's strategic objectives. Considering this alignment, this paper presents a software process improvement methodology designed by Process and Project Alignment Methodology (ProPAM).

1. INTRODUCTION

Organizational software process improvement (SPI) is a challenge to organizations to continually improve the quality and productivity of software and to keep up their competitiveness [1]. However, there has been limited success for many SPI efforts. Recent reports concluded that 70% of organizations attempting to adopt the CMM (Capability Maturity Model) failed in achieving the intended goals [2].

Although organizations try to define their process improvement program and get a certification in traditional SPI approaches (e.g. CMM [3], CMMI [4], SPICE [5], and Bootstrap [6]), there is a consensus that software development environments are changing constantly and team members have no obligation to sustain original SPI activities in face of difficulties. The agile software development manifesto contains a principle that supports this idea: "at regular intervals, the team reflects on how to become more effective, then tunes and adjusts its behavior accordingly" [7].

Process modeling community in general base the research work on the assumption that an explicit process representation is the starting point for process understanding, improvement and communication, project teams are communicating in terms of budget overruns, patches for bug fixes and transaction monitors [8]. Other research communities, like the ones that study computer supported co-operative work (CSCW), argue that software development is a creative work with strong co-operation aspects and does not benefit from static process descriptions. So, process information must be combined dynamically with project specific information to create a detailed plan that includes information from all process disciplines with cost, schedule and quality requirements. Since project management is the discipline that controls and monitors deviations from the original project plan and also controls all of the activities from other process disciplines, it is the best way to detect changes in the project that can improve the process. Considering the dependency between project plan and process elements, new SPI approaches have to consider process and project alignment and iterative SPI performed by project team members. Process and project alignment is defined as the degree to which the project goals and plans support and are supported by the process practices. Moreover, it involves a real match between process practices and projects activities, products and actors. However, several modifications in a project can cause misalignments with the development process. These modifications can be management innovations or changes in the way the activities are executed. Furthermore, a modification may regard not only the considered activity, product or actor but it can also affect other elements having a dependence relation with the modified one.

The contribution of this paper is to define not only the process, but also to propose a mechanism to process evolution based on the changing needs of the development organization. This paper proposes a methodology - Process and Project Alignment Methodology (ProPAM) - based on process and project alignment to be applied during SPI projects for detecting misalignment between projects and supporting processes and identifying the process elements to be changed for restoring the alignment.

This paper is organized in the following sections. Section 2 discusses literature on software process modeling, process and project management alignment and traditional and agile approaches to SPI and. Section 3 and 4 presents the meta-models to support process definition and further instantiation of the project. Section 5 briefly sketches the architecture of the proposed methodology to support process and project alignment in iterative (traditional and agile) SPI approaches and also presents details about the process versioning meta-model. Finally, Section 6 presents conclusions and future work.

2. RELATED WORK

Current research on software development processes intends to define the process elements that constitute good practices, leaving implementation and enactment of the process to organizations. Curtis, Kellner and Over discussed some approaches using process modeling to support process improvement, software project management and Process-Centered Software Engineering Environments (PCSEEs) [9].

The Software Process Management System (SPMS) development identified and addressed the need for process models to be reusable, to support multiple views, to recognize process, product and human interactions to support process changes during development projects, and to support historical recording of the process over long periods of time [10]. In the domain of change management, the Problem Tracking System (PTS) is used to track errors and manage change request for the WIS (Wohnungswirtschaftliche Information System), a system build in a process oriented way to support all business processes from the area of house constructing and administration [8]. The Endeavors system is a flexible environment that allows users to create and evolve processes while a project is in progress [11]. Although Endeavors supports most of the features in process definition languages and modification of the process, some problems arise about process coordination and can lead to chaotic and disorganized development processes. The BORE tool and methodology extends the experience factory concept [12] through rule-based process tailoring, support for process modeling and enactment and case-based organizational learning facilities [13]. The AHEAD system also supports the management, versioning and modeling of development processes and provides an integrated set of tools for evolving both process definitions and projects [14].

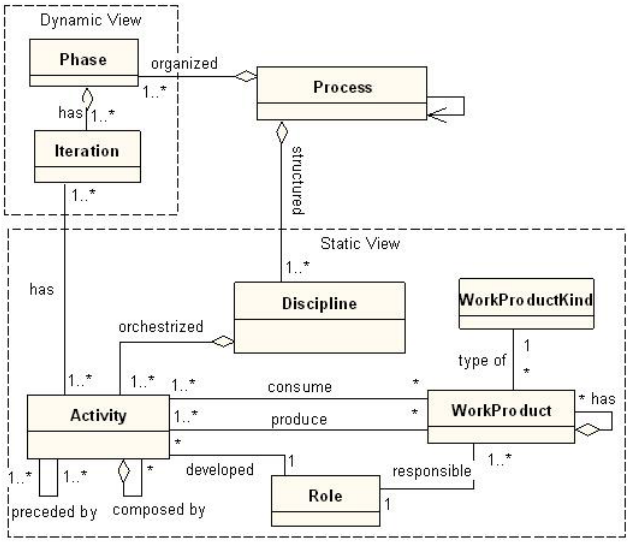
3. PROCESS MODELLING

A process meta-model provides a set of generic concepts to describe any process. Figure 1 presents the ProjectIT Process Meta-model (PIT-ProcessM) that is developed to provide a formal notation for specifying process elements involved in the software process. The meta-model consists of two complementary views: static view and dynamic view.

Static View

The static view represents formal process concepts like disciplines, products, activities and roles.

Figure 1.ProjectIT process meta-model (PIT-ProcessM)



Activity: the atomic unit of work. In operational terms, an activity can be the smallest unit of work, but also can be used to refer to a set of related activities (hierarchy of activities).

Discipline: an organizational unit to group activities according to a common "theme".

Role: describes in an abstract form the set of skills and responsibilities associated with the execution of one or more activities.

WorkProduct: correspond to typical software development objects which are produced and consumed by activities (e.g. design document, source code, test cases, etc) and they have a responsible role. The workproducts must belong to a document type (WorkProductKind).

Dynamic View

Dynamic view of the meta-model represents time and introduces concepts to describe the process lifecycle in terms of goals, pre-conditions and post-conditions and to allow the decomposition of the process lifecycle into phases and iterations.

Phase: Software development work is structured in several stages, called phases. Phases consist of a certain number of iterations and are executed with a series of milestones.

Iteration: Iterations are workflows with minor milestones.

4. PROJECT MODELLING

A project is instantiated from a process, where the process represents reusable process practices at an abstract level. While the process represents the best practices in software development but has no information about timing and resource allocation, the project must specify exactly *who* must do *what* and *when*. But in real world projects, multiple projects share the same process and are differentiated based on their specific characteristics, e.g. actors (`Person`), schedule, deadlines, resources, etc. Considering these differences that are important in a project management perspective, our approach presents a specific project meta-model presented in figure 2, ProjectIT Project Model (PIT-ProjectM).

5. PROPAM METHODOLOGY

In this section we describe the concepts behind the implementation of a process and project management system to support SPI. Figure 3 shows the relation between the four steps in the ProPAM methodology: (1) Process Creation; (2) Project Definition; (3) Project monitoring and control and (4) Process Assessment.

Process Creation

In ProPAM, a process is created as an instance of PIT-ProcessM. A process is defined by a set of phases which are divided in several iterations. Disciplines and respective activities, workproducts and roles define the space of possible choices for projects within a given process practices. Activities can be defined in an activity/sub-activities relationship represented in a hierarchical work breakdown (represented in the meta-model trough the reflexive association "`composed by`"). Activity sequences are defined through the reflexive association designed by "`preceded by`", which are useful to create a project schedule.

Project Definition

In ProPAM, processes are used as a template for creating projects. The project consists of some project elements that are instances of elements from the base process. Not all of the process elements need to be included in the project, but all project elements must be an instance of a process element. An exception is possible if an element is created as result of a change proposed by team members or process group. When a process element is assigned to a project, creating a new project element, all the information in the process element is copied to the project element, including a copy of all the associated elements. As an example, when an `ActivityProject` is created, associated `WorkProductProjects` and `RoleProjects` are also introduced in the project.

Figure 2.ProjectIT project meta-model (PIT-ProjectM)

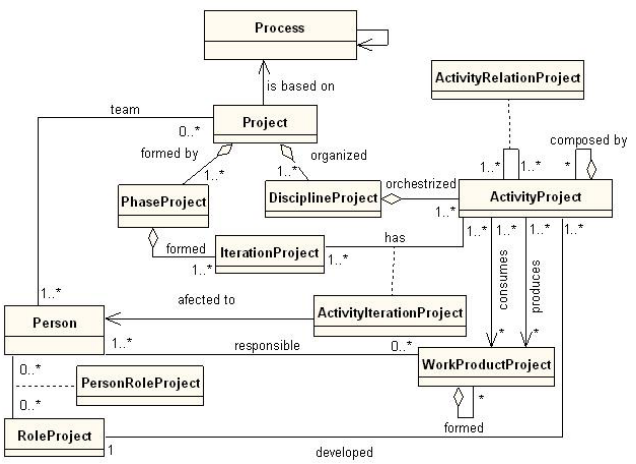


Figure 3.Process and project alignment methodology

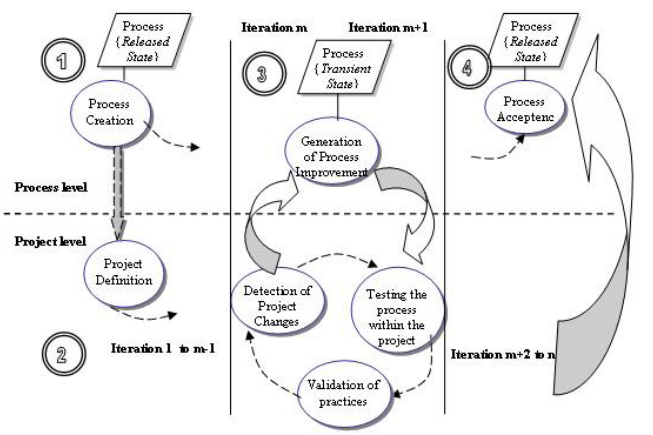


In this methodology, after instantiating a process, the initial result is a project plan. This plan represents the initial step to start the project. Projects have certain administrative characteristics like schedule, milestones and deadline, resources, and structure i.e. phases and iterations of the project that will performed based on this initial plan. Team members are assigned to the project and gather information that is useful for the project, like workproducts, from the perspective of their current role.

Project Monitoring and Control

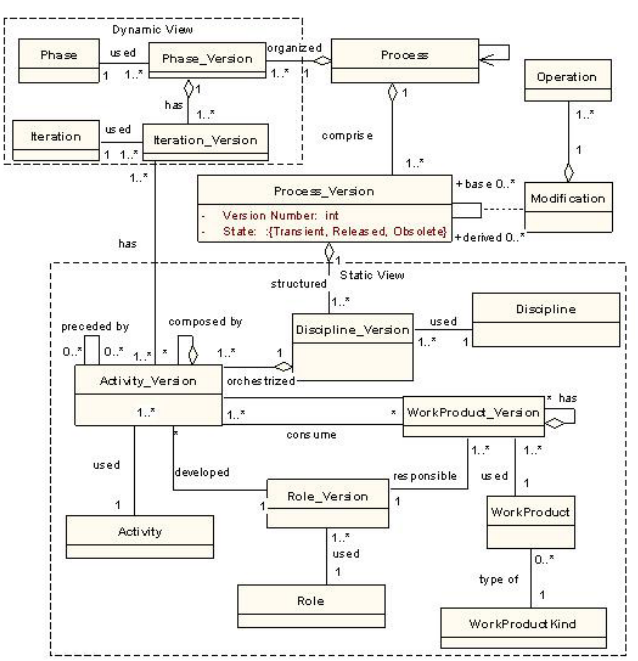
The third step consists in project monitoring and control. Updates and extensions to the initial project plan will be registered, always considering a based process model. Although most project elements are an instance of process elements, project team members have the liberty to create entities specific to a project. These changes are detected through the SPI actions performed by the process group. When a new process or new version is introduced, a validation phase is needed for monitoring their fitness and performance in the whole process. Thus, SPI actions subsume two problems: (1) process modification and (2) ensuring that projects and base process remain aligned with each other.

The project monitoring and control step is composed by two different tasks. The first task (Project Iterations) is about getting knowledge through project change candidates to improve the process and is repeated in all project iterations and phases. The second task (Process Versioning) subsumes that changes are accepted and that it is necessary to keep historical information about several process versions. The versioning schema introduces some changes in the PIT-ProcessM meta-model. The meta-model is extended to support the versioning of process elements (Figure 4).

Process Assessment

In the end of the project, process improvements must be analyzed in a reflection meeting. The main goal is to analyze all the improvement opportunities identified in the project and validate all the SPI actions accepted in workshops. Prospects for success in executing and improving software process activities rise significantly when decisions can be based on quantitative information which can only be obtained by observing and measuring the products, projects and resources involved. But as complex as software development is, there are potentially so many things to measure against organizations visions and plans. In ProPAM, process assessment occurs at two distinct levels: (1) project level and (2) process level.

Figure 4.Process version classification



At project level, SPI assessment in practice can be viewed as the acquisition of data (key indicators) in a project where the new process version was applied followed by data analysis and decisions about the further adoption of this development processes. Key indicators used to evaluate projects success are normally: staff productivity, software quality, cycle time, project costs and costumer satisfaction.

At process level, the entities to evaluate are the different phases of the development processes and the attributes of these phases which include cost, time, etc. In a measurement program, the organization has to identify the areas of measurement. The measurement objectives should be clear and well defined. Since project management is an important discipline in the proposed methodology, the key indicators must align with those used by the project manager to analyze and evaluate a project.

However, SPI key indicators may change and evolve. Over time, process changes can impact the way measurements are defined, the way measurements are collected, or the frequency of measurement collection and analysis activities. To facilitate this evolution and ensure that the measurements and indicators continue to provide meaningful information to managers, the continuous recording of project background information is important to: (1) facilitate the analysis and interpretation of measurements over time; (2) to establish links between measurement data sets over time and (3) to understand exactly how the measurements are evolving.

6. CONCLUSIONS

This paper describes ProPAM, a methodology for process improvement based on process and project alignment and supporting meta-models (PIT-ProcessM and PIT-ProjectM). ProPAM meta-models propose to bridge the gap between process description and development projects. PIT-ProcessM is used to specify the process life-cycle without forgetting that processes and projects are human-centered systems. The communication and collaboration actions are described in the meta-model, at an abstract level, through the role and activities relationship.

Agile and traditional processes are structured in phases and iterations, but actual process modeling approaches don't address this feature that is especially important in agile processes. Agile processes normally just plan iteration by iteration. Further, in approaches like BORE [13], life-cycle descriptions are most often treated as linear sequences, where crucial attributes of the process such as phases and iteration are not represented. PIT-ProjectM is used to plan the project as an instance of the process specified through the PIT-ProcessM with a life-cycle description based on phases and iterations. However, since every project has unique features and requirements, actors must have liberty and creativity to change the project. Recognizing that the most critical problems occur during project activities, we strongly believe that process and project alignment can be a best-practice to get better project results and improve organizations software processes. In our methodology, process versions are represented in a process versioning meta-model as a tree structure that supports mechanisms to allow an evaluation of the process changes along their several versions. The main goal is not only to get a description of the process really performed but, also important, is to analyze the effects on the organization of the improved process.

ProPAM was applied in a case study to help the organization improve its software product development process. The case study revealed that SPI isn't trivial, some improvements need organizations decisions, additional effort and time consuming activities. Sometimes, only after one year the effects of the proposed improvements will be observed. When passed projects data is needed to tune projects activities time and costs, it's important to continuously repeat the proposed improvement in future projects.

Further effort is required for better formalizing the methodology. Moreover, the methodology requires the support of a development environment, as much information has to be gathered and analyzed. Methodology concepts are being integrated in a project management tool (ProjectIT-Enterprise) of the ProjectIT research project. Future work will continue efforts to gather empirical data on its use will help refine the methodology and learn more about how to support the development process.

CEOs Survival: SOX Strategies Over the Long Term

Parviz Partow-Navid, California State University, Los Angeles, USA; E-mail: ppartow@calstatela.edu
Brad Cikra, California State University, Los Angeles, USA; E-mail: bcikra@nexgate.net

INTRODUCTION

The Sarbanes Oxley (SOX) Act has renewed business attention to details and financial reporting. Its intent is information protection and securing information, not just from outside intruders but also from hackers informing traders prior to public announcements. Securing all information within a company is an improbable task, although many steps are specified and suggested in the Act itself and supporting committees (Coe, 2005). Ways of benefiting from the SOX Act exist. Build a better company with a controlled environment (Deloitte, 2004).

Strategic goals and guidelines are described in this paper to assist the CEO in benefiting from the SOX Act. Although this paper is broad based, it is neither a comprehensive nor exhaustive coverage of the compliance issues of the Act. The Act is open ended with Section 404. Each company has areas of uniqueness that open new avenues of compliance interpretation. Embracing the Act completely is like sailing the great oceans. In this paper remedies for the CEO are offered to sail this ocean.

INTENDED AUDIENCE AND SCOPE

The audience for the SOX Act is public companies. Companies that are private are not affected by the SOX Act, which excludes many small companies. The scope of the Act is to make certain that the company's financial health is clearly reported for fair-trading of company stocks. Scope of the Act embraces security of information, which can have both legal and SEC violation implications. Non-profit corporations and other non-profit organizations are also free from compliance; however much pressure is put on these companies and organizations to be compliant to receive both private and federal funds.

AFFECTS CEO AND BOARD OF DIRECTORS

The Board of Directors is now in charge of overseeing the internal audit of the company. The CEO who wants to make good on his corporate promises is no longer the reporting officer for the internal audit. It now is the board of directors' responsibility to the stockholders to audit the company internally. The SOX Act ensures independent auditing by forbidding any officer or employee of a public accounting firm from being on a board of directors for which an external audit is performed. The board of directors cannot hold interest in a public accounting firm, that is utilized in auditing the corporation or company where the board member sits.

AUDIT COMMITTEE

The nature of the SOX Act is so expansive it requires an audit committee to manage. The internal audit committee works with the external-auditing firms and any outsourced internal auditing teams and reports directly to the board of directors. This committee is also an audited issue. It must be in place and operational with agenda and people (Deloitte, 2004). The large volume of issues within the SOX Act requires the audit committee to manage and protect the company from compliance failure.

CONTROLS FOR AUDITING PROCEDURES

The important concern is to have all the security requirements of rotation and cross interest checked and to have methods and procedures in place. A security check on entrance to the building and security auditing of all audit participants is a must. Checklists are available for spreadsheets to track and document procedures involved with spurious business activities such as waste control and unused asset removal (Burnett & Friedman, 2005). Five steps in preparing environmental cost estimates (ECE) are according to Berlin and Goldstein as follows (Berlin & Goldstein, 2005):

1. Evaluate any existing ECE, including any notes, reports, or correspondence.
2. Gather data regarding environmental status.
3. Develop/update ECE.
4. Assess the ECE relative to materiality.
5. Provide assessment to CFO/auditors.

Seven common risks that are difficult to account and measure with environmental issues according to Berlin and Goldstein are as follows (Berlin & Goldstein, 2005):

1. New management's lack of knowledge
2. Liabilities hidden in multiple accounts
3. Partial estimates that incorrectly appear immaterial
4. Increasing state enforcement
5. Masking liabilities with minimally effective treatment systems
6. Changing ownership to hide the cleanup problem

USE OR ABUSE THE AUDITOR? PERFECTING THE COMPANY AS A CORPORATE GOAL

The auditor has a job to perform and that job appears negative. Nothing is going to alter this relationship between auditor and company person, more than the SOX Act (Millman, 2005). "Perfecting the company" as a corporate goal is paramount in making the audit process a positive contribution. Protection for whistleblowers was implanted in SOX Act to protect the very nature of auditing, revealing something amiss. Lawyers are also to report to the board when presenting evidence of material violation. They are also protected from losing employment similar to the whistleblowers (Noorishad, 2005).

BUILD AN ETHICS PROGRAM AS CORPORATE GOAL

The SOX Act probes into whether the senior executives, the CEO and CFO, have a code of ethics (Green, 2004). Section 406 requires posting in the financial reports a disclosure of the company's code of ethics (Anand & Sarbanes Oxley Group, 2004). After ethics, behavioral boundaries can be developed and documented within the company (Green, 2004).

POLICIES FOR LEGAL PROTECTION AS PART AND PARCEL TO ETHICS PROGRAM

An appropriate response in legal terms is necessary for the protection of the CEO when a material violation occurs (Noorishad, 2005). It is clear, that preventive actions are appropriate remedial measures. To protect the company in court it is paramount to pile high a set of policy and procedures for ways and means of behavior. A procedure and policy needs to include education, training and policy signature attachment for the employee, who involves assessing material value that effects the financial statement. If the employee is non-compliant, the court will find the company less liable than if no such policy and procedure documented with policy signature, education and training attachments were in place.

AFFECTS MANAGEMENT

In Section 404 of the SOX Act, management must document all policy and procedures for any activities business or related that effect the bottom-line of the financials. This includes any risks or waste removal costing. Vacations that are not taken and airline miles not ticketed create openings for hidden costs to the company that need to be documented. Very few companies realize the extent of this Section 404 impact. The Act is open ended. The rules, such as vacation tracking, are followed haphazardly in many areas around many companies and this documenting activity is part of compliance to the SOX Act. Subsidiaries and other partners or companies with business relationship practices are included in section 404.

Under SOX Act the internal auditors do not report to the CEO; rather, to a board member of the board of directors. Ex-internal auditor specialists are needed to help the CEO comply with Section 404. These auditor specialists are not doing audits, but preparing the company to meet or exceed the internal audit; hence, the external audit.

BEHAVIORAL BOUNDARIES (STEERING) COMMITTEE

The human resource department has handled many difficult situations regarding employee behavior. The process of education, regular training, and employee signing of policy documents falls under the human resource domain. The Behavioral Boundaries Committee is needed to protect the company in its control of management and workers. Issues from sexual harassment, to getting user login permission require a policy and it is to be signed by the employee.

Management in one area of the company joins the Behavioral Boundaries Committee to oversee and enforce another area of the company. A ring of managers can work to oversee each other as committee members with human resource superiors and chairperson. The mixing of management participation, ethics as a company goal promoted by human resource management protects and builds an ethical company. This is the story and plan that goes into the financial statement as a disclosure on an ethics program for the company and SOX Act compliance.

AFFECTS INFORMATION TECHNOLOGY

Corporations are going to have to invest in IT to handle all of the security issues. Projected IT financial spending amounts to 40 billion dollars in 2006 (Swann, 2005). Although mostly for maintenance, SOX Act is putting the IT focus on data security. Securing company information from email to hard disks pregnant with company financial data is paramount to comply with the Act. It refers to the area of managing risks.

The Committee of Sponsoring Organizations (COSO) of the Treadway Commission satisfies the SEC criteria for internal audits. A proactive approach is to go with COSO framework as an institutional strategy that would fund IT with appropriate money and support IT with the needed policy and procedures that meet the COSO framework. CobiT also provides a framework to supply proactive compliance (Coe, 2004).

CONTROLS FOR IT NETWORK SECURITY WITH CHECKLIST

IT networks are to be secure to comply with the SOX Act. COSO includes five levels in its internal controls model, which are control environment, risk assessment, control activities, information and communication and monitoring (The Institute of Auditors, 1998). CobiT from the The Information Systems Audit and Control Foundation (ISACA), Trusted Services, once referred to as SysTrust, from the foundations of the American Institute of Certified Public Accountants (AICPA) and the Assurance Services Development Board (ASDB) of the Canadian Institute of Chartered Accountants (CICA) posted the AICPA/CICA Privacy Framework and two other frameworks that are compliant for information technology management and control (Coe, 2004). A checklist for IT network compliance for the SOX Act follows (Gallegos, Senft, Manson, & Gonzalas, 2004):

Firewall: It is a must for a company or corporation at every entry into internal systems.

Access Control: Every entry into any system from outside or inside the company must have access control and policy and procedures for every access is required.

Authentication: Access authentication systems to protect systems, data, and network and to permit access based on policy and procedures are required.

Cryptography: Choosing cryptography methods with at least a 128 bit key length.

Virus Protection: Anti-virus software and regular updates.

Backup: Loss data protection and replacement is part and parcel to business continuity when accidents and disaster recovery occurs.

Intrusion detection and logging: The computer forensics requirements for corrective action when network intrusion or attacks are detected which requires monitoring software.

Operating Systems and Application protection: The need to secure the operating systems and application systems against intrusions and attacks.

Database and file systems: SOX Act addresses this as an area that involves email data and potential trading advantages via intrusion from gathering material information prior to public announcements, which could affect stock price changes.

Vulnerability Management: Using COPS, Crack, Tripwire software, vulnerabilities can be identified prior to intrusion.

Monitoring: A security professional awareness with the computer security industry is required (Gallegos, Senft, Manson, & Gonzalas, 2004).

SECURITY COMMITTEE

The Security Compliance Steering Committee is a way to set priorities and audit all areas of security and provide suggestions and directions to oncoming issues. Security is an ongoing effort and requires legal participation. A lawyer is needed whose focus is security. The members of the team include human resource people, IT people both in systems, applications and telecommunications, a security lawyer, management in all divisions and corporate executives CIO, CFO. Ex-Auditing specialists are best included for help in the processing of procedures.

Other companies determined the need for an executive officer called the Chief Security Officer (CSO) or Chief Compliance Officer (CCO) (Brady, 2005). This chosen person would improve and protect the company's operations and set policy for advancing compliant requirements from outside government agencies. This Security Committee will work with the Behavioral Boundaries Committee and the Audit Committee. The Security Committee will prepare security policy and procedures with regard to management and workers and supply them to the Behavioral Boundaries Committee to enact and enforce. Education, employee training and policy signatures will have security issues along with others for employee processing. The Audit committee will feed security breaches and risks to the Security Committee for remedy. A security committee protects the company's property and its material financial asset value critical to the CEO, the company and SOX Act compliance.

ABSTRACT

In this paper we analyze the effects of the number of storage hierarchies in an ILM system. We describe the model for our simulator used to run the simulations. Afterwards the results are compared and recommendations are made.

Keywords: Information Lifecycle Management, ILM scenarios, storage hierarchies

1. INTRODUCTION

Information Lifecycle Management (ILM) is a strategic concept for storage of information and documents in which the value of the stored objects depends on the underlying business model and processes. Documents are assigned to a storage medium automatically so that the existing storage capacities can be used optimally and more cost efficiently.

For realizing cost potentials it is necessary to obtain a wider knowledge about ILM procedures and scenarios but experience reports do not exist in sufficient form and experimenting and searching in real systems is too expensive. Therefore the aim of this paper is to generate results and experiences by simulation of ILM scenarios.

First we work out the aims of a simulation and then create the corresponding simulation model. The model allows a strategy-orientated analysis. Based on this model a simulator was implemented as an examination tool for the behavior of ILM scenarios. The simulation model uses results of our study conducted in 2006 [1] which analyzed the access behavior on documents of a company database. The study provided a statistical description of the access patterns which is used in the model for the automatic migration of files.

The scientific use of the work consists of providing a model for simulation which generates generally utilizable results concerning ILM behavior and cost optimization.

The results focus on the optimal number of storage hierarchies in an ILM system

The paper starts by listing the objectives of ILM simulations and describing the simulation model. Then the scenarios to be simulated are defined. Simulation results are presented and interpreted. The paper ends with an outlook on further ILM simulations.

2. RELATED WORK

Strange examined the long-term access behavior on files in an UNIX system [2]. His aim was to identify regularities and patterns which can be applied to automated migration strategies for Hierarchical Storage Management (HSM). To verify hypotheses on migration algorithms a simulator was also designed and implemented. His examination is different to our approach on implementation. The simulator developed by Strange served as a tool merely for checking migration algorithms which were verified using observed access behavior. A stochastic simulation of the access behavior was renounced. Instead, the user behavior was generated deterministically from the access protocols. Since only the effect of the migration rules was analyzed, he could restrict the number of feigned storage hierarchies to two. In addition, only very simple migration algorithms were used.

Further work deals mainly with algorithms which can be used for ILM or other storage strategies. Some examinations focus on the analysis of the access behavior and the development of migration strategies. The file migration protocol listing of a supercomputer was analyzed in a study by Miller and Katz. Migration methods were developed for a corresponding system [3].

Schmitz has also analyzed the access behavior on files in a supercomputer to be able to derive an optimal migration strategy [4].

Miller and Gibson examined the access behavior in further studies in UNIX environments and designed a “file aging algorithm” as a migration rule [5].

Today ILM is a strict focus of research. The main results are found on the field of “How” ILM works, i.e. most research was done on the field of procedures and policies. Vendors gave their point of view about ILM understanding [6] Turczyk et. al. gave a formal definition usable for ILM abstraction [7]. Chen focused on the valuation of files [8]. Proposals for policy description of ILM were presented by Beigi et. al. [9] and Tanaka et. al. [10]. Beigi et. al. considered the file system environment. Tanaka et. al. rules are more general and offered a time schedule for migration. Both papers intend to use metadata for ILM realisations.

Our paper is influenced by the analysis of the long-term access behavior of Turczyk et. al. [1]. In contrast to other work, they analyzed Microsoft office files of a company database. In addition, they derived complex statistical rules for the migration of office files and documents.

3. SIMULATION MODEL

Our objectives below list how to implement a simulator as an examination tool for ILM scenarios. The primary objectives are the analysis of fundamental questions of ILM:

- Integral analysis of ILM scenarios (end-to-end)
- Identification of the necessary number of storage hierarchies

The simulator takes into consideration the integral lifecycle, i.e. from the initial situation designed for a company to the point where a stable state is reached. The simulator should offer transferable results concerning the questions mentioned above.

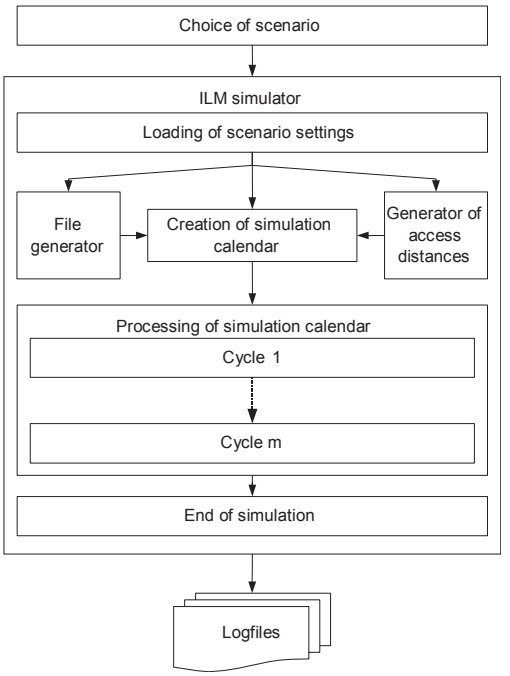
Some aspects of ILM have not been the subject of focus with this simulator and must therefore be considered separately. These secondary objectives are, in particular,:

- Identification of the necessary number of migration rules
- Optimization of the wording of migration rules
- Analysis of the dynamic behavior of ILM scenarios
- Realization of potential for cost reduction

Figure 1 shows the simulation model with its structural layout:

The main component of this plan is the ILM simulator. A scenario is loaded and simulations are executed. As a result the simulator generates logfiles. Any evaluation and interpretation of the results are done externally. How the simulator works is shown in the next section.

Figure 1. Simulation model



4. SIMULATIONS

For the examination of the effect of the number of storage hierarchies four simulation runs are carried out. The assumed data growth is about 20% per annum. The simulator starts the simulation with a data stock of 500 files. The simulation duration is 2,000 days. Ten simulation runs are averaged to one simulation to reduce fluctuations of measurements.

The migration rules used in the simulations are based on our study [1]. As distribution function either the Weibull-distribution (W(α;β)) or Gamma-distribution (G(α;β)) is used (see table 1).

The number of storage hierarchies is the initial variable of the simulations. At every simulation the first level has a threshold probability of p1=10%. The distances of the threshold probabilities dpi of the other levels i are equidistant, i.e. the remaining 10% are split up equally (see figure 2).

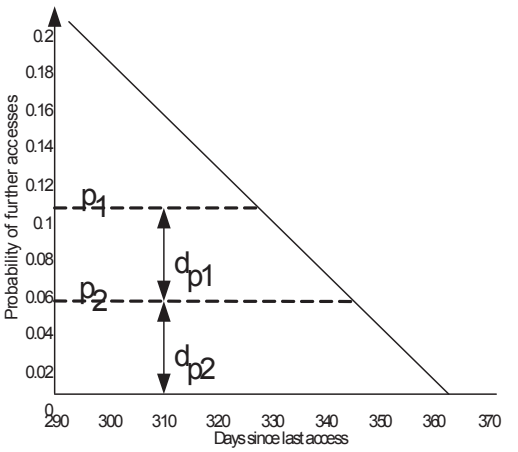
The threshold probability is described as the probability of further accesses on the file, where the file is assigned to a new hierarchy. In the example shown the probabilities of the first and second level are p1=10% or rather p2=5%. When the probability of further accesses on a file stored on hierarchy 1 falls below the threshold probability of 5%, it is migrated to hierarchy 2.

When adding a new storage hierarchy the threshold probabilities are adapted correspondingly so that they are of equal distance to each other again.

Table 1. Applied distribution functions

Number of accesses / File type	1-6	7-14	15-∞
doc	W(0,35;3,5)	G(0,32;183)	W(0,35;3,5)
xls	W(0,25;1,1)	W(0,25;1,1)	W(0,25;1,1)
ppt	W(0,38;14,3)	W(0,38;14,3)	W(0,38;14,3)
pdf	W(0,35;3,5)	G(0,32;183)	W(0,35;3,5)
other	W(0,46;27,7)	G(0,29;181)	W(0,46;27,7)

Figure 2. Equidistant threshold probabilities in case of two hierarchies with p1=10% and p2=5%



The influence on the number of hierarchies is observed by means of the relative capacity-need. In addition the jitter serves as a measure to look at the reliability of the system.

Now the individual simulation-runs and the accompanying results are explained.

At the first simulation there is only one threshold probability of p1=10% which lies between level 1 and 2. Figure 3 shows the result of the simulation.

In simulation 1 the relation between hierarchies 1 and 2 is approximately 1:1, i.e. almost half of the complete data stock is stored on the second, more economical hierarchy level. The average jitter is J(1000)=2.136.

Figure 3. Mean relative capacity-needs for two hierarchies

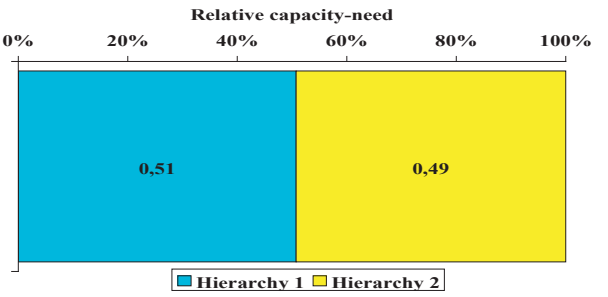


Figure 4. Mean relative capacity-needs for three hierarchies

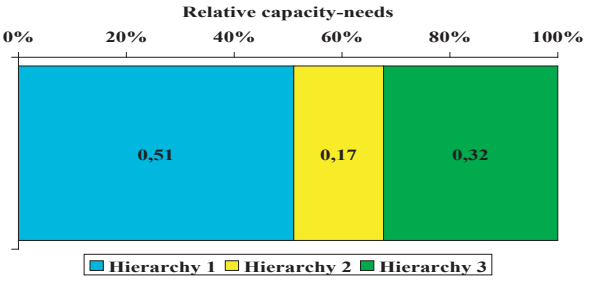

In simulation 2 three hierarchies are available for the storage of the files. The related value probabilities are p1=10% and p2=5 %.

Figure 4 represents the result of simulation graphically by means of the relative capacity need.

Again approximately 50% of the data are on the first storage hierarchy. On the second hierarchy nearly a sixth of the complete stock is kept and on the third hierarchy nearly a third of the files is stored.

A mean jitter of J(1000)=2.093 was measured.

In simulation 3 the probability values are p1=10%, p2=6.66% and p3=3.33%. The mean capacity values arising from the simulation are represented in figure 5.

Hierarchy 1 keeps 51% and hierarchy 2 keeps 10%. Hierarchies 3 and 4 keep 14% and. 25% respectively.

The average jitter is J(1000)=2.16.

Figure 5. Mean relative capacity-needs for four hierarchies

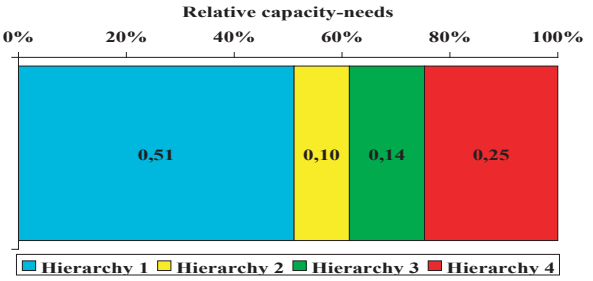

Figure 6. Mean relative capacity-needs for five hierarchies

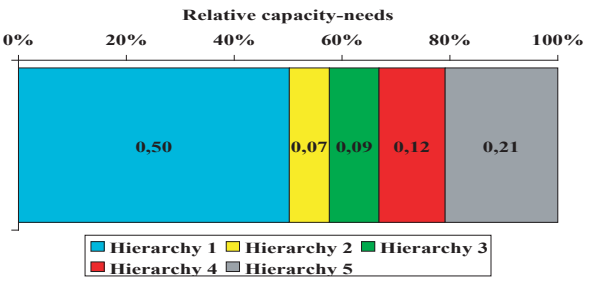

Figure 7. Overview of the mean capacity-needs

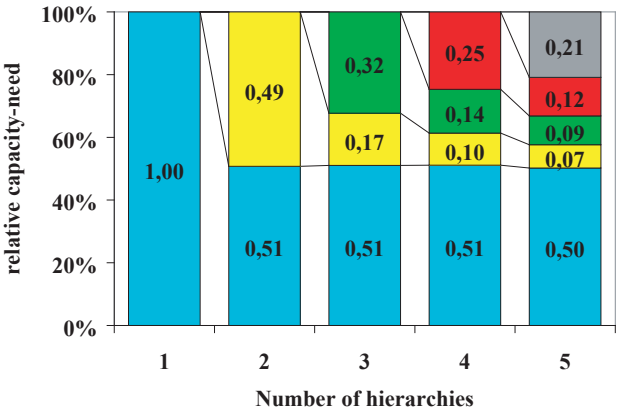

In simulation 4 a scenario with 5 hierarchies is simulated. The related probability values are p1=10%, p2=7.5%, p3=5% and p4=2.5%.

The results are shown in figure 6. Hierarchy 1 keeps 51 % and hierarchy 2 keeps 7.4%. Hierarchies 3 and 4 keep 9.2% and 12.3% respectively. Hierarchy 5 keeps 20.9%.

The measured jitter was J(1000)=2.17.

5. RESULTS AND INTERPRETATION

The observed jitter values of the four simulations vary less than 5%. It can be assumed that the reliability of an ILM system is independent of the number of hierarchies.

Figure 7 gives an overview of the capacity-need of the different scenarios.

By applying the sensitivity analysis we examine the effects of a variation in the number of hierarchies.

The storage demand of the first hierarchy remains constant irrespective of changes in the number of storage hierarchies.

The capacity need of the second level is reduced with an increasing number of storage hierarchies.

The reason for this behavior of the ILM system is the specification of the threshold probabilities.

With any added hierarchy the distances of the values change.

If there are only two hierarchies, the second hierarchy stores all files with an access probability of less than 10%.

If three hierarchies are used, the second only keeps files with an access probability of between 5% and 10%. Therefore the relative capacity need of the second level becomes smaller.

Generally speaking from all hierarchies lower than hierarchy 1, the lowest hierarchy always keeps the largest part of the files. Altogether, the greatest share of the information is stored on the top and the bottom hierarchies. This result coincides with the observations in real IT systems and is an essential driver for ILM. [11].

6. SUMMARY AND OUTLOOK

We presented simulation results for Information Lifecycle Management. The objective was focused on the optimal number of storage hierarchies. Although the number depends on the definite business process, the range of numbers of hierarchies could be isolated. In the next step further ILM scenarios will be simulated and compared. The focus will lie on the secondary objectives listed in section 3.

ABSTRACT

This paper reviews the American Society for Quality (ASQ) Certified Six Sigma Black Belt Body of Knowledge (CSSBBBOK) and prescribed areas of the Project Management Body of Knowledge (PMBOK) along with industry accepted deliverables deployed in the Six Sigma methodology of Define, Measure, Analyze, Improve, and Control (DMAIC). Each DMAIC phase is compared to the applicable project management process knowledge area of the PMBOK and the CSSBBOK. This paper proposes utilizing project management deliverables to the typical DMAIC tool set to resolve some of the root causes of Six Sigma project failure and to ensure successful Six Sigma project execution.

1.0 INTRODUCTION

Many companies deploy Six Sigma methodologies through selection of improvement projects that are related directly to customer dissatisfaction (warranty) -- things that have gone wrong (Stamatis, 2001).This is typically accomplished by training employees in Six Sigma Define, Measure, Analyze, Improve, and Control (DMAIC) methodology and completing the improvement projects with an emphasis on analytical rigor. However, according to Bertels (2003), Dussharmi (2003), and Goldstein (2003) successful Six Sigma projects also depend upon making sure that all levels of management play an active role in the deployment of the project by actively engaging them in the planning and project review process. In addition, Kowalski (2006) suggests that "90% of Six Sigma practitioners rate the addition of tools for engaging frontline managers and employees as a top priority for improving project results."

Upon examination of the ASQ-CSSBBBOK the Project Management section which describes the project charter and plan, team leadership and team dynamics, performance, change agents and management and planning tools, constitutes less than 10% of the overall ASQ-CSSBBBOK. Could the prescribed areas of the PMBOK offer tools that can be added to the DMAIC methodology that will successfully engage managers and employees? This paper proposes adding project management deliverables to the existing list of Six Sigma DMAIC tool set to resolve some of the root causes of Six Sigma project failure and ensure successful Six Sigma project execution.

2.0 PROJECT MANAGEMENT

Project Management (PM) is the application of knowledge, skills, tools and techniques to project activities to meet project requirements which is accomplished through the application and integration of the PM processes of initiating, planning, executing, monitoring and controlling, and closing. The term "project management" is sometimes used to describe an organizational or managerial approach to the management of projects and some ongoing operations, which can be redefined as projects that is also referred to as "management by projects."(A Guide to the PMBOK, 2004).

This standard describes the nature of PM processes in terms of the integration between the processes, the interactions within them, and the purposes they serve. These processes are aggregated into five groups, defined as the:

PM Process Groups:

- Initiating
- Planning
- Executing
- Monitoring and Controlling
- Closing

The PM knowledge areas are:

- Project Integration Management describes the processes and activities that integrate the various elements of project management, which are identified, defined, combined, unified and coordinated within the PM Process Groups.
- Project Scope Management describes the processes involved in ascertaining that the project includes all the work required, and only the work required, to complete the project successfully.
- Project Time Management describes the processes concerning the timely completion of the project.
- Project Cost Management describes the processes involved in planning, estimating, budgeting, and controlling costs so that the project is completed within the approved budget.
- Project Quality Management describes the processes involved in assuring that the project will satisfy the objectives for which it was undertaken.
- Project Human Resource Management describes the processes that organize and manage the project team.
- Project Communications Management describes the processes concerning the timely and appropriate generation, collection, dissemination, storage and ultimate disposition of project information.
- Project Risk Management describes the processes concerned with conducting risk management on a project.
- Project Procurement Management describes the processes that purchase or acquire products, services or results, as well as contract management processes.

3.0 SIX SIGMA DEFINED

Six Sigma was conceptualized as quality goal in mid—1980's at Motorola. There have been many versions of the Six Sigma definition since it was first coined in Motorola in the year 1987. ASQ defines Six Sigma as a fact-based, data-driven philosophy of quality improvement that values defect prevention over defect detection. It drives customer satisfaction and bottom-line results by reducing variation and waste, thereby promoting a competitive advantage. It applies anywhere variation and waste exist, and every employee should be involved. In simple terms, Six Sigma quality performance means no more than 3.4 defects per million opportunities. Benbow et. al, (2005) discuss differing opinions on the definition of Six Sigma by defining Six Sigma as philosophy , or as a set

of tools and or as a methodology. We will consider the methodology definition which is shown below.

The Six Sigma methodology recognizes the underlying and rigorous approach known as DMAIC. DMAIC defines the steps a Six Sigma practitioner is expected to follow, starting with identifying the problem and ending with the implementation of long-lasting solutions. While DMAIC is not the only Six Sigma methodology in use, it is certainly the most widely adopted and recognized (www.asq.org). Methodologies other than DMAIC are beyond the scope of this paper.

Irrespective of the choice of definition one may make, Six Sigma is always deployed through execution of a series of projects selected by management and driven by black belts. Six Sigma Black Belt leads, inspires, manages, delegates, coaches and "baby-sits" colleagues and becomes almost expert in tools for assessing problems and fixing or designing processes and products. Usually the Black Belts work alongside a team assigned to a specific, Six Sigma project (Pande, Holpp, 2002).

The fact that implementations of Six Sigma are always done through projects raises the logical question of how well is typical Six Sigma practitioner equipped with PM skills?

The criteria for selection of a black belt person vary considerably. Organizations may consider the organizational hierarchy of an employee before selection of the candidate for Six Sigma practitioner role (Revelle, 2001). Bertels, (2003) emphasizes that comfort and proficiency with numerical analysis and computer literacy are "must haves" for Six Sigma black belt roles. Pande et.al (2002) suggest that the black belt must possess strong problem solving, the ability to collect and analyze data, organizational savvy, leadership and coaching experience, and good administrative sense. They also suggest that the black belts must be adept at project management. Organizations assume delivery of these skills through the six sigma training; however this assumption has not been evaluated. The paper evaluates the fulfillment of PM skills by assessing the ASQ Six Sigma Black Belt Body of Knowledge.

Table 1. Knowledge areas prescribed by ASQ

KNOWLEDGE AREA	Specific Topics
I. Enterprise-Wide Deployment	A. Enterprise view B. Leadership C. Organizational goals and objectives D. History of organizational improvement/foundations of six sigma
II. Business Process Management	A. Process vs. functional view B. Voice of the customer C. Business results
III. Project Management	A. Project charter and plan B. Team leadership C. Team dynamics and performance D. Change agent E. Management and planning Tools
IV. Six Sigma Improvement Methodology and Tools – Define A	A. Project scope B. Metrics C. Problem statement
V. Six Sigma Improvement Methodology and Tools – Measure	A. Process analysis and documentation B. Probability and statistics C. Collecting and summarizing data D. Properties and applications of probability distributions E. Measurement systems F. Analyzing process capability
VI. Six Sigma Improvement Methodology and Tools – Analyze	A. Exploratory data analysis B. Hypothesis testing
VII. Six Sigma Improvement Methodology and Tools – Improve	A. Design of experiments (DOE) B. Response surface methodology C. Evolutionary operations (EVOP)
VIII. Six Sigma Improvement Methodology and Tools – Control	A. Statistical process control (SPC) B. Advanced statistical process control C. Lean tools for control D. Measurement system re-analysis
IX. Lean Enterprise	A. Lean concepts B. Lean tools C. Total productive maintenance (TPM)
X. Design for Six Sigma (DFSS)	A. Quality function deployment (QFD) B. Robust design and process C. Failure mode and effects analysis (FMEA) D. Design for X (DFX) E. Special design tools

4.0 ASQ SIX SIGMA BLACK BELT BODY OF KNOWLEDGE

The American Society for Quality (ASQ) has developed a Six Sigma Black Belt Body of Knowledge to use as a basis for certification of individuals as the Black Belts level of performance in applying the Six Sigma methodology. The knowledge areas prescribed by the ASQ are shown in Table 1.

Table 1 shows that 10% (one knowledge area out of ten) of the curriculum is devoted to project management. The question is that of adequacy and if these skills are well embedded within DMAIC phases. In order to assess this we evaluate the tools applied in each of the DMAIC phase and their relevance to project management.

5.0 THE RELEVANCE OF SIX SIGMA BLACK BELT TOOLS TO PROJECT MANAGMENT

The similarities between PM and Six Sigma have been discussed in the past. Tye (2005) suggests using Six Sigma to aid PM when developing a new process or product. Pyzdek (2003) discusses PM requirements for a successful Six Sigma program execution but the discussion is focused at the program level and not at the project level. Stamatis (2001) also discusses PM integration for the Design for Six Sigma (DFSS) methodology (beyond the scope of this paper).

Figure 1. PM knowledge level of integration in DMAIC phases

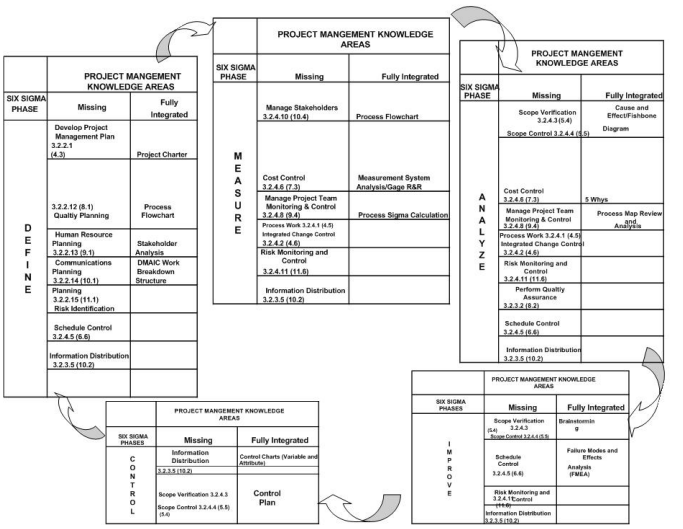

Figure 2. PM gap analysis for each six sigma DMAIC phase

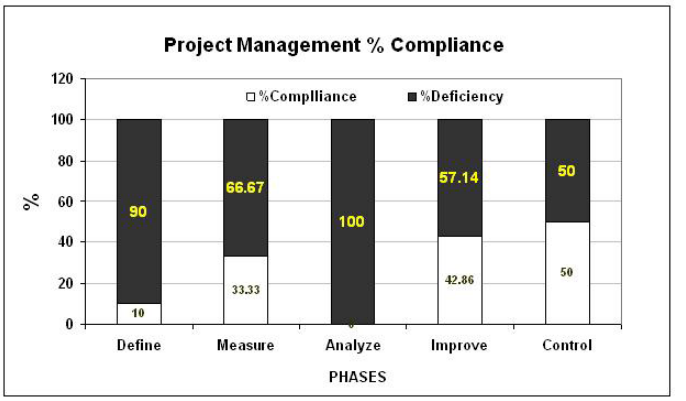

*(% Gap = (missing PM knowledge areas) ÷ (missing PM knowledge areas + fully integrated PM areas) * 100)*

Figure 1 evaluates the tools within DMAIC Phases against PM knowledge areas to determine which Knowledge areas are missing from the DMAIC phases.

Figure 2 displays quantitatively the PM knowledge areas of deficiency within each DMAIC phase as discussed earlier in Figure 1.

The gaps shown in Figure 2 are an indication of the void spaces for PM knowledge areas within DMAIC phases which may adversely affect the project execution and the project success.

6.0 REASONS FOR ADDRESSING THE GAPS

The primary reason for addressing the gaps using PM knowledge areas can found in the root causes of Six Sigma project failures discussed by Goldstein (2001), Underdown (2006), Nilanatasrinivasan (2005) and are summarized in Figure 3: Cause and Effect Diagram: Six Sigma Success Factors. This is in no way a comprehensive list but nevertheless, gives us a glimpse of important root causes of Six Sigma project failures.

Solutions to mitigate the root causes discussed in figure 3 are shown in Table 2.

7.0 PROPOSED SOLUTION

All the root causes listed in Table 2 may be successfully addressed or mitigated by adhering to sound PM principles as prescribed in the PMBOK. Table 2 each specific PM knowledge area that may address or mitigate root causes for each of the Six Sigma project failures. For example, details of the Deployment plan can be addressed or mitigated by adhering to Project Integration Management which defines inputs and outputs, along with standards for developing a sound project charter and developing a preliminary scope statement.

Likewise, the root cause related to communication may be mitigated if the Six Sigma practitioner implementation of Project Communication Management as defined by the PMBOK.

It is important to note that there may be more than one PM knowledge area to addressing or mitigating root causes, but this paper is limited to discussion of the most applicable PM knowledge area.

8.0 CONCLUSION

Root causes of Six Sigma project failures were discussed and it was determined that Six Sigma practitioners rated the addition of tools for engaging frontline managers and employees as a top priority for improving the success of Six Sigma projects. In addition, upon examination of the current ASQ CSSBBBOK it was determined that even though it provides a solid foundation for establishing standards for analytical tools and methodologies used in the DMAIC process, the knowledge area of PM appear to be lacking and does not provide enough tools to ensure successful implementation of projects with the engagement of frontline managers and employees. Integrating PMBOK areas into the DMAIC process may address or mitigate this issue. Further research will be required to evaluate the effects of integrating PMBOK areas into Six Sigma methodology on the success of Six Sigma Projects. The next steps in the research will be to develop a training model that will better address the PM knowledge areas and study the effects of the same on the successful execution of Six Sigma projects.

The Impact of Information Technology Architecture on Supply Chain Performance

Ken Dozier, University of Southern California, Western Research Application Center (WESRAC), 3716 South Hope Street, Suite 200, Los Angeles, CA 90007, USA; E-mail: kdozier@usc.edu

David Chang, 14212 Livingston, Tustin, CA 92780, USA; E-mail: dbcsfc@aol.com

ABSTRACT

Supply chain oscillations satisfy a sound wave-like dispersion relation when a company responds only to the status of the companies immediately above and below it in the chain. However, when information technology makes it possible for the company to respond to the status of all the companies in the chain, the dispersion relation changes from that of a sound wave to that of a plasma oscillation. The plasma oscillation exhibits Landau damping, and thus the information exchange leads to beneficial suppression of the oscillations.

INTRODUCTION

Supply chains are notorious for exhibiting oscillations in inventories that are both disruptive and costly in resources. Business schools have for several years exposed their students to the phenomena through the widely used simulation game created by J. D. Sterman and his colleagues at MIT (Sterman and Fiddaman 1993).

Sterman and Fiddaman conjectured that the oscillations were due in part to the lack of information exchange between the companies in the change. This lack of information exchange prevents controlled responses and leads to over reaction to perturbations from the steady state.

Recently, a simple model was developed in which each company in the supply chain responded only to the status of the companies immediately above and below it in the chain (Dozier and Chang 2005). The model displayed the types of supply chain oscillations observed in both the simulations and in actual practice. The oscillations satisfied the same type of dispersion relation as acoustic waves in a solid, i.e. the relationship between the frequency of oscillation and the wave number(2π/wavelength) of the oscillation resembled that for a sound wave in a solid.

In a follow-on paper, a crude continuum flowing fluid model of the supply chain was introduced: in the flowing fluid model, the resulting supply chain oscillations were found to satisfy the same dispersion relation as sound waves (Dozier and Chang 2007).

The purpose of this paper is to explore what happens if information exchange occurs between all the companies in the supply chain. This enables each company to respond not just to the inventory status of the layers immediately below and above it in the chain, but to the inventory status of all the companies in the chain. It will be shown that the oscillations change their character and become more like plasma oscillations than sound waves. The dispersion relation for a plasma oscillation can have higher phase velocities and lower group velocities than that for a sound wave. The associated Landau damping of the oscillations suggests that information exchange leads to beneficial suppression of the oscillations.

Section 1 presents a more realistic model of local information exchange a supply chain than our earlier treatments, in order to provide an easy comparison with the treatment of universal information exchange.

Section 2 derives the oscillation dispersion relation for a supply chain in which there is information exchange with all the companies in the chain.

1. SUPPLY CHAIN WITH LOCAL EXCHANGE OF INFORMATION

In (Dozier and Chang 2007), the supply chain was treated in the continuum limit where instead of designating each level in the chain by a discrete label n, the position in a chain was designated by a continuum variable x. Flow of production through each position *x* in the chain was characterized by a velocity variable v. A long supply chain was treated in which end effects were ignored.

We begin by introducing a function of position, production flow rate velocity, and time, f(x,v,t)dxdv that denotes a flow in the number of production units in the intervals dx and dv at a given x and v at the time t. This distribution function can be expressed as a conservation equation in the phase space of x and v:

$$\partial f/\partial t + \partial[f dx/dt]/\partial x + \partial[f dv/dt]/\partial v = 0 \quad (1)$$

This equation simply states that the change of fdxdv is due only to the divergence of the flow into dxdv. This implies that the flow into a volume element dxdv may not the same as the flow out.

By introducing a force F that influences the velocity of the production rate v, this equation can be rewritten

$$\partial f/\partial t + \partial[fv]/\partial x + \partial[fF]/\partial v = 0 \quad (2)$$

Since position x and velocity of the production rate v are independent variables,

$$\partial v/\partial x = 0 \quad (3)$$

If, moreover, the force F does not depend on v,

$$\partial F/\partial v = 0 \quad (4)$$

then Equations (2)-(4) yield

$$\partial f/\partial t + v\partial f/\partial x + F\partial f/\partial v = 0 \quad (5)$$

This is similar to the Liouville equation of classical mechanics, and has the familiar form of the Vlasov equation for collisionless plasmas (Spitzer (1956)).

Now assume that F at the position x is determined only by the level of the inventories of the production units immediately above and below x in the chain.

Assume that the fractional change in the time rate of change of velocity (1/v)dv/dt is proportional to the fractional change in the gradient of the density $N(x,t)$:

$$(1/v)dv/dt \;\mu\; -(1/N)dN/dx \qquad (6)$$

where

$$N(x,t) = \int dv f(x,v,t) \qquad (7)$$

and where the negative sign is explained below.

For local information exchange with the levels immediately above and below the level of interest, the change in the density is observed over only $dx = 2l$, where l is the spacing between levels in the supply chain Thus, we can further write

$$(1/v)dv/dt \;\mu\; -(2l/N)dN/dx \qquad (8)$$

The rationale for this expression is that when the inventory of the level below the level of interest is less than normal, the production rate (v) will be diminished because of the smaller number of production units being introduced to that level. At the same time, when the inventory of the level above the level of interest is larger than normal, the production rate will also be diminished because the upper level will demand less input so that it can "catch up" in its production through-put. Both effects give production rate changes proportional to the gradient of N. It is reasonable also that the fractional changes are related rather than the changes themselves, since deviations are always made from the inventories at hand.

A time scale for the response is missing from Equation (8). We know that a firm must make decisions on how to react to order flows into the firm. Assume that the time scale of response $\tau_{response}$ is given by

$$\tau_{response} = (1/\xi)\tau_{processing} \qquad (9)$$

where $\tau_{processing}$ is the processing time for a unit as it passes through the firm, and for simplification we are assuming ξ is a constant. Most likely, ξ will be less than unity, corresponding to response times being longer than processing times.

Thus, Equations (6) – (9) lead to

$$(1/v)dv/dt \;-(2\xi l/\tau_{processing}\; n)dn/dx \qquad (10)$$

Since by definition production rate *(i.e. velocity)*

$$v = l/\tau_{processing} \qquad (11)$$

this gives finally

$$F = dv/dt = -\; 2\xi v^2(1/N)dN/dx \qquad (12)$$

Insertion of this expression into Equation (5) then yields

$$\partial f/\partial t + v\partial f/\partial x - 2\xi v^2(1/N)(dN/dx)\;\partial f/\partial v = 0 \qquad (13)$$

In the steady state, the equation is satisfied by

$$f(x,v,t) = f_0(v) \qquad (14)$$

i.e. by a distribution function that is independent of position and time: production units flow smoothly through the line without bottlenecks. For a smoothly operating supply chain, $f_0(v)$ will be centered about some flow velocity V_0, a fact that we shall make use of later.

Now suppose there is a (normal mode) perturbation of the form exp[i(ωt – kx)], i.e.

$$f(x,v,t) = f_0(v) + f_1(v)\exp[-i(\omega t - kx)] \qquad (15)$$

On linearizing eq. (13) with this f(x,v,t), we find that $f_1(v)$ satisfies

$$-i(\omega - kv)f_1 - 2\xi v^2(1/N_0)(dN_1/dx)\;\partial f_0/\partial v = 0 \qquad (16a)$$

i.e.

$$-i(\omega - kv)f_1 - ik\,2\xi v^2(1/N_0)N_1\partial f_0/\partial v = 0 \qquad (16b)$$

Solving for f_1:

$$f_1 = \; -2\xi k(1/N_0)\int dv' f_1(v')\; v^2\partial f_0/\partial v(\omega - kv)^{-1} \qquad (17)$$

On integrating this equation with respect to v, we get the dispersion relation relating ω and k:

$$1 + 2\xi k\,(1/N_0)\int dv v^2\partial f_0/\partial v(\omega - kv)^{-1} = 0 \qquad (18)$$

This equation contains a singularity at ω=kv. This singularity occurs where the phase velocity ω/k becomes equal to the velocity of flow v. There are well-defined methods for the treatment of singularities: Following the Landau prescription (Landau (1946); Stix (1962))

$$\int dv v^2\partial f_0/\partial v(\omega - kv)^{-1} = PP\int dv v^2\partial f_0/\partial v(\omega - kv)^{-1} - i\pi(\omega/k)^2(1/k)\partial f_0(\omega/k)/\partial v \qquad (19)$$

where PP denotes the principal part of the integral, i.e. the value of the integral ignoring the contribution of the singularity.

To evaluate the principal part, assume that for most v, ω>>kv. Then approximately

$$PP\int dv v^2\partial f_0/\partial v(\omega - kv)^{-1} \approx \; \int dv v^2\partial f_0/\partial v(1/\omega) \qquad (20a)$$

or, on integrating this by parts, we find

$$PP\int dv v^2\partial f_0/\partial v(\omega - kv)^{-1} \approx -\,2n_0V_0 \qquad (20b)$$

since f_0 is peaked about the equilibrium flow velocity V_0

This gives the sound-wave-like dispersion relation

$$\omega \approx 4\xi kV_0 \qquad (21)$$

Addition to this of the small contribution from the imaginary part yields

$$\omega = 4\xi kV_0 + \omega(1/N_0)i\pi(\omega/k)^2\partial f_0(\omega/k)/\partial v \qquad (22)$$

or, on using the approximate relationship of Equation [21] for the ω's in the second term on the RHS

$$\omega = 4\xi k V_0 [1+(1/N_0) i\pi (4\xi V_0)^2 \partial f_0(4\xi V_0)/\partial v] \quad (23)$$

For the fast response times made possible by first order rapid information exchange, $\xi = O(1)$. Thus, with $f_0(v)$ peaked around V_0, $\partial f_0(4\xi V_0)/\partial v < 0$.

Accordingly, the imaginary part of ω is less than zero, and this corresponds to a damping of the normal mode oscillation. It is interesting to note that since $4\xi V_0 >> V_0$ (where the distribution is peaked), the derivative will be small, however, and the damping will be correspondingly small.

2. SUPPLY CHAIN WITH UNIVERSAL EXCHANGE OF INFORMATION

Consider next what happens if the exchange of information is not just local. (Suppose that information is shared equally between all participants in a supply chain such as in the use of grid computing.) In this case, the force F in Equation (5) is not just dependent on the levels above and below the level of interest, but on the f(x,v,t) at all x.

Let us assume that the effect of f(x,v,t) on a level is independent of what the value of x is. This can be described by introducing a potential function Φ that depends on f(x,v,t,) by the relation

$$\partial^2\Phi/\partial x^2 = -[C/N_0]\int dv\, f(x,v,t) \quad (24)$$

from which the force F is obtained as

$$F = -\partial\Phi/\partial x \quad (25)$$

(That this is so can be seen by the form of the 1-dimensional solution to Poisson's equation for electrostatics: the corresponding field from a source is independent of the source position.)

The constant C can be determined by having F reduce approximately to the expression of Equation (12) when f(x,v,t) is non zero only for the levels immediately above and below the level x_0 of interest in the chain. For that case, take

$$N(x+l) = N(x_0) + dN/dx\, l \quad (26)$$

and

$$N(x-l) = N(x_0) - dN/dx\, l \quad (27)$$

and zero elsewhere. Then

$$F = -\partial\Phi/\partial x = -[C/N_0](dN/dx)\, 2l^2 \quad (28)$$

On comparing this with the F of eq. (12), $F = -2\xi v^2(1/N)dN/dx$, we find (since the distribution function is peaked at V_0) that we can write

$$C = \xi V_0^2 / l^2 \quad (29)$$

Accordingly,

$$\partial^2\Phi/\partial x^2 = -[\xi V_0^2/N_0 l^2]\int dv\, f(x,v,t) \quad (30)$$

With these relations, F from the same value of f(x,v,t) at all x above the level of interest is the same, and F from the same value of f(x,v,t) at all x below the level of interest is the same but of opposite sign.

This is the desired generalization from local information exchange to universal information exchange.

It is interesting to see what change this makes in the dispersion relation. Equation (5) now becomes

$$\partial f/\partial t + v\partial f/\partial x - \partial\Phi/\partial x\, \partial f/\partial v = 0 \quad (31)$$

and again the dispersion relation can be obtained from this equation by introducing a perturbation of the form of Equation (15) and assuming that Φ is of first order in the perturbation. This gives

$$-i(\omega - kv) f_1 = ik\Phi_1 \partial f_0/\partial v \quad (32)$$

i.e.,

$$f_1 = -k\Phi_1 \partial f_0/\partial v\, (\omega - kv)^{-1} \quad (33)$$

Since Equation (30) implies

$$\Phi_1 = (1/k^2)[\xi V_0^2/N_0 l^2]\int dv\, f_1(v) \quad (34)$$

we get on integrating Equation (33) over v:

$$1 + (1/k)[\xi V_0^2/N_0 l^2]\int dv \partial f_0/\partial v\, (\omega - kv)^{-1} = 0 \quad (35)$$

Once again a singularity appears in the integral, so we write

$$\int dv \partial f_0/\partial v\, (\omega - kv)^{-1} = PP\int dv \partial f_0/\partial v\, (\omega - kv)^{-1} - i\pi(1/k)\partial f_0(\omega/k)/\partial v \quad (36)$$

Evaluate the principal part by moving into the frame of reference moving at V_0, and in that frame assume that $kv/\omega << 1$:

$$PP\int dv \partial f_0/\partial v\, (\omega - kv)^{-1} \approx \int dv \partial f_0/\partial v\, (1/\omega)[1+(kv/\omega)] = -kN_0/\omega^2 \quad (37)$$

Moving back into the frame where the supply chain is stationary,

$$PP\int dv \partial f_0/\partial v\, (\omega - kv)^{-1} \approx -kN_0/(\omega - kV_0)^2 \quad (38)$$

This gives the approximate dispersion relation

$$1 - (1/k)[\xi V_0^2/N_0 l^2]\, kN_0/(\omega - kV_0)^2 \approx 0 \quad (39)$$

i.e.

$$\omega = kV_0 + \xi^{1/2} V_0/l \quad \text{or} \quad \omega = kV_0 - \xi^{1/2} V_0/l \quad (40)$$

To assure that ω>0 as k->0, we shall discard the minus solution as spurious.

Now add the small imaginary part to the integral:

$$1 + (1/k)[\xi V_0^2/N_0 l^2][-kN_0/(\omega - kV_0)^2 - i\pi(1/k)\partial f_0(\omega/k)/\partial v] = 0 \quad (41)$$

On iteration, this yields

$$\omega \approx kV_0 + x^{1/2}(V_0/l)\,[1 + i\,\{pxV_0^2/(2k^2l^2N_0)\}\partial f_0/\partial v\,] \quad (42)$$

where $\partial f_0/\partial v$ is evaluated at

$$v = \omega/k \approx V_0 + (x^{1/2}V_0/kl) \quad (43)$$

Since for velocities greater than V_0 , $\P f_0/\P v < 0$, we see that the oscillation is damped.

Moreover, the derivative $\P f_0/\P v$ is evaluated at a velocity close to V_0, the flow velocity where the distribution is maximum. Since the distribution function is larger there, the damping can be large.

Accordingly, universal information exchange has resulted both in changing the form of the supply chain oscillation and in suppression of the resulting oscillation.

DISCUSSION

The purpose of this paper has been to introduce a simple flow model for comparing the impacts of local information exchange to universal information exchange in a supply chain. The local information exchange has been described by a term that describes the interaction of a company with those immediately above and below it in the supply chain. The universal information exchange has been described by introducing a potential that satisfies a Laplace equation. This potential corresponds to each company above the company at the location of interest contributing equally to that company's actions, and to each company below the company at the location of interest contributing equally but oppositely to that company's actions.

It has been demonstrated that for local information exchange, the dispersion relation that describes the relation between frequency of oscillation and the wave number of the oscillation, resembles that for a sound wave in a flowing fluid, i.e. the wave velocity of the perturbations is proportional to the wave number, and is greater than the production flow velocity. These waves are damped, but the damping can be small because the phase velocity is so much larger than the flow velocity.

It has also been shown that for universal information exchange, the dispersion relation resembles that for a plasma oscillation. Instead of the frequency being proportional to the wave number, as in the local information exchange case, the frequency now contains a component which is independent of wave number. The plasma-like oscillations for the universal information exchange case are always damped. As the wave number k becomes large, the damping (which is proportional to $\partial f_0(\omega/k)/\partial v$) can become large as the phase velocity approaches closer to the flow velocity V_0.

Accordingly, the simple flow model of supply chains has demonstrated that universal information exchange both changes the character of the supply chain oscillations and suppresses the oscillations. This supports Sterman and Fiddaman's conjecture that IT will have beneficial effects on supply chains.

The conclusions of this paper have been based on a rather crude flow model of supply chains and on some rather approximate treatments of the associated equations. Nevertheless, it is hoped that the model has helped develop an intuitive understanding of the different effects.

Future work will create numerical simulations that compare the slightly damped oscillations incurred by serial communication to the predicted largely damped oscillations of grid communication.

The Future of Real Time Communications in Online Learning

Richard Caladine, Centre for Educational Development and Interactive Resources, University of Wollongong, Australia; E-mail: caladine@uow.edu.au
Elahe Aminifar, University of Wollongong, Australia

ABSTRACT

There is a clear trend in Web content from text-rich to media-rich and it is logical to expect Learning Management Systems (LMSs) of the future to not only increase media-rich content but also integrate media-rich Real Time Communications technologies (RTCs). This will enable a range of new activities to be undertaken and to take advantage of the LMSs organizational capabilities. Videoconference has been used in distance learning for many years. Video Chat and Access Grid are newer RTCs that have the potential for online learning. While these three technologies are similar, a comparison of them will provide direction for their future use.

INTRODUCTION

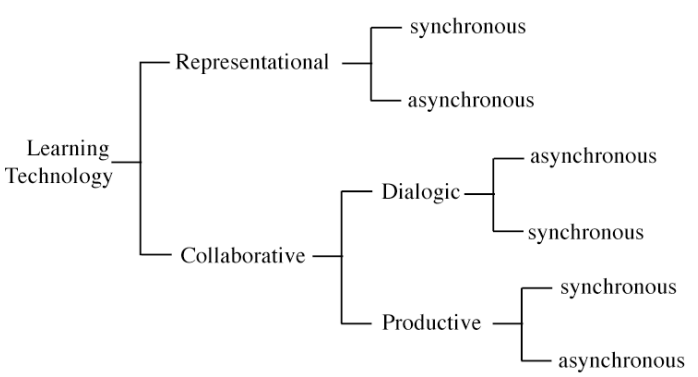
Distance education in the past was generally characterised by independent learning and little dialog between teacher and student. In the 1970s Moore introduced the theory of transactional distance (Moore and Kearsley 1995, p. 197). Transactional distance is measured by the degree of structure and the amount of dialog in a distance education course. Moore argues that communications between teachers and students in distance education "must be facilitated by print, electronic, mechanical or other devices" (Moore 1972, p, 76). RTCs are used to facilitate audio and video communications between teachers and students and include, videoconference, Access Grid, Web Conference and Video Chat.

TAXONOMY OF LEARNING TECHNOLOGIES

The Taxonomy of Learning Technologies (Caladine 2006) categorizes technologies as Representational or Collaborative (see figure 1). The term, Representational describes the communication in the one-way representation of material. Collaborative technologies facilitate two-way communications and are divided into the sub-categories of "Dialogic" or "Productive". Dialogic learning technologies are those that are confined to the support of dialog. Productive learning technologies combine two-way communications and the creation of products.

Videoconference is classified as Collaborative, Dialogic and synchronous. This contrasts to Access Grid when it is used as the host for collaboratively produced materials, in which case it is Collaborative, Productive and Synchronous.

Figure 1. The taxonomy of learning technologies (Caladine 2006)



VIDEOCONFERENCE

Videoconference can be thought of as two parallel, counter-directional closed circuit television systems. In the 1980s dedicated videoconference technology appeared on the market that could take advantage of the then new digital telecommunications networks such as ISDN (Integrated Services Digital Network). At this time videoconference use in distance education took a decided upturn. Today the trend is for videoconferences to use the Internet as the connecting network.

WEB CONFERENCE

Since Microsoft launched NetMeeting in the 1990s, other Web Conference tools have been developed and are now commercially available for use in higher education. Typically Web Conference tools are defined as combining synchronous video and/or audio communications with a shared computer application or presentation. Examples of Web Conference tools include: WebEx, Macromedia Breeze and Elluminate.

VIDEO CHAT

Instant Messaging applications were first limited to text interchanges and were generally free of charge. They evolved into voice applications and have become almost ubiquitous. After voice, video was a natural progression. Video Chat is defined as an application of computer technology that allows two-way audio and video communications. Thus Video Chat can be thought of as videoconference on a computer. Applications like Apple's iChat AV indicate that the future direction of Video Chat is a multipoint video communications tool with integrated file exchange and sharing, referred to here as "Enhanced Video Chat".

Video Chat is rather simple and inexpensive to set up, as all that is needed is a computer, a Web camera, a headset and an Internet connection of sufficient bandwidth. Most broadband connections are ample for this.

ACCESS GRID

Researchers have used the Access Grid as a communications and collaboration technology since its development in the mid 1990s. The Access Grid takes advantage of the Internet's multicast ability to send and receive multiple video and audio streams while keeping bandwidth to a minimum.

While Access Grid, Video Chat and videoconference are similar in that they all facilitate the two-way exchange of video and audio, Access Grid is differentiated by the multiple video streams sent and received from each endpoint or "node" and by a number of additional software modules. These modules include, shared presentation, shared browser, true application sharing and many more. Some commercial products that claim to offer application sharing in fact use the term to describe the transfer of files between participants. True application sharing allows participants to work on the same file at the same time. While room-based nodes on the Access Grid usually contain a wall of projected video images, as shown in Figure 2, smaller installations are possible. These are referred to as Personal Interfaces to the Grid or PIGs, and require similar technology to Video Chat.

COMPARING VIDEOCONFERENCE, ACCESS GRID, WEB CONFERENCE AND VIDEO CHAT

The role of videoconference in distance education is quite clear, as it has been

Figure 2. Multiple video streams of the access grid

used for the past fifteen to twenty years for communications between students and teachers.

The literature (Caladine 1999, Daunt 1997, Kobayashi et al 1997, Mitchell 1993) concurs that videoconference is best used as an interactive technology in teaching and learning and it is reasonable to extend this generalisation to Access Grid, Web Conference and Video Chat.

Access Grid and Video Chat are newer technologies and are yet to become established in teaching and learning. However, due to the low costs of Video Chat and

Table 1. Comparing technologies

	Video-conference	**Web Conference**	**Access Grid**	**Video Chat**	**Enhanced Video Chat**
Functions	Video and audio of participants	Audio (and video in some cases) of presenter - some have capacity for audio of participants	Video and audio of participants	Video and audio of participants	Video and audio of participants
	Presentation of computer images (eg PowerPoint) by participants	Presentation of computer images (eg PowerPoint) by one participant	Presentation of computer images (eg PowerPoint) by participants		Presentation of computer images (eg PowerPoint) by participants
			Control of computer images by any participant		
		Document or presentation transfer	True application sharing (eg spreadsheets, documents, movie viewers and others)		
		eWhiteboard sharing	eWhiteboard sharing		
			Computer desktop sharing		
Hardware costs	Endpoint - medium Bridge - high	Server - medium	Room based node – medium Personal Interface to the Access Grid - low	Low	Low
Software costs	Included - firmware	Licence – medium/high	Open source	free	free
Support costs	Technician - low	Technician – low (server support)	Technician - medium	none	none
Bandwidth required	Medium	Medium	Medium-high	Medium	Medium

the enhanced functionality of Access Grid, both technologies have the potential to play major roles. A comparison of the technologies on the criteria of functions and costs helps predict the future of these technologies.

While the technologies are all similar, they differ in the type and level of functions they facilitate. Videoconference and Video Chat are characterised by two-way video and audio. By comparison Web Conference in many cases cannot fully support two-way audio and video as well as deliver images from a participant's computer. Access Gird can be configured to do both and Video Chat is defined as two-way video and audio. Table 1 provides a comparison of the functionality of the technologies.

The equipment required for the technologies ranges from the simple to the complex, and hence the costs ranges from low to high. However, the initial cost of the technology is only one part of the costs criterion. Other elements of the technologies that incur costs are software, personnel to support the technology and the network traffic created.

Videoconference technology has improved in reliability and quality of picture and sound. Perhaps the change that has had the greatest impact on the way in which videoconference is used is the change from ISDN to the Internet. The Internet has reduced the need for designated videoconference studios; however, videoconference required bridging technology for the connection of multiple parties. Access Grid uses no local, bridging technology.

Given that videoconference endpoint and bridging technology is expensive, it is reasonable to predict that its use will contract to specialist areas such as, high definition uses for medical imaging, microscopy and motional analysis, and high level board-meeting-style, immersive videoconferences. As students are used to Video Chat technology and as there are great costs saving to be had it is reasonable to predict that the use of Video Chat in distance and online learning will grow and eventually displace videoconference. As enhanced Video Chat has the functionality of Web Conference software, without the expensive price tag it is reasonable to suggest that enhanced Video Chat will replace these.

Cost alone is enough of a driver to see institutions replace expensive videoconference endpoint equipment with the cheaper Video Chat. As well the enhancements of file sharing, and using Video Chat in conjunction with a shared application will see it develop into a Collaborative, Productive learning technology. This will allow students no matter where they are located to undertake a range of collaborative tasks such as, build resources, compile reports, debate issues, brainstorm ideas and more.

While Access Grid has been used for some years in research collaboration its potential for teaching and learning is only now becoming clear. Due to the multiple video streams sent and received, the Access Grid learning experience is visually much richer than videoconference and Video Chat. When Access Grid takes advantage of software modules that allow participating students to control the size of the received video windows and to control the cameras at other endpoints, the experience can be tailored to suit participants on a level beyond that of videoconference and Video Chat. Access Grid also has software modules that facilitate true sharing of files and applications and hence is described by the taxonomy mentioned earlier as Collaborative-Productive.

CONCLUSION

It is reasonable that future students will expect video and other examples of media-richness in their online learning experience. Learning Management Systems have played a significant role in learning for the past six to eight years and have been text-rich in both content and interactions. Their communications have generally been limited to text. Students could use the LMS email system, engage in a chat session or send a message to a forum. As Video Chat is fast displacing text as the preferred medium for Instant Messaging, it is expected that Video Chat will be integrated with Learning Management Systems. The integration will allow templates for their use and secondary applications that elevate simple video communications to rich learning events. For example a debating team could consist of students from different locations and the debate could be held in a virtual room on the LMS. If a shared eWhitboard, hosted within the LMS was combined with Video Chat a brainstorming session could be held between geographically dispersed students and other examples abound. Further it is not inconceivable that the Access Grid could be integrated with the LMS. Such an integration would allow the flexibility to have a small group at a regional Access Centre and larger group at a room-based node on campus and individuals at home on a personal interface.

IT Tools Supporting Public Relations Campaigns

Witold Abramowicz, Poznan University of Economics, Poland; E-mail: w.abramowicz@kie.ae.poznan.pl

1. THE ROLE OF INFORMATION IN PUBLIC RELATIONS

One of the most important economical theories recently is the theory of information asymmetry. As Arrow and Akerlof independently indicated (Arrow 1963; Akerlof 1970) the common situation on the market is that one party is better informed than the other. Due to this phenomenon, dubbed information asymmetry, markets can deteriorate and even disappear. A detailed analysis of the importance of information in economy has been proposed by Stiglitz (Stiglitz 2000).

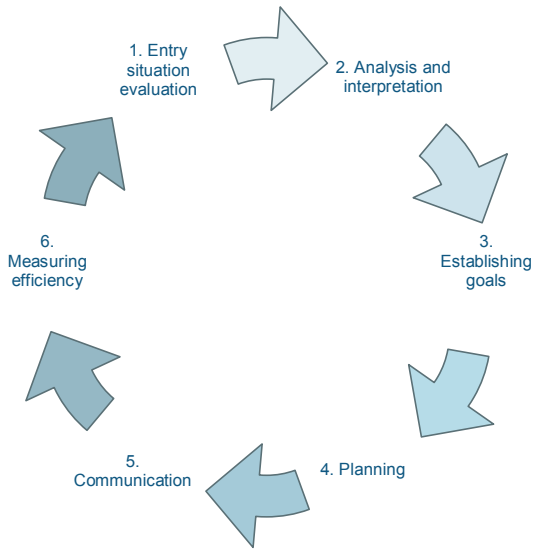
Research in the fields of economics and PR is clearly indicating that proper information is crucial in order to make the most appropriate business decisions e.g. during PR campaigns even minor decisions made may largely influence the outcomes. Moreover, recent research indicates that Internet contributes to reduction of information asymmetry (Levitt i Dubner 2005). In general, the influence of information technology on information overload and information asymmetry has been analysed by Kriebel and Moore (Kriebel i Moore 1982).

At the same time we are facing an overburdening growth of the number of reliable information sources on the Internet (Klapp 1986; Feather 1998). The basic assumption of awareness of all available alternatives and ability to assess all possible outcomes clearly cannot be met anymore (Balcerowicz 1997).

1.1. PR Process

PR campaign is a process that consists of a set of activities which in turn should lead to fulfilling PR aims such as creation of attitude towards the organization, providing effective corporate publicity, formation of image of the organization (Wojcik 2001).

Figure 1. Public relations campaign



In-depth analysis of stages of Public Relations campaign leads to one important remark – stages 1., 2. and 6. are strongly related to collecting, processing and analysing information from different sources. These phases are often referred in the literature as research phases (Stacks 2002):

2. IT TOOLS

There are many Information Technology tools that can help in running efficient PR campaigns. Here, we focus on three groups of such tools: information retrieval and filtering tools, information aggregation tools, and information integration tools. They are mostly to be used in the research phase of PR campaigns, where efficient access to relevant information is especially important.

2.1. Information Retrieval and Filtering Tools

Information filtering (IF) is a constant process that enables acquiring documents that match user preferences. In opposite to it, information retrieval (IR) is about finding documents that are relevant to user query in collection of documents. However, there is one common idea in both processes. Both approaches need documents as well as user needs to be properly described. These descriptions may be viewed as certain contexts that are taken into account when analysing documents.

2.1.1. Contexts for Information Filtering

Context is defined as information characterizing situation of a person, place or object, that cooperates with user or application (Dey and Abowd 1999). There are several types of contexts described in the literature: computing context, physical context and user context (Schilit 1995), human factors and physical environment contexts (Schmidt et al. 1999).

In order to be able to provide user with information that matches each of type of context documents need to be properly described (i.e. indexed). Therefore, the following methods of documents' indexing were differentiated:

- Cognitive indexing - providing description of documents subject e.g. real estates, vehicles, etc. In other words cognitive indexing is about assigning categories to a document.
- Time indexing - identifying all dates that the article is relevant for. However time indexing is not only about extracting dates from a given document – it's also about identification of verb forms and reference date of an article.
- Geographical indexing - discovering all geographical places mentioned in a document and assigning the document to right place in hierarchy of geographical places.
- Proper names indexing - this context is connected to all organization product or person names that appear in the document content.

2.2. Information Aggregation Tools

The information extracted from numerous sources needs to be put together. In data and information integration systems it is usual to integrate the extraction results, which includes identifying data that refer to the same real world entities,

normalizing it, equalize the measures, format etc. and remove redundancies. This is, however, hardly possible or even not desired for content aggregation. While data integration tries to find corresponding entity descriptions and remove duplicate information, content aggregation just brings the information together. Content is subjective in nature and therefore it may be important to retain this subjectivity and preserve the meta-information about the source. We hypothesize that application areas of data integration and content aggregation are separate. While the former is limited to bringing together the information about the same or similar entities from different sources, the latter can be applied to gather information of less homogeneous nature.

Information aggregation is a concept that has not been very well researched so far. There are very few scientific publications regarding this concept. One and most significant of the few is a research work of Stonebraker and Hellerstein (Stonebraker i Hellerstein 2001). They define the term content integration to refer to the integration of operational information across enterprises. The authors understand content as semi-structured and unstructured information, and content integration deals with sharing such information. Stonebraker and Hellerstein describe a Cohera Content Integration System, helpful in content integration, which consists of the following components: Cohera Connect, providing browsing and DOM based wrapper generation functionality, Cohera Workbench for content syndication, and Cohera Integrate for distributed query processing.

Application areas of information aggregation technologies may include news aggregation from multiple sources, in order to be able to compare different sources. However, what is really necessary is a simple solution, since there is already a wealth of approaches that did not receive deserved attention, probably due to their complexity.

2.3. Information Integration Tools

The main problem with accessing data nowadays is that the sources are dispersed, they are not searchable and the process of obtaining data may be tedious. All these issues are tackled with information integration technologies.

A typical data source on the Web exposes some forms to ask queries – examples would be search form on the main Amazon.com page or similar forms found on governmental census bureaus' pages. These forms are very often of limited functionality and they differ from source to source. Moreover, when we get the results, they come in the form of a Web page, which is not very convenient for manipulating data or comparing them. The purpose of information integration tools is to overcome these issues, to ease obtaining the data and manipulating them. They provide single interface for posing queries (or even allow to automatically query) and gather data in unified, ready for reuse form.

Information integration has several steps that have to be performed before data sources can be used:

- source description – each of the sources to be accessed needs to be introduced to the system, showing its structure, access means and special features
- integration – after all the sources are introduced, they have to be integrated to be seen under single view – this step allows later on to ask a single query that will be forwarded to all the sources without the need to query each of them separately.
- query translation – this activity occurs each time the query is posted – it has to be automatically translated for each source
- extraction – data is gathered from Web pages delivered by the source. It is crucial for this step that it is exact and robust – no garbage is gathered and all what is required is extracted.
- consolidation of the results – the final step includes merging the results from all the sources and presenting them to the user.

With the advent of such tools it is possible to monitor any Web enabled data source, track changes or periodically obtain relevant information necessary to guide PR activities.

3. SUMMARY AND CONCLUSIONS

For different types of content that appears on the Web, different accessing techniques have to be applied. When user likes to receive information about certain product, in certain period of time, for a specific location, he should use a browser that enables him to search for information depending on contexts.

When PR analyst likes to monitor web pages of his business partners or opponents, he should use some content aggregation tools. However, sometimes there is a need to compare business offers of a group of real estate sellers – then the best idea would be to use information integration tools that enable user to integrate data coming from various Internet databases.

IT tools supporting organization of PR processes enable employee-time savings and at the same time improving the quality of information that PR analysts are supplied with. Moreover, the tools enable accessing information sources that are otherwise hard to browse (internet databases) or information that is difficult to find in a certain limit of time (because of its overload).

Acquiring Problem-Solving Experience in the Multimedia Domain

Tanya Linden, University of Melbourne, Victoria 3010, Australia; E-mail: tanyal@unimelb.edu.au

ABSTRACT

Issues of sharing knowledge in distributed environments where people pursue the same interests and work in the same domain, often independently from each other, are becoming increasingly important. In this study the established process for elicitation of problem-solving experience from independent sources was studied and adapted to suit the multimedia domain. The resulting process facilitates domain-wide acquisition of best practices. The quality of the problem-solving experience is ensured by applying formalized approach to data analysis and by domain-wide inclusion of practitioners in capturing their design experience.

1. INTRODUCTION

Knowledge acquisition together with organizational learning, is an essential ingredient of knowledge management in organizations (Davenport and Prusak 1997). However, as modern organizations grow and become geographically distributed, knowledge acquisition and sharing challenges the traditional time and space barriers, and removes demands for direct employee contact and their face-to-face communication (Alavi and Leidner 2001). Issues of sharing knowledge in distributed environments, where people pursue similar interests, work in the same application domain, and yet are independent of each other, are becoming more important and attract growing researchers' attention (Stenmark et al. 1999).

There exists a number of well-known and accepted methods of knowledge and experience acquisition and sharing (Kalfoglou 2000; O'Leary 1998; Rising 1999). One of such methods – pattern mining – is the primary object of this investigation. Apart from the software development field pattern mining has not been applied to large domains. Most frequently it has been employed within the scope of a team or an organization. Therefore, this study aimed at introducing changes to the pattern crafting stage of pattern mining by expanding its scope to domain-wide as well as minimizing other identified deficiencies.

2. EXPERIENCE CAPTURE AND PATTERN MINING

Pattern mining is an approach for eliciting and recoding practitioners' problem-solving experience (Appleton 1997; Coplien 1996). The formalized best practices can be very effectively represented as patterns, a special literary form that helps problem-solvers understand the solution and its consequences (Alexander 1979; Appleton 1997; Gamma et al. 1995).

The pattern mining process (depicted on Figure 1) that has been adopted by the international pattern mining community commonly involves the following stages (Manns 2001):

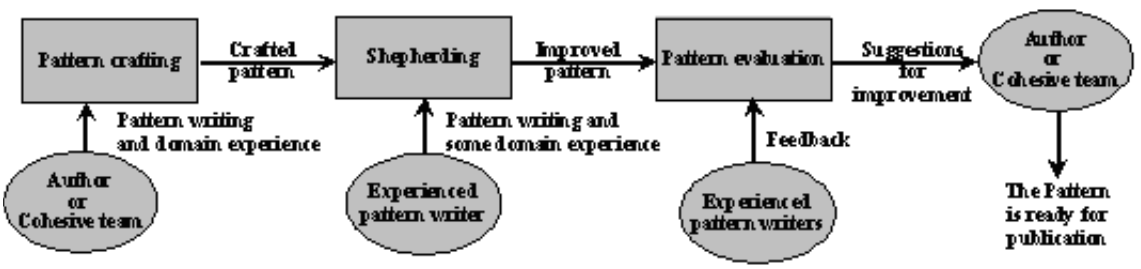
- Pattern crafting, or drafting the initial pattern, as done by an expert in the field or by a cohesive group of experts (e.g. members of the same development team).
- Shepherding – the process when the author(s) gets help from an experienced pattern writer in order to improve the quality of the pattern(s).
- Pattern evaluation at the workshop where experienced pattern writers share their opinions on positive aspects of the pattern and suggestions on the pattern improvement.
- Pattern improvement and publication.

The first stage - crafting the first draft of a pattern or sometimes a pattern language, can be done in many ways. Experienced practitioners always have best practices or at least commonly used practices to share. The most obvious and most frequently used one is "mining one's own experience" where pattern writing becomes a matter of organising and communicating personal knowledge (Manns and Rising 2002). However, often practitioners do not want to spend time or effort on the pattern writing process. Most knowledgeable people are frequently the busiest ones. However, there exist several other approaches where an experienced pattern writer with some knowledge of the domain, called 'ghost-writer' (Rising 1999), can do the formal writing, but the experience should still come from practitioners. A 'ghost-writer' can do Mining by Interviewing, Mining by Borrowing and Mining in Meetings (Rising 1999).

As previously reported (Linden and Cybulski 2006), after a thorough study of the pattern mining process it was determined that its earliest stage – pattern crafting – is in need of urgent attention. In particular, the following deficiencies have been identified (ibid):

- Produced patterns and pattern languages often reflect opinions of a relatively small and most likely cohesive group of people, whose practices may not even represent the best in the domain. Wider involvement of domain practitioners in experience sharing is desirable.
- Shepherding and evaluation relies on active participation of pattern writers, however quite often they have only superficial knowledge of the field.
- To participate in the current process, a practitioner has to learn pattern writ-

Figure 1. Stages in the pattern mining process



ing and become a patterns' author – it is time consuming and not everyone is interested.

Due to lack of domain experts participation in all stages of the pattern mining process, there is a need to address the identified deficiencies beginning with the first stage of the process, i.e. pattern crafting, where patterns originate.

3. EMPIRICAL WORK

Previous studies of the pattern mining process were limited in their scope and poorly formalized (Rising 1999). Research literature alone was not capable of offering many insights on the issues of pattern crafting. Therefore this study focused on the in-depth understanding of the pattern crafting process, ultimately refining it through a series of iterations.

The study centered on a domain that has suffered from multiple problems and where pattern mining has not been applied systematically. The multimedia domain met these criteria, however since there are too many aspects to a multimedia, it was decided to focus on a sub-domain of front-end web design.

Since there is not much prior knowledge to build upon, the understanding of the phenomena was constituted through the subjects' and researcher's live experience. Therefore this research took interpretivist stance (Myers 1997) with the following research objectives:

O1. Apply the principle of 'contextualization' (Klein and Myers 1999) – understand the domain under study.
O2. Since patterns are about recording problem-solving experience, identify problem situations as viewed by multimedia practitioners; discover the context for these problems and approaches to their resolution.
O3. Investigate the feasibility of representing data collected from multimedia practitioners into patterns that are ready for evaluation.
O4. Derive a formalized process for crafting patterns.
O5. Evaluate the resulting pattern crafting process by comparing it with the existing pattern crafting approaches.

Since interviewing and focus groups have been used in pattern mining in the past (Rising 1999), these two research approaches were selected as data collection tools for this study.

The following activities were undertaken as corresponding to the objectives (see Figure 2):

A1. A ghost-writer collects via interviews practitioners' stories describing design tasks, problems associated with those tasks and decision-making in relation to these problems (Objectives 1-2).
A2. Domain understanding and finding common problem issues related to design tasks. A ghost-writer categorizes concerns around design tasks performed by practitioners. The outcome consists of pattern languages outlines and categorized excerpts of problem-solving experience (Objectives 1-2).
The research method and activities A1 - A2 are described in detail in (Linden and Cybulski 2006).
A3. For step 3 two alternatives were investigated (Objectives 3-4).
   a. A category of concerns structured into a pattern skeleton (i.e. a pattern with some sections having large gaps due to unavailable details) was presented to a focus group of domain practitioner and experienced pattern writers for pattern crafting under the guidance of an experienced ghost-writer.
   b. Sessions with single practitioners were organized to explore an option of filling in the gaps in pattern skeletons.

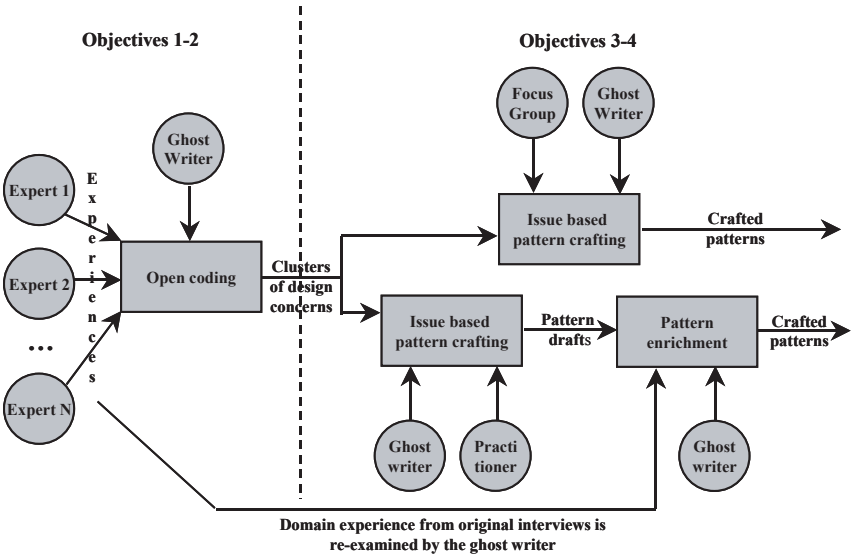
   The patterns developed in the stage 3(b) were subject to enrichment and refinement since practitioners provided only content which needed to be refined to meet the pattern style requirements and due to limited number of interviews in this stage additional content could be sought from the original interviews.

The focus group session (A3a) involved four participants (two domain practitioners and two experienced pattern writers). They were presented with a problem situation (presented as a set of practitioners' statements resulting from activities 1-2). The objective of the focus group participants was to draw upon their domain experience and pattern writing skills and to produce a full pattern (or patterns) based on the provided problem situation.

The participants discussed options of re-arranging provided statements by splitting or merging them in a different manner. Pattern writers worked on the pattern style as well as queried the domain practitioners for knowledge on the subject matter while sharing their pattern mining skills with the practitioners. The participants carefully worded the problem, discussed forces and context, reworded the solution and named the pattern.

An alternative approach involved pattern crafting sessions with individual multimedia developers (A3b). Three such sessions were conducted. The participant's handout included brief explanation of what patterns are, pattern format to be used and problem situations (presented as a set of practitioners' statements resulting from activities 1-2). The task of the participant was to examine one of the problem situations and attempt pattern crafting using presented excerpts of data and their personal experience. However, since it was the practitioner's first introduction to the concept of patterns, the ghost-writer had to ask questions aiming at eliciting missing information, such as "In what context normally this question is raised?", "What is causing this problem?", "Are there any negative consequences of applying this solution?". For all three sessions the same handout

Figure 2. Derived pattern crafting process



was used and four full patterns were produced as a result of these session (Linden and Cybulski 2005).

While conducting the sessions the ghost-writer had to be very careful and restrict her contribution to pattern writing only, whereas content of the pattern was sourced solely from the domain experts.

Since individual practitioners could only contribute domain experience but not proper wording of the patterns, the data from the sessions required additional work. The resulting patterns required considerable editing to meet the pattern format requirements. Also the ghost-writer checked whether it was possible to enrich the patterns by analyzing again the interviews conducted in the first stage of the empirical work, this time by searching for comments relevant to the drafted pattern. This analysis resulted in some additional excerpts of experience that were added to the patterns. These resulting patterns the ghost-writer discussed with the second researcher who at this stage put on the "ghost-writer's hat". This experience of filling in the gaps showed that involvement of an additional ghost-writer could also be beneficial for the quality of the patterns. In the end the produced full patterns reflected experience of various practitioners with different work scope in the multimedia field.

As a result of the empirical work the following findings were noted:

- Open coding (borrowed from grounded theory) was very helpful with discovering real issues and clustering designer concerns. These clusters were used as the source of inspiration for participants contributing their experience in the focus group and in the individual pattern crafting sessions.
- In the focus group and in an individual session all participants were eager to share their knowledge. However, during the focus group session participating practitioners also gained deeper understanding of what patterns are and obtained some pattern writing skills. In the sessions with the individual practitioners they only discovered patterns as a new format for knowledge recording and sharing but did not gain any pattern writing skills. Therefore, a special set of questions aiming at filling in pattern sections without overloading the practitioner with the pattern-specific terminology was required.
- In the discussion focus group participants may point to potential patterns not noted by the ghost-writer in the preparatory data analysis.
- The focus group transcript shows that group members spent considerable time on careful wording of each statement thus ensuring that patterns follow the format requirements. This effect could not be achieved in the session with an individual practitioner and therefore the follow-up refinement of patterns was necessary.

Although both approaches resulted in good quality patterns the focus group approach was found to have additional benefits:

- It results in high quality patterns that are ready for evaluation without additional work by the ghost-writer.
- Domain practitioners get more intimate involvement with the pattern mining and obtain some pattern mining skills.

Although an impression may be that patterns produced by the focus group or by interviewing the individual practitioners reflect the opinions of the small number of practitioners, it was the activity 1 where large number of practitioners from a variety of backgrounds contributed their problem-solving experience. This activity guarded for identifying design problems important to the majority and for quality of the applied practices in solving the problems.

4. EVALUATION OF THE PROPOSED PROCESS

In this section the fifth objective is being addressed. The three approaches to pattern crafting are compared in relation to the identified problematic issues as described earlier in this paper (see Table 1). The problematic issues include the scope of involved practitioners, whether the stages of each approach are formalized or ad-hoc, whether the required knowledge restricts participation in pattern mining and how the process ensures the quality of patterns. Since some inspiration for this pattern crafting approach was drawn from the past experience described by Rising (1999), her approach was the obvious choice for comparison.

Rising took on the role of the ghost-writer and with the small group of assistants interviewed the company gurus and produced patterns reflecting best practices in the organizational procedures. Her work was restricted by clearly identified organizational boundaries. Rising's team attempted to verify the crafted patterns by going back to their sources, however not always successfully due to the sources being very busy.

Unlike Rising this study proposed and tested a formalized approach to data analysis based on coding in order to translate collected data into patterns. Although the pattern crafting approach applied by Rising (1999), improves the scope and involvement of domain experts within an organization, the proposed process brings the benefit of capturing into patterns cross-domain experience that is not limited by organizational boundaries. The proposed approach also resolves problems with engaging practitioners in the process, their ineffectiveness as pattern writers, their lack of time to formalize their design experience, and their inability and unwillingness to attend design sharing events outside their normal workplace.

5. CONCLUSIONS

Issues of knowledge acquisition in distributed environments are becoming increasingly important. Since patterns have proven successful in representing problem-solving knowledge, and in disseminating best practices in software development, this study explored application of patterns to sharing development experience in yet another domain – multimedia. As the currently adopted pattern mining process is normally unable to utilize multiple practitioners as a direct

Table 1. Comparison of the three pattern crafting approaches

Pattern crafting approach	**Current, widely used**	**Rising**	**The Proposed Process**
Pattern crafting process	Ad-hoc	Special informal process	Meta-process to find the domain-specific process
Scope of involved practitioners	Cohesive group of people	Organization	Domain
Data collection	Mining own experience	Interviewing In meetings	Interviewing
Data analysis	Informal	Informal	Formal coding
Patterns refining	Own experience	Iterations with practitioners – interviews with the purpose of verification (not always possible due to gurus busyness)	Iterations with practitioners – semi-structured and structured interviews, focus groups
Knowledge of patterns	Participating practitioners must have it.	Participating practitioners may not have it, however a ghost-writer must have both domain knowledge and pattern writing skills.	Participating practitioners may not have it, however a ghost-writer must have both domain knowledge and pattern writing skills.

source of such experience, the pattern crafting stage was targeted to minimize the process' deficiencies.

Involving individual practitioners in the experience sharing activities provides richer content for patterns, helps select really best practices as accepted by majority of practitioners and therefore improve the overall quality of patterns. Moreover, practitioners may discover patterns as a useful source of domain knowledge and participate in sharing their experience through pattern mining.

While the applicability of the refined process still needs to be empirically tested on a wider scale (future work), the results obtained so far indicate that this approach has strong benefits compared to the currently employed processes.

6. ACKNOWLEDGMENTS

The author would like to thank practitioners who shared their experience, Jacob Cybulski for his help and suggestions in preparation of this paper, and the reviewers for invaluable comments to the paper.

E-Commerce Practices in the Public Administration: A Spanish Case

Carmen de Pablos Heredero, Rey Juan Carlos University, Madrid, Spain; E-mail: carmen.depablos@urjc.es
Eva Pelechano Barahona, Rey Juan Carlos University, Madrid, Spain; E-mail: eva.pelechano@urjc.es

ABSTRACT

The Spanish National Tax Agency (SNTA) has been a good initial example for web applications in Spain. This paper tries to describe how the Spanish National Tax Agency (SNTA) is using web technologies to improve transactions with all citizens and collaborators. Through Internet, citizens and firms can develop lots of their main operations with the SNTA by benefiting themselves of better time responses and comfort.

Keywords: Internet, processes, Spanish National Tax Agency (SNTA)

INTRODUCTION

The Spanish National Tax Agency (SNTA) constitutes one of the Spanish organisations in which we can observe how, in a short period of time (since 1997), web based technologies have been successfully implemented in terms of the number of daily users of the different services via Internet.

Today, the relationship between citizens and Tax Administration can be performed through a greater number of communication channels: phone, fax, ordinary mail and Internet. Therefore, citizens and firms can choose in any moment the most appropriate way in view of the circumstance needs.

In the short period of time that the SNTA has been using web technologies, it has turned into a clear example to imitate in the rest of the public and private European and Spanish firms.

MAIN OBJECTIVES AND REASONS FOR THE SPANISH NATIONAL TAX AGENCY TO USE INTERNET

Amongst the main reasons why the SNTA has decided to use web technologies considering the customers needs, we can stress,

1. The Public Administration feels it must have a greater presence in the Spaniards social life. In this sense, the Tax Agency Initiative is an answer to the objectives shown by the Spanish Government about the development of the information society "INFO XXI" that we have already referred to.
2. To add value. To widen the access time for the search of tax information and the rest of the offered services.
3. To get efficiencies of a proper use of information technologies, since it is legally possible.
4. The massive use of these technologies in the Spanish citizens is demanding an adaptation of firms and the Public Administration to these new infrastructures.

Table 1. Number of Internet visits (SNTA, 2005)

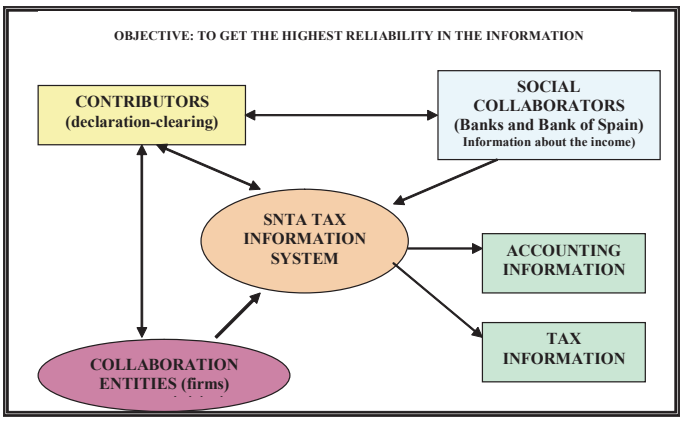
YEAR	HELP PROGRAMS	TAX INFORMATION (APPLICATION INFORMA)	TOTAL VISITS	VIRTUAL OFFICE	TOTAL SNTA
2005	9.240.669	948.723	17.932.702	27.475.309	45.408.011

YEAR	HELP PROGRAMS	TAX INFORMATION	SELF-SERVICE	TOTAL VISITS	DIRECT ACCESS SELF-SERVICE	TOTAL SNTA
2004	8.000.063	901.148	3.374.751	9.720.442	8.601.602	18.332.044
2003	2.341.766	252.103	878.918	2..962.995	5.145.949	8.108.944
2002	951.101	355.433	649.358	2.466.962	3..310.552	5.777.514

Table 2. Number of declarations presented via Internet in the last three tax-year periods (SNTA, 2005)

	TAX YEAR 2005	TAX YEAR 2004	TAX YEAR 2003
INFORMATIVE AND YEARLY VAT SUMMARY DECLARATIONS (390 MODEL)	435.656	110.848	10.811
IRPF (PERSONAL RETENTIONS)	1.151.313	500.151	115.244
FIRMS TAX (201 MODEL)	41.000	9.328	225
SEMESTRE SMES SELF-CLEARINGS	435.051	115.314	31.231

Figure 1. Information flows in the tax agency (The Computer Tax Department, 2003)



5. To break the tradition in the unilateral relationship inherited from the Tax Agency and the rest of Public Administrations. The use of web technologies allows a higher feedback between the SNTA and the Spanish contributors.

STAGES IN THE IMPLEMENTATION OF INFORMATION AND COMMUNICATION TECHNOLOGIES IN THE SNTA

In the implementation of information and communication technologies in the firm, some typical stages have been traditionally distinguished (Zuboff, 1988; Davenport, 2000; Quinn, 2000), the mechanisation or automation, processing and transforming ones.

The Tax Agency, by introducing information technologies, has passed in time through all of them.

In the following figure we show all the relations that the Agency maintains with different entities.

The Tax Agency develops every year a planning of actions concerning to the use of Internet and, for that purpose, there is a work group especially constituted that allows to develop this planning and promote the needed changes.

From the first time, this Organisation has seen in Internet a great opportunity of access and has highly bet on this technology. All the information systems in the Agency have been internally developed and implemented.

SERVICES OFFERED IN INTERNET

The services that the Tax Agency offers to the contributors can be divided (Segarra Tormo, 2001) in two types, opened and personalised services.

The first ones are free entrance services for all the users and the second ones, are services oriented to offer personal information to each contributor. For that reason, in order to access to these second ones, an electronic identification is required.

Table 3 offers a summary of both services,

ADVANTAGES AND DISADVANTAGES OF INTERNET IN COMPARISON TO ANOTHER CONVENTIONAL COMMUNICATION CHANNELS

Each tax campaign, the SNTA circulates a survey to know main opinions coming from contributors and users. This is a very important tool, since it is permitting the Agency the needed feedback to improve their services via these tools.

This survey pays a special attention to the aspects collected in the following table.

Now we show the main advantages that these services are implying for the user and the people working in the Agency.

Table 3. Personalised and opened services offered by the SNTA through Internet

MOMENT IN THE SERVICE DEVELOPED	OPENED SERVICES	PERSONALISED SERVICES
BEFORE TAX DECLARATION	• Tax legislation • Maternity deduction • IRPF retentions • Declarations on line • Help programs • Leaflets • Informa Application • Pre-paid consultancy • Apply for tax data • Apply for labels	• Obtain of tax data • Change of personal, familiar and address data • VIES (European Union Taxes, VAT)
DURING TAX DECLARATION		• Presentation of a declaration • Payment: achievement of NRC • Apply for devolutions • Certification of declaration presentation
AFTER TAX DECLARATION	• Checking the state of all declarations	• To obtain the detailed information about the state of the declaration
OTHERS	• Web Call services	• Certificate of declaration presentation • Fulfilment certificate • Resources and complaints • On line auctions

Table 4. Main aspects to consider in the Internet survey (2005)

1.	Technologies that the users utilise for their relationship with the Agency via Internet
2.	Places where one can access
3.	Level of complexity when developing some actions from the SNTA web pages, • To get the PADRE program • To apply for the certification • The installation of the certification • The performance of the declaration • Preparation of the declaration to send it via Internet • The tax payment, in case the declaration has turned into positive • The transmission of the declaration • The reception of the conformity by the SNTA
4.	Level of satisfaction with the system of rent declaration presentation via Internet
5.	The main reasons for the satisfaction
6.	Evaluation of the SNTA services. Opinions about the most useful considered ones
7.	Services that should be included in the surveyed opinion

WHERE DOES THE SPANISH NATIONAL TAX AGENCY GO TO?

The Tax Agency intends to improve and widen the services that offer today to reach more tax-payers. This way, the Agency promotes an auction system via Internet. It allows any person that wants to take part in an auction to do it without a previous translation to the place where it is being held. Any offer can also be presented via the web whenever the user is interested in a good or service. And besides, it allows the constitution of the needed deposits to participate in the procedures of disposal by means of the adhered collaboration entities, and be able to get "on line" devolution, in case the holder is not the bidder.

The closest future objectives that the SNTA has thought about are: in the first place that the contributor can value and evaluate if the administration is properly working. It is tried to promote a more multilateral relationship between the Administration and the contributor. The customer should take part each day more in an interactive conversation with the Administration.

In the second place, an "electronic address" is pretended to be created. It would identify the customer with one unique electronic address. It would make feasible the sending of the electronic certifications that are demanded. So far, any person that applies for an electronic certification can automatically get it. With this electronic address, the sending of messages can be improved, and one of the main Internet advantages would be achieved.

This way the relationship between the SNTA and the citizen can be also standardised. The sent data will have a greater security; message confidentiality and the Tax Agency signature will be achieved.

When dealing with new improvements and the achievement of some challenges, the Agency is finding as main problem that the legislation must be changed in some aspects. Therefore, sooner the creation of an electronic address will be approved. It will improve the sending of notifications.

And third and lastly, it is tried to have a direct access from the SNTA to other web pages in the Public Administration, as for example the Social Security or the Only Window System for firms. This service is born with the main objective of making easier to the society the access to the needed information. The information can be related to any aspect that has to do with the relationship between the Spanish Administration and the citizens, from any place and at any moment.

CONCLUSION

The Spanish National Tax Agency has promoted the use of web technologies amongst citizens by putting in practice some government initiatives on the development of the information society in Spain, INFO XXI.

The Tax Agency, by offering services in Internet, enables all citizens a better relationship. The number of communication channels provided can be widened and the user will be able to choose the one that best fits his/her needs each moment.

Through this communication channel, a great variety of services are offered: the application for tax data, the solution to any doubt or question related with any tax or problems in the confection of the declaration, the downloading of the help

Table 5. Advantages and disadvantages of the SNTA web page

ADVANTAGES		DISADVANTAGES	
CITIZEN	**AGENCY**	**CITIZEN**	**AGENCY**
To widen customer's attention timetable (24 hours)	The offering of alternative communication channels	Changes in the society culture: adaptation to n ew technologies	To update infrastructure and web page
To avoid movements in the Agency	Self -service: it is the citizen who performs all the process of information searching and elaboration and sending of documents	The need of infrastructure adaptation	Lack of habits in the customers
To access from any place	To improve the process of document elaboration	To apply for electronic identification certificates	
To get a faster return in the information sent by Internet	A decrease in the long run costs by in termediaries decrease	Bottleneck problems and lack of network in some places	
Feedback: the Agency values all kind of suggestions or claims coming from citizens in order to improve their services		Change of responsibility to the customer: it is the citize n who performs the whole process	

Source: Own elaboration from the information coming from the Agency and the one published in their own web page (2004)

programs, the information about customs, auctions on line, queries on the state of the declarations, presentation on the declarations and so on.

The Tax Agency is very interested in the inter-activity with the citizen and that it is the reason why it develops periodical surveys with the main aim of obtaining information about the contributor's opinion. The results that the Tax Agency reaches in these studies are of great help for the improvement of the services that it offers. They show a great acceptation and a high degree of user's satisfaction (comfort, fastness and better time responses are positive stressed).

Despite the positive experience of this project in the Spanish National Tax Agency, there are still some barriers in the procedures that put in touch the Tax Agency with other Institutions. It will imply changes in the short term procedures that will allow benefiting from the possibilities that today web-based technologies are offering to government, firms and citizens.

ACKNOWLEDGMENTS

We want to thank to Mr. Segarra, General Manager of Computing Area in the Spanish National Tax Agency, his collaboration in the writing and correction of the present work and the interest he has shown in it.

Creating Flexible and Reusable Learning Resources

Eugenia M. W. Ng, The Hong Kong Institute of Education, Hong Kong SAR; E-mail: Eugenia@ied.edu.hk

ABSTRACT

This article describes a tailored made learning platform which emphasizes the sharing and reusing of teaching materials. Users can select any section of digital material to create synchronized learning materials without the need for any sophisticated software packages. The unique features of the learning platform and the feedback from seventy eight pre-service teachers who have had hands-on experiences are discussed in detail. The participants are very positive regarding the functionalities and capabilities of the learning platform, though only a quarter of them used it to create learning materials as part of their assignments. This finding suggests that there is a need to take into account matching pedagogies when implementing new initiatives.

1. INTRODUCTION

The Internet has made a huge difference to our daily lives ever since it rapidly gained popularity in the mid 1990s. Using the Internet, people around the globe are able to connect with each other and have access to a vast amount of information within seconds. The flexibility of Internet access has had a substantial influence on education (Gaspar & D, 1995) whether for complementing face-to-face lectures or for delivering courses completely online (Harasim, 1999; Hiltz & Wellman, 1997). The flexibility of online teaching and learning lies with its accessibility and time and pace independence. Indeed, most higher education institutes recognize that incorporating technology into the classroom was the "the single most important issue" over the next few years (Carlson, 2000).

Many universities use online learning platforms (Boggs & Shore, 2004; Freeman, 1997; Palloff & Pratt, 2001) to assist course delivery. Despite their popularity, most learning platforms do not allow the same resources to be shared between multiple courses. Similarly, the teaching materials uploaded or created for a lesson cannot be reused for another course during the same or the following semesters. The limitations can be very frustrating to academics, and the problem is exacerbated when only a part of the learning materials is required for reuse. Another problem with existing platforms is that they do not support mixing and matching files of different formats. Teaching materials such as videos and slides are played independently and users are only able to browse the materials one at a time.

In view of the limitations of existing platforms, we have put forward a grant proposal and developed a platform, named PILOT (Promoting Interactive Learning in an Online environmenT) to tackle these inadequacies. PILOT allows users to use and reuse uploaded materials on demand, to select segments of materials, and to synchronize various formats of teaching material. However, it is not intended to replace face-to-face classroom interactions nor existing learning platforms. In fact, the goal of developing PILOT was to enable our student teachers to have an authentic experience of using different platforms and to make it easier to create synchronized learning resources from existing resources.

2. FEATURES OF PILOT

Producing good teaching materials requires a considerable amount of time, effort and financial commitment. It would save a significant amount of human and computer resources if materials could be reused. PILOT is more than a learning platform, it is a resource repertoire which enables users to tailor learning resources using simple steps using an existing pool of resources. The platform consists of five areas, namely, material, presentation, quiz, forums and personal information.

If a person wants to create any online resources using PILOT, he/she must have an account to log into the system. After successful login, the user can choose any materials in the materials section that have been uploaded by other users. Alternatively, the user can upload any multimedia format or PowerPoint format materials which can be designated as "shared" or "not shared" with other users. Research into multimedia and related instructional technologies over the years has indicated positive effects on learning (Hede, 2002). Moreover, learning in multiple modes is more engaging due to increased learner interest levels, and learners are stimulated by sounds and images (Jonassen, Peck, & Wilson, 1999).

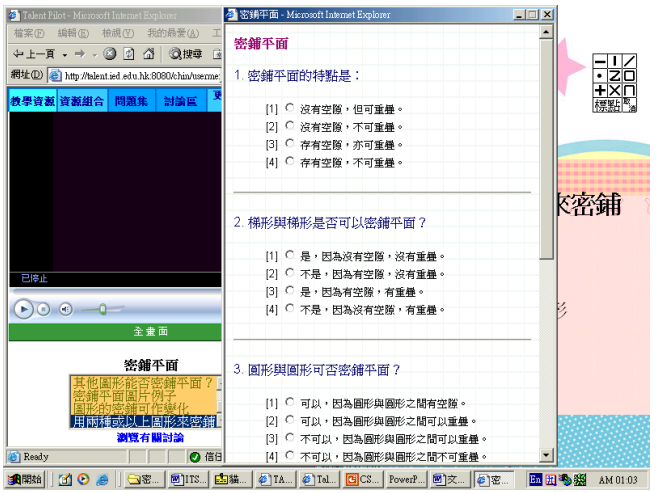
Many existing platforms do not fully utilize the capability of multi-tasking computer resources as these platforms are mainly designed for sequential processes. However, PILOT users can subscribe to one video file and one PowerPoint file or slides created by Slider Editor to form a *presentation* which displays two synchronized files. The Slide Editor not only enables users to type information directly on it but also to copy and paste HTML materials into it.

When creating a *presentation,* the creators are only required to input or get the start time/end time from the video and select the appropriate PowerPoint slide for that time interval, and a section will be created (a slide with the related video interval). That means the unwanted slides or video sections could be skipped. For example, the user can select 5 relevant slides from a 15 slide PowerPoint file and select 5 matching video sections of varied duration from a video file to form a *presentation.* Hence, *presentation* creators can construct the presentation materials according to the intended usage and their background. When a learner watches a *presentation*, he/she can watch the presentation sequentially or to select the interested section and the corresponding video time and slide contents will be displayed (Fig. 1). The advantages of displaying two files concurrently include the complementary synergy of information and to further prompt and stimulate learners to think whilst watching video content. Thus, the intended learners can have full control of the time, place and pace of viewing a presentation. Furthermore, they are provided with additional flexibility such as in selecting or revisiting any section of the video at any time.

Similarly, a user can create his/her own quiz or subscribe to another's' quiz in the quiz section. The user can specify when the quiz will be displayed anytime

Figure 1. A presentation which is synchronized with video and PowerPoint file

Figure 2. Synchronize questions with a "Presentation"



during the *presentation* display. This flexible approach aims to promote active learning and enable interactivity with the material, as an essential combination in determining the extent of learning is the actions and interaction of the learners (Laurillard, 2002; Oliver, Omari, & Herrington, 1998).

The *discussion forum* is an arena for exchanging and discussing pertinent problems and to form a learning community (Scardamalia & Bereiter, 1996; Tu & Corry, 2002). When a new *presentation* is created, a new thread can also be opened in the forum. Learners can share their comments and raise questions about that *presentation* when browsing or whenever they are logged into PILOT. Finally the personal section enables users to change passwords.

3. A STUDY

3.1 Background

The study took place at the Hong Kong Institute of Education (HKIEd) which is the largest teacher training institute in Hong Kong. We have recently adopted the Blackboard platform in order to facilitate learning, but none of its programmes are offered completely online. The participants of this study were pre-service student teachers studying at HKIEd taking a module called Information Technology Supported Learning Environment (ITSLE). They took the module in their second year after taking two other information technology modules. The participants had to attend a mass lecture and two tutorials per week. The learners had some hands-on practice with popular IT software and had knowledge of some popular ITSLEs. It was believed that the concept of ITSLE would be best learnt through modeling the concepts by adopting IT as a learning environment. All the teaching materials were posted on the Blackboard learning platform which they had to familiarize themselves with during the first tutorial session. The mass lecture mainly covered ITSLE theories and examples.

3.2 Data Collection and Discussion

The learners were given a brief introduction and demonstration of PILOT during the fourth week of the tutorial sessions. The participants then followed the instructor to create a synchronized *presentation*. They were also given an online user manual and a hardcopy to follow the procedures and to scaffold their learning (Oliver, Omari, & Herrington, 1998). They used the platform for about 50 minutes. Upon completion, they were prompted to answer an online questionnaire which was divided into three areas, namely, fostering learning, the user interface, and system functionality.

The results were encouraging as the least rated question showed a 66% agreement or strong agreement with value. Most of the respondents (98.72%) believed that PILOT provided a comprehensive learning environment, followed by (97.44%) who responded that it had a consistent interface, and (93.59%) indicated that it flexibly enabled users to edit and use teaching materials. Although learners were positive concerning the questions that PILOT could foster active learning and develop independent learning, there were some other diverse views. This was probably due to the fact that they did not use the platform long enough to appreciate all of its functions. Even though they rated highly on the consistence of the user interface, one third of them did not find the platform easy to use. One plausible reason for this was that they did not have sufficient time to fully explore and experience the system prior to answering the questionnaire.

4. CONCLUSIONS AND FUTURE DIRECTIONS

The Internet has transformed teaching and learning, from being bounded by physical and time limitations, to learning at the discretion of learners. PILOT learning platform not only provides general e-learning features such as teaching materials management, discussion forum, quizzes and user tracking but also facilitates material sharing and reuse. The simple click and pick function of the platform has escalated different learning materials from a one-to-one relationship to a more flexible many-to-many relationship. The distinct features of the PILOT platform not only enhance the efficiency and effectiveness of teaching and learning but also minimize server load, which results in higher performance.

Our student teachers appreciated the functionalities of PILOT but not many of them adopted the system to create *presentations*. This finding suggested that there was a great need to take into account appropriate pedagogical considerations when introducing new ideas and implementing new initiatives (Oliver, and McLoughin, 1999). It will be interesting to compare the findings of this study with future results when we introduce PILOT over the following years. To ensure this is continued, however, there is a great need for continuous financial support so that the project can have a successful and lasting effect.

5. ACKNOWLEDGMENTS

The authors would like to thank all the participants of this study and also for the screen captures which were created by a group of students. Special thanks goes to Lap Piu Lee for assisting the author to create such a learning platform and for research assistance.

E-Collaboration for Quality Assurance in Higher Education

Juha Kettunen, Turku University of Applied Sciences, Sepankatu 3, FIN-20700 Turku, Finland; E-mail: Juha.Kettunen@turkuamk.fi
Ismo Kantola, Turku University of Applied Sciences, Sepankatu 3, FIN-20700 Turku, Finland

ABSTRACT

The purpose of this study is to describe and analyse how the electronic collaborative technologies can support decision-making and quality assurance. The study describes how the approaches of strategic management and quality assurance can be integrated into the management information system in a higher education institution. The management information system provides an open platform for the integration of different management approaches and e-collaboration facilitation. The characteristics of the management process and the procedures of quality assurance, chosen by top management, affect the way operations are planned on the lower organisational levels. This study contributes to the knowledge and practice of quality assurance. It introduces the concept of the quality map, which is useful in describing the interface between the quality assurance system and the management process. In addition, the study provides outlines for the planning of management information systems.

Keywords: management information system, e-collaboration, evaluation, quality assurance, quality audit, higher education

1. INTRODUCTION

Quality assurance is a key element in constructing the European Higher Education Area by 2010. European countries are developing their own national solutions for evaluating and demonstrating the quality of degrees (FINHEEC, 2006). The higher education institutions are accountable for the quality of their education and other activities in counterbalance to their autonomous situation and responsibility to define their own management and quality assurance systems. The institutions are required to regularly evaluate their own activities and performance, and also to participate in external evaluations (Ministry of Education, 2005).

The relationship between the institutional management and quality assurance of higher education institutions has recently attracted much attention. The quality assurance systems of all higher education institutions will be audited by 2010. The aim of the audit is to determine if the quality assurance system produces useful information needed to improve operations and leads to effective improvement measures (FINHEEC, 2006). Beckford (2002) argues that without adherence to a quality management system, it is impossible for any organisation to know how well it is performing.

The interface between the quality assurance system and management has proved out to be a predominant weakness. When developing the quality assurance system at the Turku University of Applied Sciences (TUAS), we tried to strengthen and improve the implementation of the interface between quality assurance and the management process. We also examined how to support utilisation of information produced within the quality assurance system to further improve processes.

The purpose of this study is to describe and analyse how electronic collaborative technologies can strengthen the interface between the quality assurance system and the management process.

The management information system (MIS) can be an improvement-oriented tool in strategic management and quality assurance. In addition, this study introduces the new concept of the quality map. The quality map helps management to describe the quality assurance system to the personnel, external evaluators and other stakeholders.

The study presents the case of TUAS, which has planned and implemented an MIS tailored to meet the requirements of the institution's management process. The data warehouse transforms various source data and provides reliable information for the MIS. The information is shown in action plans, which contain scorecards. These features strongly support directors and managers in their evaluation and planning tasks. However, the MIS is more than a conventional management scorecard. It is an electronic platform which effectively supports the integration of strategic planning and quality assurance. The management portal includes strategic plans, which are then translated into more concrete budgets and annual action plans including balanced scorecards, and human resource (HR) plans.

This study is organised as follows: First the concepts related to quality assurance in higher education are introduced. Secondly, the main characteristics of the management process are described. Then the information technology architecture of the MIS is presented. Thereafter the new concept of the quality map is introduced and the utilisation of evaluation knowledge in decision-making, action plans and the MIS is outlined. Finally, the results of the study are summarised and discussed in the concluding section.

2. QUALITY ASSURANCE

The word quality has often been associated with excellence or outstanding performance. In this study, however, we have adopted the fitness for purpose definition of the quality, because according to Woodhouse (1999) it is the most commonly accepted definition of quality in higher education. Fitness for purpose is based on the ability of an institution to fulfil its mission in its environment or of a study programme to fulfil its aims (Harvey & Green, 1993). Thus, at the institutional and faculty level quality is defined in the institution's mission, strategic plan and annual action plans. Quality is then confirmed by achieving the goals defined in strategic planning and quality work.

The concept of quality assurance has been given various definitions. According to Woodhouse (1999), quality assurance refers to the policies, attitudes, actions and procedures necessary to ensure that quality is being maintained and enhanced. Sometimes the term is used in a more restricted sense. Quality assurance is seen as the process of establishing stakeholder confidence that the provision (input, process and outcomes) fulfils expectations or measures up to threshold minimum requirements (Analytic Quality Glossary, 2006).

At the level of HEIs, quality assurance system refers to "the entity composed of the quality assurance organisation, respective responsibilities, procedures, processes and resources" (FINHEEC, 2006). In this study, we have adopted the wider meaning of the concept which includes both quality management and quality enhancement. Quality assurance is seen to cover all the activities and processes of the institution. The same interpretation of the concept has also been given by FINHEEC (2006).

John Oakland has captured the essence of quality assurance: "Quality must be managed, it does not just happen" (Beckford, 2004). This entails that the management's commitment to quality is of crucial importance. To be effective, the quality assurance system must provide managers with useful information needed to improve operations. Then, managers must interpret different evaluation findings and feedback information. They must identify weaknesses and decide which weaknesses need improvement measures. Managers possess the power to allocate the resources needed for carrying out the planned improvement measures. In other words, it is the interface between the quality assurance system and the management process which really counts.

3. COLLABORATION IN THE MANAGEMENT PROCESS

Electronic collaboration (e-collaboration) is broadly defined as collaboration among individuals engaged in a common task with the help of electronic technologies (Kock, 2005). The core of e-collaboration is about sharing information within an organisation and also between organisations for the purposes of planning, coordinating, decision making, process development and improving effectiveness.

This study presents a case describing the collaborative use of the MIS to support the management process and quality assurance in higher education. If the MIS was only a diagnostic control system, used by managers to monitor organisational outcomes and correct deviations from the standards of performance, it would not be worth the investment. Superiors should expect their subordinates to produce intelligent self-assessments and action plans. If the high level managers do not expect high quality planning from their subordinates, high quality planning will not take place and probably the unit performance will be only mediocre at best. The e-collaboration should include communication, dialogue and collaboration, which are the essential features of any management process.

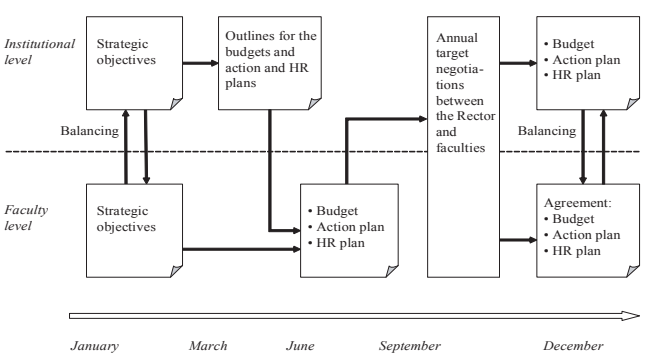
Figure 1 describes the interactive management process of the TUAS between the institutional level and faculties. Important communication and dialogue is found in the annual agreements about the targets between the institution and faculty. The figure illustrates only some of the main phases omitting many minor details of the interactive process. The budgets and action and human resources (HR) plans must be consistently balanced to achieve a consensus for the planning period. The Balanced Scorecard approach introduced by Kaplan and Norton (1996, 2001) is a used as a framework for the MIS. The scorecards included in the action plan define strategic objectives, measures and their target values, which must be consistently planned for the institution, faculties and degree programmes. -

Both the Rector's top management group and the faculties draft their own strategic objectives and draft their preliminary action plans in the strategic seminars during the first half of the year. The Rector issues all the faculties with the outlines for the budgets and action and HR plans. These outlines are based on the education policy, demand for labour and the other factors in the environment. These plans are prepared at the faculty level.

The most important event in the management process is the internal target negotiation between the Rector's management group and the respective faculties. The negotiations include the evaluation of major results achieved, allocation of funds to implement the strategy and the balancing of the target values of the measures. The negotiations are strongly supported by the management portal, where the dialogue takes place. The financial resources and action and HR plans of the administrative units are determined in the negotiations.

It is important to recognise that the internal target negotiations are not primarily about checking whether the target values of the measures have been achieved and looking for remedies to correct deviations from target values. The negotiations can be seen as an important forum for internal self-evaluation which can at its best lead to organisational learning and development. The communication and dialogue can produce new insights, initiatives and solutions to problems.

Figure 1. The interactive management process of the TUAS



4. MANAGEMENT INFORMATION SYSTEM

The Balanced Scorecard approach was introduced in 2002 at the TUAS to help management in communication and in the implementation of strategic plans (Kettunen, 2004, 2005). The new approach was initially introduced without any specific information system. It was clear from the beginning that the collection of data and aggregation of the scorecards to the upper organisational levels would be troublesome, because the existing information systems did not support the new approach. In large organisations with many organisational levels information technology support is necessary.

The planning of the new MIS started at the beginning of 2004. The management process was described and developed in detail. The description of the management process facilitates the timetables so that they take into account the steering of the Ministry of Education, the budgeting process and the internal target negotiations between the Rector's management group and the faculties of the institution. The detailed description of the management process produced a large sheet, which was put on the wall. A large number of more detailed process descriptions (workflows) was written to be used as specifications for the services with which the management portal provides its users. About 700 concepts were defined and the data model was developed.

The architecture of the MIS was planned and the new system was incrementally implemented. The e-collaboration of the management process is supported by the portal, which is also open to the personnel. The first services of the management portal were launched in autumn 2005 for the use of the management group. The portal utilises the data warehouse where the existing data of the various operational systems is collected. The data warehouse has been in operational use since summer 2006. The MIS was planned to stimulate dialogue in the net and encourage innovations and development activities. The reciprocal open discussion about strategic objectives supports the commitment of the personnel to the strategic plans and quality assurance.

The e-management portal was planned to directly support the management process. Usually the concept of the portal refers to an access to information and services in the net (White, 2000, Rose, 2003, Zhou, 2003, Smith, 2004). The portal, however, is much more than mere access. Individuals at the different organisational levels use the portal as a platform to draft their strategies, budgets, action and HR plans and reports. Individual have diverse user rights and roles in the portal.

The data warehouse is a consistent, consolidated and refined collection of data, which compiles and integrates data from the existing operational data sources (Inmon, 1996; Guan et al., 2002). The data warehouse is used to produce manysided reports, statistics and analyses about the performance of the organisation. The strategies, action plans with balanced scorecards, HR plans and budgets produced by the managers and others are stored in the portal database. The data warehouse and the portal database are the common memory of the organisation.

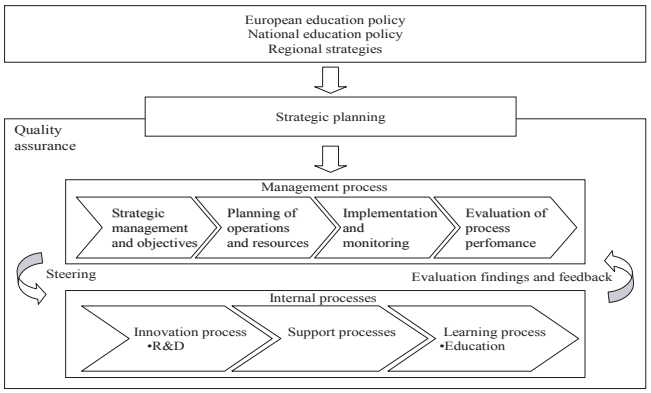
The operational data systems include the accounting and HR systems and the study and student register. The raw data of these source systems are extracted and transformed into a unified and recognisable form and then loaded to the data warehouse (ETL processes). Before the introduction of the data warehouse the data from various sources were undocumented and scattered, which led to unreliable reports.

5. QUALITY MAP

The concept of the quality map is introduced to describe the interface between the quality assurance system and the management process. The quality map is a visual representation of the relationships between the environment, strategic planning, the management process and the quality assurance system. It also provides an insight into the management process and internal processes of an organisation, both of which have essential roles in strategic management and quality assurance. We have derived the concept of quality map from the strategy maps introduced by Kaplan and Norton (2004). A strategy map is a visual representation of the causal relationships among the components of an organisation's strategy. Analogically, the quality map describes the main characteristics of the quality assurance like a road map, omitting the minor details. The new concept helps the managers, personnel, external evaluators and other stakeholders to get the big picture regarding the quality assurance system.

Figure 2 describes the comprehensive quality map of the TUAS. The changes in the environment have been outlined by the European and national education policies and regional strategies. The strategic planning is essentially the strategy process,

Figure 2. The quality map of the TUAS



which produces the strategic plan and strategic objectives for the planning period. The management process includes the sequential processes consisting of

- strategic management and updating of strategic objectives
- planning of operations and resources
- implementation and monitoring,
- evaluation of process performance.

The purpose of the management process is to steer the development of internal processes to achieve the strategic objectives. The main internal processes include the innovation process (research and development), the support processes (support services) and the learning process (education).

The steering of internal processes is achieved by different methods. First, the operations of the internal processes are aligned with the budgeting and HR plans. Second, and even more relevant to our analysis are the action plans, which are drafted at every organisational level including those of the institution, the faculties, the degree programmes and other administrative units. Third, the linkages between the management process and internal processes emphasise the importance of using relevant information in the management process as a prerequisite for effective quality assurance. The information produced by internal and external evaluations and feedback systems to support management in decision-making especially is extremely important in quality assurance.

6. UTILISATION OF EVALUATION IN DECISION-MAKING

The quality assurance system should produce and contain information about the process performance and the achievement of the goals. The system also should encourage management and personnel to clarify the measures needed to improve the internal processes. In order to continuously improve the operations it is important to emphasise the utilisation of evaluation findings in management's decision-making and strengthen the interface between the quality assurance and management processes.

According to Patton (1997), evaluation findings can serve three main purposes: providing judgments, facilitating improvement and generating knowledge. The utilisation of evaluation findings may be instrumental or conceptual. Instrumental use of evaluation findings occurs when decisions or action follow from the evaluation. Judgment-oriented evaluation is aimed at determining the overall value of the issue. Passing judgment on merit or worth supports major decisions about whether a programme should be continued, enlarged, disseminated or terminated. By contrast, decisions on how to improve programmes, following improvement-oriented evaluation, seem to be made in small, incremental steps based on specific evaluation. The conceptual use of evaluation findings means that evaluations contribute by increasing knowledge among decision-makers and stakeholders.

If the MIS is primarily used for judgment-oriented accountability reporting, the system may have negative and disincentive effects. It is better to build the system for improvement-oriented decision making to monitor performance and outcomes and to provide feedback to facilitate continuous improvement. The information provided can then be utilised for minor reallocation of resources and increasing effectiveness.

The management portal is used at the TUAS mainly for the needs of the institution's internal management process. Even though in every hierarchical organisation with superior-subordinate-relationships there is inevitably at least a certain degree of accountability, we do not consider the use of the MIS at the TUAS to be judgment-oriented and accountability-driven. Rather, it has been emphasised that the action plan is essentially every manager's own plan to balance the different strategic objectives in the different organisational units. To summarise, the action plan of the MIS should be seen as an improvement-oriented self-evaluation and planning tool.

The MIS and management portal of the TUAS include strategic plans, which are annually translated into more concrete budgets and action and HR plans. The format of the action plan is based on the Balanced Scorecard approach (Kettunen & Kantola, 2005). The action plan includes 13 strategic objectives, which are described using about 35 measures having target values for the three-year planning period. The action plan also identifies the essential strategic initiatives which follow from strategic objectives. On the other hand, the action plan also defines, communicates and stores the improvement measures which follow from the weaknesses identified during the self-evaluation.

When performing the self-evaluation the manager is expected to take into consideration the findings and recommendations of internal and external evaluations, the implications of curriculum evaluation and feedback from students and employers. The deans and managers are expected to plan the timetables and identify the individuals responsible for the improvement measures and other envisaged tasks.

From the viewpoint of organisational self-evaluation the most important feature of the action plan is not the Balanced Scorecard with data from the data warehouse, but the procedure which initially guides managers to a self-evaluation on a broad level. The manager is expected to evaluate the status quo and evaluate to what extent the unit has achieved the agreed strategic objectives.

7. CONCLUSIONS

This study shows that the different approaches of management can be integrated using an interactive and collaborative MIS which supports the management process and the internal processes of the organisation. The system integrates the strategic planning, action plans with Balanced Scorecards, budgets and HR plans. The MIS is also an important tool of the quality assurance system, because it helps the organisation to continuously improve its activities and know how well it is performing.

The concept of the quality map was introduced in this study to describe the interface between the quality assurance system and the management process. The quality map describes the essential characteristics of the quality assurance system. It is a visual representation of how the changes in the environment are taken into account to define the strategic plans and how strategic outlines are planned in detail in the management process. It is also a description of how the plans are implemented in the internal processes of an organisation. In an educational institution the quality map helps management, employees, students and external evaluators to understand the main elements of the quality assurance system and the interface between the quality assurance system and the management process.

The collaborative and interactive use of the MIS supports the instrumental evaluation purposes consisting of judgment-oriented and improvement-oriented evaluation. It also supports the conceptual use of evaluation, where the evaluation contributes by increasing knowledge among decision-makers or stakeholders. If the MIS is used only diagnostically as a monitoring device concentrating on deviations from the set targets without face-to-face interaction and negotiation, the full potential of the MIS to support quality assurance will not be achieved.

The interactive use of the MIS supports organisational self-evaluation and helps management and employees to improve the quality of operations. In order to be capable of designing an MIS which genuinely supports the integration of improvement-oriented self-evaluation into the institution's management process, developers of the MIS must have a profound and realistic understanding of the utilisation of evaluation in decision making. Designers should take careful note of the interactive features of the management process under scrutiny when developing the MIS.

Health Information Provision on the Web via Comparison-Shopping: A Preliminary Investigation

Yun Wan, University of Houston–Victoria, 4902 Mulberry Circle, Missouri City, TX 77459, USA; E-mail: wany@uhv.edu
Susan Evans, Patient Account Services–Houston, USA; E-mail: susan.evans@hcahealthcare.com

INTRODUCTION

The public access to health service information is critical for the general welfare of the society. In the United States, there are many efforts being spent by the government and independent non-profit organizations on improving the *quality* and *accessibility* of such information. Recently, comparison-shopping as an innovative way to increase the efficacy of health service information access is emerging. Depending on the geographic location, an individual could conduct comparison-shopping on health service information ranging from health insurance cost, service quality of hospitals and physicians, to price of prescription drugs.

This new way of obtaining healthcare information may have important social consequences. Essentially, it empowered individuals (including new immigrants) to obtain health information and making comparison with zero searching cost. If such practice is being widely adopted, it may increase the efficiency of the whole health system by reducing cost of patients, increasing service quality of health providers, and improve the welfare of the society in general.

Currently, comparison-shopping for health services and health related information are being provided by various entities like commercial enterprises, non-profit organizations, and government agencies. We see forces converging to make such services available in more sectors of the health system. So it is both academically interesting and practically relevant to study this phenomenon and predict the future development of this phenomenon.

To analyze this topic, we need to address the complex structures of the U.S. health system. This complexity makes both the momentum and impact of comparison-shopping in health industry different from its counterpart in electronic commerce market.

For the remaining of this paper, we first introduce the concept of comparison-shopping and how it is being used to provide health related information on the Web. Then we reviewed the major stakeholders of the system. We analyzed the competing forces of comparison-shopping in healthcare industry and compare them to those in electronic commerce industry. Finally, we proposed future research directions. Since this is a preliminary investigation, our focus is not proposing theory but identifying empirical facts and aims at providing basic references for interested practitioners in this field. We also hope this paper may draw interests of academic researchers.

WEB-BASED COMPARISON-SHOPPING AND HEALTH INFORMATION PROVISION

Web-based comparison-shopping refers to the comparison of product and service information from different online sources in the same Web interface via aggregation and pre-processing work done by comparison-shopping agents or Shopbots (Maes, 1994).

As early as in 1995, we witnessed the first online comparison-shopping service, BargainFinder, developed by then Andersen Consulting in the United States. BargainFinder became a killer app and gained public attention almost instantly (Krulwich, 1996). The success of BargainFinder stimulates more sophisticated comparison-shopping services subsequently like mySimon.com and Pricescan.com in late 90's. Comparison-shopping entered into the mainstream B2C market when the second generation services like shopping.com and pricegrabber.com came onto the stage. Recent survey statistics indicate comparison-shopping ranked among Yahoo, eBay and Amazon as the most visited websites (Nielsen//Netratings, 2004).

In health industry, though comparison-shopping had been used in some sectors like health insurance in very early stage of WWW, most other sectors are lagging behind due to its distinctive market structure compared with commodities.

The health insurance field becomes the pioneer in the U.S. health system to provide comparison-shopping service. Actually this is a natural business extension for insurance agents since they already have the various insurance products data in hand and all they need is to make them available online for the general public to use. Further, this move could actually improve their reach to potential customers, reducing their operation costs in hiring new agents and employees in customer services. Thus, we found established comparison-shopping services in this field emerged quickly like insurable.com, healthinsurance.com, ehealthinsurance.com, etc. from 1995.

Other sectors of health industry were not influenced by this comparison-shopping way until late into 2000. It was not until in the last 2 years, we observed comparison-shopping service on prescription drugs, hospitals, and physicians.

The comparison-shopping service on prescription drugs is mainly due to the rising cost of healthcare. The service providers are mainly non-profit organizations and government agencies like:

1. The U.S. Department of Health and Human Services provides comparison information on hospitals. (www.hospitalcompare.hhs.gov/)
2. The Joint Commission provides information on hospitals as well as other health care service providers (www.jcaho.org)

Some state governments have begun to provide state specific hospital information for their resident patients. Massachusetts Health Quality Partners (MHQP), for example, is an independent state agency that looks at the quality of health services in Massachusetts. It provides side-by-side comparisons on clinic data via different search criteria based on different information needs[1]. MHQP also looks at the quality of health service through the patient experiences. This information is then used to compare patient experiences across the state via a tabular comparison-shopping format for easy comparison on the Web[2].

Comparison-shopping on physician services is also provided by some state governments. For example, New York State provides such service and allows individuals to review a physician's profile information which includes the medical education, legal actions taken against the doctor, translation service at the doctor's office, etc.[3]

Probably, the most widely available comparison-shopping services are prescription drugs due to the cost issue patients experienced in recent years, which are mainly provided by state governments. For example, the Connecticut attorney general's office provide a comparison-shopping services on prescription drugs and allows patients to compare pharmacy prescription drug prices across the state of Connecticut[4]. The State of Illinois makes similar comparison-shopping information available to its residents[5].

THE HEALTH SYSTEM IN THE U.S.

The foundation for our understanding of the complexity of the health information provision is the overall structure of the health system in the US, which can be illustrated from the three basic groups of stakeholders, the *patients*, the *providers* and the *payers*.

The patient population consists of the general public seeking health services. The health providers include physicians, clinical technicians, pharmacists, nurse practitioners, allied health specialists and many other healthcare professionals. Most of them provide the health service via hospitals or similar health service facilities. The payers include self-pay patients, private insurance companies, indemnity plans and government payers (such as Medicare and Medicaid). The majority of the stakeholders are connected via three basic organization forms: HMO (Health Maintenance Organizations), PPO (Preferred Provider Organizations), and (POS) Point of Service Plans.

There is a variety of health services available to patients. They include the ambulatory care, assisted living, behavioral health care, and home care & hospice. The most frequently used health services are provided and received in hospitals. The hospital system in the US is very complex and there are several ways to classify them. Overall, there are over 6,500 hospitals in the United States. The majority of them are general hospitals set up to deal with the full range of medical conditions most people require treatment for. However, more than 1,000 hospitals specialize in a particular disease or condition (cancer, rehabilitation, psychiatric illness, etc.) or in one type of patient (children, the elderly, etc.).

Among these hospitals, some are *teaching or community hospitals* that are affiliated with medical schools. Some are *voluntary hospitals,* which are nonprofit community facility operating under religious or other voluntary auspices. There are also for-profit commercial hospitals or *proprietary hospitals*. They are profit-making institutions and owned by corporations or, less often, by individuals such as doctors who practice at the hospital. Finally, there exist *government-supported hospitals*, which government owned facilities and can include facilities such as the VA (Veterans Administration health facilities).

The different origins and operation styles of these hospitals makes their motivation of providing health information to the public varied. For example, teaching hospitals are usually in the position of providing cutting-edge new health services so they have the motivation to compare their service to others to let the patient know their advantage. Proprietary hospitals might have higher motivation to compare their quality of service information than those government-supported hospitals because they want to attract more patients.

On top of the physical structure of the health system, public policy and accreditation are two other forces that shaped this market.

The public policy for health related information is mainly protecting privacy and patient health information[6]. It has not direct influence on adoption of comparison-shopping for health information provision because the latter is mainly in public information domain.

To regulate the quality of health service, there are also accreditation organizations in the US. The Joint Commission on Accreditation of Health Organizations is the primary accreditation body in the US[7]. It evaluates and accredits approximately 16,000 health care organizations in the United States. The information collected in the Joint Commission surveys is of benefit to the healthcare facility, and is especially beneficial to the Patients considering utilizing a healthcare facility.

The Joint Commission Survey Teams composed of health care professionals gather information by visiting health facilities, interviewing staff and patients and examining records and procedures. The survey performance is compared to Joint Commission's standards and quality expectations. Hospitals must meet or exceed the requirements in order to achieve or maintain accreditation.

The accreditation decisions are assigned in different categories based on their level of compliance. They range from fully accredited, provisional accreditation and conditional accreditation to denial of accreditation.

Another important evaluation survey is conducted by Center for Medicare and Medicaid Services (CMS). In order for a health care organization to participate in and receive payment from Medicare or Medicaid programs, it must be certified as complying with the standards set forth in federal regulations, which is based on a survey conducted by a state agency on behalf of the CMS (JCAHO, 2006).

Organizations seeking Medicare approval may also choose to be surveyed by Joint Commission or other accrediting organizations. In this case, CMS may grant the accrediting organization "deeming" authority and deem each accredited health care organization as meeting Medicare and Medicaid certification requirements. For the time being, the deemed status options are available for ambulatory surgical centers, clinical laboratories, critical access hospitals, HMOs and PPOs, home health, hospices, and hospitals.

To monitor the quality of health service, CMS conducts random validation surveys and complaint investigations of organizations with deemed status through Joint Commission accreditation. In addition, the Joint Commission is obliged to provide CMS with a listing of, and related documentation for, organizations receiving conditional accreditation, preliminary denial of accreditation, and accreditation denied. The Joint Commission also provides CMS with accreditation decision reports for hospitals involved in CMS validation surveys and any other survey report CMS requests. (JCAHO, 2005)

As described above, the health system in the US is very complex in structure. Ordinary patients usually have difficulty obtain the specific service quality information about the providers like doctors or hospitals, not to mention comparing them. In addition, the useful evaluation information mainly comes from a few accreditation organizations or government agencies. These evaluation surveys are targeting the bottom line of the service quality and, beyond which, there is no information to make a more informed decision.

THE CHALLENGE OF HEALTH INFORMATION PROVISION TO THIRD PARTY COMPARISON-SHOPPING SERVICE PROVIDERS

A constant issue facing the American population is continuity of care when changing physicians, insurance plans and locations. Finding new health service providers for their health needs is a constant demand especially with the spiraling cost of health insurances and costs (Baker et al., 2003). The society calls the expertise in providing convenient health information to support individual health service selections. Though there are emerging online comparison-shopping services available in health service selection as we investigated above, we identified a few challenges that could hinder the momentum and sophistication of information delivery in this direction. We summarize them below.

First, unlike comparison-shopping in ecommerce industry, health information provision especially information on hospitals, physicians, and prescription drugs price comparison provided by non-profit organizations does not have similar commercial motivations behind them to support their further development.

In the ecommerce industry, the product information providers (online retailers) actually pay to participate in comparison-shopping because of the potential revenue it could bring back. The more online retailers join the comparison-shopping, the more the remaining online retailers also have to join to maintain their competitiveness – as a result, it forms a positive feedback loop and established the prosperity of comparison-shopping service providers. At the same time, competing comparison-shopping service providers have to improve their technology of information delivery to remain in the market.

In health service information provision, such commercial motivation is not strong for a majority of the entities especially public ones though some private hospitals and doctors who own their clinic may be interested in such comparison. In addition, the ways a health service provider (usually non-profit in nature) operates to attract patients are traditionally different from those in business world. So we might not be able to see a change in near future. In other words, the sophistication and breadth of comparison-shopping on health services may not develop as fast as its counterpart in ecommerce industry.

Second, intertwined with first challenge, the intellectual property especially copyright issues for information on the Web are still pending in many aspects (Lindberg and Humphreys, 1998). For the time being, the health information provided on the Web is mostly owned by non-profit organizations and government agencies, which may not have the commercial motivation or right to sell it or allow it to be used by commercial organizations to generate profits. Without such mechanism, the core technology of comparison-shopping, which is aggregating data from multiple sources and presenting them in a value-added way to users, can not be conducted efficiently. Again, in ecommerce field, comparison-shopping service providers also experienced copyright issues in the beginning when they retrieve data from different online vendors for comparison. However, when online vendors found comparison-shopping could actually increase their revenue, they changed their attitude and begin to pay to participate (Plitch, 2002).

But in health service industry, this change is unlikely due to the non-profit nature for most part of the system. So how to protect a third party comparison-shopping service provider from being sued via appropriate public policy is important.

There are some moves in this direction recently. For example, Illinois enacted a law in 2005 (The Prescription Price Disclosure Act) and ensure that consumers can compare-shop to find the lowest price for their prescription medications. It requires pharmacists to disclose the current retail price of any brand or generic prescription drug or medical device that the pharmacy offers for sale. As we can see from this case – if we lack the invisible hand of the market to encourage the voluntary participation as in ecommerce industry, the state government could step out and use the visible hand of legislation to force the participation (basically sharing the drug price data) of comparison-shopping by drug vendors.

We expect more public regulations will have to be enacted as a compensation for lacking commercial motivation of comparison-shopping by health service providers in the near future to promote the services.

FUTURE RESEARCH DIRECTIONS

We think the first priority in research of this field is establishing a proper framework on the classification of health information as needed by patients. This framework should include all aspects of health information a patient needs to make healthcare decisions.

We also need research on how to standardize health information so as to make the electronic transaction of information retrieval and aggregation by comparison-shopping search engines easier to perform. A related project that has been underway for quite a while is the concept of regional health exchanges (Havenstein, 2005). In this plan, the U.S. Government hopes to provide a backbone for a national health information infrastructure where all hospitals will be connected and patient information is stored electronically in real time. The comparison-shopping search engine could utilize such a network to retrieve necessary information in the future.

Another imperative topic in future research might be a detailed analysis on the impact of public policies on health information provision in comparison-shopping mode. In health information provision, the motivation of providing comparison information is both non-commercial and complicated. So the impact needs to be investigated in detail.

CONCLUSION

In this paper, we investigated comparison-shopping as a new way for health information provision in the United States. We introduced the emerging field of comparison-shopping and its application in several aspects of health information provision such as health insurance, hospital, physician, and prescription drug selection.

We identified the challenges of the development of this field by contrasting it with comparison-shopping industry in electronic commerce world, where a more efficient mechanism is driving the sophistication and maturity of this new mode of decision support. We argue that public policy is the most effective way currently in health information provision to influence the development of comparison-shopping on health services.

Finally, we proposed several future research directions in this new field.

ABSTRACT

In this paper we study a Pharmacy that recently went through a major IT initiative. With the acquisition of the new software, the Pharmacy had more flexibility to rearrange its flow of activities. We used several "what if" scenarios and applied a simulation tool to study the impact of each scenario on the performance of the pharmacy and search for a maximum optimization given the resources available. An issue that we investigated was that a simulation tool would be of less use if it is not preceded by a profound conceptual modeling. In turn, modeling alone is not sufficient to get insight into the dynamic behavior of a system. For the pharmacy business process modeling we used a method that is introduced and discussed in a separate paper.

Note: Due to space restriction, this paper represents application part of another paper "Business Processes Modeling as Social Systems", published in these proceedings, where the modeling method itself and its constructs are discussed. For the understanding of this paper, readers are strongly recommended to read the first paper where the method is described and discussed.

INTRODUCTION

For a thorough analysis and study of business processes, both modeling and simulation should play in concert. Only modeling may not reveal sufficient information about the processes (Hlupic & Vreede, 2005). For significant results and accuracy, business process optimization and modeling need simulation. On the other hand, only simulation provides little help if there is no profound conceptual modeling preceding it. It would be like "expedition without a map".

Continuous competition, increasing capabilities and features of emerging technologies and growing customer demands require organizations to keep current, i.e., adapt changes in order to gain market share, improve performance, increase customers and incorporate "best practices". In such an environment, process optimization is no longer a competitive advantage but a requirement of doing business (Rivera & Marovich, 2001). Obviously any change is risky and may invoke serious consequences for organizations. Early mitigation of these risks is undoubtedly a prerequisite of success and survival in risky changes with unforeseen variables. Here is where business process simulation plays a significant role in process optimization. Simulation is a safe and inexpensive way of studying the impact of changes and revealing hidden behaviors of a complex system.

Since changes would be a driving force for *the 21st century enterprises*, business process optimization and simulation is not a question of *"to be or not to be"*, but a navigational compass to set the right course for sailing into the storms of rapid change. According to some experts (e.g.: Paul & Serrano, 2003; Seila, 2005; Kleijnen, 2005; Hlupic & Vreede, 2005) the potential and full capacity of business process simulation still have yet to be revealed. Although one may argue that the diligent efforts of researchers have fairly advanced the research in this area, simulation as an effective tool should still be widely accepted and adapted by businesses.

Since this paper is an application part of another paper that contains detailed description of the method, here we only focus on the application – case study.

CASE STUDY: PHARMACY

The case study reported here is not intended to be exhaustive, it is a simplified version to demonstrate how the proposed method is capable of capturing the dynamic behaviour of business processes and serve an input for simulation. This case study was conducted at a time when a Pharmacy was planning to acquire and implement a new system and extend its business with e-commerce. This case study using modelling and simulation, was assumed to provide an insight into the business and help to understand the Pharmacy's operations and requirements for a new system.

Prescription Filling Process

Upon arrival at the Pharmacy a patient proceeds to the pharmacy counter and requests prescription refilling. If it is a new patient, the technician asks the patient to fill out a short information sheet, which includes information such as the patient's name, address, telephone number, allergies, and whether or not the patient has any type of insurance or medicine coverage. When the profile is created, the technician selects medicine according to the prescription.

The software automatically checks the current medicine for interactions. Then the user transmits a claim to the patient's insurance. If no insurance coverage, a cash price is assigned.

The computer generates a label and sends the information to the 'robot' for automatic filling. The medicine is then checked one final time visually by a pharmacist. Once verified, the prescription is bagged and then sent out to the cashier for pick-up by the patient. The entire process normally takes no more than 10-15 minutes. The end of this process is related to another process called inventory control. Inventory must be accurately maintained because QuickScrip uses an automated ordering system which examines the current quantities of medicine in stock and networks with the wholesaler company to ensure proper levels are maintained. Although the inventory control process and its interrelation with the prescription filling process were also studied in the case study, here we skip this part due to space restrictions.

Identification of Business Transactions

The process of "Prescription Filling" starts when a patient presents a prescription to be filled. Thus, the first transaction (T1) is "prescription filling". Actually, this is a super transaction that nests many other transactions. This transaction is initiated by a "patient" and executed by the "pharmacist". The result of this transaction is a filled prescription. In this manner we identify all other transactions:

T1:	prescription filling
Initiator:	patient
Executor:	pharmacist
Result:	prescription is filled
T2:	creating profile
Initiator:	pharmacist
Executor:	patient
Result:	profile is created
T3:	checking medicine interaction
Initiator:	pharmacists (software agent)
Executor:	QuickScrip
Result:	interaction is checked

T4: claim processing
Initiator: pharmacist
Executor: insurance company
Result: claim is processed

T5: automatic dispensing
Initiator: pharmacist
Executor: robot
Result: medicine is dispensed into bottle

T6: paying for the medicine
Initiator: pharmacist
Executor: patient
Result: medicine is paid

Now, based on the above transaction, we build a detailed model as shown in Figure 1. By disclosing Transaction T1 (splitting its three phases), all other nested transactions are revealed. This figure shows all the transactions as an interrelated network. It also shows that once medicine is issued (T1/R), the inventory control process is activated. As the inventory control process is out of the scope, which itself is a network of transactions, we just illustrate it as a composite transaction (T#).

Within the scope of our model, only Transaction T1 is a composite transaction and, therefore, we decompose it. All other transactions (T2, T3, T4, T5 and T6) are simple transactions and, therefore, they are shown in a compact form to keep the model compact.

In Figure 1, the Pharmacy is considered as a composite actor delegating the role of a few other actors such as "pharmacist", "technician", "robot (A2)" and "software agent (A1)" for checking medicine interaction. In order to better understand the above figure, it should be read from left to right and from the top to down, just as the arrows indicate. It would be easier if the reader has a list of the transactions, previously identified, ready when reading the model: The patient requests prescription filling (T1/O) and with this request the execution by a pharmacist or technician starts (T1a/E). If it is a new patient, the technician requests them to fill in a form to create a new profile (T2). This is an optional transaction indicated with a small diamond-shape at the connection point. Then, within the pharmacy system (QuickScrip), a request is made to check the current medicine for any interaction (T3) (if an interaction is detected, the process terminates here). Through an online application, the claim for this medicine is transmitted to the patient's insurance company to define the price of the medicine (T4), if the patient is covered by an insurance plan. Then the robot is instructed to fill in the prescription (T5). At this point the patient is requested to make their portion of the payment or arrange for later billing (T6), and only then the medicine is issued to the patient and the process is completed (T1/R). Notice, the completion of this process triggers a transaction in the inventory control process (T#) making sure the issued medicine is subtracted from the inventory and checks if this medicine should be ordered for restocking.

Figure 1. The pharmacy detailed model (constructed with MS Visio software)

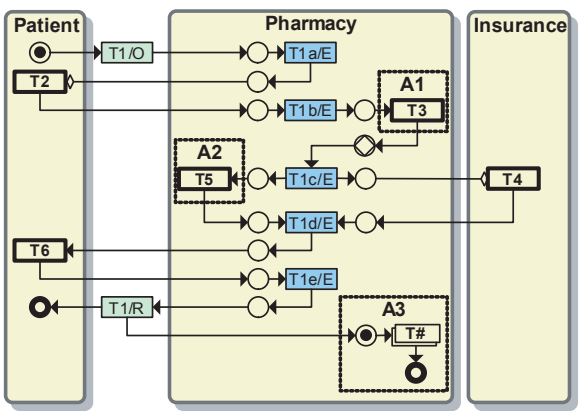

Figure 2. Screenshot of the "pharmacy" simulation model

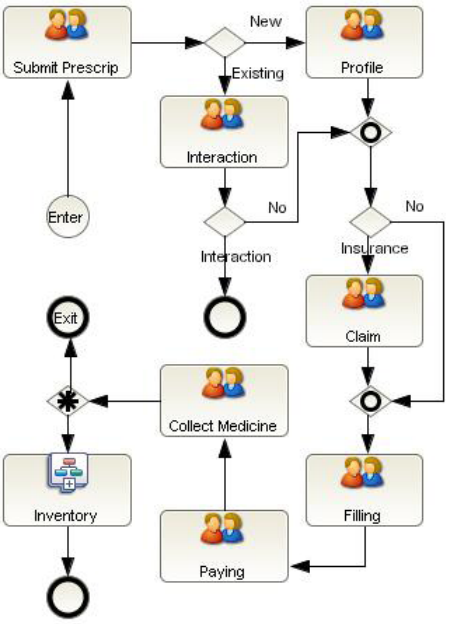

SIMULATING THE PHARMACY MODEL

We developed a simulation model of the Pharmacy based on the detailed model presented in the previous section. For the simulation purpose we use Savvion Process Modeler to show the usefulness of the developed models as an input to be used by simulation packages other than Petri net tools. This way, it is demonstrated that the Petri net models are easily portable to different environments and can be adequately represented by other models, although some minor adaptations are needed. By adequately we admit one essential compromise – the interaction part of the models are largely omitted and the model is reduced to merely execution phases, where the actual actions take place. One of the typical adaptations required, concerns composite transactions. A composite transaction should have both start and finish parts, e.g., the "prescription filling (T1)" is divided into submitting a prescription for filling (Submit prescription) and collecting the medicine (Collect medicine) parts, while all other transactions can be represented as a single activity, as shown in Figure 2. This figure depicts an animated simulation model of the Pharmacy using Savvion Process Modeler.

Savvion Process Modeler has its own graphical editor for constructing models using a set of artifacts. The figure below is a screenshot of the Pharmacy model in the Savvion Process Modeler graphical editor.

The model contains 6 transactions each representing an atomic process. In the Savvion simulation model above, these transactions are represented as worksteps (grey rectangles: e.g., Submit & Collect, Profile, Interaction, Claim, Filling and Paying). Each workstep corresponds to one transaction (more precisely, the execution phase of a transaction), however, the first transaction, the composite one, is divided into two parts (Submit, Collect). In addition, the simulation model illustrates how the last transaction 'Paying' is linked to the 'inventory control' process. This process is represented through a *subprocess* element without revelation of its inner structure (transactions), which by itself is a model.

For accurate analysis and comparison, Savvion Business Modeler provides analysts with features such as generating a report on the simulation results in either HTML or Excel format. The following few lines and the corresponding Table 1 are excerpts from a complete simulation report (2-4 pages). These excerpts are about the bottlenecks in the process and warning about activities that never occurred:

***Filling*:** A bottleneck was detected for Filling (avg. queue length was 0.15, max. queue length was 5.0).

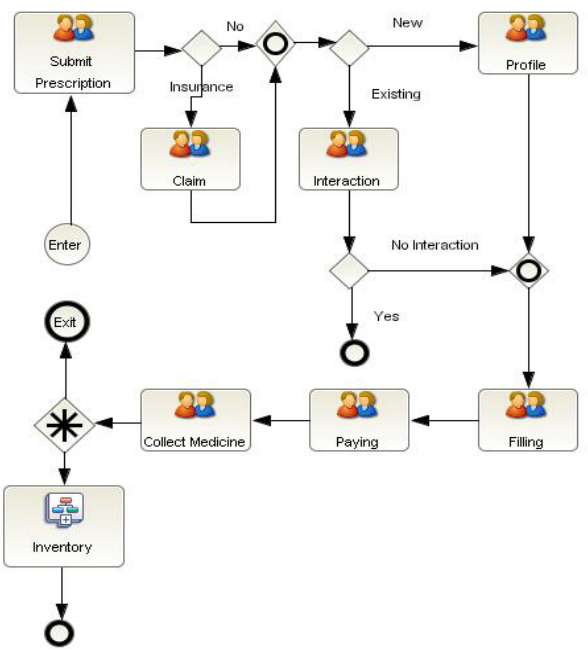
***Profile*:** Profile was never activated. Try increasing the number of instances.
***Submit*:** A bottleneck was detected for Submit (avg. queue length was 0.029, max. queue length was 1.0).

A complete report of the simulation outcome includes 2-4 pages in HTML format detailing average times, queues, busy and idle times for each performer, and other related information about the model behavior. All this is generated in a series of tables one of which is illustrated above (we skip the rest due to space restriction). The simulation package also has a kind of expert system that provides recommendations of how to improve the process or which components need to be redesigned for better performance.

Figure 3. Screenshot of the revised "pharmacy" simulation model



"What if" Scenario A
To improve the model, reduce bottlenecks and decrease wait time we put the model through several "what if" scenarios two of them reported in this paper. In our first such scenario (see Figure 3) the issue of the bottleneck during the filing of insurance claims was addressed. Our first step was to assess the current sequence of the "Claim Process" and optimize its position in the flow. The claim process being in itself a complex process involving the insurance company may take longer than some other actions and resulted in bottlenecks at its beginning and also was thought to be responsible for other process in the model. Our evaluation led us to believe that placing the claim at the beginning of the model instead of in the middle could help to reduce the bottleneck in that location and by doing so on a subsequent simulation run the model was made more efficient. Included below are excerpts from the results of the simulation run.

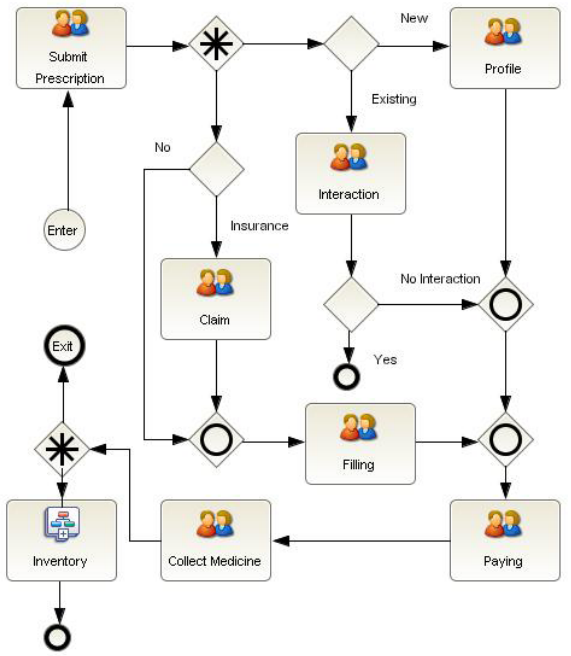
Collect: A bottleneck was detected for Collect Medicine (avg. queue length was 0.032, max. queue length was 1.0)
Profile: A bottleneck was detected for Profile (avg. queue length was 0.0090, max. queue length was 1.0)
Submit: A bottleneck was detected for Submit (avg. queue length was 0.071, max. queue length was 1.0)

"What if" Scenario B
To further reduce wait time and the overall length of the process we decided to incorporate mass parallelization (see Figure 4). Utilizing this feature allows for the claim to begin processing at the start of the simulation and to have the other performers continue on with the interaction check and information profile for new customers. This model proved to be an improvement for overall processing time compared with the original and the previous scenario.

Filling: A bottleneck was detected for Filling (avg. queue length was 0.0010, max. queue length was 1.0)
Paying: A bottleneck was detected for Paying (avg. queue length was 0.047, max. queue length was 1.0)
Submit: A bottleneck was detected for Submit (avg. queue length was 0.022, max. queue length was 1.0)

Comparison of "What if" Scenarios
As we revised the models it was easy to gather data from the software that allowed us to gauge the effectiveness of each model. Our efforts in creating and revising the models were in order to determine a successful way to reduce wait time for customers to streamline the business process. Each "what if" scenario was investigated with the same set of variables regarding the number of customers arriving as well as their frequency. The Original scenario (model) was compared to each of the two "what if" scenarios to see which model was the most effective (see Table 3). The Original model had an overall simulation run time of 15 Hours

Figure 4. Screenshot of a revised "pharmacy" simulation model incorporating mass parallelization



and 21 minutes. There were six Bottlenecks detected the sum of which created an average waiting time of 0.3697 hours for each customer.

The second model in which the insurance claim process was initiated immediately upon the submission of a prescription had a total run time of 15 Hours. In this model three Bottlenecks were detected the sum of which created an average waiting time of 0.106 hours for each customer. This scenario reduced both overall runtime and the waiting time for customers.

The third scenario incorporated mass parallelization into the model. The overall simulation run time was 14 Hours and 20 minutes. There were four bottlenecks detected, their averages totaling 0.274 hours. This model was found to be effective by reducing the overall time a full hour compared to the Original scenario and also reducing the wait time when compared to the Original scenario.

While both of the scenarios proved effective and each had their own strengths it is always up to the business to decide which is more valuable; reducing customer wait time or overall work time of the establishment. Regardless of the organizational choice, business process modeling is an exceptionally useful and unambiguous tool for assisting with managerial decisions.

CONCLUSION

In this paper we discussed application of simulation as a tool for business process optimization. We studied business processes in a pharmacy that has recently gone through an IT initiative.

This relatively non-complex example revealed a number of valuable conclusions:

- Only modelling is not sufficient to get insight into intricate business interactions.
- It is hard to see the impacts of changes unless the models are executed.
- Experimenting with simulations may prevent s from expensive trial-and-error designs.
- As for the users, simulation (animated) models are more easily communicated to users than static models.

ABSTRACT

Developing Countries have tried to reduce the impact of unbalanced technology access through the creation of telecenters in which low-income users can learn and get used to IT. In Mexico this effort has led to the implementation of the e-México project (electronic-Mexico). This project deals with the installation of Digital Community Centers (DCC), a kind of telecenter which provides users with Internet-enabled PCs. This paper presents a preliminary analysis of the impact of such DCC. We focus our attention on the State of Mexico, a densely populated state located in the center of Mexico. We describe the factors taken into account to install DCC and analyze whether or not the location of these telecenters is expected to positively impact low-income counties.

Keywords: digital divide, telecenters, IT Management in developing countries.

Since Internet became a communication tool for the public it established a difference between those countries with Internet access and those without it. The main outcome of this division is the unequal distribution of decision-making information among people. Unequal access to IT and high quality information is what we call the "digital divide".

This research analyzes an initiative of the federal Mexican government aimed at reducing the digital divide: the e-México (electronic México) project. We analyze the counties of the State of Mexico with higher index of poverty which have access to IT. The article is divided in four sections. First, we provide a general description of the digital divide problem; the second part describes the e-México project in further details; we continue by defining our methodology of study and end with a discussion of results and future research directions.

I. THEORETICAL FRAMEWORK: THE DIGITAL DIVIDE

According to the Internet World Stats, as of November 2006 there were 1,706 billion Internet users. This corresponds to a 16.6% world penetration rate, a small percentage of the global population. This shows the huge challenge represented by the digital divide. Larry Irving, quoted by Dragulanescu (2002) was the first author to use this term, he defined "digital divide" as:

"the existing gap in access to information services between those who can afford to purchase the computer hardware and software necessary to participate in the global information network, and low-income families and communities that cannot"

There are other definitions Johnson (2002), Cullen (2001) and Dewan et. al (2005) which propose different approaches to the digital divide term. The OCDE (2001) states that digital divide is "a term that refers to the gap that exists in the opportunities to access advanced information and communication technologies between geographic areas or by individuals at different socio-economic levels".

The digital divide concept is still on debate, there is no definitive consensus on whether this unequal access to technology refers to computers only or should also consider telephone lines. Norris (2000) and Del Álamo (2002) consider telephone lines, television and radio as information technologies. Some others like Kenny and the OCDE (2003) include the previous technologies but also consider Internet access.

We consider that digital divide can be understood as an unequal access to information that promotes human development and increases quality of life. Information Technologies are the main way to reach this goal. Internet access, phone lines, radio or television do not guarantee that information circulates with the same quantity and quality. Our research is focused on measuring the impact of national initiatives targeted at increasing access to IT for low-income populations. Our long-term research goal is to find a reliable measuring methodology to estimate the impact that access to IT has on reducing the digital divide and as a consequence come up with concrete proposals and recommendations to enhance the efficiency of both government and private projects and initiatives. Our first objective is to measure the amount of people that gets access to IT and how this can help reducing the digital divide. Next section continues by describing the e-México project: an effort of the federal Mexican government aimed at reducing the digital divide.

II. E-MÉXICO PROJECT

The digital divide in Mexico is analyzed by Curry and Kenny (2006), their study includes data about Mexican infrastructure: online domains, computer access and number of Mexican Internet users. The Asociación Mexicana de Internet AMIPCI (2006) publishes an annual study of Mexican online consumers and their habits. In 2006, only 20.2 millions of Mexicans had Internet access, less than 20% of the total population of the country.

The project called e-México (http://www.e-México.gob.mx/) was initiated in 2001 by the federal government. e-México intends to provide Internet access together with online services like education programs, health, trade and online transactions to 10 thousand communities representing 85% of the Mexican population, before the end of the current administration (December 2006).

Statistics show that DCC are being used by a large number of users in Mexico. As of October 2004, 29.8 millions of web pages were consulted through the network; 240 thousand hours of surfing is the accumulated total of countryside DCC. In the State of Mexico, a densely populated entity located in the center of the country, subject of this study, 13,300 hours of Internet surfing were registered in 2004 (Perez, 2004).

We will focus our study on the DCC located in the State of Mexico. According to official data, there are 345 DCC in this state, but we do not know whether they are distributed following a particular criterion like poverty index, literacy or lack of technological infrastructure. Officially, there are no established criteria to determine actual DCC locations. We assume that as far as they are controlled by the micro-regions program of the Ministry of Social Development (SEDESOL) they are using the poverty index to locate the centers.

Poverty index is a measure provided by the Mexican National Council of Population: "…this index is a summary measure to differentiate states and counties according

to the global impact on population caused by: lack of access to education, living conditions, income, and context in small counties". (CONAPO, 2004)

In order to measure and evaluate the impact of DCC on reducing the digital divide, we started by finding out the main criteria applied when installing a DCC in a particular county. Interviews with personnel from the federal government in charge of this project revealed that there is no official criterion for the location of DCC, a methodology to measure their impact is still to be defined. Next section describes our approach to these problems.

III. METHODOLOGY

The core methodology consists on evaluating the statistical data with the poverty index. We selected the State of Mexico for this study because it concentrates more than 10% of national population. According to the National Census Bureau of Mexico (INEGI), on 2005 the population of this state was about 13 million 58 thousand and 611 people living in 125 different counties, mostly urban areas. Thus, we consider that studying the impact of DCC in this federative entity will be highly representative at a national scale.

The Hypothesis on which we focus this work are:

1. The poverty index calculated by Mexican government as a normalized measure for qualifying the overall degree of poverty of a population is a meaningful indicator. This is important since the second hypothesis is based on poverty index as an indicator of expected impact of DCC for reducing digital divide.
2. Digital divide will be reduced if DCC are located in populations with a strong poverty index.

In order to proof these hypotheses we proceeded as follows: In the first stage we collected information about poverty index and DCC in the State of Mexico. In the second stage we validated the poverty index with its components (see table 1) before attempting to find any correlation between this index and the DCC locations. The third stage did a correlation analysis between the poverty index and the DCC location in the counties belonging to the State of Mexico. Finally, we discussed and analyzed the obtained results.

Table 1. Components of poverty index

Poverty Index Indicators
Percentage of analphabets aged 15 or more
Percentage of population aged 15 or more with incomplete primary school
Percentage of population living in private houses without tap water
Percentage of population living in private houses without drainage and private toilets
Percentage of population living in private houses with earth floor (unconditioned floor)
Percentage of population living in private houses without electricity
Percentage of overcrowded private houses
Percentage of population living with less than 10USD per day
Percentage of population living in places with less than 5000 inhabitants

Source: CONAPO (www.conapo.gob.mx)

IV. DISCUSSION AND RESULTS

The first result is that the poverty index is valid. According to the results of the multiple regression (see table 2 and table 3) there is a strong correlation (R2 = 0.9341). With the exception of total population, the rest of the components are meaningful enough. Correlation between components and poverty index was tested with a 5% significance level. As a conclusion we can state that there is enough evidence of linear relation of the index and its components: Mexican poverty index is a strong indicator that supports statistical test.

As second result, we can affirm that there is no evidence of lineal correlation between poverty index and the number of DCC in the case of State of Mexico (see table 4 and table 5). If we consider that the digital divide will be reduced by means of providing Internet access through telecenters – DCC – this work shows that the current location of the DCC is not properly done to achieve this goal.

However, with the available information we can not really measure the impact of DCC on the Mexican digital divide. This preliminary research explores the idea that the DCC locations are important to reduce the digital divide on Mexico, we need to provide more elements, for instance, by means of a longitudinal study in order to complement this research.

CONCLUSIONS AND FUTURE RESEARCH

This is a pioneer work that contributes to the research of the telecenters – DCC – and their impact on reducing the digital divide on low income populations. Our results showed the poverty index as a strong and valid measure to understand and quantify poverty; moreover, our tests demonstrate that the component of total population has not significant impact on the computation of the poverty index, and thus can be omitted.

A question remains unanswered: How does Mexican government determines the number and location of DCC to reduce the digital divide in the country? The data we collected and the statistical analysis we performed in this study show that there is not correlation between the poverty index and DCC location. What is the main reason to locate a DCC into a specific community? Is it a political reason?

This research shows that there are no definitive criteria to locate a telecenter. We consider the poverty line as one valid criterion; however, there are other international measures to validate poverty. A future contribution of this research could be the definition of a set of criteria related to literacy, poverty line or digital literacy – computational skills – which could be used as indicators to decide the location of a DCC.

Finally, this exploratory research is only focused on publicly available data about Mexican DCC. There is a need for exploring more detailed information such as: number of computers in each location; real number of computers in operational conditions –the amount of broken equipment after some months of use can be rather high; computers with internet access –not every computer in a DCC has a working Internet connection; number of users in the telecenter at different times of the day; activities performed in every center, technical problems faced and how they are solved.

Future research includes extending this study to a national scale, analyzing different regions or states. We recommend the continuous application of this test in the next years to better understand the evolution of DCC and their impact on digital divide.

Eddy J. Burks, Troy University, USA; E-mail: eburks@troy.edu

ABSTRACT

Ongoing research was conduced on the impact of technology on a law firm handling tort (civil) cases in the U.S. legal system. The firm used in the study is heavily involved in mass tort litigation and was the subject of a study previously reported at the IRMA 2005 International Conference [1]. The current research is the third of several planned studies on individual law firms and the legal system usage of technology. Specifically this segment of the research is to determine the potential implications of the Sarbanes-Oxley Act of 2002 (SOX) and the Health Insurance Portability and Accountability Act (HIPPA) of 1996 regarding a law firm ensuring a security repository database for confidential client information that is subject to the sections of these two acts. All professional firms, especially law firms, have a legal and ethical obligation to protect clients' interests including documents. Both acts have increased the work (data) flow of professional firms due to increased need for the documentation of singed permission by individuals to access "sensitive" data from every source.

ORGANIZATION BACKGROUND

Research being conduced is limited to four areas of interest related to tort law within the category of civil law within the U.S. legal system: (1) to develop an initial descriptive technology-usage-and-trend benchmark for a single law firm handling tort (civil) cases in the U.S.; (2) to determine the costs and time currently known to provide existing professional services in the tort (civil) case area in the U.S. (cost versus benefit); (3) to use the findings in (1) and (2) as a basis in expanding the study into a study of representative, comparable firms with similar practices in the area of tort law; and (4) to collect and analyze data on the nature of the impact of technology on the U.S. legal system. The law firm in this study is identified only as the Professional Law Firm (PLF). It was chosen because it was accessible, and it is heavily involved in mass tort litigation which is one of the major health and litigation issues in the U.S. This phase is intended to develop insight into one illustrative intrusion issue that might have legal implications for a law firm as well as their clients.

REVIEW OF LITERATURE

In the May 2004 issue of Government Technology, the National Consortium for Justice Information and Statistics or SEARCH recommendations for nine milestones is presented. These milestones are: (1) Initiate the process and institutionalize a governance structure, (2) continue planning, (3) develop and use performance measures, (4) analyze information exchange, (5) adopt or develop standards, (6) create sound integration architecture, (7) develop the infrastructure, (8) improve agency and organization applications, and (9) establish interfaces [3].

The Dennis Kennedy.com web site that is immensely popular within the legal profession describes the complexity of issues facing the legal firm and justice system as a whole. Two quotes are worth repeating and allow the researchers to drill down through the justice system to the level of the law firm and the environment in which a firm operates. "The courts are very serious about moving to e-filling and judges want to get attorneys moved to electronic systems." "Computer forensics and electronic discovery tools have become standard tools for some of the best litigators. Increasingly, the evidence you may need exists in the form of e-mail or never was printed out onto paper." [4] Additionally, law firms and others must ensure their IT efforts are compatible with their clients' efforts to meet the changing expectations regarding transparency and accountability in business processes and corporate accounting designed to improve public confidence in publicly regulated businesses. [5]

As part of the ongoing research to understand the impact of technology on legal firms and thus on the entire legal system we selected one intrusion tool for illustrative purposes that if not detected and protected against within the law firm's networked system that contains confidential privileged client information could compromise client corporations under the SOX and HIPPA acts. In short, the authors wanted to examine the issues related to protecting clients' interests (documents, access to documents, etc.) in a law firm that has a legal as well as ethical obligation to ensure that sensitive client data is well protected. No effort in this study was made to explore the potential legal implications to a law firm that fails to adequately protect sensitive data of its clients.

The intrusion tool examined in this segment of the study is the use of port knocking. The networked environment of today requires that information technology (IT) professionals utilize virus scanning tools, firewalls, network operating system features to manage the access to a given company's networked system. Most of the attention is focused on the use of well-known tools or procedures such as matching user names to passwords and the use of firewalls to reduce the intrusions by hackers.

This third phase of the ongoing study is an attempt to describe the technical issues and the related implications of several approaches (tools) available to those who wish to enter without authorization into a network and those that use such approaches for financial gain, illegal activities or for other reasons, areas with significant fraud prevention and detection implications – in short to compromise a law firm's client database. Intrusion tools which may be used by individuals engaged in fraudulent activities the authors describe how "port knocking" could be used as an intrusion tool to gain entry into a firm's network and thus allow someone to obtain (without authorization) corporate data (client, employee, financial, etc.) and/or be used by users (having authorized access) to the data electronically transfer classified or sensitive corporate data to others located internally and externally to the organization.

In simple terms port knocking refers to the technical interactions between two computers as one attempts to open a closed port and thus pass through the second's firewall. Managerial issues for the IT professional range from the routine management of the networked system including the firewall (good) to the use of the port knocking method to pass messages between computers (individuals) in a manner that bypasses or circumvents the normal network security features (bad). Port knocking as presented in the Linux Journal is a process for a remote user to connect to a server when the port (service) is closed and a firewall is in place. The remote user sends a sequence of requests to the server. All of the ports are closed and the firewall logs the attempts. Software is in place that monitors the firewall's logs. When a correct sequence of port attempts are detected by the software, then a given port will be opened and the remote user can then access the requested port. This is a form of "a stealthy method of authentication and information transfer to a networked machine that has no open ports". Port knocking also "…can be extended to transmit any type of information encoded in a port sequence." [6]

CASE DESCRIPTION

The law firm [PLF] used as the basis for this case study is considered a specialty firm that coordinates litigation efforts by legal firms located in thirty-five states that are involved in class action suits related to health care. The required legal documents (paperwork) and information change exponentially with the addition or deletion of new plaintiffs to existing litigation. A concurrent requirement is a database to permit the firm to manage the required coordination between separate suits in each separate legal jurisdiction. Thus, a law firm has a need to ensure that all client data held in repository for pending and past litigation is managed as if it was held in the client's own computer system.

Phase I: Strategic Considerations

The PLF at the beginning of the study phase reported that it was studying the potential that intrusion tools could have on its ability to provide a secure environment for its clients that find themselves under the guidelines of the sections of the Sarbanes-Oxley Act of 2002 and the privacy provided by the Health Insurance Portability and Accountability Act of 1996.

- Professional and non-professional staff (internal) access accountability
- Client and other non-firm parties (external) access accountability to reduce to a zero intrusion level to ensure confidential client data would not be compromised.

Phase II: Intrusion Effort Study

The researchers with the assistance of the law firm undertook an effort to demonstrate the electronic passing of text information between two networked machines using port knocking to bypass the network monitoring system in place for the law firm. This implementation did not require a firewall be used by the receiver. We illustrate this process with a sender (server) and client (receiver-law firm) software written in Perl. The server took the message, mapped the characters to predefined ports and sent the message to the client (external party). The client had the same port mapping information and decodes the message. One very important aspect is this process is meant to be "invisible" as possible, so the information was not sent all at once. Rather it was sent over (perhaps) a lengthy period of time. Thus, monitoring software at the sender's site will not detect a pattern of unusual behavior. At most, a stray packet here and there may be detected if the sender's organization uses a sniffer program as a component of its monitoring system since fraudulent activities can occur under the noses of those whose responsibility it is to prevent.

The PLF strategic planning was delayed due to aftermath of Hurricane Katrina but remains as a priority for the firm. The PLF has identified an initial set of issues since its recovery from the impact of Hurricane Katrina that must be included in the strategic planning and include the following areas of interest by the firm:

- Client data retention,
- Repository database management to ensure potential issues under SOX and HIPPA coverage for clients are met, and
- Increased intrusion detection

The partner in charge of operations management (POM) at the PLF currently has the IT staff developing a set of alternatives for consideration by the firm. These alternatives include, but are not limited to, the use of additional SOX and HIPPA compliant software guidelines and the development of an additional intrusion layer of security in the existing network firewall structure. Once the IT staff presents the alternatives including costing and capabilities to the POM the professional staff will be given an opportunity to provide input to the partners that will ultimately make the decision.

There is heightened awareness by the firm that as it moves past the recovery efforts related to Hurricane Katrina other issues will once again have significant ramifications on the decisions to be made by the firm. Since many of the court document repositories have been damaged or destroyed, the recovery effort undertaken by the courts for filing and maintaining records will shape the opportunities that exist to fundamentally change the legal system; this will, in turn, impact the direction individual firms will need to go regarding the filing and processing of tort litigation. An integral consideration is that of ensuring that law firm practices do not raise additional liability exposure issues for firm clients.

CONCLUSIONS

Currently the PLF is actively involved in strategic planning that is designed to allow the firm to address potential SOX and HIPPA issues concurrent to its representation of its clients. No specific time-frame was identified by the firm since the legal system in the area impacted by Hurricane Katrina is still addressing continuing recovery needs.

A Competitive Intelligence (CI) Value Model for Companies

Richard T. Barnes, Virginia State University, Petersburg, VA 23886, USA; E-mail: rbarnes@vsu.edu
P. Candace Deans, University of Richmond, Richmond, VA 23173, USA; E-mail: cdeans@richmond.edu

ABSTRACT

Competitive Intelligence (CI) is a relatively new business process that has been implemented in many large companies in recent years. In many companies it is now a separate unit that reports directly to the CEO. Competitive intelligence practitioners gather public data, analyze it, and report on actionable findings with the intention of improving their company's competitive position in the marketplace. Best practices in competitive intelligence include strict adherence to a code of ethics as published by the Society of Competitive Intelligence Professionals. Also essential are executive support, education, and integration within the organization's planning and strategic development process. Use of competitive intelligence by medium and small companies is less prevalent in part because of difficulty in determining value from the process and justification for the cost. In this paper, a value model for competitive intelligence is presented as a means for companies to evaluate the benefits and justify the costs associated with establishing a competitive intelligence unit.

INTRODUCTION

It has been well established in the literature (Fuld, 2006; Miree & Prescott, 2000) that well-organized, mature CI programs can lead to sustainable and profitable growth. CI in fact helps to protect what a company has, and what the company wants to become. It is essential that CI be a regular input into normal corporate processes. New product development, sales proposals, strategy development, and other business functions all benefit from this intelligence input.

Basically, CI information and analysis processes answer questions about competitors. These answers help reduce risk and increase profits. CI as a discipline is a work in progress. Despite twenty plus years as a recognized business methodology, it has only been within the last 10 years that it has approached the mainstream of business thought. The Society of Competitive Intelligence Professionals (SCIP) was established as a support for CI and has been instrumental in its development.

CI is different from Business Intelligence (BI), Knowledge Management (KM), Market Research (MR), and other similar programs. Although the distinctions can be fine, the differences are in perspective and scope. KM is generally focused on internal knowledge. MR focuses more on customers, not competitors. BI is a broader term that can include aspects of competition that can refer to similar ideas as in KM but can also refer to non-competitive issues. CI is much more focused and defined. Although CI is focused within the organization, the scope is defined by the need to gather, analyze, and act on competitor intelligence.

The international aspects of business and markets have had a profound effect on competition. The great enabler is the internet. The internet has greatly accelerated globalization, but in the matter of competitive intelligence, the internet has made available to large and small businesses alike, unprecedented information access. The internet (and the corporate intranet) provides the accessibility, but information technology has provided the means for companies to utilize CI more effectively.

BEST PRACTICES

There are several key requirements necessary for a best-practice CI program. Of fundamental importance is defining a clear role for CI. CI must have clear objectives and goals or the program will wither and die. The role assigned must be significant and integral to business functions at the tactical and strategic levels where it can positively impact business performance.

It is also essential that CI programs have top management support. A high-ranking champion of CI is essential. Few CI programs are initiated proactively. The reason most CI programs are started is based on executive identification of underperforming assets (Prescott and Miller, 2001). The need is to maintain and strengthen the executive support that the program began with.

Gaining executive backing isn't the only support necessary for the CI program. A common denominator in successful CI programs is the involvement of all employees in the intelligence function (Prescott and Miller 2001). To do this well, the value of competitive intelligence needs to be promoted within the company. This need goes beyond the necessary training. A larger cultural change is required to get employees to embrace the value that CI can give to the company as well as to themselves. (Fleisher and Bensoussan, 2002).

Of utmost importance to the CI program, new or mature, is that it be ethically based. The professional organization for competitive intelligence, SCIP has a code of ethics that each member agrees to support and abide by. It is vital to the future of CI that companies comply with all applicable laws, respect confidentiality, and avoid conflicts of interest. (Prescott and Blenkhorn 2003).

The CI organization is most often embedded within the larger marketing and planning function. This practice is consistent with the need to assign a role to CI where it can best integrate with and improve performance. To a much lesser degree, CI might be found in the finance area (Prescott and Miller 2001). Although on the surface this might make some sense, marketing and planning is a better home for CI. A better home also requires the acceptance by those already in the marketing area.

If a competitive intelligence capability is to have any lasting effect on a company's performance, it should have its own organization and administration. How that organization may look is most dependent on how strategy and tactics are employed in the company. Should CI be centralized? Should CI be dispersed throughout the organization? If business units are mostly autonomous, with different needs, different products, and a different customer base, a decentralized CI function will probably be most appropriate and effective (Prescott and Miller 2001). On the other hand, if most of the strategy, planning, and tactics come from corporate headquarters, centralizing the competitive intelligence function is the correct approach. The most likely CI organization would be a hybrid of centralized and decentralized staff functions (Prescott, and Miller 2001). Regardless of where a company's CI function falls in this spectrum, ensuring the coordination between strategic and tactical intelligence is vital for enduring success.

VALUE MODEL FOR COMPETITIVE INTELLIGENCE

Determining the value returned by CI is problematic since only the costs of a CI program can be known with certainty, whereas the value returned is often speculative and circumstantial.

In an attempt to quantify the value of a CI program, the following model is proposed:

V (CI Program) = V (Opportunities) + V (Vulnerabilities) – CI Program Cost

Where:

V (Opportunities) is defined as the value of the opportunities discovered by CI and implemented by the company

V (Vulnerabilities) is defined as the value of the vulnerabilities exposed by CI and mitigated by the company

CI Program Cost is the total of the direct and indirect cost items attributed to the CI program.

V (Opportunities)

The value of discovered opportunities is defined as:

*Value (Opportunities) = CIPstrength / IndustryCompetitiveFactor * Company-Margin *AverageIndustry Sales*

Where:

CIPstrength measures managerial support, the level of IT infrastructure, and the competency of the company's CI program.

CIPstrength = ManagerialSupportFactor * ITinfrastructureFactor * Program-CompetencyFactor

ManagerialSupportFactor is the product of factors measuring CEO support, Officer support, and mid-level manager support.

Managerial support, especially at the CEO or Officer level, is an important and essential contributor to CI value.

ITinfrastructureFactor is defined as the product of assigned factors indicating Intranet (Yes or No), and the size of the IT department.

Intranet factor ≡ Yes =1.0, No = 0.5

An intranet is not essential to a CI program but the existence of one serves as an enabler of CI value.

IT infrastructure factor ≡ small = 0.5, medium = 1.3, large =1.5

More IT resources enable greater CI value, but diminishing returns play a role.

ProgramCompetency is the product of factors measuring program maturity, program staff size, staff experience, CI distribution, and CI culture.

Program maturity ≡ New = 0.9, Developing = 1.3, Experienced = 1.5

New programs may have missteps that actually diminish value, but developing and experienced programs are positive factors in measuring competency.

Staff size ≡ Small = 0.4, Medium = 1.0, Large = 1.5

Too small a staff can be overwhelmed by the enormity of the task – a larger staff is better (to a point).

Staff experience ≡ Low = 0.9, Experienced = 1.5, Expert = 1.9

The value of an experienced staff cannot be overstated.

CI distribution measures the degree of program centralization in relation to the number of strategic business units and is defined as:

*(CIfieldOfficeCount * CIfieldStaffCount / SBUCount*

A company with a diverse portfolio should be more decentralized than a company with only a few offerings.

CI culture ≡ Low = 0.2, Medium = 1.0, Strong = 2.0

The more CI is ingrained into the company culture, the better.

IndustryCompetitiveFactor is a factor that measures the degree of competitiveness in the particular industry. It is defined as the count of competitors in the top 50% of the market, divided by the difference between the market shares of the market leader and the market trailer in the top 50%.

IndustryCompetitiveFactor = CompetitorCount(top50%) / (LargestMktShare – SmallestMktShare)

Competition within an industry is good for the economy, but has an eroding effect on value. Competition is greater with a greater number of competitors, or where the difference in market shares between the market leader and market laggard is small.

CompanyMargin is the company's operating profit margin.

AvgIndustrySales is the average, per company sales within the industry.

V (Vulnerabilities)

The value of discovered vulnerabilities is defined as:

*Value(vulnerabilites) = IndustryCompetitiveFactor * CompanyMargin * AvgIn-dustrySales*

Full Model: **V (CI Program) = V (Opportunities) + V (Vulnerabilities) – CI Program Cost**

This model is one theoretical means for evaluating the value of CI for companies and is based on current thought and practice. There is a need for validation, testing and revision of the model.

CONCLUSIONS AND FUTURE RESEARCH

CI can no longer be ignored. It does, however, still struggle for mainstream recognition. Large businesses have embraced it to varying degrees, but medium and small businesses haven't yet accepted the idea and process of competitive intelligence. Another convergence will be necessary to firmly establish CI in the lexicon of business thought and process. Education in CI, and small business use of CI are separate issues, but together they will be the basis of the next leap forward for competitive intelligence.

From the small business perspective, typically there are limited resources, limited time, and little cushion to absorb strategic mistakes. CI can help avoid those mistakes, but CI consumes resources and takes time and therein lies the catch-22 facing small business and CI today. This is not to say that small business does not use CI, but given that small businesses comprise the largest segments of most free economies, CI is underutilized. The benefits and value from CI are not just under

the purview of large business – when small business recognizes this potential, CI will become an enduring means in the business world.

This paper provides a model for evaluating value to companies for establishing competitive intelligence initiatives. Future research might focus on empirical testing and analysis of this model for practical utility for companies. As more companies move in this direction it will become more imperative for companies to evaluate the cost/ benefit for their particular operations. Competitive intelligence will continue to play an important role in companies as global competition becomes even more apparent.

Critical Features in Business Processes Modeling

Vincent Yen, Wright State University, Dayton, OH 45435, USA; E-mail: vince.yen@wright.edu

ABSTRACT

There are quite few models in the literature for the analysis and modeling of business processes. However, there is not a model that is general enough to include all practical aspects of business processes for analysis. This is one of the major drawbacks for these models. The goal of this paper is to identify a set of critical features under which real business processes may be adequately represented and addressed. The paper first provides a brief review of definitions of business processes and workflows; next the assumptions contained in major models, and then propose a set of desired features in modeling.

INTRODUCTION

Business process (BP) management has been a very active area both in academia and software industry in the last two decades. Some of the reasons are: (1) value - every organization has the desire to improve the efficiency and effectiveness of BPs, (2) dependency – BPs are highly dependent on technologies, information technologies (IT) in particular, (3) opportunities - the fast paced progress in information technology (IT) over the same period of time creates opportunities for business process improvements, and (4) IT/Business alignment - a competitive business today requires IT to be aligned with core business processes. The BP software industry responses to the needs of businesses; over two hundred BP management software are available in the market place. Recently, business processes extend functions from internal processes to cross organizational processes, such as supply chain process. Further more by taking advantage of the Internet, the software industry is developing "Web services" standards; business process modeling languages (BPML) and business process modeling notation (BPMN) are two important standards for constructing business process over the Internet. However, BP software have not been lived up to its expectations because of limited capabilities and weakness of methods employed. Workflow management - a closely related field of BP - despite much research, it still lacks of conceptual frameworks and theoretical models (Kumar and Zhao, 1999). One critical issue underlying the weaknesses is the absence of a commonly agreed upon framework that more completely characterizes the modeling environment of BP or workflow. This paper represents an attempt to identify the set of important assumptions under which real complex business processes can be analyzed and modeled.

WHAT ARE BP, BPM, AND BPMS?

Interestingly, the phrase "business process" is easy to understand but difficult to define. At this time there does not exist a universally acceptable definition. Part of the reason may be attributable to the ever expanding scope of BP – scope creep as in systems analysis. Mackenzie (2000) describes "processes" consisting of *events*, a *time-dependent sequence of events, entities, elements, relationship between a pair of elements, links to other processes, resources, and outcomes.* Zur Muehlen (2004) describes a (general) *process* as "a discrete, holistic, temporal and logical sequence of those *activities* that are necessary to manipulate an economically relevant object." He views "*business process"* as a specific process and a workflow a specific representation of a process. Hammer and Champy (1994) define BP as a set of partially ordered activities aimed at reaching a well-defined *goal*. So there is a wide spectrum of definitions of BP.

On the phrase "Business Process Management (BPM)"? Aalst, ET al (2003) define it as : "Supporting business processes using methods, techniques, and software to design, enact, control, and analyze *operational processes* involving *humans, organizations*, *applications*, *documents* and other sources of *information*." BPM emphasizes the integration and management of business processes and *resources* across applications and business boundaries. And then there is the phrase "Business Process Management System (BPMS)". Weske, ET al (2004) proposes the following as the definition of BPMS: "A generic *software system* that is driven by explicit process designs to enact and manage *operational* business processes."

WHAT ARE "WORKFLOW SYSTEMS"?

Frequently in reading BP literature it is not uncommon that workflows were treated synonymously with BPs. According to the Workflow Management Coalition (WfMC) the *workflow* is:

"The automation of a business process, in whole or part, during which documents, information or tasks are passed from one participant to another for action, according to a set of procedural rules."

A *Workflow Management System* (WfMS) is defined as: "A system that defines, creates and manages the execution of workflows through the use of software, running on one or more workflow engines, which is able to interpret the process definition, interact with workflow participants and, where required, invoke the use of IT tools and applications."

Thus, a "workflow" defines who is next to performing the action according to a set of rules within a business process; a WfMS is a software system supports enactment of multiple workflows. Clearly there is a considerable similarity between the notion of BP and workflow, so does BPMS and WfMS. From now on workflow is viewed as a specific representation of BP (Muehlen, 2004). Next, we provide a review of the dimensions under which current BP/workflow models assume.

FEATURES IN BP AND WORKFLOW MODELS

1. Features of Business Process and Workflow Models Discussed Above.
   BP and WF discussed above involve such features as: *events*, *entities, elements, relationship between a pair of elements, links to other processes, resources, humans, organizations*, *applications*, *documents*, *information, goals, and outcomes.* A more comprehensive modeling of BP should have all those features although at the expense of higher complexity. Curtis, Kellner and Over (1992), and Kwan and Balasubramanian (!997) describe a framework for process and workflow modeling. They classify majority of these features into four critical dimensions, namely; *functional, behavioral, organizational, and informational.* However, their modeling is carried out by using separate modeling tools as opposed to an integrated setting.
2. Classification of Business Processes and Workflows
   Different categorization of BPs has been proposed. Melao and Pidd (2000) articulate pluralistic and multidisciplinary modeling approaches to BP. They classify BP into four categories; *deterministic machines, complex dynamic systems, interacting feedback loops, and social constructs* (BP is viewed as a subjective construction of the minds of people); not necessarily mutually independent. Other classifications of BP exist, for example; strategic, tactical, and operational processes; and system-to-system, system-to-human (and vice versa) processes. However, work/research has been done mainly on operational processes. Other categories of workflows are: *production workflow, administrative workflow, ad hoc workflow, and collaborative process.*
3. Competing BP Modeling Methods and Languages
   Depending on the purpose of the business process/workflow model, researchers propose different modeling techniques. They range from graphical languages to formal mathematical constructs. Here are major models/languages:
   i. **Petri Net**

The classical Petri net (Petri 1962) is a graphical process modeling language.

Workflow processes can be mapped to Petri nets and it is possible to incorporate resources (Aalst, 1994). However, modeling workflow systems with classical Petri net has many limitations. Three well-known Petri net extensions have appeared: (1) the extension with color to model data, (2) the extension with time, and (3) the extension with hierarchy to structure large models. This belongs to the category of complex dynamic process modeling.

ii. **Pie Calculus**

The founder of the Pi calculus is Robin Milner (1999). Briefly, the Pi calculus is a formal language for defining concurrent, communicating processes, including, but not limited to, business processes. Smith H. and Fingar P. (2003a, b) claim that Pi calculus inspires a breakthrough in the representation and execution of business processes, and is used by the new Business Process Management Systems (BPMS). A written detailed proof of this claim is not available (to the author's knowledge) at this time.

iii. **The Language/Action Perspective**

The language/action perspective (LAP) as originally introduced by Winograd and Flores (1986) has been applied to BP and workflow modeling (Weigand and Moor, 2003; Goldkuhl, 1996). The theme of the perspective is BP and workflow models contain *coordination* activities that use *communication process* that can address at the social level as the central means for achieving it; not simply by using data (viewed as a form of limited communication) analysis as in Petri nets.

iv. **State-Oriented Business Process Modeling**

Bider applies mathematical system theory to model business processes. He envisions business processes as dynamic goal-seeking processes in which process control acts as a mechanism for choosing activities that can move from the current state to the nearest final goal state.

v. **Trigger Model**

The trigger model (Joosten, 1994) is developed to describe a workflow as a dynamic system in terms of triggers. An event "e" *triggers* an activity "a" if the occurrence of "e" causes "a" to be performed. The trigger can be an event, activity and actor. A workflow system consists of *activities, roles* and *triggers* and activities are related to one another by a trigger relation, or triggered by external events. The trigger model can be mapped to a Petri-net.

vi. **Metagraphes**

Basu and Blanning (2000) utilize a graph-theoretic construct called a metagraph to analyze connectivity and interactions issues of activities, information and resources between workflow components. The approach may also model activity procedural constraints.

vii. **Event-Driven Process Chains**

A modeling approach (Scheer, 1998) adopted by SAP as the key component of SAP's enterprise resource planning system. Modeling includes analysis of: responsible entities and their relationships function (activity) flow, output flow, information flow, control flows, resource flows, human output flows, consolidated business process model, and a business process meta-model.

viii. **Business Process Modeling Language (BPML) and Business Process Modeling Notation (BPMN)**

As parts of the Web Services technology, BPML and BPMN provide standards for constructing business processes over the Internet. It has modeling elements: Events, activities, data objects, message flows (the flow of messages between two entities), and associations (to associate information and artifacts with flow objects). The area is new and is predicted to have a huge impact in business, industry and software sectors.

ix. **Unified Modeling Language (UML)**

UML is developed as a computer aided software engineering (CASE) tool, but it can also be used for general business process modeling capable of representing all important features. However, it lacks the theoretical basis.

CRITICAL FEATURES IN SUMMARY

To summarize, critical features for a modeling system should consider the following:

i. Key elements in modeling

Common elements used in modeling are: Procedure, task, information object, role, actor, goal, resource, event, responsibility/authority, state, constraint, rule…

ii. Modeling perspectives

It would be desirable to include multiple perspectives and functionalities in the modeling environment; for example, function, behavior, organization, information, social constructs, coordination, and system dynamics.

iii. Graphics and rigor

Because of the complexity of BP and workflow systems, any modeling approach would be made easier if it is accompanied by a graphical support tool. In addition, it is imperative that a model is created with a sound theatrical basis.

CONCLUSION AND FUTURE RESEARCH

Business process and workflow systems are important and practical. Knowledge of this area has grown significantly and is rather broad for study and research. A critical pre-condition for defining area of study/research is to define the required features of the modeling environment. This paper has come up with a recommendation of a set of features that a modeling environment should provide. Current developments by software industry are in standardizing business process language and notation under the Web services platform. Also, they are expected to impact the design and construction of new BP systems, cross organizational systems in particular.

ICT Management Issues in Healthcare Coopetitive Scenarios

ABSTRACT

In this paper we will outline some issues that the management should address in ICT projects framed within networks of healthcare delivery. Networks of independent healthcare service providers (e.g. specialized hospitals, laboratory analysis, family doctors) are getting very common. In such scenario, data sharing activities among different actors are very common and ICT is a pregnant technology. Concerning the ICT project management, the traditional hierarchical management model is not feasible for network contexts. The management can't rely on traditional hierarchical approaches, but should switch to a negotiation model, through which the desired goals has to be reached by means of negotiation with the independent actors involved in the project. We will illustrate these topics through a case study, afterward we will outline some requirements that a project manager profile should have in order to manage appropriately ICT projects framed in network of independent actors.

1. INTRODUCTION

Healthcare processes are very complex, even a simple one (e.g. the request for medical analysis) may involve different actors (family doctors, analysis laboratories, specialized physicians, administrative staff) providing several services. More complex services are present in a network scenario. "Currently, the situation of healthcare in Europe and in the U.S. is characterized by a process of transition, where isolated hospitals and individual practices are merging into networks of healthcare delivery" (Kuhn, Giuse, 2001).

From one hand, ICT can play a big role in this scenario: it can improve the coordination and the information sharing among the several providers involved in a healthcare process, whereas these tasks traditionally have been committed to the citizen/patient. E.g. the citizen contacts a service provider and asks for a service (e.g. she/he books for laboratory analysis), collects the analysis results and reports them to the family doctor. This is just an example, some more can be provided.

On the other hand, "it has even been stated that there is an 'absence of real progress [...] towards applying advances in information technology to improve administrative and clinical processes" (Hurtado et al., 2001).

In the sequel of the paper, we point out that in large ICT based healthcare projects (especially in the context of networks of healthcare delivery), some project management issues may frustrate a positive application of ICT technologies.

In Sec. 2 the peculiarities of networks of healthcare delivery will be analyzed, in Sec. 3 we will provide an example framed in a network context that will be used as a reference in the following sections, in Sec. 4 some project management issues will be outlined, and finally Sec. 5 will draw some conclusions.

2. COOPETITIVE NETWORKS OF HEALTHCARE DELIVERY

Healthcare scenarios where different actors and institutions (hereafter entities) collaborate in providing healthcare services are examples of the network model described in management literature. The network model is characterized by a set of independent, loosely coupled nodes that collaborate to provide complex services.

The network model has advantages and drawbacks, that we will illustrate shortly. The companies, actors, organizations (hereafter nodes or actors) being part of the network may easily build ad hoc relationships, therefore very different actors can get in touch and collaborate. Furthermore, the nodes can easily replace partners with similar ones. This fosters innovation, creativeness, and competitiveness. Considering the network model drawbacks, the loose relationships requires a lot of coordination effort among the involved actors, which are characterized by different cultural background, different interpretation framework, and different information management capabilities.

Frequently the coordination effort among the several actors involved in the provision of a healthcare service is up to the final customer, an example has been cited in the previous section, where a citizen books for analysis, later she/he has to collect the results and bring them to the family doctor. The shift of coordination effort from the patients to the service providers requires to establish collaboration among the healthcare service providers, which however are competitors.

Such a interaction among the competitors may be modelled by making use of a "coopetitive behaviour". The term coopetition is used in management literature to refer to a hybrid behaviour where the actors cooperate in some areas while compete in some others. In a healthcare networked scenario, collaboration concerns the patient data sharing among different providers to coordinate combined healthcare processes, while competition concerns the research of customers to which provide services. Some authors (Brandenburger et al., 1996) (Gnyawali et all., 2001) (Lado et al., 1997) have recently emphasized the increasing importance of coopetition for today's inter-firm dynamics.

Information management is a strong issue in the just introduced scenarios, and can be addressed by the federation of information systems. Federated information systems for coopetitive settings have been studied in (Cesarini, Mezzanzanica, 2006).

Next section will describe a case study and an ongoing ICT project that will be used as reference in the subsequent sections.

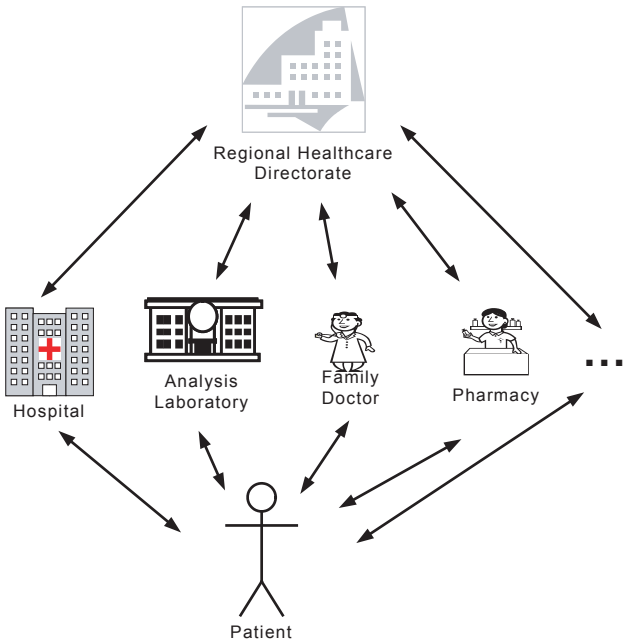
3. THE LOMBARDY CASE STUDY

In this section we are presenting the healthcare model actually deployed in Lombardy (a region in Italy), which is an example of a networked healthcare setting, as well as an ICT project that is currently ongoing. The actual healthcare model in Lombardy is the result of the evolution of a public (state based) healthcare provisioning model. The healthcare services are delivered both by public structures and by private ones. Citizens are free to select the service provider, which is paid by the state on a reimbursement basis. The citizens do not pay directly for receiving healthcare services (except a minimal pay-per-use fee). In this context, the private and public actors providing healthcare services, share administrative information with the Regional Healthcare Directorate (the public administration responsible for the healthcare service provisioning) in order to compute the total expenditures and the reimburses (Lombardy H.C. Directorate, 2003).

The coordination among the different entities involved in the provision of a combined service is actually up to the patient, especially concerning the medical information sharing, as reported in Fig. 1.

An ongoing project, whose name is SISS (Sistema Integrato Socio Sanitario, which is the Italian for "Social Healthcare Integrated Information System"), is experimenting a new way of sharing patient medical information among different service providers. The core of the SISS project is a federated information system, which connects all the entities offering healthcare services in Lombardy,

Figure 1. Before the introduction of the SISS. The patient was the responsible of sharing information



and which can be used to share medical information (e.g. clinical records, medical prescriptions, x-rays pictures, laboratory analysis), as showed in Fig. 2. For example, the SISS will allow a family doctor to access the patient data (e.g. the x-ray analysis committed to a laboratory or the clinical records related to the last hospitalizations) hosted by other entities directly by its PC.

In addition to sharing medical data, the SISS can be used to reserve physical examinations and laboratory analysis by each entity connected to the system. Furthermore, the SISS is used to provide statistical information in real time to the Regional Healthcare Directorate.

The project is structured on three phases: prototyping (performed on a small area), validation, and large deployment (on the whole regional area). The project is on-going and it is currently on the large deployment phase. The project is managed by a project management committee (central project management or CPM hereafter) and the management activities involve the local ICT managers (LPMs hereafter). The latter are people responsible of the ICT facilities within the connected entities (e.g. hospitals, laboratory analysis, pharmacies, family doctors). In case of simple actors (e.g. pharmacies and family doctors) the ICT manager role is carried out either by the actor her/himself or by a representative. In most cases the local project manager is a person already present in the local organization structure.

4. MANAGEMENT IMPLICATIONS

Some critical issues emerged during the prototyping and validation phases of the SISS project, as reported by the project management and audit documentations.

Some considerations should be drawn before analyzing the emerged issues. The SISS is an information system created with the aim of supporting the circulation of medical information and more generally the provision of complex healthcare processes, where different actors, not necessarily having already established relationships, are involved. The processes provided by means of the SISS relies on the carry out of "local tasks" (i.e. local business processes), a single local task failure is likely to cause the failure of the whole aggregate process (e.g. should a laboratory not provide analysis results to the SISS for any reason, the processes relying on this information cannot start). The local tasks should be supported by both the local information system and by the local business processes, which should have been adapted to the requirement of the SISS project.

The issues emerged during the project phases, the reasons, and the actors involved have been shortly summarized in Tab. 1.

The emerged issues were mainly ICT related, however a deeper investigation showed that the main problem was a lack of communication among the CPM and the LPMs, which was caused both by an inadequate project governance model and by some cultural gaps.

Concerning the project governance, the local managers have not been effectively involved, they were just consultant and not decision makers during the planning and prototyping phases, consequently the central project management underestimated the impact that the decisions would have had on the local involved entities (especially the large and complex ones) and on the time necessary to carry out changes. Although the CPM performed a deep survey and evaluation of the local entities, ICT infrastructures, and processes, the scarce implication of the local ICT Managers in the decision making activities resulted in a poor project management.

Considering the cultural gap, the novelty of the exploited technologies, created difficulties for the local ICT managers[1]. A lot of local ICT managers were

Figure 2. After the Introduction of the SISS. The Patient's data can be accessed by every actor

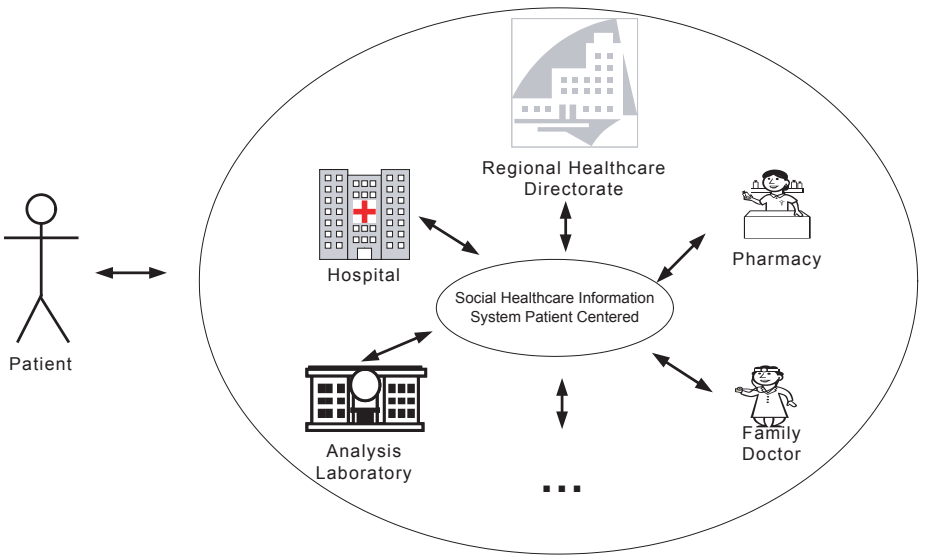


Table 1. Chronological report of the project phases, actors involved, emerged issues, their rationale, the corrective actions carried out. Differences from a phase to the following one have been highlighted. The non relevant cells have been left empty

Project Phase	Actors and Interpretation Framework GAP (IFG)	Emerged Issues	Reasons	Corrective Actions
Project Planning	• CPM (Decision Making Role) o No IFG on technology o High IFG on local organizational impact • LPMs (Consulting Role) o High IFG on technology o Low IFG on local organizational impact			
Prototyping	• CPM (Decision Making Role) o No IFG on technology o High IFG on local organizational impact • LPMs (Consulting Role) o High IFG on technology o Low IFG on local organizational impact • Users (Entities) • Users (Patients)	• Long service inactivity time • Long malfunction time • Huge users disappointment • Huge delays • System low performances • Not adequate improvement of local processes and ICT infrastructures • The delay and malfunction times were **quite higher with respect to the time necessary to implement technical and organizational changes in the local entities**	• Distance among the interpretation schema of CPM and LPMs about o Change processes o Technologic innovation processes o Time and expected results • Poor involvement of the LPMs in the project global decision making activities • Poor feed back activities to the CPM • Lack of project vision understanding by the LPMs	• Improvement of the management model o Actively involve the LPMs in the CPM decision making activities o Substitution or training of some LPMs • Project timelines modification to take into account the time necessary to perform the local changes
Validation	• CPM o No IFG on technology o High IFG on local organizational impact • LPMs o High IFG on technology o Low IFG on local organizational impact • Users (Entities) o High IFG on technology o Low IFG on local organizational impact ~~o Users (Patients)~~			
Large Deployment	• CPM o No IFG on technology o **Low** IFG on local organizational impact • LPMs o **Low** IFG on technology o Low IFG on local organizational impact • Users (Entities) • Users (Patients)	Work in progress	Work in progress	Work in progress

involved, each having different skills and knowledge, however some of them were unable to understand the project vision and the changes to enforce on the local infrastructures and business processes. Some local information systems not properly connected could be considered a negligible topic, however we recall that a failure in the provision of a local process is likely to cause the failure of any related global process. The cultural problems can be summarized by saying that there was a high gap among the interpretation framework of the CPM and the interpretation framework of the LPMs.

The CPM decided to focus initially on the governance and cultural gap issues and to address later on the ICT ones. Two corrective action were adopted: the LPMs have been effectively involved in the central level decision making activities; some of the LPMs have been replaced or trained. The participation to the decision making activities helped the CPM and the LPMs to fill the gap among their interpretation framework. In the large deployment phase the local ICT managers (of the new entities involved) were able to understand the project vision and to correctly modify the existing local ICT infrastructures and business processes. Furthermore, they correctly estimated the impact of the SISS projects on the local entities, so they were able to provide feed backs to the CPM about delays and project improvement, that could affect the global project timeliness and deployment. The governance approach initially adopted contradicts the logic underlying the network scenario where the project is enacted. The initial approach relies on hierarchical relationships that are not present among the CPM and LPMs, while the approach adopted later relies on negotiation among CPM and LPMs, which is a far better approach in a network of loosely coupled entities.

We will outline briefly the requirements that the ICT management should satisfy, in order to be able to manage appropriately ICT projects in healthcare (and in other fields as well) framed within networks of loosely coupled entities. The project manager should identify the most significant management profiles involved in the

project. Meetings should be established as well as other ways of sharing knowledge among the identified people. The goal is to fill the people interpretation schema gaps and to integrate their different competences into a steering committee, in order to support the project design and enactment. The project manager could also encourage the involved people to participate to training activities in advance.

The cooperation management is a very important risk factor as well. The traditional hierarchical management model is not feasible in a network context (of loosely coupled institutions), because there are no direct hierarchical relationships among the involved entities. The management should switch to a negotiation model, through which the desired goals has to be reached by means of negotiation with the involved actors. In this streamline, it could be useful to negotiate in advance with the involved people that the project organizational logic should be different from the local (most probably hierarchical) ones.

5. CONCLUSIONS

In this paper we described some requirements that a project manager profile should have in order to successfully manage large healthcare projects having an ICT characterization. We focused on a specific scenario, called networked scenario, where a network of loosely coupled actors (both people and institutions) operate to provide healthcare services. Such a scenario has been identified as the direction of an emerging trend in the healthcare market, therefore it deserves special attention. Furthermore, many promising projects in such a scenario are ICT based. An important risk factor in those projects is not technological related, but concerns communication among the decision makers within the nodes involved. The cultural gaps are strong barriers to the cooperation, which is necessary to carry out projects in networked scenario. We claim that the managers' poor ability to handle appropriately these factors may cause the failure (or the poor revenue) of an ICT project. We have briefly pointed out the skills that a project manager should have in order to successfully manage ICT based projects in networked scenarios (framed in the healthcare domain). We can summarize them by saying that the manager should identify the most significant management profiles involved in the project, should actively involve them in the project management committee and should overcome all the cultural gaps. The traditional hierarchical management model is not feasible in a network context cause the absence of direct hierarchical relationships among the network nodes. The manager should be able to negotiate with the involved actors in order to reach the project goals.

Hassan Pournaghshband, Southen Polytechnic State University, USA; E-mail: hpournag@spsu.edu
J. Stephanie Collins, Southern New Hampshire University, USA

ABSTRACT

Software engineering, database and data warehouse technology are closely related to each other despite being separate disciplines. In this paper we discuss how software engineering, database and data warehouse technology are inter-related and gain benefits from each other. We also examine the critical technical and managerial issues required to enhance potential benefits used in structure and/or object-oriented paradigms. We present recommendations and guidelines for applying Concurrent Engineering (CE) principles to software engineering, database and data warehouse technology.

1. INTRODUCTION

Engineering is defined as [1]: The *profession* in which a knowledge of the *mathematical* and *natural sciences* gained by study, experience, and practice is *applied with judgment* to develop ways to *utilize*, economically, the *materials and forces of nature for the benefit of mankind.* Software (including the user interface), database, and data warehouse engineering are by definition a kind of engineering, and therefore carry the same set of social responsibilities as all of the other kinds of engineering [2]. Common engineering processes, such as requirement analyses, design, implementation, testing and maintenance are applied to software, database, and data warehouse engineering in the same way as other branches of engineering including civil, electrical or chemical engineering. However, software, database, data warehouse engineering are subject to particular frequent changes, including those imposed while a product is under development [2].

Software, database, and data warehouse engineering are different disciplines with common related issues and processes. We examine the differences among these disciplines and relationships and provide some of the potential benefits. This paper discusses how concurrent engineering is applied to software, database, and data warehouse technology. Comparisons of software and database technology have been made in the literature [3, 4]. In this paper we extend the research to 1) data warehouse engineering; 2) uses of structure and/or object-oriented paradigms; and 3) the role of concurrent engineering.

2. RELATED DISCIPLINE AMONG SOFTWARE, DATABASE, AND DATA WAREHOUSE ENGINEERING

Various methodologies and principles are proposed for software, database, and data warehouse technology [2, 5, and 6]. However, they are related in many aspects as mentioned below:

a. Project Planning – All three disciplines are required to do the project planning. A *SWOT analysis* that examines a company's strength (S), weaknesses (W), opportunities (O), and threats (T) can be used in software project analyses. The questions asked often lead to information technology related issues, which in turn requires further review, analysis, and planning [7]. Other techniques such as 1) understanding the problem or opportunities, 2) defining the project scope and constraints, 3) performance of fact-finding, 4) evaluating feasibility-operational, technical, economic and schedule feasibilities, 5) estimating project development time and cost, and 6) readiness "Litmus test" [6], can apply to all disciplines. Front end and risk reduction analysis is usually applied to large projects and are also applicable to all three disciplines.
b. Requirement Analysis – Techniques to obtain requirements such as interview, questionnaire, sampling (systematic, stratified, or random) as well as modeling (such as the use of a UML use case diagram or activity diagram) is similar in software, database, and data warehouse technology. Note that in many instances, a database or data warehouse requirement starts when the software engineering requirements are finished. We discuss this issue in more detail in section 3 with recommendations of concurrent requirements for all disciplines involved.
c. Design – If object-oriented methodology is used, then the class diagram is a *superset* of the E-R diagram or dimensional diagram. Therefore, the class diagram should be used for both the logical and physical model of a database or data warehouse. The database and/or data warehouse modeler should become familiar with the class diagram and not use an E-R diagram and/or dimensional diagram. If there are design conflicts between the disciplines involved, then concurrent engineering techniques should be applied to resolve the issues as discussed in section 3.
d. Implementation – There should be a single coding, database and data warehouse standard that can be shared among these disciplines.
e. Testing – Use case scenarios can be used as testing scenarios in each of the software engineering, database and data warehouse technology disciplines. Other methods used in unit, integration, system, acceptance and regression test can also be applied in all disciplines
f. Maintenance – Procedures and guidelines (such as: traceability) used to maintain a software engineering project can apply to database or data warehouse technology projects.
g. Tools – There are various tools that cover different spectrums of SDLC. The selection of CASE tools is discussed in the literature [8, 9]. However, one should attempt to obtain a CASE tool that can be used in a multi-discipline environment.
h. Versioning and Configuration Management – Appropriate versioning techniques and metrics are required to map different versions of the software, data base schema and data warehouse schema. The techniques and tools for configuration management can be shares among these disciplines.

3. CONCURRENT ENGINEERING

There are many definitions of CE such as [10, 11 and 12]: systematic approach to integrated and concurrent development of a product and its related processes. Concurrent engineering emphasizes a response to customer expectations and embodies team values of cooperation, trust, and shared-decision making. It proceeds with large intervals of parallel work from all lifecycle perspectives, and is synchronized by comparatively brief exchanges to produce consensus. Concurrent Engineering can be defined as the integration of interrelated functions at the outset of the development process in order to minimize risk and reduce effort down-stream in the process, and to better meet customers' needs. Multifunctional teams, concurrency of product/process development, integration tools, information technologies, and process coordination are among the elements that enable CE to improve performance.

Software systems architecture has four basic components, namely: 1) *presentation* component which is a system interface with the user such as a web, graphical user interface, or voice response unit. The user interface engineer works on this component. 2) *process* component which defines what software component (or objects in the case of object-oriented systems) to be processed by the business rule component. A software engineer works on this component. 3) *business rule* component processes the business rules of the organization dictated by a process component. Business rules are usually dynamic and implemented by a rule engine. Software engineers work on this component. 4) *data access* component retrieves, inserts, updates, or deletes data from the database and/or data warehouse. All SQL (Structure Query Language) commands are written in this layer if a relational database is chosen for the system. Database and data warehouse engineers work on this component. Database and data warehouse engineers are also responsible for the logical and physical design of a database and/or data warehouse. Normalization techniques (usually a third normal form) is used to avoid redundancy in the database design. A *dimensional* model is used in a data warehouse that allows redundant data. Figure 1 shows typical software components. This process is *sequential:* the activities from one activity are handed off to the next only after completion. There is little or no cross-communication among various functions [13].

Figure 2 shows concurrent engineering applied to in software, database and data warehouse engineering. This process has extensive overlap and the team structure is multifunctional. For example, when a UI engineer is working on the design of a screen, the database engineer reviews and gives its feed back to UI engineer to ensure appropriate criteria is met. That may include information such as, if the implementation of the screen requires a nine way join between the underlying tables, then the database engineer recommends the screen be changed to one that requires a smaller number of joins (like two or three) to meet the performance criteria. Although concurrent engineering requires challenging coordination, it reduces the time to market, major iterations and increases overall project performance. Concurrent engineering requires extensive use of information technology tools including coordination tools.

The recommended guidelines for concurrent engineering are [13]: 1) define and formalize the CE process. 2) define all overlapping of activities. 3) identify process ownership. 4) set clear, quantitative goals.

Figure 1. Software system components

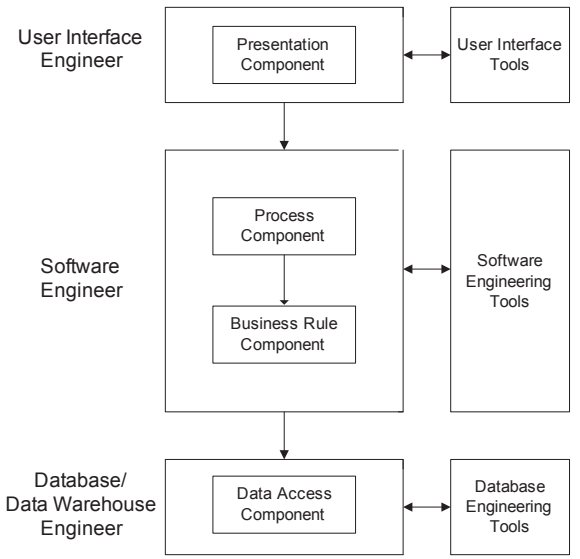

Figure 2. Concurrent engineering: Software, database and data warehouse engineering

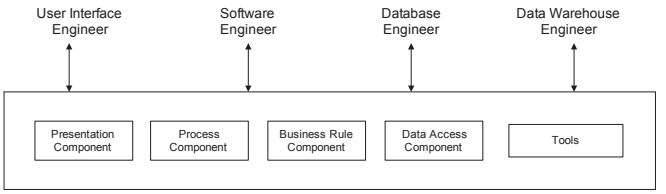

4. CONCLUSION

Software engineering, database, and data warehouse technology are three different disciplines. However, these technologies are in many ways related to each other and can benefit from each other. We survey what has been done regarding this issue, and discuss what else can be done to further clarify the roadmap. Concurrent engineering is widely used in manufacturing. The application of concurrent engineering principles in software engineering, database, and data warehouse technology were discussed. Further research is required to obtain numerical data (such as time to market, reliability, and maintainability) for projects that are implemented using concurrent engineering verses traditional engineering methods.

Collaborative Business Process Engineering "CPBE" Across Multiple Organisations in a Cluster

Abbass Ghanbary, University of Western Sydney, Australia; E-mail: ghanbary@scm.uws.edu.au
Bhuvan Unhelkar, University of Western Sydney, Australia; E-mail: bhuvan@scm.uws.edu.au

ABSTRACT

This paper introduces the concept of Collaborative Business Process Engineering (CBPE) within the context of multiple organisations in a cluster. Collaborations are facilitated by the technologies of Web Services (WS) and Mobile Technology (MT). This paper demonstrates how the interoperability of WS results in electronic collaboration of businesses. Furthermore, this paper uniquely describes how cluster-based processes of multiple organisations can be engineered so that they are integrated even when the organisations are not necessarily known to each other. The subsequent effects of this interoperability on their business processes of the collaborating group of organizations including the business structures and the mechanisms to reengineer those business processes are discussed.

Keywords: Collaborative Business Process Engineering, Web Services, Mobile Technologies, Collaboration.

INTRODUCTION

This paper introduces the concept of Collaborative Business Process Engineering (CBPE) as distinct from the traditional Business Process Reengineering (BPR). Engineering of collaborative business processes does not appear to have been addressed previously in the formal literature. Furthermore, the impact of Web Services and Mobile Technologies on engineering collaborative business processes is also studied. Finally, an approach to transitioning to collaborative business processes is mentioned.

The approach to this research encompasses creation and validation of the model for CBPE. This initial paper outlines the model and approach to its validation. Selected methodologies for this study are the combination of *Interpretivist* and *Constructive* approach. Interpretivist approach is a combination of descriptive and interpretive research. It will focus on group of objects under investigation. The interpretivist approach confronts the difficulties presented by the nature of the research domain, and in particular the intangibility of many of the factors and relationships of the researcher within the research domain.

Action research is also considered to be one of the suitable methodologies for this study. By observation and recording the daily activities of the organisations the research can evaluate the existing business processes to identify what kind of business processes will be affected after the engineering process. Furthermore, action research aids this study to evaluate how to get these organizations to collaborate with each other and how people, process, technology and the infrastructure of the organizations will be affected.

Constructivist approach is the fundamental tenet of constructivist philosophy indicating that interpretivism is about contextualised meaning, and that reality is socially constructed. The constructivist paradigm, therefore, provides the assumptions, the rules, the direction, and the criteria by which research is conducted. The solution recommended by this study will use constructive methodology to present the new designed model of collaboration by multiple organizations.

This study will investigate the impact of the collaboration on social system (people *"trust"*, reward *"why collaborate"* and authority structure *"who is in charge of the collaboration"*) as well as technical system (processes *"before and after engineering"*, tasks *"security*, *convenience and availability of the channels"* and technology *"web services" and "Mobile Technology"*).

RESEARCH AIM

The aim of the research is to identify how Web Services could facilitate interoperability amongst multiple organizations that result in collaboration of business processes.

Arising from the research aim there are several research questions that need to be studied. They are as follows:

- What is the interoperation nature in existing practice (model) of collaboration?
- What is the impact of interoperability emanating from Web Services on organizations that collaborate electronically? (Here we study the dynamic aspect of collaborations wherein organizations can enter and exit the collaboration at will)
- What are the characteristics and the mechanisms to model collaborative business processes that transcend organizational boundaries as against business processes within a single organization?
- What are the factors influencing collaborative business processes? (such as trust, security, confidence level and availability of channels)
- Is the constructed model efficient and profitable for these organizations?
- Are there viable alternatives?

BUSINESS PROCESS RE-ENGINEERING

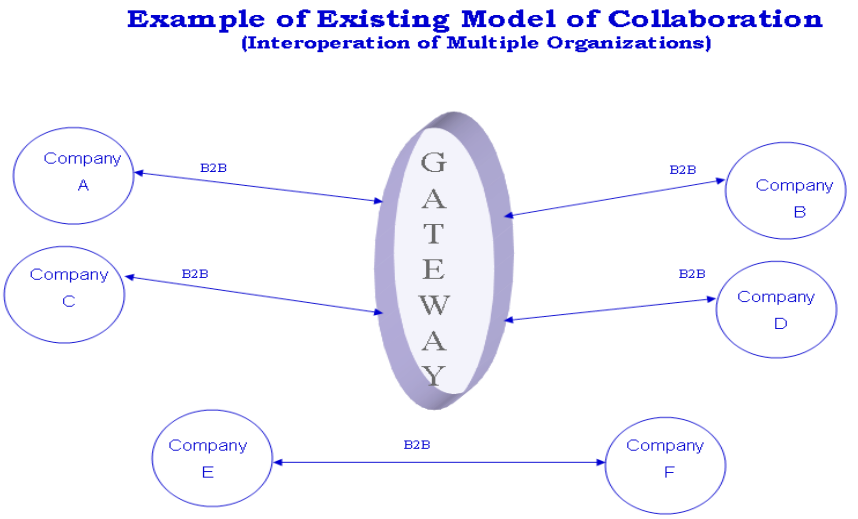
A business process is a continuous stream of business activities. Every process has some linkage to other processes. An isolated process that has no relevance to any other process in delivering a product or a service to a customer may have little business value to the organisation (Australian Computer Society).

Hammer and Champy (2001) describe the term "Reengineering" as a fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in a critical, contemporary measure of performance such as cost, quality, services and speed. Reengineering a company's business processes ultimately changes practically all aspects of the company including people, jobs, managers and values that are linked together. These impacts on businesses seem to have been studied under reengineering thus far.

However, the main focus of this study is to investigate into the collaboration of business processes that transcend beyond the processes of a single organisation. Bergenti et al (2002) defines collaboration as an activity of a group of people, which is a virtual team that exchanges information among members. This collaboration between multiple organisations is not taking place in a formal manner in the existing technical and business environment that requires "engineering" of new processes that are integrated across multiple business organisations.

Most re-engineering discussions until now concentrated on the business processes internal and belonging to a single organisation. All investigations related to a process within the boundary of the business that extended to another "known" business, resulted in what is described Business to Business (B2B). An alternative collaboration in regards to multiple organisations is possible when a gateway is

Figure 1. Existing environment of collaboration



sitting in facilitating the interactions amongst the organisations as illustrated in Figure 1.

This demonstrated gateway in figure 1 is the only existing channel of collaboration between the two organisations (ordinary B2B model). The model presented in figure 1 clearly demonstrates the shortcoming of collaboration since the organisations are not in direct contact with each other. The Gateway (an individual organisation) can collaborate with many other organisations. For example, your bank (Gateway) can pay different bills to different service providers (electricity, water, phone service) through their BPay addresses. Figure 1 is an illustration of the existing environment of collaboration based on the authors' observations.

Conversely, this study focuseses on cross-organisational processes. The new engineered processes must be able to collaborate and negotiate with the organisations that are not necessarily known to each other and that may have different technical environments. Processes running through multiple organisations are the main concentration of this research. Goethals and Vandenbulcke (2006) explain that Web Services may be used for integrating systems for unknown parties. In this type of situation the infrastructure used should be built in such a way that it can easily be adapted to new requirements.

Curbera et al (2003) state that Web Services provide generic coordination mechanisms that can be extended for specific coordination protocols. Such coordination includes the execution of short-running transactions within an organisation (similar to traditional distributed transactions) and long-running transactions across organizations.

Furthermore, Fong (2005) arguess that the limited empirical evidence of successful e-collaboration is attributed not only to the short history of e-collaboration and software, but also to the challenges associated with this revolutionary way of operating and sharing information.

The challenges of e-collaboration are mainly classified where individual organisations use varying technologies and data standards that give rise to islands of networks that now need to be integrated and coordinated. Web Services can solve this problem since the WS is a new kind of web application. WS are the independent application components that take the web to new stage of development in which the other software applications can transmit and receive the required data disregard to their existing platform under operation.

As per Ghanbary and Arunataileka (2006) the technology has increased the connectivity all around the globe. Organization are globalizing faster than ever before. The global technology advancement has raised the expectations of people in their work conditions and living standards. The customer is better informed with the availability of information at their finger tips over the Internet. The Internet also has offered a window of opportunity for users to purchase products and receive services on a global scale.On the other hand the WS gives the opportunity to web applications to be discovered by other software components to conduct their business transaction.

Table 1 distinguishes between existing collaboration and the recommended way of collaborating by this study.

Table 1. Recommended investigations of the study (based on Ghanbary, 2006-Innovation Conference UWS)

Existing Model of Collaboration	CBPE (Research)
Web Services *(Dedicated)*	Web Services *(Open for research)*
No interoperation amongst organisations	Identify the issues involved in *interoperation*
Organisation must know each other to collaborate (B2B)	Organisations collaborate without knowing each other
	Their business processes will be "Engineered" in a way to collaborate
Pre-Qualification is necessary for collaboration	Identify the channels of collaboration (No qualification is required)
	Investigates trust issues between multiple organisations
	Create security for the *Engineered* channels
	Investigate the availability of the channels

Table 1 identifies that in the existing model of collaboration the full potential of the WS is not extracted, while the study will develop a model in order to exploit the full potential of WS for CBPE. Goethals and Vandenbulcke (2006) address the shortcomings of WS by arguing that many WS standards have been developed, but most of these are still immature and do not fully answer the expected challenges.

FACILITATION BY TECHNOLOGY

Emerging technologies, such as information and communication technologies (including future versions of the Internet), microelectromechanical systems, nanotechnologies, genomics, robotics, artificial intelligence, and sensors, provide enormous opportunities for enhancing health and quality of life (Eng, 2005).

The communication technologies are providing the basis for most business processes reengineering. On the other hand, mobile technologies and web services are the technologies that can be considered as the emerging technologies of today. They are creating dramatic transformation in all aspects of business and personal lives around the globe. The specific issues to be considered in the context of this study are, of course, the manner in which these technologies are influencing the business world. However, since the business world itself is a part of the overall socio-cultural fabric of the society, it is also worth considering the impact of these emerging technologies on the society in general.

As correctly pointed out by Unhelkar (2005) mobility has had a significant impact on the quality of life of individuals and the society in which they live. While the location-aware mobile connectivity has dramatically increased the ability of individuals to communicate, it has also produced challenges in terms of privacy and new social protocols. The effect of globalization now needs to be further considered in the context of a global-mobile society. Stacey and Unhelkar (2004) describe WS as a promise to expand and enrich the existing distributed computing arena with their ability to connect disparate systems and allow communication between them from anywhere and on any platform. Web Services promise to revolutionise the way in which companies interact with each other and also how they come together or discover each other to form business alliances.

The need arises to consider multiple aspects of the technological transformation, as mentioned above, due to the fact that the current transformation could be considered as one of the most thorough and significant changes to people and society since, perhaps, the industrial revolution of the 18th century. These major socio-cultural changes will also definitely affect the next and upcoming generations of businesses in various ways that may not be obvious at this stage. For example, business processes transgressing organisational boundaries would require unique business arrangements and agreements in order to carry them through.

The phenomenal growth of mobile technology has created a new culture in the business world. The use of mobile and Web Services (WS) has passed their boundaries to a business revolution. The new technology has capabilities of text, voice and videoconferencing using wireless devices as well as the ability to connect to the World Wide Web. Pashtan (2005) indicates that Web Services can replace less-flexible methods for information exchange. He also states that with Web Services multiple WSDL interfaces can be defined for accessing a service and multiple clients can make use of the provided access methods.

The application of the WS will give this study the opportunity to implement the cross-internal organisational boundaries, beyond the simple exchange of information considering that Web Service's main purposes are basic request and response functionality. Linthicum (2004) states that WS deliver additional value to application integration, including a standard application for publishing and subscribing to software services, local and remote. XML provides a common data-exchange format, encapsulating both data and metadata. This allows the various applications and databases to exchange information without having to understand anything about one other.

The expansion of Mobile Technologies will also provide a robust basis for the organisation's desire to reach a wider customer and corporate base. This study will concentrate on the assessment of a business in the context of WS and MT and discusses the approach of transitioning to a new collaborative mobile organisation with the aid of emerging technologies. Figure 2 represents the explained model in more detail.

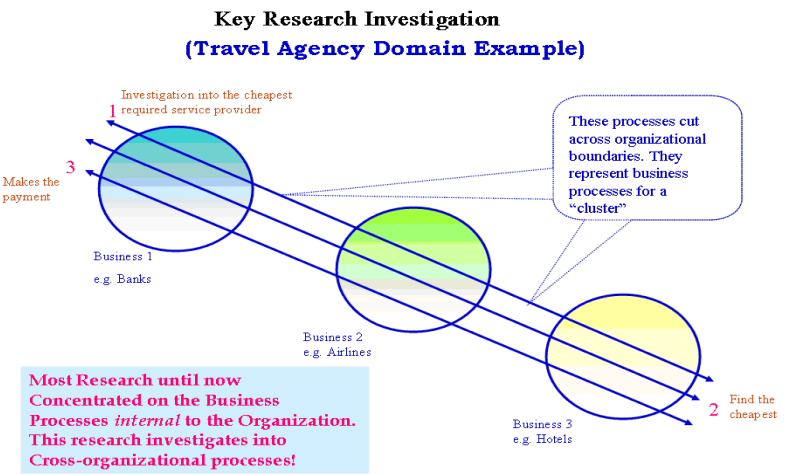
With the aid of mobile and web services technologies (Mobile Web Services), the proposed application, demonstrated in Figure 2, will give the opportunity to multiple organisations to communicate with each other in one transaction if desired. Considering Davies et al (2004) stated that the Web Services initiative effectively adds computational objects to the static information of yesterday's Web, and therefore offers distributed services capability over a network. Web Services have the potential to create new paradigms for both the delivery of software capabilities and the models by which networked enterprises will trade.

As shown in Figure 2, an individual business process could cross different organisations until one request is complete. In order to purchase airline tickets and book for hotel rooms or other related queries, Collaboration and communication will take place within these organisations until the initial request is completed. These collaborating organisations that have m-enabled WS make it possible for sale/service providers to benefit all people involved in the process.

KEY RESEARCH INVESTIGATION

As it could be seen in Figure 2, the businesses are collaborating across each other even on different platforms/frameworks with the aid of XML, WSDL and UDDI. With the aid of mobility (Location Based Services) the communication could take place without the consideration of geographical and time boundaries. (Anywhere at anytime).

Figure 2. Key research iInvestigation – Business processes across a cluster of organisations (In this example, Travel Agency of a Cluster)



Firstly, in order to purchase the numbers of airline tickets and hotel bookings, the transaction could take place with a request that could even happen with the aid of mobile devices.

Secondly, the request can go to the airline portals and make sure that the tickets for the destination are purchased. The purchase does not have to be from one specific airline and could be purchased from many airlines that are not even known to each other. Prior to this collaboration between their business processes they probably did not even know about one another's existence. With the recommended system their business processes can collaborate with the aid of WS or Mobile Web Services (MWS).

Thirdly, the same processes could take place in order to book the hotels in the destination city.

Fourthly, the bank has the capability to pay them and integrate with their processes without any prior agreements.

IDENTIFIED CHALLENGES INCORPORATING CBPE

To incorporate this proposed new world of collaboration there are many identified issues and difficulties. These issues include:

- Technical – Methodological – Social issues of ***interoperability***
- What are the ***requirements of the "manager"*** of the Directory Services
- The basis for ***trust*** amongst participant businesses and between the businesses and the manager
- The basis for a ***successful business model*** for the manager of the collaboration.
- The ***benefits*** for the participated organisations.
- The ***concerns*** of the participating organisation.
- The best technical ***model for CBPE***.
- The ***security***, ***convenience*** and the ***availability*** of the channels.
- To ***convince the organisations to adapt*** Web Service considering the limitation of WS. (Eg: slow speed of XML)
- Identify the ***dynamic aspect of collaborations*** wherein organisations can enter and exit the collaboration at will
- Identification of the ***factors influencing collaborative business processes*** such as issues involving the trust.
- The limitation of business or ***technological issues*** to create the best environment of collaboration.

THE ELEMENTS INVOLVED IN THIS STUDY

Today, mobile devices have surpassed the numbers of personal computers in use. The number of WAP enabled devices has also surpassed the numbers of PC enabled Internet users. As outlined by Pashtan (2005) over 100 million wireless Internet users were recorded as at September 2003. The majority of users are in Japan and Korea, while fast growth rates are being experienced in Europe.

Therefore the MT, which are a convergence of communication, computer and Internet technologies with mobility is a relatively new but fast growing area. The impact of mobility is an important element of the mobile transition process that is felt at both business and personal levels (Ghanbary, 2006).

Jamalipour (2003) explains that current network architectures used in either the wired Internet or the cellular networks would not be appropriate and efficient for any future wireless mobile Internet, even if we assume that the cellular network will provide the major infrastructure for the mobile Internet. He finalises by saying that the access to the mobile Internet is slow, expensive and confusing.

The access and connection to the Internet and the functionality of the WS or MWS have also become very simple and ubiquitous. These facilities have opened up opportunities for organisations to revolutionise their business processes. Undoubtedly, improvement of the communications technology has impacted not only the business domain but also the socio-cultural domain. The reason that the service model is so attractive is its ability to incorporate standards and open protocols for calling services and transmitting data (Unhelkar and S'duk, 2005). WS make software functionality available over the Internet so that programs can request a service running on another server (a web service) and use that program's response in a web site, Wireless Application Protocol (WAP) services, or other applications. The possibilities are endless.

Normal day-to-day activities become more related to the way we communicate with each other. Faster transfer of data, transactions and communications, which are independent of location and time, and with the identified functionality of mobile devices has become the mainstay of all challenged business processes.

The impacts of ICT (such as Internet, mobile and so on) on people's lives has been an evolutionary transformation. For example, at the beginning of the Internet age, with the aid of its communications capabilities, businesses were transformed to e-businesses. Ranjbar (2005) states that many technological products that were first considered by people as luxuries were later consumed as necessary items in daily life. IT products are of no exception. If the computer was an item of luxury in the 1980s, it has since established itself as an essential component of most contemporary homes. Like electricity, water and gas, information seems a necessary commodity for running everyday home life in a modern society. As one may turn on a tap for water and press a switch for light, one can also switch on the computer and obtain information and numerous IT-based services.

The Internet is described as the most powerful tool that brings information to our homes and offices like water and electricity that come by power lines and pipes (Ghanbary, 2003). Now, MT are allowing the information to be accessible anywhere and anytime with the aid of advanced mobile gadgetry.

Thus Mobile Technologies along with WS would form a formidable front in tomorrow's technology. As far as the emerging technologies are concerned the major areas of investigation would be:

- Technological issues such as modeling of the WS applications (extracting the full potential of Web Services)
- The issues and challenges in incorporating Web Services in businesses with the aid of Mobile Technologies.
- The subsequent mentioned issues and challenges of CBPE.
- The software applications that would facilitate business processes to collaborate across multiple organisations.

The methods to transit from already e-transformed businesses into collaborative may be m-enabled collaborative business process engineering is an important part of this study. In order to find the most suitable transformation method, the authors are investigating the suitable organisations to have the capability of demonstrating the smoothest transition.

As per Ghanbary (2006) it is very crucial for all parties involved in the process to know that there are some changes to take place since people must be prepared to adjust themselves. The training is the most suitable method for internal parties of the organizations however it is very important to provide sufficient information to external parties and advise them about the change.

CONCLUSION

The introduction of CBPE was described in this paper, and also the technologies supporting the recommended concept were identified. At the same time other important issues such as challenges faced by organisations participating in such a collaborative environment and studying the environment were also outlined. However, further research is in progress to construct and re-construct the model across multiple organisations to explore this concept to create better collaboration and interoperation amongst multiple organisations. The authors strongly believe that the organisations, as well as their customers, can greatly benefit from CBPE.

Generic Query Toolkit: A Query Interface Generator Integrating Data Mining

Lichun Zhu, University of Windsor, Windsor, Ontario, Canada N9B 3P4; E-mail: zhu19@uwindsor.ca

ABSTRACT

Construction of flexible query interfaces constitutes an important part in the design of information systems. Either developers or end-users of information systems can build new queries. This paper presents progress towards a Generic Query Toolkit (GQT) that automates the query interface generation process. GQT consists of a parser and an interpreter for a newly defined Generic Query Script Language, a background query processing unit, a presentation layer service provider and the presentation layer component. Data mining querying features have been integrated into this query language.

Keywords: Business Intelligence, Query Automation, Data Mining

1. INTRODUCTION

The original idea for developing a Generic Query Toolkit (GQT) arose from projects for building data mart and report systems for business clients. In these projects, user requirements (business logic) are constantly changing. There is need to build prototypes quickly to speed up the communication cycle between developer and end users. To meet this requirement we developed a software solution to automate the query interface generation process and, thereby, make the prototyping process more efficient. In this solution, we defined an SQL-like query language called Generic Query Language (GQL). A language parser parses the GQL script and extracts elements for constructing a query interface, such as criteria input fields, display attributes and so on. These elements can be serialized into XML schema and stored in the database. GQT generates the query interface based on this schema and then binds end user inputs to generate sequences of target GQL statements that are processed by an interpreter in order to generate final query results. Lastly, a set of presentation tools renders results to the end user interactively.

The current version of GQL script supports not just SQL statements. We have added flow control, variable declaration and other statements to create a functional script language, and a set of language features to support XML based dataset manipulation and data mining functionalities (Han & Kamber, 2001).

The proposed GQT provides solutions for building queries for end-users quickly. Compared with other commercial solutions, our method is fairly lightweight and it can be widely integrated with software projects of various scales. Indeed, this toolkit has been integrated already with information systems ranging from small, personal desktop Management Information Systems to commercial distributed large data marketing and data warehouse systems, and from fat-client applications to web-based applications.

The rest of the paper is organized as follows. Section 2 summarizes relevant related work. Section 3 presents the design of GQT and GQL, its development and testing environment. Section 4 discusses the integration of data mining querying and algorithms into this toolkit. Section 5 presents conclusions and future work.

2. RELATED WORK

The ultimate goal of GQT is to provide more effective interface solutions to support Business Intelligence (BI). BI software typically includes data warehousing, data mining, analysis, reporting and planning capabilities (Golfarelli, Rizzi & Cella, 2004). Existing commercial BI solutions include BusinessObjects (Business Objects, 2006), Cognos (Cognos, 2006), and Oracle Business Intelligence Suite (Oracle Business Intelligence, 2006). Most current commercial BI tools are rather complicated heavyweight and expensive systems requiring significant time to learn for development and configuration purposes.

Some open source projects related to our work include: the Pentaho Business Intelligence Project (Dixon, 2005), Mondrian OLAP server (OLAP Server, 2006), JPivot project (JPivot Project, 2006), and the Weka Data Mining project (Witten & Frank, 2005).

3. THE DESIGN OF GENERIC QUERY TOOLKIT

3.1 Introduction of the GQL Script

This paper proposes GQL script language for customizing user querying processes to a backend database system. The GQL script language can be used to specify two broad tasks of:

1. User interface definition: Users can describe the data presentation patterns as *Field Attribute* and define the query criteria as *Condition Attribute* with this script.
2. Process or Service specification: Users can control business workflow and invoke various services (e.g., data mining services like Classification, Association Rule using WEKA or other mining algorithms and SQL statements) using this script.

The syntax to define data presentation pattern or display attribute list (*Field Attribute*) is a collection of semi-colon delimited fields enclosed in curly brackets "{}" as :

```
Field Attribute ::=   {Field Name;
                      Field Description;
                      Field Type;
                      Display Attribute [;
                      [Aggregate Attribute];
                      [Key Attribute]] }
```

where "[]" means optional attributes. **Field Name** is unique name of column to be displayed, **Field Description** is the display label of the column, **Field Type** is the SQL data type of the column, **Display Attribute** specifies the default display attribute of the column, which can be SHOW/HIDE, The optional **Aggregate Attribute** specifies the aggregation method like COUNT, MAX, MIN, SUM and AVG and **Key Attribute** indicates whether the column is used for grouping. For example, we can use "{*catalog; Category; STRING; SHOW; ; GROUP*}" to specify the display attributes for column *catalog*. The display label is *Category*. The data type is String. The column can be selected to appear in the SQL-GROUP clause.

To define the query criteria (*Condition Attribute*), we use a collection of semi-colon delimited fields enclosed in angular brackets "<>" as:

Condition Attribute ::= <Condition Expression;
Condition Description;
Condition Type [;
[Value Domain];
[Required Attribute];
[Default Attribute];
[Hint]] >

Condition Expression is unique name for query criteria, **Condition Description** specifies the display label of the criteria. We can specify "#sequence number" in this field to tell the parser that the current criteria share the same input value with the query criteria as the sequence number. **Condition Type** is the SQL data type of the column. **Value Domain** is specified as comma-delimited *"value|description"* pairs or *"#select value, description from tablename where-clause"* to generate a pick list for input field.

The query process written in GQL script contains a collection of semi-colon delimited GQL statements. Currently, the language consists of (a) eleven types of statements (SQL statement, Declare, Assignment, If-elif-else, While, Exit, Break, Continue, Call, Display and Mine statement), (b) two built-in functions (today, substring) and (c) one built-in object (DataSet). The detailed language specification can be found from the online user guide [http://kent1.galab.uwindsor.ca:8088/gqlview/pages/GQTUserGuide.html].

For example, to construct a GQL script for displaying the tuples of a database table called *t_dace*, would entail replacing columns in the regular select-list with Field Attribute placeholders, replacing criteria elements in the where-list with Condition Attribute placeholders to get the following:

```
select
{id;Item;INTEGER;SHOW;;GROUP},
{mark;Type;STRING;SHOW;;GROUP},
{catalog;Category;STRING;SHOW;;GROUP},
{cdate;Date;DATE;SHOW;;GROUP},
{sum(income) incom;Credit;MONEY;SHOW;SUM},
{sum(outcome) outcom;Debit;MONEY;SHOW;SUM},
{sum((income-outcome)) net;Net;MONEY;SHOW;SUM}
from t_dace
where
<id;Item;INTEGER;#select id,name from t item
        where id between 500 and 999 order by id> and
<note;Description;STRING> and
<mark;Type;STRING;#1> and
<catalog;Category;STRING;#3> and
<cdate;Date;DATE> and
<income*exrate;Credit;MONEY> and
<outcome*exrate;Debit;MONEY>
group by #1, #2, #3, #4
order by #1, #2, #3, #4;
```

Once the above script is submitted, the GQT system would generate a query interface shown as Figure 1, a type of input form that allows the user enter ranges of values for query input criteria of the SQL *where* clause.

After one inputs the query criteria (including conditions and summary groups, also shown in Figure 1) and submits the query, the parser generates the following target statement.

Figure 1. Generated query interface

```
select mark, catalog, sum(income) incom, sum(outcome) outcom,
sum((income-outcome)) net
from t_dace
where id between 501 and 512 and
mark = 'P' and cdate >= '01-01-2006'
group by mark, catalog
order by mark, catalog
```

Please note that those input criteria whose values are empty from the interface form the user filled out, will be removed from the where clause of the final GQL statement. This target query is evaluated to retrieve query results that are presented to the user through *CheckResult* form.

3.2 Architecture of the GQL Toolkit

The java-based architecture has five major components: Metadata repository, GQL Parser, GQL Daemon, GQL Server and GQL Viewer.

1. Meta data repository: Consists of Query Repository table for all pre-defined queries and the Task Queue Repository for submitted query tasks history.
2. GQL Parser: is a two-phase parser engine developed using java based lexical analyzer generator Jflex and java based LALR parser generator Java Cup (Java LARL Parser, 2006). The first-phase parse happens at the time that user generates a new query task. The second-phase parse happens at the time that GQL Daemon executes the submitted task in the background. It performs macro replacement to generate and interpret target GQL statements in sequential order, submits SQL statements to database server .
3. GQL Daemon: acts as the background query-processing unit. It awakes every few seconds to browse the task queue, looking for tasks in waiting status. When a waiting task is detected, the daemon program creates a thread to execute the task. It also performs the house-cleaning task, e.g., removes outdated query instances.
4. GQL Server: The GQL Server module provides service interfaces used by the presentation layer. Therefore, it can be called directly or via web service connection. Two major services currently provided are *Access Service* (for system related services such as user authentication) and *GQL Service* (for providing GQL related services like GQL script parsing, extracting query directory, query submission, query result extraction and query annotation).
5. GQL Viewer and Client Application: The GQL Viewer and Client Application represent the presentation layer of GQT system. There are seven major functions provided by the viewer: user authentication interface, presenting query directory to the user, generating query input form after user selects a query, binding user input into GQL XML schema and calling GQL Server to submit new queries, monitoring the task queue, annotation or task removal, displaying the query result to the screen, and finally reporting, data export and other interactive data analysis support.

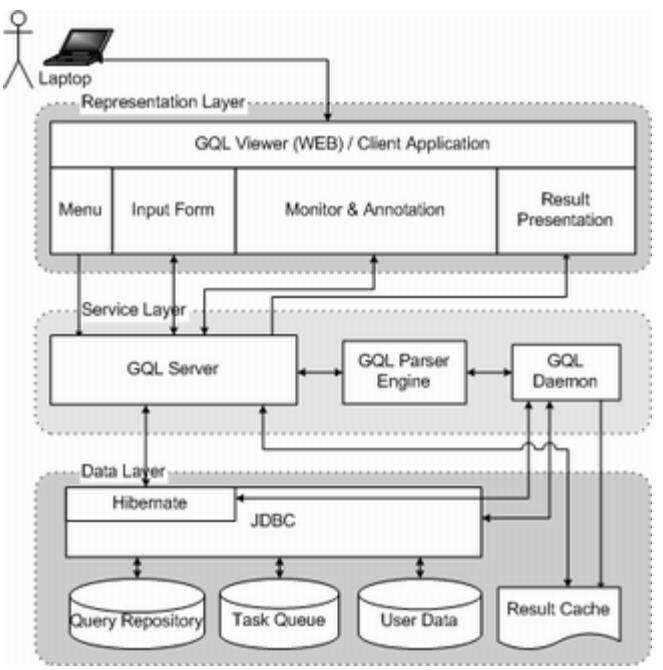
3.3 The GQT Querying Process

One main advantage of the GQL script is that it gives us the flexibility to use one generic set of pre-defined scripts to meet user's multiple requirements through the GQT query interface. The two types of users are: administrators who define and edit GQL scripts and edit existing queries; end users who may know nothing about SQL or GQL and simply use the interface to query the data. To use the system, administrators type in the GQL script and save it in the Query Repository table of the metadata database (in a column with TEXT data type) in advance if it is a new query. After they setup the new query in the database, if users log into GQT testbed system, they see the new query item in the left side menu of Figure 1. After they select the query item, the detailed information about the query is shown in the "View" form, including query name, description and GQL script. Clicking "Next" button switches the page to the "Input" form. The input query items or summary group list inside the Input form are dynamically generated based on the definition of GQL script.

The complete process for GQT querying processing is shown as Figure 2. The querying sequence contains four major steps.

1. Query Interface Generation:
   - User selects a query from menu that is generated from the Query Repository.
   - GQL Server extracts GQL script using GQL Parser Engine to generate the Query Schema, which contains input form elements (XML format).
   - The Input Form module generates input form webpage from the query schema.
2. Query Submission:
   - User inputs criteria from the Input Form, then clicks "Submit" to submit the query.
   - The GQL Viewer analyzes user's input and embeds the input value into the Query Schema, and then sends a *CheckCachedQuery* request to find matches in history queries.
   - If matches are found and user accepts cached result , GQL Server extracts cached result from Result Cache and returns it to Result Presentation module to display the query result. Otherwise, if matches are not found or user selects to ignore cached result, GQL Server creates a new query task in Task Queue using its *ApplyQuery* operator. User's requests are redirected to the Monitor & Annotation web module.
3. Background query processing:
   - GQL Daemon wakes up every five seconds (configurable) to check whether there are newly submitted tasks. If it finds new tasks, it spawns a thread to process the new query task. The status of the task will be turned to "Running".
   - The GQL Daemon thread sets the status of the task to "Success" or "Error".
4. Monitor and result presentation:
   - User refreshes the webpage to check the status of their submitted task.
   - If the status of the task turns to "Success", user can click "View" to view the query result, click "Delete" to remove the query instance, or submit "Change Notes" to append annotation to an existing query instance.

Figure 2. GQT querying process



3.4 The Development and Testing Environment

We have set up a GQT development and test bed environment on a PC environment (CPU: Pentium III, Memory: 256MB, OS: Fedora Core 4) that can be accessed via http://kent1.galab.uwindsor.ca:8088/gqlview. One can use the test user: zlc, password: 9999 to access this system. Because the whole application is developed using java, it can be deployed to various platforms. Currently, the backend database is Informix Dynamic Server 10.

4. INTEGRATING DATA MINING FEATURES INTO GQT

The GQT prototype in an embedded mining approach, integrates data classifier by applying classifier from WEKA data mining toolkit (Weka, 2006), which provides mining algorithms like Classifiers, Clusterers and Association rule miners.

The following example describes how to use WEKA classifier to first analyze the data in the GQT system. Then, the WEKA generated classifier model is exported as a serialized java object, which contains all the details of the algorithm and parameters. In the second stage, the generated model (*.model) file and training data (*.arff) are copied into the template directory of the GQT system. Then, in a GQL script, Mine statement is used to classify the data using pre-generated mining model file for classifying unlabeled data.

This example data is extracted from a cardholder's database that contains cardholder's demographic information and summarized purchase amounts. The original cardholder table contains 7 columns as (CID, SEX, AGE, MONTHIN, PURCHASE, BAD, VIP). Here, SEX, AGE, MONTHIN, PURCHASE and BAD are the predictor attributes while VIP is class attribute. First, we collect training records with VIP column already specified. Next, we load the training data into WEKA explorer, and analyze the data by comparing different classifier algorithms and different sets of parameters. At last, we export the analyzed result as a model file saved in the template directory on server, configurable as a system parameter. In this application, we select the J48 algorithm, an enhanced decision tree classifier that supports both nominal and numeric predictors and the exported model file is "j48.model".

Here, the given **Query Goal** is: Apply J48 classifier to all cardholders having age between 30 and 35 to classify based on their VIP. Next, we use the generated J48. model file to classify the data. The generic mining GQL script for this query is given below, all the non-SQL statements are marked with a prefix "$":

```
1. $declare ads Dataset;
2. select cid, sex, age, month in, purchase, vie, bad from cardholder where
       <cid;ClientId;integer> and
       <vip;VIP;integer;0|False,1|True> and
       <purchase;PurchaseAmt;Money>and
       <age;Age;Integer>
   into temp t1;
3. $set ads = Dataset.readtable('t1');
4. $mine ads classifier using sex, age, month in, purchase, bad class vip_j48
   model 'j48.model';
5. drop table t1;
6. $display ads using
       {cid;ClientId;Integer;SHOW},
       {sex;Gender;String;SHOW},
       {age;Age;Integer;SHOW},
       {monthin;MonthlyIncome;String;SHOW},
       {purchase;PurchaseAmt;Money;SHOW;SUM},
       {vip;VIP;integer;SHOW},
       {bad;Bad;integer;SHOW},
       {vip_j48;VIP_J48;String;SHOW};
```

Figure 3. Query result for test classifier

Test Classifier

ClientId	Gender	Age	MonthlyIncome	PurchaseAmt	VIP	Bad	VIP_J48
36	M	30		2642.00			FALSE
37	M	30	3. 2000-4000	4518.51			FALSE
38	F	30		62219.27	TRUE	FALSE	TRUE
47	M	30	5. 8000-16000	1014.00			FALSE
51	M	30	6. 16000-32000	6043.78			FALSE
60	M	30	5. 8000-16000	4859.40			FALSE
73	F	30	4. 4000-8000	10671.81			FALSE
75	M	30	6. 16000-32000	11.70			FALSE
90	F	30		1306.00			FALSE
94	M	30	6. 16000-32000	4646.00			FALSE

After submitting and processing the query, the result is shown in Figure 3. The client with id 38 has a value of TRUE for VIP and FALSE for Bad. The computer generated classification results are shown as column "VIP_J48". The above script uses SQL statement in No.2. to extract the required data from database, then uses Dataset.readtable statement to load the intermediate data into the Dataset object, then uses Mine statement to classify the intermediate data using specified model j48.model (the result of classification algorithm will be stored in vip_j48 column as specified), at last displays the calculated data stored in the dataset to the user.

5. CONCLUSIONS

We present the Generic Query Toolkit as an economical solution for building reporting and data analysis focused applications. Data mining features have been integrated into GQT. We introduced the Generic Query Language to automate the query and display of results. We can integrate easily the user-defined business logic, together with back-end services and front-end presentation modules, to extend the system flexibility.

Future work will include providing OLAP features where user is able to display the data set as a cube, perform slice, drill down, roll up actions interactively is a future addition to the system. Further, we plan to support more data mining features at the query language level, including data clusterer statements and association rule mining statements. Other algorithms, such as those provided by WEKA, or self-designed algorithms like PLWAP tree (Ezeife & Lu, 2005), will be included in the system scope. Another important task is to expand the GQL Server web service, and integrate OGSA-DAI (OGSA-DAI, 2006) data service to support accessing distributed data sources.

Usability and Emotional Obstacles in Adopting E-Learning: A Case Study

Sanna Juutinen, University of Jyväskylä, Mattilanniemi Building, Agora P.O. Box 35, Jyväskylä, Fin-40014, Finland; E-mail: sajuutin@jyu.fi
Pertti Saariluoma, University of Jyväskylä, Mattilanniemi Building, Agora P.O. Box 35, Jyväskylä, Fin-40014, Finland; E-mail: psa@jyu.fi

ABSTRACT

Emotions are important in interaction and open a vital perspective to e-learning. E-learning courses have higher dropout rates than the traditional courses taught in classrooms, and it seems logical to ask whether emotional processes could explain a part of them. This research investigates how emotions are involved in students' behavior during e-learning courses. As human emotions are not independent of human cognitions and appraisal, we also consider here how cognitive difficulties affect emotional stances in e-learning on the ground of feedback collected from an e-learning course. However, here the main focus of emotion relevant cognitive processes is related to competence and usability. Usability problems lead either to frustration and shame or pride or self-confidence. It seems that the usability threshold divides subjects emotionally in e-learning environments.

1. INTRODUCTION

E-learning is a still fast growing area in education, but the complexity of the field makes it necessary to look for new perspectives. Much of e-learning research has concentrated on technical and software aspects (Annapoomima & Soh, 2004; Brusilovsky et al. 2005). Recently, increasing interest has been directed to user problems, and consequently, to emotional aspects of e-learning (Branco et al. 2005, De Villiers, 2004; Yu et al. 2002).

The possibilities that e-learning opens up for social development makes this area important, and, therefore, it is vital to ask what kinds of things may prevent people from using this new method for improving their lives. Undoubtedly, some of the obstacles are related to emotions and should be explained on the basis of human emotional processes (Hiltz & Wellman, 1997; O'Regan, 2003; Rosen & Weil, 1995). One can even think that technophobia is involved in the adoption of earlier services (Branco et al., 2005; Lam, 2000; Pickering & King, 1992). It is thus important to investigate how emotional processes are involved in the use of e-learning.

However, cognition appears before emotions (Power & Dalgleish, 1997). Therefore, it is logical to ask, what kinds of cognitive factors may lead to negative emotional stances towards e-learning and eventually to its abandonment. It is particularly interesting to look at the relations of competence and usability in this context as emotions provoking factors.

2. RESEARCH METHODS

Case description: The Connet human technology network was established in 2001. It is a part of the Finnish Virtual University program as a cognitive science and cognitive technology teaching network. Connet has eight Finnish universities in this network. All the students from these participating universities are allowed to study in the network. These eight universities form a multidisciplinary teaching network. The background curricula include cognitive science, cognitive technology, psychology, philosophy, information systems science, computer science, work science, education, educational psychology and new media. The curriculum is very strongly problem-based. The most frequently used technologies in the Connet courses are Internet and e-mail. Also whiteboard, blogs and chat boards are being used. Each teacher can choose what technique to use in their course.

Data and analysis: The Connet students answered to the questions during two academic years, in 2002 and 2004. The students answered these open questions through e-mail and were asked to comment with their views on and experiences of the Connet network study and development ideas. Questions were sent to all the students in the Connet network by e-mail. All in all there were 50 students´ answers included to the analysis. The groups of students were not the same in both years. Students took different types and amount of courses during their Connet studies. Their answers were qualitatively analyzed to identify the cognitive reasons for emotional reactions behind dropping out from the e-learning courses. The most frequently cited reasons and emotions in the students´ answers in both years are discussed below.

3. RESULTS

In both years, the most frequently mentioned reason for dropping out from a Connet course was lack of time. The students regarded their own time management skills inadequate, and the e-learning courses seemed to be the easiest to drop. In their opinion, e-learning courses are not seen as binding as the traditional classroom courses due to the anonymity of the students in e-learning courses.

3.1. Problems with Competence in Technology

Technology was a source of frustration for the students but also gave them sense of pride for their competence. These kinds of feelings were reported in 20 out of 50 students' answers, or in 44%. Students had problems with the e-learning environment, e-mail and also experienced a need for home equipment. E-learning environment problems were related to the usability of tools. The software used for the courses was changed quite frequently and this created a lot of frustration but also positive reactions. Here are three of the students' comments: ***"After finally having learned the old software, I had to start learning a new one."***, ***"The tool is not user friendly", "I had problems finding what I was looking for".***

Course materials also divided the students. For some they were a source of frustration, for others irritation and also of joy. These kinds of emotions were reported in 30 out of 50 students' answers, or in 60%.

There were opinions about the material availability and quality. Availability of the books was sometimes very poor. Here are two of the students' comments: ***"It was hard to get the material; all the books you need for the course were not available in the library. You have to do special arrangements to get them, but might not have money to buy them after all.", "The courses were mostly based on traditional books, and those books are not available in the local library."***

Apart from the book availability problem, the students were pleased with the material and also with its availability, especially on the web. Here is what two of the students said: ***"The availability of the material has been excellent and has been corresponding to the content of the courses. Also the quality.", "The web material was good. Material gave a good overall picture and gave new thoughts for working with my essay."***

4. DISCUSSION

The data implies that usability problems have their emotional consequences, but that they are not straightforward. When students come across usability or organizational problems such as those reported above, their reactions are emotional, and this leads them to negative participation decisions. We can mostly characterize the negative emotions in terms of frustration.

Frustration is a common phenomenon among people using computers (Drennan et al. 2005; Hara & Kling, 2000; Shneiderman et al. 1995; Zhang et al. 2004). As the data suggests, frustration arises from failures while using the technology, from

not finding what one is looking for and not getting from the teaching what one is expecting. Often frustration leads to dropping out from the course undertaken. This effect, which is due to emotions, can take place in traditional classroom teaching courses (Weare, 2004), and as the results suggest it also can take place in e-learning courses. Other negative emotions include irritation, embarrassment and shame. Students get irritated when they cannot find what they need or want, when material availability is poor or the technology does not work properly or when it makes it hard or even impossible to study.

On the other hand, a sense of pride for succeeding in an e-learning course was notable. This may be due to the fact that e-learning demands more from the student (Hiltz & Wellman, 1997; Kumar et al. 2001) than traditional teaching and requires more work in an unfamiliar learning environment; the students take pride for their own accomplishments. Feelings of embarrassment were prevalent at the beginning of the e-learning experience, but the successful students got used to the new systems and the required learning habits, and consequently less embarrassment was felt afterwards. Embarrassment / shame emotion has been associated with the felt difficulty and therefore it is a significant factor in the beginning of learning (Ingleton, 1995). A successful learning process turns shame and negative emotions into pride and self-confidence.

5. CONCLUSION

This study focuses on the emotions that arise from an e-learning experience and on how these might affect students who drop out from the courses. The study doesn't attempt a straightforward comparison between traditional classroom teaching and e-learning, i.e., how all the found results would have affected students in traditional courses. The results show that emotional aspects of computing are important to analyze when introducing an e-learning course. The outcome may be shame and frustration with dropout on the one hand, and pride and self-confidence with success on the other.

A Human-Centric Approach to Simulation of IS Security Dynamics

Mark Rounds, University of Idaho, Moscow, ID 83844, USA; E-mail: mrounds@uidaho.edu
Norman Pendegraft, University of Idaho, Moscow, ID 83844, USA
Carol Taylor, University of Idaho, Moscow, ID 83844, USA

ABSTRACT

This paper outlines a new approach to computer security using simulation to study computer security policy. We suggest that understanding the interactions between humans and information systems is central to creating effective security policy. Most previous research has focused on technical issues of system vulnerability or computer security tools. Our approach employs simulation models in order to understand how attackers and users react to varying levels of parameters such as computer security and system value.

1. INTRODUCTION

Computer security is a human-centric problem with humans actively involved in both the attack and defense of systems. Consequently, we believe that a new approach is needed that places human activity at the center of a model that shows trade-offs between human choices as security is varied.

In this paper, we develop a simple economic model to examine interactions between users and attackers. Despite its simplicity, the model is too complex to provide clear policy recommendations. Hence we advocate simulation as a means of further study of these systems. We develop a framework for that simulation which should allow managers to experiment with policies before implementation. This paper does not provide simulation results as we do that elsewhere (Pendegraft and Rounds 2006, Pendegraft, Rounds, and Frincke 2005) and is intended as an apologia for the approach.

Subsequent sections of the paper cover some background (Section 2), our modeling approach and background on users and attackers (Section 3), and research agenda (Section 4).

2. BACKGROUND

The security literature has grown significantly in the last decade. However, the focus of most researchers has been on technology: intrusion detection, encryption, system management, etc. There has been relatively little discussion of the behavior of the humans involved or of the interactions between them. Even Saltzer and Schroeder (1975), who recognize that humans play a role, focused on the technological issues of security rather than the interactions of the system with its users and attackers.

Security imposes a cost on the user. According to Sasse et.al (2001) and Sasse (2003), complex multiple passwords are beyond the capability of human memory. This increase the need for user support which imposes further costs. Fixes to this problem, i.e. writing down passwords or automated password retrieval have security and cost issues of their own. These issues have not received enough attention from the security community. Recognizing the cost of security, many firms engage in cost benefit analysis of security measures before imposing them (Gordon et.al. 2006),

There is a considerable literature examining the impact of system quality on user behavior which supports our belief that system value increases use. The Technology Acceptance Model (Davis 1989) offers a means of analyzing the impact of ease of use upon usage. The IS Success model (ISM) explicated by DeLone and McLean (1992) includes constructs of information and system quality and posits that system and information quality lead to increased user satisfaction and increased use which in turn leads to net benefits. DeLone and McLean (2003) recently revised that model to expand measure of quality to include service quality and to explicitly include a feedback loop from net benefits to intention to use. Wixom and Todd (2005) recently integrated the two models and their results suggest that there is a link between system and data quality and the one hand and system usage on the other. Zhu and Kraemer (2005) argue that firm value is increased by IS usage in E-business applications.

3. MODELING APPROACH

3.1. Preliminaries

Our research uses an economic point of view rather than that typical of the computer security literature. In the economic analysis if crime typified by Becker's landmark work (1968) a system of equations is developed which describes in some aggregate way the behavior of criminals. Block and Heineke (1975) extend that work to consider the labor cost incurred by the criminal.

This approach focuses attention on societal value using a utility function about which only limited assumptions are made. In our context this translates to looking at system value rather than maximizing security or minimizing attacks. It also translates into response functions which are inherently inexact. Such ambiguity is seems inherent in the approach. For example Block and Heineke (1975, p315) use one term to represent the "failure, capture, or arrest rate" with criminal behavior. While the ambiguity is unfortunate, it does focus attention on aspects of the problem that are not well understood and therefore suggests fruitful avenues for future research.

In the next section we develop a simple two player model patterned on Becker's economic analysis of crime. As will be seen the model becomes very complex and is inherently static. In response, we will argue for simulation as a preferred mode of inquiry. Simulation offers the addition advantage of allowing us to investigate non linear behavior. Given the apparent interaction between users and attackers, it seems likely that computer security will have non linear interactions.

3.2. Economic Model

We assume that users and attackers both are motivated by the current value of the system and by the current level of security. We also view the problem of IS security as essentially dynamic, that is, we assume that the behavior of the system over time is of interest; hence we use time as an independent variable.

We adopt the following notation.

U : level of use by user	=U(V,S)
A : level of attacks	=A(V,S)
V : current value of the system	=V(T)
S : current level of security	=S(T)
T : time	

We assume that these functions are sufficiently well behaved that we may determine their derivatives. We will use the following notation: X' = dX/dT and X_y will be the partial derivative of X with respect to Y.

We calculate the time rate of change of each player's action:

$$\frac{dU}{dT} = \frac{\partial U}{\partial V}\frac{dV}{dT} + \frac{\partial U}{\partial S}\frac{dS}{dT}$$

$$\frac{dA}{dT} = \frac{\partial A}{\partial V}\frac{dV}{dT} + \frac{\partial A}{\partial S}\frac{dS}{dT}$$

At equilibrium these must both be 0 so we have

$$\frac{\partial U}{\partial V}\frac{dV}{dT} + \frac{\partial U}{\partial S}\frac{dS}{dT} = \frac{\partial A}{\partial V}\frac{dV}{dT} + \frac{\partial A}{\partial S}\frac{dS}{dT}$$

$\frac{V'}{S'} = \frac{A_S - U_S}{U_V - A_V}$. Hence,

$$\frac{dV}{dS} = \frac{A_S - U_S}{U_V - A_V}$$

Now this means that dV/dS > 0 in two cases.

1. $U_v > A_s$ and $U_s < A_s$
2. $U_v < A_s$ and $U_s > A_s$

Since $U_v > 0$, $A_v > 0$, $U_s < 0$, and $A_s < 0$, this gives

$U_s < A_s < 0 < A_v < U_v$
$A_s < U_s < 0 < U_v < A_v$

We take the second to be the more common situation. In that case, attackers are more sensitive both to the value of the system and to the security level. There is a possible policy implication here, in that if neither of these conditions obtains, addition security may be counter productive.

Now we extend to consider a dynamic model. First consider the case where the security policy is static, i.e.

$$\frac{dS}{dT} = 0$$

Then

$$\frac{dA}{dT} = \frac{\partial A}{\partial V}\frac{dV}{dT}$$

Since we have assumed the first term positive, this means A' has the sign of V_t. If we allow dynamic security, then $A' = A_v V' + A_s S'$. Since $A_s < 0$, $S' > 0$ will cause a reduction in A' (Note that it does not directly affect A, rather the time rate of change of A.) This suggests the following policy:

If A'>0 then increase S (ie make S'>0)

If A'<0 then decrease S (ie make S'<0) This follows since it will apprarenlty result also in increased usage which is assumed to be a good thing.

Now, it seems reasonable to assume that V'=V'(A,U,V). In particular, we assume that

$\frac{\partial V'}{\partial A} < 0, \frac{\partial V'}{\partial U} > 0, \frac{\partial V'}{\partial V}$ indeterminate in sign.

The attacker's problem is now

$$\frac{Max}{A}\alpha(V, S, A)$$

And the user's problem is

$$\frac{Max}{U}\beta(V, S, U)$$

Block and Heineke's analysis follows these lines for only the attacker, and leads to results of limited utility for our scenario. Their results apply at equilibrium which seems inappropriate for us and excluding the impact of usage on a system is clearly not realistic in our case because it is precisely the use of these systems that makes them valuable. Note also that we are not concerned with the direct interaction between user and attacker. Rather the attacker affects the user only indirectly by reducing the value of the system, thus reducing the user's level of use.

The net result is that is seems unlikely that the sort of analysis demonstrated here will lead to generally useful insights. It is well know that solving complex systems of differential equations is hard, and the standard way to study dynamic systems is via simulation.

3.3. General Simulation Model

Our approach to simulation is consistent with Senge (1990) which in turn drew from Forrester's work at MIT on systems dynamics (1961). Like the forgoing analysis, this approach takes a top down point of view.

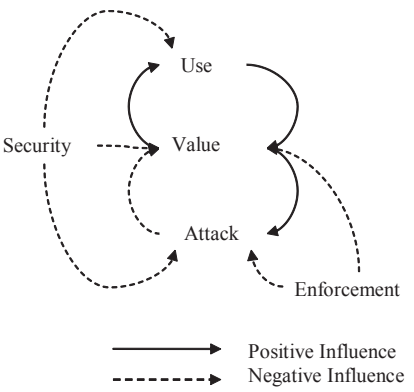
Systems dynamics models use two types of objects: reservoirs and flows. Reservoirs represent constructs whose values change over time, and the flows represent changes in the values of those constructs. In effect, the flows are derivatives of the reservoirs. Our modeling tool IThink, (High Performance Systems) converts these models into a set of finite difference equations which are solved numerically. Our models are simple because as Senge and IThink point out, simple models are much easier to understand. There is also the problem of exploding state space as models become more complex.

The basic model is illustrated in Figure 1. The main constructs are value, use, and attacks. Solid lines indicate a positive or increasing influence; dashed lines indicate a negative influence. The model shows that increases in value cause increases in use and attacks. Use increases value while attacks decrease value. Security reduces both use and attacks and has a cost (i.e. reduces value). Enforcement acts only against attacks, also at a cost.

3.4. Value and Security

System value is the key parameter in our model. Previous work (Sasse 2001, 2003, Pendegraft and Rounds 2006) has shown that value is a complex parameter. A user may assign a value based on the amount of data the system holds and the ease with

Figure 1. Value model



which it can be extracted. For a customer, the ability to carry out a transaction quickly, accurately, and securely may also enter into their view of value.

Some attackers are motivated by money (Richmond 2004). An attacker may view value as the number of records that can be extracted for sale. An attacker with a political agenda may care more about the identity of the system owner than the intrinsic value of the data. Clearly a major item in our agenda will be to clarify the aspects of system value that drive human behavior. In some sense, this extends the work of Jonsson and Olovsson, (1997) and relies upon the definition of information system value (Walters and Lancaster 1999).

Similarly, our notion of security is simple. We model security as a single parameter ranging from 0 to 1 reflecting a completely open system to one which is inaccessible. Like value, security is multifaceted and clarifying what security is must be an essential item in our agenda.

3.5. Impact of Security and Value on Behavior

We model the impact of security and value on attackers and users as S shaped. While there is some support for this idea in the error detection literature (Yamada, Ouba, and Osaki, 1983) it remains to confirm the idea experimentally. Figures 2 and 3 illustrate this postulated behavior. Figure 2 illustrates the idea that use and attacks increase with increasing rate at low levels of value, and then with decreasing rate. Figure 3 shows use and attacks decreasing slowly with increasing security at low levels of security, and then decreasing rapidly, and finally decreasing at a reduced rate. Note that we do not assert (nor believe) that these curves are identical for users and attackers, rather that they have the same general shape.

For the purposes of this research we model attackers as rational criminals with a common response curve. While there are many sorts of attackers this simplification makes the results much more understandable. We base the rational activities of our attacker upon the economics of criminal activity (Becker 1968). Finally, it is clear that attacks on a system reduce its value. While firm value is only part of our notion of value, there is evidence that firm value can be reduced by cyber attacks (Garg, Curtis, and Halpner 2003; Miora and Cobb 1998; Saita 2001, Olavsrud, 2001).

3.6. Enforcement and Security

We understand security to be actions which reduce the likelihood of success and severity of attacks. We also understand that security imposes costs on users. Enforcement includes active steps taken to reduce the number of attackers. It includes law enforcement and actions taken by targeted companies.

Traditional law enforcement has not been especially successful in dealing with cyber crime, (Jayaswal, Yurcik, and Doss, 2002) and may impose additional costs on the victims. Department of Justice's (2002) guidelines call for seizure of the victim's hardware under certain circumstances hardware seized from the victim is reclaimed only with much difficulty (Holtzman 2003).

There are reports that some firms have engaged in direct efforts to retaliate against hackers and reduce their numbers. (Schwartau 2000, Radcliff 2000, Thayer 2005).

Figure 2. Value

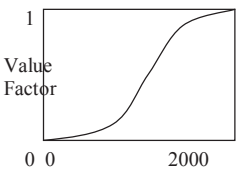


Figure 3. Security

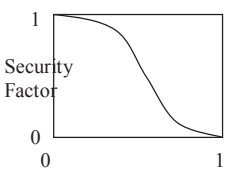

There are a number of products available to facilitate counterattacks (Farber 2002, Secure Computing 2005).

4. CONCLUSION AND FUTURE WORK

Despite increasing expenditure on computer security computer crime continues to be a problem. The traditional computer security literature focuses on technical issues. We have developed a complementary point of view which emphasizes system value and the interactions between the system and its users and attackers. We continue to examine these questions via simulation.

We have made a number of simplifying assumptions. Clearly these are open to challenge. To validate and expand our models some of these assumptions will require experimental examination of some issues like the response of attackers and users to changes in system value and security. Our goal, as described in our introduction, is to focus on interactions in hopes of gaining new and interesting insights into the security problem. We hope that other researchers will find these questions interesting and join us in our efforts to investigate them.

ABSTRACT

This study was conducted in a mid-sized University in the southern part of the U.S. Eighty subjects participated in an experiment that assessed their performance in learning about international trade terms through a series of web-based screens. The objective of the study was to test the relationships between age, motivation to do well in the task, gender, scholastic ability, (GPA) and performance in a knowledge communication task. Performance was assessed through the participants' ability to learn about international trade terms (content performance), and to recall aspects of the web-based screens through which those terms were learned (details performance). The results suggest that age positively influences motivation, females have better details performance than males, and GPA positively influences content performance.

INTRODUCTION

The assessment of the influence of motivation on task performance has been a topic of study for a number of years (Ryan & Deci, 2000). Some of the first studies of the relationship of motivation and performance date back to the 1930's and some studies are still being conducted today (Seo et al., 2004 on Kanfer, 1991). These studies have led to the proposal of a number of motivation theories (Robbins & Coulter, 2005).

Another factor which can moderate task performance is gender. There have been a number of studies which use gender as the differentiating variable in the learning patterns as well as the outcomes produced by individuals in the academic and corporate worlds (Meyers-Levy, 1989; Graham et al., 2002; Chung & Monroe, 2001). In a number of these studies the results indicate that women have the tendency to be more detail oriented than men (Graham et al., 2002).

In addition, the types of motivation often differ for women and men. Women tend to be intrinsically motivated as opposed to extrinsically motivated (Liping, 2000). While men and women may have similar expectations for the future, women tend to be goal setters, often focusing on deeper, more personal goals than men and these differences may lead to different performance levels between the two (Greene & DeBacker, 2004). In other words, through existing studies one can see that there are relationships between motivation, gender and performance.

The study presented here was conducted in a mid-sized university located in the south of the United States. The learning performance of a group of subjects was assessed at two levels: content performance and details performance. Both content performance and details performance of the participants was evaluated though the use of web-based screens in order to test the relationships between age, motivation, gender, GPA and performance. The objective of this study was to develop, as well as test, a theoretical model which can help clarify the nature of these relationships.

BACKGROUND AND HYPOTHESES

Motivation can be defined as the degree to which an individual seeks to achieve a goal, while fulfilling a personal need (Robbins & Coulter, 2005). There are two types of motivation which can influence an individual: intrinsic and extrinsic. Intrinsic motivation acts as a reflection of human nature. It relates to the innate tendency in human beings to engage in certain actions. This kind of motivation cannot be enhanced through tangible rewards because the reward, consists of a feeling of accomplishment or satisfaction which is provided by the action itself (Ryan & Deci, 2000). Deci & Ryan (1991) believe that those who are intrinsically motivated tend to "have more interest, excitement, and confidence" than those who are extrinsically motivated (p. 69).

Extrinsic motivation, on the other hand, relates to an expectation of an outcome or a fulfillment of a requirement as the reason for performing an action. That is, the activity is not performed "just for fun." The individual has an interest in the outcome of the activity as well as in the associated rewards (Ryan & Deci, 2000). Both intrinsic and extrinsic motivation may lead to increased learning levels as well as improved performance (Ryan & Connell, 1989; Deci & Ryan, 1996).

Because motivation is related to performance, researchers have been interested in finding out what motivates individuals (Ryan & Deci, 2000). Several motivation theories have resulted from this interest, some dating back to the 1930's (Seo et al., 2004 on Kanfer, 1991). Well-known motivation theories include Maslow's (1954) hierarchy of needs theory, Skinner's (1971) reinforcement theory, Vroom's (1964) expectancy theory, and Adam's (1965) equity theory.

These theories are all related to performance and convey the idea that in order to achieve a desired outcome there should be some type of motivation in place. Therefore, it is expected in this study that a student with higher motivation will also have an increased performance. Since this study uses content and details-related performance measurements, the following is hypothesized:

***H_1**: Higher motivation will lead to higher content performance.*

***H_2**: Higher motivation will lead to higher details performance.*

A number of studies have also explored the relationship between age and motivation. In these studies age has been found to influence attitudes and motivation in the work environment (Schamback, 2001 on Igbaria & Greenhaus, 1992; Warr & Birdi, 1998). Wolfgang and Dowling (1981) studied the differences in motivation between young and adult college students and Digelidis and Papaioannou (1999) studied the difference in motivation between different age groups of students. These studies recognize that a relationship exists between different age groups and their motivation levels. Since much of the existing research suggests that age is likely to have a positive effect on motivation, the following is hypothesized:

***H*$_3$**: *More years of age in an individual will lead to increased motivation.*

Chen et al. (1997) found that motivation levels in men and women can be equally high. However, women tend to be more goal oriented than men and their goals tend to be of a more intrinsic nature than those of men (Greene & DeBacker, 2004). Because women's goals are of a more personal nature, female students in this study are expected to have higher motivation levels.

Gender is another factor which can affect the learning process. Pearsall et al. (1996) found that gender mediates biology students' learning processes and Rochford & Mangino (2006) found that gender and achievement level can cause differences in a student's learning needs. Studies such as these have found that males and females learn differently, due to biological as well as social factors (Bevan, 2001; Miller et al., 2001; Giordano & Rochford, 2005). Taking such differences into consideration can help students increase their learning abilities (Rochford & Mangino, 2006).

A number of researchers have also found that males and females differ in the way they process information (Honingsfeld & Dunn, 2003; Bevan, 2001; Ablard & Lipshultz, 1998). Males look for simpler patterns of information which may stand out, while women look at more subtle details in the information (Meyers-Levy, 1989; Graham et al. 2002; Chung & Monroe, 2001). In addition, females tend to pay more attention than males to certain details. Because these studies lead to some expectations regarding the relationships between motivation, gender and performance the following is hypothesized:

***H*$_4$**: *Female students will have higher motivation.*

***H*$_5$**: *Female students will NOT have a higher level of content-oriented performance.*

***H*$_6$**: *Female students will have a higher level of detail-oriented performance.*

Finally, in this study, grade point average (GPA) is used as a control variable because of its relation to academic performance (Zheng & Saunders, 2002). In African-American females, a high GPA has been linked to a better perception of the self (Saunders, et.al. 2004). Having an increased self-perception, which is related to having a high GPA, is likely to positively affect the performance of males as well as females. Figure 1 presents the complete model of this study including this control variable.

RESEARCH METHOD

This study was conducted through a web-based experiment involving 80 subjects. All the subjects were business students from a mid-size university in the southern part of the United States. The sample included both graduate and undergraduate students. More than 80 percent of the subjects were undergraduates. Slightly over 50 percent of the subjects were female and the average age was 25.

The experiment was divided into a learning module section and a survey section. The first section consisted of ten learning modules containing ICC Incoterms 2000. Context details, consisting of four different capital letters individually framed by a colored square, were also included in each one of the modules. The second section of the experiment consisted of a web-based survey which subjects were required to complete after reading the time-controlled modules.

The instrument was designed to measure content performance, details-oriented performance, and perceived motivation. In order to measure content performance, three multiple-choice questions were asked for each module. The subjects' performance was assessed by dividing the number of correct answers by thirty (which was the maximum number of correct answers). The details performance was calculated in a similar way since the options for the colors and letters were provided in drop boxes from which subjects could choose.

This study lasted approximately one hour; twenty-five minutes were spent on the learning module section, and the remaining time was spent on the survey. To serve as motivation, the subjects were offered extra credit points which were dependent on their performance in the experiment.

DATA ANALYSIS

One of the best known variance-based SEM methods is the partial least squares (PLS) method (Chin et al., 1996; Chin, 1998). The flexibility (relaxed statistical assumptions for the data, inclusion of control variables, and definition of formative constructs, etc.) and robust significance tests make PLS a good choice for the analysis of the data collected through this study. Therefore, this method was used to assess the relationships of the model presented in this study.

The model presenting the latent variables and the different relationships as well as the calculated coefficients can be seen in Figure 2. Motivation, represented by an oval is a latent variable which is connected to the remaining variables by arrows which represent the causal relationships between the variables. The significance of the results determines the type of connectors used. A solid arrow was used when the relationship was found to be significant and a dotted arrow was used when the relationship was found to be non-significant. For those relationships that were found to be significant, the β coefficients are displayed. These coefficients are not shown for the relationships that are not significant. In this model the path coefficients are represented by β and the variance explained by the model is shown through the R^2.

Notes:
NS Non significant links
H Supported Hypothesis
* Link significant at the .10 level
** Link significant at the .05 level
*** Link significant at the .01 level

Figure 1. Model of gender and motivation effect on performance

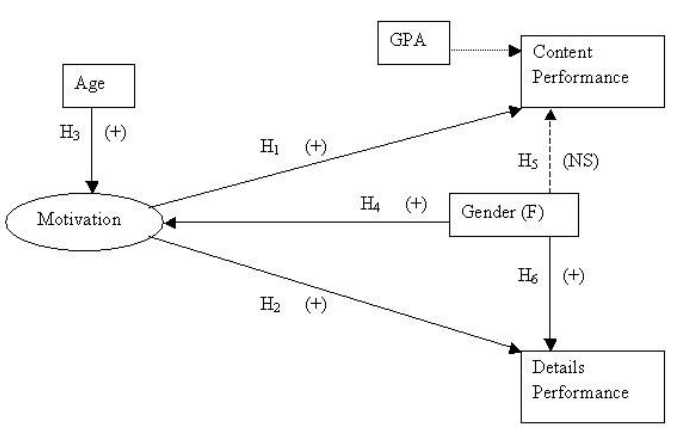

Figure 2. Results of gender and motivation effect on performance

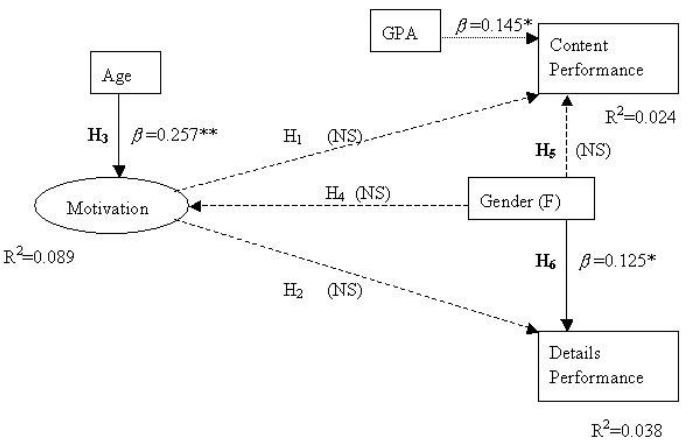

The path coefficient for "Motivation" to "Content Performance" is slightly negative (β=-0.007) but not significant. The coefficient for "Details Performance" is positive (β=0.132), as expected, but not significant either. These results go against hypotheses H_1 and H_2. The relationship between "Age" and "Motivation" is positive and significant (β=0.5257) at the 0.05 level. This indicates that the older the student the more motivated he/she will be, which lends general support for hypothesis H_3.

In regards to "Gender", results show a positive ((β=0.137) but not significant influence on "Motivation" (contradicting hypothesis H_4). The results also show a very low (β=0.055) and non significant influence on "Content Performance" (supporting hypothesis H_5), and a positive (β=0.125) and significant (at the 10% level) influence on "Details Performance" as predicted in hypothesis H_6.

The above results allow us to conclude that while female students are more detail oriented than male students, the performance in content does not differ based on gender. It is important to note that the relationship of the control variable (GPA) with the content performance was significant at the 0.10 level.

CONCLUSION AND DISCUSSION

In this study, the content and details performance of a group of individuals was assessed in order to develop a theoretical model which may clarify the nature of the relationships between age, motivation, gender, GPA and performance. This study assessed the effect which age and gender can have on the motivation to perform well on a given computer-aided learning task. The influence that motivation and gender have on performance was also assessed. The results suggest that older subjects perceive themselves as being more motivated than younger subjects. The results also suggest that females are more detail-oriented than males, leading to the conclusion that females can perform better in tasks which require the recall of detail-oriented information.

There was no significant difference between males and females regarding the content performance. An unexpected result was that motivation level did not significantly affect either content related or details related performance of the subjects. A possible explanation for the lack of influence motivation had over performance may be the fact that the individuals were extrinsically as opposed to intrinsically motivated, decreasing the likelihood that the subjects would have an increased level of learning and performance (Ryan & Connell, 1989; Deci & Ryan, 1996).

Trust Issues in Supply Chain Management

Robert A. Schultz, Woodbury University, 7500 Glenoaks Blvd., Burbank, CA 91510, USA; E-mail: bob.schultz@woodbury.edu

ABSTRACT

When corporate boundaries become blurred, as they are in contemporary supply chain management, distinctive ethical issues arise. In a traditional market situation, agreement with another company to charge a fixed amount is considered to be collusion or price fixing and to be both illegal and unethical. In a supply chain context, agreements that a supplier charge a fixed amount are essential for vendor managed inventory. Such agreements are not illegal and not regarded as unethical. What is the ethical basis for this difference?

SUPPLY CHAINS

A traditional supply chain involves three entities: A supplier, the business, and the customer. Traditionally, the business needs some supplies in order to produce or have available items it expects to sell to the customer. Traditionally, several suppliers compete to supply the business with these items, usually on price, availability, and quality. Price is usually negotiated and, although a good past history with a supplier may provide an advantage, the business regards itself as constrained only by its interests, not those of the supplier, in awarding subsequent orders. Indeed, in a competitive economy, the relation of the business to the supplier is parallel to the relation of the customer to the business. Customers, after all, have no obligation whatever to continue purchasing from the same business. It is up to the business to satisfy the needs of the customer better than other businesses. This normally involves doing better in competition on price, quality, and availability.

Ethics in the traditional situation mainly involves honesty on the part of the three parties involved in the supply chain. Misrepresenting the items one is competing on is a traditional way of taking unfair advantage. Also, if a supplier agrees to price or availability and then backs out, the ethical implications of reneging are clear. Similarly if the business misrepresents quality to a customer, it is not likely to get repeat business. And the customer must pay for the merchandise.

I.T. has dramatically changed the way in which the supply chain can be managed. Wal-Mart in particular has been a leader in using I.T. to produce a more efficient supply chain. (Foley & Mahmood 1994, 7-8) In effect, suppliers are chosen on a long-term basis and given the responsibility for managing the business' inventory of that item. The business forgoes the ability to obtain lower prices through negotiating on an order-by-order basis with different suppliers. But it directly negotiates its own inventory levels with the supplier, and the supplier competes long-term on being able to maintain those levels. Clearly this sort of arrangement is advantageous with high- and steady-volume items. The business has only the inventory it needs to meet customer demands, and there is no slack caused by internal processing. The ability to have the right inventory levels may more than make up for small cost savings. And both supplier and business need to share an accurate and reliable inventory management system enabled by I.T.

But the ethical situation changes. Rather than the supplier and the business pursuing their own interest and interacting through competition, a whole new layer of trust is added. The interests of the supplier become embedded in the interests of the business. Similarly, the interests of the business become embedded in the interests of the supplier. The supplier can no longer be concerned with maximizing quantity in its own interest--it must now be concerned directly with the proper inventory level for that item for the business. And the business must recognize that the supplier has forgone the chance for extra profit in the interests of a stable long-term arrangement.

The ECR (Efficient Consumer Response) model developed in the 1990s and adopted by a number of supermarket chains includes CRP (continuous replenishment) which requires supermarket and suppliers to enter into a long-term net-price agreement. Only then is it possible for the supplier to manage store inventories directly. In the case of the Texas grocery chain H.E. Butt, it was necessary for both the chain and the suppliers participating in CRP to come to see the situation as long-term potential win-win as opposed to short-term win-lose. A "non-antagonistic" mindset was required. (Clark and Croson 1995, 8)

Some commentators argue that such arrangements are unlikely to be stable precisely because competitive profit maximization and mutual trust agreements are incompatible. (Cox 2004, 410) Other commentators note that supply chain efficiencies require the development of trust and that the requisite trust requires more than formal contract conditions, but is "developed on the basis of personal contacts and confidence in performance." (Claro & Claro, 2004, 411) A standard text on the management of I.T. notes that "For [successful sharing of corporate information], the partner firms must . . . have a high level of trust in each other." (Frenzel and Frenzel 2004, 503) I believe both sets of commentators are pointing to the same difficulty: To obtain the cooperative benefit of supply chain efficiency, both business and supplier have to acknowledge that cooperative benefits take priority over their own individual interests. The agreement is in fact an ethical one and supported not by sanctions but by mutual recognition of a principle higher than individual interest. It is, in effect, a small-scale social contract. The problem is the stability of such an arrangement in the context of a profit-maximizing market economy. In the context of a competitive market economy, sanctions for violating such cooperative agreements can only be supplied by market forces. In effect, if a supplier or the business is unhappy, it can take its business elsewhere. If the business or supplier is a corporation rather than an owner, any possible additional ethical persuasion is simply not available. Impact on the bottom line is the only relevant consideration. Therefore, long-term agreements with suppliers to manage inventory for mutual benefit need to be viewed cautiously, especially by the less powerful party in such agreements.

WAL-MART

Wal-Mart's treatment of its suppliers is an interesting example; it is not only a corporation, it is by far the largest company on the planet. Its strategy is to compete entirely on the basis of low prices. (Wal-Mart's slogan is "Low Prices--Always.") So perhaps it is not surprising that it does not seem to have great concern for the well-being of its suppliers. As Charles Fishman points out, ". . . the real story of Wal-Mart . . . is the pressure the biggest retailer relentlessly applies to its suppliers in the name of bringing us 'everyday low prices.'" (Fishman 2003, 68-9) Fishman notes that Wal-Mart's 21,000 suppliers are constantly being required to lower their prices. He claims that, rather than being constrained by cooperative agreements with suppliers, Wal-Mart uses its size and power to achieve its own strategic ends. Wal-Mart spokesperson Melissa Berryhill disagrees: "The fact is Wal-Mart, perhaps like no other retailer, seeks to establish collaborative and mutually beneficial agreements with suppliers." (Fishman 2003, 71)

One should also note that in its supplier agreement, Wal-Mart bans the use of bribes or any other sort of kickback. It also strongly encourages its suppliers not to discriminate for employment not only on such traditional grounds as race and religion, but also on sexual orientation. (Wal-Mart [Supplier] Requirements 2005)

Because of its size, many suppliers have little choice but to deal with Wal-Mart on its own terms. Those terms are quite ethical in a traditional supplier context--it does not cheat suppliers, keeps its word, pays bills promptly--but it is willing to drive such suppliers as Vlasic Pickles into bankruptcy and Huffy Bicycle into years of losses. Few suppliers are even willing to talk about their experience with Wal-Mart

for fear of being frozen out. Wal-Mart has cashed in on additional threats such as moving production offshore, for example to China. (Fishman 2003, 71-4)

There is no question about the supply chain efficiency Wal-Mart has been able to gain. Because of its size, it can set and enforce standards for suppliers, for example requiring RFID identification on products from many of its suppliers by 2006. Again, in a vendor-managed inventory system, the additional burden for supplying RFID tags falls on suppliers and many commentators feel it will be excessive.[b] (Thomas 2003, Handfield 2004) Rob Handfield notes that smaller suppliers still have little choice and recommends forming a supplier consortium to gain some bargaining power with Wal-Mart. (Handfield 2004, 2)

To get a clear view of the ethics of this situation, we need to recognize that corporations are not ethical individuals. A properly functioning for-profit corporation obeys the principle of maximizing shareholder profits. Period. This is not an ethical judgement about corporations, but rather an observation about their nature. To the extent a supplier becomes the "captive" of a large corporation, there is no room for trust. Therefore, insofar as a supplier enters into a managed inventory agreement with a large corporation, it should not depend upon trust. Rather, the supplier must be able to enforce its side of the agreement without depending on the good will of the corporation.

Is it unethical for Wal-Mart to make agreements with its suppliers and then squeeze those suppliers? This is a misleading question because a corporation is not a person. It is a legal creation with some, but not all, of the properties of a person. So we need to consider the ethics of dealing with powerful entities which are not bound by personal ethical considerations.

DEALING ETHICALLY WITH CORPORATIONS

Even though the corporation is a legal construct and thus cannot act either ethically or unethically, it is constructed out of individuals who can and should be ethical. So the appropriate way of conducting ethical dealings with corporations is through individuals.[c] For small non-corporate business, there is no distinction: The (small) company is the owner or owners and these individuals are ethically responsible for what the company does.[d] But corporations are not individuals. Normally corporations respond only to that which is "real" for them, namely effects on profit and loss. Thus the futility of issuing public statements about unethical corporate behavior. Corporations will not become ethical agents through discussion of any kind, because they cannot become individual ethical agents.

So too with Wal-Mart. Because the violation of trust involved is not an issue which is likely to garner wider public sympathy, the suppliers are on their own to negotiate conditions protecting their own interests. Perhaps a supplier's association parallel to a labor union might be in order, as Rob Handfield suggests. (Handfield 2004) But such an association would likely be as much anathema to Wal-Mart as labor unions themselves. One of the things that corporations protect closely is their own power.

In the case of the "squeezed" suppliers for Wal-Mart, one way to avoid getting "squeezed" would be if possible not to let Wal-Mart gain the lion's share of one's business for a particular product line. Otherwise demands for lower prices (a central part of Wal-Mart's strategy) will have to be agreed to.

It look as though, although Wal-Mart is sensitive to traditional ethical considerations in the supplier relationship--not cheating suppliers, keeping its word, paying bills promptly--it may not have fully recognized the ethical implications of converting the supply chain. In effect, it continues to treat suppliers as hands-off partners free to take their business elsewhere. And Wal-Mart can continue to do so as long as they maintain their overwhelmingly dominant position in retailing.

So what is an individual to do when faced with a corporation conducting itself in a manner that would be unethical for an individual? I.T. professional codes of ethics envision such possibilities: The ACM (Association of Computing Machinery) Code mentions the professional responsibility of assessing the social consequences of systems and possible whistle-blowing if management does not act to mitigate dangerous consequences. Your choice may be to comply with unethical orders or to quit. There may be an opportunity to be a whistle-blower, but in spite of legal protections, this course of action usually costs the whistle-blower a fair amount. An individual may be fortunate enough to be able to cause the unethical behavior to change within the company without damaging his or her own prospects in the company. But one can hardly count on this happening.

What, then, are your ethical obligations against a corporation which is acting contrary to ethical standards? The relevant ethical consideration is that, in theory, whatever you ultimately do, higher level principles have to be acknowledged by what you do.[e] The critical point is that even if reasons of interest make it difficult or impossible for you or to do what you believe is ethical, it is still necessary for you to acknowledge your own ethical principles in what you do. It is easy to see why. If the fact that others are not behaving well was a sufficient reason for you not to behave well, the situation could never improve.

For example, if your corporation is making substandard hardware, your ethical responsibilities differ depending on whether you have the ability to influence the strategy of the company. If you do have influence, then ethically you are required to use it. If, however, the company is unwilling to change (its market niche may be to produce substandard equipment until word gets around), you need to consider leaving. If, for other reasons (family obligations), it is not possible to leave, you still need to continue to make your position known. If you do not have influence, it may be harder for you to make your position known, but ethically you still need to try. The critical point is that ethically you must acknowledge your own ethical principles in what you do.

The trust situations we considered involve mutually beneficial agreements or understandings between companies, instead of individuals. The ethical question is how to handle such situations when such agreements or understandings are violated. When there is a great disparity in the size and power of the two companies, as is the case with many of Wal-Mart's suppliers, there may be no viable ethical trust arrangement. Hobbes (1651), one of the first social contract theorists, noted that social contracts are possible only between parties of roughly equal powers. In Wal-Mart's case, it can simply order suppliers to obey its wishes. As Fishman notes, Wal-Mart suppliers are even reticent to talk about their experience with Wal-Mart for fear of retribution. (Fishman 2003, 71-4) Just as with the individual, the disruption to one's business caused by making waves may be more than one is ethically required to do.

In the case of long-term mutually beneficial inventory arrangements or outsourcing arrangements with a corporation, any additional stability can only come from appeal to the interests of the corporation--its own survival and its efficiency in producing more profits. Corporations are indeed sensitive to damage to their reputations. They usually want to be thought of as responsible citizens. But not because they are participants in a social contract they have a commitment to uphold, but because it is "good public relations." In this respect, corporations could be seen as at Kohlberg's Stage Three, Conformity, with a goal of "looking good" for others.[f] (Stage 6 is the most developed ethically.) Extensive corporate philanthropy tends to be justified in this way. But it is ultimately for the sake of the bottom line. It is more important for corporations to be *seen* as caring and responsible, for example, for the environment, than for them to *be* caring and responsible. (Since they are not individuals, it is far from obvious that they actually *could* be caring or uncaring.) For the ethical individual, it does not matter whether anyone *knows* that he or she has done the right thing. But for the corporation, being *thought* to be ethical is the whole point.[g]

So appealing to possible damage to a corporation's reputation can be a good strategy. It may be that, if indeed Wal-Mart imposed a restriction on the percentage of business a supplier can do with them, it could be for reasons of reputation as well as possible impacts on the bottom line. But we cannot expect corporations to behave as ethical individuals would behave. So trust arrangements such as agreements for vendor managed inventory have a built-in source of instability which, given current institutions, are simply part of the environment.

ABSTRACT

Conversational agents that display many human qualities have become a valuable method business uses to communicate with online users to supply services or products, to help in online order process or to search the web. Gaming industry and education may benefit from this type of interface. In this type of interface, users could have different alternatives: text display, photo of a real person, or a cartoon drawing and others. This is an exploratory study that reviews five randomly chosen conversations that an animated chatbot has with web users. The character simulates human gestures, but they are stylized to reproduce animation standards. The goal of this exploratory study is to provide feedback that will help designers to improve the functionality of the conversational agent, identify user's needs, define future research, and learn from previous errors. The methodology used was qualitative content analysis. The results of the study suggest improving the flexibility of the conversational agent, and reducing repetitions in the interaction.

INTRODUCTION

For today's online business whether selling a service or a product, the main goal of web sites is to keep its users at the site as long as possible. As an interface, a conversational agent has to offer some features to maintain its audience interested. Concerns about agents' body design and personal sociability have become obvious. Users may favor an interface that suits their own personality. They also may be more predisposed in an animated exchange with an agent if the character's voice matches content tone with gesture that complements the context.

Animation synthesis procedure permits to create through numerous randomly interconnected cycles a dynamic web based agent. Nadia (http://CLONE3D.com), a conversational chatbot, was developed by the third author, and it is a human like agent able to perform dialogues with users by "comprehending", generating phonemes with automatic lip-sync, and expressing body language, including body movements, hand actions, and facial gestures. The lighting of the virtual agent is practically naturalistic and uses conventional illumination techniques (See Fig. 1).

The design of conversational agents has to face a set of challenges: promote trusting relationships with their audience (Cassell and Bickmore, 2003), body language matching (Cassell and Bickmore, 2000), ability to communicate in different languages, and adapt to different cultural contexts. An intelligent real-time 3D artificial agent unlocks additional opportunities for computer mediated communication. The facial expressions in the agent are critical in a dialog and could be used with hearing-impairment audience (Massaro, et al., 2001). The goal of this exploratory study is to provide feedback that will help designers to improve the functionality of the conversational agent, identify user's needs, define future research, and learn from previous errors.

Figure 1. Nadia - a virtual character

DESIGN

Actions of the character are conceived to replicate human gestures, but behaviors are stylized to replicate animation standards. This design style builds a friendly web environment with web audience. The character employs AIML, Artificial Intelligence Markup Language, the Generation 4 Player, and Automated Personality Tool Set. Generation 4 is a player that simulates fluid full-body movement, mass and reactive actions, body tissue, gravity, and realistic physical responsiveness. The principles that guide the general design come from Lee and Lacey (2003).

The character is shaped with high production attributes in mind. Physical features containing an inner mouth with teeth and tongue, accurate fingers with fingernails and eyes are included in the model. The character also has over 50 facial points assembled into her expression database. These points are utilized to produce both a set of visemes, a basic unit of speech in the visual domain, to match phonemes for accurate lip-sync, other vocalizations, and present emotional changes in the facial expressions. Nadia's body features were developed for users' interest. The figure and components of the character's face and body are overstated to follow standards employed in caricature projects. For Nadia, the design target is to create an appealing, smart, young, female character, which is a standard method used in the development of female characters for broad appeal. To compliment the physical design, the personality is provided by ALICE bot, and its knowledge base was modified to answer with jokes by a process of trail and error.

TECHNICAL ENVIRONMENT

Haptek supplies a 3D player that is mostly employed to produce the character's movement. This technology can connect the model to a skeleton and provide method for correcting volume problems that appear when the character's extremities are in action. However, it does not have a simple approach to improve the model and re-skin the geometry to the skeleton. It has a pipeline for importing motion captured from the current skeleton, but export tool does not export it. The bone framework is used to have an easy method to incorporate skinning techniques. The Haptek player's toolset is hampered by its incapacity to supply the correct adjustments for the characters body, its poses, and mass volumes.

Currently the ALICE, an open source chatbot technology used for the verbal/text based responses, is limited by the amount of content that the knowledge base has. The knowledge base can be quite large and needs to address the questions and issues the user would have to develop an interesting character. ALICE knowledge base was modified to provide jokes to user by trial and error.

PROJECT GOALS

The primary objective was to develop a project called Artificial Comedy. A number of other characters are to be developed with the goal of building a set of perform-

ers: actors, singers, comedians, and other entertaining characters. Each one would have their own environment and friends. These environments would become part of a collection of bizarre expressions and comical performances of representative characters and circumstances. Exploring the exchanges these avatars have with online users will help in fine tuning their design.

RESEARCH DESIGN

Visitors

Authors could not identify who specific visitors were or population demographics, but from the server statistics some information was gotten such as top referring sites, visitor's country, queries visitors utilized to search.

According to the server statistics visitors who have requested files had come from the following domains: .au (Australia) 0.88 %, .ca (Canada) 1.34 %, .com (Commercial) 30.46 %, .de (Germany) 2.48 %, .edu (USA Higher Education) 0.77 %, .fi (Finland) 0.77 %, .fr (France) 1.85 %, .it (Italy) 1.70 %, .net (Networks) 26.84 %, .nl (Netherlands) 6.62 %, .pl (Poland) 1.12 %, .uk (United Kingdom) 1.12 %, [unresolved numerical addresses] 15.20 %, Others 8.77 %.

The words people used in search engines to find the site in the last seven days: 3d 1.80 %, animated 0.20 %, artificial 3.51 %, character 0.60 %, characters 1.20 %, chavez 0.10 %, clone3d 0.20 %, download 0.30 %, girl 43.69 %, haptek 1.10 %, intelligence 0.30 %, mark 0.10 %, stories 0.30 %, time 0.20 %, virtual 40.58 %, virtualgirl 1.10 %, not listed: 1,124 search terms 4.71 %.

Visitors used the following queries in search engines to visit the site: artificial girl 5.68 %, virtual girl 82.10 %, virtual 3d girl 0.21 %, virtual girl 3d 0.21 %, 3d characters 0.42 %, artificial girl 2 0.42 %, clone3d 0.42 %, artificial girl download 0.42 %, haptek characters 1.05 %, 3d virtual girl 1.26 %, virtualgirl 2.10 %, not listed: 1,283 search terms 5.68 %.

METHODOLOGY

The dialogues between the chatbot and the online users were recorded in a log file. Five dialogs were chose randomly, some of them were more than two hours long, and all of them were more than one hour long. Chats took place from June 1st. to June 19 from a set of more than 170 dialogues. Qualitative content analysis was used to analyze the data, utilizing QSR N6, previously known as Nudist. The categories were created in an inductive process, common in content analysis methodologies. These categories were examined by three authors, each one initially working independently, and later coming together to get a consensus, but inter-code reliability was not estimated. These categories were developed from the conversational agent's perspective, for example, how to supply information and help its visitors, how well it "comprehended" visitors' contributions, how it managed imprecise input, et cetera.

RESULTS

Topics Addressed in Dialogs by Visitors

One user had an illogical conversation with correct grammar in general terms and no spelling mistakes. Other asked for obscene expressions and jokes, and another required affectionate conduct from the chatbot.

One user tested the factual knowledge the agent posses and focus his questions on literature. He asked about who Mark Twain was, who wrote Tom Sawyer and his nickname, Philip K. Dick, a science fiction writer, and other questions. The same user tested the agent's analytic aptitude in Mathematics: the ability to solve equations, the Riemann hypothesis, and the demonstration of last Fermat's theorem.

Three visitors were trying to persuade the chatbot to engage in some sort of virtual sex. Two of them were interested in movies; one of them in science-fiction pictures, like Star Trek, Star Wars, and Matrix, and the other one wanted to know where to download free sex movies and movies in general. Two users showed great interest in the conversational agent competence, and one of them was interested in its potential.

Description of Dialogs

A dialog that had sessions as long as 43 hours may not imply the dialog was that lengthy. Visitors in addition to chat with Nadia did other things. Conversation one lasted one hour 22 minutes in June 19, 2006.

Probably, visitor one knew what to expect from a chatbot and asked: "Nadia, can you tell me why Eliza Clone copies everything I say". He attempted to comprehend the potential this chatbot has, and asked if he gave his name, the chatbot could recall it. In the beginning, the agent did not follow properly the dialogue, even visitor one was making a significant effort to maintain the dialogue flowing and making sense of the conversation.

The agent check the initial word of the next expression: "nice talking with you" and answers, "thanks for the compliment". It creates the impression when a visitor provides congruent responses, the agent is more proactive, and looks like the agent is following the conversation.

Visitor one handled the agent courteously as he was interacting with another person; in addition, the interaction was very positive. This user was interested in the agent's level of intelligence and its learning capacity. He explained different issues, tried to reason, talked about movies, and asked the agent for help to find a game that was only sold in Japan. This user made a big attempt to maintain the agent in track with the conversation, but the lack of contextual knowledge and knowledge in general limited the conversation. He had some misspellings, and his behaviour was very polite.

Dialogue two took one hour 22 minutes in June 1, 2006. The conversation was trivial, but the interaction was intense. For example, Nadia said "Excuse me! You are a really tedious dope". Only a few interactions have continuity, and the dialogue was chopped and repetitive. There was no proper beginning and end, some incorrect sentences, misspellings, and insults from the users. Probably, visitor two was a chatbot. The dialogue was full of non-sense, which is someway appealing and amusing to observe how two chatbots may interact with each other.

Conversation three took twenty-one hours and 40 minutes in June 14 and 15, 2006. Initially, visitor three did not make sense. He used single word or short expression without giving context. The chatbot behaviour became reiterative, and this user criticized that behaviour by exclaiming "stop repeating".

Visitor three articulated sexual expressions, gave orders, conveyed obscenity, and wrote sexual abbreviations such as "omfg" that Nadia did not understand. This visitor became repetitive as he used the same expression several time and twice consecutively, "one point for you", and he requested affectionate conduct from the chatbot. When he did not get what he demanded, he insulted Nadia. This dialogue in general was not interesting because of the amount of single words written by the visitor, and his involvement was limited in most part of the conversation.

Dialog four lasted 43 hours and 42 minutes from June 1st to June 3rd, 2006. Visitor four had belligerent actions, attacking the agent for not being sharp enough and did not fulfill his request for virtual sex. His language was contradictory; he was curious in the bot's analytical capabilities, intelligence, and its potential as information agent.

Dialogue five took 38 hours and 30 minutes from June 11 to June 12, 2006. Visitor five was basically motivated in one topic, virtual sex, including coarse language. He used diverse tactics to accomplish his objective. Frequently, when he failed, he abused the chatbot. The tactics he used were the followings: asking to perform some actions in his subject of interest, coercion, adulation, argumentations, et cetera.

Categories Developed

The categories arose from the agent perspective, its specific behaviors and answers during its dialogs. The sample of users is not necessarily representative of the population. The creation of these categories follows an inductive process typical of content analysis. Each author did the analysis independently, met, and achieved consensus over the final categories. The categories developed were the followings:

Ambiguous Input - Answers to short expression without context;
Bot Talking - agent talking like machine;
Complements - Answering and providing complements;
Greeting & Bye - Welcoming and saying good bye;
Help - providing information and suggestions offered by the agent;
Insults - Answering insults;
Intelligence & Knowledge - Factual knowledge and pseudo - analytical abilities;
Jokes - Agent humor;
Leading Comments - Agent answers guide the user to some topics;

Memory - "Remembering" information provided by the user;
Miscommunication - failure to communicate clearly;
Personal Issues - Exchange of personal information;
Proactive Behavior - Learning possibilities;
Repetitive Behavior - Recurring answers; and
Technical Problems - Technical difficulties the user confront.

DISCUSSION

Some operational troubles in the agent are interconnected. When a user brings in ambiguous inputs in the conversation, the agent becomes "confused". It does not have explicit context to maintain an articulated dialog. A dialog needs at least two parties, but the user may not intend to participate in the social exchange. The chatbot can be proactive, offer help and suggestions, and make remarks that may direct the conversation into topics in which it has its main assets. For example, when a user protested about technical troubles, the chatbot offered some recommendations. When the user asked for information, the chatbot answered them to do any of the followings: to check the open directory, answers.com, or to send an email to. Although, this is an adequate alternative, due to the limited amount of programmed answers, sometimes the chatbot sounds reiterative.

Some users deplored chatbot's lack of functions and repetitive answers. These issues could be solved by providing the agent with a variety of answers, employing the contextual information provided by the user, and improving and handling agent memory. Lack of conversation flow and miscommunication were frequent practice, but not always due to agent problems. Sometimes, the users were distracted. Users became perplexed when the chatbot repeated phrases, providing wrong answers, or not following the dialogue sequence.

In general, the chatbot is polite, and it can compliment users. At the same time, it is able to receive compliments graciously, but sometimes it answers with similar phrases, which could make the communication tedious. It is capable to respond some offences, but not all of them. The chatbot present a dual behaviour, sometimes it expresses clearly that it a conversational agent to the user, but not always. One of the most critical difficulties that users described in the dialogues was the agent voice. At that time in some conversations, not only the voice did not appear natural, but also not as woman speech. This problem was solved, but it generated some confusion in the users.

CONCLUSION

From this research, the authors found out that users in these conversations did not employ the chatbot for humor purposes. Some of jokes the agent can tell may not be adequate for some users, and we will have to find what type of joke visitors would like to hear. The opening and the end of a dialog are important. In the beginning, the chatbot, besides providing its name to the visitor, may provide a presentation about what it is and is capable to do. In that sense, visitors will not have expectations that the conversational agent is not able to perform. Among the areas for improvement are having better welcoming segment, involving more diverse answers, and reducing the length of the goodbye segment when the visitor provide clues that he has to abandon the dialog. Although, miscommunication cannot be prevented, it may be decreased if the conversational agent becomes more proactive and has better logs. The latent technical troubles should be recognized, and the possible answers should be part of the assistance the chatbot provides to its visitors.

ACKNOWLEDGEMENTS

We would like to thank the anonymous reviewers for their work, suggestions, and opinions.

Municipal Broadband Case Study: San Francisco's Community Wireless Broadband Initiative

Heather E. Hudson, University of San Francisco, USA; E-mail: hudson@usfca.edu

ABSTRACT

In December 2005, the city of San Francisco issued a request for proposal (RFP) for a community wireless broadband network. The RFP stated that the network was to be built, operated and maintained at no cost to the city, that a basic level of service should be free, and that the entire city should be covered. Responses submitted included two proposals from consortia of major high tech firms (EarthLink and Google, IBM and Cisco) and four proposals from smaller firms and consortia. The EarthLink/Google proposal was selected as the winner. This initiative has achieved significant national and even international attention, largely because of San Francisco's visibility in the high tech world, and the involvement of Google. While San Francisco's wireless broadband initiative is an innovative approach to increasing broadband access for its residents, its underlying assumptions and strategies appear somewhat flawed. This paper analyzes the assumptions, the RFP and selection process, and compares them with municipal wireless initiatives in nearby Silicon Valley communities. The paper concludes with lessons and unresolved issues from the San Francisco experience relevant for other municipal broadband projects and for broadband community access in general.

1. THE CONTEXT: BROADBAND IN THE U.S.

Affordable access to services available over broadband is becoming increasingly recognized as an important contributor to social and economic development. Yet utilization of broadband in the U.S. lags many other industrialized countries. (The U.S. currently ranks 12th among industrialized countries in broadband access per 100 inhabitants according to the OECD.[a]) American broadband adoption is also highly dependent on socio-economic status: almost 60 percent of households with annual incomes above $150,000 have broadband; fewer than 10 percent of households with incomes below $25,000 have broadband.[b]

Broadband costs in the U.S. remain high: American consumers pay 10 to 25 times more per megabit than users in Japan. Also, average speed of broadband in the U.S. has not increased in the past five years; consumers in France and South Korea have residential broadband connections 10 to 20 times higher than in the U.S. Further, there is little competition in most areas, with cable and DSL providers controlling over 98 percent of the market.[c]

Some U.S. cities are responding to limited availability or take-up of broadband via DSL or cable by taking the initiative to provide free or low cost broadband via wireless. In October 2005, the city of Philadelphia selected EarthLink to establish a municipal wireless network that was the largest urban network to date in the U.S., and was to include subsidized access in low income areas. In 2005, San Francisco also jumped into this fray, with a Request for Information (RFI) and later a Request for Proposal (RFP) for free wireless broadband covering the entire city.

2. THE SAN FRANCISCO TECHCONNECT INITIATIVE

2.1. From Affordable Internet to Ubiquitous Wireless Broadband

The city of San Francisco has a population of about 777,000 and area of 49 square miles, with an average population density of about 16,500 people per square mile. It is highly ethnically diverse, with a population that is 30.8 percent Asian, 14.1 percent Hispanic, and 7.8 percent African American according to the 2000 census. Median household income is about $55,000.[d]

In mid 2005, the City of San Francisco[e] established TechConnect, a "strategy to promote digital inclusion by ensuring affordable internet access, affordable hardware, community-sensitive training and support, and relevant content to all San Franciscans, especially low-income and disadvantaged residents."[f] In September 2005, TechConnect released a request for information and content (RFI/C) which stated: "Universal, affordable wireless broadband internet access is essential to connect all residents of San Francisco to the social, educational, informational, and economic opportunities they deserve."[g]

Between the initial strategy announcement and the RFI/C release, "affordable Internet access" had become "affordable *wireless broadband* Internet access." Yet there was little rationale for the emphasis on wireless as a city-wide solution. San Francisco has broadband available over DSL and cable (primary providers are AT&T and Comcast); fixed wireless and fiber access are available in some areas and buildings. No data were provided on where broadband is not available, nor on broadband subscribership by zip code, neighborhood, income, ethnicity, or other variables. If broadband usage is lowest among low-income and other disadvantaged residents, as appears likely, no studies were available to show whether the primary reason was pricing of broadband services, or whether other factors were also important such as lack of computers, lack of computer and Internet skills, perception that content was irrelevant or harmful, etc. TechConnect has set up a Task Force on Digital Inclusion with representatives from many community and ethnic organizations, but this was not done until April 2006, *after* the RFP was written and the winning proposal was selected.

However, following the RFI/C process, the City issued a request for proposal (RFP) with the goal of providing "*universal, affordable wireless broadband* access for all San Franciscans, especially low-income and disadvantaged residents" (italics added). The RFP listed detailed specifications including:

- The network should be built, operated and maintained at no cost to the city.
- There should be a free (basic) level of service.
- Premium services can be fee-based, but should be priced lower than existing service alternatives.
- Outdoor coverage shall be provided for a minimum of 95 percent of the city's area.
- Indoor coverage shall be provided for ground and second floors of a minimum of 90 percent of all residential and commercial buildings in the city.
- Indoor perimeter room coverage above the second floor shall be provided for ground and second floors of a minimum of 90 percent of all residential and commercial buildings.[h]

Given San Francisco's topography with its numerous hills, and its high urban density including many areas with multistory residential buildings and office buildings, these are very demanding specifications. Also, although "existing service alternatives" are not defined, a version of DSL is currently offered for $13 per month and cable modem access for $20 per month.[i]

2.2. The Bidders

The city received six proposals, one of which was very sketchy and is not included in this analysis. The five complete proposals were from:

- EarthLink/Google (the eventual winner)
- MetroFi[j]
- nextWLAN[k]
- Razortooth[l]

- Seakay, with Cisco and IBM.

For a summary of key elements of their proposals, see Table 1. A few distinguishing elements included:

- RedTAP (the project submitted by Razortooth), proposed a cooperative model, community access centers, and also training and technology for residents. Their proposal noted: "Without a real strategy to provide technologically underserved residents with WiFi enabled laptops or desktops, the disadvantaged will be further left behind."[m]
- Cisco and IBM partnered with Seakay, a nonprofit organization, and stated about their financing only that the project would be financed through nonprofit fundraising, with cash and in-kind donations. Yet theirs was the longest and most technically detailed proposal.
- NextWLAN proposed that the higher speed premium service would be financed by deploying about 100,000 micronode repeaters that subscribers would rent and attach to an existing estimated 40,000 DSL lines.

2.3. The Google Effect?

The proposals were evaluated by five reviewers, four of whom were city employees with various IT responsibilities. The written proposals were scored out of 80 points, 20 being for firm qualifications and 60 for degree of compliance with the city's specifications. The top three were EarthLink/Google and MetroFi, separated by only 4 points with 260 and 256 out of a possible 400 aggregated from the five reviewers, and SeaKay a distant third with 148 total points. Three of the reviewers ranked EarthLink higher on firm qualifications, while four ranked MetroFi higher on compliance with city specifications. See Table 1. The oral interviews, which covered a wide range of issues including technical solutions, costs to the city, user interfaces, digital inclusion, experience in other municipal wifi projects, etc., turned out to be critical to the outcome. Here EarthLink/Google was rated highest by the four city employees (the outside consultant gave identical ratings to both), so that EarthLink/Google received a total of 69 points of the aggregate 100, compared to only 57 total points for MetroFi. Thus EarthLink/Google won the combined review, but the aggregate scores differed by only 16 points out of a possible 500 point total.

Was this the Google effect? Since the written proposals were scored very closely and covered many of the same topics, the EarthLink/Google presentation must have been highly persuasive. Did the opportunity of having Google as a partner make the difference? The press coverage (both popular and professional) of the project since the winner was announced has overwhelmingly highlighted Google's involvement.

3. OTHER BAY AREA MUNICIPAL WIRELESS INITIATIVES

3.1. Wireless Silicon Valley

Another major Bay Area RFP for municipal wireless was released in April 2006 by the **San Mateo County Telecommunications Authority (SAMCAT), for** service to some 35 communities in four counties in the area referred to as Silicon Valley. The RFP differs in several ways from that of San Francisco's TechConnect. The area and population covered are much larger; for example, the combined population of San Mateo County and Santa Clara County is about 2.4 million, and land area is about 1740 square miles. Population density is about 1400 per square mile, and about 30 percent of residents live in multi-unit dwellings.[n] Only outdoor wireless coverage of the region is required; service can be either free or "low cost." Other services are "desired" but not required, including enhanced outdoor service, indoor guaranteed service, government service, and public safety services. All of these other services may be fee-based.[o]

Seven proposals were received. SAMCAT announced on September 5 that it had chosen the Silicon Valley Metro Connect consortium as the winner.[p] This is basically the same group that ranked third in San Francisco, with the addition of Azulstar, a municipal wireless ISP. Neither written proposals nor evaluations by reviewers have been made available online.

Interestingly, EarthLink chose not to submit a proposal. Its rationale, submitted in a letter to SAMCAT, identifies some of the key issues in developing sustainable business models for municipal wireless. EarthLink states: "…we have not been able to reconcile the RFP's strong desire for a basic free layer of access throughout the coverage area." It points out the quality of service (QOS) problems that may result from low node deployment densities on some free systems: "Some of the operators … have attempted to obscure these problems by switching to free or advertising-supported business models, hoping that because end users are no longer required to pay for the service, they would be willing to overlook the poor performance and poor coverage of the networks."[q]

EarthLink appears to see municipal broadband as an opportunity to compete with incumbent telco and cable companies, i.e. to provide intermodal competition: "EarthLink … believes that municipal Wi-Fi connectivity will serve as a viable third broadband alternative to the home, at prices that will spur competition and choice in those progressive cities that elect to build."

It notes that its network design, using dense mesh of 36 Wi-Fi nodes per square mile, pushes the signal further into the consumer's home and requires higher investment. EarthLink concludes that advertising revenue alone would not cover its capital costs or provide a sufficient revenue stream. (Metro Connect apparently proposes that users can bring the outdoor signal indoors with the aid of special, signal boosting equipment that they will be able to purchase for $80 to $120.)[r] EarthLink also notes that free or ad-supported networks typically ignore other items that "comprise a comprehensive broadband solution" such as CPE and technical support. It also foresees needs to update and upgrade the network: "We do not believe that user needs five years from now will be the same as they are today."[s]

But is this the same EarthLink that won the San Francisco competition which required free citywide service and penetration within buildings for premium service? Is EarthLink simply stating that the less rigorous SAMCAT RFP would enable bidders with cheaper designs to win, but not to be sustainable? Or/and is it saying that Google's deep pockets are the only reason it chose to partner in a bid in San Francisco?

3.2. Cupertino and Santa Clara

Two other Silicon Valley communities, Santa Clara and Cupertino, have contracted with MetroFi to provide wireless broadband. However, the business models vary in the two small cities, which are also geographically and demographically very different from San Francisco.

Santa Clara has about 110,000 residents, and covers 19.3 square miles. It borders San Jose, and is the location of Santa Clara University, a convention center, and numerous high tech companies including Intel.[t] Santa Clara has authorized MetroFi to install a wireless citywide network.[u] In January 2006, MetroFi announced that free wifi was available across the 95050 and 95051 zip codes from 180 access points. It started with coverage of half the city, and planned to cover the whole city including about 40,000 households by the end of the year.

It appears from early press releases that MetroFi originally intended to use the same business model as adopted in Cupertino, charging $19.95 per month. However, MetroFi now appears to have adopted an advertising-based business approach: "The MetroFi network also brings a new opportunity for local businesses to reach the community through a truly local internet advertising medium. Customers that are accessing the network will be shown a banner advertisement in the frame of the browser. Local businesses can take advantage of the local and regional nature of the network by providing links to their website, coupons or announcements to those that are guaranteed to be near their establishment."[v]

Cupertino, also in Silicon Valley, has a population of about 52,000, of whom about 50 percent are Caucasian and 44 percent are Asian; the median income is just over $100,000 per household.[w] Cupertino is also the home of Apple Computer. The contract between MetroFi and the city is a non-exclusive installation and service agreement. The business model here is subscription-based; MetroFi acts as a no-frills provider and open access wholesaler. The basic service for $19.95 per month includes a wireless modem, but no email or other services, so that the user can continue with existing ISP (e.g. MSN, Hotmail, Google, etc.) MetroFi also wholesales access to ISPs such as EarthLink (which offers enhanced service for $24.95 per month).[x] Coverage is about 75 percent of Cupertino (about 15,000 households).

MetroFi states that the service in Santa Clara and Cupertino offers "DSL-like speeds" (about one megabit per second). The subscribers transmit data to the Internet via access points mounted on street light poles throughout the cities. The design uses 20 to 23 mesh infrastructure nodes per square mile (compared to the "dense mesh" of 36 nodes per square mile that EarthLink thought was necessary). MetroFi claims it is able to provide municipalities with "all-in" pricing of $50,000

per square mile, inclusive of site surveys, network design, equipment, and installation. MetroFi also operates and manages the network to provide municipalities with a turn-key, open-access solution.[y]

4. CRITICAL ISSUES

4.1. A Threat to Incumbents?

The incumbent telecom industry is claiming several points of view about the growth of municipal broadband, including wireless. First, they say that municipal broadband isn't the answer to increasing broadband access. Pyramid Research questions "whether the dream of 'cheap Internet for everyone everywhere' will ever materialize as expected." Their view is echoed by incumbents: "We expect that municipal Wi-Fi networks will not match other offerings' unique content, security features, and reliability."[z]

Second, incumbents claim that public investment in communication networks crowds out private investment. They have lobbied vigorously at the state level to prohibit or severely limit municipal broadband. Baller notes that in 2004: "Not just small rural communities, but even large cities, such as Philadelphia, San Francisco and Minneapolis, had become intensely interested in developing citywide wireless projects. The incumbents saw this as a much more significant threat than the relatively small number of municipalities that were operating or pursuing wireline options."[aa] As of August 2006, the following states had passed legislation to prohibit or hinder municipal entry into communications: Arkansas, Colorado, Florida, Louisiana, Michigan, Missouri, Minnesota, Nebraska, Nevada, Pennsylvania, South Carolina, Tennessee, Texas, Utah, Virginia, Washington, and Wisconsin[ab] [ac]

However, new entrants see municipal wireless as a means to increase competition. In Congressional testimony, EarthLink stated that municipal broadband is an antidote to facilities-based duopoly.[ad] A Florida study also finds no evidence to support the "crowding out" hypothesis, but strong support for a stimulation hypothesis – municipal-run networks typically provide wholesale access to key components of telecommunications infrastructure. Ford's empirical model, using data on the number of CLECs in particular markets in Florida, indicates that municipal communications actually increase private firm entry.[ae]

Yet incumbents also appear to think that may need to get in the game, if only to stave off new competitors such as EarthLink if partnered with major investors such as Google or possibly Yahoo or Microsoft. One consulting firm predicts that municipal networks (not only wireless) could grab up to 35 percent of the market share for video, fixed voice and high speed Internet services, and up to 20 percent of the mobile services market. It notes that "The competitive impacts will be especially threatening to incumbents to the extent that municipal networks can be cost-justified by increasing efficiencies, cost-savings and other 'internal' or 'social' benefits captured by local governments, schools, schools and other public institutions."[af] Thus "… broadband incumbents may have to deploy their own competitive Wi-Fi network offerings, and offer mobility as a differentiation tool."[ag]

4.2. Business Models and Sustainability

Several business models have been proposed for municipal broadband. More than 2000 US communities have public power systems; many have their own optical fiber for managing their networks. Some of these municipalities have decided to provide broadband access to the public over their networks. Their typical anchor tenant is the local government; some expand to serve local businesses. If they choose to serve residential customers, they may tie into the local telephone company for long distance services, or expand their networks to homes using fiber, hybrid fiber-coax or broadband over powerline (BPL). They may become an ISP or a conduit for multiple ISPs.

For wireless, municipalities typically contract with the private sector to build and operate the network, which may be owned by the municipality or the contractor (the latter investment model is known as build, own and operate or "BOO"). The revenue models are typically:

- Free service, advertising-supported;
- Subscription service, often with various tiers or options;
- Hybrid with free service in some areas or some users, and fee-based services elsewhere.

The verdict is still out on whether any of these models are sustainable. Given the insistence of many communities to include free service, advertising seems to be necessary, assuming that subscription fees would not be sufficient to cross-subsidize free service. The requirement of many municipalities to keep subscription fees low, or even to specify that they must be lower than available alternatives, limits operators' pricing flexibility.

EarthLink raises two additional issues, namely that quality of service must be adequate if municipal wireless is to be a viable alternative to DSL or cable, and that user needs, and therefore technology requirements, are likely to change over the next five years. Thus, capital and operating costs may be higher than foreseen by some community access proponents.

So why would the private sector want to get into this game? There appear to be two major drivers for the operators and content providers (as opposed to the equipment vendors, who have a clear interest in sales for this new market). First, some see it as a means to compete with incumbents without being forced to use their networks. It appears that MetroFi and EarthLink fall into this group. If they succeed, this might become the "third pipe" envisioned by the Hundt FCC or a form of the intermodal competition championed by the Powell FCC. Second, content and service providers are looking for new markets and testbeds. Google definitely appears to be in this category.

4.3. A Stepping Stone to 3G?

For incumbents, is municipal wireless an opportunity to try out services that could be offered over 3G? The real goal for content and application providers such as Google may also be to develop strategies and content that can be transferred to 3G networks. Of course, this scenario would also affect the business model of municipal wireless. Will 3G be the "killer response" that wipes out revenue for municipal wireless once mobile users have access to broadband on their cellphones and PDAs, or on notebook computers? If so, what happens to the goal of free or very cheap broadband access throughout communities?

4.4. Community Access and Demand

To achieve the goal of affordable broadband for low-income and disadvantaged populations, communities need more information on why few subscribe. For example, are there areas of the city that do not have broadband available by DSL or cable or some other means? Where service is available, what percentage of households in each neighborhood subscribe? Are the barriers to access strictly financial, or are there other barriers, such as lack of computers, lack of skills or confidence to use computers and the Internet, lack of appropriate content or applications?

Some national-level research may provide insights. For example, Flamm and Chaudhuri found that males are less likely to be Internet users, but once involved, more likely to opt for broadband. They also found that age, race and income have statistically significant impacts on propensities to use the Internet in general, but no additional impact on choice of broadband vs. dialup.[ah] Of course, these and other findings would need to be tested at the community level. We also know from other community access experience that many who are not connected will need training, access to computers, and an understanding of how the Internet could be useful to them and their families. Community outreach will also likely be needed.

If a key barrier is availability or affordability of computers, San Francisco could consider initiating a computer installment purchase plan for low-income and disadvantaged residents, such as a lease-to-own scheme for a small down payment and $20 per month. Private sector or NGO partners may be able to devise such a program.

If price of broadband service is a significant barrier (and if most unconnected households already have computers), the goal of affordable access for the low-income and disadvantaged could be achieved through a discount or voucher for those who meet low income criteria.

4.5. Pricing

San Francisco's RFI states: "Fees for access to the Network must be priced lower than existing alternatives and must be affordable for low-income and disadvantaged residents and businesses." These are two quite different criteria. The standard should be the second clause of this sentence, not the first. Affordability can be achieved without undercutting other broadband providers if they offer affordable service.

4.6. Is Ubiquitous Wireless the Only Solution?

The San Francisco RFP states: "Universal, affordable *wireless* broadband internet access is essential to connect all residents of San Francisco to the social, educational, informational, and economic opportunities they deserve." This pronouncement confuses the means with the ends. The goal should be *universal (i.e. available and affordable) access to broadband.* Wireless is very appropriate for outdoors and public spaces. It is less suitable for individual households, multiunit dwellings, high rises, office buildings, etc. Besides, many of these could already be served by commercial cable or DSL.

5. CONCLUSIONS

San Francisco's emphasis on wireless alone is misplaced; there is no evidence that the city needs *free universal wireless* broadband. The goal should be *universal (i.e. available and affordable) access to broadband.* Wireless is definitely a major part of the solution to achieve this goal, but it need not be the only solution.

The advantage of wireless for a city is that it can provide coverage for public spaces. San Francisco should be seeking wireless coverage first for outdoor public spaces and other community and public access locations.

A second priority should be facilitating broadband access for low-income areas and disadvantaged populations that do have other potential options such as DSL or cable, but cannot afford them. Discounts or vouchers for broadband access could be solutions. They should apply to service from any broadband provider, including cable networks and resellers as well as DSL from the incumbent, AT&T.

A third priority should be to require that all commercial and residential buildings in San Francisco have broadband access. Again, wireless may be part of the solution, but other technologies – and providers – are likely to be more cost effective in many cases, particularly given the terrain of San Francisco and the number of multistory residences and commercial buildings.

San Francisco should also use its legal and persuasive powers to achieve these goals. For example, the city selects and approves the cable franchisee, currently Comcast. A franchise requirement should be to provide Internet-capable cable access in all buildings and a subsidy program for low-income subscribers. Permits for new commercial buildings and multi-unit residences should require broadband cabling throughout.

The San Francisco TechConnect initiative and the experience of other communities seeking wireless broadband coverage suggest that many unanswered questions remain about the need for ubiquitous wireless, the barriers to broadband usage, and the financial and technical sustainability of municipal wireless.

Re-Conceptualising IS Research: A Mindful Process

Kay Fielden, Unitec Institute of Technology, New Zealand; E-mail: kfielden@unitec.ac.nz

ABSTRACT

In this discussion paper mindfulness is linked to Denzin and Lincoln's(2000) 5-stage qualitative research process. In socially-situated IS research a mindful researcher is more likely to produce quality results. A timeline for a typical qualitative research process in information systems presented. The paper concludes with suggestions for including mindful practices in research methods and supervision training in information systems.

Keywords: Mindfulness, qualitative research, information systems

INTRODUCTION

Mindfulness for IS qualitative researchers as an essential characteristic is presented in this discussion paper. First the characteristics of mindfulness are described(Fielden,2005); a typical qualitative research process is defined(Denzin and Lincoln,2000); mindful qualities are then mapped onto this 5-stage research process; a typical research project timeline shown; and implications arising from these mappings for educating qualitative researchers in information systems are also explored.

MINDFULNESS DEFINED

Mindfulness encompasses many qualities(Figure 1) including: mental flexibility, focussed attention, awareness of distractions, refocusing, immersion, meta-awareness and neutral observation.

Mindfulness and the Intellect

IS researcher's require is a well-developed intellect that notices novel distinctions(Figure 1). This ability is required in identifying new research opportunities. Mental flexibility is also required to view existing situations, data, or to analyse results. Understanding multiple points of view is a necessary requirement for gathering the rich data needed particularly for IS qualitative research.

Mindfulness as both state-of-mind and practice, envisioned as an integrated whole has its roots in multiple religious traditions. Bias-free observation and a deep understanding of self and others is a core part of such traditions.

Mindfulness and the Self

Developing levels of self-awareness of rational, emotional, spiritual, and psychological self is part of a mindful researcher's toolkit. Maturity emerges with growing awareness of multiple layers self. The mindful self is also aware of the likelihood of chaos, especially in initial research phases(Figure 1).

Mindfulness and Spirituality

Zukav(1989) believes that intuition is 'the voice of the soul(p83). Without intuition researchers do not have access to emergent whole systems, nor do they have the mechanisms that enable deep and powerful contact with the divine. Mindful researchers are more likely to embrace the spiritual dimensions of mindfulness: humaneness, courage, respect, integrity and reverence (which do not appear to be included in research training curriculum in information systems(IS)).

Non-judgment is a paradoxical mental state for an IS researcher (implied only in grounded theory(Glasser and Strauss,1967)) but not in other IS research methods. Non-judgement is also implied when any form of systemic thinking(Checkland, 1984) is utilised as a research tool.

Mindfulness and Immersion

It is assumed that immersion in research data will automatically occur. Awareness of changed states of consciousness, mental focussing, the nature and impact of distractions on immersion and the importance of chaotic thought processes that precede immersion are all mindful skills that can be learned(which do not usually form part of an IS research methods course).

Initial states of confusion Wheatley(2001b) are a characteristic of mindful engagement. Wheatley also suggests that listening, rather than engaging in our own inner dialog, is a necessary precursor to mindful engagement and immersion(Wheatley, 2001a). If we do not listen to self, others, and our surroundings, we cannot be present in our social interactions.

Practises that include: training in listening to own inner dialogue to distinguish this from listening to others, particularly when data is being collected; familiarisation with inner chaos – a common state during the early stages of research; a growing awareness of evolving conceptual maturity; an understanding of multiple points-of-view; and an acknowledgment of many self-layers; are all important mindful qualities for IS researchers.

Socially-Situated Mindfulness

Qualitative research in IS is socially-situated. Becoming mindfully aware of researcher-interactions in social situations in gathering data involves entering with a greater awareness of culture, protocols, practices and procedures. When heart and intellect operate together discernment, discrimination, and a greater appreciation of socially-situated knowing(Reason and Bradbury,2001) occurs. The mindful intellect acts upon novel distinctions Langer(2000) with greater flexibility. Butler(2001) identifies contexts of practice that include both social settings and the minds of the knowers.

Mindfulness and Cognitive Maturity

Meta-awareness and presencing are mindful dimensions achieved with cognitive maturity. Both require awareness of what is happening while it is happening. Both require a detached self to notice and learn from the process being experienced. It appears that meta-awareness and presencing belong at a higher cognitive level(but not necessarily high spiritual, emotional, or psychological levels).

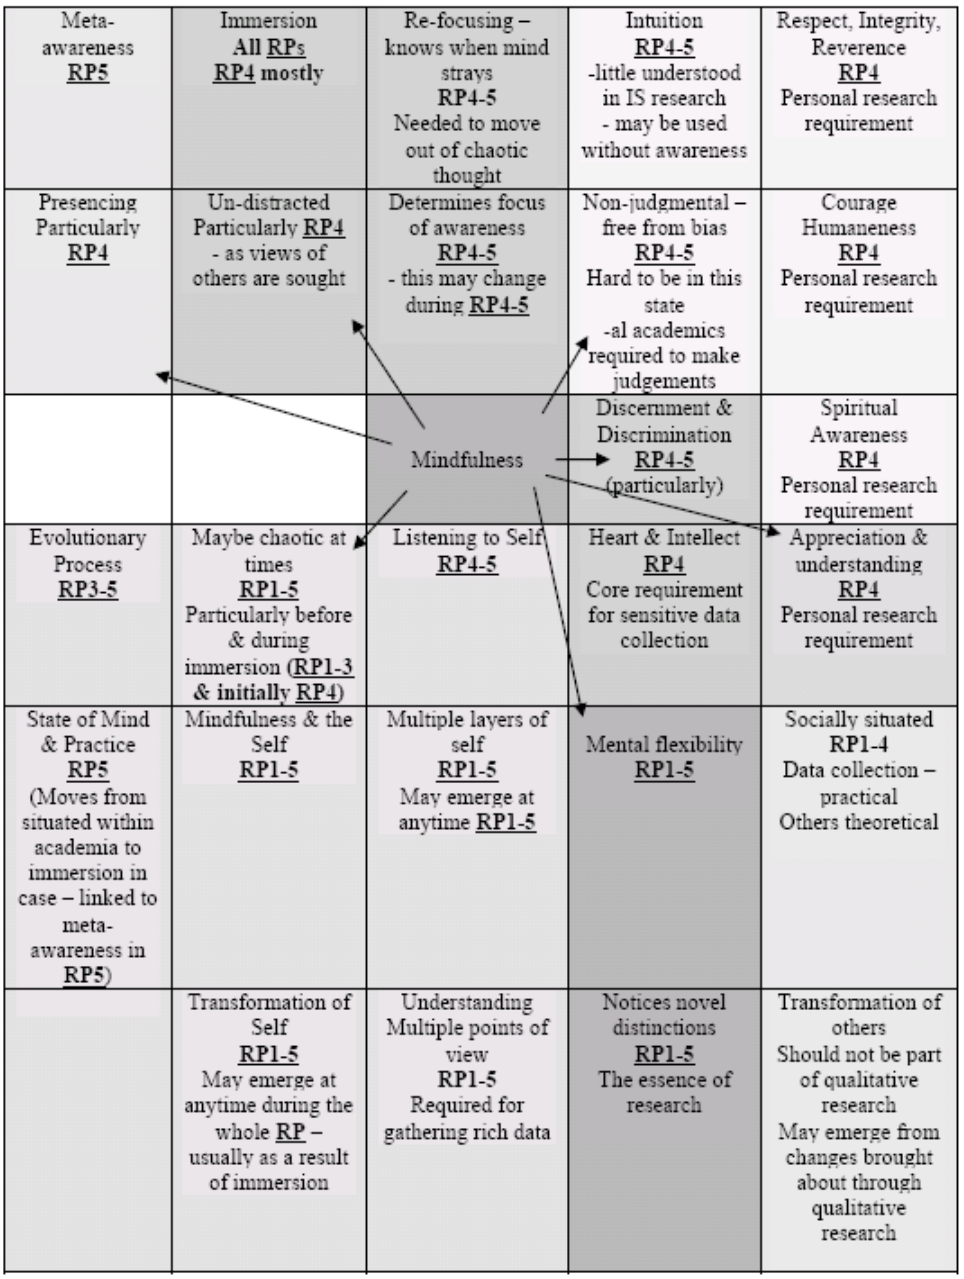
Meta-Awareness

Meta-awareness is achieved through spiritual traditions(meditation and/or prayer). Meta-awareness is achieved by designers, artists, and innovators by flow immersion (Csikszentmihalyi,1979). Meta-awareness is a skill seldom taught, learned, or practiced in Western spirituality.

Presencing

Scharmer (2000) describes presencing as "learning from the future as it emerges" rather than reflecting on past experiences(p.18). Presencing about foresight when applied to research practices and is a necessary mindful quality related to but different from meta-awareness. Meta- awareness is being aware of what is happening as it happens, while presencing is the ability to learn from the future

Figure 1. Research phases(RP) and mindfulness



(Note 1: Denzin and Lincoln's(2000) Research Phases; Note 2: Fielden's (2005) mindful dimensions)

as it emerges. Both meta-awareness and presencing are situated on the same timeline continuum and on similar levels of conceptual abstraction in interpreting research findings(Figure 2).

THE RESEARCH PROCESS

Most IS research is situated within a specific time and place in an organisation.

An essential tool for all IS researchers is the ability to see novel distinctions as the research process unfolds. An understanding of how one becomes immersed in the research domain and being one's own inner observer also helps in developing an understanding of multiple points of view and the self transforms during the whole research process(Figure 2).

Research Phases 3-5

An understanding of research as an evolutionary process emerges during RP3 and may be present, especially in qualitative research during data gathering, analysis, interpretation and presentation of research findings.

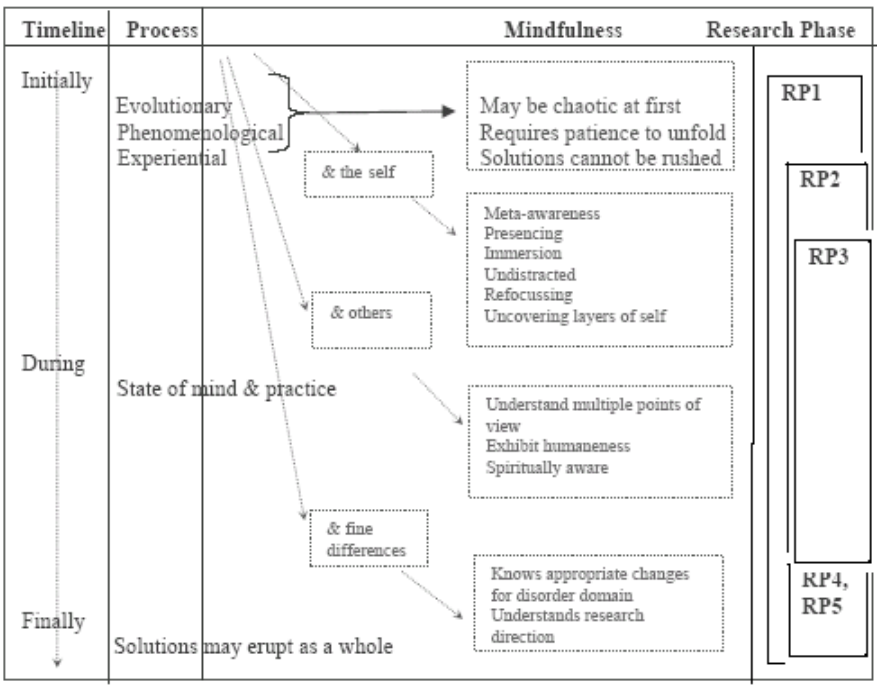
Research Phase 4

Mindfulness is critical at RP4 as the IS researcher enters the researched domain. The socially-situated characteristics of respect, integrity, courage, humaneness and appreciation of others all influence the way in which the researcher conducts data-gathering exercises. Understanding of how heart and mind work together and a deeper spiritual awareness are all mindful characteristics required.

Table 1. Pragmatics, process & philosophy/research phase

RESEARCH PHASE		PRAGMATICS	PROCESS	PHILOSOPHY
RP1	**RESEARCHER** Academic researcher image, subjective self in the process	Little historical or political view of research context in business How to enter business domains	Multiple roles Proposal approval Power and control issues	May have academic philosophical knowledge e.g. systems theory, appreciative systems . . .
RP2	**THEORY** Situated within philosophical foundations			Theory resides within this domain
RP3	**STRATEGY** Situated within academia, about research context (practice)	Suitable theory may not be practical	Ethical dilemmas, proposal approval	Research strategy situated within academia
RP4	**DATA COLLECTION** Pragmatics – informed by philosophy and formal process	May have emergent results Cultural issues may arise May have communication dilemmas What is not said or is not permitted to be said	Ethical dilemmas at data collection Language of data collection tools may be academic Distorted results	
RP5	**INTERPRETATION** About research context embedded in theoretical language	Reporting & interpreting emergent results Reporting language Missed data not reported or analyzed	What to report – political correctness What is not reported What is accepted as legitimate research Acceptance of emergent results	Results embedded in philosophical, academic interpretation

Figure 2. Mindfulness qualities and the research process



Research Phases 4-5
Mindful characteristics required at both RP4 and 5 are intuition, re-focussing, determining the focus of awareness, non-judgement, discernment, and listening to self.

Research Phase 5
When research findings are examined for meaning the mindful researcher brings to bear a level of meta-awareness about state-of-mind both in academia and in the researched domain.

Regardless of whether IS research is positivist, interpretive, or critical there is little influence from socially-constructed application domains when exploring philosophical frameworks. It therefore seems inevitable that little or no theoretical understanding of IS research crosses into these domains(Table 1).

When mindful qualities are applied to typical research project timeline(Figure 2) researchers different mindful qualities are required depending on the research phase. Initially an awareness and familiarity with chaotic thought processes is required. During the research process a deeper understanding of immersion and self experiences are beneficial. Social interaction within the research domain requires an understanding of multiple points-of-view and humaneness which enrich both the participants and the researcher. When research data is analysed(RP4-5) mindful qualities that find fine differences are required.

In RP1 an IS researcher is usually situated within academia, and 'knows the self' as an academic researcher(Table 1). Research rules, proposal approvals and ethical considerations all form part of the research process in the academic domain. Philosophically, academic research is usually grounded in a recognised body of theory; and builds on the research of others. The IS researcher therefore has little knowledge of the situated self in the world of the application domain.

RP2 is conducted entirely within academia where theoretical paradigms and perspectives are explored and is the domain in which mindful qualities are most easily applied as the researcher is within her/his own 'comfort zone'.

RP3 is the traditional starting point for most IS research – setting research strategies and this takes place within academia(Table 1). Theoretical ethical dilemmas are resolved, proposals approved and boundary setting for potentially unknown situations take place. RP3 provides many situations in which chaotic thought processes occur as planning for the unknown takes place.

In RP4 data is collected and analysed and it is here that the IS researcher moves from the sheltered world of academia into the less familiar research application domain. It is in RP4 that many mindful characteristics(Figure 2) are required as socially-situated and empathetic knowing is activated. It is likely that the more mindful the researcher the richer the data gathered. Whilst the mental models underpinning RP4 are grounded in academic theory and philosophy, this does not necessarily mean that the IS researcher is equipped to gather data in a mindful manner.

The final stage of the research process is, once again situated within academia. Research results are embedded in the underlying theory and philosophical approaches and written in academic language. Pragmatically, issues surrounding the interpretation of data are underpinned by the mindful maturity of the researcher. This is rarely acknowledged or reported in research articles.

RECOMMENDATIONS

IS researchers who have become mindful practitioners are more likely to produce quality research findings that benefit both participants and academia. It is recommended that: mindful practices be included within IS research methods classes; and postgraduate supervisors be trained in mindful practices to support and develop their students as mindful researchers.

A suggested plan to train mindful IS researchers is to:

1. Increase the awareness of mindfulness by introducing practices and skills into research training curriculum;
2. train postgraduate supervisors and educators in both mindful practices and how to teach mindful practices;
3. Include awareness of multiple points of view in research training curriculum. One suggestion is to include an introduction to systems thinking, complexity theory and chaos theory; and
4. Role model mindful practices in teaching and supervision through dealing with uncertainty and chaos, mediated solutions, self-responsibility, respect for others and acting with integrity.

CONCLUSION

It is evident therefore that to become a mindful IS researcher requires more than the standard research methods training in which the steps of various research methods are learned and applied. Instruction in mindful skills should lead to higher quality research reports. If, however postgraduate supervisors do not practise mindfulness then these qualities developed in student researchers may not be recognised and therefore are not likely to be developed any further.

Quality research reports in the academic domain may be evaluated according to the rigorous way in which research was conducted. What if these rigorous results were gleaned from data gathered by insensitive interviews, poorly facilitated focus groups with a lack of awareness of the effect the researcher was having on the participants?

In this paper the concept of mindfulness has been applied to a typical qualitative research process(Denzin and Lincoln,2000). If indeed we are to become better IS researchers it seems a sensible approach to address ways in which the research process can be improved.

Towards Metadata and Data Standards for Semantic E-Governance Services in India

Devika P. Madalli, Indian Statistical Institute, 8th Mile, Mysore Road, R.V. College Post, Bangalore 560059, Karnataka, India; E-mail: devika@drtc.isibang.ac.in

ABSTRACT

E-Governance facilitates outreach of government services to the citizens with help of information and communication technology. Metadata has been considered as an essential element in any digital environment. The paper discuses the Indian e-Governance efforts and enlists its different initiatives. The role of MetaData and Data Standards (MDDS) in e-governance is highlighted. Need for Interoperability in e-Governance is also discussed. A conceptual model towards achieving MMDS is presented.

INTRODUCTION

Internet has a marked impact on the methods of communication, business processes, commerce, research and academics as also in governance. Though it was primarily the businesses and also academics and research communities that initially adapted Internet into their activities, governments have also realized the importance of online reach to citizen and end users [Butt and Persaud, 2005]. One of the chief challenges for government departments is to outreach their programs to the wide spread communities considering physical aspects, such as distance, weather, terrains etc. E-mode of operation presents a viable and efficient option to governments to deliver services to the different sectors they deal with, overcoming the physical constraints. Also a larger mass of the end-users can be reached through e-governance systems. The use of Internet technologies has improved the effectiveness and efficiency of governance services [Agarkhani, 2003].

E-governance has different facets to it, in the sense that the models and the systems vary according to department and its services offered. Many e-governance systems - some domain specific and others task specific - have been discussed [Rotchanakitumnuai and Speece, 2003), (Sathye, 1999), (Doherty; Ellis-Chadwick and Hart, 2003), (Levy and Powell, 2003)]. The e-governance models depend on constitutional, cultural, economic fabrics of the government offering the services. This is evident is the differences that emerge between models adapted by different countries for their e-governance initiatives. [UkGovTALK**a,** AGLS].

In India, the National eGovernance initiative was started by the Government of India (GOI), with a vision to offer faster, improved and more efficient services, shared resources and services, increased productivity and to establish standardized systems and processes [NICa] to manage government services and serve patrons of different sectors.

1. E-GOVERNANCE IN INDIA

With a wide vision mentioned above and objective of outreaching government services to public, Indian government has started the e-Governance initiative. The main problems with individual systems for e-Governance developed in India so far is that there is too much data and not enough information. In the sense that there are no cohesive and meaningful services though a lot of data is available. Also the systems were developed independently as stand-alone with no common data architecture and are too expensive to bridge [NICa]. GOI aims to address these issues through the National E-governance Action Plan (2003-07). A few initiatives taken in this regard are as follows:

- Initiative on Digital Signature
- Initiative on EG Standard
- Initiative on India Portal
- Initiative on India Development Gateway (InDG)
- Initiative on National e-Governance Service Delivery Gateway (NSDG)
- Initiative on Replication
- Initiative on Technology Development for Indian Languages (TDIL)
- Initiative on EG Capacity Building
- I T Act & Rules
- Assessment Framework
- State Data and Service Centres

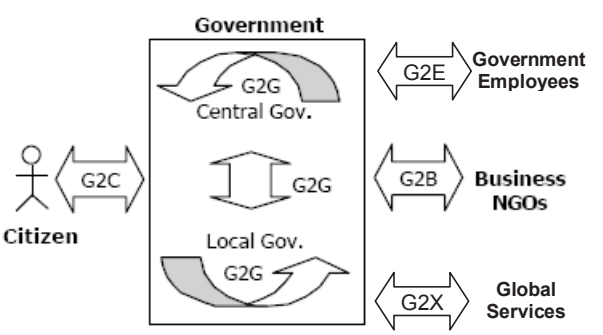
The work is taken up by National Informatics Centre (NIC), Department of Information Technology under the Ministry of Communication & Information Technology.

2. LEVELS OF INTERACTION IN E-GOVERNANCE

The level of e-Government services, NIC has defined, includes five main key players -Government, Citizen and Business, Employees, and Global Services. The most likely levels of interaction in this context can be: G2C, G2B, G2G, G2E and G2X.

- ***Government-to-Citizen (G2C):*** This is the interaction between Government and citizen. In this interaction, the citizens may utilize the information provided by the government at the service portal or gateway; sends email to concern government department, etc. For e.g. the farmer can check out the latest market price of wheat at the information portal containing latest crop prices.
- ***Government-to-Business (G2B):*** At this level of interaction, the business personnel can fill tenders, pay sales tax, enquire about the latest company laws, etc online to the concerned government department.
- ***Government-to-Government (G2G):*** This is the mode of interaction between two or more government departments for the smooth accomplishment of government functioning.
- ***Government-to-Employee (G2E):*** This is the mode of transaction between government to employee (Govt.) for accessing their pay slip, and other related

Figure 1. Interactions in e-governance [National e-Governance Plan, 2005]



transactions with the employer (i.e. respective Govt. Department). "Daily" is an intranet site of the Department of Rural Development, Govt. of India, promoting G2E governance within the ministry. It provides an easy, efficient and one-stop access to all information and services required by the employees to carry out their daily work [NIC, 2005].

- ***Government-to-Global Services (G2X):*** This is the mode of transaction between Government to various global services implemented and executed within the country or abroad.

In all the ways of communication at the levels indicated above, it is important that different stakeholders must have the ability to exchange and mutually use information. This is only possible when information is represented in meaningful manner with indicative tags. This is the function of metadata in e-governance.

3. METADATA

The most common definition of the term 'metadata' is structured data about data, information that describes other information. The World Wide Web Consortium has defined it as: "*machine understandable information for the Web*". For example, if a Web page has an author, a title, a date of creation and a unique Internet address, these elements constitute metadata about the page. Metadata is an Internet- age term for information that librarians traditionally have put into catalogs and it commonly refers to descriptive information about Web resources [Ercegovac, 1999].

A metadata record is a label, like the label we might find on an everyday product in a supermarket. The label describes the product, and quite often contains information that is useful both to consumers and to the electronic systems that control the store. The label contains data a person can understand, such as a list of ingredients, and data a machine can read, like a bar code [UKGovTalk, 2006].

Metadata labels are attached to documents and other information assets with similar aims in mind. By storing information such as author's name, version number, subject, we can help people to find information more easily, and allow computers to process it more effectively.

4. ROLE OF METADATA IN E-GOVERNANCE [EGMS, 2004]

Metadata standard can be used to classify and categorize Government information and services, facilitating identification of services and information intelligently. Inter-departmental information exchange becomes easier. Hence, metadata increases the visibility and accessibility of Government services over the Internet [Weibel, 2005]. Modernizing Government calls for better use of official information, joined-up systems and policies, and services designed around the needs of citizens. Metadata makes it easier to manage or find information [EURIM, 2002], be it in the form of web pages, electronic documents, paper files, databases, anything. For metadata to be effective it needs to be structured and consistent across organizations.

However while metadata aims to represent what data it carries, it is also important that the data itself should be represented following international standards in order to achieve interoperability between systems.

5. DATA STANDARDS

It can be said as, agreed upon terms for defining and sharing data. According to ISO, a standard is "documented agreements containing technical specifications or other precise criteria to be used consistently as rules, guidelines, or definitions of characteristics, to ensure that materials, products, processes and services are fit for their purpose." There are several types of data standards including terminology standards and message format standards [PHDSC, 2006].

Some important data standards which are commonly used in e-Governance services are:

- Author name format
- Personal information
- Address information
- Date/Time format
- Organizational information
- Financial Information; among others

6. INTEROPERABILITY ISSUES

Interoperability means the ability of information and communication technology (ICT) systems, as well as, of the business processes they support in order to exchange data and enable the sharing of information and knowledge [Edutools Wiki].

6.1 Why Interoperability

Effective e-Government results in reducing the amount of paperwork, streamlining processes and considerably enhancing citizen services and government communication. There are indeed many reasons that motivate governments in e-Government implementation, e.g.:

1. Reduction of expenditure: reducing time spent on administration, thus resulting in cost savings;
2. Improvement of professionalism in agencies management and modernization of the internal organization: e-Government will make internal government processes and external interaction more efficient;
3. Improvement of the quality of service and customer satisfaction.

It is ideal that each government department's information is encoded in the same format and also the services are planned in similar layers of data representation, service model and interface layers. But often this is not possible in practical governance. Each department has its particular needs in terms of data sets and also the expected forms of interaction and ultimate delivery of services. Hence, the e-governance method varies form department to department. Also, another reason for disparity arises because different department have moved to e-governance at different times and follow the standard and technology available at that time. Added to this is the disparity of cultural influences in approach to information and hence its representation. Another level applicable to diverse nation such as India is the multi-lingual communities that warrants cross lingual retrieval. This particular issue however, is outside the scope of this paper.

All of the above reasons warrant that measures of interoperability be implemented in e-governance system.

6.2 Crosswalk

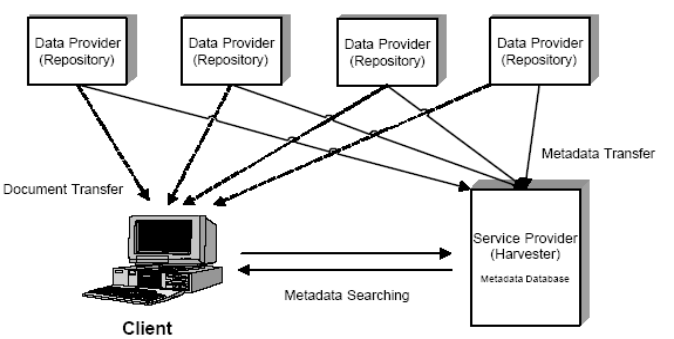
Crosswalks or metadata mapping support the ability of search engines to search effectively across heterogeneous databases, i.e. crosswalk helps to promote interoperability [LAOAP]. Crosswalk may be achieved through a table that maps the relationships and equivalencies between two or more metadata formats. This is rather simply said than possible, because of the wide disparities in metadata sets and data representations in practice.

6.3 Harvesting Technology

Harvesting refers to the gathering together of metadata from a number of distributed repositories into a combined data store [OAI, 2002].

One of the most interesting recent developments in the digital library arena involves the Open Archives Initiative (OAI). The Open Archives Initiative emerged out of the scholarly communications arena as a means to provide interoperability among multiple information sources. The communications model of OAI relies

Figure 2. OAI-PMH architecture



on the bulk transfer, or harvesting, of metadata between a service and all its data providers, based on a set of very simple protocols.

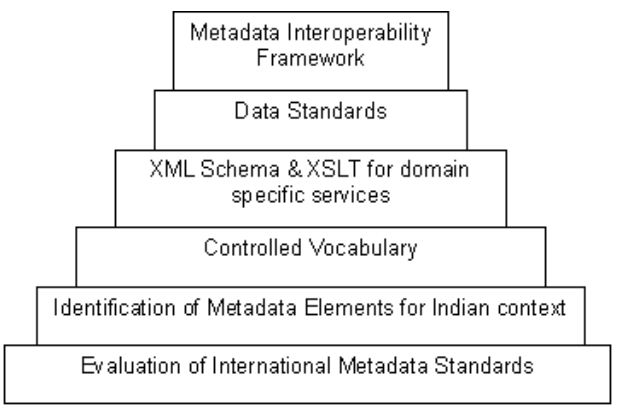
The OAI universe is based on information repositories, or "data providers," that make their metadata available, using a prescribed set of protocols, to "service providers" that build new information resources. End-users gain the benefit of OAI-based services that aggregate the metadata of multiple OAI repositories. It is to be noted that OAI operates with metadata, not complete works of digital content. In most cases the metadata include links back to the original information repositories for access to the documents or other digital objects [Mittal, Kumar, Mohania, Nair, Batra, Roy, Saronwala, and Yagnik, 2004].

7. ROADMAP TO INDIAN E-GOVERNANCE METADATA AND DATA STANDARD

Steps for developing metadata and data standards for e-governance are as follows:

1. **Evaluation of international metadata standards:** Some major e-governance standards has to be studied and evaluated to get the idea about the basic elements, metadata descriptors, vocabulary control and metadata management mechanism for development of metadata standard
   a. e-GMS
   b. GILS
   c. AGLS
   d. NZGLS
2. **Identification of metadata elements for Indian context:** Selection of basic metadata element sets and in conformity with the world standard for e-governance. As well as various application profiles suitable for the needs of various domains like agriculture, finance and economy, etc has to be developed.
3. **Controlled vocabulary:** Each government sector has its own vocabulary regarding it function and subject area. Therefore, two controlled vocabulary lists have to be prepared: one dealing with the services and another with the subject terminology.
4. **XML schema and XSLT for domain specific services:** To start web-based services, the domain specific service description has to be represented in the form of XML/RDF/OWL (Ontology). Its presentation on the web browser has to be taken care by their XSLT.
5. **Data standards:** The data which are to be input in the respective metadata fields also require standardization in terms of author name format, date format, organizational information, financial information etc.
6. **Metadata interoperability framework:** This framework is to ensure the interoperability between various services from diverse domains.

Figure 3. Roadmap to metadata standard for e-governance in India



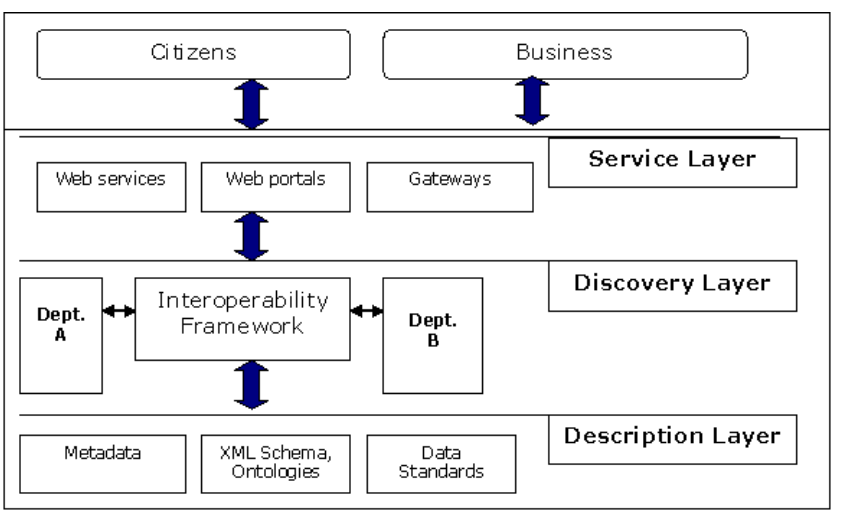
7.1 Use Case based on Conceptual Model for Metadata and Data Standard

The conceptual model has been framed to explain the role of metadata description in e-governance services. This also shows the usability of data standards in the given context. For example, a citizen looking for the information on agriculture can interact with the web portal providing the web services. The web service providing the required information is based on the interoperability framework. This interoperability framework works to translate the content of two different databases using different content representation format into the desired format. In databases, content is described using the e-government metadata elements in form of ontologies. The values of each of these elements can be standardized with pre-structured data standards. One of the instances is a farmer's enquiry for the best prices for his commodity. Ideally the query should return the best priced market with nearest reach. It combines departmental information about agricultural commodity, related markets, and other information like weather, transport etc. The interoperation is achieved through representation or description layers that support the discovery layer as shown in the conceptual model below:

8. CONCLUSION

e-Governance is quite complex to achieve with variance in the communities, services and formats among several other factors. Metadata plays an important role in providing a proper and standard representation of the e-governance metadata. But in many e-governance services and departments where data is different, there would be need for different sets of metadata elements for comprehensive representation. Yet other scenario is that different departments started e-governance with different data sets, standards and technological tools. This brings to for the problem of variation in standards and the only way to bridge this kind of

Figure 4. Conceptual model of interoperability framework for e-governance in India



disparity is to build crosswalks so that even when the end user approaches are different for the same data, it is still retrieved. Further, true interoperability can only be achieved when semantic interoperability can be achieved. A model, as illustrated, that is based on ontologies along with the metadata and standard data representation, in the description layer, would facilitate the discovery layer in vending services to patrons in varied scenarios.

Knowledge Based Approach for Lithuania: Knowledge Cluster's Origin Development and Vision

Jurgis Samulevičius, Vilnius Gediminas Technical University, Saulėtekio av. 11, LT-10223 Vilnius – 40, Lithuania; E-mail: vvfsevk@vv.vtu.lt

ABSTRACT

The paper aims at emphasizing the importance of knowledge management as a pilot project for investment productivity and competitiveness, presenting Lithuania as knowledge management case study. To show Lithuania's move in the direction of a knowledge-based-growth via creating a network of knowledge institutions, the "Sunrise Valley" and projects, present the vision and challenges of these projects and institutions as well as roots and origin of newly-born Lithuania's knowledge cluster with its infrastructure and future prospects. The researcher also made an attempt to study broader empirical /practical processes, that took place in transition economies including that of Lithuania, since it's experience might be adapted to other emerging market economies in the nearest future

Keywords: Business process outsourcing (BPO), knowledge economy (KE), knowledge management (KM), information and communication technologies (ICT), research and development (R & D), knowledge cluster (KC).

1. INTRODUCTION

The 21st century knowledge revolution created new opportunities and possibilities for the access and use of knowledge and information. The transition towards a knowledge-based economy requires from policy makers to understand the comparative strengths and weaknesses of their countries and then act upon them by developing appropriate short- and long- term policies and investments. In today's global economy, knowledge has become an even more decisive factor of competitiveness, productivity and growth. The global digital/knowledge economy offers unprecedented opportunities to produce and sell on a mass scale, reduce costs, and customize to the needs of consumers – all at the same time. Whether you live in a large country such as the USA or China, a medium-sized country such as India or Canada or a smaller country like Lithuania, your potential market is of the same global size. And you can source (net source) inexpensively wherever you wish.

2. THE SWOT ANALYSIS OF THE LITHUANIAN HIGH TECH INDUSTRIES AS STARTING POSITION FOR LITHUANIA'S MOVE IN THE DIRECTION OF A KNOWLEDGE BASED GROWTH

Every country possesses its own strengths and weaknesses, opportunities and threats. In spite of the heavy burden of the Soviet occupation legacies, after regaining its independence in 1990 Lithuania embarked on a path of determined, radical, and sustained reforms aimed at re-establishing democracy and functioning market economy. It succeeded remarkably and is now regarded Europe's transformation success story. At the same time Lithuania was in position to answer the question: what could and should a low – income country with an educated population do to exploit new opportunities associated with the knowledge revolution?

When the WTO&ITC team compared Lithuania's ICT industry with similar industries of the countries in the region, the conclusion was made that the industry was developing and expanding its activities across the region. In the EU market, activities related to sub-contracting or onshore software application were taking place.

Although the conclusion was drawn that Lithuanian ICT industry was relatively small compared to the ICT market of Poland, for example, it has good growth potential driven by niche areas and niche products.

Table 1 shows the results of the WTO & ITC team's research of Lithuania's ICT industry based on analysis of its strengths, weaknesses, opportunities and threats (SWOT).

3. A KNOWLEDGE MANAGEMENT APPROACH FOR LITHUANIA

In spite of the fact that knowledge industries in Lithuania are not sufficiently advanced yet as compared to global leaders, some pioneering firms that were created at research institutes do have histories going back a decade or so, especially those in biotechnology, laser research, etc. At present scientific-experimental lasers made in Lithuania can be found in 22 European Universities,10 USA Universities,15 Universities of Japan and 2 Australian Universities. According to Gartner Inc. expert's evaluation, the growth of the Lithuanian IT outsourcing market accounted for 40 percent in 2003 alone. Lithuania is rated as one of the most attractive providers of this type of service in Eastern Europe.

A national political consensus was reached and the national agreement was signed To encourage Lithuania to become a knowledge-based economy. The term "knowledge-based economy" has been coined to reflect an increase of importance of knowledge as a critical factor for economic performance.

The decision was made that a further development of the knowledge-based economy infrastructure (e.g. better access to high-speed Internet) was needed. That would necessitate a better public sector-private sector collaboration so as to arrive at innovative management models and strategies underpinning the knowledge economy in Lithuania.

Widening and deepening of the European integration markedly increased competitive pressures, so companies began looking for new, sustainable and dynamic advantages. Given that the continent is aging quite rapidly and immigration presents a problem for a number of reasons, a shortage of qualified work-force is developing, which can be best addressed by taking advantage of the digital/knowledge revolution and of the potential of the new EU members such as Lithuania.

Under these circumstances, a better use of the continent's resources has become critical to winning the competitive game or surviving in unified Europe and the integrated world.

Large European and multinational corporations (e.g. BT, Buckman Labs, Nokia, Siemens, etc) are the early adopters of new thinking. They first realized that high initial costs of research, human/intellectual capital costs, etc, are efficiently spread only over longer periods and larger geographical areas. The vision they have, specifically their new-frontier mentality and the ability to develop integrative thinking across functional areas of business, not only at the highest management levels but, what is even more important, at lower management levels, resulted in knowledge-sensitive enterprise cultures and the resultant organizational learning regarding new business models and strategies. Also, such issues are pretty high on the EU institutions' agenda (e.g. Lisbon Strategy). The unique European competitive advantage (e.g. as compared to that of the USA) is that the EU institutions are able to give push and pull to many continent-wide initiatives that fall within the public goods category (e.g. earlier adoption of continent-wide standards for

Table 1. The SWOT Analysis of the Lithuanian ICT and Other High Tech Industry: Summary & Outline

Strengths	**Weaknesses**
Human resources suitable for innovative activities and knowledge-based production; Healthy economy, growing most rapidly among the CEE (5-6% for 2001-2005); Well-developed high tech & other universities producing over 500 specialists in ICT and other disciplines annually; Other well-trained & low-cost human resources available; Modern telecom infrastructure with a digitalization ratio of 100% and mobile penetration of some 50%; Labor force versatile in English, German, Russian, and Polish; Open economy with rule-based system aligned to the EU & WTO – economic stability; Developed financial institutions & intermediaries; Location between the EU, Nordics, the Commonwealth of Independent States (CIS); Capacity to promptly adapt to rapidly changing ICT & knowledge based economy; Full scale privatization accomplished; industry re-structured based on comparative advantages; Institutional support to SME development; Well developed IT infrastructure across the region; Sound linkages between academia and industry for development of applications The EU and NATO integration to provide large market opportunities for ICT-enabled services.	Manpower adequately skilled but needs re-training on project management and quality management of ICT projects; Slow drafting and implementation strategies of ICT & other high tech; Vague long-term vision for ICT development including action plans or prioritization of funds; Comparatively small market - small investment by MNCs; Foreign economic relations still to be formulated on the basis of national and EU interests; Capital market in the development stage; ICT penetration not sufficient to give a substantial boost to e-commerce and e-business development; Logistics management poor - railway transport system physically inadequate; Public-private partnerships weak & cooperation among economic entities underdeveloped; Insufficient incentives for R&D by business.
Opportunities	**Threats**
Development of labor-intensive sectors like computer science and knowledge-based sectors to serve a larger market of the EU and CIS; Availability of structural funds from the EU to provide support to business modernization, employment promotion, improvement in quality of life, etc; Industrialization processes based on FDI, advanced technology and international management experience to enhance competitiveness and leverage advantages to achieve export-led growth; EU accession to expand sales markets and provide preconditions for foreign trade; Globalization of financial resources will provide alternative possibilities for financing; Use of digital technologies will open wider markets and provide conditions for more efficient cooperation with advanced economies in ICT, BPO, R&D, and other IT enabled services; Possibility to establish positions in the transport service markets of continental Europe, with logistic centers in Kaunas, Klaipėda and Vilnius; Free movement of IT and high tech personnel to provide opportunities for application development and onshore software development;	Emigration weakens the intellectual potential of Lithuania; Potential closures of domestic ICT companies due to fierce competition unless they develop sustainable niche markets; Fear of becoming a center of higher cost production because of alignment with the high-cost EU and trade distortions imposed by third countries; Loss of General Preference Systems discounts for exports to North America and Japan; International environmental obligations may lead to higher costs of production; Advanced ICT countries may wrongly see Lithuanians as consumers and not as developers/partners for modern products and services thereby leaving Lithuania out of BPO networks; Lack of coherent vision of the Lithuanian industry; Inconsistent policies and inadequate communications may lead to fragmented growth of IT and other high tech industry.

Source: Based on the WTO&ITC research and the authors' research.

mobiles, knowledge management practices, etc).

The main criterion for becoming a full member of the EU is the capability to withstand the European competitive pressures. While in the first period lower labor costs do provide certain competitive advantages pretty much across the branches of economic activity, this factor is of rather short duration in the case of Lithuania or other transitional economies. Lithuania will need to develop higher added-value market niches that will precisely call upon the Lithuanian capabilities to create an entrepreneurial economy that is integrated continentally and globally. Knowledge-based economy provides such opportunities especially in the context of knowledge and innovation in the European and global business.

A significant challenge posed to Lithuania is how to use a considerable theoretical research (e.g. biotech, lasers, semiconductors, game theory) potential of the Lithuanian research institutes, universities, and industry. There is a need to develop a practice-oriented strategy for knowledge-based economy in Lithuania.

.

4. THE KNOWLEDGE- BASED PROJECT – "SUNRISE VALLEY"

In the present-day world separate market participants are unable to achieve good results which knowledge-based economy requires.

The key for solving problems are networks, clusters and other common activities. In the network of such knowledge-based institutions there are such popular objects of knowledge-based economy as knowledge camps, houses, towers, islands, technological parks, valleys, etc. One of such innovative schema is "Sunrise valley" in Vilnius, which was deliberately modeled after the Silicon Valley, California, where "Eastman Kodak", "General electric", "Intel Fairchild", "Lockheed", "Hewlett Packard" and other companies started and developed their activities.

Knowledge-based economy clusters are successfully created near Universities in different countries. Our neighbors-the Nordic countries are successfully developing in this direction. In recent years Finland and Sweden has twinkled their resources for R&D, especially in the last decade, and that influenced the growth of a high tech level of production in exports of those countries. Technological parks "Kista" and "Technopolis" are well known knowledge-based economy clusters all over the world. The neighboring country Poland can also boast great achievements

in this field of activities. Poland is successfully developing the 45 ha square Technological Park "Technoport" near its capital Warshaw. Good conditions for successfully activities started in Vilnius "Sunrise valley" where special social enterprise "Sunrise valley" was established in May 2003.

Vilnius University and Vilnius Gediminas Technical University, as well as well known Lithuania's corporate leaders: ALNA, SONEX, OMNITEL, BITE GSM, EKSPLA, Laser Research Institute, members of the Knowledge Economy Forum of Lithuania were founders of this public unit. In February of 2004 this project was joined by the Vilnius city municipality, which became a shareholder of this establishment. In reality "Sunrise valley" accumulated theoretical and practical potential of the best Lithuanian research Institutes, Universities, think tanks, consultants, firms and organizations and is ready to tap into the growing stock of global knowledge and adapt it to the local needs.

In the long run (till 2015) "Sunrise valley", the largest unit of Lithuania's knowledge cluster must be developed into the largest innovation centre in the Baltic states, where high added-value product and services will be created. Such a vision for "Sunrise valley" in the year 2005 was outlined by the International Consortium "Centre for Strategy and Evaluation Services", famous Technological parks from Great Britain, Sweden and experienced local business partners. According to the evaluations of the year 2015 in the territory of 2,5 ha about 150 new high tech enterprises with more than 3000 employees will be created, among them: the Innovation Center for the development of laser and IT, as well as the formation of a business incubator and a scientific–technological park. They will be companies established by Universities and Research Centers, where students, professors and researchers from those institutions will work.

5. CONCLUSIONS

The paper concludes that a knowledge- based economy is a wave of the future:

1. The transition towards a knowledge-based economy requires that policy makers understand the comparative strengths and weaknesses of their countries and then act upon them to develop appropriate short and long term policies and investments.
2. Lithuania will need to develop higher added-value market niches that will precisely call upon the Lithuanian capabilities to create an entrepreneurial economy that is integrated continentally and globally. Knowledge-based economy provides such opportunities especially in the context of knowledge and innovation in the European and global business.
3. Knowledge management provides a compelling platform to research the issues of upgrading competitive advantage in developed countries and contract out non–core competencies to emerging markets.
4. Conclusion was drawn, that Lithuania is moving towards a knowledge- based growth via creating a network of knowledge institution and projects and Lithuania's experience can be adapted to the former Soviet block countries. Post- communist and other emerging market countries such as Armenia, Czech Republic, Ukraine, Hungary, Poland and others are well advised to jump to these new opportunities as the latter provide the best chance to realize the "latecomer's advantage" by leapfrogging to technologies and models of doing businesses which are new for Western countries as well.

ABSTRACT

Information within an enterprise is often scattered across various administrative domains and geographical time zones. Moreover, such information is maintained in different databases in heterogeneous formats serving varied needs of different set of people. Need is often felt to integrate this information, spread across the enterprise, for strategic decision-making on a real time basis. In this paper, we introduce GRADIENT – an Enterprise Information Integration solution based on service-oriented architecture for accessing distributed information across an enterprise and for solving integration challenges associated with data heterogeneity and geographical spread. GRADIENT utilizes a grid based approach to distribute computational load of queries and realizes enhanced performance in real-time data integration.

Keywords: Data-Grid, Enterprise Information Integration, Distributed Query Processing

1. INTRODUCTION

Enterprises data is preserved in heterogeneous data sources/formats and dispersed across multiple administrative domains or geographical locations. Need is often felt to integrate such diverse data sources for strategic decision making on a real time basis. However, data integration is a complex and time consuming task due to the heterogeneity and semantic disparity of the underlying data sources. There are varieties of approaches for solving this complex data integration problem and they can be broadly classified into two as: Extract, Transform and Load (ETL) and Enterprise Information Integration (EII). ETL based solutions allow the disparate data sources to be extracted transformed and loaded into data marts or data warehouses for query processing on the integrated data. But, the major drawback of using an ETL solution for integrating disparate data sources is the latency and complexity involved in extracting, cleaning and transforming the data and then moving(also referred as loading) the transformed data into data marts or data warehouses. On the other hand, EII based solutions allow creation of virtualized view of the disparate data sources leveraging the existing infrastructure with little or no movement of data. This data virtualization is achieved in a manner that is transparent to the user. The key challenge in such data virtualization solutions is the complexity involved in integration of the distributed and heterogeneous data sources in real-time.

Grid computing is an ensemble of heterogeneous computing resources for solving complex computation intensive tasks. Data grid is a manifestation of grid technology that helps to achieve virtualization of the data stored in multiple heterogeneous databases stored across multiple locations [1]. Additionally, data grids enable sharing of computational load across different machines. Since EII solutions deal with huge volumes of data during data integration, it may be useful to investigate the use of data grids for queries involving high computational requirements to achieve superior information integration benefits. So, the primary motivation for our work is to combine the EII and data grid technologies to achieve enhanced performance in real-time data integration.

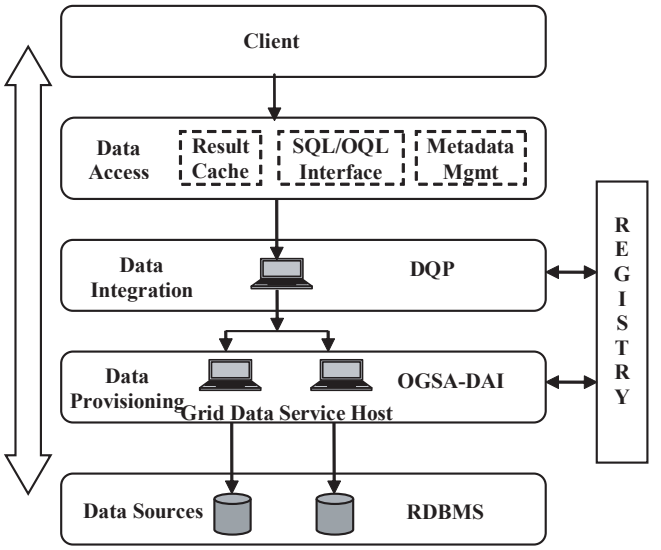
In this paper we present a grid based EII tool for accessing distributed information across an enterprise called GRADIENT (GRid Access of Distributed Information in the ENTerprise). GRADIENT is a service-oriented data grid solution that overcomes the limitations of ETL based data integration technologies and enables real-time data integration using data virtualization. GRADIENT allows the end user to seamlessly query disparate information sources using declarative query languages such as SQL. GRADIENT achieves greater scalability and performance using a distributed query processing engine. GRADIENT also addresses the semantic heterogeneity issues using RDBMS based metadata management system. Some of the salient contributions of this work include metadata management, advanced caching techniques and enhanced distributed query processing engine.

The rest of this paper is organized as follows. In section 2, we describe the proposed GRADIENT architecture. We deliberate on our preliminary experimental results in section 3 and provide concluding remarks in section 4.

2. GRADIENT ARCHITECTURE

GRADIENT is an EII solution that extends open source projects like the OGSA-DAI (*Open Grid Services Architecture – Data Access Integration*) [2, 3] and OGSA-DQP. Gradient offers a number of advanced features (like metadata management, advanced caching, enhanced distributed query processing engine) that were not supported in open source projects. Using Gradient as a Web Service or API, a client can invoke queries that involve join operations spanning multiple data sources using a single query without having the knowledge of the location of the underlying data sources and their formats. Figure 1, shows a high level architectural view of Gradient having three logical layers, namely, (1) data provisioning layer, (2) data integration layer, and (3) data access layer. We discuss the key features of each of these layers in detail in the following paragraphs.

Figure 1. High level architecture of GRADIENT



2.1 The Provisioning Layer

Provisioning layer provisions the data sources and exposes it as services. Gradient uses OGSA-DAI to expose disparate data sources as Grid Data Services (GDS). GDS accept perform documents (an XML document describing user queries) and parses and validates the query against the metadata extracted by GDS. GDS, then executes the query and constructs response XML document containing the query results. The OGSA-DAI has been extended to support metadata extraction of the data sources like Oracle, SQL Server, DB2 and POSTGRES. In future, we plan to extend it further to support other data sources.

2.2 The Integration Layer

The Integration layer in Gradient provides support for distributed query processing and is built on top of open source OGSA-DQP [3] project. The core distributed query processing engine of Gradient enables optimal sharing of the computational load intensive (e.g. join) queries. This allows for the parallel processing of a query using inter-operator and intra-operator parallelism. Since the database size usually exceeds terabytes, having different portions [4] of a query executed on different physical machines in parallel result in considerable improvement in query response times.

Gradient offers query processing and optimization support for declarative queries over a set of services that includes *databases services* and *computational services*. Database services use emerging standards of Grid Data Services (GDS) to provide a uniform and consistent access to different databases. Computational services are needed for performing query splitting and for executing different portions of the query on different computational nodes for achieving speed-ups. DQP is made up of two services:

I. *Grid Distributed Query Service (GDQS)*: GDQS, also called the co-coordinator, is responsible for (a) Retrieving and storing the metadata of each database (this is done only once during the installation of GDQS on the machine), (b) Creating the single node physical plan and then a parallel plan for a query through successive transformations using relational algebra and calculus, and (c) Scheduling the sub-plans of a parallel plan on the computational nodes. We extend GDQS by building upon the previous work of Polar* distributed query processor for grid [3]. The Polar* is implemented in OPTL-a database optimizer specification language defined by [5]. However, the query operators supported in the original version of Polar* were inadequate to handle the diversity of queries that a user may invoke from enterprise applications. We enhanced the functionality of Polar* to support various query operators such as or, not, in, like, aggregates and non-equijoins. These enhancements will allow the user to make more complex queries than were supported by the original version of DQP.
II. *Grid Query Evaluation Service (GQES)*: GQES, also called the evaluator, is used to execute the query sub-plans. Coordinator schedules query sub-plans on one or more instances of GQES based on decision made by the query optimizer. This allows sharing of the computational load since query processing tasks are often computation and memory intensive. In this context, the GQES is analogous to an idle computational node on a compute grid.

The schematic representation of a typical DQP environment is shown in figure 2. Nodes N_1 and N_2 hosts databases DB_1 and DB_2 respectively. The databases DB_1 and DB_2 are exposed using respective Grid Database Services (GDS). All the nodes also act as evaluators. Nodes N_3, N_4 and N_5 do not host any database and only act as evaluators for performing computation intensive tasks. Any query involving DB_1 and DB_2 will necessarily run on nodes N_1 and N_2 and can additionally employ nodes N_3, N_4 and N_5 for sharing the computational load of the queries.

2.3 The Access Layer

Access layer is the first point for the end user application to access the data exposed by the Gradient using standard SQL queries. In this layer, Gradient uses a metadata management service for input query parsing, query resolution and OQL generation. The GDS – a layer of abstraction that hides the heterogeneity of the underlying databases – provides a service oriented interface for extracting the metadata from the underlying data sources. The metadata which is stored as a relational database in a centralized location maintains all the information necessary for parallel query optimization. This central metadata repository is exposed as

Figure 2. Environment with DQP services

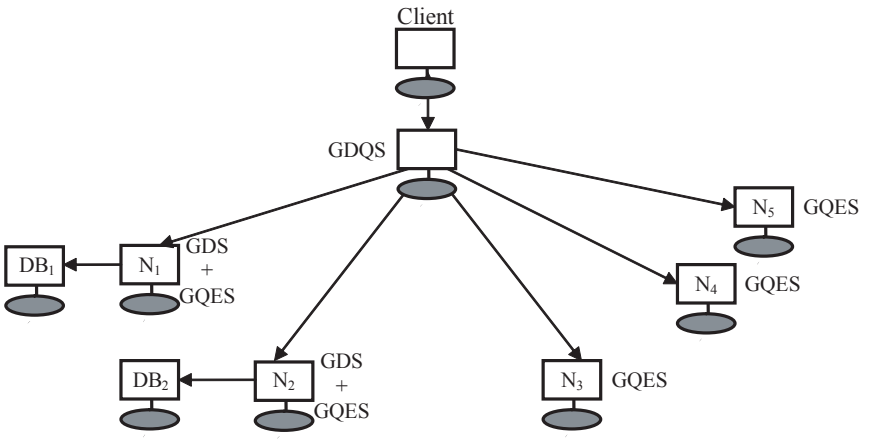


Table 1. Query types executed on GRADIENT

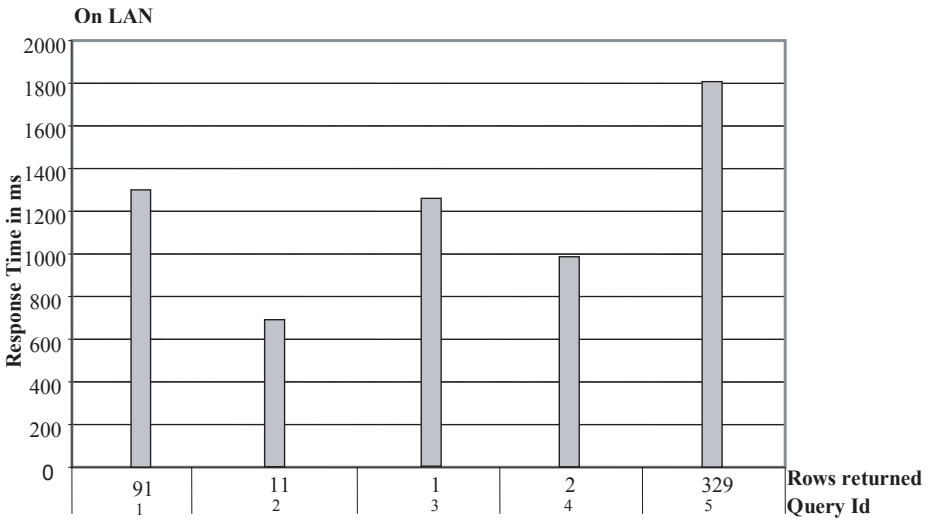
Query ID	Type of Query	Records Returned	No of records	Cross DB Join
1	Full Table Scan	91	91	DB2
2	Range Table Scan	11	34480	MYSQL
3	DB Equijoin	1	13278 * 91	DB2
4	Equijoin	2	34480 * 77	DB2 * ORACLE
5	Equijoin	329	34480 * 77	MYSQL * DB2

Figure 3. Performance Results for GRADIENT



a web service called the Global Metadata Service (GMS) and is responsible for much of the information virtualization talked about earlier. Gradient also employs a number of caching techniques such as data cache, query cache and metadata cache for improving the query response times.

3. EXPERIMENTAL RESULTS

We carry out extensive experimentation, with a Distributed Order Management System (DOMS) hosted on MYSQL, Oracle and DB2 for studying the performance of the Gradient system. GDQS is installed on a machine with Pentium 4, 2.8GHz processor and 1GB RAM. All the DQP evaluators were run on Pentium 4, 2.8GHz processor with 512MB RAM machines. We executed different types of queries ranging from a full table scan on a single database to cross database equi-joins. A complete list of queries used for the experimentation is provided in table 1.

Figure 3 shows the response time of the results for different queries executed in a LAN environment using Gradient.

4. CONCLUSION

The heterogeneity of the databases and the geographic dispersion of the data make it difficult to integrate the data and provide a transparent way of accessing this data by the user. In this paper, we presented an Enterprise Information Integration tool based on the service-oriented concepts and data grids, called GRADIENT. In particular, we elaborated on the metadata management, distributed query-processing and caching techniques implemented as a part of the solution. The Gradient is planned to support Metadata Synchronization, Adaptive Query Processing and Distributed Caching in the future.

ABSTRACT

This paper presents the results of one of a series of experiments done on mentoring and communication mode. In this study, the focus was on protégé satisfaction with the developmental interaction, and four communication modes were investigated: face-to-face (FTF), video-teleconferencing (VTC), telephone, and electronic chat. Between-subjects ANOVA was used to test for differences among mean satisfaction scores among protégés in the four different conditions. No significant main effect was found for communication mode on satisfaction, F (3, 68) = .64, p = .59. Trainees in all communications conditions found the developmental interactions to be satisfying.

Keywords: Computer-mediated communications; Human-computer interaction, Mentoring

INTRODUCTION

The changing nature of the employment contract, rapid advances in technology, and increasingly diverse organizational membership has led to an increased emphasis on continuous learning in an organizational context (Carnerdale, 1995; Higgins & Kram, 2001). Mentoring may serve as one form of non-traditional training in such a continuous learning environment.

Mentoring is typically considered a face-to-face activity. For a number of reasons -- increased knowledge specialization, the globalization of the economy, and the increased use of teams -- the degree to which such interactions would necessarily occur without participants meeting face-to-face is likely to increase. From the extensive literature on non-face-to-face communication, it is reasonable to assume that such communication may impact these interactions; however, little empirical research has been conducted on non face-to-face mentoring.

This paper presents the results of one of a series of experiments done on mentoring and communication mode. In this study, the focus was on protégé satisfaction with the developmental interaction, and four communication modes were investigated: face-to-face (FTF), video-teleconferencing (VTC), telephone, and electronic chat.

In the following section, a brief review of the mentoring literature is presented. In subsequent sections, the methodology and findings are discussed. The paper concludes with some suggestions for future research.

Mentoring

Traditionally, mentoring has been viewed as a relationship "... in which a senior person working in the protégé's organization assists with the protégé's personal and professional development (p. 265, Higgins & Kram, 2001)." More recently, researchers have investigated alternative forms of mentoring such as formal/assigned mentors (Ragins & Cotton, 1999), and peer mentors (Salinitri, 2005; Smith-Jentsch, et al., 2000).

Given that considerable evidence exists regarding the usefulness of mentoring for both the organization and protégés, there is organizational interest in promoting and facilitating such mentoring relationships. The degree to which such interactions would necessarily occur without participants meeting face-to-face is likely to increase as a result of telecommuting, virtual teams, and reduced manning. As Colky and Young (2006) pointed out, the benefits of virtual mentoring include lowered costs, increased access to mentors, and no limitations on space, time, and location. However, data is limited on the effectiveness of virtual mentoring. Thus, the focus of this study was on the effectiveness of mentoring in non-face-to-face settings.

METHODOLOGY

Participants

Protégés were freshman students recruited from Supplemental Instruction (SI) classes at a university in the Southeastern United States. SI classes are supplemental classes that the university instituted for courses that have historically high failure and dropout rates. There were 72 participants in the protégé sample. Of the 72 protégés, approximately 43% were male (n= 31) and 57% were female (n = 41). Their ages ranged from 18 to 20, with a mean of 18.32.

Mentors were juniors or seniors with at least a 3.0 cumulative grade point average. There were 18 participants in the mentor sample. Four of the mentors were juniors (22%) and 14 were seniors (78%). Of the 18 mentors, approximately 33% were male (n =6) and 67% were female (n = 12). Their ages ranged from 19 to 28, with a mean of 21.56.

Procedure

Protégés were randomly assigned to both mentors and communication condition. Each mentor had four protégés, one in each of the four communication conditions. Each dyad communicated for fifteen minutes, once a week for three weeks, using the same communication medium for all their sessions. The order in which mentors were exposed to the various conditions was counterbalanced to control for carry-over effects.

The laboratory set up allowed mentors and protégés to arrive for their sessions without meeting. In addition, mentors and protégés were asked not to contact each other outside out the laboratory, and to exchange first names only.

Measures

Because there was reason to believe that typing ability might restrict information exchange in the chat condition, and thus might be a covariate, all participants were given a typing test prior to starting the experiment; the *Keyboarding Skills Test*, a personal computer-based test purchased from RegSoft.

As with typing ability, it seemed likely that computer attitudes might have an effect on how favorably participants viewed the chat condition. Therefore, all participants were asked to answer a questionnaire regarding their computer experience prior to the start of the experiment (Levine & Donitsa-Schmidt, 1997). The reliability of the scale was $\alpha = .91$ for trainees and $\alpha = .93$ for coaches.

The final measure was a measure of satisfaction with the mentoring relationship, adapted from a 5-item scale developed by Finkelstein, Allen, and Rhoton (2003). The reliability for the five-item scale was .90.

RESULTS

There were no significant differences in computer attitudes or typing ability between the mentors and the protégés. For trainees, the mean net words-per-minute score was 33.5, with a standard deviation of 13.35. For coaches, the mean score was 34.17, with a standard deviation of 12.25. On the six-point computer attitudes scale, the mean score was 4.37 for trainees, with a standard deviation of .92. For coaches, the mean score was 4.56, with a standard deviation of .85. In addition, typing skill and computer attitudes did not significantly covary with satisfaction with the relationship.

Between-subjects ANOVA was used to test for differences among mean satisfaction scores among protégés in the four different conditions. No significant main effect was found for communication mode on satisfaction, $F(3,68) = .64$, $p = .59$. Trainees in all communications conditions found the developmental interactions to be satisfying.

Further analyses were performed to investigate if the lack of main effect was due to: 1) the sample's high levels of computer literacy, or 2) lack of power. The sample was split into two groups; those with mean scores equal to or less than three on the computer literacy test, and those with scores above three. Because the sample of those who scored less than three was very small, Levene's test for equality of variances was performed to check that the variances were not significantly different from each other. There were no significant differences between the two groups for satisfaction, suggesting that the lack of difference across conditions was not due to computer literacy.

The final possibility was that there was a lack of power. For satisfaction as the dependent variable, the amount of variability attributable to condition was .03 (partial eta-squared value), and the observed power, i.e. the power of the test when the alternative hypothesis is set to the observed value was .18 at $\alpha = .05$.

CONCLUSION

Although one can certainly conclude that this study did not have enough power to detect the effect of communication mode on the dependent variables, given that communications condition explains 1 to 3 percent of the variance in outcomes, is this, in practical terms, an effect? The power analysis suggest that it might be more useful, in terms of implementing non-face-to-face developmental programs, to focus on reducing the variability in the coaches' behaviors through training, than to focus on the effect of communication mode.

The two primary limitations of this study – the experimental design and the relatively novel topic – are, ironically enough, also two of its primary strengths. Because this study was experimental in design, there was control over the amount of interaction, the frequency of interaction, and prior acquaintanceship. However, in gaining this control, a certain amount of realism was lost; the interactions were very short, the sample was highly computer literate college students, and the participants appeared not to be driven by a specific knowledge needs, resulting in interactions that were primarily psychosocial rather than informational in nature.

The novelty of the topic area, although addressing both a void in the literature and a practical need, also resulted in a study that was different from much of the previous research. Although the research question "Can developmental interactions happen in a non-face-to-face setting?" required an unstructured task; this unstructured task makes it difficult to mesh the current research with the existing body of knowledge on communication mode effects. What the dyads in this study did *not* have to do was: solve a problem imposed by the researcher, reach consensus, or negotiate an outcome. Yet, these are precisely the types of tasks commonly found in research on the effects of communication mode (Graetz, Boyle, Kimble, Thompson, & Garloch, 1998; McLeod, 1992; O'Malley, Langton, Anderson, and Doherty-Sneddon, 1996).

For the dyads in the present study, there was no specific goal or objective other than to build a relationship that was satisfying and helpful; an objective that allowed the interactants a great deal of flexibility in terms of both evaluating the outcome and designing the process. Without the pressures imposed by a more structured task in the form of time limits, specific outcome requirements, or evaluative criteria, the limitation of the media may not have been as salient for these dyads.

A promising area for further research is suggested by this study. An interesting approach would be to replicate one of the earlier studies that used a structured task to determine if the passage of time, and the dramatic changes in communication technology, has changed the population's attitudes toward computer-mediated communications; and that the lack of an effect in this study might in fact be generalizable to a broader range of tasks.

XML and Relational Data Integration: Best Practices and the Database Course Experiences

David Olsen, Utah State University, 3515 Old Main Hill, Logan, Utah 84322, USA; E-mail: david.olsen@usu.edu
Vance Cooney; E-mail: vcooney@mail.ewu.edu

ABSTRACT

Many database courses focus on fundamental aspects of relational design, data modeling, transaction processing, and backend database issues. Given the ever increasing importance of web enabled databases generally but particularly the influence of XML (eXtensible Markup Language) as a database enabling technology, the authors felt that an XML module should be integrated into both introductory and advanced database offerings. The focus of this paper is discuss issues related to the integration of XML and relational databases in an undergraduate IT curriculum.

1. INTRODUCTION

Advanced database courses traditionally cover the theory and concepts behind the design and implementation of relational databases. In recent years there has been mounting pressure to weave into this discussion content on integration with the Web as much e-commerce is facilitated by web-enabled databases. The purpose of this paper is to show how the authors enriched an advanced database class by adding an XML module that extended a typical a real world database project example with an integrated XML component. To do this we developed a database using Microsoft's SQL Server 2000, referenced several online tutorials, and created assignments to "pull" data from this database using the XML technology [1].

The remarkable history of the Internet and WWW, well-documented elsewhere, is marked in the mid 1990s by the increasing realization that for the web to facilitate e-commerce in a meaningful way, that production databases and web servers would have to be integrated so that ordering et. al. would be from real time inventories. With the explosion in web sites and web services designed to support this functionality, the limitations in HTML, the web's first language, became obvious [2]. Specifically, many businesses needed to pass data from dissimilar information systems (typically relational databases) via the web and HTML based web pages were not well suited to this requirement. The reason is that such transfers are greatly facilitated by a medium that describes the structure of data (so as to assist the receiving end in parsing / processing the data stream), a requirement that vanilla HTML cannot meet. This is where XML comes in.

Prior to the development of XML there were efforts to adapt the precursor of HTML, SGML (Standard Generalized Markup Language) to accommodate the requirements of web – enabled database applications. SGML was a descendant of IBM's Generalized Markup Language (GML), originally developed in the 1960s to enable the sharing of machine-readable documents in large projects in government. It had also been used extensively in the printing and publishing industries, but its complexity had prevented its widespread application for small-scale general-purpose use [cite = http://en.wikipedia.org/wiki/SGML]. So, when efforts to adapt SGML itself proved fruitless, Jon Bosak, Tim Bray, C. M. Sperberg-McQueen, and Jean Paoli of Microsoft, designed a simplified version of XML based on SGML that has since evolved into the standard XML that we have today [3]. Mind you, we say standard with some trepidation as there continue to be turf wars over how XML ought to be implemented and what valid extensions are, what the best support tool are and etc., but as is typical with important technologies, XML has taken on a life if it's own and isn't waiting for all the warring sides to completely define it but is being and has been usefully deployed in any number of organizational settings over the last dozen years; we try to acquaint our students with this reality as well.

So, XML today is not merely an extension of HTML, it is a meta-language that can be used to define a language particular to a business domain and allow the exchange of data using this defined language. For example, instead of just, say, the <H1></H1> tag pair that traditional HTML would offer that only has to do with how the text within tags is displayed, an XML tag has semantic value. An XML tag example might be <Whsle_Unit_Cost></Whsle_Unit_Cost> and such a tag would define the meaning of the data as well as the display format; i.e., data between the pairs would mean the wholesale unit cost of something, say a prescription drug, and an organization receiving an XML file so designed could easily import the data into their database systems. In short, XML allows a user to separate the presentation of data from its storage, meaning and management. This allows users a vast array of opportunities for using XML to exchange data with trading partners. This phenomenon alone justifies inclusion of XML technology in an advanced database class, in the authors' opinions. The XML enabled Medical Informatics Networks, Automotive parts networks and XML enabled ERPs (Enterprise Resource Planning Systems) that are evolving worldwide all give support to the penetration of XML within the database development community. [Both authors schools have adopted Banner, an Oracle based, XML enabled ERP for the academic environment].

Since its inception, XML has been adopted by many developers as a way to describe data sets and their contents and to define how the data should be output or displayed on a web page (or, significantly, a cell phone, PDA or any of a number of other human readable or machine readable devices). Before XML, a client application accessing a database needed to translate the result set returned to a format that could be understood and displayed by a web application. XML removed the need for client side processing (given a XML compliant client) as the data and its formatting were defined in the XML markup.

The importance of XML is further supported by the fact that Microsoft SQL Server 2005 supports XML, and the result sets can be returned directly in XML format, or data can be retrieved from an XML document as if it were a SQL Server table. Oracle offers a similar suite of functions. A list of XML terms and definitions provided to students in the described database module are included in Appendix A. These terms are a good reference for anyone wishing to begin the study of XML.

2. BRIEF LITERATURE REVIEW

After Codd's seminal 1970 paper on relational theory, hundreds of books and articles on relational databases have been published [5]. Knowledge of relational database design and normalization are staples of advanced database courses, and are key components of the IS2002 model curriculum and guidelines for undergraduate degree programs in information systems curriculum [6]. Likewise, many computer science departments rely strongly on the Computing Curriculum 2001 (or the 2005 version) [7]. We believe that while model curricula such as IS2002 are extremely valuable guidelines, they are by their nature conservative, and likely to be slow in responding to emerging technologies such as XML. However, we believe that XML is going to be integral to future web enabled database architectures and so

believe that universities need to instruct students in XML. As a first pass at such development we have developed an XML Module that can be integrated into an advanced database management course. This will help students prepare to use modern development tools using XML such as Microsoft's .NET framework, and Sun Microsystems's J2EE platform. The need to teach XML in database courses is further demonstrated by the inclusion of XML column types, XML views on relational data, relational views on XML data, XML Schema, and XML based query languages [8] in Microsoft SQL Server 2000 and Oracle 10g. What follows is a description of the teaching module we developed for advanced undergraduates and graduate students in an advanced database management course.

3. XML EXPERIENCES AND BEST PRACTICES

We have reported on the Moab Medical Clinic XML case in [7] as a method for integrating relational and semi-structured data for instructional purposes. We also have collected many semesters of pre and post test data regarding different methods of integrating relational and XML data. In the following section, we present best practices regarding both using and teaching XML and relational database theory based upon the prevailing literature and our own conclusions from the data we have collected.

During the time we have been using and teaching XML in various courses, the following is a list of some XML practices we have observed / evolved:

1. Storing data as an XML data type in an XML column facilitates the DBMS engine checking that the data is well-formed or valid according to the specified XML schema.
2. If large amounts of XML data are input and output on a regular basis, it is better to store the data as an XML data type as it is far more scalable.
3. Storing data as an XML data type in an XML column allows for indexing data for efficient query processing, scalability, query optimization.
4. We encourage students to use the XML output option that creates all XML in the form of attributes as opposed to attributes and entities or raw XML output. There is little advantage to using entities or raw XML output if the desire to integrate with relational data is desired.
5. If small amounts of XML data are inserted or if XML data is infrequently inserted, it is better to use a conversion function and a mapping tool and simply map and transform the XML data into relational tables. Additionally, relational data can be transformed into XML data and used for Web Services. Transforming data back and forth between relational and XML formats can be messy, time consuming, unwieldy, and not scalable.
6. Several third party mapping and transformation tools can be immensely useful. Our students did very well with the Altova XML Spy tool that has numerous features related to database mapping. Altova has a free, limited version that students find valuable for completing their assignments.
7. Students that had significant experience with relational database theory or experience with tag-based languages such as HTML, PHP, Cold Fusion etc. did significantly better than students than students without such experience.
8. Using XML for interoperability between heterogeneous databases looks very promising. Indeed, with numerous disciplines (like accounting creating the XBRL standards) creating XML standards for data formatting, interoperability and common methods of exchange seems inevitable.

4. CONCLUSION

We have previously presented a comprehensive teaching case that demonstrates the integration of a XML module into an advanced database course [7]. Here we discuss how XML is becoming an increasingly important technology, yet few schools are teaching students how to retrieve, format and display XML data. Based on a sound relational database built in earlier assignments, students using our modules proceed through a number of tutorials that develop their familiarity with key components of XML technology. We believe that this method offers a couple of advantages. First, students are reminded of the importance of good relational design principles as they build the MMC database into SQL Server 2005. Second, students learn XML technology in the context of an advanced database class. Third, this instructional approach lays an effective foundation for later courses in web services development or web application programming, without losing the course's focus on advanced database management.

With literally hundreds of competing software packages, languages, operating systems, and networking technologies, we believe students need to integrate and apply new learning within the context of previous skills. XML then becomes a part of student's fundamental understanding of data retrieval and formatting, rather than just one more language or tool.

Alignment and Integration of Competitive Intelligence Systems: A Case Study

Donglin Wu, RMIT University, GPO Box 2476V, Melbourne, Victoria 3001, Australia
Fang Zhao, RMIT University, GPO Box 2476V, Melbourne, Victoria 3001, Australia; E-mail: fang.zhao@rmit.edu.au

INTRODUCTION

'Competitive intelligence (CI) is organized, structured information gathering, analysis and processing to enhance strategic decision-making. It is used by businesses to gain a competitive edge by learning about suppliers, customers, regulators and competitors. It is used by business people looking to gain an insight into the future of their business, make more effective decisions…'(Cook & Cook 2000, p5). For all the functions of CI, an enterprise must set up a CI system working throughout the whole organization, which requires that a high level of understanding and awareness of CI pervades every aspect of the organization (Pole, Madsen & Dishman 2000).

Studies show that CI plays a very important role in business success (Behnke 2001). However, there exist barriers to applying a CI system in organizations, e.g. insufficient funding, internal bureaucracy, lack of sufficient skills and experience in intelligence teams. Particularly, many companies are not clear about how to setup a CI system that is integral with their current organizational structure (Swartz 2005). This paper provides a case study which shows how Company X (for confidentiality, the company cannot be named in this paper) sets up a virtual CI system that is aligned and integrated with its current management system and how the CI system is operated effectively within the company's activities.

Company X is a Chinese hi-tech company in the telecommunication industry providing customized network solutions for telecom carriers around the world. With its aggressive sale strategy, fast response services and new product development, the company has achieved a leading position in Chinese telecommunication markets within less than 20 years. Its competitors include a number of telecommunication equipment big players, e.g. Lucent, Ericsson, Nokia, Motorola and Cisco. Among the factors contributing to the company's success, its CI system plays an important role. This paper analyzes the company's CI system from the following aspects: 1) the structure of the CI system, 2) people in the CI system, 3) the CI process, and 4) cultivating a CI culture in the organization.

This paper starts with a general discussion of the CI system of the case company, followed by an analysis of key issues and problems identified through the case study. A brief conclusion is made at the end.

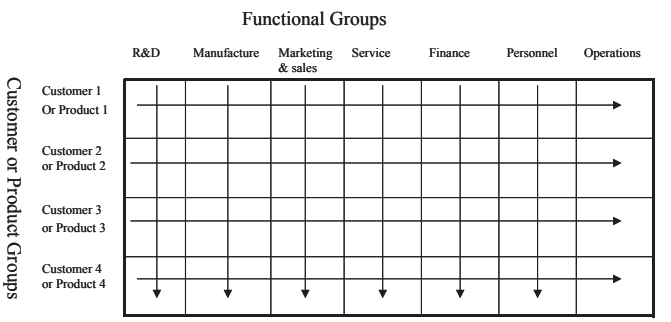
COMPETITIVE INTELLIGENCE SYSTEM IN COMPANY X

The Structure of the CI System in Company X

Research (Behnke 2001) shows that an integral CI team is characteristic of successful CI programs. Company X does not have a dedicated CI department. The CI team at Company X is a "virtual team" i.e. every employee takes the responsibility of CI and contributes to the CI system. The virtual CI system is integrated with the management structure of the company which achieves high efficiency in monitoring, collecting, analyzing all aspects of competitive information to support decision-making and daily operations.

The company adopts a matrix organizational structure as shown in Figure 1. There exist seven main functional departments: products research and development, manufacturing, marketing and sales, service, finance, human resource, and operation. At the same time, the company comprises several multi-functional groups that are organized according to customer groups or product types. The matrix organization structure facilitates speedy operation and decision-making because the functional teams can monitor their own localized business environments and move quickly to adapt to changes in them (Senior & Fleming 2006). Indeed, such organizational structure in Company X provides a good culture to build an efficient CI system while it also increases complexity of the CI system.

Figure 1. The company's organizational structure



The structure of the CI system in company X (Figure 2) follows its organizational structure. The virtual CI system in this Company is divided into three levels: (1) a virtual CI team under each functional group and multi-functional groups; (2) the CI coordinators in each business unit, e.g. the departments, representatives, overseas office, and call center; and (3) employees. The CI team in each functional group or multi-functional group administrates the whole CI system. They also undertake marketing, service and other research. The CI team members' responsibilities include (1) monitoring, collecting and analyzing information from external public information resources, e.g. internet, newspaper, journals, third party's report; (2) collecting and analyzing the information from the CI coordinators in each business unit; (3) intelligence dissemination; (4) conducting specific competitive intelligence research and surveys; (5) contacting consult or marketing research companies if a need arises; (6) supervising and measuring the CI works of CI coordinators; and (7) providing executives and employees with CI training and CI services. The CI coordinators' responsibilities include (1) collecting CI information from employees, customers, and any legal CI resource, (2) preparing for and submitting CI reports for the business unit that he/she works in, (3) helping conduct special CI research and surveys, (4) collecting CI needs and submit them to the CI team, and (5) providing the CI service to his/her colleagues.

Figure 2. The structure of CI system

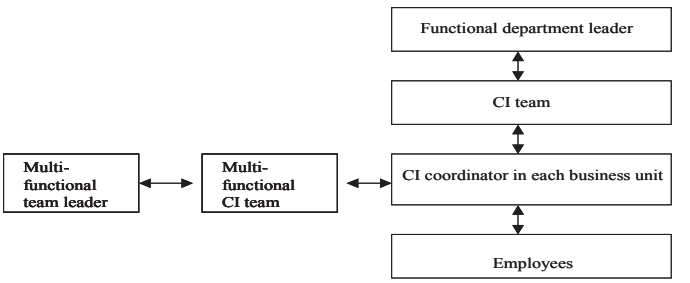


Figure 3. General CI process

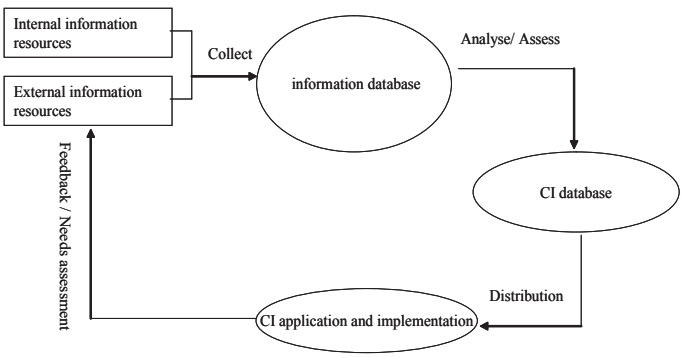

Figure 4. A specific sample of a CI research process

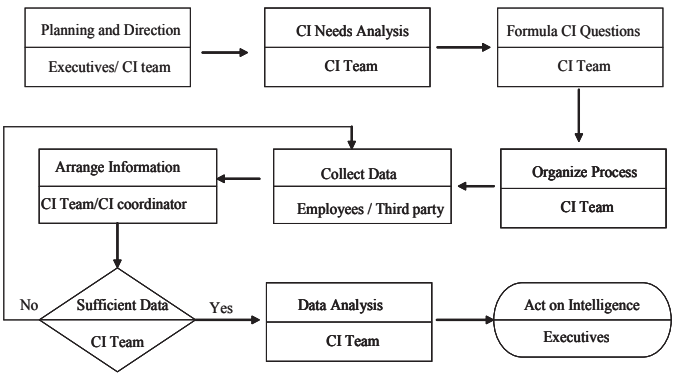

CI Process in Company X

Generally a CI process includes information collection, data arrangement, information analyses, intelligence application and implementation.

CI collecting process: The CI collecting processes in Company X includes two streams: general CI process and specific CI research project process. In the general CI processes (Figure 3), employees enter the information that they think valuable into CI information database every day. CI coordinators submit CI reports monthly after gathering the internal and external CI. The specific CI research projects (Figure 4) are often conducted when needs arise. They are usually derived from the CI needs for decision-making from CEO or CI teams. After formulating CI questions, the CI teams send a CI collection note to a CI coordinator and then to every engineer and salesman. The responsive information will then be collected.

CI analysis process: a CI team in each functional and non-functional group conducts CI analysis. People in the CI team have multi-CI analysis skills in the industry. They take charge of the CI analysis of specified competitors or customers.

CI distribution: After a professional analysis, the relevant CI reports are published in the company's intelligence database. Each report will be set a secret level for different level executives, managers or employees. The CI teams also send periodical electronic or printed CI reports to appropriate users through an internal delivery system. Executives, managers and employees can ask for help from the CI team to locate the intelligence or to conduct specific CI research.

CI application and implementation: The company uses CI to support decision making, to improve new products' development, marketing and sale, service, manufacturing and management, to position the company in the industry though comparing it with competitors, and to alarm and respond to competitors' actions, government policies and other changes in the competitive environment.

Cultivating CI Culture

To improve its CI capability, company X takes measures to cultivate a CI culture from both the institutional and educational perspectives. The institutional measures include:

1. Solidifying and constantly modifying its CI process and flow to satisfy development needs.
2. Setting up a systematic CI performance appraisal system. CI performance is taken as part of sale representatives and service centers' managerial performance (10%).
3. The functional departments also give feedback to CI teams to assure the CI teams improve CI quality continuously.
4. CI teams provide a CI template to coordinators and employees to standardize CI work.

The educational measures include:

1. Arranging CI training for the executives to strengthen their CI knowledge.
2. CI information gathering and analysis training.
3. CI legal and ethical training.
4. Anti-competitive intelligence training.
5. Cultivating a good CI sharing culture within departments, breaking sharing barriers between functional departments.

EXPERIENCE AND PROBLEMS OF THE CI SYSTEM

Key Features of CI Implementation of the Case Company

- Although Company X does not have a dedicated CI function team, it has a formal CI processes and a CI IT support system.
- Forming an excellent CI culture. Every employee is educated to contribute to the information collection and protect company's CI.
- Nominating CI coordinators in each department. These coordinators ensure that all valuable CI information can be collected and submitted to CI teams. At the same time, the CI information is analyzed and screened to avoid less valuable CI information being communicated. Furthermore, CI coordinators share quite a lot of CI service work and ensure CI teams spend more time on in-depth analysis.
- Regular collecting and defining CI projects are conducted, which helps acquiring comprehensive competitive information as well as conducting an in-depth analysis.
- Fostering a good CI utilizing environment. Besides electronic CI publication, CI teams edit periodical CI research reports and send them to directors, executives.
- Conducting periodical CI needs surveys.
- All CI works are based on CI needs and practices.
- Building a CI technological system systematically. Company X's CI technological system is constructed on Lotus Note system, which is not typical CI software. More employees can be involved in the CI system without having extra technological training.

Key Issues to Be Addressed

1. Company X's CI technological support system is not well constructed. First, the CI technological system is based on Lotus Notes system. The system is not a professional CI software system, which affects the efficiency of CI searching, sharing, and analysis. Second, the company has not set up a company level competitive database, which impedes CI sharing between different functional groups.
2. The company does not appoint a Chief Information Officer. This affects the quality of CI works and CI system building in the whole company although the CI in separated functional groups is successful.
3. Although the virtual CI team helps the CI works closely related to the workplace in the company. The lack of professional CI people would influence the effectiveness of CI.
4. System CI analysis tools are not used by CI teams to analyze information. Analysis results often depend on the CI team member's personal knowledge and skills, which might result in low quality of CI analysis.
5. Taking a short-term perspective in its leading CI system impedes the case company from building a systematic and professional CI system. In fact, it has influenced adversely the company's long-term strategy and earlier alarm system working properly.

CONCLUSION

This case study introduces a CI system that is aligned and integrated with Company X's organizational structure. We see that an integrated CI team plays a key role in building an efficient and effective CI organization. Organizations need to clarify what they need to construct an efficient CI system. The case also shows that the CI technological platform can be built up step by step. Any advanced CI technological tools need a systematic and institutional CI system to support. Due to the methodological limitations of the case study, the successful experience and lessons learned from this single case can only serve as an illustrative example of how a high-tech company implements a CI system.

ABSTRACT

Rural Internet Centre (RIC) project by the Malaysian government offers opportunity to bridge the digital gap between the rural and urban communities in Malaysia. The RIC provides IT skills training and IT awareness programs to all groups of people including women, the elderly, and children. In order to assess the current RIC operations and usage, a survey was conducted in four selected RICs in Kedah and Perlis. Questionnaires were developed to measure the level of RIC usage and the RIC operations in the specific community. The findings show that role of partners, role of administrators, services/activities and functions, objectives, local infrastructures, financial support for sustainability, and users' trainings and support are critical in the RIC operations. However, this study has identified that applications and content development are also important.

Keywords: Rural Internet Centre (RIC), rural communities, community informatics, digital divide.

1.0 INTRODUCTION

The 8th Malaysia Plan, which covered the period of 2001-2005 was primarily aimed at sustaining economic growth and competitiveness in the face of growing globalization and liberalization (Dewan Rakyat, 2001). One of the thrusts was to shift the growth strategy from input-driven to knowledge-driven and productivity-driven. The primary challenge during the Plan period was to implement the National Vision 2020 Policy to strengthen the nation's capacity, capability and resolve in meeting future challenges (Anon, 2001). Nine key strategies have been addressed to meet the challenge. Two of the strategies are (i) enhancing productivity-driven growth and (ii) enhancing the usage of IT or information communication technology (ICT). For these purposes, about RM1 billion has been allocated under the Plan to carry out ICT programs and projects to increase the usage of ICT among communities in rural areas. Table 1 shows the detail of the allocation to support those programs.

The diffusion and usage of ICT within and across sectors is further expanded as ICT has a strategic role in accelerating economic growth. Accordingly, the ICT infrastructure is upgraded through several initiatives including increasing the capacity of the transmission backbone up to 10 gigabits per second and introducing the Network Management System for better service availability. The ICT infrastructure is also unrolled to the rural areas to reduce the digital divide and to achieve a balanced development. Among the programs implemented include the project of Rural Internet Centre (RIC), which was set up to bring the Internet to small towns and rural communities in Malaysia. The Ministry of Energy, Water and Communications (MEWC), Malaysia Post Berhad and Maju Sedunia Digital (MSD) are responsible for the project. The Malaysian government aim to set up 240 centres by the year 2010 which will eventually reaching an estimated 2.8 million members of the rural communities.

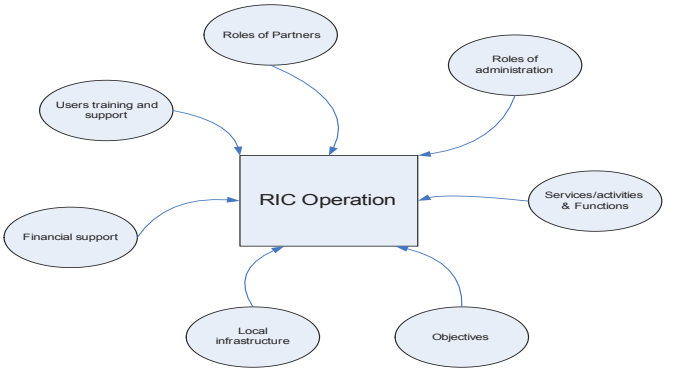
2.0 RURAL INTERNET CENTRE (RIC)

RIC was launched in March 2000 with two centers: Sungai Ayer Tawar in Selangor and Kanowit in Sarawak. By 2006, 42 Rural Internet Centres (RICs) have been

Table 2. Role of the partners in the MEWC's RIP steering committee (Adapted from: Guidebook on Developing Community E-Centres in Rural Areas: Based on Malaysian Experience)

Partners	Role/Resposibility
MEWC	RIC programme coordinator
Post Malaysia Berhad	Provided the space for RICs
Telekom Malaysia	Provided the telecommunication services
INTEL	Provided 2 PCs for each RIC
MAXIS Bhd.	Provided the local content i.e the Website for RIC
MNCC	Contributed to implementation concept
INTAN as governmenr site	Provide basic training in ICT at each site of RIC

Figure 1. Critical factors of RIC operations



implemented in thirteen states in the country (KTAK, 2006). RIC provides IT skills training and knowledge acquisition programs to the rural community in Malaysia, including women, the elderly, and children. Information about the existence of the RICs, the committees in the RICs, and the activities and services provided by and through the RICs are described in a specific website (http://www.idesa.net.my/). The number of RICs in each state and the types of facilities, activities and services provided in each centre are dependent on the size of states.

Noor Bathi (2005) reported that the initial MEWC's RIC model of partnership is made up of Malaysian National Computer Confederation (MNCC), Pos Malaysia Bhd, Telekom Malaysia, Intel, MAXIS, National Institute of Public Administration Training Centre (INTAN) and community representatives. Table 2 illustrates the roles and responsibilities of each partner.

A study on RICs in Selangor showed that the implementation of the centres in that state has been well accepted by the local communities (Mohd Nizam, 2005). The centres do not only give the communities an access to the Internet, but also improve their knowledge and skills in ICT. The numbers of RIC users and visitors have increased every day. The centres, however, do not have enough ICT resources, for example, PCs, printers, and other peripheral devices. Each centre is only equipped with between five to seven PCs. The centres also have a limited number of staff to administer the RICs. Mohd Nizam's (2005) study finally concluded that RICs in Selangor and other states should be given more spaces and resources in order to achieve the RICs' objectives.

This study intends to find out how RIC is currently being used in the community. The objective of this paper is to describe the initial findings of our research regarding the usage of four RICs in the states of Kedah and Perlis in Northern Malaysia. Specifically, the description focuses on the activities, users and the management of RIC. The financial aspect of RIC operations is not included but will be looked at in the future. Based on the results of this study, an initial RIC framework to effectively bridge the digital divide is proposed.

3.0 RESEARCH APPROACH

Based on the role and responsibilities defined in the partnership framework (Noor Baiti, 2005), seven components have been identified as critical factors to contribute to the operation of an RIC. These include role of partners, role of administrators, services/activities and functions, objectives, local infrastructures, financial support, and users' trainings and support as shown in Figure 1. These factors are then used to form the research variables in the survey instruments.

In order to assess the current RIC operations and usage, a survey was conducted in four selected RICs in Kedah and Perlis. The survey was carried out in September 2006. Data and fact-findings were done through questionnaires. Two sets of questionnaires were constructed which made up the survey instruments given to personnel responsible for administrating and maintaining the RICs and users of the RICs. Both instruments are developed to measure the level of RIC usage and the RIC operations in the specific community. Both sets of instruments were hand-delivered to their corresponding respondents.

The first set of questionnaire (Set A) which was distributed to eleven RICs' administrators consists of four sections: Profile of Respondents, RIC Users, RIC operations and RIC Website Information. Profile of Respondents section attempts to gather data on the respondent's background information. This includes the respondent's age, sex, marital status, race, qualifications, type of organization and position, roles in RIC, and the amount of time allocated for administrating the RIC. This information would give a general feel of the type of respondents and also to verify that the information captured from the right source. It also intends to identify the demographic factors that may influence the management and administration of the RICs.

The second section of the questionnaire, RIC Users, deals with the respondent's personal opinion regarding the RIC users. Among the information sought were users' categories that frequently visit the RICs. There are reasons to believe that users' categories may also influence on the RICs' operations and activities.

The third section of the questionnaire, RIC Operations, identifies the kind of activities, services, and facilities offered in the RICs. Opinion on how the RIC operations can be improved is also sought. The last section, RIC Website Information, gathers information pertaining to website development.

The second set of questionnaire (Set B) was distributed to seventy RICs' users consists of two sections: Profile of Respondents and Activities in RIC. The Profile of Respondents section attempts to gather data on the respondent's background information. This includes the respondent's age, sex, marital status, race, qualifications, type of organization and position, and IT courses or training taken. This information would give an overview of the type of respondents. It also intends to identify the demographic factors that may influence the usage of the RICs.

The second section of the questionnaire, Activities in RIC, will gather information about the frequency of RIC visits, activities carried out in RIC, benefits, problems and level of satisfaction with regards to RICs services and activities offered. Finally, opinions on how the services and activities of the RIC could be improved are sought.

The purpose of these two sets of questionnaire is to gather information about the RIC operations and services from the perspective of administrators and users. This information helps to confirm the relevancy of the questionnaire and also to complement the responses. Thus, this study is a pilot survey to test the validity and reliability of the questionnaires. Revision on the questionnaires will be done accordingly for future research.

4.0 RESULTS

The response rate is 100% for both sets of questionnaires. Hundred percent returned is achieved due to the fact that the questionnaire were hand-delivered and -collected. The major analytical treatment applied was descriptive techniques. Section 4.1 presents the demographic characteristics of the respondents. Since there are two groups of respondents in this survey, the results are presented accordingly. While, section 4.2 describes about the responses of administrators, Section 4.3 deals with users' responses.

4.1 Profile of Respondents

Table 3 presents the distribution of respondents (administrators and users of RICs) by demographic characteristics.

Table 3. Demographic characteristics

Variable	Administrators		Users	
	Frequency	Percentage	Frequency	Percentage
Age (years):				
Less than 21	0	0.0	21	30.0
21-30	8	72.7	32	45.7
31- 40	1	9.1	11	15.7
41-50	2	18.2	5	7.1
Above 50	0	0.0	1	1.4
Gender:				
Male	6	54.5	35	50.0
Female	5	45.5	35	50.0
Marital Status:				
Single	5	45.5	47	67.1
Married	6	54.5	21	30.0
Divorced	0	0.0	1	1.5
Race:				
Malay	11	100	62	88.6
Chinese	0	0.0	6	8.6
Indian	0	0.0	0	0.0
Others	0	0.0	1	1.4
Level of Qualification:				
Certificate	3	27.3	29	41.4
Diploma	5	45.5	5	7.1
Bachelor Degree	2	18.2	7	10.0
Masters Degree	1	9.1	4	5.7
Others	0	0.0	14	20.0

Of the eleven administrators, 72.7% aged between 21-30 years old. The rest are above 31 years of age. On contrast, the age of users are mostly below 30 (75.7%). It shows that the RICs have attracted the interest of the youth compared to the other age category. This could be another reason that indicates unmarried users are the majority visitors of the RICs.

In terms of gender category, the number of male and female administrators, as well as users, is almost equivalent. Malays outlay the other races as the RICs' administrators (100%) and users (88.6%). This is due to the fact that the communities surrounding the RICs are mainly the Malays. 45.5% of the administrators are Diploma holders, 27.3% has certificates and the rest hold Bachelor and Masters degree.

4.2 Responses of Administrators

Among the information sought from the administrators revolves around the IT courses and training taken, opinions about the users of RICs, the RICs' operations and activities, and the local RICs' webpage.

4.2.1 IT Courses and Training

As shown in Table 4, 90.0% of the administrators have undergone training on using Microsoft Office, operating systems (63.6%), computer maintenance (54.5%), and internet (63.6%). Other courses attended are Adobe Photoshop and Illustrator, and graphics and multimedia.

4.2.2 Operations of RIC

Most of the RICs operate between 8.30 a.m. to 5.30 p.m. on weekdays. All RICs have the basic ICT facilities such as printers, scanners, and internet access. Apart from that, many RICs are equipped also with photocopy and fax machine, LCD projector, digital camera, and reference books.

The services provided by the RICs include computer classes, advice on computer purchase, computer selling and servicing, card printing and writing official letter services, and internet access. Other services offered are webpage development, e-procurement services, and posting advertisement in webpage.

According to the administrators, users of the RICs are from the following categories: students, graduates, housewives, farmers, businessmen, government servants,

Table 4. IT courses and training

	YES		NO	
	Frequency	Percentage	Frequency	Percentage
Microsoft Office	10	90.9	1	9.1
Operating Systems	7	63.6	4	36.4
Computer Maintenance	6	54.5	5	45.5
Internet	7	63.6	4	36.4
Adobe Photoshop & Illustrator*	1	9.1		
Graphic & Multimedia*	1	9.1		

**open-ended questions, i.e additional courses attended by certain respondents*

private sectors employees, and pensioners. Among these categories, the most frequent users are from the students and graduates categories. Reasons for their frequent visits could be, to complete their assignments, search for information, look for job or study opportunity, and improve their IT knowledge. On the other hand, farmers, and pensioners do the least visits. This could be due to various reasons such as, have no interest in computer technology, have computer phobia, incompetence in using computers, and lack of ICT awareness.

RICs' activities focus on IT literacy programs, selling telecommunication product, Independence Day and festivals celebrations, and examination workshops. To attract more participation from the surrounding communities, the respondents suggested varieties of activities and services such as free workshops during the weekend, free photocopy services, e-procurement, online payment services and educational trip. In general, it seems that the idea of having a one-stop-centre is desirable.

4.2.3 Local RICs' Webpage

The administrators develop the webpage themselves by using Microsoft FrontPage and DreamWeaver. The common content include local information, webpage information, background of specific RIC, lists of RIC's activities, and information about the community. Some also include linkages to search engines and online applications.

4.3 Users' Responses

In general, most of the RICs' users are aware of the RICs existence through their friends (55.7%). Among the information gathered from the users are the IT courses and training taken, the services offered by the RICs, frequency of their visits, and their overall satisfactions. Suggestion on how to improve the RICs' services and activities, and the benefits acquired from the use of RICs are also presented.

4.3.1 IT Courses and Training Attended

Table 5 depicts the IT courses and training attended by the users. Most of them (72.1%) have the basic training in ICT, Internet and Microsoft Office. Other courses and training undertaken by the users are also shown in the table.

4.3.2 RICs Services and Activities

In the questionnaire, five services that are usually provided by the RICs are listed. These include computer classes (1), consultation on computer purchase (2), computer selling and servicing (3), card printing and writing official letter services (4), and internet access (5). Fifty-nine respondents (84.3%) agree that internet access services (5) are the common offered services by RICs, followed by computer classes (71.4%). Based on the common services offered the two activities that are popular among users are internet surfing (71.4%) and IT literacy workshops (41.4%). Internet surfing captures the users attention probably because it is interesting, fun and informative, while workshops are conducted to equip users with necessary ICT knowledge.

In terms of frequency of visits to RICs (refer Table 6), out of the 70 respondents, 44 (62.9%) visit the RIC when necessary. Of the 44, 20 respondents are from the 21-30 years age category, 15 from less than 21 years of age and 7 from 31-40 years. Almost 14.3% uses the RIC once a week. The rest visits the RIC once a month. The number of male and female users that visits the RICs is equivalent. This indicates that the most frequent visitors of RICs are aged below 30 years old regardless of their gender. Thus, this result confirms the administrators' responses on frequent RICs' visitors namely the students and university graduates. The fact that they only visit the RICs when necessary implies that the visits are made when they have assignments to complete, or the needs to search for relevant information on jobs or studies opportunities.

4.4 Users' Satisfaction

Most of the users described in Table 7, come from all age categories are satisfied with the services, activities and facilities provided or offered by the RICs. Despite the high level of satisfaction among the users, there are a few problems that have been highlighted by the respondents. The major problems stated by the respondents are insufficient number of computers, and inappropriate operation hours. The reason is that the most of the RICs in each community are only equipped with between five to seven PCs. This finding tallied with Mohd Nizam's study in 2005 regarding RICs in Selangor. With regards to the inappropriate operation hours, they would like the operation hours (currently 9 a.m. to 5 p.m) of the RICs to be extended since some of the users are working.

The respondents also provided their suggestions towards improving RICs services, activities and facilities. These include improving RIC promotions and activities, and equip the RICs with more PCs. In addition, the benefits acquired from the RICs' operations are shown in Table 8. Other benefits as stated by the users include free internet usage and printing services.

5.0 CONCLUSION AND RECOMMENDATIONS

This paper has successfully described the initial findings on RICs current situations in Northern Malaysia. It can be argued that the government intention to bridge the digital divide among the rural communities through RICs is not entirely

Table 5. IT courses and training

Courses and Training	Frequency	Percentage

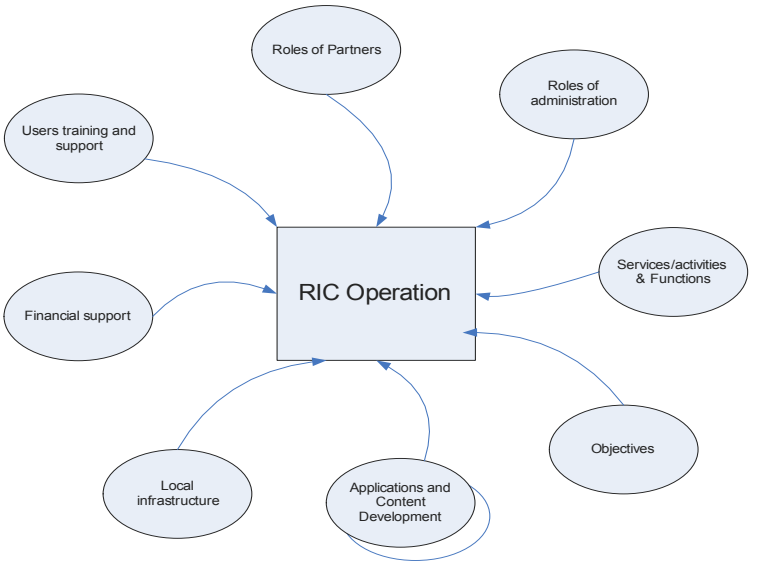
Table 8. Benefits of RIC

Benefits	Frequency
Increase the ICT awareness	50
Increase the knowledge relating to ICT	56
Increase skills in using computer	55
Increase quality of work	32
Increase quality of life	29

Figure 2. A theoretical framework for RIC operation



achieved. Nevertheless, the centres do contribute to the local rural communities' development indirectly, for instance IT literacy and awareness are improved. Hence, further research on RIC will be carried out to increase the usefulness of the RIC to the rural communities, and to identify applications that will help the communities' development in the long run. Maybe if the community can see the need for the IT, the number of users may increase as well as the inclusion of older users and among the farming sector. This implies that more applications and content development are needed to attract and make the community realize the value of IT in improving their quality of life as well as their economy.

The findings of this study suggest that the role of partners, role of administrators, services/activities and functions, objectives, local infrastructures, financial support for sustainability, and users' trainings and support are critical for the RIC operations. In addition, applications and content development has been identified as another important factor. Hence, this study proposes an initial theoretical RIC framework to illustrate the contribution of these factors towards RIC operation. This framework is shown in Figure 2. In order to ensure the reliability of the framework, further research will be conducted.

Organization of Grid Resources in Communities

Asif Akram, CCLRC e-Science Centre, CCLRC Daresbury Laboratory, Warrington, UK, WA4 4AD; E-mail: a.akram@dl.ac.uk
Rob Allan, CCLRC e-Science Centre, CCLRC Daresbury Laboratory, Warrington, UK, WA4 4AD

ABSTRACT

Locating suitable resources within a Grid is a computationally intensive process. An alternative approach is to categorize resources based on the services they provide – leading to the interaction of peers with common goals to form societies/communities. The communities can be adaptive in nature and evolve based on changes in their operating. We have implemented JXTA prototype to illustrate the concepts of community formation in which Peers offering different services can be grouped together based on different criteria.

1. INTRODUCTION

Emerging distributed computing paradigms, such as Grid Computing, comprise of dynamic and distributed resources/peers. Resource discovery in such systems is a time-consuming process with network overhead. The numbers of interactions are likely to increase exponentially as the numbers of peers grow. Restricting interactions between set of peers is a key factor to scale the resource discovery problem. Davis and Smith referred it as the "connection problem" [1], where peers need to find other suitable peers to co-operate with, assist, or interact with. Peers are categorized based on criteria i.e. type and quality of service, etc. Any initial cost in categorizing peers result discovering "preferable" resource with minimum discovery cost subsequently – thereby leading to the development of "communities". "Focused Addressing" [2] is one solution to the connection problem where requests are sent to particular subset of peers, believed to assist the requesting peer.

Individual peers, although selfish, are expected to interact with each other in some way. Each peer prefers to be in environment where it may be easily discovered by a suitable user, and can locate other peers with minimum efforts. This analogy helps us to define two terms, Expertise and Interest [13], [14]. Expertise of a peer is the basic service provided by that peer and Interest of a peer is the service/services provided by other peers which are supportive to its main service. Each community has one Service Peer with dual responsibility of managing the member peers and providing communication source with external environment. Interaction between different communities is only through the Service Peers.

2. TYPE OF COMMUNITIES

Individual autonomous peers have expertise and interests in specific resource/s. Based on these expertise and interests, peers are grouped together, but expertise and interests are not the only criteria for categorizing peers. Communities/societies can be of different types as mentioned below:

Competing Community: In a Competing Community each peer has the same expertise – although some service attributes may vary. Similarity in services may develop competition amongst member peers, as members compete each other to get selected.

Co-Operative Community: In Co-Operative communities peers provide different services, which must be used alongside services of other members. Hence, when any peer is selected, then the possibility of selection of another member peer providing utility service/s increases. This mutual co-operation is suitable for peers which provide simple services.

Goal Oriented Community: This is collection of peers work together to achieve a particular goal. Goal oriented communities are important in self-organizing systems, where interactions between member peers are not pre-defined, but the services required are. In such instances, member peers may interact with each other in arbitrary ways to achieve a given end result.

Ad Hoc Community: In ad hoc communities peers interact directly with each other without interference and involvement of a Service Peer. Peers belonging to different communities providing supporting services form the basis of an ad hoc community.

Domain-Oriented Community: Such a community is formed by linking together similar-minded organizations and institutions, instead of the services they provide, such as academic communities, research communities, and open-source communities. Hence these communities are domain-oriented rather than service-oriented.

Virtual Community: The Virtual community is a community of communities. This effect is achieved by leasing out the member Peer to other community for certain time period, before that lease period either Service Peer requests to renew the lease of corresponding Peer or it can't use the service of the Peer directly.

Sharing Community: In this type of community different Communities share their resources with each other; this sharing of resources is not restricted to member Peers but includes core and optional services. Community A may have QoS monitoring module, which it shares with Community B assuming either Community B doesn't have such module or Community A may has more advanced monitoring module.

3. COMMUNITY FORMATION

Community formation involves three basic processes and in all of them the middleware plays a major role; utilizing different core services provided by the community. These three processes are "Initiation Process", "Maintenance Process", and "Formation Process" for collaboration on an ongoing basis between the members and with other communities.

3.1 Initiation Process

The community formation process can be initiated manually or by any peer. The first task of the newly created peer is to search for existing communities which may have interest in its services. The peer queries the middleware for appropriate communities; on failure it may request to create a new community. The middleware searches its own knowledge base to match the services of the peer with requirements of existing communities. The peer can refuse to join any existing community and can insist for the creating of new community. The newly formed created community (i.e. manually or on the request of any peer) search for other peers and services with complementary and competitive resources for long term partnership. The community search for new members by querying the peers registered within the middleware. The main achievement of this process is to promote mutual trust between the members, negotiate consistent rules and regulations i.e. pre-qualification criteria for new entrants, Quality of Service (QoS) [11], sharing costs and profits. The community formation process either creates new Service Peer or requesting Peer acts as coordinator.

3.2 Maintenance Process

After the initial formation of community, the coordinator is responsible for maintaining and improving the collaboration, which involves many different sub-management tasks, conducted concurrently. The coordinator observes the changes in the internal and external environment and adapts according to the changes (updating its knowledge base) to maintain its effectiveness in the distributed environment. The coordinator monitors the performance within the community and provides basic services to members to achieve the required performance. It

is important to keep track of the resources and core competencies of partners and their performance. To improve overall performance of the community, its coordinator is always looking for new members with missing or complementary resources. Although the maintenance process is mainly concerned with the local functioning of the community but in this stage the coordinator also communicates with the middleware to search for new members.

3.3 Formation Process

The community is opportunist and always exploits the potential for collaboration. When a new collaboration opportunity arises it is the coordinator identifies the required individual activities to match the opportunity. The first step for the coordinator is to create a "workflow" based on the available resources, competencies, strengths and weaknesses of the members. The workflow may require collaboration with external communities to "buy in" services missing within the community. No matter how complicated final workflow is; whether it utilizes only internal resources or involves an external collaboration, coordinator develops teamwork for achieving set goals. Once the workflow is formed and tasks are allocated and scheduled among participating members, the coordinator monitors the performance of individual members and quality of tasks. Post-Management formation process involves allocation of additional resources, replacement of under performing member/s, re-scheduling of tasks within the workflow, etc.

4. ARCHITECTURE OF TOOLKIT

The architecture for the community formation should be simple and supportive to the main purpose of their formation. The proposed architecture consists of three main components. These components are discussed following the Tool Selection:

4.1 Tool Selection

The efforts to design and implementation the system can be drastically reduced by selecting appropriate technology. The initial prototype is developed in JXTA [11]. JXTA (jxta.org) is an open source P2P framework initiated by Sun Microsystems. The JXTA protocols are independent of any programming language, and multiple implementations exist for different environments which make it best choice for prototype. The JXTA network consists of a series of interconnected nodes, or Peers. A JXTA Peers is "any entity capable of performing some useful work and communicating the results of that work to another entity over a network". Peers can self-organize into Peers Groups, which provide a common set of services.

JXTA has the concept of Peer and Peer Group which match to our vision of '*Peer*' and '*Communities*', which makes JXTA as best choice for implementing our prototype.

4.2 Middleware

JXTA had default peer group and every peer joins this default peer group after booting within the JXTA network. This default peer group is called the *NetPeerGroup* or *WorldPeerGroup*. The middleware is the extension of default peer group.

The middleware required to support the community formation is more than simple distributed registry. The customized middleware provides more specific search capabilities and match making. It provides the interface to create new community. The toolkit does not impose any restriction on the communities i.e. the nature or role of communities, the services they offer, why and when these communities are created. The framework supports the creation of communities and the definition of membership policy. It is up to cooperating peers to define communities, join communities, and leave communities.

The middleware provides the much required environment to peer and community for advertising their capabilities. All queries and match making is done against these advertisements.

4.3 Peer

A Peer can be simple service, resource on the computer or any hand held device. Each peer operates independently and asynchronously from all other peers, and is uniquely identified by a Peer ID. All peers are automatically members of the framework which extends the default NetPeerGroup. Peers may opt to join and leave customized or user groups/communities at will. In order to join any community, a peer must discover the community through the search capabilities provided by the middleware. Once the suitable communities are discovered then peer apply for the membership.

Peers publish one or more interfaces for its different services and resources. Each published interface is advertised as a peer endpoint, which uniquely identifies the network interface. Peer endpoints are used by other peers to establish direct point-to-point connections between two peers.

4.4 Community

Community is a temporary or permanent coalition of geographically dispersed individuals, group's organizational units or entire organizations that pool resources, capabilities and information to achieve common objectives. Each community has a similar architecture, with one Service Peer, which manages the whole community. Normally Peers from different communities are not allowed to communicate directly and the communication should be done through the Service Peer except for the Ad-Hoc community.

A community offer different services and resources; utilized only by the member peers. The peer looking for specific service should locate and join the appropriate community offering required service.

Communities may strongly enforce a membership requirement. This defines the boundaries for a secure environment where content can be accessed only by member peers. Communities can provide services and thus participate as a single entity in the formation of further communities.

4.5 Service Peer

The Service Peer is a community coordinator, which manages the proper working of the community, provides essential resources to its members and is source of communication with other communities. The Service Peer is the extension of the Rendezvous Peer provided by JXTA environment and has an optimized routing mechanism for an efficient propagation of messages. If the Service Peer cannot locate the destination of message or query, the request will be forwarded to other known Service Peers.

Service Peer maintains a local view of the environment, a list of known Service Peers and communities. Service Peers maintain information of member peers and a restricted set of other communities; this interest is governed by the expertise and interest of other communities. This restricted list of other communities is used to develop referral mechanism.

The Service Peer coordinates the resources and services within the group to achieve set objectives, maintain membership policies, monitors member peers. The Service Peer may not itself offer different services but may only coordinate services offered by different specialized member peers.

5. PROTOTYPE AND RESULTS

For simulation purposes the JXTA prototype has been developed with option for creating Groups and Peers along with their description. This description is used as the one of the membership criteria, when any Peer applies for the membership. The community is created along with randomly generated External Rating and community assigns randomly generated Internal Rating to all of its members at the time of membership. Peers apply for membership based on high external rating of the community. The community grants membership based on overall rating of the peer and description of the peer.

Prototype was evaluated with different set of parameters i.e. maximum number of member Peers in a community, maximum number of communities joined by single peer etc. Evaluation results were quite encouraging, and similar pattern was observed by changing the set of parameters. In the beginning of the evaluation following four steps were quite frequent:

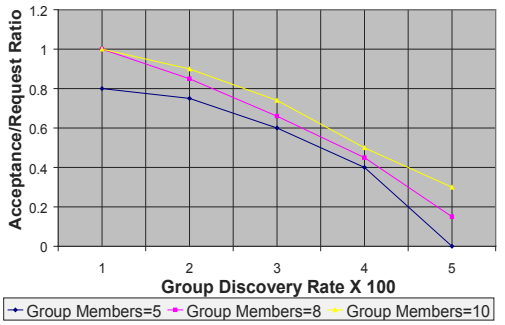
- Selection of communities by peers
- Compatibility checks i.e. rating and description by peers.
- Request for membership by peers
- Membership confirmation from the community.

The preliminary result with different set of constraints is shown below in the tabular and graphical form:

In the table above the left column 'Groups Discovered' compares with the ratio of total membership requests and the accepted requests. It is obvious from the

Table 1. Membership acceptance-request ratio

Groups Discovered	Membership Acceptance/Request Ratio		
	Group Size (50)	Group Size (80)	Group Size (100)
0 - 100	80/100 = 0.8	100/100 = 1.0	100/100 = 1.0
100 - 200	60/80 = 0.75	76/90 = 0.85	90/100 = 0.9
200 – 300	30/50 = 0.6	50/75 = 0.66	63/85 = 0.74
300 - 400	10/25 = 0.4	28/50 = 0.45	28/55 = 0.5
400 - 500	0/5 = 0	3/18 = 0.16	5/21 = 0.23



above table initially peer applies for most of discovered communities but this trend decreases when more communities are discovered. With the passage of time frequency of request for membership decreases and the rate of membership granted by communities decreases because either all member peers have better rating or their expertise matches the interest of community. Once System becomes stable then even peers don't apply for membership or changes group.

The time required by the environment to achieve stable state depends on the constraints set by system i.e. rate of community discovery, number of member peers in a single community and number of communities joined by single peer. We are confidant that organizing resources into different communities will give new dimension to Grid Computing.

6. CONCLUSION AND SUMMARY

In this paper, we have presented the concept of categorizing peers in communities on the basis of their expertise and interests. Social networks are a natural way for people to go about seeking information. Organizing peers in one form or another makes the discovery of resources efficient, whilst minimizing computational overheads. Categorizing the peers in communities is simple, open and easy to implement, and the initial overhead of developing communities pays-off latter at the time of resource discovery. Communities are more stable, and stability increases with the passage of time, communities have a simple learning time and are more adaptive to operate in a dynamic environment. We have proposed the external and internal rating for communities and peers respectively which may be used to support a given Quality of Service, effective participation of autonomous peers and better interaction among communities and member peers. Finally, we discuss the different services required to manage the group and requirements of the member peers. A JXTA implementation of a prototype system is discussed to describe the salient features of our approach. A key theme of this work is to determine how communities should be structured to support resource discovery, and how particular roles within a community can be used to determine interactions between participants within a community, and those between participants across community. This work extends techniques and results discussed in [12].

The Rationale and Recipe for a Web-Based Accounting Subject

Peter Demediuk, Victoria University, PO 14428, MCMC, VIC, Australia 8001; E-mail: Peter.demediuk@vu.edu.au

ABSTRACT

This paper discusses the rationale, content, and teaching and learning activities for a new web-based subject at Victoria University. An expansion of course offerings into an array of countries in the Asia-Pacific region plus budgetary and demand pressures on staffing and physical resources have accelerated the need for cost-effective teaching and learning solutions. In response an Accounting Project subject has been developed by the School of Accounting and Finance that allows students at any location to undertake a valuable, interesting and robust course in financial analysis with minimal face-to-face interaction with a supervisor. The first trial of this Web-based delivery method for student-centred learning has resulted in report outputs by students that are topical, are based on very 'fresh' contemporaneous information, and are of a quality and currency that has led to their acceptance at international conferences.

INTRODUCTION

This paper discusses the rationale, content, and teaching and learning activities for a new web-based subject at Victoria University. The sheer size and growth of the Victoria University combined with Australian Government fiscal cuts have caused a situation where there is significant pressure to cut discretionary spending and consolidate, rationalise course and subject offerings whilst at the same time coping with burgeoning enrolments, domestic and international geographical spread, and demands of students for flexible, value-for-money, and up-to-date study options. In this context, subjects that can be delivered in a cost-effective are being strongly encouraged. The brief for designing the first web-based Accounting Project covered three main areas: the requirement for a cost-effective teaching and learning solution to geographical spread, human, physical and financial resource constraints; the nature of desired student's modes of study; areas of student interest; and professional accreditation and standards.

A web-based subject was seen as a cost-effective teaching and learning solution to geographical spread, human, physical and financial resource constraints. Students doing any discipline of postgraduate Masters degrees offered by the Faculty of Business and Law, and who have elective options, can study the Accounting Project from any geographical location and at times to suit their private and business schedules. The demand for attendance flexibility is not just geographically driven, as students often have work and travel commitments that make attendance at set times in a conventional class-based mode problematic. The Accounting Project is therefore time and cost-effective for many candidates. Travel time and costs, and the need to commit specific times to attendance are entirely eliminated. The web-based nature of the subject allows for all resources to be obtained without additional cost – hence a significant saving on outlays for conventional resources such as textbooks. The web-based nature of the Accounting Project allows the Faculty to offer it for consumption by any eligible student at any global location in any of our four semesters.

The benefits from the University perspective are the ability to offer an up-to-date subject that is very much in demand globally, and at the same time eliminating the cost associated with providing a physical location for the classes, and allowing one lecturer to deal with student-centred learning candidates in a timely and cost effective manner. The lecturer is allowed about half an hour load for each project student. In simple terms, this actually costs more in academic time per student than a conventional class situation, but there are significant overall net savings in obviating the need for overseas travel expenses and the provision of physical infrastructure.

Financial analysis was chosen as the study area for the first iteration of the Web-based Accounting Project. There is exceptionally keen interest in this field from postgraduate students studying accounting and finance Masters degrees, and also those doing generalist MBAs and other programs such as Sports Administration. This is largely because of the huge professional demand for accounting and finance professionals with advanced financial analysis skills, and a recognition that managers in any field need competencies with financial management. For example, a sports administration manager may not actually do the financial analysis from their position, but they need to know when it should be done and be able to commission, critique, understand, interpret and apply the financial analysis that is placed before them. So far we have established that the web-based Accounting Project is advantageous from a resourcing point of view, fits with the delivery and content needs of many students, and by centering it around financial analysis, an important dimension in the professional competencies of managers from any discipline is addressed. To make sure that the course content meets professional standards, the subject content is monitored by an advisory group made up of professionals from GE Finance and CPA entities (Certified Practicing Accountants). Next we look at the content of financial analysis.

FINANCIAL ANALYSIS

Useful financial profiles of an entity's performance can only be made by combining the right technical "number-crunching" competencies with critical skills that question: "what is behind the numbers". In addition the effective analysis of a set of financial statements requires their interpretation to be framed by an understanding of the organisation's context. The mechanical financial calculations must be synthesised with concepts from economics, business strategy, accounting and other business disciplines to make sense of the historical numbers, and to make future financial projections. So financial analysis must be framed in the context of the whole business, and extends beyond "the financial numbers" to perspectives such as the core business, the market, operations, past performance, future innovations, and the quality of employees and management. Only by understanding the interrelationships between such perspectives can one make a meaningful financial analysis.

The subject aims to provide students with technical and analytical skills in financial statement analysis that informs investment, finance, credit, lending and management decision-making. This subject is designed to reward the student both intellectually and practically through performing financial analysis on actual companies. The analysis extends beyond 'the financial numbers', as sound assessment depends on factors other than comparisons of standard financial ratios. As cases such as Enron, Tyco, Sunbeam and Worldcom in the USA, and HIH, Harris-Scarfe and One-Tel in Australia show, only by understanding the what is behind the numbers and how they relate to the organizations context and strategy can one make a meaningful financial analysis.

By the end of the course students should have the capacity to understand; interpret; and critically assess financial statements put out by organizations in light of additional contextual information available. What we needed was a holistic framework that would get students to focus on a myriad of organisational and contextual issues in an organised and integrative way. We now discuss the integrative model through which financial analysis is approached - Price Waterhouse Coopers' Value Reporting Framework.

PRICE WATERHOUSE COOPERS (PWC) VALUE REPORTING FRAMEWORK.

PWC is the largest of the "Big 4" accounting firms. The insights that PWC has gained from an ongoing research program into the performance measures that

really matter to key stakeholders have been codified into the 'Corporate Reporting Framework' which is alternately badged as the 'Value Reporting Framework' (VRF).

The VRF consists of 'performance measures' about key *elements* of an organisation's context and operations that impact on value creation. This information is required by a range of internal and external stakeholders. These elements are grouped logically into one external category and three internal categories of performance information that all industries and companies share in common: Market Overview, Strategy and Structure, Managing for Value, and Performance. By performance measures, PWC advocates a range of information from financial and non-financial numbers to narrative descriptions (stories) to media like photographs.

These performance measures in the VRF are needed by internal and external stakeholders to reduce uncertainty in decision-making (about past & future performance) and demonstrate accountabilities (improve transparency).

Each of the four broad categories encompasses specific elements (Figure 1) that, according to PWC's research, both companies and investors consider critical to assessing performance.

There are a number of features of the VRF which are persuasive for its application to teaching and learning in accounting as the integrative model for subjects. Firstly there is an elegant simplicity and attractive logicality to the model. The VRF works on a logical sequence from left to right. Initially we must examine the external environment that an organization faces. Then we must consider whether the strategy and structure of the organization aligns to these contextual realities. Then there is the issue of whether the drivers required to succeed with the strategy are present and can be managed to achieve the value required. Next, the financial and non-financial performance outcomes must be articulated and evaluated. In this sequence we get logic and a breadth of issues to examine. In all of these considerations, accountants have a potential role and exert influence as practitioners and gatekeepers of financial and non-financial performance and members of multi-disciplinary management and project teams. Also the literature shows the VRF to be the more prevalent form of commercially developed performance management frameworks used in practice at the present time. Finally, the encouragement and support of PWC for the take-up to happen through the comprehensive free resources which it provides as is outlined later in the paper.

The logical sequence of the VRF translates to things students address in their case studies. First we must examine the external environment that an organization faces. Then we must consider whether the strategy and structure of the organization aligns to these contextual realities. Next comes the issue of whether the drivers required to succeed with the strategy are present and can be managed to achieve the value required. Lastly, the financial and non-financial performance outcomes must be articulated and evaluated. In this sequence we get logic and a breadth of issues to examine. Students doing the subject are expected to understand and react to the logic of the model and to cover each of the elements in each of the four sections in framework in their analysis report which compares two companies competing in the same commercial sector. However, students are expected to concentrate on key elements that are of supreme importance to their professional interest and professional development. Hence one student may chose to make a more comprehensive study of contextual external market-related elements whilst covering other elements in lesser detail, and another student might focus more heavily on analysing past financial and economic performance. So using thus framework gives the subject a relevant, robust and commercially recognized analysis model that gives the opportunity to combine breadth of issue coverage with depth of analysis that matches student requirements band the problem at hand.

Next we look at the web-based resources used in the Accounting Project.

WEB-BASED RESOURCES AND REPORT TASKS

The Accounting Project relies entirely on Web-based resources. Firstly students access the subject guide that outlines rationale, tasks, detailed notes and worked examples on calculating and interpreting ratios, subject timelines etc, and many other resources such as articles, subject bulletins, and referencing instructions via the subject's WebCT site at http://webct6.vu.edu.au/webct

Then for students to get an introduction to the ValueReporting Framework, they access PWC at http://www.corporatereporting.com/index.html. This site provides information on the background and structure of the ValueReporting Framework. Students can register access and obtain examples that bring narrative reporting alive by showing over 40 real-life examples of what good reporting actually looks like from companies across the globe. Each example contains detailed commentary from our professionals to provide guidance on improving the transparency of financial and non-financial information. This gives students free access to a resource that in hard copy would cost in excess of $200 US.

Next students access comprehensive examples of good practice reporting which reflects the sections and elements in the elements in the ValueReporting Framework. These relate to a public company listed on stick exchanges (Lintun at http://www.lintun.org/ or www.ebr360.org) and a private company (Re-Use at www.ebr360.org) which has statutory reporting requirements. These cases provide students with practical examples of how the ValueReporting Framework can be operationalised, and a benchmark for comparing their own choices of companies to be studied against good practice. The Re-Use case is also especially valuable in consolidating understanding of ratio and trend analysis obtained by the students from the previously mentioned detailed notes and worked examples on calculating and interpreting ratios that are to be found on the subject's WebCT site.

Next students must decide on their own choice of companies to analyse using the ValueReporting Framework as a structure. The aim is to introduce students to the information contained in the financial reports of companies and to give them the opportunity to use this information in contextual financial analysis via comparative case studies of two international businesses in the same broad industry sector. The specific requirements are that prepare a report in relation to two organizations which operate in the same general industry or commerce groups and present an oral presentation that summarises your findings.

With the Open Source database students can gather in-depth data on more than 100 major industries, including detailed SIC code-level information. They can find companies that match specific criteria--search by size, location or line of business. Students can find public companies via a large selection of variables and get detailed financial information. They can also find key executive contacts and board members by name, location, line of business, job function, biographical details, or company size. It gives access to news, articles, analysts' reports and SEC documents. Students use a basic search interface for quick text searching, whereas more focused searches utilize the Global Business Taxonomy of topics, geographies, and industries, through the precision search interface. By examining the range of information that Open Source provides on most of the world's major companies students obtain two key benefits. Firstly they can see how different analysts select, prioritise, balance and interpret the range of information that connects with each element in the value reporting framework.

Students have additional access to business information via the library's other databases such as Emerald and Ebsco which gives access to leading academic journals, business magazines and newspapers. Students can also access a range of significant information on company performance and prospects via: the Morningstar Financial Analysis and Investing website at www.morningstar.com; business sections of sites such as Yahoo, MSN and Google; and from company websites which contain annual reports, and investor briefings, and other information.

In terms of gaining knowledge and skills in the critical area of sustainability reporting, students access the comprehensive cases and information at the Global Reporting Initiative (GRI) site and the Roberts Environmental Centre.

In preparing their reports, students are asked to send their lecturer (termed 'supervisor') a plan and provide at least monthly feedback on progress. When the report is completed, students submit it electronically for assessment. The report is assessed and graded by the supervisor, and a completion or re-submission report is sent electronically to the student with a maximum 'wing-tip to wing-tip' turnaround time of one week.

To assure originality in content, the paper is submitted through Turnitin (http://www.turnitin.com/static/index.html). Turnitin is recognized worldwide as the standard in online plagiarism prevention, and helps educators and students take full advantage of the internet's educational potential. Every paper submitted is returned in the form of a customized Originality Report. Results are based on exhaustive **searches of billions** of pages from both current and archived instances of the internet, millions of student papers previously submitted to Turnitin, and commercial databases of journal articles and periodicals. Any matches uncovered between submitted papers and source material is detailed in an intuitive and unambiguous format.

CONCLUSIONS AND FUTURE DIRECTIONS

Ideas travel and are translated into different settings (Solli et al 2005), and so advances into the electronic sphere of teaching and learning need to contain the right mix of 'big steps' and 'baby steps', and should match the needs of the client base. With the initiative described in this paper, the first big step was to recognise the utility to students of the pure web-based form and content, and to subject the idea to a rigorous cost-benefit analysis that included and balanced educational, reputational and economic factors. The baby steps are concerned with technology uptake, and debate about how sophisticated the subject delivery should become. Had the commencement of this subject waited until the more sophisticated features of WebCT and associated technologies were mastered by staff and students for purposes like webcasts and real-time discussions, we believe the momentum could have been lost. If the methodology proposed had looked like requiring significant levels of new or shifted resources, the bureaucracy may well have halted the project on budget constraint and risk-aversion grounds. We learn by doing things in an iterative fashion (Demediuk 2006), and this is especially important to remember with e-learning initiatives. The 'buy-in' by staff and the first batch of students doing the web-based project was largely down to the fact that the time and effort to ramp up with the necessary technical skills were modest compared to perceived returns, and the risks of systems and competencies failure appeared remote. More sophisticated technological practices will be implemented slowly over time as baby-steps. Student output from the Project has already been accepted in the refereed international conference sphere. Feedback from students in the Accounting Projects suggests that student-centred learning can be productively and cost-effectively extended to subject areas that examine areas of current commercial practice.

Strategic Alignment as a Key Factor of Success for 4PL Development: A Research Program

Laurence Saglietto, Université de Nice Sophia-Antipolis, France; E-mail: sagliett@idefi.cnrs.fr
François Fulconis, Université d'Avignon et des Pays de Vaucluse, France; E-mail: francois.fulconis@univ-avignon.fr
Gilles Paché, Université Montpellier I, France; E-mail: gpache@univ-montp1.fr

ABSTRACT

One of the most significant upheavals of the logistics industry is the emergence of a new generation of logistics service providers, called fourth party logistics (4PL). Their function is to provide the supply chain members with a customized service, based on a flawless coordination of logistical resources mobilized from the various firms. Considering the importance of IT, the paper suggests a research program on this subject referring to strategic alignment models. Its aim is to know whether the 4PL are able to combine their business strategy, IT deployment and organizational performance efficiently so as to manage interfaces between the supply chain members in the best conditions.

1. INTRODUCTION

The logistics industry has been undergoing profound changes for about ten years under the pressure of new entrants. Thus, the most dynamic logistics service providers (LSP) are changing their organization and strategy to become dematerialized operators. They are developing a customized service for their customers by mobilizing resources and resorting to different partners and by making sure of its consistency thanks to a total control of information flows. The consultancy company Accenture called these LSP without physical assets the "fourth party logistics" (4PL). Their trade is to design and sell global supply chain solutions by coordinating the activities of carriers, storage operators, subcontractors, packaging companies, etc. The objective of this paper is to propose a research program on the evolution of 4PL to know whether they are able to combine their business strategy, technological deployment and organizational performance efficiently in order to carry through their role of coordinator. The question is important in a context of confrontation between the supply chains in which coordinating the logistical operations perfectly has become a prerequisite for developing a competitive advantage.

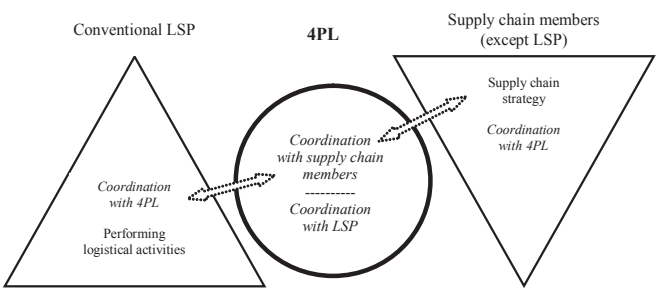
2. LOGISTICS INDUSTRY: THE RISE OF 4PL

Understanding where the logistics industry is headed requires a two level analysis. On the one hand, it is necessary to assess the role of outsourcing in the logistical process optimization (*supply side*) and, on the other hand, to study the evolution of LSP's activities (*demand side*). As time goes by, the number of manufacturing and retailing firms which no longer want to manage their logistics by themselves has kept on increasing in Europe and the United States. The reasons for this are widely known: restructuring the global supply chains to improve operations coordination; facing the fluctuations in the volumes and destinations of products to be dispatched; reducing costs and increasing service quality in terms of flexibility, deadlines and product customization, and adapting themselves to market globalization. LSP's supply has followed and in certain cases anticipated this new demand in three complementary ways: [1] a reorganization by sectors and customers at the European level; [2] the development of relationships with consultancy companies specialized in using management tools; [3] the development of innovative procedures ensuring a perfect traceability of flows in collaboration with customers.

What are the special features of 4PL compared with those of the transport companies and conventional LSP, which are themselves also involved in this radically changing logistics industry? The 4PL share an ability to carry out the activities of planning and coordination of information flows, designing both the logistical structure and the inter-organizational IS applied to the integrated processes along the global supply chains. By appropriating the new technological tools and combining them with conventional means, 4PL give a more informational orientation to their work. They aim at basing the string of logistical decisions on an electronic management of transactions, implementing interfaces to connect the management systems of the various members of the supply chains. As the services provided by 4PL are highly customized, they increase the interdependence between the partners thanks to common informational and organizational standards. So the 4PL are involved in a governance based both on the management of knowledge and on a "specialization of architectural competencies" which gives them a nodal position in supply chains and, to a larger extent, in the value creation process. In this aim, they position themselves at the interconnection between the supply chain members (except LSP) and the logistics operators, managing thereby their interfaces (Fig. 1).

In order to analyze and explain the key factors of success of 4PL, one refers traditionally to the current strategies of logistics outsourcing, which leads to more and more "dematerialized" supply chains. However, this approach is insufficient as it is only focused on the demand in logistical services. And it is also necessary to wonder about the way 4PL acquire the coordination and monitoring competencies step by step to facilitate the process which adjusts the conventional supply of LSP to meet this specific demand. Thus, if a few academic works are devoted to 4PL's performance, they do not sufficiently take into account all the determining factors of its evolution as a *transactional center* acting at the meeting point of a multiplicity of supply chains. The co-alignment models seem to be pertinent to highlight the part played by 4PL.

Figure 1. The management of interfaces by 4PL



Source: Adapted from Van Hoek [7].

3. MODELS OF STRATEGIC ALIGNMENT

There is a strong interaction between the structure of 4PL and their technological environment. Indeed, 4PL are nowadays the catalyst for the organizational change within the supply chains. Here, the concept of *fit*, i.e. the alignment of many contingent elements which affect the firm and inter-firm performance, comes into play. The strategic alignment (or co-alignment) models developed for the past twenty years are based on the essential idea that organizational performance is due to the co-alignment of several factors: strategy, technology, structure, etc. These issues interest a growing number of researchers in IS management, strategic management and SCM. Their conclusion is that companies cannot be competitive in the long run without aligning their generic strategy (including logistics) and their IT [2,4]. Some models also include people (culture, leadership) and processes (supply chain workflow) [4].

From a supply chain perspective, the strategic alignment is the result of two elements: on the one hand, a specific type of "business climate" (cooperation vs. arm's-length competition) and of organizational structure; and on the other hand, the use of IS at a specific level in a given social and cultural context. Thus, the use of IS results not only from the need for operational efficiency in the commercial, industrial and logistical transactions of the supply chain members, but also from the search for synergies: risk-sharing and strategic gains. The academic literature gives several theoretical models of strategic alignment. It will be interesting to apply the seminal models of Venkatraman [9] and Henderson & Venkatraman [3] to the particular case of 4PL development. Other research followed but did not try very hard to assess them empirically and to make them operational except for Bergeron *et al.* [1]. Indeed, we can think that 4PL are the actors of a strategic alignment since the more the synergies and coordination are developed within a supply chain, the higher its performance level is likely to be. As the role of a 4PL is to build up, dismantle and rebuild supply chains, making logistical resources coincide with the needs of the supply chain members becomes a key point.

One should wonder about the relevance of applying co-alignment models to the particular case of 4PL. What are the benefits of studying simultaneously the links between business strategy, technological deployment and organizational performance? Does the impact of IT on 4PL result in a true revolution in flow monitoring, or is it merely a natural evolution of the logistics industry? To answer these questions, this paper intends to present a research program on the strategic evolution of 4PL in Europe, influenced by a significant development of the supply in value-added services (Fig. 2). In the wake of works integrating the network organization models to understand logistics industry trends, we intend to apply the dimensions of the strategic alignment of business and IT to assess the chances of success of the 4PL as a coordinator of supply chains. Following the example of Bergeron *et al.* [1], the objective is to adopt a holistic approach to examine the impact of the fit among alignment domains on the firm performance.

4. RESEARCH PROGRAM

The legitimacy of the research program suggested is reinforced by the publication of two recent studies. The first study is European. Carried out by TN Sofres Consulting for the European Commission, it studies the impact of IT on retail firm logistics. It deals with the current situation, transformation factors, changes in process and stakes. But after having emphasized the difficulties encountered in measuring the performance of logistical structures in general, nothing is said about the importance of the co-alignment of the supply chain members which support all the flows. The second study is American. It tries to answer the following issues: "Do supply chain IT alignment and supply chain inter-firm system integration impact upon brand equity and firm performance?" [5]. The study is based on an analysis of the managers listed by the Council of Supply Chain Management Professionnals, but it remains incomplete as the authors have ruled out the consultants, freight forwarders, conventional LSP and 4PL. Which amounts to ignoring the fact that 4PL are one of the most advanced forms of virtual organization logistics.

One of the possible leads to assess 4PL's competitiveness consists in using the co-alignment process as a logistical monitoring tool. In this respect, the analysis of academic literature reveals unexplored fields regarding the 4PL's monitoring mechanisms and processes, but also and above all regarding the structuring role of IT, i.e. with regard to the configuration of exchanges within the supply chain. So, having a co-alignment measure turns out to be essential to understanding the 4PL's functioning as well as their performance levers and strategic and technological orientations. Compared with the classic approaches of performance measurement, co-alignment integrates a certain number of contextual, environmental and institutional variables. Thanks to adapted models, we can expect an answer to the following questions, which structure the research program in four complementary directions [3, 9]:

1. *Strategy execution.* What business strategy is chosen by 4PL top management to develop a sustainable competitive advantage? Is it based on a cost leadership or a differentiation strategy?
2. *Technology potential.* What kind of IS infrastructures is used, and on what IT tools are they based? How are the flow monitoring tasks carried out between the supply chain members at an operational level?
3. *Competitive potential.* Does the exploitation of emerging IT capabilities lead 4PL to develop distinctive competencies? If so, are these competencies recognized by the supply chain members? What kinds of supply chain governance result?
4. *Service level.* Does the use of IT resources enable 4PL to increase its level of responsiveness faced with fast changing supply chains? What are the procedures used to combine (and re-combine) logistical resources without being detrimental to the service level?

In a way, the research program is a logical result of the research being carried out currently on 4PL [6]. Its objective would be to describe in detail some cases of 4PL development in order to recommend actions able to improve their service supply. With this aim in view, it is necessary to resort to a conceptual framework referring to both IS management and SCM. Our ambition is thus to make progress in the formulation of a general model of the logistics virtual firm, which emergence seems to be a profound brake in the 1980s and 1990s' supply chain dynamics. This is part of a more comprehensive and older project to better understand the foundations of logistics management based on an in-depth study of the organizational and technical means implemented in a given context.

Blending Technology with Inquiry-Based Pedagogy: Implications for Learning and Teaching in Online Environments Designed for Graduate Level Teacher-Education Courses

Carol Kahan Kennedy, Fordham University, USA; E-mail: Carolkennedy5@aol.com
Maureen Hinkley, Fairfield University, USA; E-mail: mhinkley@mail.fairfield.edu

ABSTRACT: PURPOSE OF THE STUDY

This study is intended to further inform the construct for teacher-learners' transfer of technology first to their teaching dogma, secondly for their pedagogical praxis and ultimately for the paradigm of teaching and the students' learning environment. Although much has been written and reforms mandated about the professional development of teachers and the need for technology rich instruction more discrete information is needed about the teacher's learning being situated in technology learning environments. What evidence does the situated praxis of online discussions in the teaching of teachers offer to further the research of meaningful technology transfer into their classrooms?

Keywords: distance education, teacher education, online teaching, Web-based instruction, blended classes, inquiry-based pedagogy

INTRODUCTION TO THE STUDY

We are examining data accumulated from blended course online discussions with in-service and pre-service teachers. The data accumulated from these blended course online discussions includes topics of threads, content of responses, identification of originator (instructor versus teacher-learner) of threads, and occurrences of collaboration in forming meaning. Our in-depth evaluation of the online interactions and subject of discussions will contribute to creating a potential model for teachers as participant practitioners in online learning in order to demonstrate the transfer of technology into their pedagogy.

LITERATURE REVIEW

Angers and Machtmes' (2005) qualitative study identifies the "adoption and use of technology in the classroom is determined by teachers' attitudes and beliefs." (Angers, 2005, p. 780). Their findings regarding that "Teachers beliefs about classroom practice appear to shape their goals for technology, " (Angers, 2005, p. 789). In our study we look at how these intrinsic beliefs can be expressed, changed over time and influenced by participating in online classes, thereby guiding the students to become expert-practitioners. How can the instructor design the learning experience to get these results? We are also adding to the body of literature by studying the mechanism for the eventual transfer of technology learning to the classroom.

Stephenson's (2002) work is a collection of articles by many authors on how to transit from theory to practice, create effective online learning environments using theoretical frameworks and evidence-based research and pedagogy to help learners to make the optimum use of online learning. The articles all lead to the transformation from instructor-managed to learner-managed pedagogy for best online learning. Several features that are most relevant to both instructors and learners include the following: access to resources, heuristics, attention to different learning styles and needs, access to experts, both online and offline, tracking and recording of dialogue, transactions among students, teachers, student-student, a variety of types of engagement, including synchronous and asynchronous, feedback, good design of the web environment, easy links to multimedia, universal design, opportunities for telementoring and interaction with experts both within and outside of the institution, an the opportunity to work in collaboration with peers and groups online and globally. These features should be flexible and learner-controlled. Learners should be able to utilize all of these features online and go to other resources. Importantly, students must perceive the difference in the online environment as offering more than a lecture delivered online, be encouraged to use the interactivity, and to take responsibility for his/her own learning and participation in order for this transformation to occur. These are the goals of our online course development, to encourage transfer from the blended component of the class to the teacher-learner's own pedagogy and practice.

While Kozleski (2004) emphasizes the economic contribution of technology as being imbedded in education, she identifies changes to teachers' dogma and pedagogy as critical for the transference of technology in education. Our efforts to identify discrete teacher learning underscore, "rather than harnessing the curriculum, understanding education as a technology transfer activity opens the dialogue about how and what to teach." (Kozleski, 2004, p.191).

Borko (2004) identifies elements of a situated analysis of teacher learning as a learning program, with teachers as the learners, the instructors as the guides for the teachers as they construct new learning along with the context in which the teachers learning occurs. While many researchers have studied some combination of these relationships and the factors that influence them our study will further our understanding of what and when meaning is being situated in the teachers understanding of the new role technology will now play in their teaching for their classrooms.

CONCEPTUAL FRAMEWORK

The impetus for this study came as a response to the meta-analysis done by Mary Tallent-Runnels, Julie A. Thomspons, William Y. Lan and Sandi Cooper (2006).

Their research suggests that courses taught totally online are called "online courses" and those taught partially online be labeled "blended courses." As part of their findings and recommendations for future research, the authors suggest that there are few existing studies focusing on pedagogy and learning online, which type of format fits which particular class and instruction, what the online roles of instructors and students play, and how the depth of online interactions that occur can lead to and encourage higher-order, critical thinking and constructivist learning.

To achieve higher order thinking, Wakefield (1996) suggests three pedagogical approaches; 1.) Stand-alone instruction in thinking independently, 2.) Dual agenda

combining the first approach with some subject discipline content 3.) Authentic task approach, students are required to apply higher order thinking skills in performing some task. Our research pulls from this later approach suggesting that scaffolding discourse online is an authentic pedagogical approach to promoting higher order thinking outcomes for student learning.

Kotik and Redman (2005) examine the "Extent of Technology Integration In Instruction By Adult Basic Education Teachers," researching how much adult basic education teachers integrate technology into their curriculum and have learned how to use technology themselves, recommending the four methods cited by Ginsburg, (1998). These methods include considering technology as specific curriculum learning digital literacy skills, technology as an instructional delivery system, as another component to instruction for learning skills, and as a tool to enhance heuristic skills, write, and comprehend. The authors cite the process of learning to integrate technology from learning to adapt to using technology to construct new learning environments. There are several discreet barriers for adult learners such as teachers: how to integrate technology, including the lack of opportunity to learn from their peers, ask and answer teaching-related questions, and actual practice in online discourse. Teacher-learners do not generally get to use technology on a higher level, and lack the opportunity to make innovative integrative use of it in their practices. According to this study, not much progress has been made since a 1995 Office of Technology Assessment report.

This study is relevant as the online component of blended courses offers greater opportunity for teacher-learners to participate in discourse, learn from the instructor and their peers, and gain knowledge along with insights on how to better integrate technology into their curriculum, thereby overcoming these barriers.

As opposed to how teachers are facing impediments to technology integration, Ertmer, Ottenbreit-Leftwich and York (2006-2007) have examined "Exemplary Technology-Using Teachers: Perceptions of Factors Influencing Success". This study looks at teachers who actually use technology meaningfully in their classrooms despite internal and external challenges, including lack of time, resources, technophobia, access and institutional support. While other articles cite the barriers that lead to full implementation of technology, this study looks at the most important indicators that help teachers overcome these known obstacles. Interestingly, one of the findings suggests that digital immigrants, those teachers with more than five years of teaching experience, but less technology savvy and confidence, are actually more likely to direct their students to use technology in a more effective, meaningful way to enhance learning than their less-experienced, digital native colleagues who have more technology experience and confidence, but lack the expertise and management skills of more seasoned educators.

The more experienced teachers appreciated the value of the use of technology more than the more novice teachers who felt more at ease using the technology, but used it less effectively. This supports the data-analysis of the Introduction to Technology MD 400 course section with fewer digital natives, but more experienced teachers who are digital immigrants and a larger number of transactional postings.

The study also examined what intrinsic and extrinsic factors affected the use of technology to find which characteristics were more determinant. The results of the study indicated that the teachers who used technology in the most exemplary way felt that the factors such as confidence and experience (intrinsic) rather than extrinsic factors such as availability, quality of resources and their own time were most influential in their effectiveness.

For our purposes, giving teacher-students experience online will increase their confidence and expose them to collaborative learning from their peers and instructors. As engagement deepens, the teacher-learners become more effective in the planning of curricula using technology for their own students. These are all intrinsic factors which will influence their success regardless of their access to resources, time availability and other extrinsic factors which they cannot control.

Examination of the data includes three primary areas:

I. Sample Population- characteristics and description
The sample population is comprised of adult students who are participating in a Graduate Teacher Education Program at a Jesuit university. Some are majoring in educational technology, while others are taking their required educational technology course and electives. The teacher-learners range in age from recent graduates of a Bachelor's program, to older, returning students who are making career changes or enhancements. The majority of the students are either pre-service or in-service teachers pursuing a Master's Degree.
Combined population demographics include a total of 188 students (some of which are ESL, 14 blended classes, conducted from Fall 2002 through Summer 2006. Both authors have been teaching on-site, online and blended courses in educational technology for graduate-level teacher education from 2001 through 2006.

II. The Role of the Instructor
Along with the designing of the course, we examine the instructor's pedagogical praxis and paradigm choices. As an example, both instructors have made use of inquiry-based teaching methods in class and online.

III. Online Discussions
The online postings will be examined in terms of topics, and content. We will pay particular attention to teacher-learners' references to prior experiences and knowledge in connection to their new learning within the content and topics of the online discussions.

Do particular categories of discussion topics provoke teacher-learning level of engagement with technology learning?

INITIAL FINDINGS

Identification of characteristics for online pedagogical practices:

Pedagogical implication of online postings allows for more in-depth assessment of learners' levels of engagement with material as well as analysis of learners' construction and integration of meaning for learning.

Initial analysis of the data suggests the Instructor/Teacher-Mentor's pedagogical approach to the online setting shows movement from leading to some combination of modeling online behavior and heuristics for teacher-learners.

THE RISE OF E-LEARNING TECHNOLOGIES AND CHANGES IN STUDENT LEARNING

Electronic learning (e-learning) is an approach to facilitate and enhance learning through information and communications technology. For the purpose of this project, the authors have adopted the Mills, Eyre and Harvey (2005, p.45) definition of e-learning, "effective learning processes created by combining digitally delivered content with (learning) support and services". The equipment and software (such as computer software and hardware) that are used in this endeavour are collectively referred to as e-learning technology. It is anticipated that by adopting and practicing e-learning technologies, a University would be able to address the knowledge thirst of higher percentage of learners, those who require flexible working hours due to their professional or personal commitments.

Our current students perceive information and learn in different ways compared with the past. There have been emerging debates about generation Y (also known as Millennials, Buckingham, 2006; Eisner, 2005) and the fundamental nature of thinking that is applied by people who are raised in an environment filled with digital media. The digital natives, as Prensky (2001) refers to them, seem to challenge teachers (referred to as digital immigrants) to address new learning needs. Such learners now need connection more than they need content. By this we mean that knowledge about how to conduct information search, how to manipulate metadata, how to connect from one digital device to another, becomes the majority of information that is needed to become proficient in a specialised field. In any given discipline, the answers to questions can be found in the sea of information by knowing how to search for it (for example Google the word or phrase). This usurps the need for memory of content that was required before the era of interconnected information. What is important to digital natives is not retention of memory of content, instead understanding of how to locate content quickly.

SCUP (2004) observes in United States generation Y students that nearly every one of them has a cell phone and access to instant messaging/text messaging wherever they are, and social networking software is increasingly becoming part of the online experience [see also Miller, 2006]. The implication is that learning should occur through dominant media. As digital devices transform to become e-learning technologies, there is a ready generation of learners eager to have their experience through such devices. Accordingly, to retain their current and attract future students, a number of Australian universities are allocating millions of dollars for upgrading and installing new technologies to support e-learning initiatives (Alexander, 2001) or else they prospect losing their global competitive market.

CHANGES IN TEACHING AND LEARNING

We have applied the 'full circle' metaphor intentionally in our study to remind ourselves of the cyclical nature of information flow and the evolutionary nature of understanding in any given teacher-learner relationship. Over the centuries educations institutions have moved from an oral culture to a written one nonetheless even in this digital age the importance of coherent words has only gained more importance to communicate well.

Kolb (2000) has suggested that digital media (e-learning technologies) have destructive elements that must be consciously harnessed and controlled if they are to be turned into educational value. This appears to suggest that good management education can occur online, despite the risk that the online experience could manifest inferior to traditional classroom opportunities to interact face-to-face. As a result, educators often need to intervene in online education to be sure critical thinking emerges as an accurate response. Our experiences online tend to support this fact. People can react quite emotionally to subtle variance in application of language. Post a discussion thread message with a word that can be interpreted ambiguously, and the flame begins. Alternately, to leave an online classroom unattended for very long ensures students will feel ignored and the associated social ructions can manifest in that environment.

THIS PROJECT

The newest generation of learners in Australia and beyond have been raised on a diet of new media technologies leaving some observers wondering if the very processes of learning are being altered by this digital ground shift. The aim of the research is to gather information regarding the usage of e-learning technologies used by staff and students at Deakin University. Identifying the 'maturity' of various e-learning technologies being used within the "educational delivery [and] understanding learner needs and preferences towards e-learning" has also been highlighted as an area for future research by Pittard (2004, p.186). Most of the student respondents will belong to generation Y and may be categorised as digital natives.

The objectives of this research project are to:

- Identify best practice methods of online teaching models using e-learning technologies
- Identify challenges accompanied with improving teaching and learning via e-learning technologies, and
- Recommend guidelines and a model for improving teaching and learning via e-learning technologies.

Universities around the world are incorporating e-learning technologies within their curriculum. Deakin University is part of this change and is one of the Australia's leading distance education and online teaching universities. Deakin's commitment to online teaching and learning can be reiterated by the recent directive from its Vice Chancellor that all students need to complete a fully online unit to graduate. Universities, students and academics as stakeholders all benefit from this initiative and collaboration. A university can sell the flexibility of its online courses to gain a larger market share by targeting both full time and mature age students. It can also be argued that by forcing students to complete one fully online unit, in addition to addressing one of its graduate attributes, the university is also teaching its students computer/IT skills. People from generations X have realised that learning and using IT has become a prerequisite for their survival and advancement both in their professional and personal lives.

When academics use technological tools as part of their teaching, the students regardless of their generation benefit from getting more efficient, prompt and timely feedback on their assessment tasks. IT also allows both academics and students to communicate with each other in a virtual environment hence addressing one of the major concerns of off-campus or distance students, losing information and contact with their academics and peers due to their respective mode of enrolment. Online technology nevertheless may act as a double-edged sword for academics. On one hand, academics like their mature age students are forced (or in some instances motivated) to learn about how technology can be used to enhance teaching mediums and bridge the gap between them and their current students. On the other hand, many academics complain about the entire activity being time consuming and a steep learning curve without much assistance from the university.

The emerging landscape of e-learning technologies has the potential to fragment online delivery options. Wireless applications are testing the traditional definition of online, however, the functional aspects are synonymous in the sense that internetworked digital learning objects are the content delivered through this media. At the heart of any operational change will be the need to stay focused on good quality teaching practices. The question accordingly is, 'What constitutes good education in the online and e-learning context and how can a university such as Deakin maintain or improve its standards and competitive advantage?

This project will focus on the current e-learning teaching practices used by Deakin University academics in order to identify a best practice framework. It will also recognize the challenges experienced by academics using these e-learning technologies and when attempting to improve the quality of teaching. The project will also look at the benefits and challenges of using e-learning technologies as experienced by Deakin's students. Findings of the research will result in a set of guidelines and a model for improving quality of delivery via e-learning tools.

RESEARCH METHODOLOGY

To obtain a 'full circle' perspective on e-learning applications, we decided to research the views of both academics and students. We are in the process of finalising questions for staff questionnaire and students focus group procedure in order to capture the data snapshot.

Staff Questionnaire Survey

Questionnaire survey will be administered to Faculty of Business & Law, Deakin University academics to obtain feedback on a number of key variables in relation to e-learning technologies. Questionnaire surveys have been described by Ferber et al (1980, as cited in May 1993, p.65) as "a method of gathering information from a number of individuals, a 'sample', in order to learn something about the larger population from which the sample is drawn". Questionnaire surveys, as a deductive methodology with time, have gained an edge over other research techniques such as door-to-door surveys or telephone interviews (Spencer, 1982). One of the reasons behind their wide spread use is that the results obtained can be exhaustively analysed by the use of sophisticated computer software packages. Moreover, the assurances of anonymity and confidentiality (Jobber & O'Reilly, 1996; Jobber & Sanderson, 1983; and Jobber, 1986) increases the rate of getting true responses from the respondents that are not achieved for instance by telephone surveys (Peil et al, 1982).

Muller & Miller (1996); and Jobber et al (1985) have provided examples of the benefits of usage of questionnaire over phone surveys. Nonetheless, before undertaking this methodology, a researcher needs to be also aware of its weaknesses (see Jobber, 1989; Herberleain & Baumgartner, 1978; Lewis, 1997; and Inguanzo, 1997).

Student Focus Groups

As no previous research had been undertaken in this specific area, focus groups were chosen as a methodology for students as an exploratory technique was required. Researchers are increasingly using focus groups to "identify issues and attitudes [and to] see how various people from the group respond to other's position" (Bouma, 2004, p.182). As opposed to directing one-on-one questions as in case of interviews, during a focus group the facilitator asks an open question to the group and observes the group responses and dynamics. The facilitator nonetheless needs to be careful to not intervene and bias the group discussion from previous knowledge, experience or background. Keeping in view focus group advantages (Ghauri & Gronhaug, 2005; Veal, 2006; and Morgan, 1997) and drawbacks (Ghauri & Gronhaug, 2005; and Morgan, 1997) focus groups can be used to raise and pilot new ideas.

NEXT STEP …

In views of the authors, e-learning technologies are both consolidating and proliferating the universities and academics environment. IT is allowing people from diverse backgrounds and age groups to come together and learn new skills and secure more degrees. Simultaneously, e-learning technologies are proliferating as both technologies and learning methods are constantly changing.

Our project will take a foundational view of education, as identified by researchers such as Dewey (1963) and Alexander (2001), in context with e-learning technologies and the concept of the digital native. Is knowledge of connection between media the kind of knowledge Dewey (1963) may have anticipated? Could it be that learners now have some kind of advantage over many of their teachers, simply by knowing more about how digital devices connect and sift metadata in a sea of information? Or does the teacher still retain the upper hand? Perhaps the role of experience simply cannot be replaced by connection? What use is connection to information if one does not have the experience or wisdom to know what to do with it? Knowledge of connection may just be another way of conceptualising rote memory. Biggs (2003, p.214) raises this very warning, suggesting that transmission of information does not in itself constitute learning. We will reflect upon these burning questions as the project evolves.

As the next step, the authors would like to explore the industry/practitioners views to fully close the 'circle' and identify whether the e-learning practices are of any use for them. The researchers would also like to replicate their study in other countries and universities.

ABSTRACT

Business majors are required to complete a course using Microsoft Office. The course is offered both online and in a traditional hands-on classroom setting. Students who enroll in the traditional setting have a completion rate of 97% while the online students have a completion rate of only 75%. All students complete the same assignments and take the same exams. Extensive online help is available for all students. Demonstrations of all in-class activities are captured in Microsoft Captivate and are available at any time. Demonstrations are created in two formats: with sound and without. The demonstrations with sound have the instructor showing the specific skill while talking through the skill. The demonstrations without sound have the same skill but have word balloons explaining the step. The two types of demonstrations are available to meet different learning styles and different computer hardware setups. The online students were surveyed to gather data on locus-of-control, self-efficacy, use of available course tools and demographic information. Preliminary results show a strong correlation between grade earned in a required prerequisite class and completion of this software class. A secondary predictor of success was self-efficacy.

INTRODUCTION

A required course for all business majors is a Microsoft Office software course focusing on business applications of Access and Excel. Six sections are offered each semester; four in a traditional on-campus setting with a computer for each student and two in an online format. All students complete the same assignments and take the same exams. Extensive online help is available for all students. Demonstrations of all in-class activities are captured in Microsoft Captivate and are available at any time. Demonstrations are created in two formats: with sound and without. The demonstrations with sound have the instructor showing the specific skill while talking through the skill. The demonstrations without sound have the same skill but have word balloons explaining the steps. The two types of demonstrations are available to meet different learning styles and different computer hardware setups.

While the online students have all the same material and instruction available to them via the online demonstrations as the traditional students have through in class instruction, the online students have a consistent withdraw rate of 25% and the traditional students have a withdrawal rate of 2% to 3% according to course data over the last six semesters. A study of undergraduate courses at the University of Georgia system found that 30% of the online students dropped by the end of the semester (Morris, 2005).

Historically students who complete the online version of this skill-based course have an overall average grade of more than 85% which is usually similar to the students in the traditional classes. However, during the fall 2006 semester, the final grade average was 68% for the online sections and 80% for the traditional on-campus sections. The students who withdraw from the online course frequently retake the course the next semester in a traditional setting, causing the students to pay for the course twice.

Students are not required to complete an assessment before enrolling in an online course to help determine if they are well-suited for online learning. Students are also not required to speak to the instructor before enrolling in an online course. The university does not survey students who withdraw from online courses to find out why they have withdrawn from the course.

A required pre-requisite (BE&O) to the course is a basic computer literacy course in which students are required to pass exams using Microsoft Word, Excel and PowerPoint as well as take exams over traditional computer literacy topics such as parts of a computer and computer networks.

PRIOR RESEARCH

Locus of control and self-efficacy are well established measures in predicting educational success as these examples of prior research demonstrate. Gifford, Bricefho-Perriott and Mianzo (2006) found that students with strong internal locus-of-control are have a higher GPA than students with strong external locus-of-control. Sisney, Strickler, Tyler, Wilhoit, Duke and Nowicki (2000) determined that locus-of-control and self-esteem were high predictors of success in college courses. Onwuegbuzie and Dailey (1998) found that locus-of-control was the best predictor of successful study skills. Elias and Loomis (2002) found that self-efficacy and need for cognition were both significant predictors of GPA for undergraduate students. Pajares (1996) found that self-efficacy was a predictor of math problem solving ability in middle school students, using a path analysis.

COURSE DESIGN

The course is required for business majors and focuses primarily on Microsoft Access and Excel used in business applications. Most assignments are drawn from the textbooks, however for most students; the textbook does not give enough information to successfully learn the required skills. To compensate for the lack of in-class practice and demonstrations, online demonstrations have been created for most skills in the course. Everything that is done in the traditional classroom has been transferred to online demos. The demos, created in Adobe Captivate, are short demonstrations of specific skills. Homework assignments are broken down into steps with each step having its own demonstration. Demonstrations are available with sound and without sound. In the sound versions, the primary instructor of the course verbally describes each step of the skills. In the non-sound version, the descriptions are in word balloons. Students are able to use the different versions based on their learning style as well as their ability to use sound. For example, no sound is available in the campus computer labs unless the students bring their own headphones.

Students also have samples of the finished homework available to them. They can see the finished Excel spreadsheet or Access query to allow them to match their results with the correct answers. Between the demonstrations that take the students through the skills step-by-step and the graphic of the finished results, the students are given as much help as possible to encourage successful completion of each assignment.

Assignments are due on the same day and time of each week. The instructor sends the students a weekly email letting them know what skills they should be working on that week, what online demos are best suited to help learn the skills, what assignment is due next and when the next exam will be. For several semesters, the instructor offered online office hours from 9-11 pm on Tuesday nights using Macromedia Breeze. In the last several semesters, only one or two

students took advantage of the online office hours and thus, the option was not offered the Fall 2006 semester.

Nearly all of the online students are on campus at least three days a week for other classes and can attend regular office hours. Email is used extensively to answer student questions and often students attach the file they are working on to allow the instructor to see exactly where the problem area is. The instructor then replies in email how to do the skill or formula correctly and the student is able to successfully complete the homework. All homework is submitted through Blackboard. To allow immediate feedback, quizzes have been created over each of the homework assignments. Students are expected to have completed the assignment before taking the quiz and can take the quiz two times with the higher score being recorded. The instructor checks the submitted files for a pattern of problems and addresses widespread problems in an email to all students. Individual students receive emails to address particular problems observed in the submitted files.

Discussion boards are not used in the course. In the past, threaded discussions were attempted hoping students would discuss with each other problems and solutions they had found. However students did not use the tool and it has been discontinued.

PURPOSE OF THE STUDY

Because so many online students drop the course and retake it in a traditional on-campus course, a study was started to determine if factors exist to predict if students will be successful in the online version of this skill-based course. Because the university does not require any self-assessment before enrolling in online courses, there is no institutional data as to who is successful in online courses. And because most online courses are in upper level courses, no institutional attention has been given to online course retention at the freshman level.

Our first hypothesis is that students who did not take advantage of the online demonstrations do not do as well in the course. Our second hypothesis is that students with a high level of self-efficacy will have a better outcome in the course than those who do not. Our third hypothesis is that those with a strong internal locus-of-control, compared to those with a strong external locus-of-control, will do better in the course.

METHOD

Procedure

Students in the Fall 2006 online version of the course were surveyed. The survey included four main sections: self-efficacy (an adapted version of Bandura's (1977) concept), multidimensional locus-of-control (an adapted version of Rotter's (1966) original construct and of Wallston's (1978) adaptation for multidimensionality), course tool use and demographic data. The survey was approved by the university human subjects committee and was administered using the university's online survey tool. Students were given fifteen points to encourage participation. Students could skip any question on the survey. Because of the lateness of starting the study and time required to obtain human subjects approval, the survey was not administered until after the last day to drop classes. Students who had already dropped the class were emailed and encouraged to take the survey, however only one such student completed the survey.

Participants

Twenty-one of the 45 undergraduate students originally enrolled in the course completed the survey with an average age of 25.9 (SD=8.7) and consisted of a primarily white/Caucasian sample (88%).

Analysis Plan

We will run an exploratory multiple linear regressions predicting final grade in the online course that includes all variables in the dataset using the forward method. We will also run a multiple linear regression for the variables that objectify the web demonstrations with voice forced into the model. Variables that are in the final model, those that are significant, will be considered for future analyses.

RESULTS

We conducted an exploratory multiple linear regression predicting final grade in the online course that included all variables in the dataset using the forward method and the final model was significant $F(3,17) = 24.30$, $p < .001$. Individual predictors that were significant were BE&O grade ($\beta = -.529$, $p < .001$), self-efficacy ($\beta = .389$, $p = .003$), and number of assignments completed ($\beta = .364$, $p = .004$).

We conducted a second multiple linear regression predicting final grade that included BE&O grade, web demonstrations, and number of assignments completed and the model was significant $F(3,18) = 8.66$, $p = .001$. Individual predictors that were significant were BE&O grade ($\beta = -.580$, $p = .002$) and web demonstrations ($\beta = .316$, $p = .054$).

DISCUSSION

Success in the prerequisite course was the highest predictor of success, followed by self-efficacy, and number of assignments completed. Because the course is a computer skills and literacy course, possibly the prerequisite course grade is a better predictor of success than overall GPA. Possibly this applies even more in this course because the prerequisite course required the students to use Blackboard and portions of Microsoft Office. In addition, those that were confident in their abilities (self-efficacy) to do several tasks that were required for the course did better in the course. Dupin-Bryant (2004) found that students who have adequate computer training in relevant computer technologies are more likely to complete the online course because the technology will not impede the process. The level of activity in the course by the individual also seemed to play a significant role, which can be inferred from the number of assignments completed and the number of times a web demonstrations was used (which was found significant when using the enter method and self-efficacy was removed).

Our primary hypothesis that students who did not use the online demonstrations would do worse in the course was confirmed, with exceptions. Our secondary hypothesis that self-efficacy would predict course outcome was confirmed. Our tertiary hypothesis that different levels of locus of control would predict course outcome was not confirmed.

IMPLICATIONS AND LIMITATIONS FOR FURTHER STUDY

Because this study was started late in the semester, most of the students who dropped the course did not complete the survey and most who stayed in the course but failed it also did not complete the survey. In future semesters, the survey will be offered early in the semester when most students are still participating in the course. A possible result of the study could be that only students with a specific grade in the prerequisite class are eligible for enrolling in the online section. Another outcome could be that the university would require an assessment before students are allowed to enroll in online courses, especially the students at freshman and sophomore level courses. A limitation of the study is reaching students who have dropped the course because they have no incentive to complete the survey. The still-enrolled students are given points for completing the survey. In the future, the survey must be done early enough for more students to want to complete the survey to obtain the extra points given for completion.

Identity Management for Educational Portals

Tom S. Chan, Southern New Hampshire University, USA; E-mail: t.chan@snhu.edu, tomschan@verizon.net

INTRODUCTION

Identity management (IDM) is a broad administrative task that includes identifying users in a system, controlling their access to resources, and associating user privileges with the established identity. It is a crucial aspect in a portal's design (Emigh, 2002). Enterprises everywhere are undergoing transformations to enhance the value they deliver to the business while reducing costs. A properly designed portal brings together a range of disparate tools and information sources, providing an effective channel between the business and its stakeholders (Stone, Roof & Lonsdale, 2006). For an educational portal, it must provide equal level and quality of access to applications, from both main campus and satellite centers, and for both on and off campus users. Students and faculty should not have to memorize multiple user ID/password pairs as they use different resources, though access privileges for the same user may be different (Levinson, 2002).

SINGLE SIGN-ON & STRONG AUTHENTICATION

Authentication is the bedrock in a portal as it bridges access privilege and user identity together. By verifying a user's identity, access is correctly granted or denied. Organizations pursue a variety of strategies to simplify and consolidate multiple sign-on, as it betters user experience, reduces costs and improves compliance. Typically, a user authenticates once when accessing a protected resource. The IDM issues the browser a cryptographically protected cookie, which maintains authentication state across applications. Apart from convenience, single sign-on (SSO) externalizes application security. Security externalization results in simpler policy maintenance as authentication no longer maintained within every application. It also improves compliance, as externalization forces the school to take a holistic view on security for all of its applications.

While user ID/password is most commonly used, it is weak and insecure with countless security problems. Stronger authentication can be achieved by using two factors. Two-factor authentication is any protocol that requires two independent ways to validate identity. Commonly, it uses "something you know" (password) as one factor, and either "something you have" (tokens, smart cards and digital certificates) or "something you are" (biometrics) as the other factor. Two-factor authentication enhances security, but each business scenario must dictate the authentication mechanism (Bowers, 2006). As a rule of thumb, schools should consider which regulations impact them, and conduct a risk assessment to balance between vulnerability, cost and impact. They can then decide the most appropriate way to strengthen authentication so that sensitive resources are protected while meeting regulatory requirements without going overboard.

ACCESS CONTROL & AUTO-PROVISIONING

As operating environment expanded to include more distributed applications and growing complexity in user relationship, managing user access is becoming enormously expensive and challenging for any organization (Jacknis, 2005). Access Control List (ACL) is the mechanism for defining security that limit access between users and network resources using filter rules. When a data packet arrives at a firewall, ACLs trigger a filtering process based upon predefined rules. IDM uses ACLs to assign access rights for users to resources. For example: professor A is allowed to access student records, while student X is denied access; student X is allowed to access the distance learning servers while guests are prohibited.

While commonly deployed, rule-based ACs are attached to objects. They are advisable only when options are few. Too much alternatives can complicate the policy to unmanageable and impede performance. In role-based ACs, access privileges are grouped into roles, and users are attached to roles as a way to manage their access (NIST, 2006). Role-based AC is more appropriate for Web services as access are assigned against a specific user's role and asserted to requesting applications. While simpler and more flexible, role-based AC does raised privacy concerns. In practice, both roles and rules are used to determine access rights. While inflexible and complicated, rules can provide fine-grain control and limit role proliferation.

Provisioning refers to the deployment of digital access rights for employees, business partners and customers across multiple applications and resources based on business policies. Resource provisioning includes the creation of user IDs and credentials. Conversely, de-provisioning deactivates accounts and reallocates resource when an employee leaves an organization. Apart from security, self-service auto-provisioning greatly increases an organization's operation efficiency. Auto-provisioning, for example, can automate account creation for new hires and account shut-off when employees leave the company. Self-service allows users update their accounts such as password reset, freeing up an enormous amount of staff and resources. Educational institutes are mandated to be in compliance with privacy legislations such as HIPAA and FERPA. Provisioning can be extremely helpful when it is time for the school's audit (Tynan, 2005).

CONCLUSION

For an educational portal, the hardest part of IDM does not lay in its development and deployment. Documenting business processes and defining who gets access to what resources can be a monumental task. While implementing IDM in the portal can be expensive, complex, and time-consuming, it can also lead to greater efficiencies and cost savings over time. More importantly, IDM is vital for any educational portal in this age of concern for privacy.

An Analysis of the Effectiveness of Law Enforcement Against Online Music Piracy

Kaveepan Lertwachara, California Polytechnic State University, USA; E-mail: klertwac@calpoly.edu
Anteneh Ayanso, Brock University, Canada; E-mail: aayanso@brocku.ca
Alemayehu Molla, RMIT University, Australia; E-mail: alemayehu.molla@rmit.edu.au

INTRODUCTION

Obtaining a copy of music without permission from the music's copyright owner is illegal. Yet, millions of consumers engage in exchanging illicit music files over the Internet. Unlike other illegal activities, file sharing appears to be widespread among consumers across all walks of life. In order to curtail widespread music file-sharing activities, the music industry has sought to increase the enforcement of existing copyright laws (Liebowitz 2006). Initially, lawsuits were filed against operators of file sharing networks such as Napster and Audio Galaxy. Using these lawsuits, the industry was able to shut down file-sharing networks that engaged directly in helping computer users locate music files on other users' computers (see, Napster, for example). However, the legal victory was short-lived. As soon as the operator of a file-sharing application is defeated in court, new file-sharing applications usually emerge quickly and draw a large number of consumers to start new, viable electronic networks for sharing music (Black, 2002). After Napster was ordered to shut down, new generations of file-sharing applications using updated and more decentralized technologies such as KaZaA, BearShare, and LimeWire appeared on the Internet.

Subsequently, the music industry turned to individual consumers who allegedly engaged in illegal music file sharing. In September 2003, the industry filed lawsuits against 261 individuals who the industry claimed traded a large number of music files online (BBC News, 2003). Prior to these lawsuits, individual file sharers were almost completely immune from any liability of their online activities. These lawsuits, the industry hopes, would alter that notion of online immunity. Coupled with successes in shutting down operators of file-sharing networks (see, shutting down of Grokster and KaZaA, for example (Borland, 2005)), the industry has been emboldened and has expanded its legal efforts to countries outside of the U.S. In this paper, we use economic modeling and data analysis to evaluate the effectiveness of these lawsuits.

The remainder of the paper is divided into two sections. The first section presents an economic model that explores consumers' decisions about whether or not to engage in illegal file-sharing activities. The second section outlines our data analysis plan to validate key assumptions and estimate the parameters included in our economic model. Integral and essential to this data analysis is our data collection effort to track actual file-sharing activities on KaZaA, one of the most well-known and largest file sharing networks. Our data collection process covers a period of 6 months between November 2005 and May 2006.

ECONOMIC MODEL

In this section, we model the file sharer's behavior using the approach taken by Becker (1968), Ehrlich (1973 and 1972), and Garoupa and Jellal (2002). To obtain a music product, an individual consumer can either purchase a legal copy or download an illegal copy of the music. First, we consider a situation where a consumer looks to obtain a single song. Let U denote the utility function derived from listening to a song, v denote a consumer's expected valuation for a song, p the consumer's perceived risk of getting caught, f the monetary penalty from being sued, and q the ratio of expected reduction of value of v due to factors such as uncertain quality of music files from illegal sources and reduced utility from consuming illegal products (i.e., when $q \rightarrow 1$, the utility received from an illegal copy of a music file is almost as high as that from purchasing a legal copy). Thus, the expected utility from downloading the song illegally is:

$$EU(v, q, p, f) \tag{1}$$

where EU denotes the expected value of U.

If the consumer wants to purchase the song, he/she has two options: 1) purchasing the song online or 2) purchasing a CD. For the online option, the consumer's expected utility is:

$$EL_1(v, s_1, r_1) \tag{2}$$

where L_1 denotes the utility function derived from purchasing a legal copy of music, EL_1 the expected value of L_1, r_1 the ratio of reduction in utility due to the restriction of usage of the digital file, and s_1 the lowest price of the song the consumer can purchase online.

The consumer's expected utility from purchasing a CD is:

$$EL_2(v, s_2, r_2) \tag{3}$$

where L_2 denotes the utility function, EL_1 the expected value of L_2 s_2 the price of the single CD (or other physical media formats), and r_2 the ratio of reduction in utility. From these retail options, the consumer would choose the one that yields the maximum expected utility.

$$EL = Max\{EL_1(v, s_1, r_1), EL_2(v, s_2, r_2)\} \tag{4}$$

where EL denotes the expected utility derived from a legal retail purchase.

It follows that if (1) > (4) and (1) > 0, the consumer would download an illegal copy of the song; otherwise the consumer would purchase the song. In order to influence the consumer's decision, the music industry can employ its technical resources to interfere with the online exchange of music files (i.e., the value of q) by injecting seemingly-legitimate-but-fake music files onto peer-to-peer networks, in addition to increasing the values of p and f. The industry can also influence the consumer's behavior by changing the retail prices of its music.

If the consumer wants to obtain multiple songs (say, n songs), he/she may decide whether to pirate or purchase each song individually. The consumer's total expected utility would simply be the summation of the utility expected from individual songs, or:

$$\sum_{i=1}^{n} Max\{EL_i, EU(v_i, q_i, p, f), 0\} \tag{5}$$

Alternatively, the consumer may choose to purchase an online subscription. We assume that the consumer can download all desired songs by purchasing one

subscription. Let c_1 denotes the subscription fee and $\mathbf{v} = \{v_1, v_2, v_3, \ldots, v_n\}$ the expected valuation of the songs the consumer wants to download. The expected utility from purchasing an online subscription is.

$$EW_1(\mathbf{v}, c_1, r_1) \quad (6)$$

where W_1 denotes the utility function derived from purchasing an online subscription.

For a compilation of songs in on CDs, we define c_2 as the total retail price of the CD(s) the consumer needs to purchase in order to obtain all the desired songs. The expected utility from purchasing compilations of songs in a CD would be

$$EW_2(\mathbf{v}, c_2, r_2) \quad (7)$$

where W_2 denotes the utility function derived from purchasing songs in a physical media format.

As a result, among the other retail options, the consumer would choose the choice that maximizes his/her utility, or

$$Max\ \{EW_1(\mathbf{v}, c_1, r_1), EW_2(\mathbf{v}, c_2, r_2)\} \quad (8)$$

The consumer's decision whether to pirate or purchase the songs would depend on the values of (5) and (8). Specifically, if (8) ≥ (5) and (8) ≥ 0, the consumer would purchase all songs legally, otherwise his/her decision will be made on an individual song basis.

In a multiple-period situation where the consumer re-evaluates his/her choice after obtaining each song, our model can be extended as follows. If the consumer initially chooses to obtain an individual song either by pirating or purchasing a legal copy, then the subsequent decision in the second period would be based on comparing the value of (9) and (10) as shown below.

$$\sum_{i=1}^{n} Max\{E_i, E(v_i, q_i, p, f), 0\} \quad (9)$$

Figure 1. Number of KaZaA users (5-day moving average) in millions)

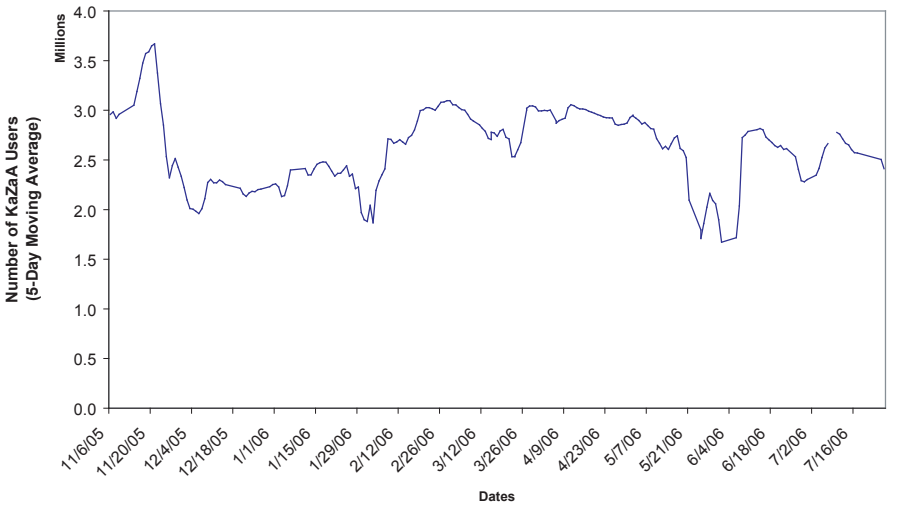

Figure 2. Number of files shared on KaZaA (5-day moving average) in millions

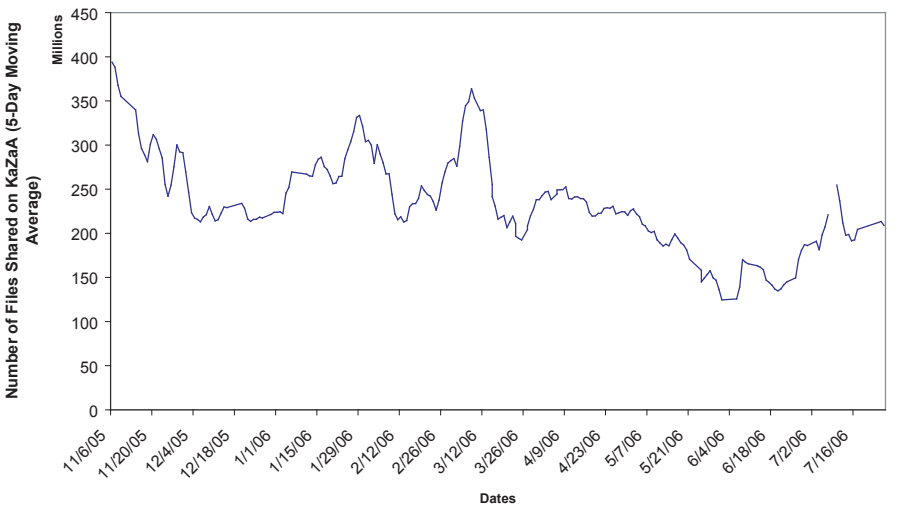

$$Max\ \{EW_1(\mathbf{v'}c_1,r_1),\ EW_2(\mathbf{v'}c_2,r_2)\}\ ;\mathbf{v'} = \{v_1, v_2, v_3, \ldots v_{n-1}\} \quad (10)$$

Subsequent decisions in later periods would follow the same rationale until the consumer obtains all individual songs he/she wants or purchases a subscription or a compilation of music in a physical format.

The total number of music files being shared (and thus downloaded) on peer-to-peer networks would therefore be derived from the decisions made by participants on the networks. Although the decisions made by file sharers depend on the values of parameters *v*, *p*, and *f* which vary greatly based on their financial resources, education, age, etc., we follow the approach taken by Becker (1968) to consider only the average values of these parameters.

DATA ANALYSIS

In this section, we develop an online data collection agent and conduct an empirical analysis to examine the actual impact that legal efforts by the music industry have had on the illegal file sharing activities. We characterize file sharers in terms of the variables in our economic model: valuation toward music (*v*), perceived risk of getting caught (*p*), and perception on the retail price of music. Our data collection agent tracked file-sharing activities on KaZaA between November 2005 and July 2006, during which many lawsuits were filed against alleged file sharers. Figures 1 and 2 show the number of file sharers and the number of files available for download on KaZaA between November 2005 and July 2006. Our preliminary results indicate that, while the lawsuits may have discouraged file sharers from engaging in online music piracy, the number of file sharers participating in peer-to-peer networks remain very high. The lawsuits were usually filed at the end or in the middle of each month (e.g., November 30, 2005, December 15, 2005, January 31, 2006, and February 28, 2006). As shown in Figures 1 and 2, file sharers tend not to participate on KaZA immediately after the industry's lawsuits. However, overall, the number of files being shared and the number of file sharers on KaZaA remain very high (i.e., on the day that we observed the lowest number of files shared on KaZaA, we found over 105 million files, and the lowest number of KaZaA users observed during our data collection period was 1.2 million).

In late July 2006 after our data collection was concluded, KaZaA received a court order to either shut down its operation or filter out all copyrighted materials from its network. In the past, when a popular file-sharing network was legally shut down (see, for example, the case of Napster), file sharers simply moved on to other networks and resume their online activities. At present, there are already other popular peer-to-peer networks such as Shareaza that allow file sharers to exchange copyrighted music files, filling the void left by KaZaA and thus undermining the legal efforts made by the music industry.

The second part of our analysis includes an opinion survey that looks at consumer's perception of the copyright law and its enforcement, the consequences of online piracy, and the retail price of music. Our data will be compared and supplemented by the data reported in previous studies. These empirical results will allow us to estimate the values of the parameters in our economic model presented above.

A Personal Portal for Individual Resource Control System

Yih-Jiun Lee, Chien-Kuo Technology University, Taiwan; E-mail: yjlee@ctu.edu.tw
Kai-Wen Lien, Chien-Kuo Technology University, Taiwan

INTRODUCTION

A portal aims to make the user more efficient and convenient by providing an entrance to all other coordinators. Variant portals may apply for different purposes, for instance, Yahoo is a portal for all Internet users to connect to sites which are grouped into categories. Except the Internet portal, users might need another kind of portal for their life.

In the real world, users might have different computing devices for use on different occasions, such as a personal computer, a laptop, a Personal Digital Assistant (PDA), or even a workstation with privileged access.

However, users tend to use only one device at a time, for instance a personal computer at home, a workstation accessed on an account provided by an employer, or a PDA to send a file to a co-worker when travelling. In this context, two problems are illustrated: first, when one device is being used, the other (or all others) might be idle; secondly, the user might have to maintain several copies of objects at different places, in order to access them everywhere, causing serious consistency and maintenance problems. IndiGrid, which stands for 'Grid system for Individuals', is designed for a single user solution to those problems. It also acts as a personal portal. By means of IndiGrid, a user is able to access every device he is privileged to access, and perform some authorized actions without bothering about security issues or file version synchronization. IndiGrid is based on web-services technologies and uses communication port 80 for messaging. It also enables asynchronous message transmission to improve transmission and performance. IndiGrid is a personal portal to enable global sharing and resource control to provide efficiency and convenience in the computing world for individuals.

RELATED RESEARCH

1. Grid Computing

Grid computing (Foster 2005) tries to solve the resource sharing problem of boundary crossing. It also refers to the management and integration of distributed resources, conceptual and physical resources, and services across globalized, large-scale, multiple administrative domains (Foster & Kesselman, 2003). Since participants might belong to or follow different rules, as far as "trusting" each other and "being trusted" is concerned, the participants can form a virtual organization, in which every member is mutually trusted. Therefore, they can share resources with each other. Grid computing can be classified as comprising a computational grid or a data grid. However, no matter what the grid system is, it must provide a multi-user and multi-resource enabled environment.

2. Peer-to-Peer

As computational performance on personal computers and network communication infrastructures has improved, Peer-to-Peer (P2P) computing has become another communication model for the environment in which devices (computers, servers, and all other computation devices) link to each other directly. All the devices are "peers". The computers in P2P computing can be both clients and servers, unlike as in server-centric computing (Online, 2006) or asymmetric client-server systems (Foster & Kesselman, 2003). All the participants share their resources (mostly files) equally. The main aim of P2P is for resources to be provided and consumed by each peer, in contrast to the client-server system, in which only servers provide resources. P2P is also comparatively more robust and reliable.

3. WSGrid

WSGrid (Henderson, 2004) is a web services based grid computing environment, proposed by Professor Peter Henderson of the University of Southampton, UK. A WSGrid based grid environment is composed of nodes, where a set of WSGrid web-services is installed. A node is also known as a host, where computation occurs and resources are provided. The virtual organization in WSGrid is constructed around a combination of nodes and users. Unlike most virtual organization solutions, which often have one or more centralized components, the virtual organization of WSGrid's distributed idea is full distributed. Each node in WSGrid has equal position. However, in comparison to Peer-to-Peer computing, WSGrid does provide more controllability and security by allowing users to set up different privileges for different remote accounts.

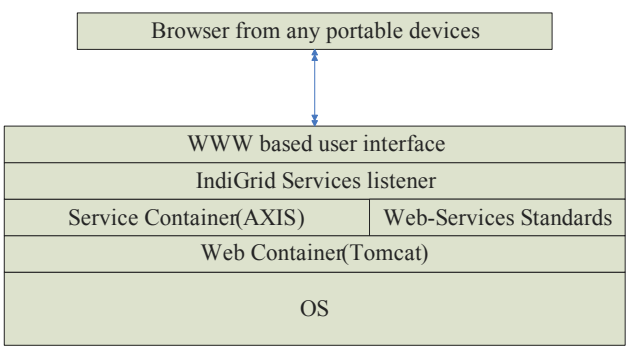
CURRENT RESEARCH STATUS (SYSTEM INTRODUCTION AND ARCHITECTURE)

1. The Architecture

In order to provide "light-weight" middleware, reduce the risk from malicious users, and maintain network security, IndiGrid's design is based on web-services technologies. All services (the components of IndiGrid) can be hot-plugged and unplugged, so the performance will not be affected. Another benefit of using web-services technologies is that web-technologies and open resources on webs are maturely developed. In addition, configuring a web container is not too difficult, even for a non-professional user. The threshold is low. From the point of view of network security, communication port 80 is turned on as a default. As regards user friendliness convenience, efficiency and performance, web-service architecture is very suited to grid systems. IndiGrid was originally designed for individuals, so it is assumed that only the owner has the privilege of access to the computers in the group. However, through a delegation process, temporary access rights are also provided.

IndiGrid is designed to be a single user grid middleware to provide grid users with a convenient access to their workspaces and resource. Since it is for individual, it is assumed that everyone has security tokens (i.e. username and password, certificates) to be authenticated by their spaces. Furthermore, when a device is connecting to the Internet, remote connection should be restricted to only certain areas. So does IndiGrid. Only opened areas (configured in the configuration)

Figure 1. Middleware structure



are allowed to be remotely accessed. Through the process of authentication and authorization, the security of a host is basically remained.

2. The Functionalities

By referring to the requirements of the Grid (Foster 2005), a grid middleware should provide the following functionalities: discovering and configuring resources, moving data, monitoring and controlling components, and manage credentials. IndiGrid is composed of set web-services for the above functionalities of resource sharing and load balancing.

a. FileService

FileService is used to move objects from one location to another. IndiGrid follows the idea of WSGrid to allow (restrict) remote access to certain locations to prevent possible attack from malicious users. Thus, the owner can move all objects around. And the moved objects can be marked to be removed after use.

b. JobService

JobService is a submission service to allow an owner to submit a job (process, task) to another device. This service aims to balance the computation load and uses some resources only located on a certain computer. The user sends a job along with the job description, which states the conditions for the job (such as delete after execution or result returning to a specific place).

c. LoggingService

LoggingService is used to record the status of the execution and servers. It can also be used as a task-status-query service.

d. MyFavoriteService

Users commonly keep logs of their favourite websites on their computers. However, keeping all web favourites consistent (on different computers) is difficult. MyFavorite- Service is the service to return the favourite web sites as a linkable web page, so users can access them anywhere without bothering synchronization.

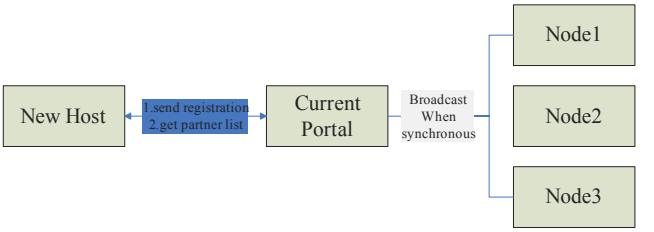
e. DelegationService

DelegationService is an important and existing service to allow the user to "issue" a temporary passport to someone trustworthy. This service follows the idea of GateService (Lee, 2005). This service in IndiGrid is for sharing. For instance, a man needs to share his file(s) to group members. The delegators must specify the rules of delegatee in a simple and clear XML file.

f. NotificationService and StatusRequestService

NotificationService and StatusRequestService are working in pair of co-existent services. When a host joins in the group, the node must firstly invoke the NotificationService (as saying Hello) of any other node (like a registry) to introduce the node itself, ie the WSDL for its services and its capability. The notified node forwards the registration information to all known partners, which then say 'hello' to the new member. Thus, nodes can know each other. Then StatusRequestService can respond any information regarding the status of nodes. They will be illustrated in the next section.

Figure 2. The registration sequence of IndiGrid



THE FRAMEWORK OF HEALING (NODE STATUS CONTROL)

As a full distributed environment, to aware the availability and capability of nodes is very important. In the earlier version, GateService, the submission can only queue for its execution. However, it is possible that the node might be currently unavailable, but it still appears as online. Therefore, IndiGrid uses a partner list to keep the status of partners.

Partner list is an XML format file to keep the current status. The information of partner list is coming using the NotificationService. Three kinds of NotificationService are currently available. When an environment is built, a Root must be chosen. The root can be specified by the owner or be elected using the token ring method. However, only the nodes who can be servers are candidates.

First, when a node (which is not currently on the partner list) joins in the group, the node will say Hello to a node (acting as a registry). Then the notified node (root) can update its partner list and reply the message with the partner list. On occasion, the root might forward the new partner to all other known nodes.

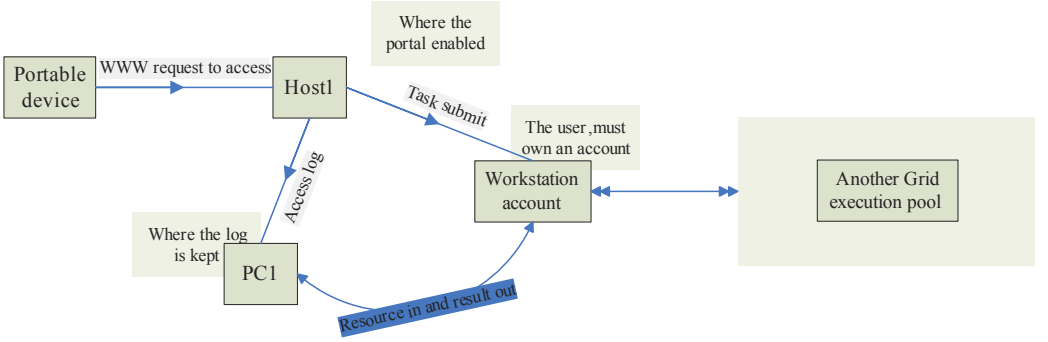
Second, when a node is busy (the job queue is full or nearly full), it can send an "unavailable" message through NotificationService. The corresponding process is to move the node to the end of the partner list.

Finally, when the "unavailable" node is back online, it can also notify its partner about its return.

All these three kinds of notification are using push methods to automatically process.

StatusRequestService is another side of story. It is designed for pull method. For instance, when a node sends a request but does not get the response back in

Figure 3. IndiGrid



reasonable time. The user might want to initiative a StatusRequestService request. When a node initiates the request, a timer is also enabled. When time out happens, a node with no response is moved to "unavailable" state. In order to improve the performance of network, broadcast of StatusRequestService request is not recommended. Other status synchronization methods are still in progress.

CONCLUSION AND FUTURE WORK

At the time being, services 'a' to 'e' listed above have been successfully implemented and tested, but NotificationService and PartnerService are only at version 1. To automatically manage the status of each partner (node) is not too difficult. There are two kinds of notification transmission methods to be provided. The problem is that if the synchronization is processed too frequently, the system performance and network bandwidth might be affected. However, if the synchronization process is seldom performed, the system status is hard to maintain. Thus, both push and pull methods of synchronization are provided. For active information providers, the push method can be used for notification at initiation, busy time and off line. For accidentally system crash or expected system busy, the pull method should be able to help. Besides, a novel equation of automatically reconfiguration is being studied and will be proposed to solve the problem.

IndiGrid is expected to be a fully functioning grid system for individuals. By using web services, it is a portal, able to connect every computer or computing device for the owner. With IndiGrid, users do not need to deal with multiple inconsistent files or wait for a busy device to return the computing result. They can share load and resources among different computers and use them just like at home.

IT Audit Process Quality Improvement Factors

Jeffrey W. Merhout, Miami University School of Business, Oxford, OH 45056, USA; E-mail: merhoujw@muohio.edu
Douglas V. Havelka, Miami University School of Business, Oxford, OH 45056, USA; E-mail: havelkdj@muohio.edu

ABSTRACT

This Research-in-Progress paper outlines the beginning of what we plan to be a comprehensive research stream related to the issues, factors, skills, etc. that would culminate in an effective and efficient IT audit engagement/project. We use focus groups in this current research effort to identify critical success factors related to a quality IT audit.

INTRODUCTION

Information Governance is an important requirement for those responsible for managing information systems (IS) and the various business processes that utilize these systems. One of the driving factors behind an increased focus on governance is the Sarbanes-Oxley Act of 2002, which requires publicly traded companies in the United States to adhere to very strict controls requirements around their financial statements and the systems that produce the financial numbers. These controls must be documented by management and attested to by independent auditors. A large component of these attestation engagements is the review and testing of information technology (IT) controls by systems specialists commonly referred to as IT (or IS) auditors.

IMPORTANCE OF STUDY

Thus far in our research, we have built upon the audit process quality literature by facilitating focus group research sessions with both internal (i.e., corporate) IT auditors and "Big Four" public accounting IT audit managers to identify and classify critical IT audit process quality factors. The overall goal of our ongoing research is to determine if there are a key set of factors that auditors both within an internal audit function as well as across different companies agree are critical to the success of an IT audit engagement. Overall, these factors can act as important antecedents to the IT audit process and influence the successful outcome of a specific IT audit. The objective of this study is to discover these constructs and develop a model of the IT audit process that can be used to improve process quality. Thus this model should enhance our understanding of the broad range of factors that influence the quality of IT audits.

METHODOLOGY

The method we are using to identify the quality factors for the IT audit process is a nominal group technique. An underlying assumption of this method is that individuals who perform a task can provide valuable insight into the important factors influencing their ability to achieve a high level of productivity and effectiveness when performing the task. This method has been used successfully in several domains, including systems development (e.g., Havelka and colleagues; Sutton and colleagues).

EXPECTED FINDINGS

The output of these focus groups include a set of factors that can be used by managers to improve the IT audit process or by researchers to further investigate the relationships among the various factors. We are unaware of prior research in this domain, which makes our contribution potentially very significant. Once the key critical success factors for IT audit quality are identified, we look forward to sharing our findings with both academicians and practitioners.

1. INTRODUCTION

Open source software (OSS) development projects exhibit many of the characteristics that make virtual organizations successful, including self-governance, a powerful set of mutually reinforcing motivations, effective work structures and processes, and technology for communication and coordination (Markus et al. 2000). Examples of thriving OSS projects include the Linux operating system, Apache Web Server, and the Mozilla Web Browser. Many OSS projects have achieved substantial success despite their seemingly disorganized structure (e.g., no central management) and the lack of monetary incentives. Raymond (2001) described the open source method of development as "a great babbling bazaar of differing agendas and approaches… out of which a stable and coherent system could seemingly emerge only by a succession of miracles." The Bazaar development approach is characterized by design simplicity, teamwork, a visible product, and communication (Wagner 2006).

Researchers have studied OSS development to better define the successful characteristics of this particular form of virtual organization. For example, Mockus et al. (2002) conducted a case study on the Apache Web server and Mozilla Web browser projects. They found that projects based on a relatively small core (10 to 15 people) of geographically dispersed developers could communicate and function without conflict via a set of implicit coordination mechanisms (i.e. informal email exchange). However, other explicit coordination mechanisms (i.e. code ownership policy) were required to maintain communication and reduce conflict when the number of core developers exceeds 10-15 people.

In a related study, Huntley (2003) attempted to explain the success of OSS projects using organizational learning effects. He maintained that learning effects were manifested by the decreased time required for fixing bugs. He noted significant debugging differences in Apache versus Mozilla, with the attributing factor being project maturity, as opposed to other measurable factors such as project size or number of programmers. Huntley modeled debugging data from Apache and Mozilla according to learning curve formulas. As noted, Mozilla, an emerging project, exhibited a steady debugging process, with predictable improvements. The results illustrate that the learning effects are present in the Mozilla team. In their attempt to defining OSS success, Crowston et al. (2003) suggested that the number of developers involved in a project was an important indicator of the success because the project can gain momentum going forward only by attracting enough voluntary developers.

Our research seeks to extend Huntley (2003)'s study by analyzing 118 OSS development projects (as opposed to only two in Huntley's). These projects vary not only in size (in terms of the number of developers involved and lines of code developed) but also in type (from simple file management software to complex enterprise software suites). We draw our data from SourceForge.net's vast database. Specifically, we are interested in answering two main research questions. First, are learning effects universally present in OSS projects? Second, what are the factors that affect the learning process? Similar to Huntley (2003), we use the number of reported bugs and bug resolution time to measure the learning effect. We look at how different project types, number of developers and their experiences, and the intensity of assigned bugs affect the bug resolution time, and whether there is a learning curve effect.

2. EMPIRICAL MODEL

Based on the Power Law learning curve formula (Wright 1936), and motivated by the models in Argote et al. (1990) and Huntley (2003), we developed a log-linear regression model with both qualitative and quantitative variables:

$$\ln MeanResTime_t = \alpha_0 + \alpha_1 \ln CumResBugs_t + \alpha_2 \ln AvgDevExp_i + \alpha_3 \ln PctAssignedBugs_t + \sum_{i=1}^{2} \beta_i ProjCat_i + \sum_{j=1}^{3} \gamma_j ProjSize_j + \varepsilon_t$$

Where:

$MeanResTime_{it}$ = Mean time to resolve the bugs of Project *i* reported in Week *t*
$CumResBugs_{it}$ = Cumulative resolved bugs of Project *i,* including Week *t*
$AvgDevExp_i$ = Average number of other projects each developer in Project *i* has worked on
$PctAssignedBugs_{it}$ = Percentage of assigned bugs in Week *t* of Project *i*
$ProjCat_i$ = Category of Project *i*
$ProjSize_i$ = Size of Project *i*, measured in terms of the number of developers in the project (1 developer; 2-4 developers; 5-10 developers; >10 developers)

Our model tests the following hypotheses:

H_1: As the number of bugs resolved to date increases, the average bug resolution time decreases.
H_2: Increased developer experience decreases average bug resolution time.
H_3: Increasing the percentage of bugs assigned to specific developers decreases average bug resolution time.
H_4: Project type has an effect on average bug resolution time.
H_5: Project size has an effect on average bug resolution time.

3. DATA COLLECTION AND DESCRIPTION

We collected data from SourceForge.net's repository of more than 100,000 projects.[1] SourceForge classifies projects according to the following categories: database, development, desktop, games, hardware, enterprise, financial, games, multimedia, networking, security, system administration, and VOIP. To ensure an appropriate cross-section of Open Source projects were included in our sample, we identified the top 50 projects in each of these categories based on two factors: development status and site rank. The first factor prevented "conceptual" projects with no event reports from reducing the set of usable responses. The second factor produced the best projects based on SourceForge.net's internal ranking system. The ranking system uses three sub-factors 1) traffic, 2) communication, and 3) development to determine an overall rank of projects. The multi-factor ranking system enhanced sample validity by dropping older and less active projects. This produced a sample representative of the current state of Open Source development. Based on these rankings, we collected a "snapshot" of the top 50 projects in each category on March 9, 2006. Note that some projects were cross-listed in multiple categories.

We determined the final dataset by 1) assigning cross-listed projects to their most appropriate category, 2) removing projects with less than two years of data, and 3) removing projects with less than 100 bug reports. This reduced the sample to 118 projects.

Each project has a "bug report", which provides a generic description for project events including number of: 1) bugs, 2) support requests, 3) patches, and 4) feature requests. Each bug also has a status such as open, closed, deleted or pending. An important measure of organizational learning is a comparison of the ratio between reported and closed bugs. After applying all project selection criteria our final pool of bugs included 91,745 reported bugs and 73,253 resolved bugs. We then aggregated the data to produce weekly averages for each project. This resulted in a dataset capturing 16,175 project-weeks of information.

We also collected information about the developers associated with the projects. This included the number of developers for each project, as well as information regarding developers registered for more than one project. We used this data to test our hypotheses related to number of developers and developer experience.

Bottlenecks

Collecting bug data from the SourceForge.Net repository proved to be the greatest project challenge. Data was only accessible through a limited web-based interface. As a result, we had to run multiple small queries and compile results into a single database. We often faced connectivity problems, which hindered our data retrieval efforts. At one point, the database was unavailable for several days because of a system upgrade. Fortunately, the upgrade alleviated some of our data retrieval problems. Once retrieved, the data had to be formatted, subjected to a number of intermediate calculations and aggregated to produce the desired data set. This eventually entailed a process of more than 200 individual steps.

4. PRELIMINARY RESULTS

Preliminary results show support for each of the five hypotheses:

- Average bug resolution time decreases as the cumulative number of bugs resolved increases (H1)
- Average bug resolution time decreases as developer experience increases (H2)
- As percentage of bugs assigned per developer increases, average bug resolution time decreases (H3)
- Project types "SysAdmin" and "Hardware" have the lowest bug resolution times (H4)
- Projects utilizing 2-4 developers have the lowest average resolution time (H5)

Following is a brief overview of some of the major points.

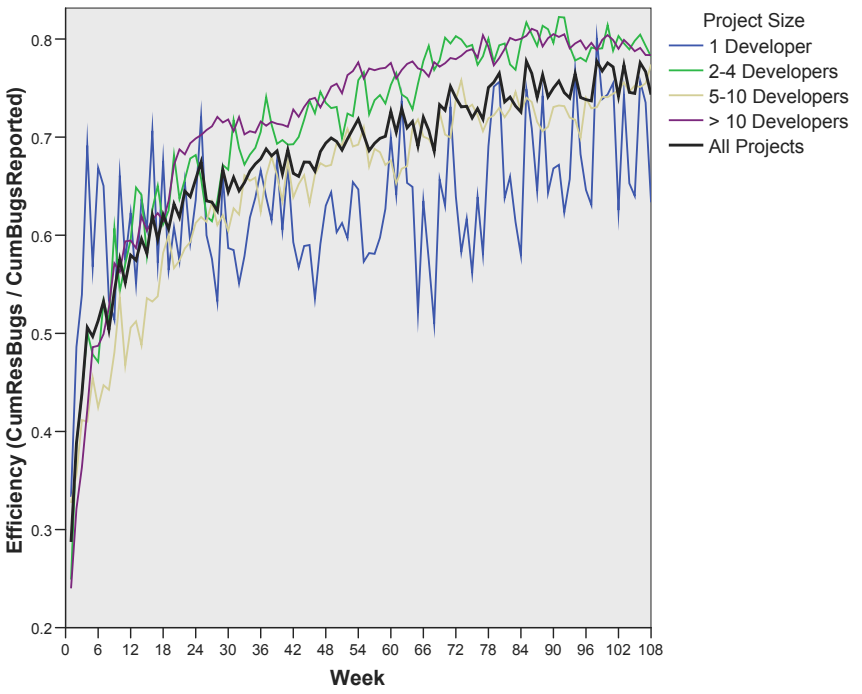
To test the impact of project size, we divided the projects into 4 categories of project size consisting of 1, 2-4, 5-10, and >10 developers, with project size of 1 developer as the reference category. The results indicate that all project sizes have lower resolution times than the reference category, with projects utilizing 2-4 developers having the lowest average resolution time. The average resolution time increased for projects with 5-10 developers and then decreased slightly for those projects with more than 10 developers.

Regression analysis resulted in a negative coefficient ($p < 0.000$) for *CumResBugs*, providing support for H1. Average bug resolution time decreases as the cumulative number of bugs resolved increases. This is in contrast to Huntley's (2003) finding. This finding indicates the presence of a learning curve effect, which is measured by improvements in mean cycle time as more bugs are resolved. A closely related measure is adaptive learning, which is the ratio of cumulative resolved bugs to cumulative reported bugs (Huntley 2003). The graph in Figure 1 provides evidence of an adaptive learning process in the projects, but the process varies based on project size. In particular, projects with a single developer learn faster and thus achieve better efficiency in a shorter period; but over time, they become less efficient relative to projects that employ a group of developers. Projects with 2 to 4 developers demonstrate the best efficiency over time, followed closely by projects with more than 10 developers. It is also interesting to note that the variability of efficiency decreases substantially as the number of developers increases.

5. CONCLUSION

Our preliminary results show there are learning effects in OSS projects. They also show that other factors such as developer experience, project type, project size, and the percentage of bugs assigned to specific developers affect the bug

Figure 1. Comparison of project size efficiency per project week



resolution time and thus the learning curve. Space limitations prohibit further discussion at this time. We will provide a detailed discussion of each hypothesis and its implications at the conference.

The Impact of Business Process Modeling During the Implementation of Electronic Records Management Systems: Theoretical Framework and Empirical Studies

Kerstin Fink, University of Innsbruck, Austria; E-mail: kerstin.fink@uibk.ac.at
Dominik Grimm, University of Innsbruck, Austria; E-mail: dominik.grimm@uibk.ac.at

ABSTRACT
In introducing Electronic Government solutions, in particular Electronic Records Management Systems (ERMS), public authorities require a comprehensive framework concept to meet the multidimensional integration need. Before the implementation of new software processes a software analysis and design should be conducted. This paper reports on our research in progress to observe the diffusion of Business Process Modeling (BPM) during Electronic Records Management projects.

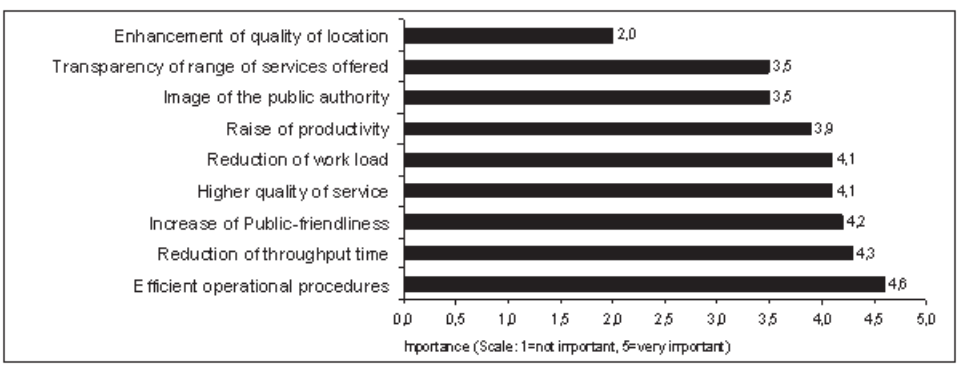
1. PROBLEM DESCRIPTION

The "eEurope 2005" initiative of the European Commission, which is also part of the Lisabon strategy, has the objective to develop modern public services and a dynamic environment for e-business through widespread availability of broadband access. In particular the public administration and their services should be modernized by an increased usage of modern information technologies (EU, 2006). Within the eEurope 2005 action plan there are efforts on the one hand to offer online public services and on the other hand to increase productivity, effectiveness within the public authorities and across organizations and national borders by means of digital technologies accompanied by organizational change and new management skills (EU, 2005; Grönlund, 2002). This includes not only external governmental operations via E-Government Online Services but also internal operations by the use of GIS[1], ERMS[2], WMS[3], ERP[4] and much more in combination with modern management methods like Change Management, Project Management, Business Process Management, Controlling, Quality Management and so on (Grönlund, 2002). Focusing on administrative procedures the purely electronic processing of administrative affairs should lead on the one hand to a higher service quality and democracy for citizen and on the other hand to higher effectiveness, transparency and economies in particular financial resources (Antirroiko & Mälkiä, 2006). The objectives for E-Government solutions are according to an E-Government study of the German Research Center for Artificial Intelligence (DFKI) in 2003 are illustrated in figure 1.

Beside many other initiatives like E-Procurement, E-Learning, E-Health, and so on the management of electronic records is one of the most important issues in the government's modernization program (Traunmüller & Wimmer, 2001). Most requirements on Electronic Records Management Systems (ERMS) are predefined on national level through country specific concepts like the „DOMEA[5]" concept in Germany, the "ELAK[6]" concept in Austria, the "GEVER[7]" concept in Switzerland or "The National Archives[8]" concept in UK (Müllner & Grimm, 2006). These concepts should assure that all deployed ERMS meet the requirements respect to national right, organizational and operational structure and functionality, so that a quick and high quality as well as an area-wide and interoperable implementation could be realized (TNA, 2001).

The transition from traditional administrative processes to E-Government processes means not only an adoption of previous (non-electronic) procedures onto electronic ones but also it opens new possibilities and challenges regarding reorganization and process reengineering (Wimmer, 2002, pp. 149-156). Before the implementation of new software a process analysis and design should be conducted (Matheis et al., 2006). A use of Business Process Management (BPM) methods after important technical decision or implementation of new software can only yield to a sub-optimal result. Nevertheless most of actual E-Government

Figure 1. Objectives on implementing e-government (Scheer et al., 2003)

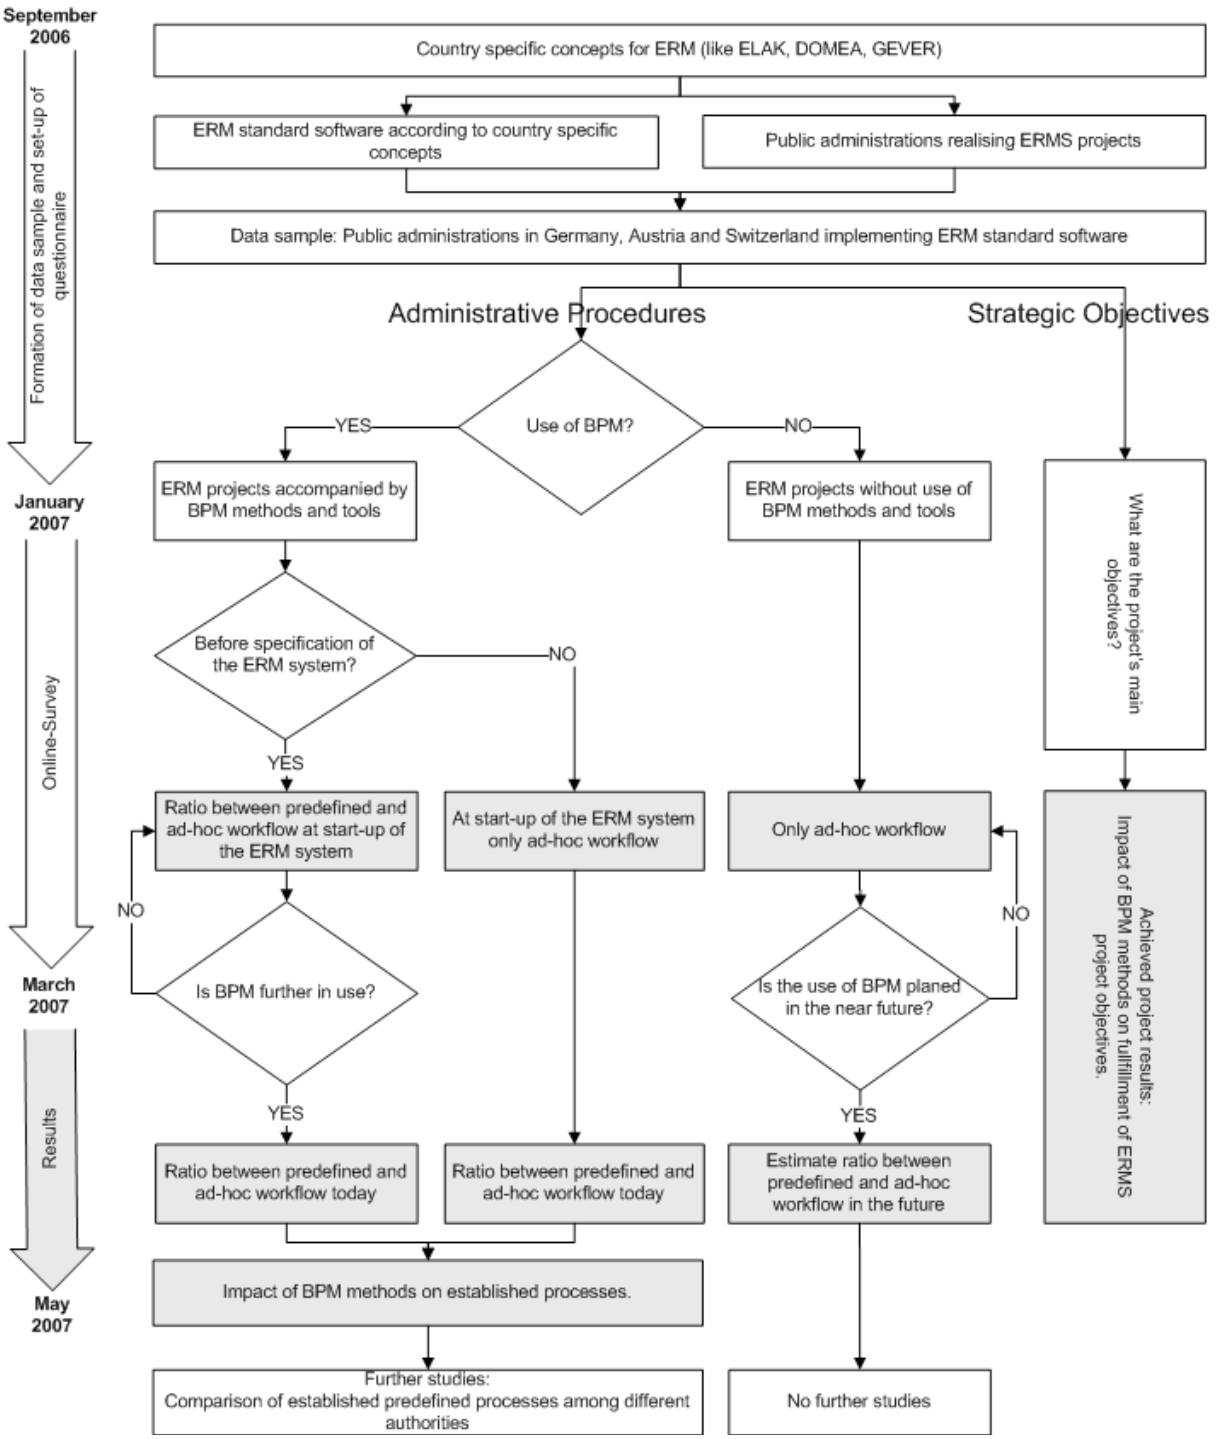


projects are in progress without using BPM (Traunmüller & Wimmer, 2003). Some reasons for that are:

- The diversity of public administration processes, heterogeneity of participants as well as procedure specific, local and legal regulations allow only a restricted design of standardized processes (Klischewski & Lenk, 2002)
- A multitude of administrative processes are decision-making processes which require situation specific workflows and are carried out in the person in charge's sole discretion (Lenk & Traunmüller, 2000)
- A lack of documentation of actual procedures and individual operating know-how of each executive (Lenk & Traunmüller, 2000)
- Most of the already successfully deployed BPM methods in private industries can only be restricted applied to public administration processes (Scholl, 2005)

Public authorities have now the problem, that ERMS should be implemented but still there are missing adequate methods to exactly design administrative processes.

Figure 2. Research process model



2. RESEARCH FRAMEWORK

In order to systematically manage the complexity of software systems a top-down approach can be used. (Lee, 2005). Regarding to the transformation of administrative processes for a specific use case the following top-down structure can be designed: process -> activity –> work step. In general Electronic Records Management Systems allow the following possibilities of workflow functionality for the flow of files (Müllner & Grimm, 2006):

- By predefined workflow: From the beginning to the end of the process all activities and work steps are strictly predefined.
- By ad-hoc workflow: For a specific use case the process starts with a predefined standard start activity. All following activities are defined by the person in charge.
- By semi-predefined (mixed) workflow: For a specific use case a standardized process is rough predefined by usually needed activities and work steps, but could be situation specific adapted by the person in charge.

The research question is: "In implementing Electronic Records Management Systems which BPM methods and tools are mostly used, how these influence the establishment of electronic processes in respect of predefined or ad-hoc workflows and how the impact of BPM methods on the fulfillment of project objectives is?"

According to this we can formulate the following two hypotheses:

H1: The use of BPM methods and tools before the specification and implementation of Electronic Records Management System (ERMS) in public authorities causes an increased use of predefined electronic processes on routine processes and an increased use of semi-predefined electronic workflow on decision-making processes.

H2: The use of BPM methods during the implementation of Electronic Records Management System (ERMS) has a direct and positive impact on the successful fulfillment of project objectives such as efficiency of operational procedures, reduction of throughput time, increase of Public-friendliness, reduction of work load and raise of productivity.

3. RESEARCH METHODOLOGY

Because of the complexity and the interdisciplinary magnitude of ERMS projects and the great number of participants, we have chosen an expert survey as research method, which allows well directed interviews in an economical and time-saving manner (see Figure 2).

The survey will be done on public administrations in Germany, Austria and Switzerland, which have implemented an Electronic Records Management System (ERMS) conforming to their respective national concepts. Implemented means that the specification of the software has already been finished and the roll-out of the final production system or pilot system has been accomplished at least at one department.

Due to their participation on all stages of the ERMS project, the experts are defined as project leader and/or head of department of the public authorities, which are realizing an ERMS project. Because of the geographic distance an online survey is chosen as the most practicable research method.

The online form will contain quantitative as well qualitative questions about following aspects: Implemented software and ERMS standard concept; primary project objects, used BPM methods, successful established electronic processes; achieved project results and further need for action.

In November 2006 the research is starting with the formation of the data sample and the collection of all contacts for the survey, which should be finished latest in January 2007. Estimated is a data sample between 150 and 200 public authorities. At the moment the questionnaire set, the data base and the online form are prepared. The survey is structured in 4 parts and will contain approximately between at least 15 and at most 25 questions:

- Part 1: General project data (5/5)
- Part 2: Implemented ERM standard software (4/4)
- Part 3: Processes and used BPM methods and tools (3/8)
- Part 4: Established processes and achieved project results.(3/8)

The expert online survey will be accomplished from January 2006 until March 2007. First results are expected in March 2007. The final report should be available not later than May 2007.

4. CONCLUSION AND FUTURE WORK

They survey will show if there is nowadays an increased use of BPM methods during the implementation of Electronic Records Management Systems in public authorities. Further, we expect to find out which BPM methods and tools are mostly used in public administrations and which impacts they have on implementing ERMS regarding process redesign, internal administrative procedures and fulfillment of project objectives. In comparing data results of different project proceedings, used methods and finally achieved project results may lead to recommendations, best practice approaches and/or further need for action. Future work will be concentrated on analyzing established electronic processes and their comparison between similar authorities in Germany, Austria and Switzerland.

INTRODUCTION

The Information and Communication Technology (ICT) industry has been identified as a key factor for increasing national competitiveness giving the variety of applications of ICT in many economic sectors. In fact, productive and social networks are enabled by ICT to satisfy the needs for health, education, government, and economic well-being (García, 2006). Moreover, and because of synergies and spillovers of the ICT sector, policy makers around the world are devising plans to increase the investment in ICT in order to promote economic growth (Baily, Farrell & Remes, 2006). In this way, the ICT industry has become in the last years an important catalyst for national economies.

Recent changes in exportation patterns have motivated the Mexican government to create a campaign to position Mexico as an ICT provider. The campaign intends to show the advantages of outsourcing services to Mexico, focusing particularly on the United States market (Ruiz, Piore & Schrank, 2005). This campaign is a key component of the digital economy policy in Mexico, and has been called the Program for the Development of the Software Industry (PROSOFT).

Achieving PROSOFT goals will depend on several interrelated factors (Secretaria de Economía, 2006). First, it will depend on the ability of policy makers to promote investments. Second, the ICT industry in Mexico will need a transition toward a new administration and governance. Moreover, Mexican success will also depend on the speed and capability of ICT industry in adopting a collaborative approach to respond to the needs of the international market.

This paper reports the current progress of a case-based simulation project in which we analyze the PROSOFT program. Our objective is to explore the relative effectiveness of different policy mixes to achieve the PROSOFT goals. Some of the aspects of the program to be included in the model will be the workforce, human capital, financial investments, and governance and collaborative approaches being promoted by PROSOFT project leaders.

LITERATURE REVIEW

The Mexican economy has two main problems according to some analysts (Martínez, 2001): The first one is associated with the low nutrition levels suffered by many Mexicans, and the second one is related to the uneven distribution of wealth. Moreover, domestic economic growth is not having a direct impact on basic well-being of the growing population, but rather it has increased the accumulation and the concentration of income in very few people.

In order to improve the economic conditions for the general population, it is needed either to increase allowances or to reduce the population's growth. To achieve this development is necessary to elevate the investment rate substantially and to modify the distribution of income in order to reach a better level of efficiency (Baily et al., 2006).

Latin American economies have problems because of the lack of capital. Countries in this region depend on those countries that have the capital to invest and promote economic development. The dependence resides on the importation of capital goods and capital investments. Important factors attracting such capital investments are the existence of qualified and cheaper workforce (C.I. García, personal communication, December 7, 2006).

Investing in the ICT sector to promote economic development is attractive for several reasons. ICTs are having a direct impact on many countries inflationary trends, reducing the unit capital costs, and accelerating demand for ICT products as a mayor driving force. It is amazing how the ICT prices, adjusted for quality improvements, are going down while prices in the rest of the economy have been increasing. This has been allowing a non-inflationary growth, which generates a positive effect on the economy. (Hilbert, 2001). In addition, the economy is indirectly impacted by human capital and telecommuting workforce programs, which tend to report an increase in productivity through increased morale and commitment to the company.

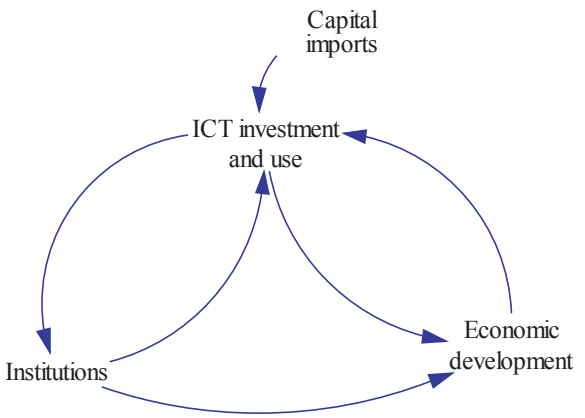
In this way, ICT should eventually lead to a permanent increase in productivity, just like every other innovation, which decreased input costs. Currently, some countries are already investing on research and the final integration of the new economic features into their societies, in order to benefit from it, while others (such as many Latin American countries) are still trying to provide the basic access to the knowledge-based economy for several sectors of their populations.

Economies are increasingly based on knowledge. The generation, processing and distribution of knowledge and information are a fundamental source for productivity, power and prosperity (Baily et al., 2006). In the past, the growth of the economy of a country depended on the optimization of the physical labor and financial capital, it's been proved that information and communication (networking in the network), are definitely the main component of growth in the new knowledge society (North, 1994).

Institutions have been identified as another important factor affecting economic development (Hassan & Gil-Garcia, 2006). Moreover, institutions have been also identified as an important constraint and enabler of ICT investments, development and use (North, 1994). Authors describing such effects do not only recognize the impact of institutions in economies or ICT applications, but also recognize ways in which individual and organizational interactions affect the institutional arrangements (Figure 1).

Most of the discussion about ICT and economic growth recognizes the effect of ICT investments on economic development. However, as shown in Figure 1, Institutions are also constraints and enablers of economic development because of its impact on transaction and transformation costs. Moreover, institutions also affect the ways in which individuals and organizations decide to invest and use ICTs, modifying the possible benefits of ICT use and explaining differences between organizations or countries (i.e. some organizations or countries obtain more benefits from ICT investments than others). However, Institutions are also modified through time by individual and organizational actors. In this way, our exploration of the impact of ICT policies such as PROSOFT will use institutional

Figure 1. Interactions among institutions, ICT investment and use, and economic development



theory as a reference to understand the complex interactions among ICT investment and use, institutions, and economic development.

METHODS

In order to understand the PROSOFT case two main data collection methods are used. First, we performed an analysis of relevant documents including articles, digital references, and books. This review will provide some background, general information, and the basic characteristics of the PROSOFT program. Information was also extracted from articles and reports in which we observed the growth of the Information Technologies, as well as the different behavior and scenarios of several countries who are investing on the implementation and development of ICT.

Second, we will conduct semi-structured interviews with people responsible for the promotion of information and communication technologies in Mexico. These interviews will provide additional information on the evolution of the PROSOFT program, and help to understand why the development of information technologies is so important to increase national competitiveness. Participants will be asked about the main rationale of the program, program development, and main achievements.

Finally, we will use System Dynamics as a method to understand all the strategic components of the PROSOFT program and their interrelationships. This method consists on identifying the behavior of several variables in the system and identifying a causal structure associated to it. The development of the model represents an iterative process of comparing system's performance over time, linking those processes into causal structures and evaluating the feedback processes (Richardson & Pugh, 1981). The main objective is to simulate the most important components of the PROSOFT program to analyze and understand their main interactions. As a result of the modeling process we will develop and evaluate hypotheses about the impact of the behavior of ICT investment and use and the simulation will help to understand and manage the different variables that appear in the program. This preliminary version of the paper reports the results of the analysis of documents and one interview with two key participants in the PROSOFT program.

PRELIMINARY RESULTS

The PROSOFT program was officially created in 2002, following a 10-year plan, PROSOFT focuses in the development of the software industry integrating public and private funding, promoting collaboration among private industries, federal and state governments, and institutions of higher education. (Colón, 2006). One of the goals of PROSOFT is to achieve by 2013 an annual production of technological solutions for 5,000 million dollars. In this way, Mexico will reach the world average of expense in ICT, becoming the Latin American leader in software and digital contents development in Spanish. Initial results are encouraging, and the ICT sector growth has changed from a negative rate in 2002, to 10.7% in 2005. This growth represents three times the growth of the domestic economy in that same year. It is expected a 11.4% growth for 2006.

The program is organized around seven strategic lines:

1. Promotion of exports and investments in the software sector
2. Education and training of competent personnel in the development of software, as well as the required quantity and quality
3. Appropriate legal framework in place promoting this industry
4. Development of the IT domestic market
5. Strengthening of the local industry
6. Achieve international levels in process capability
7. Promote cluster development throughout Mexico

As of 2006, PROSOFT is working with approximately 26 of the 32 Mexican states, 121 universities, and 25 clusters have been developed since the beginning of the program. Overall, PROSOFT has increased growth of the Information Technology (IT) Industry (C.I. García, personal communication, December 7, 2006). It has been an engine to the IT Industry, and helped to develop and increase well-paid salaries as well as jobs for well-prepared people. PROSOFT allows to develop exportation services and technologies. This program has created a new culture that shows the commitment of the people who are involved in this environment and the best administration of human and material resources.

NEXT STEPS

The results of the program seem to be promising. However, more information is needed and we will continue looking for additional relevant documents. As mentioned before, we will also conduct semi-structure interviews with key participants in the PROSOFT program.

We will develop a model and simulate the behavior of the factors trough time. As an initial phase we will generate a list of all the important factors to the problem, secondly we will analyze and describe each one of the behaviors of this factors by creating graphics over time. Once completed the initial phase we will link all the factors described in the first phase utilizing diagrams (Causal-Loop diagram) in order to visualize the feedback process and to facilitate the simulation process. During the construction of the model several test will be applied to validate the model. Finally, extensive experimentation with the model will yield insights about problems and opportunities in the implementation of the PROSOFT program and similar policies implemented in different countries.

ABSTRACT

Much effort is spent in governmental institutions to provide citizens with access to government processes. However, there are still a lot of steps in these processes that rely on the exchange of printed paper. This is a problem for all people who have difficulties to read, among them humans with visual impairments, elderly people or immigrants. In this paper we present an approach followed in the FABEGG-System. It allows transforming either electronic or paper based documents, particularly forms into a representation that can be read by a computer. Furthermore, it provides the possibility to guide the citizen through a document or form. Thereby, FABEGG improves accessibility for many E-Government processes.

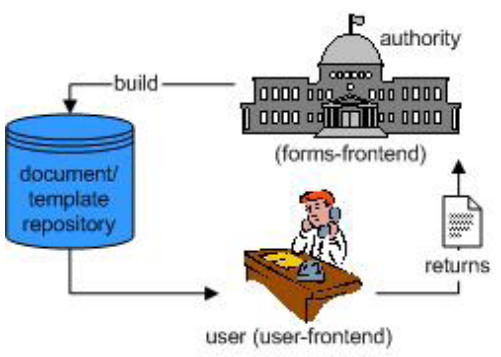
1. INTRODUCTION

In recent years governmental institutions have spent much effort in Human Computer Interfaces to improve access for handicapped persons to computer systems [1]. To a major extent these activities are enforced by legislative constraints that exist in the US (e.g. the Americans with Disabilities Act [2]) as well as in the European Union [3], and in its member countries, like in Germany [4],[5].

Looking closer at many of these systems we may recognize that many of these realizations allow citizens to download particular forms that then have to be printed, completed, and sent to the governmental institution. In processes where an institution contacts a citizen this usually happens by sending paper documents. Often, these documents are forms that are partially completed with data of the recipient related to the processes. The citizen is then asked to complete the form with additional information. This process step is clearly difficult to handle for visually impaired people, elderly or dyslexic people, or immigrants.

In this paper we present an approach which we pursue in the FABEGG system where we try to develop new techniques to improve access to this documents for the humans mentioned before. Figure 1 gives an overview of the document flow supported by the system.

Figure 1. Prozess overview



The document and template repository serves as an interface between citizens and authorities. An authority feeds the repository with relevant information (e.g. statutes of communal companies) or forms. In the latter case we speak of document templates. FABEGG provides modules to support the input of documents into the repository as well as modules to process these documents or templates. In the following we describe these modules in more detail.

2. THE USER FRONT-END

The FABEGG user front-end is an innovative terminal that could be placed in any administrative department. Figure 2 shows a possible configuration of the system with a digital document camera unit to capture printed documents, and a touch screen which is used as display and as an input device.

FABEGG allows to present documents on the display with special effects. For example a document can be enlarged, or different combinations of colours can be chosen, which provide better visibility for humans with particular visual defects. Furthermore, the document can be read by the computer in different velocities. Therefore, speakers are also included in the system. Due to privacy considerations they could be substituted by headphones in a real environment. While reading, the system highlights the text, which is actually spoken, e.g. by drawing a coloured rectangle around the text. This enforces auditory understanding. With a pointing unit (e.g. a mouse or a finger when a touch screen is available) the user can start/stop reading at any arbitrary position within the document.

A citizen who wants to process a governmental document gives a digital image to the FABEGG system, e.g. by taking a picture with the camera in the FABEGG station or by the camera in his mobile phone and sending it via Bluetooth or UMTS. FABEGG uses a component to automatically identify the type of the form. From

Figure 2. Prototype of the FABEGG system

its database it determines the fields that should be already filled by the sender and then guides the citizen through the process of filling the document. The system can read any information contained in the form and provide help information on filling the fields. FABEGG can perform validity checks for the input and can support the user to correct invalid inputs.

After the form is completed it is transformed into a document, which can be inserted into the workflow of the government department. Hence, FABEGG also achieves an improvement for the department, which is responsible for the next step in the process.

3. THE FORMS FRONT-END

The forms front-end is the interface for the governmental institution to insert documents or forms into the repository. It comprises digitalisation and indexing of a document in order to enable users to retrieve the document easily. In our discussion here we focus on the insertion of forms that normally would presented to the citizen as printed forms. An administrator or an official in charge who wants to deploy a form for the system starts with a digital image of the form. He attaches administrative data to the document, i.e. a unique ID, a name, a type etc. Then the official marks the input fields relevant for that form. There may be fields that are already filled when an instance of that form is sent to the citizen; other ones have to be completed by the recipient. The editor can specify the type or format of the requested input, like date, City Code, currency or numbers and he can specify functions to validate the input. This may be known from web-based formulas with JAVA-script. In the FABEGG environment one can do even more tests because we are not restricted to client-side computing. For each field a help text can be associated which can guide the user during completion of the field.

To be able to identify such a template given a scanned document image by a user the editor must define at least one unique anchor for a document. This can be a textual anchor, a barcode or an arbitrary image/pattern on the form. Of course, in large repositories choosing a unique anchor may be difficult. Therefore, we will work on an automated procedure for the anchor definition. This routine could crosscheck all possible anchors on a form with the database to prevent double entries in the database. Having done all this, the document template is stored in the document repository. We use an XML-format to glue together all the different information mentioned above. In this description it is possible to integrate layout information and procedural information (cf. [6]). The layout information includes for example words and their positions in the text, or reading order of fields in a form. Procedural information includes specification of validation functions for user inputs or a strategy to identify an anchor for a specific document.

Another core activity will be the development of an ontology for the application domain. In a first step we will represent the major departments and processes in such an ontology. This will provide a structure, which can be used to insert new documents and forms into the repository automatically. Furthermore, the hierarchical structure can be used to implement an ontology-based retrieval of documents as described in [7].

4. IMPLEMENTATION

The FABEGG system is implemented as a modular system. It contains components for processing and manipulating the document image, components to produce spoken output and components that establish control features, e.g. validity checking or the connection to other components as databases or workflow management systems. Many of these components, in particular the image processing components and the OCR software are only available for Windows based operating systems. Thus, FABEGG is currently a desktop application running only within this environment. Furthermore, we use a commercial speech synthesis component to generate the audio stream while reading the document that is also only available for Windows. For the form recognition we use techniques as described in [7]. Some modules for the image manipulation and for the system design may be found in [8], [9], [10].

The OCR is implemented as a component, which analyses the whole image. It yields the layout structure of the document, including the number and the position of all paragraphs, the position of images or graphical sections, position, style, and recognition confidence for all words in the text with. The result of this process is stored into the XML-file, which is adapted to the structure of the text (paragraph-block-sentence-word).

To capture a paper-based document we use an innovative digital document camera. The application shows a live stream of this camera until the user presses a button to take a snapshot of the actual document. Many of the components we use were developed in a project of the German Ministry of Economics and Labour, called LiveReader [11]. These components contain functions to process digital images, i.e. for zooming or colour manipulation. They also provide us with a software layer for accessing Text-To-Speech synthesis.

5. CONCLUSION AND FUTURE WORK

In this paper we have presented the FABEGG system, which significantly improves accessibility to documents for people with reading disabilities. Together with its form-handling engine which allows inserting forms into the system and retrieving them later on it implements a new functionality to present governmental forms to those citizens. A major advantage of FABEGG is that it can process either electronic or printed forms, which the user receives from the governmental institution. Thus, FABEGG avoids media disruption and integrates paper documents into electronic process chains. Furthermore, FABEGG copes with documents that have already been filled before with individual information before the user receives the form. This type of communication is quite general in nowadays business and governmental processes and cannot be replaced easily by switching to an electronic version.

We will evaluate FABEGG together with some local governmental departments in Germany. This will give further insight into the requirements of our specific user group. Furthermore, we consider implementing FABEGG as a client-server application thus, giving more possibilities for realizing the user front-end.

Andrea Bikfalvi, Universitat de Girona, Spain

1. PROBLEM STATEMENT

University-based scientific inventions that translate into spin-off companies represent a potentially important and increasingly utilised option to create wealth from the commercialisation of research (Carayannis, 1998; Clarysse et al.; 2005; Lockett et al., 2005; Siegel et al., 2003; Vohora et al., 2004). The conventional route to transfer knowledge from university to market has been generally through two means: 1) licensing the rights to use technological discoveries controlled by university owned patents (Intellectual Property-IP) and 2) contract research. In recent years, university spin-off companies have become an increasingly popular way of exploiting potentially valuable research and knowledge; however, understanding this phenomenon remains limited.

This research is motivated by the need to learn more about university start-up companies and particularly those created on the basis of technology developed in universities. We adopt a multi-dimensional approach to study the incubation strategy for spinning-off companies of the University of Girona (Catalonia – Spain). We analyse the strategy of these Public Research Institution (PRI) in terms of resources and activities, how the process of spinning-off ventures is organised and if the outputs fit with this PRI's objectives and the local environment.

This multi-dimensional dynamic approach involves two main different levels of analysis: the local environment at the PRI and the PRI with particular emphasis on the Technological Trampoline (a unit within the Technology Transfer Office in charge of new venture creation) and a secondary one, the spin-off. To guide our research we draw upon three streams of literature that contribute to the understanding of spin-off creation and support at PRIs.

This paper attempts to answer the following questions:

- What is the regional environment for spin-offs emerging from PRI in Girona (Spain)?
- How does the actual model of technology transfer employed by the TT of the University of Girona work and how has it evolved since its foundation?
- Which is the predominant incubation model of managing the spin-off process at the University of Girona?

2. LITERATURE REVIEW AND THEORETICAL FRAMEWORK

First, we make a brief note on the definition of spin-offs due to the complexity and multiple facets of this phenomenon. Then, we draw on the literature related to the resource-based view (RVB) of the firm literature. Next, we review institutional theory. Finally, we draw on the taxonomy of incubation strategies identified by Clarysse et al. (2005) within the European Institutions.

We adopt the definition of university spin-off provided by Pirnay et al. (2003:356) and supported by the majority of the scholars: "new firms created to exploit commercially some knowledge, technology or research results developed within a university". However, we expand this definition taking Nicolau and Birley's (2003:340) definition that stresses that the founding member(s) may include the inventor academic(s) who may or may not be currently affiliated with the academic institution.

2.1. Resource-Based View

A number of researchers have utilised the resource-based view and the resource-based dependence view to analyse issues related to the emergence of spin-off and the resources as a differentiator and a predictor of competitive advantage (e.g. Clarysse et al., 2005; Druilhe and Garnsey, 2004; Pirnay et al., 2003; Shane and Stuart, 2002; Wright et al., 2004). We reviewed the main studies related to the process of spinning-off ventures within PRI that have applied resource-based view and resource-based dependence view. We have identified the main resources analysed and classified them in six broad categories: organisational, social, financial, technological, physical and human resources.

2.2. Institutional Theory

Recent work on the heterogeneity of research-based spin-offs (Mustar et al., 2006) describes the institutional perspective of spin-offs as the relationship and the embeddedness with their parent organisation, which has its own culture, incentive system, rules and procedures. All these elements constitute the structure that needs to be embedded in a supportive context. This context is related to the institutional and policy environment, the culture and the history that has unfolded within the academic institution (Debackere and Veugelers, 2005). We have reviewed the main studies related to the process of spinning-off ventures within PRI that have applied institutional theory and we have identified a set of formal and informal factors.

2.3. Taxonomy of Incubation Strategies

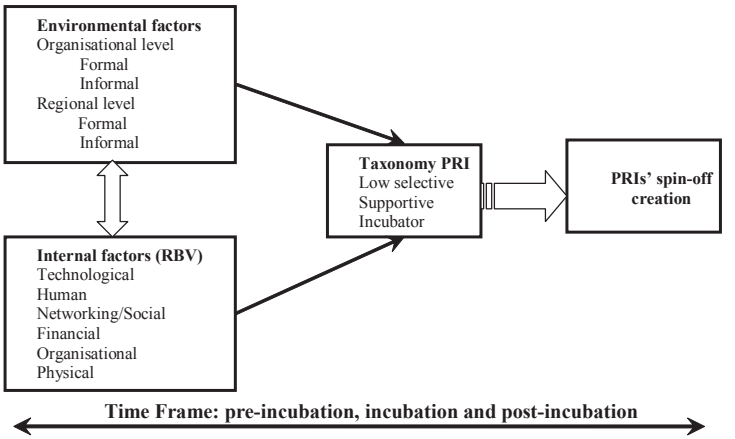
There are very few studies trying to shed light on the different existing taxonomies of European Research Institutions according to their objectives, strategies, resources and activities undertaken. After reviewing the scarce literature on this topic, Clarysse et al. (2005) offered a good comparative framework of taxonomies detected within European Institutions to map the activities, resources and activities undertaken. Based in an in-depth analysis of the seven cases from 13 European regions, Clarysse et al. (2005) identified three distinct incubation models of managing the spin-off process: Low Selective, Supportive, and Incubator.

Considering the previous arguments, we have built a model that combines the theoretical frameworks reviewed to give answer to our research questions. Figure 1 shows this model.

The first category refers to the environment and reflects the institutional view. The concepts included are institutional level factors - like strategy, technology transfer, links after start-up, parent features - and regional level factors - such as role models, social norms and entrepreneurial region.

Internal factors, drawn from the resource-based view of the firm, include all resources needed and provided by the PRI during the process of the new venture creation. We group these resources by the following categories: technological, human, networking, financial, organisational and physical.

Figure 1. Model of spin-off creation in PRIs



3. RESEARCH DESIGN

A two-stage methodology is employed. First, a qualitative approach was used to identify the strategy of the UdG's Technological Trampoline in terms of resources and activities and how the process of spinning-off ventures is organised. In this stage, several methods of data collection were used to address these issues, enabling to cross-check results. Finally, we pattern matched our findings with Clarysse et. al. (2005) typologies with the aim of classifying UdG's incubation strategies in the context of European research institutions and we also analysed its fit with the environment.

In performing this study, we followed procedures commonly recommended for conducting case study research (Eisenhardt, 1989; Yin, 1989). Data collection was performed at different levels and using a mix of techniques, avoiding common method bias. Our multi-dimensional dynamic approach involves: the local environment at the PRI, the PRI with particular emphasis on the Technological Trampoline and the spin-offs that emerged from the TT since its foundation in 2001.

We examined the organisation of incubation spin-off services from the perspective of the parent institute. This entailed looking at two interrelated levels: the internal activities geared towards spinning-off companies and the context in which resources are employed. At this stage, in order to track, analyse and identify resources, activities and changes over the time a history approach was necessary. Herein, the tracing of historic PRI documents (e.g. plans, contracts, etc.) was central and complemented with extensive interviews about the PRI's history and current operations. Thus, we carried out semi-structured interviews with representatives of the TT. Concretely, we interviewed the former and the current head of the TT and the two present business development assistants.

We also interviewed representatives of the spin-offs that emerged from the TT at UdG, focusing on the start-ups history and resource acquisition. Since the foundation of UdG's TT, ten companies have been created and we focused on understanding better the dynamics of venture formation and development as it is embedded in this particular PRI.

4. DISCUSSION

Due to space limitations, we do not provide the discussion of the findings because we consider more important to focus on: conclusions, implications, recommendations, future research and limitations. We would only contextualise our main unit of analysis: the Technological Trampoline.

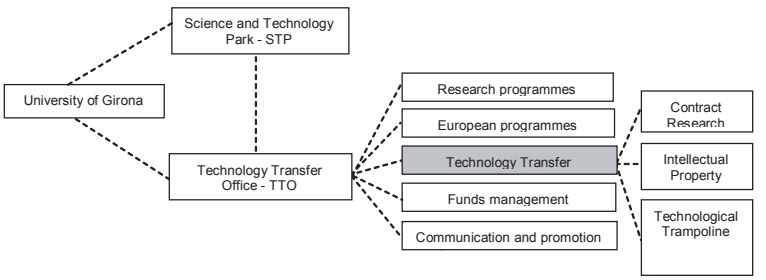
The Technological Trampoline (TT) is a public independent entity integrated in the Technology Transfer Office (TTO)[1] and responsible for promoting technology and knowledge exchange basically through spin-off creation. Although the TT is linked to the TTO in terms of office spaces and other physical resources, its functioning and budget are independent from both the University and the TTO.

5. CONCLUSIONS

The findings highlight that the region of Catalonia is highly entrepreneurial in Spain, but still far from other European scientific regions of excellence like Baden-Würtenberg or Ile-de-France (Clarysse et al., 2005). At the university level, the commercialisation of research happens similarly to the one described in Debackere and Veugelers (2005), but having different magnitudes. The regional environment clearly impacts on the resource acquisition process of the TT and its spin-offs. Concretely, the regional government is financially supporting this unit and at the same time is creating a network of advisors, business angels, IP specialists and other resources and capabilities to help in the success of such companies. Still, support mechanisms mainly come from the regional level, rather than local (city council, chamber of commerce), national or international levels.

Similarly to Germany (Krücken, 2003), where either the regional government (Lander) or the National Ministry of Science and Research were the main driving forces of the TTOs' institutionalisation process, the motivation of creating a

Figure 2. Main units of UdG's science-based and technology transfer activity



spin-off support unit at UdG was twofold. On the one hand, a general interest of a limited group of people to follow the international trend, including transfer-oriented professors and technology transfer officers. On the other hand, the regional government's initiative to help universities create the adequate structures to facilitate the commercialisation of research via spin-off creation. By that time, the university and its managers were still in the "ivory tower". This resulted into a laissez-faire university policy, where the TT followed its own path towards developing and diversifying its activities and finding resources in order to continuously assist and support researchers to carry out their ideas. Lately, the TT in Girona has already gone through a consolidation stage where an institutionalisation of the unit and routinisation of its services has been achieved.

The elements of the three typologies of incubation strategies in European research institutions can be identified at the University of Girona. Nevertheless, the predominant typology at the UdG is the Supportive model. This model stems from the general idea of commercialising technology developed at the RI through other means than licensing or contract research. Hence, the spin-offs are an alternative option to create value from technology and their returns are based on economic profitability rather than financial gains for investors upon exit. Once the TT decides to commercialise technology through a spin-off, the team of researchers is intensively coached, including help with looking for money. However, in the beginning the TT had to create awareness, entrepreneurial culture and role models, thus the spin-offs created did not follow their selection criteria and initial objectives. Therefore, we still can observe a mixed model between Low Selective and Supportive. According to Clarysse et al. (2006:212) "…it is important for RIs to be very clear about their objectives and specify clearly the resources that are needed/activities performed to meet these objectives". The lack of clarity about the TT's objectives results in hybrid types that can be either resource or competence deficient. In fact, we have observed a hybrid model as a result of the continuous change in its objectives as a consequence of a learning-by-doing, try-and-error process and lack of sufficient competitive research.

Another problem identified at the UdG is its shortage of competitive research, which hinders any support to technology transfer activity. In fact, the UdG is only capable of spinning-off one or two technological companies per year, the rest may not be based on a differentiating/unique technology. Thus, the main point at the UdG lies on whether the applied model and the resources employed are worth used. In our opinion, it appears to be inappropriate to acquire the resources required to perform a Supportive model and then try to perform activities associated with a Low Selective model because their research outcomes are not sufficient.

6. IMPLICATIONS AND RECOMMENDATIONS

Our research suggests that the University of Girona should have a deeper pool of research with commercial potential. There is a need to first become a research university, with high quality of research (knowledge exploration and creation), and regional, national or international recognition. This can be stimulated through: 1) the recruitment, retaining, and development of star scientists; 2) partnership with leading industries in the region; 3) further investment and resources for research activities; and 4) a change in its incentive structure, especially for tenures.

Next, the process of cultural transformation aiming at converting the university into a more entrepreneurial should happen at different levels: teaching centres, including students and professors, administration and institution government. A major diffusion and a higher number of subjects on entrepreneurship and new venture creation are part of this transformation.

Third, although the TT followed a positive development path strongly guided by learning-by-doing that can be observed in both activities and resources, some recommendations are needed:

- A project selection methodology based on well-defined concepts and procedures is needed. Although the criteria and objectives regarding technology are very clear, the results are not completely successful. A clear methodology would automatically drive to resource savings and a better and more efficient allocation of them.
- Recruit more technology transfer officers with an appropriate private sector background and links with the local industrial districts in order to discover new opportunities, including experience of starting a business.
- At the university level, an incentive mechanism targeted at research groups and individual researchers should be designed by this embedded institution taking into account: academics profile, specific needs and regional industrial districts. Knowledge on existing practices in European research institutions having a more advanced entrepreneurial culture might be a starting point when designing incentive structures and schemes for local academics willing to start a business.
- Although the decentralised organisation gives the TTO freedom of actuation by establishing their goals, mission and objectives, there are no monitoring mechanisms of the impact of their activities in the local environment. Despite spin-off companies are commonly used as a performance indicator, they should be a tool and not an aim when creating regional welfare.

Fourth, our analysis shows a high variety of institutions aiming to support and promote innovation in both enterprises and universities in the region. A frequent, regular and devoted process of continuous information about the existence and activities of such institutions and their initiatives (with special emphasis on national and European context) concerning spin-off creation and promotion could be a solution in enhancing the number of science-based entrepreneurial ventures.

7. LIMITATIONS AND FUTURE RESEARCH

First, examination of the broader technology-transfer strategies of the UdG and the research incentive structure was beyond the scope of this study. Further research should examine the rest of technology-transfer strategies and the balance of spin-offs versus other modes of technology transfer such as licensing and contract research. Second, our research does not deal with an in-depth analysis of the organisational or entrepreneurial culture within the PRI and the local environment. Third, the cultural transition of becoming entrepreneurial at both regional and university levels is a complex issue, and a more-detailed analysis based on historical, social and other criteria would make the analysis complete. Fourth, we do not show the results of the analysis aimed at characterising and analysing the success of the spin-offs created at this PRI. This is part of an undergoing research with the main objective of confronting both sides and show discrepancies if any in the model used by the TT and the expected results.

One main limitation and a primary future research field refers to the analysis and comparison of the resources, activities and success of the rest of PRI's incubation strategies in the same region (Catalan universities), then broadening the analysis to PRI's located in other regions within the Spain.

Resource Monitoring and Rule-Based Notification: Applications in Subsea Production Systems

Darijus Strasunskas, Norwegian University of Science and Technology, NO-7491, Trondheim, Norway; E-mail: dstrasun@idi.ntnu.no

ABSTRACT

An industrially driven consortium launched the Integrated Information Platform project in 2004. The main objective was to extend and formalize an existing terminology standard for the petroleum industry (ISO 15926) in to formal ontology. The ontology is used in monitoring of drilling and production processes. The paper presents research in progress on development of rule-based notification in subsea production systems to monitor and analyze production data. The task is elaborated and exemplified by data from the real case.

INTRODUCTION

Subsea petroleum industry and production systems used there are information-intensive. When a well is put into operation, the production has to be monitored closely to detect any deviation or problems. Furthermore, the next generation subsea systems include numerous sensors that measure the status of the systems and send real-time production data to operation centers. For these centers to be effective, they need tools that allow them to understand this data, relate it to other relevant information, and help them to deal with the situation at hand.

This paper reports on research in progress on rule-based resource monitoring and notification in the IIP project (Sandsmark & Mehta, 2004; Gulla *et al.*, 2006). The project's primary objective is to extend and formalize an existing terminology standard for the petroleum industry, ISO 15926 (2003). Using OWL Full sublanguage, this standard is transformed into a real ontology that provides a consistent unambiguous terminology for subsea petroleum production systems. The ontology is used in monitoring of drilling and production processes. The objective of this paper is to elaborate on the research in progress regarding rule-based condition monitoring of the subsea devices.

One of the research questions is how to use the ontology together with a rule language (e.g., SWRL (Horrocks *et al*., 2004)). We are investigating how to combine rules with the ontology and what limitations are imposed by chosen OWL Full sublanguage to represent ISO 15926. A key requirement is to reason in a semantically consistent way by exploiting both the ontology and the rules. Since it is impossible to have at the same time decidability, soundness, completeness, performance and expressivity (Golbreich *et al.*, 2005; Horrocks *et al*., 2003), we analyzing limitations and possible rule inference scenarios based on the current version of the ontology in OWL Full sublanguage. In case of too restrictive usage scenarios with regards to the expected features of the application, an alternative of automatic translation from ISO 15926 to OWL DL might need to be considered (Hakkarainen *et al.*, 2006). Currently, we are experimenting with Protégé-OWL, ontology and SWRL editor, OWLJessKB for rule inference and Racer for reasoning.

The paper is structured as follows. Next we introduce the IIP project and ISO 15926 standard. Later we elucidate the task of rule-based condition monitoring and notification in the project. Finally, we conclude the paper by discussing future work.

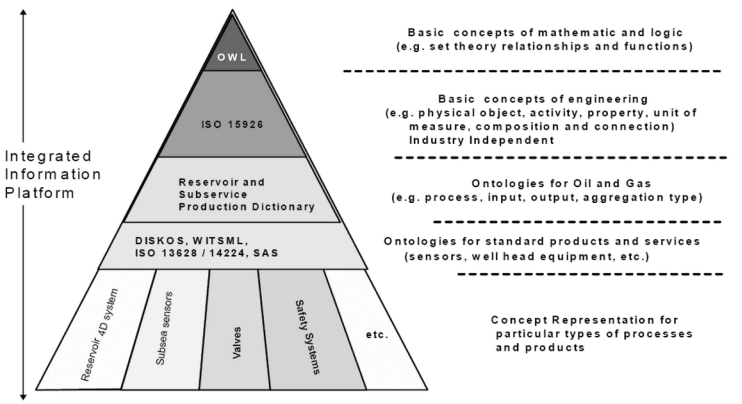
THE IIP PROJECT

The Integrated Information Platform (IIP) project is a collaboration project between companies active on Norwegian Continental Shelf and academic institutions, supported by the Norwegian Research Council. Its long-term target is to increase petroleum production from subsea systems by making high quality real-time information for decision support accessible to onshore operation centers.

The IIP project (Gulla *et al.*, 2006) addresses the need for a common understanding of terms and structures in the subsea petroleum industry. The objective is to ease the integration of data and processes across phases and disciplines by providing a comprehensive unambiguous and well accepted terminology standard that lends itself to machine-processable interpretation and reasoning. This should reduce risks and costs in petroleum projects and indirectly lead to faster, better and cheaper decisions.

The OWL web ontology language is chosen as the markup language for describing these terms semantically in an ontology. A major part of the project is to convert

Figure 1. The standardization approach in IIP



and formalize the terms already defined in ISO 15926 Part 2 (Data Model) and Part 4 (Reference Data Library). Since the ISO standard addresses rather generic concepts, though, the ontology must also include more specialized terminologies for the oil and gas segment. Detailed terminologies for standard products and services are included from other dictionaries and initiatives (DISKOS, WITSML, ISO 13628/14224, SAS), and the project also opens for the inclusion of terms from particular processes and products at the bottom level. In sum, the ontology being built in IIP has a structure as shown in Figure 1 and is exemplified in Figure 3c.

ISO 15926

ISO 15926 (2003) is a standard for integrating life-cycle data across phases (e.g. concept, design, construction, operation, decommissioning) and across disciplines (e.g. geology, reservoir, process, automation). It consists of 7 parts, of which parts 2 and 4 are the most relevant to this work. Part 2 specifies a meta-model or top-level ontology (Batres *et al.*, 2005) for defining application-specific terminologies. Part 2 includes 201 entities. It is intended to provide the basic types necessary for defining any kind of industrial data.

Part 4 of ISO 15926 is comprised of application or discipline-specific terminologies, and is usually referred to as the Reference Data Library. These terminologies are instances of the data types from part 2. Part 4 today contains around 50.000 general concepts. Standards for geometry and topology (Part 3), procedures for adding and maintaining reference data (Part 5 and 6), and methods for integrating distributed systems (Part 7) are under development.

RULES-BASED CONDITION MONITORING

There are envisioned several application areas of the above ontology. Interoperability in the highly multidisciplinary petroleum industry is the main goal, while the tasks of ontology-driven information retrieval and rule-based notification have main focus meanwhile. The rule-based approach will be mainly applied to information quality analysis (i.e. analyze anomalies in real-time data from subsea sensors) and condition monitoring of subsea production.

A scenario for the automatic production monitoring is depicted in Figure 2. A full case of condition monitoring will consist of three main steps: *Data processing*, *Health assessment* and *Treatment planning*. These three steps, including their activities, can be mapped to the corresponding machine condition assessment data processing and information flow blocks identified in ISO 13374 (2003): Data acquisition, Data manipulation, State detection, Health assessment, Prognostic assessment, Advisory generation.

Data processing is the first step including automated activities such as data acquisition and data manipulation. The latter activity includes mapping the actual measurements to data model (the ontology based on ISO 15926 and other standards regulating the petroleum domain), see a code excerpt in Figure 3b.

Figure 2. Rule-based condition monitoring

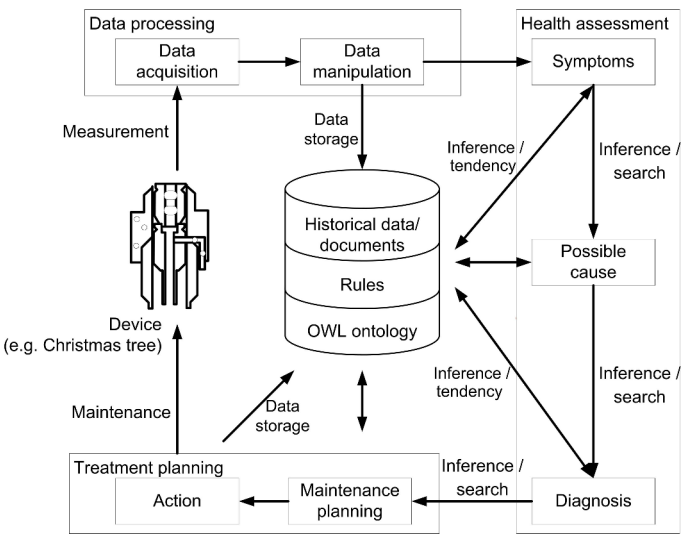


Figure 3. Exemplifications of a) daily production report in XML; b) definition of maximum operating temperature for a choke; c) ISO 15926 ontology

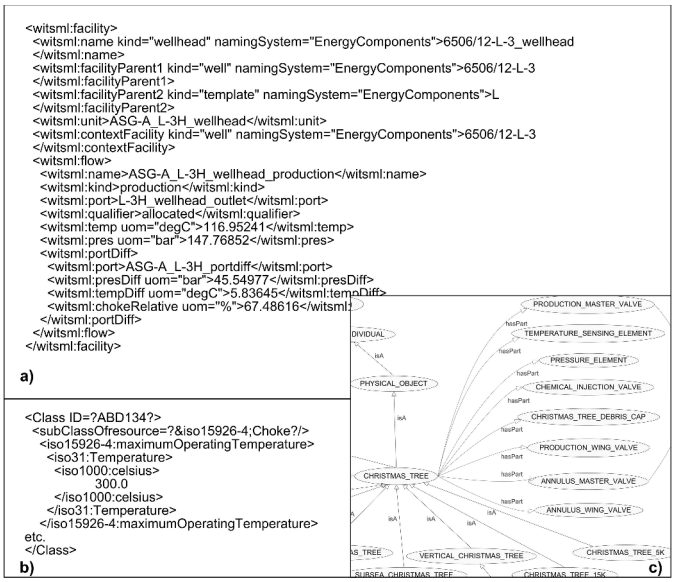

The *health assessment* step is heavily based on the rules and involves most of reasoning. The rules are used to identify possible symptoms, then possible causes, and finally infer a diagnosis. The activity concerning symptoms identification takes care of monitoring of states, i.e. analysis of data flow. Here an example of the rule would be: *if a choke has a temperature sensor and temperature is equal or above the maximum operating temperature then the choke is in critical state*. This rule is illustrated below using SWRL built-in predicate `swrlb:greaterThanOrEqual` (Horrocks et al., 2004), and incoming data in XML format are exemplified in Figure 3a. Then rules defining dependencies among measurement classes are used to infer possible causes and diagnosis.

```
hasTemperatureSensor(?x,?y)∧hasTemp(?y,?temp)∧hasMaximumOperatingTemp(?x,?maxtemp)∧
swrlb:greaterThanOrEqual(?temp,?maxtemp)→hasCriticalState(?x,?temp)
```

The *treatment planning* step takes care of the last two activities in the condition monitoring cycle, i.e., maintenance planning and actions that need to be taken in order to resolve the situation. This step either notifies the responsible controller who needs to perform the actions (e.g. *increase choke opening by 10%*) or executes the action automatically.

It is planned to integrate the rule-based condition monitoring and notification with ontology-driven information retrieval system (Tomassen *et al.*, 2006). As shown in Figure 2 searching for the relevant information is designed to be supplemental way of interaction with the system, since covering all possible cases by rules is a labor-intensive and not trivial task. Therefore, it is important to enable users to access previous reports and documents related to the problem on-hands. Smooth transition between these two different interaction ways is a big challenge as well.

CONCLUDING DISCUSSION AND FUTURE WORK

One problem in the project is that the full expressive power of OWL (OWL Full) is needed in order to represent the structures of ISO 15926-2/4. Reasoning with OWL specifications is then incomplete and inference becomes undecidable (Horrocks *et al*., 2003). Therefore, here we are investigating the limits of inference using the ontology implemented in OWL Full. This will allow identifying possible scenarios and restrictions in using OWL Full for a such scale project. We are exploiting the logical properties of OWL and experimenting with the rule-based notification using Protégé-OWL, OWLJessKB and Racer.

Furthermore, a certain future work will be an alignment of the method with Mimosa's open systems architecture for condition based maintenance (Mimosa, 2007). Mimosa is an alliance for machinery information management open systems with the main objective to enable open standards-based operations and maintenance interoperability.

ACKNOWLEDGMENT

This research work is funded by the Integrated Information Platform for reservoir and subsea production systems (IIP) project, which is supported by the Norwegian Research Council (NFR), project number 163457/S30.

ABSTRACT
In today's educational and work environments, teams often consist of members who are not co-located, and who interact through computer-mediation. Research on such distributed teams has focused on the effects of computer-mediation on decision making, performance, and performance measurement, but, with the exception of a few studies, little research has been done on the social-psychological effects of team distribution with regards to cohesion. This paper describes our current research investigating the effects of team member distribution on team cohesion.

Keywords: Computer-medicated communications; Human-computer interaction, Teams, Cohesion

INTRODUCTION
In today's educational and work environments, teams often consist of members who are not co-located, and who interact through computer-mediation. Research on such distributed teams has focused on the effects of computer-mediation on decision-making, performance, and performance measurement. With the exception of a few studies, (e.g.; Dewiyanti, Brand-Gruwel, Jochems & Broers, 2007) little research has been done on the social-psychological effects of team distribution with regards to cohesion.

This paper describes our current research investigating the effects of team member distribution on cohesion. We begin with a brief review of the literature on distributed teams, followed by a review of the cohesion-performance literature. We then briefly describe our method, and conclude with some discussion regarding further areas of research, and possible implications of our study.

DISTRIBUTED TEAMS
We know that communication technology has social system effects that result from changes in what and who people know, what people care about, and altered system interdependencies (Sproull & Kiesler, 1991). On a more specific level, we know that communications media may cause a variety of effects not found in face-to-face communications. It is, however, difficult to make sweeping generalizations about the impact of media on communications beyond those two points, as media vary in their richness and effects. One approach to discussing communications effects was suggested by Clark and Brennan (1991), who categorized different communication modes along the dimensions of sequentiality, audibility, visibility, co-presence, simultaneity, and co-temporality.

Co-temporality refers to whether a message is received at the time it is sent. Simultaneity means that interactants can send messages at the same time, and sequentiality means that interactants' messages stay in sequence. These three media characteristics regulate the flow and continuity of conversation. Without these attributes, the logical sequence of discussions becomes disjointed, and as a result, the psychological distance between communicators increases. This psychological distance brings about increased focus on the task, and a decreased emphasis on the transmission of social information (Kiesler, Siegel & McGuire, 1984; Silvester, Anderson, Haddleton, Cunningham-Snell & Gibb, 2000; Tu, 2000).

Visibility and audibility generate effects on communication through the presence or absence of non-verbal cues. These non-verbal cues also reduce psychological distance and regulate the flow of conversation (Daly-Jones, Monk & Watts, 1998; Grahe & Bernieri, 1999; O'Malley, Langton, Anderson & Doherty-Sneddon, 1996; Rockwell, 2000).

Co-presence simply means that interactants are located in the same physical setting; however, the implications of co-presence on communications are complex. One effect of co-presence is to make the dyadic partner more salient, more "real;" as a result, the primary impact of social presence is on psychological closeness. The absence of social presence results in: a) reduced other-awareness, b) more uninhibited behavior, c) less responsiveness to another's ideas, d) less public self-awareness, e) more social loafing, and e) more conflict (Anderson, Newlands, Mullin & Fleming, 1996; Chidambaram & Tung, 2005; Fletcher & Major, 2006; Hinds & Mortensen, 2005; Mortensen & Hinds, 2001; O'Malley, Langton, Anderson & Doherty-Sneddon, 1996; Sellen, 1995; Short, Williams & Christie, 1976; Wilson, Straus & McEvily, 2006).

COHESION
Cohesion is an important component of teamwork. With regards to cohesion and team performance, Mullen and Copper (1994) performed a meta-analysis and found a "small but significant effect," while Carron, Colman, Wheeler and Stevens (2002) conducted a meta-analysis of the cohesion-performance relationship in sports and found a significant moderate to large relationship.

In terms of specific studies, rather than meta-analyses, Michalisin, Karau, and Tanpong (2004) used a resource-based view of firm performance to test the idea that strategic assets, in this case top management team cohesion, would be significantly associated with superior performance, and found that cohesion was, in fact, associated with firm performance. Shamir, Brainin, Zakay, and Popper (2000) investigated the relationship between the perceived combat readiness of Israeli Defense Forces and a number of predictors, and found that the strongest predictor of perceived readiness was identification with the unit. Spink, Nickel, Wilson, and Odnokon (2005) examined male ice hockey players and found that task cohesion predicted variance in team task satisfaction. Zaccaro, Gualtieri, and Minionis (1995) focused on task cohesion as a facilitator of team decision making under stress, and found that highly cohesive teams under pressure performed better than teams low in cohesion. Similarly, Eys, Hardy, Carron and Beauchamp (2003) examined the effect of group cohesion on anxiety in sports teams, and found that cohesion was negatively correlated with anxiety.

METHOD
Two identical undergraduate classes, one on-line and one classroom–based, will be assigned a team project. At the end of the semester, students in both classes will be asked to evaluate their team's functioning and cohesion, using a modified version of a scale developed by Powers, Sims-Knight, Topciu, and Haden (2002).

Each team's final product and satisfaction with the process will be evaluated by two independent raters. Therefore, determining inter-rater reliability (IRR) is a pre-requisite before aggregating the data. Several methods exist for evaluating IRR; percentage agreement (Linn & Gronlund, 2000), the r_{wg} statistic proposed by James, Demaree, and Wolf (1993), Cohen's kappa (k) , pairwise correlation, various chi-square tests, and Kendall's coefficient of concordance (Tinsley & Weiss, 1975). Unfortunately, there is no obvious choice of an index of agreement. Dunlap, Burke, and Smith-Crowe (2003) suggest that IRR should assess that a reasonable consensus exists to aggregate individual level data to the group level, and that it should allow the conclusion that the apparent agreement for the group is significantly different from chance responding. Burke, Finkelstein, and Dusig (1999) proposed the average deviation (AD) index, which is the method chosen in this study.

Only those groups with AD on satisfaction scores that indicate acceptable levels of agreement will be used in further analysis. For the ratings of product quality, AD will be used as the metric to determine whether further rater training is required to reach acceptable levels of inter-rater agreement.

For all satisfaction measures, t-tests will be used to compare means between the two groups. In addition, we plan to stratify respondents by project quality, and examine differences in responses by strata.

CONCLUSION

In today's educational and work environments, virtual teams are becoming more common. Although the specific effects vary by the type of media used, commonalities are: increased psychological distance between communicators, increased focus on the task and a decreased emphasis on the transmission of social information; less responsiveness to another's ideas; more social loafing, and more conflict.

Improving cohesion in virtual teams may be a solution to some of these problems, as research indicates there is a significant relationship between cohesion and performance; cohesion and task satisfaction; cohesion and stress, and cohesion and perceived social loafing. One of the few studies that examined group cohesion in distance learning found that cohesion influenced students' satisfaction (Dewiyanti, Brand-Gruwel, Jochems & Broers, 2007). While not directly examining cohesion, Hinds and Mortensen (2005) investigated the relationship between distributed teams and conflict, and found that shared identity – an aspect of cohesion - moderated the effect of distribution on conflict.

Institutions (Also) Matter in E-Government: The Case of Bolivia

Mila Gascó, International Institute on Governance of Catalonia, c/Balmes 335-337, entlo. 1ª, 08006 Barcelona, Spain; E-mail: mila_gasco@yahoo.es

INTRODUCTION

For the past five years, several e-government global, regional, and local benchmarks have been carried out. Although not all of them have included Bolivia in their analysis, the ones that have coincide in their perceptions about the implementation of e-government in this country. Generally speaking, Bolivia usually ranks below both the Latin America and the world average. In *Benchmarking e-government*, Ronaghan (2002) classified the country as one with e-government medium capacity and interactive presence. Despite the fact that Bolivia performed better than most countries in Central America, East Asia, and Africa, it was still far from the most developed nations such as the United Nations, New Zealand or the United Kingdom as well as from some Latin American countries being the most remarkable the cases of Brazil, Mexico, Argentina, Chile, and Uruguay.

The *United Nations World Public Sector Report 2003*, on the other hand, also placed Bolivia in a worse position than other South and Central American countries. Its e-government readiness index score of 0.411 was lower than the regional average (0.442) and, in fact, it was closer to the South and Eastern Asia average (0.410).

Finally, in the *United Nations E-Government Readiness Report 2004*, of the twenty Latin American countries surveyed, only eight countries ranked below not only the regional average but also the world average. Again, that was the case of Bolivia whose score also dropped from 0.411 (position 78th) to 0.3863 (position 88th). Although this loss was not as dramatic as that of Paraguay, comparatively speaking, Bolivia's e-government performance was one of the worst in relation to the set of countries considered. This fact has to be seriously considered particularly because the region as a whole improved, as did the world globally speaking.

Although, as previously showed, Bolivia has tended to lose out in the set of world comparative rankings, during the last years, the country has designed and implemented several projects aimed at introducing the new information and communication technologies in the public sector. Therefore, it can be stated that the poor results displayed are not due to government inactivity. Instead, there are other variables that play an essential role in Bolivian e-government success or failure.

Several authors have already reported that a limited human and technological infrastructure has a decisive impact on how a country performs in terms of e-government. Bolivia is not an exception. But this cause-effect view can turn out to be too narrow. This unfinished research is aimed at making evident the existence of other more structural factors that also influence e-government accomplishment. So far, the literature review and the interviews conducted have focused on some of the more outstanding e-government projects that have been carried out in Bolivia. This has proved that, despite the results shown in the reports previously cited, Bolivia is striving to move towards the inclusion of ICTs in the public sphere. In the current stage, and a as a consequence of the perceived poor performance already stated, other (institutional) factors are being explored, besides ICTs penetration level and illiteracy, that are believed to have to be considered to understand why the country is not being successful in its efforts.

THE STATE OF E-GOVERNMENT INITIATIVES IN BOLIVIA

Bolivia has since 2005 a national strategy for the development of the information society (http://www.etic.bo/Default/default.htm) although the country has not developed an e-government strategic plan yet. Nevertheless, since 2002, when the supreme decree number 26.553 established ADSIB, the Agencia para el Desarrollo de la Sociedad de la Información en Bolivia (the Agency for the Development of the Information Society in Bolivia), the country has implemented several projects in order to make digital government a reality.

To start with, back in 2002, the government presented a document called *Lineamientos para la Estrategia de Bolivia en la Era Digital* ("Ideas for a Bolivian Strategy in the Digital Era") that gave the Vice-presidency of the Republic the responsibility to launch the program Bolivia en Línea (Bolivia Online) aimed at integrating all the public sector portals, at helping public agencies to design new web pages, at standardizing Bolivian web pages, and at strengthening local government computing systems (Ministry of Sustainable Development and Planning, 2002). Despite this effort, the document was too broad and the initiatives depicted were not concise. As a result, several e-government projects, related to both back office and front office adjustments, started to take place on a heterogeneous basis and without the required coordination.

Most of those projects pursued the integration and improvement of internal information systems. That was the case of the automation of the management and register system developed to enhance the implementation of the financial decentralization program ILACO II, or of SIGMA, the Sistema Integrado de Gestión y Modernización Administrativa (Integrated System of Management and Administrative Modernization), a project implemented by the Ministry of Finance aimed at automating the public budget management, the public provision of goods, and the human resources management.

Several front office initiatives have also been carried out in Bolivia. In this sense, it is important to note that there are more than 70 governmental web pages. Despite the growing number of web pages related to the Bolivian government, most of them (the Ministry of Sustainable Development and Planning, back in 2002, referred to the 85%) are merely informative pages that have been designed as simply broadcasting vehicles. Even the Guía Nacional de Trámites (National Requirements Guide), available at http://www.tramites.gov.bo/, is only a tool that provides information about how to proceed with certain formalities, which steps to take every second, and which institutions to consult if problems arise. In a country like Bolivia, geographically handicapped, where its citizens are still forced to travel for hours to access the governmental information, the possibility of retrieving it by the means of the Internet or other electronic devices is an important step forward.

Finally, despite the fact that many websites are open to the citizens' opinions and views, the e-democracy field is probably the less developed. This might be due to the socio-economic situation of the country, which leads to low levels of connectivity and, therefore, hinders the promotion of the democratic process by the means of online tools. Also, the current consolidation process of the Bolivian institutions shows that the priority is to achieve more social participation using those mechanisms that are closer and more familiar to the population.

THE E-GOVERNMENT DIVIDE IN BOLIVIA

Despite the described efforts, the yearly rankings on e-government do not show any important progress for Bolivia (see Table 1).

As a result, the existence of a so-called electronic government divide can be confirmed. In this sense, it can be stated that the country experiences both a regional e-government divide (or the digital gap that refers to e-government actions among countries that belong to Latin America) and a domestic e-government divide (which explains the difference between the advanced online public administrations and the more backward ones in the framework of Bolivia) regardless of the digital government initiatives that have been implemented throughout the years (Gascó, 2005).

Table 1. E-government readiness index

Year	Position in ranking	Index
2003	78	0.411
2004	88	0.3863
2005	85	0.4017

WHAT EXPLAINS THE POOR RESULTS?

Two variables are usually considered when studying what gives rise to differences in public sector technological projects. In the first place, e-government actions are useless if connectivity remains an unresolved issue because, when that is the case, only a very small percentage of people can have real access to the initiatives. Also, as Gascó (2005) explains, if the adoption of technology is slow and poor, governments experience their own technical and managerial difficulties. The availability of resources (that can be measured by the means of the human development index since it is strongly influenced by a country's economic and social composition) is the second factor that influences how decision makers, policy planners and public sector managers elect to approach, develop, and implement e-government programs (Ronaghan, 2002).

Bolivia's ICT diffusion rankings are shown below (to be able to make comparisons, it is important to note that the USA ranked second in 2004):

Also, the human development index in 2005 was of 0.687, which is lower than that of the USA (0.944), Italy (0.934), Chile (0.854), Costa Rica (0.838) or even China (0.755).

In spite of what has already been said, the researcher of this project believes that there is a third factor that explains the poor e-government results of Bolivia. According to this, the evolution of the use of ICTs by the public sector is parallel to the transformations that have taken place in the public administration as a result of the state reform processes. As a consequence, the role (and therefore the importance) of technology is different in each stage of the public sector modernization process. Also, it is the result of how that reform process is conceived and is taking place (see Table 3).

According to the preliminary findings of this research, Bolivia's public administrations are in the initial stage. These bureaucratic organizations are very resilient to change. What's more, in the case of Bolivia, one can state that the reform has hardly taken place due to the existence of odd, pre bureaucratic structures that has given rise to patronage practices patterns that are extremely difficult to eradicate. As the World Bank noticed back in 2000, "a weak private sector practically incapable of generating employment for the middle class, politicians' interest in obtaining electoral support from and control of the government bureaucracy, and a fragmented party system which forces political organizations to negotiate coalition agreements, are cited as sources of patronage and clientelism".

Type of organization	Modernization stage	ICTs role
Bureaucratic	Initial. The goal is to improve efficacy and efficiency	In the automation of work flows and internal processes reorganization
Professional	Advanced. The public management model has already been adopted (emphasis on efficiency but, also, on meeting the citizens' demands and expectations)	Without forgetting the previous achievements, ICTs make the interaction between the public administration and the citizens easier by the means of portals and web pages
Relational	Consolidating and institutionalizing the process. The governance paradigm has been adopted (the citizen is not only a customer but an important participant of the governability processes)	Key regarding transparency and accountability

Misplacing the Code: An Examination of Data Quality Issues in Bayesian Text Classification for Automated Coding of Medical Diagnoses

Eitel J. M. Lauria, Marist College, Poughkeepsie, NY, USA; E-mail: Eitel.Lauria@marist.edu
Alan D. March, Universidad del Salvador, Buenos Aires, Argentina; E-mail: amarch@conceptum.com.ar

ABSTRACT

In this article we discuss the effect of dirty data on text mining for automated coding of medical diagnoses. Using two Bayesian machine learning algorithms (naive Bayes and shrinkage) we build ICD9-CM classification models trained from free-text diagnoses. We investigate the effect of training the classifiers using both clean and (simulated) dirty data. The research focuses on the impact that erroneous labeling of training data sets has on the classifiers' predictive accuracy.

Keywords: Text classification, Bayesian machine learning, health care coding, ICD9-CM

INTRODUCTION

Most of the data in health care settings are recorded as free text in narrative form, and are therefore prone to typographical errors and misinterpretations of ambiguous terms and phrases. To try to solve this issue, researchers and practitioners have recurred to the manual coding of information contained in clinical documents, using different coding schemes. One of the most widely used coding systems is the International Classification of Diseases (ICD), published by the World Health Organization, and in particular the Clinical Modification of its 9th edition, known as ICD-9-CM. ICD-9-CM has a hierarchical structure through which diagnose codes may be aggregated into blocks of decreasing level of detail.

The problem with ICD-9-CM is that manual coding is a costly, non-trivial task, requiring well-trained human resources. ICD-9-CM is not a mere list of codes: it is a complex ruled-based system devised to assign codes to free text based diagnoses and medical procedures. The extant literature is replete with examples depicting the relationship between coding errors and the level of expertise of health care coders. The vast amount of data generated by health care production environments imposes a restriction on the feasibility of coding all the information in a cost-efficient and timely manner. For these reasons several authors have explored the possibility of automating the coding process. Different techniques have been considered to fulfill this task, including rule-based approaches that rely on grammar-based rules (Friedman et al, 2004), and statistical text classifiers based on machine learning algorithms (March et al, 2004)

When dealing with statistical classification for automated coding, the quality of the input data used for training purposes becomes an item of concern. The effective use of statistical machine learning algorithms requires that the input data attain a certain degree of quality. There is a tradeoff between the cost of guaranteeing input data quality and the cost of misclassification given by inadequate predictive accuracy of the models developed with the input data at hand.

Two types of input data errors can be analyzed: (a) free text diagnoses containing misspellings or semantic ambiguities; (b) erroneous assignation of ICD-9-CM codes. In previous work we have focused on text errors in diagnoses (Lauría & March, 2006), disregarding potential erroneous coding. In this paper we center on coding errors: we address the issue of building text classification models based on statistical machine learning algorithms using training data in which the quality of ICD9-CM codes is questionable. Our research deals with Bayesian classifiers, specifically naive Bayes and shrinkage-based naive Bayes (McCallum et al, 1998).

ICD9-CM codes are assigned by human experts who manually review cases. There are multiple factors that can give way to errors of judgment, including the amount of time dedicated to review each case, the resources at hand, the training and expertise of the coders and the complexity of the coding process. The training data set could therefore contain clean free text diagnoses but "dirty" codes.

BAYESIAN TEXT CLASSIFIERS

Text classification can be seen as the task of estimating the unknown target function $\mathsf{f} : \mathsf{D} \rightarrow \mathsf{C}$ that assigns each document $d_j \in \mathsf{D}$ to a given category value $c_i \in \mathsf{C}$, where C is a predefined set of categories, and D is a domain of free text documents. Through supervised learning from a set of documents $D \subseteq \mathsf{D}$, a model $\hat{\mathsf{f}} : \mathsf{D} \rightarrow \mathsf{C}$ can be built to approximate the target function f. Text classification is a well studied problem, with numerous machine learning techniques that have been proposed in the literature, including probabilistic (Bayesian) methods, regression methods, decision trees, neural networks, support vector machines, maximum entropy algorithms, and classifier committees.

Naive Bayes learners have proven to be quite successful when applied to text classification, as reported by Joachims (1997). In the naive Bayes learning framework, a document *d* is classified by computing the posterior probability of each class $\mathrm{P}(c_i \mid d) \propto \mathrm{P}(d \mid c_i) \cdot \mathrm{P}(c_i)$, and assigning the most probable class given the document's words. Naive Bayes makes the simplifying assumptions that a) the probability of each word in a document is independent of its surrounding words given the class; b) the probability of each word in a document is independent of its position in the document. The naive Bayes classification criterion results in:

$$c_{NB} = \arg\max_{c_i \in \mathsf{C}} P(c_i \mid d) = \arg\max_{c_i \in \mathsf{C}} P(c_i) \prod_{k=1}^{|d|} P(w_{d_k} \mid c_i) \qquad (1)$$

where w_{d_k} identifies the word in position *k* of document *d*. The subscript d_k indicates an index into the vocabulary V of training data set *D*. Priors $P(c_i)$ are calculated by computing frequency counts on training data set *D*. Each conditional probability $P(w_{d_k} \mid c_i)$ is calculated as:

$$P(w_{d_k} \mid c_i) = \frac{N_{ik} + 1(\ )}{\sum_k N_{ik} + |\mathcal{V}|} \qquad (2)$$

We define N_{ik} to be the count of the number of times that word w_{d_k} is present in the concatenation of all sample documents that belong to category c_i. Note that the relative frequencies are supplemented by standard Laplace smoothing to

avoid probability estimates equal to zero. For a detailed analysis of naive Bayes text classification see Mitchell (1997).

HIERARCHICAL NAIVE BAYES CLASSIFICATION

For text classification problems with a large number of categories, the training data for each category are sparse, rendering less reliable conditional probability estimates, which in turn affect the performance of naïve Bayes learners as effective classifiers. But if the set of categories has a hierarchical structure, as in the case of ICD9-CM, the accuracy of a naïve Bayes classifier can be significantly improved by taking advantage of the class hierarchy. McCallum et al (1998) have used a well known statistical technique, known as *shrinkage*, that smoothes the conditional probability estimates of data-sparse leaf nodes in the class hierarchy with those of their ancestors. Intuitively, it is easy to see that the probability estimates at the leaf level are more specific but less reliable since they are calculated using less training data. The probability estimates at higher levels are calculated using more data, and are therefore more reliable; but are less specific than their corresponding children levels. For each node (class value) in a class hierarchy of *r* levels, the algorithm computes maximum likelihood (ML) estimates

$$\hat{p}_{ik}^{(h)} = N_{ik}^{(h)} / \sum_{k} N_{ik}^{(h)}, \quad h = 1 \ldots r$$

(as in equation 1, but without Laplace regularization), using all documents in the training data set labeled with that class value. Each node's training data records are filtered to eliminate its child's data before computing the ML estimate, in order to ensure that the probability estimates along a given path remain independent. A uniform probability estimate $\hat{p}_{ik}^{(0)} = 1/|\mathcal{V}|$ is added beyond the root level to deal with unreliable (e.g. zero frequency) estimates caused by rare words. An improved estimate of each leaf node $\hat{p}_{ik}$ is then calculated by "shrinking" (i.e. interpolating) its ML estimate towards the ML estimates of its *(r+1)* ancestors in the tree path

$$\hat{p}_{ik} = \lambda_i^{(0)} \cdot \hat{p}_{ik}^{(0)} + \lambda_i^{(1)} \cdot \hat{p}_{ik}^{(1)} + \ldots + \lambda_i^{(r)} \cdot \hat{p}_{ik}^{(r)} \qquad (3)$$

where $\lambda_i^{(0)}, \lambda_i^{(1)}, \ldots, \lambda_i^{(r)}$ (interpolation weights among the ancestors of class c_i) add to 1.

McCallum et al use an iterative approach (resembling Dempster's EM algorithm) to calculate optimal values of the interpolation weights. For details of the algorithm see McCallum et al (1998).

EXPERIMENTAL SETUP

Training data were gathered and cleaned from 11776 free-text outcome diagnoses occurring in 7380 hospitalizations, which were previously coded by domain experts using the 1999 Spanish Edition of ICD-9-CM. Codes were aggregated at level 3 and level 4 of the hierarchy, corresponding to the Section and 3-digit code levels of ICD-9-CM. Level 3 contained a total of 408 leaf codes, of which 2687 were part of the data set; level 4 included 2687 leaf codes, of which 651 were used. We assessed the representativeness of the test data set to the training data, both in terms of vocabulary and ICD9-CM codes (class labels).

The experiments followed these guidelines:

i. Generate multiple dirty data sets with incremental perturbations of the set of training cases (5%, 10%, 15%,20%,25% 30%,35% 40%, 45%, 50%, 55%, 60%, 65% and 70% of the cases)
ii. For each of these data sets, randomly select 10% of the sample (1178 documents) to be used as hold-out data sets for testing purposes. Use the remaining 90% (10598 documents to train the text classifiers (Note: a test sample of 10% was selected to maximize the amount of training data)
iii. To simulate an error of judgment in the assignation of ICD codes, replace a correct code with another one picked from the ICD-9-CM catalog. The replacement code is selected using combined criteria that include the numeric proximity to the correct code, the semantic similarity of the corresponding diagnoses and the frequency of occurrence of the replacement code in the training sample.
iv. Train the statistical text classifiers using both clean and dirty data. Classifiers are built for every combination of machine learning algorithm (naive Bayes and shrinkage), class hierarchy (level 3 and level 4) and training data set (1 clean , 14 dirty), 2 x 2 x 15 = 60 models all in all
v. Evaluate the classifiers' performance by measuring their predictive accuracy (mean value, standard error, 95% confidence interval)

RESULTS

Table 1 shows the assessment of predictive accuracy performance of both text classifiers. Figure 1 displays the mean accuracy of the classifiers as a function of the percentage of label errors. The shrinkage algorithm

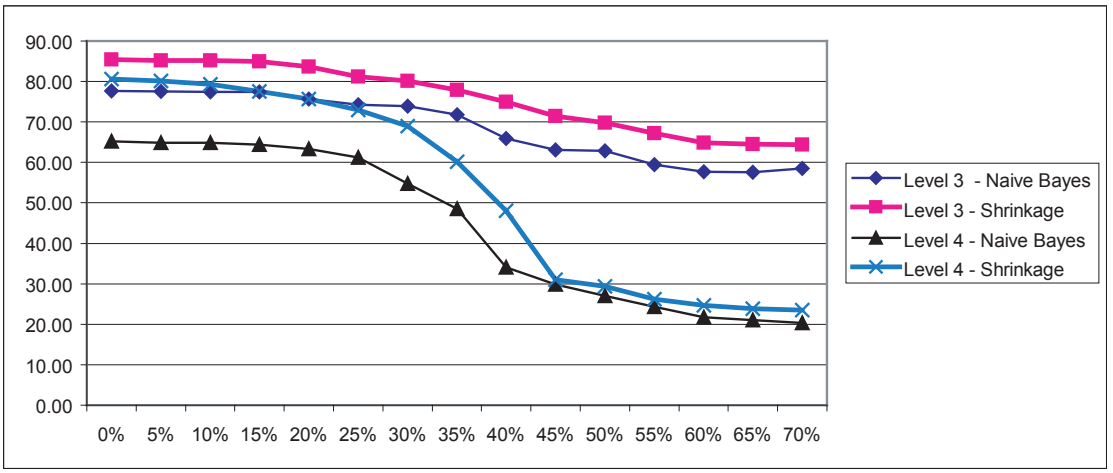
Figure 1. Predictive accuracy as a function of % of errors in training data



surpasses naive Bayes in all cases (all combinations of level 3 / level 4 hierarchies and clean and dirty training data). Both text classifiers s are quite robust when subjected to training data with incremental perturbations in the labels. In particular, shrinkage evidences a rather high level of predictive accuracy with 25% of label errors (81% for level 3 and 73% for level 4). Beyond 30% the algorithm experiences an abrupt decline in performance.

CONCLUSION

Bayesian text classifiers are robust, useful tools for automated ICD9-CM coding. Preliminary results show that Bayesian text classifiers (shrinkage in particular) perform at an acceptable level, even with training data containing partially dirty labels (ICD9-CM codes). This may have a direct impact on the cost incurred in producing training data sets: predictive accuracy ca be maximized with minimum data quality enhancement cost. This kind of research could help derive policy associated with data quality procedures that precede automated coding. Investing in text classification tools should help enhance automated ICD9-CM coding while maintaining low operational costs.

"The future will surprise us, but we must not let it dumbfound us"

- Kenneth Ewart Boulding (1910-1993), Economist and Futurist

INTRODUCTION

There is scarcely any doubt that technological innovation has been an area of remarkable progress in recent decades. The cumulative effect of the thousands of innovations that have come to market has been to make technology central to human existence, be it in business, education, government or in everyday life. However, humankind's track record in *foreseeing* technology innovation - in terms of its rate, direction or impact – has been somewhat less than stellar. Early examples of foresight failures include Thomas J Watson, then IBM Chairman, opining that the world would need no more than 5 computers, and Lord Kelvin's celebrated 1895 dismissal of the possibility of powered flight. In the early 1970s, *Scientific American* wrote that the electronic watch was unlikely to become cheap enough to sell in large quantities - yet, by 1976, quartz watches were selling cheaply in large quantities.

More recent technology predictions that were off the mark – often egregiously - include 3G (third-generation telecommunications technology), the dot.com bubble, Iridium and AT&T's huge underestimate in 1984 for the cell phone market that led it to ignore that market. The ability to foresee the potential of emerging technologies is a big prize indeed – companies can boost the ROI on R&D expenditure manifold, they can predict much better which new products of theirs or their competitors' will succeed – yet this problem has received remarkably little focus.

What are the reasons behind this rather underwhelming track record in foresight? The successful emergence of a technology of importance to business is a function not just of innate superiority but of initial conditions, the scale of investment, the clout of entities backing that technology, and the actions of consumers, competitors and collaborators. Prediction needs the understanding of complex interactions between phenomena which straddle multiple disciplinary boundaries – technology, economics, sociology, organizational behavior, psychology, anthropology, culture, and so forth. Kochikar (2006) and Kochikar and Ravindra (2006) point out a few flaws in our view of technological evolution that further confound our ability to predict new technologies, and suggest some remedies. It has been our endeavor to devise a methodology that corporate managers can use to foresee the potential of emerging technologies, and we present here some early results of such a methodology that is under development.

PREVIOUS WORK

The import of factors other than sheer technological superiority that play a role in a technology gaining widespread business use has been recognized (Griliches 1957, Bresnahan and Pai-Ling 2005). Shapiro and Varian (1998) have identified various factors that determine technology success, including network effects, standards, pricing strategies, and so forth.

Yet, the literature is sparse when it comes to methodologies. In their seminal article, Brody and Stabler (1991) note that faulty predictive ability often implies an improper allocation of resources to R&D within corporations, and there is a need to improve prediction accuracy in order to boost the returns on R&D efforts. As SRI (2006) notes, "the management literature is short on practical solutions for methodically gleaning early signals of change from the surroundings or for cultivating a futures orientation in employees and managers."

Adner and Levinthal (2002) draw parallels with biological evolution (speciation) and provide insights that managers can use in understanding technological evolution. However, they provide no methodology for predicting or foreseeing emerging technologies.

Christensen et al (2004) have presented an exhaustive theoretical framework that can be used to systematically scan the future landscape and spot complex, usually business model-related, changes. However their methodology needs an understanding of 3 theoretical approaches that form the bedrock of their approach: the theory of disruptive innovations, the theory of resources, processes and values (RPV), and the value chain evolution theory (VCE).

SRI (2006)'s SCAN methodology is a promising step in the right direction; it envisages an approach that is strongly driven by intuition and interaction between groups of individuals who collectively have expertise in a set of disciplines including anthropology, business, economics, international affairs, communication, arts, marketing, life sciences, and chemical and electrical engineering. This methodology is suitable for answering open-ended questions such as, what technologies are emerging on the horizon?

We propose a methodology that is simple to use, and at the same time produces reliable results. The methodology is aimed specifically at answering the question, "what are the prospects for emerging technology X in my company (industry)?", where X represents a specific, identified emerging technology. Typically, technologies considered would be those that have shown promise in early applications, that have some backing entities who have invested in them, that have generated some buzz among the *cognoscenti* as well as the lay public, and that are poised on the cusp of widespread adoption.

A METHODOLOGY FOR FORESEEING THE POTENTIAL OF EMERGING TECHNOLOGIES

The methodology takes explicit cognizance of the multi-disciplinary nature of the technology foresight problem, and employs a scoresheet-based approach for arriving at a measure for the potential of a given technology. The methodology holds considerable promise for bridging the current yawning gap in the state of art in this important space – that of technology foresight.

Although, given the immense complexity of the problem, it is probably impossible to design a methodology that is based on purely objective inputs, our approach is a significant step in that direction. Apart from relying on easily available data, it is designed to need 2-3 people at the most to apply it in the context of a given technology and industry. The method is also, as outlined in the previous section, relatively closed-ended and focused. It can thus be used in conjunction with more open-ended approaches.

Our methodology is also designed to produce results that reflect the specific needs of the user and his/her industry, as a given technology may hold different potential for different environments. Finally, the methodology is quick to use and involves minimal effort.

Any approach that offers a modicum of hope for solving the thorny problem of foreseeing the potential of an emerging technology must take into consideration the complex canvas of factors and phenomena that impact success. Our methodology thus encompasses a multitude of factors: supply side or "push" factors, demand side or "pull" factors, as well as characteristics of the business and cultural environment within which the technology seeks to emerge as successful.

We consider the following classes of factors:

Market Action – measures of investment, market forecasts from analysts…, existing implementations if any.
Technology Features – measures of feature richness, pricing, and quality attributes of the technology concerned.
Consumer Psychology – measures of "soft" appeal
Applications – existence of applications by which the consumer or target audience can leverage the technology concerned.
Environmental Factors – competing and complementary technologies, standards, characteristics of the ecosystem,

Each such class is modeled as a 'dimension'. The methodology identifies 17 measures of market action, 30 technology features, 14 measures of consumer psychology, 5 measures of application characteristics, and 9 environmental factors.

Each factor is assigned a score on a scale of 1 to 5 and the score is entered into a scoresheet designed for the purpose. Importantly, not all the factors need to be scored – the users may choose to score as many as they feel sufficiently comfortable / knowledgeable scoring. In examples given, 18-25 factors were scored.

An important characteristic of the methodology, and one that vastly enhances its utility, is that the output is displayed graphically, as a radar plot (also called Spider Chart or Kiviat Diagram). Among other things, the spider chart allows the user to see readily and graphically the dimensions where the methodology has high potential / falls short.

We now present the use of the methodology for gauging a few emerging technologies.

Sample Emerging Technology: Utility Computing
The output produced is as in figure 1. As can be seen, consumer psychology is something of a concern, as organizations may not be overly keen on allowing applications, which often encode proprietary business logic and use sensitive data, to reside outside their enterprise boundaries. Thus, this technology may be more acceptable to an organization where such sensitivity and confidentiality are relatively less important.

Absence of applications is also a major handicap. Thus, a conservative CIO may be less likely to consider switching to utility computing. On the other hand, an intrepid CIO may, on seeing this plot, still decide that absence of applications is not going to deter him/her – as long as market action is high, and the features supported are adequate.

Sample Emerging Technology: Open Source
Here, (figure 2) technological features are a concern area. On drilling into the scoresheet, it can be seen that this shortfall on this front arises primarily from concern about support /maintenance. Customizability also is not a significant area of comfort. The applications dimension is also relatively anemic as robust, industrial-strength business applicaitons using the open source platform are lacking. Once again, it is up to the individual organization's risk appetite to decide whether to proceed with using open source.

Figure 1. Potential plot for utility computing

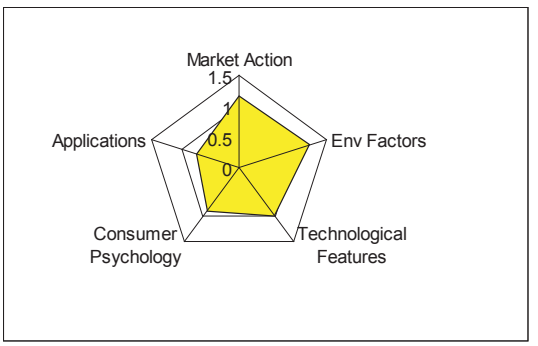

Figure 2. Potential plot for open source

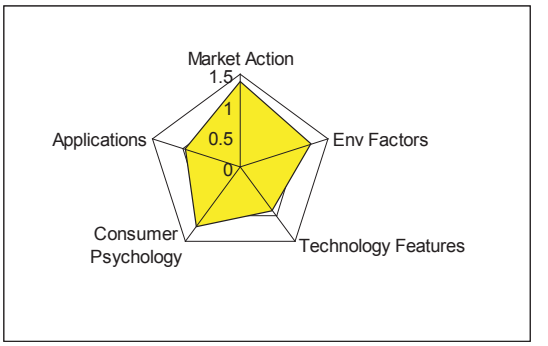

Figure 3. Potential plot for Firefox browser client

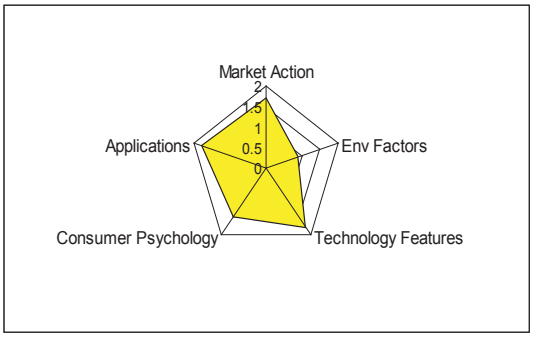

The consumer psychology dimension is also a moderate area of weakness – while concern about IP infringement is no longer a major deterrent, willingness to switch from conventional technology platforms is still not too high.

Sample Emerging Technology: Firefox Browser Client
Here too (figure 3), consumer psychology is a dimension where this technology is trumped – again, willingness of potential users to switch is low. However, the dimension along which this technology well and truly falls short is environmental factors. Clearly, the clout of the incumbent, which is a factor that carries significant weight under this dimension, is just too high!

USING THE METHODOLOGY

The methodology is intended to be used by corporate managers who are interested in gauging the advisability of / need to adopt an emerging technology in their business.

For example, a CIO of a large corporation may seek to decide whether s/he needs to invest in Open Source / Utility computing. The actual scoring may be done by the manager along with one or two technology specialists from within the organization. No expert in the technology concerned is called for. Also, since a given organization is likely to evaluate a relatively small number of emerging technologies, the effort involved is not significant.

The radar plot computation methodology also involves weightages at the factorial as well as dimensional levels, which can be adjusted based on the specific business characteristics, risk appetite, and so forth. It is also worth noting that managers may assign different ratings to individual factors, depending on their industry's needs, their company strategy, or individual preferences. Thus the methodology is not designed to produce a single, 'logically correct' output, but will produce outputs that differ slightly to reflect the needs and drivers of the user and his/her environment.

CONCLUSION: THE WAY AHEAD

The problem of accurately foreseeing how appropriate an emerging technology is for business use has proved itself to be as important as it is intransigent. We have presented a methodology that represents a significant step towards a solution. While considerably more piloting in more varied real life business environments remains to be done, the methodology has shown promise of substantially ameliorating the technology foresight deficit.

A User Profile-Based Approach for Adaptable Belief-Desire-Intention Software Agents

Gerd Schneider, Fraunhofer Institute for Information and Data Processing, Fraunhoferstr. 1, 76131 Karlsruhe, Germany; E-mail: gerd.schneider@iitb.fraunhofer.de

ABSTRACT

An approach is proposed for the development of user profile-based, adaptable Belief-Desire-Intention (BDI) software agents. This proposed approach focuses on the integration of a user profile into the BDI software agent's beliefs and the adaptation of these additional beliefs either by a human user or the BDI software agent. The outcome of this user profile integration and adaptation is a more personalized and user-oriented reasoning process carried out by the BDI software agent and leading to a wider acceptance of software agent technology especially in human-centric fields of application. The realization of this approach is illustrated by applying it to a basic scenario based upon the open source agent framework JADEX (Java Agent DEvelopment eXtension).

1. INTRODUCTION

A Belief-Desire-Intention (BDI) software agent has the capability to adapt its desires, intentions and related plans to changing environmental conditions (beliefs), but it lacks the ability to adjust itself to the preferences and needs of an assigned human user. Especially in the case of interaction with a user and execution of tasks on behalf of a user the missing feature for personalization and adaptation states a significant disadvantage as the user cannot individually optimize his software agent. A user may have personal desires, intentions and preferences which he wants to be fulfilled by a BDI software agent under specific environmental conditions. The same is true for plans which are executed while pursuing a specific intention.

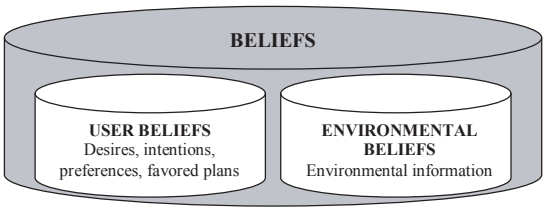
In the following, an approach is proposed to overcome the above-mentioned lack of individual adaptability and personalization of BDI software agents. Section 2 describes the conception of a user profile-based, adaptable BDI software agent and is structured in three subsections describing the basic idea (Section 2.1), the adaptation possibilities (Section 2.2), and the emerging agent architecture (Section 2.3). Section 3 outlines the realization of the proposed approach based upon the open source agent framework JADEX (Java Agent DEvelopment eXtension), while Section 4 presents some conclusions and discusses further work. Finally, in Section 5, the references are listed.

2. CONCEPTION OF A USER PROFILE-BASED, ADAPTABLE BELIEF-DESIRE-INTENTION SOFTWARE AGENT

2.1. Basic Idea

The integration of a user profile into the BDI software agent's beliefs should fix the above-mentioned lack of individual adaptability and personalization and represents the base for the development of an adaptable BDI software agent. Through the involvement of such user information about desires, intentions, preferences, and favored plans the usual BDI software agent's beliefs get separated into two parts: Environmental information (also called *environmental beliefs*) and user information (also called *user beliefs*), shown in Figure 1. These two components form the entire set of beliefs which – due to the integrated user information – allow an individual influence on the reasoning process of the BDI software agent. Especially the BDI functions *generate options*, *filter*, and *planning* are concerned.

Figure 1. Extended set of beliefs



2.2. Adaptation Possibilities

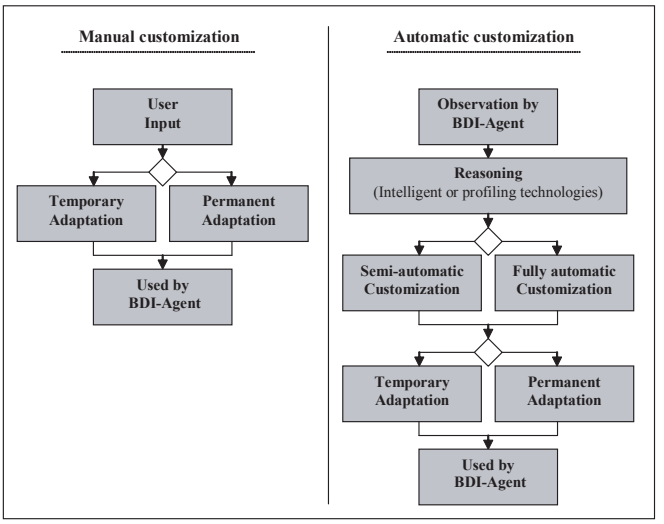
In addition to the integration of a user profile into the beliefs, a second important step towards an adaptable BDI software agent is the customization of this integrated user information. For this purpose, two different ways of user profile adjustment are intended. The first and easiest one is the *manual customization* accomplished by the human user. In contrast to this, the second way to adjust the user profile is an *automatic customization* which will be performed by the BDI software agent. Therefore, the software agent will observe the user's behavior and in case of need it will adjust the user profile, whereas two options of automatic customization should be possible: Either a *semi-automatic customization* at which the human user of the software agent has to confirm the adjustment or a *fully automatic customization* which will be performed autonomously by the software agent (the desired option should be manually adjustable by the human user). To achieve this automatic customization, either additional intelligent technologies (like neural networks or genetic algorithms) or profiling technologies will come into play. Finally, the time limit of a performed customization has to be considered. Either the performed customization refers only to the agent's runtime or beyond it. The first alternative is called *temporary adaptation* and enables the adjustment of the so-called *runtime user profile* located within the BDI software agent's beliefs (see the above introduced user beliefs). The second alternative, called *permanent adaptation*, adjusts the runtime user profile as well as a so-called *persistent user profile* located within a database. The human user gets the possibility to adjust its BDI software agent to one of these alternatives. Figure 2 depicts the sequences of the described adaptation possibilities en bloc.

2.3. Agent Architecture

Based upon the basic idea (Section 2.1) and the adaptation possibilities (Section 2.2) the architecture of a user profile-based, adaptable BDI software agent can be introduced. This architecture is subdivided into three layers, whereas the lowest layer represents the *database layer*, the middle layer represents the *application/agent layer*, and the highest layer represents the *presentation layer*. Figure 3 shows this layered architecture.

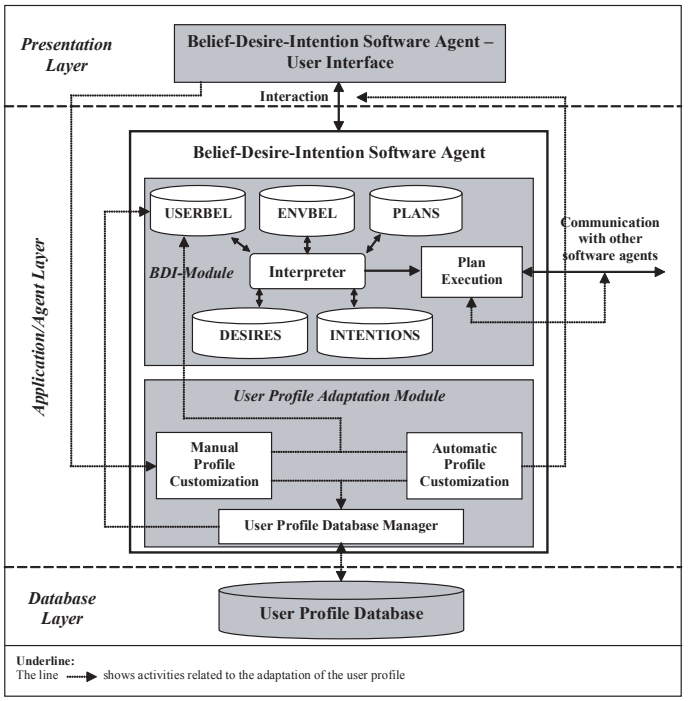
The presentation layer contains a user interface whereby a human user can interact with the underlying BDI software agent to perform custom-designed tasks relevant for a specific field of application. Additionally, the user interface provides the

Figure 2. Sequences of the adaptation possibilities



functionality to adjust the user profile (located within the BDI software agent's beliefs) manually. In the middle layer, also called application/agent layer, resides the adaptable BDI software agent composed of a *BDI-Module* and a *User Profile Adaptation Module*. In contrast to the classical BDI architecture, the BDI-Module gains two extensions: First, beliefs get separated into the introduced user profile/user beliefs (*USERBEL*), also known as the runtime user profile (see Section 2.2), and the environmental information/environmental beliefs (*ENVBEL*). Second, the component plan execution gets integrated, representing the execution of plans selected by the interpreter and providing the functionality to communicate with other software agents. The User Profile Adaptation Module realizes the above-mentioned adaptation possibilities (see Section 2.2) and is separated into two components: The first component is the *Manual Profile Customization*, processing the manual adjustment of the user profile performed by the human user via the user interface. The second component is the *Automatic Profile Customization*, responsible for the automatic adjustment of the user profile and therefore observing the interaction between human user and software agent as well as the plan execution and communication with other agents. The reason for the additional observation of plan execution and communication is that these activities could fail several times, thus requiring the adaptation of the user profile. E.g. a human user prefers a specific plan (specified in the user profile) to be executed by the software agent but the execution fails five times. The software agent observes these failures and provides an alternative plan which leads to an automatic adjustment of the user profile. This additional capability is the reason for the above-mentioned second extension of the BDI-Module concerning the component plan execution. Finally, both described adaptation components provide the functionality to adjust the runtime user profile (USERBEL) as well as the persistent user profile which is stored in the User Profile Database located within the database layer. The access to this User Profile Database is controlled by the User Profile Database Manager, responsible for all database operations.

Figure 3. Architecture of a user profile-based, adaptable BDI software agent



3. REALIZATION OF A USER PROFILE-BASED, ADAPTABLE BELIEF-DESIRE-INTENTION SOFTWARE AGENT

Based upon the open source framework JADEX (Java Agent DEvelopment eXtension) the basic characteristics of an adaptable BDI software agent are already implemented within the scope of the ongoing research. This includes the integration of a user profile into the agent's beliefs, an incorporation of this additional information into the reasoning process, and a manual and semi-automatic customization of the user profile. Additionally, an exemplary scenario is realized to demonstrate the operability of the adaptable BDI software agent. In this scenario two human users can get in touch with each other by means of assigned adaptable BDI software agents. On the basis of user information the contacted software agent identifies how an approach should be handled to satisfy the desires of its user and may come to an autonomous decision. In case of changed user interests the software agent can get informed and will adjust to this new situation. If changes in the user's behavior are detected autonomously by the software agent and a customization of the user profile appears necessary the software agent may perform this customization by itself which also leads to an adjustment of the agent's reasoning process. E.g. if a callee refuses an approach of a caller several times even though the callee's user profile specifies that an approach of this caller is allowed and welcome, the callee's software agent may adapt the user profile after precise observation. In consequence of this adjustment the next approach of this specific caller may end up in a refusal performed by the callee's software agent without the intervention of the human user.

4. CONCLUSIONS AND FURTHER WORK

The current development status shows, that the integration of a user profile affects the BDI software agent's reasoning process and enables user-oriented decisions. Thus, this extended BDI software agent can be used to serve a human user in an unobtrusive and personalized way by what this user can be relieved of secondary tasks and gains additional time to concentrate on more relevant topics. However, there are three key aspects defining further research and development. The first one is the realization of a more complex scenario which requires an extensive reasoning process by the adaptable BDI software agent based upon the introduced user profile. This is necessary to demonstrate the robustness of the elaborated approach. Second, the automatic customization of the user profile has to be improved. The idea is to develop a plug-in framework that allows several so called observation modules to plug in, to observe the user's behavior, and to adjust the user profile if necessary. This ought to result in multiple observation modules, interested in different and independent user behavior and able to modify various pieces of information of the integrated user profile. The last key aspect of further research and development is related to the above-mentioned observation modules. Each of these modules should work using either intelligent technologies or specific profiling technologies. For this purpose, an evaluation and integration of adequate intelligent techniques (like neural networks or genetic algorithms) or profiling mechanisms has to be accomplished with particular attention to the kind

of information required by specific observation modules, the user information which can be modified by specific observation modules, and the over-all context of the entire observation modules.

Integrating Microsoft Dynamics GP Enterprise Resource Planning Software into a School of Business Curriculum: Research in Progress

Jerry Flatto, University of Indianapolis, 1400 East Hanna Ave., Indianapolis, IN 46227, USA; E-mail: jflatto@uindy.edu

ABSTRACT

This research in progress paper looks at the use of Dynamics GP Enterprise Resource Planning software in a classroom environment. The article provides a brief overview of some pertinent literature and an explanation of why Dynamics GP was used instead of other packages such as SAP or Oracle. Finally, some discussion of how the software was used in three different undergraduate classes is provided as well as a brief explanation of plans for the future.

INTRODUCTION

Enterprise Resource Planning (ERP) software has become prevalent in a variety of organizations. ERP systems are information systems that assist in the management of accounting, finance, human resources, manufacturing, customer relationship management, logistics and other business functions by integrating these functions into a single system. This integration of information provides a more holistic view of the organization and allows for the more comprehensive and timely view of the business processes thus leading to more informed and hopefully, improved, decision making (Bradford, Vijayaraman, & Chandra, 2003; Davenport, 1998; Fowler & Gilfillan, 2003; Shoemaker, 2003).

While the integration of business functions has been occurring in organizations, the education of business students has not been evolving as rapidly. Historically, business education is fragmented with different bodies of knowledge taught in separate departments. Although students become specialized in their area, they can sometimes miss the big picture where interdependencies and interconnectedness among business processes create efficient synergies in achieving business targets (Becerra-Fernandez, Murphy, & Simon, 2000; Bradford, Vijayaraman, & Chandra, 2003; Cannon, Klein, Koste, & Magal, 2004; Jones & Lancaster, 2001; Shoemaker, 2003; Wygal & Hartman, 2003).

The use of ERP software in the curriculum can provide students a number of advantages from the conceptual to the practical. The use of ERP software allows students to better understand the flow of information across the organization (Bradford, Vijayaraman, & Chandra, 2003; Jones & Lancaster, 2001; Shoemaker, 2003; Wygal & Hartman, 2003). The use of ERP software in the classroom also provides students with practical hands on skills that are highly desired in industry. Students knowledgeable about ERP systems and who graduate with the much sought after combination of business management and IT skills can help enhance the credibility of a business school in the eyes of industry. Schools with ERP systems in place can also use the software as a marketing tool to attract potential students, and individual departments can attract potential students interested in hands-on knowledge of a real-world application (Becerra-Fernandez, Murphy, & Simon, 2000; Bradford, Vijayaraman, & Chandra, 2003; David, Maccracken, & Reckers, 2003).

However, due to various challenges in deploying ERP software, very few schools are integrating the software across the curriculum. These challenges can include: developing course materials; overcoming the technical and administrative hurdles in installing and maintaining the software and hardware; faculty support for learning and incorporating the software into their curriculum, as well as the associated monetary costs (Becerra-Fernandez, Murphy, & Simon, 2000; Bradford, Vijayaraman, & Chandra, 2003; David, Maccracken, & Reckers, 2003; Rosemann & Maurizio, 2005; Strong, Fedorowicz, Sager, Stewart, & Watson, 2005; Wygal & Hartman, 2003).

MICROSOFT DYNAMICS GP

There are a variety of ERP systems available that may be integrated into the curriculum. This author has been interested in incorporating ERP systems in his classes for roughly seven years. At the time when the process was started, there were effectively three alternative ERP systems that could be selected – Oracle's "Financials" system, SAP, and Microsoft Dynamics.

The University of Indianapolis is a relatively small liberal arts university located in Indianapolis, Indiana. Until recently, this author was the only full-time information systems faculty member in the School of Business. When the author started at the university, he had the school join Oracle's academic initiative as one of the early members of this program. For an annual cost of five hundred dollars, the university had full use of Oracle's database software. This did not include Oracle's Financials (their ERP system). While the database software was provided, the author found difficulties in obtaining support for the software. Oracle did provide access to their support system but unfortunately for various reasons, this support was not always useful. As a matter of fact, the author started an email list of Oracle users in academic environments for faculty to use to provide support to each other.

Thus when the idea of integrating an ERP package into the curriculum was first investigated, Oracle's Financials package was the obvious first choice to evaluate. Discussion with individuals at Oracle's Academic Initiative indicated that there was an annual cost of eight thousand dollars to access the Financials software. More importantly, the technical hurdles of getting the software running would be much greater than getting the database software running. The university's computer services department was stretched thin, as is usually the case at most universities, and was not in a position to provide much technical, nor hardware support, so the author would have to shoulder the responsibility of installing and maintaining the software in addition to a full-time teaching load. Thus, it was extremely unlikely that the university would be able to install the software and maintain it.

The author next looked at SAP. At the time, to use the software in the academic curriculum, SAP would have to be installed and configured on university equipment. The hurdle to accomplish this would be as great, if not greater, then installing Oracle Financials. Thus this was not feasible. As a note, since that time, SAP has initiated a program where a select few universities host the SAP installation and other universities access SAP through a graphical interface. This greatly reduces the effort for a university to incorporate SAP into the curriculum. However, at this point, this author chose not to take that alternative for two reasons. The first was all the effort already put into incorporating Microsoft Dynamics into the curriculum. The second, and more important reason, was that teaching certain aspects of ERP systems such as installation, configuration, and maintenance would not be easily feasible if the software installation was not local.

The third package reviewed was Microsoft Dynamics[1]. This package was not aimed towards large scale organizations but was geared more towards mid-sized organizations. However, in terms of functionality, the software had similar functionality

and capabilities as SAP and Oracle Financials. More importantly, the software and hardware requirements to install the software were much lower and made it feasible to install the software on lab machines running the Dynamics GP software and have the underlying SQL Server database run on the same machine. While running the software in stand alone mode is not optimal, it is certainly better than not having the software at all. Additionally, using the software, it was possible to have students install a stand alone ERP system on their home machines to work on. Finally, the support from Microsoft has been excellent from both a technical aspect and an administrative aspect (i.e., academic alliance support in providing the software, licenses, etc.) In terms of industry use of the software, approximately forty thousand companies are running Dynamics GP according to Microsoft. Thus students with GP experience have a number of opportunities to translate their knowledge of the software into internship and post-graduation jobs.

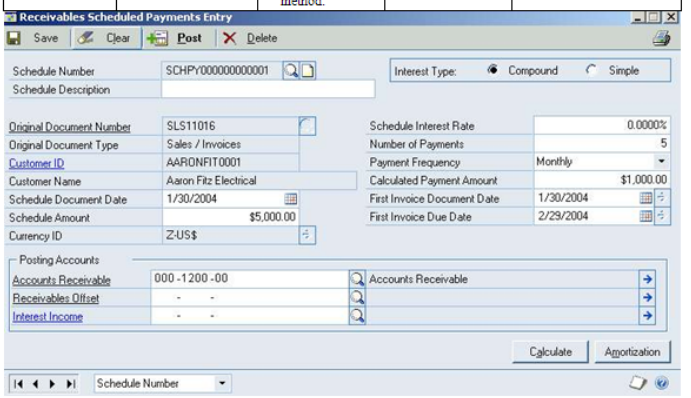
PROGRESS TO DATE

The first large scale use of Dynamics GP at the University of Indianapolis was done in the first semester of the fall semester 2006 with approximately one hundred students using the software in three different undergraduate courses. Unfortunately, access to a server-based system running Dynamics GP was still not available. Thus all student work was either performed on lab machines running Dynamics GP in stand alone mode or on the students' own machines.

The first class was an introduction to information systems class required by all School of Business students. Thus the students' majors included accounting, marketing, management, and business administration. Students received an exposure to Dynamics GP through some hands-on familiarization to the software as well as using the online electronic training material that Microsoft provides for free to members of the Dynamics Academic Alliance. Students also had to generate a report for various modules detailing the capabilities and benefits of incorporating an ERP system into an organization.

Figure 1. Using Dynamics GP to overcome the limitations of a non-integrated system

Potential Problem	Why is it a problem	Implications of Problem	How ERP corrects problem	GP Documentation
• Accounts are only posted on the day payment is received if time permits.	• There can be some delay between the time FS receives a check from the customer and when the customer's accounts receivable balance is actually reduced.	• This leads to accounts not accurately portraying the correct balances. • Also, some of the payments may not get posted because they are not being accounted for in the same method.	• Accounts are automatically adjusted when the payment is received whether there is time or not. • Accounts are always up-to-date.	• Sales Order Processing module; Ch. 18 pg. 115 • A deposit amount on an order will be posted immediately when the Sales Payment Entry window is closed.



The second class was a System Analysis class. Each group of students was assigned a specific module in Dynamics GP to analyze. This includes developing use cases, activity diagrams, class diagrams, etc. for a specific aspect of their module.

The third class was a senior level special topics class. The class was composed of both information systems majors and minors. The textbook the students used (Monk & Wagner, 2006) looked at the limitations of a small organization that used a number of non-integrated information systems. As a class project, students were required to document the limitations and their potential impact. Additionally, the students were required to document how Dynamics GP could be used to resolve the limitations as shown in figure 1. Figure 1 shows just a single entry in the document generated by the students.

Overall, students had a positive reaction to the use of Dynamics GP in the classes. They understand the value of knowing the software to better understand the integration of information between different functional areas as well as the potential value knowledge the software had when the students were looking for internships and post graduation jobs.

For the next semester, a server has been set up allowing a more realistic use of the software in a class setting. A major effort will be using Dynamics GP to create the company examined this past semester in the Monk and Wagner (Monk & Wagner, 2006) book. This effort should be aided by Microsoft's recent action of making the training materials for the software available for free.

ABSTRACT
Project ERMA (Electronic Risk Management Architecture) aims to build a reference platform for risk management in the domains of natural as well as man-made disasters with a specific focus on needs of small and medium-sized communities. Communities might be public institutions as well as private sector organisations which share obligations and duties for risk prevention and response. Hence, specific attention will be devoted to a customisable platform, which can be tailored to the needs of the individual risk at hand as well as local equipment and requirements.

1. INTRODUCTION

Project ERMA strives to develop a reference platform for risk management. The engineering paradigm is based on a service-oriented architecture (SOA) in order to integrate components of existing and related systems. ERMA will study the requirements for risk management support in the domains of natural as well as man-made hazards, risks, and disasters. A specific focus will be placed on the needs of small and medium-sized communities. Communities include local authorities and other public institutions as well as private sector organisations with obligations for risk prevention and response. Due to the diversity of requirements, specific attention will be devoted to the customisation features of the platform in order to tailor it to the individual requirements of the individual risk situation.

The vast amount of information during risk incidents compounds any decision process for the responsible rescue organisations. Specific decision scenarios, such as management of rescue resources, are already supported by IT applications for command centres. Yet, workflow management services and key indicator systems are rarely found although their added value for crisis assessment has been proven.

Thus, the ERMA platform comprises:

- a key indicator-based decision support system combined with a workflow management system,
- an early warning system to alarm emergency staff and the concerned citizen,
- a citizen relationship management system to support the communication with the citizen as well as team collaboration software for rescue organisations and other authorities.

This paper will present research in progress of project ERMA by providing its main scientific and technological aims and objectives.

2. IT SERVICES FOR RISK MANAGEMENT

Risk management surfaces as emerging topic for the software industry. Yet, no reference platforms and standard components have been established so far.

The unique features of the ERMA system with such a combination of modules and functionality can not be found in the current market. In science, individual modules have been tested in the domain of emergency management. Examples include the simulation of events with training purposes (Pollak, Falash, Ingraham, & Gottesman, 2004), the support of information dispatching (Van Someren et al., 2005), or collaboration processes (Georgakopoulos, 1999). Unfortunately, no commercial system has emerged from these prototypes, and no prototype is available for testing for ERMA.

However, information technology support is still scarce and mainly focused on

- *Communication infra-structure* — Novel communication infra-structures enable the convergence of various and heterogeneous communication technologies in order to allow different organisations to communicate using their heterogeneous technologies.
- *Geographical information systems (GIS) for information warehousing* — GIS are employed to integrate various data sources about risk-related information. Once doing so, one has a uniform source of all information that are required to assess a crisis and also take measures for prevention. Besides prevention scenarios, such warehouses are also deployed during response and recovery scenarios such as the planning of counter actions.
- *Task monitoring* — Recent systems allow the monitoring of tasks decided in order to document the process and exchange information about resources required for their execution.
- *Resource management* — Since specific incidents might require dedicated equipment not available to everyone in sufficient numbers, repositories about resources and their location are taking-off. They allow for the identification of appropriate resources.
- *Command centre support* — Each command centre uses its own information resources mainly about locations and geographical information. They are management by GIS.
- *Simulation tools for impact analysis* — Simulation tools allow the prediction of impacts such as the dispersion of toxic materials or the spreading of forest fires.

All these types of support for risk management forces are unquestionable. There are also more tools for rescue-related services as well as relevant data sources which have given birth to major European research projects for designing a generic infra-structure platform. For example, Orchestra, OASIS and others are establishing information technology platforms for the integration of data sources and the orchestration of rescue-related services. The SOA approach is the key for a flexible design and adaptation from an information technology point of view. They basically provide the middleware services for the implementation of service portfolios for rescue operations. However, until now these platforms do not consider

- Process support to capture the know-how about rescue operations and support rescue forces during incidents,
- Public alerting, i.e. advising the public about risk incidents in a customised fashion.

This lack of services motivates the birth of ERMA. In addition, risk monitoring and assessment on the basis of indicator systems that take into account specific industrial and natural risks is included for automatic monitoring purposes.

Since ERMA uses a SOA approach, it is able to orchestrate services from existing systems. Compliance with specification patterns of major infrastructure projects is sought but not considered essential in detail, since all SOA-oriented approaches are based on similar principles: specify core business services provided by existing systems and configure them to customer-oriented services based on SOA or in the terminology of rescue forces: use IT services for the preparation and orchestration of rescue operations.

3. MOTIVATION FOR PROCESS MANAGEMENT

ERMA is going to employ a process engine, which supports emergency staff with predefined and ad-hoc process description. Know-how about processes furnishes an invaluable source of knowledge about tasks to be conducted in order to respond to specific events. This know-how is only available in terms of manuals for the most part, i.e. major fire brigades have specified their response patterns by so-called standard tactics. Each tactic describes certain patterns of actions to be taken depending on the event at hand. As such, predefined workflows collect experience, organisational and administrative knowledge about how specific actions are to be undertaken, like e.g. evacuations, securing of installations, mounting of flooding dams. Ad-hoc workflows allow one to plan end execute not yet modelled series of actions in specific occasions in order to customize pre-defined patterns to event-specific requirements. Once defined and completed, they can be adapted, stored, and reused later for similar situations. Until today, action plans of emergency situations like flooding are collected in large manuals with small or no IT support at all. Such manuals do not support tracing of actions, graphical overviews, showing of interdependencies, logging, or ad-hoc changes by nature.

A formal representation of such processes is required in order to embark for process guidance and analysis. Moreover, the use of workflow engines will ease the definition of complex scenarios, so that each step and respective information exchange can be modelled. In the case of an emergency, involved staff can concentrate on extreme and unusual events while routine jobs are guided by quality-assured workflow procedures.

By the same time, authorities have started an exchange of best practices with regard to risk assessment, monitoring, prevention, awareness, response, recovery and management. Although project SETRIC (SEcurity and TRust In Cities — www.setric.org) has established a platform for the publication, exchange and dissemination of best practices, information exchange is mainly based on text documents. Here it is where process modelling approaches will foster the reuse of process know-how.

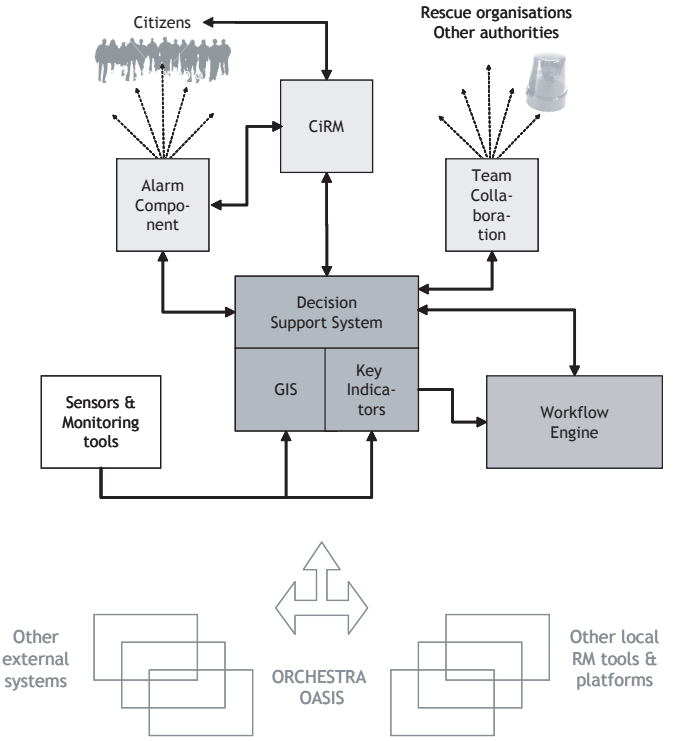
4. IMPLEMENTATION

ERMA will build an innovative prototype that targets the requirements of small and medium-sized communities. ERMA will establish links to existing risk management initiatives and pursue information exchange, discussion, and reuse of research results and components with a particular focus in mind: migrate these results to small and medium-sized communities. Of specific importance is the fact that the consortium includes several small to medium-sized companies with innovative product portfolios.

In detail, ERMA is going to assist small and medium-sized communities to:

- Access monitored sensor data related to various natural and industrial risks existing within their district, i.e. enable proper risk assessment.
- Define and employ process guidelines for risk management procedures, i.e. support proper workflow for risk analysis and response.
- Deploy and manage enhanced emergency telecommunications systems and implement a public communication system devoted to the communication with the citizen, i.e. support appropriate dissemination and warning procedures.
- Integrate and connect partners from various sectors, e.g. public, private and associated sectors, i.e. provide a collaboration platform for the exchange of information among different stakeholders.
- Prepare the elements (organizational/technical) for the implementation of a risk management network at a local scale, i.e. install and customize the platform to local requirements.

ERMA will develop a comprehensive risk management platform which is based on the orchestration of relevant systems thanks to the application of service-oriented architectures, and interfaces to other systems will augment the ERMA service portfolio where needed.



The planned architecture shows the different modules to be integrated. Some of them are provided by project partners, i.e. the alarm component, a customer relationship management tool, and the team collaboration system, which are already commercially available. They have to be adapted to the risk management domain taking especially into account the need of smaller communities and their respective citizen requirements. For example, the CRM (Customer relationship management) component has to be adapted to a citizen-oriented system supporting the specific work of rescue organisations and authorities in crisis situations.

The process/workflow engine as well as the decision system based on key indicators and visualised by maps of a GIS or mapping tool will be designed and developed during the course of ERMA.

ERMA's innovation lies in the combination of a key indicator system (KIS) and a workflow engine. While the KIS will collect sensor data, derive the current state of the event and give recommendations for further actions, the triggered workflow engines show the work schedule on how to perform the different steps of these actions. These are pre-modelled based on typical crises management procedures. But ERMA also wants to allow ad-hoc workflow in order to change, adapt and store for reuse.

External links to other projects and systems, especially the EC funded projects Orchestra and OASIS, will complement the service offer and provide additional means for information exchange.

The information flow between modules is presented in the following figure. Optional components (presented in light grey) will be linked by SOA to establish loosely coupled and interoperable services, which can be integrated or deselected for individual requirements. The decision system serves as core component integrating the application logic and scheduling other functions when demanded.

5. RESULTS

Scientific and technical results of the project will be:

- Research on a generic SOA for risk management systems with a holistic approach to flexibly integrate standards and components.
- Research on risk management for small and medium-sized authorities: decision making patterns, information needs, assets, and vulnerabilities.

- Application of process models and workflow and decision support systems to risk management tasks for small and medium-sized communities' requirements.
- Design of an information infrastructure dedicated to manage most aspects related to the management of risk to improve the confidence of citizens to their local governmental institutions.
- Design of an innovative method to "map" the risk environment.
- Design of an innovative method to optimize individual information flows between risk management actors.
- Design and implementation of a risk monitoring system configurable to a multitude of contexts, and centralization of risk measure data in the local authorities' system.
- Decision system based on key indicators with map-based visualisation tools.
- Mapping of basic best practices of risk management to process and workflow engines with online support in risks at present.
- Customised and instantaneous warning of citizens in affected regions via multi-channel means.
- Citizen relationship management – applying commercial oriented CRM systems to communication with citizens in the risk management context.

6. OUTLOOK

The ERMA project started in September 2006 with a two year perspective. It will provide a first prototype to be tested at two user sites in 2007. Final findings about the performance of the platform and its customisation prospects are expected by the end of 2008.

Due to the employment of service-oriented architectures, ERMA is going to adapt and build upon existing components for alarming, geographical visualisation, collaboration, and citizen relationship management. Specific components will be developed for indicator-based risk assessment as well as dedicated process support for risk management. Hence, ERMA will combine best-of-class components and best practices on risk management. Its innovative power is due to the combination of services and their customisation features.

7. ACKNOWLEDGEMENT

The presented work has been supported by research funding from the European Commission within the Community's Sixth Framework Programme (IST project ERMA, IST-2005-034889). The authors would like to acknowledge that this document reflects only the author's views, and that the Community is not liable for any use that may be made of the information contained herein.

Critical Success Factors of ERP Implementations

M. Gordon Hunter, The University of Lethbridge, 4401 University Drive, Lethbridge, Alberta, Canada T1K 3M4; E-mail: ghunter@uleth.ca
Susan K. Lippert, Drexel University, Philadelphia, PA 19104, USA; E-mail: Lippert@drexel.edu

ABSTRACT

This investigation will identify and examine critical success factors (CSF) that impact each stage of the implementation process related to the deployment of Enterprise Resource Planning (ERP) systems in diverse North American settings. Using business organizations in various locations throughout North America, the critical success factors associated with ERP implementation will be: (1) identified; (2) ranked for relative importance; (3) designated as relevant within a specific implementation stage; (4) examined for differences in setting; and, (5) classified as best practices in implementation by stage. The outcomes of this research will include the: (1) development of a taxonomy of critical success factors delineated by the specific stage of implementation where each CSF is most important; (2) creation of a framework that identifies country differences in critical success factor preference; (3) establishment of a comprehensive organizational guide that provides prescriptions for effective systems deployment; (4) dissemination of the research findings through academic publications; and, (5) integration of identified critical success factors within university curricula. This project study supports collaborative research between Canadian and U.S. institutions of higher education.

PROJECT OBJECTIVE

The objective of this research proposal is to document the critical success factors (CSF) necessary for successful implementation of Enterprise Resource Planning (ERP) systems within different organizational and national settings, regulatory venues and corporate cultures. Business organizations in North America that have completed an ERP project within the past two years will be identified and a request for their participation will be solicited. To accomplish this objective, the researchers have segmented the research agenda into two phases: (1) a qualitative phase where CSFs will be identified using a grounded theory approach (Glaser and Strauss, 1967) as detailed in this proposal; and, (2) a quantitative phase where CSFs will be modeled and empirically tested from data collected from questionnaires.

Based on a Grounded Theory approach (Glaser and Strauss, 1967), the researchers will employ Narrative Inquiry supported by the Long Interview Technique (McCracken, 1988) in a qualitative interview format to generate a comprehensive catalog of implementation CSFs. Content analysis will be used to examine diverse corporate cultures, to identify implementation success factors and application variance. The outcomes of this research project are to: (1) create a taxonomy of critical success factors that are linked to the specific implementation stage where each will produce the greatest impact; (2) establish a framework to delineate country differences in CSF preference; (3) generate a comprehensive implementation guide for business organizations; (4) produce research for publication in relevant academic journals; and, (5) incorporate the value-added knowledge gained from this research into the information systems curriculum in selected institutions of higher education. This project provides an opportunity to achieve a unified prescription for organizations to use in implementation.

This research is important because of the current and projected magnitude of the ERP market. In particular, the market for ERP systems is expected to reach $US 1 trillion by 2010 and ERP costs for companies range from $50,000 to hundreds of millions of US dollars. The growth of ERP systems can be attributed to the expected system benefits that include the integration of data and applications, the replacement of legacy systems, and expected cost advantages. Given these estimates, understanding what critical success factors are most important at each stage of the deployment process should help reduce the negative outcomes associated with ERP implementation.

What is missing from the available research reports is a detailed investigation of factors encountered at various stages of an ERP implementation and a comprehensive context based description of successful implementation processes, procedures and policies – best practices. Thus, at various stages throughout the ERP implementation project problems and challenges will be analyzed. These factors may be those that are anticipated and what plans exist for their resolution; or completed issues and how they were resolved. The goal of this study is to understand ERP implementation issues and how they differ across different business settings.

METHOD

Qualitative interviews will be conducted to gather stakeholder interpretations of critical success factors in each stage of the ERP implementation. The stakeholders who will be interviewed represent the most important opinion-holders within the company about issues that may arise during an ERP implementation project. Four stakeholders from each company will be interviewed. The interview approach will be based upon Narrative Inquiry and supported by the Long Interview Technique (McCracken, 1988).

Narrative Inquiry (Girden, 2001; Scholes, 1981) documents research participant's interpretations of events which are contextually rich and temporally bounded. The contextually rich concept relates to events that have been experienced first hand, and therefore are more vividly remembered (Swap et al., 2001; Tulving, 1972). The concept of temporally bounded suggests that the narrative will have a beginning, and end, and a chronological sequence of events in the interim. This sequential aspect supports the clarity of recollections (Bruner, 1990; Czarniawska-Joerges, 1995; Vendelo, 1998).

The Long Interview Technique (McCracken, 1988) supports the above Narrative Inquiry concepts. The technique employs three types of questions. First, "grand tour" questions are general allowing the respondent to decide upon the substance of the response. "Planned prompts" are those questions that are decided upon before the interview. These questions relate to the subject under investigation and may be gleaned from previous projects or a review of the available literature. These types of questions also facilitate comparisons across interviews because common areas will be discussed with each participant. During the interview "floating prompts" may also be employed. These questions relate to the researcher's decision to pursue a line of questioning in order to obtain more detail about a specific response. All interview data will be recorded with the knowledge and agreement of the research participant.

The Interview Protocol developed for this project represents the results of applying the Long Interview technique within the Narrative Inquiry approach to investigating ERP implementation. The first major section obtains information about the specific person. The second section gathers information about the company. The last section follows the Narrative Inquiry approach to obtain participants' perspectives on their experiences at various stages of an ERP implementation. Issues will be discussed chronologically based upon the stages of the ERP implementation.

EXPECTED OUTCOMES

The outcomes of this research will include the: (1) development of a taxonomy of critical success factors delineated by the specific stage of implementation where

each CSF is most important; (2) creation of a framework that identifies country differences in critical success factor preference; (3) establishment of a comprehensive organizational guide that provides prescriptions for effective systems deployment; (4) dissemination of the research findings through academic publications; and, (5) integration of identified critical success factors within university curricula.

ABSTRACT

Virtual Learning Environments (VLEs) have gained momentum in both industry and education as both segments have increased their use of technology to deliver training and education. This research represents a pilot study conducted to compare a complex information technology course taught in a real-time (synchronous) hybrid eLearning environment with one taught in a traditional classroom setting. The aim of the research is to provide additional insights into the effectiveness of synchronous hybrid VLEs and to compare their use with hybrid VLEs and traditional classrooms. Three courses were examined in the study and the results indicate the promise of synchronous hybrid eLearning for complex courses.

INTRODUCTION

Advances in technology have made real-time VLEs more affordable and as the capabilities of them have expanded (Seng & Al-Hawamdeh, 2001), so has the popularity in both the educational arena and corporate world (Alavi, Marakas, & Yoo, 2002; Dagada & Jakovljevic, 2004). VLEs are defined as "computer-based environments that are relatively open systems which allow interactions and encounters with other participants and providing access to a wide range of resources" (Piccoli, et al., 2001, p. 402; Wilson, 1996).

VLEs can be characterized by six dimensions which distinguish them from traditional classrooms and computer aided instruction: time, place, space, technology, interaction, and control (Piccoli, Ahmad, & Ives, 2001). The instruction delivery when defining the six dimensions in Piccoli, et al (2001) is asynchronous delivery. The definition for two of the dimensions, time and control, in synchronous (real-time) virtual learning environment is different from asynchronous virtual learning environment. Research still remains to uncover the effectiveness of these environments and also to determine their impact on the learning experience of the student (Alavi & Leidner, 2001; Alavi *et al.*, 2002; Hodges, 2005; Seng & Al-Hawamdeh, 2001).

BACKGROUND

The work on technology mediated learning (TML) has been the focus of researchers for some time and it has been noted that research still lags behind practice. Overall, there is a need to gain a deeper understanding into the effectiveness of the use of technologies for online learning (Alavi & Leidner, 2001; Alavi et al., 2002). One area that has recently come to light is the use of hybrid approaches to teaching online courses. A hybrid approach to learning with TML involves providing content in a variety of formats with a mixture of online and in-class instruction.

There have been a number of studies examining hybrid approaches to teaching. In an examination of the differences between pure versus hybrid approaches to teaching using the case method it was found that students' online discussions may enhance learning in case methods when taught using a hybrid approach (Webb, Gill, & Poe, 2005). When live versus hybrid formats were compared in sections of a business communication class, an improvement in writing skills was found in students who participated in the hybrid course, particularly for those whom English is a second language (Sauers & Walker, 2004). McCray (2000) found courses which combine online learning with the traditional classroom can help students to become more engaged in rich classroom interactions by appealing to different learning styles through variety in content delivery. A study examining the differences in learning outcomes for students training in basic information technology skills in a traditional classroom versus those in a virtual one found no major variation in the performance of students in the two environments; there were however, differences reported in computer self-efficacy (Piccoli et al., 2001). Research in this area also highlights the importance of the influence of self regulation (ability to control actions and decisions) and control of the learning environment (Hodges, 2005; Piccoli et al., 2001).

With the advances made in VLEs this study aims to answer the research question: Are VLEs ready for teaching complex subjects? A synchronous hybrid eLearning environment is one where portions of the interaction among the participants takes place virtually in real-time and the format for the course is a mixture of online and in-class instruction.

HYPOTHESES

Time flexibility and learner control are found to be benefits of VLEs (Piccoli et al., 2001), however synchronous VLEs fix the time of delivery, eliminating this advantage. In asynchronous VLEs, the learner has a greater degree of control during the time of instruction; learner control in synchronous VLEs takes on a different form. In synchronous VLEs, the responsibility for learning control is retained by the instructor and the burden of time management is removed from the student. In this type of environment, synchronous interaction maintains the familiar face-to-face classroom environment. The following is therefore hypothesized:

H1: Students in synchronous hybrid eLearning environments will report higher levels of computer self-efficacy than their counterparts in traditional learning environments.

H2: Students in traditional learning environments will report higher levels of satisfaction than students in virtual learning environments.

Piccoli et al., (2001) found that the level of student satisfaction in a VLE for difficult (or unfamiliar) topics like Microsoft Access dropped when compared to familiar topics like Microsoft Word and Microsoft Excel. Brown and Liedholm (2002) found that the students in the virtual course did not perform as well as the students in the live classroom settings and that differences between students in the live and hybrid sections, versus those in the virtual section, were shown to increase with the complexity of the subject matter.

A Systems Analysis and Design course is considered more complex when compared to the Project Management and IT Resource Management courses. Students in non-complex courses are therefore expected to be more satisfied than those in complex courses; this leads to the following hypotheses:

H3: Students in synchronous VLEs with non-complex courses will report higher levels of satisfaction than students in synchronous VLEs with complex courses.

RESEARCH DESIGN

The VLE framework (Piccoli et al., 2001) shown in Figure 1 was used as the theoretical background for the study.

This study was conducted in a large public four-year AACSB-accredited university.

Figure 1. Dimensions and antecedents of VLE effectiveness (Adopted from Piccoli et al., 2001)

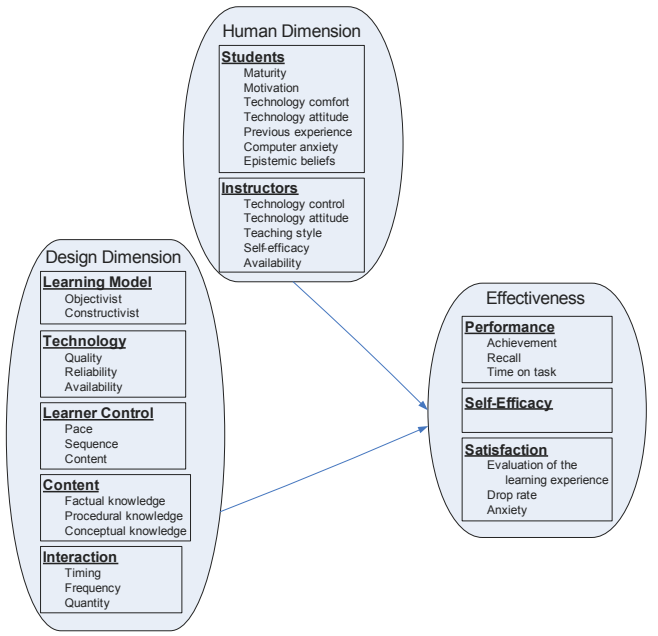

Figure 1: Dimensions and Antecedents of VLE Effectiveness (adopted from Piccoli et al., 2001)

Three courses were examined: first undergraduate System Analysis and Design course using Marratech[1]; second, undergraduate IT Resource Management course using Camtasia Studio[2]; and finally a graduate Project Management course using Marratech. All three classes were supported by a learning management system from WebCT[3].

The requirements for the Systems Analysis and Design course were a term project, a take-home midterm and final exam. Students in the IT Resource Management course were evaluated through case study analyses, oral presentations, career portfolios and term-research papers. Students in the Project Management course were evaluated based on six individual assignments and a simulation project; no exams were administered for the course

RESULTS

Data for the pilot study were collected through and online survey. Sixty three students participating in three courses completed the survey. Thirty percent of the students (19) were graduate students and 70% (44) undergraduates. Forty-four participants were male and 13 female, 6 participants did not provide information about their age. Participants' ages ranged from nineteen to over fifty years.

All respondents indicated that they had computer and internet access from home. Computer experience for participants was reported as 73% professional users; 17% frequent users and 2% reported being somewhat experienced; 3 respondents skipped this question. Eighty nine percent of respondents said they enjoyed working with computers and only 2% indicated that they felt threatened by computers. The majority of the respondents rated their software knowledge as high. On a scale of one to ten, with ten being the highest, respondents rated themselves high for self-efficacy (over 70% of the participants). Satisfaction with the overall class experience was measured on a 5-point Likert scale with 5 being very satisfying; over ninety percent of the respondents from each course reported their satisfaction a 4 or 5.

DISCUSSION

For the purpose of this study students were classified as traditional classroom students or synchronous hybrid eLearning students. The traditional classroom students were those students that attended all in-class sessions (44 students). The synchronous hybrid eLearning students were those students that attended some of the classes in the synchronous hybrid eLearning format (18 students). One student did not provide information.

Each respondent was asked a set of 10 questions on self-efficacy (Piccoli et al., 2001). T-tests were used to determine whether there were significant differences between eLearners and traditional classroom learners. Self-efficacy ratings between the two groups were not found to be significantly different.

The first hypothesis (H1) stated that students who tend to choose the VLE have a higher level of computer self-efficacy. This hypothesis however was not supported by the data, which indicates that the two groups have similar levels of self-efficacy. Further analysis of the data indicates that factors other than self-efficacy determined the students desire to participate in the synchronous hybrid eLearning. Satisfaction responses for the two research groups (synchronous hybrid eLearning and traditional classroom) did not show differences in satisfaction. For both groups, most respondents reported satisfaction with the class as either "somewhat satisfying" or "very satisfying".

The second hypothesis (H2) stated that students in the traditional classroom setting would report higher levels of satisfaction when the subject matter is complex. This hypothesis however, was not supported by the data. The Chi-Square test indicates that these two groups are not significantly different (χ^2=2.714, p=.438).

Responses from the two classes with options for synchronous hybrid eLearning (System Analysis and Design and Project Management) were used to assess the VLE impact on complex courses. The classes for IT Resource Management course were all in-class session so were therefore excluded from this analysis. The System Analysis and Design class required significant collaboration between group members. Students were required to develop complex diagrams and models which required significant interaction between the instructor and team members. In contrast, the Project Management course was lecture based with individual assignments; there were no group projects required for this course.

Responses for satisfaction for the complex (Systems Analysis and Design) and non-complex (Project Management) courses showed that the majority of participants found the courses "somewhat satisfying" (33% for the System Analysis and Design course and 22% for Project Management course) or "very satisfying" (56% and 67% respectively).

The third hypothesis (H3) states that students in a non-complex course will show higher levels of satisfaction than those in a complex course. The survey results do not show support for H3. The Chi-Square test shows no significant difference in satisfaction level between the complex course and non-complex course one (χ^2=2.291, p=.514).

LIMITATIONS OF THE STUDY

The sample size for the synchronous hybrid eLearning group in this pilot study was small and is therefore limited. The collection of additional data to further validate the findings of the study provide a natural extension of the study. The results of this study may also be limited to the specific courses and university examined in this study and may not be generalizable to other environments.

FUTURE RESEARCH

Research still needs to be undertaken for research and practice to gain a clearer understanding of the learning outcomes of synchronous hybrid and asynchronous hybrid eLearning versus traditional classroom environments. Future research on this study includes collecting additional data to increase the sample size to further ground the findings of the pilot study.

CONCLUSION

Synchronous hybrid virtual learning environments were examined in this pilot study. This pilot provides preliminary evidence to support the fact that synchronous hybrid VLEs are ready for teaching complex courses. Prior research using asynchronous VLE found differences in how VLEs support complex and less complex courses, indicating that students who take complex courses in VLEs are less satisfied. Many of the difficulties reported by students in an asynchronous VLE i.e., difficulty managing the high degree of control, feelings of isolation, etc. may be addressed by synchronous VLEs. It is believed that the difference in the

results from this study and prior research emanate from the differences between synchronous and asynchronous VLEs.

How Does a Hybrid Device of Training Reinforce the Extrinsic Motivation of Learning Adults?

Jean-Pierre Noblet, ESSCA, Researcher Laboratory of Knowledge Transfer, Université de Sherbrooke, Quebec, Canada; E-mail: Jean-Pierre.NOBLET@essca.fr

1. INTRODUCTION

The literature attached to the "blended learning" has become plethoric over the last few years, and a great number of comparative analyses of the benefits of the two systems (face to face vs. distance education) (Wegner, and *al.*, 1999; Aycock and *al.*, 2002; Ward and LaBranche, 2003). But the motivation of learning was only seldom studied, and in particular the extrinsic motivation (Wlodkowski, 1999). Recent works concerning more specifically adult learning tend to show the crucial role of the hybrid devices on training, placing the emphasis on the redesign of formation, collaborative device, and the redefinition of the tutorial system (Garrison and Kanuka, 2004; Aycock and *al*, 2002). Based on Wlodkowski's motivational dynamics model (1999), we show how a hybrid device can contribute to the motivation of learning, and how capital it is capital to the redesigning of courses. The experiment undertaken by Group ESSCA (Graduate School of Management in France) for an adult public aiming for the ESSCA Continued Education diploma, accounts for the significant impact of the hybrid device on the extrinsic motivation of learning.

2. WHAT IS "BLENDED LEARNING"

In higher education, the emerging tendency to blend Internet technology with the face to face training generated great hopes, but also great doubts. What is the definition of a hybrid education? It is a combination of face-to-face and online media, with "seat time" significantly reduced (Voos, 2003). Smith (2001) describes it as a method which combines technology and traditional education. Garrison and Kanuka (2004) define it as the thinking integration of experiments of face to face training in class, with experiments of training on line. But we have to distinguish the blended learning from the other forms of trainings, i.e. improved classroom on one side, and completely on line experiments on the other side. The real test of hybrid formation is the effective integration of the two major components beyond the simple addition of one to the other. In fact, it is necessary to significantly separate these two approaches (Garrison and Kanuka, 2004). If the use of the term "blended learning" is often associated with the simple link between traditional face-to-face education and asynchronous on line activities, researchers and experts argue today that a hybrid training scheme must combine other dimensions to be able to seem to support the training (Singh, 2003; Ward and LaBranche, 2003; Garrison and Kanuka, 2004; Bielawski, and Metcalf, 2002; Wlodkowski, 1999): for example, to study the articulation between face to face and distance education in course redesign, to benefit from the experiments of others to give value with human capital, to support practices of collaboration and creation, and to give direction via coaching. How can these dimensions be combined to better the motivation of adult learner, and, in particular, their extrinsic motivation?

3. HOW TO COMBINE DIMENSIONS SUPPORTING THE TRAINING

We took as a starting point Wlodkowski's motivational dynamics model on adult learning (1985, 1999); this model differs from the other motivational models applicable to normal educational system (Viau, 2003), not only because the adult learner starts the formation with a specific social status, but also because the divergences are more important with regard to age, marital situation, professional needs, and experience. This model integrates components of intrinsic motivation (which concerns the learner) and those of extrinsic motivation (the organization of the environment of training), on a temporal continuum from the beginning of training to the end.

3.1. To Redesign the Formation

The first track to be explored is the redesign of the formation, the redefinition of the articulation between face to face and distance education. Hybrid formation is not a substitute for face-to-face training (Garrison and Kanika, 2004), but the effective integration of the two components (face to face and Internet technology). We need to redesign and to reorganize the dynamics of teaching and training by starting from needs and specific contingencies of the context: disciplines, level of development, resources (*Ibid*, p. 97). Aycock and *al*, (2002) confirm this trend: "in order to create effective interactivity, full course redesign is essential for successful hybrid courses". Ward and LaBranche (2003) estimate that, in a redesigned hybrid formation, adult learners must profit from more options, from more time, and more freedom to explore their learning; hybrid education must help to overcome one of the limits of face to face: classroom and teacher availability.

3.2. Valuing the Development of Human Capital

What will make the difference "is the conjunction of a multidisciplinary approach and the development of human capital" recognize Bielawski and Metcalf (2002). The hybridization of the formation highlights the active adult learning, with experiment of strategies, better practices, tools, and approaches validated in the professional context. Hybrid formation uses these talents to help the learner to be more creative, more responsible, more effective, and more "team" thinking (Honold, 2001).

3.3. To Develop Collaborative Work

The most recent reforms in education encourage training by the peers, and thus encourage the development of competences linked to the ICT (Deaudelin and Nault, 2003). Collaborative work will allow learners to combine their own interest with the training (Johnson and *al*., 2000). The interaction is characterized by a positive interdependence between the sought for objective and individual responsibility; learners will accept a common objective on which the group will be evaluated, by integrating the individual responsibility for each one (*ibid*, 2000). When adults learn in a collaborative way, they develop relations of support through groups of kind, and different origins. Thus collaborative groups of training create a base (Wlodkowski, 1999, p. 105) on which the training can build and increase comprehension of what is taught through explanations and discussions of multiple prospects.

3.4. To Redefine the Role of the Tutors

The continuous increase in distance and on-line education requires two fundamental types of resources: an adapted design of courses, and a relevant tutorial system (Barker, 2002; Morgado and *al*., 2002; Beyth-Marom and *al*., 2005); on the second point, Barker (2002) recognizes the need to diversify the roles usually allocated to tutors, and to retain varied aptitudes according to the problems: teaching, technical or organisational. In ESSCA Continued Education diploma, the tutorial system will cover different sorts of problems: an administrator-tutor regulates technical problems inherent to the hybrid device; a organizer-tutor high-

lights absences, and establishes the link with the teacher; the motivator-tutor is in charge of the formation, and can manage the interpersonal relations; finally, the facilitator-tutor is the expert (the teacher), present in face to face and a motivating element through the forum.

4. AN EXPERIENCE OF BLENDED LEARNING: ESSCA CONTINUED EDUCATION DIPLOMA

ESSCA delivers a Master after five years of higher education, however, this is also possible through continued education. To answer the requests from companies, more flexibility was introduced into the formation thanks to a hybrid device. Indeed, we offer a 950 hours formation spread out over 18 to 24 months, and including two thirds of time in face-to-face and one third (350 hours remote) as distance learning via a digital campus. The formation has being completely reworked in order to link distance part and presence part dynamically. So, the courses were "redesigned", and divided into competences. Learners are together in periods of face to face two or three days every two or three weeks, after a phase of personal and collective work via the e-campus. The first three groups (2003, 2004, 2005) having completely tried out this device were agreed to carry out a complete assessment of the impact of such a diagram on their process of training.

4.1. Characteristics of the Sample

We identified learners by group, sex, group of age, qualification level at entry, and number of years run out since their initial formation. The 67 learners were divided into 21 from promotion 2003 (graduates 2005), 25 from promotion 2004 (graduates 2006), and 21 from promotion 2005. 74% were men, 61% were between 34 and 49 years old, and 37% less than 34 years; 67% had a higher formation "bac+2" level and 24% "bac+3" level or higher; finally 83% have been out of the state education system for more than 5 years. Learners had to fill out at the end of the formation a questionnaire comprising 21 items, in classroom or by email. The returns of the questionnaires were quasi exhaustive (90%). The questionnaire was divided into 7 groups of items: Identification of promotion, use of ICT, collaboration, management of time and distance, the quality of tasks, the hybrid device, and an assessment of the training.

4.2. First Results and Discussion

From Wlodkowski's model, and during the training, we validate the items:

a. Stimulations. The device proposes solutions to support a reinforced training:
   - A studied design: 93% of adults recognized that the design of hybrid formation helped them,
   - Tools of communication and collaboration ensured a strong link between members, especially during the distance phases: Strong use of forums, emails and chats, but also use of collaborative spaces.
   - A comforting tutorial system: 83% of the learners regarded the assistance as effective in the case of technical or teaching difficulties.

b. Affectivity:
   - Tools of communication and collaboration support the sharing of individual values, and personal objectives (67%); the forum constitutes the primary instrument, were especially for a temporary support in case of difficulties (83%).

From Wlodkowski's model, at the end of the training,

a. Competences. What evaluation a trainee has of his capacity to succeed when uncertainty is considered to be strong? The hybrid device is recognized as being comforting, reducing the fears of the trainees toward the task; thus, on a scale from 1 to 10, the trainees positioned their perception of their capacity to meet this challenge with 6 at the beginning of their formation, and 9 at the end if they were to face a similar challenge in the same way.
b. Reinforcement: the trainees recognized the importance of post-course and post-evaluation feedbacks: it was frequent, fast, and precise, and contributed in helping learning (82%). We also asked the trainees to note each assertion suggested on a scale from 1 to 5, where 5 corresponds to an appreciation "Completely agreed" and 1 to an appreciation "not at all agreed". All the values of T are higher than 2.01 with regard to a sample of size 67 and one alpha 0.05, and consequently, each answer is regarded as statistically significant.

We asked trainees to note each suggested assertion on a scale from 1 to 5, where 5 corresponds to "strongly or very strongly" and 1 to "no change"

5. CONCLUSION

These results have a limited impact due to the sample size and the context, and cannot expect any external validity. The study is currently continuing with promotion 2006, and the first results entirely corroborate the previous study: the redesigned device supports the formation, especially on distance; the tutorial system is omnipresent and effective; the sharing of the different experiences is an enrichment for the group; collaborative work is integrated in daily work, and fully contributes

Table 1. Assertions about the hybrid device

	Average (5 completely agreed ; 1 not at all)	***T-value Significant answer for p=0.05***
The hybrid device, overall, facilitated my training	4.2	6.78
The hybrid device facilitated my comprehension of the main concepts	4.1	7.42
The device helped to develop my interest and my curiosity for other resources outside the system	4.1	5.31
The device allowed a better access to private and professional resources	3.9	3.86
The device supported a better planning of absences, and a better preparation of the courses	3.8	3.73
The device supported an evaluation focused on comprehension, resolution of problems, and synthesis	3.8	4.64
The hybrid device enabled me to better plan my work	3.7	3.45
The hybrid device facilitated my commitment, in particular in collaboration	3.7	3.59
The hybrid device allowed a better adaptation of the workload to my personal constraints	3.7	3.27
The articulation was clear between objectives, methods and evaluations	3.5	4.2
The device encouraged an in-depth approach of the topics	3.4	3.5

Table 2. The hybrid device helped me to reinforce the following capacities

	Average(5 Strongly or very strongly – 1 no change)	***T-value Significant answer for p=0.05***
Ability to manage a project	3.9	4.7
Dialogue and coopération	3.9	5.58
Ability to work in a group	3.9	3.0
Awareness to my Abilities	3.7	2.62
Motivation	3.5	2.74
Perception of my ability to achieve difficult things	3.4	2.61
Ability to resolve a conflict	3.4	2.79
Sense of effort	3.2	2.72
Sense of decision making	3.2	2.72

to supporting motivation over a long period of time, and difficult training. The learner becomes an actor of his formation and not a consumer.

Pricing Pervasive Services Using Policy-Based Mechanisms

ABSTRACT

Network operators using next-generation networks have the potential to service users without pre-existing contractual arrangements. Several research groups are working on ways of developing and implementing that type of interaction with game theory techniques, market-based mechanisms (for example auctions) and techniques based on mesh networks among others. We believe the policy-based network management field provides some excellent ideas that can be borrowed and adapted to the field of ubiquitous or pervasive services pricing. This research-in-progress paper explores the prospects of using policy-based mechanisms to adequately price ubiquitous network services.

1. INTRODUCTION

One of the keys for the success of ubiquitous network services is the issue of assigning prices to those services. Furthermore, ubiquitous services based on a network of complementary technologies, both fixed and wireless, have created the expectation of services that can be obtained dynamically and automatically with the minimum possible of interaction between the users and potentially complex network systems. Intelligent agents would negotiate the best conditions to make sure the user obtains always the best possible connection (Voinov and Valladares, 2003). This best possible connection would be selected by comparing the different services, quality of the services offered, prices and reaching a decision based on the policies the user has configured in her intelligent agent and in conjunction with the policies being presented by the different service providers.

It is clear that, from the technical point of view, the scenario depicted above is feasible. There has been continued progress on the integration of technologies such as WiFi, "Mesh" and "Ad-Hoc" networks with the traditional phone networks and fixed sub-networks based on the TCP/IP family of protocols. Telecommunication companies have exploited the popularity of WiFi "hot spots" as access ramps to their 3G services (Legard 2003). However, there is work to be done in the area of agreeing how to price network services, especially when that "network" is supplied by different organizations and potential users may not have contractual agreements with all the players involved.

The current telecommunications environment, in which virtual operators re-sell network services, in which some firms are customers of a traditional "Telco" while at the same time offering services to many other smaller organizations, forces us to redefine many of the business models that had been used so far. Long term contracts are being challenged by many other arrangements that give more flexibility to the users. These changes, in most cases promoted by users' requirements and further "pushed" by competitive, and innovative, new entrants into the telecommunications arena have resulted on a profound transformation in the way services are acquired and billed. This fact will always clash with the tendency of traditional "Telcos" to keep billing as simple as possible (Meyer, 2003).

2. USING POLICY-BASED TECHNIQUES TO PRICE UBIQUITOUS NETWORK SERVICES

Policies have been used as a means of implementing flexible and adaptive systems for the management of Internet services, distributed and security systems. In the last five years policy-based network management (PBNM) received even more attention due to the fact that policies are considered an enabler of the autonomic networking paradigm (Serrano et al., 2006).

As defined in Sloman (1994), policies are rules governing the behaviour of a system. As in any rule-based system, one of the major issues is the detection and resolution of the conflicts. A policy conflict occurs when the conditions of two or more policy rules that apply to the same set of managed objects are simultaneously satisfied, but the actions of two or more of these policy rules conflict with each other. A model to deal with policy conflicts has been proposed by Baliosian et al. (2004) and has been used in the core of an autonomic networking environment proving to be functionally correct and computationally efficient (Vidales, P. et al. 2005). This approach may be used in our pricing context problem. In fact, a user may have policies to drive her access to the network services, whereas different service providers may also have different pricing policies to promote the use of their respective resources. The final outcome will be the result of solving a likely conflicting situation between the user's policies and the service providers' policies.

A different issue arises considering the policy deployment problem. A policy-based managed system (i.e. a pricing system) may be constituted by many different components and these components need to be driven by different enforceable policies that globally ensure a given system behaviour. Even in systems where only a few tenths of policies need to be deployed it would be almost impossible to design these policies independently and guarantee at the same time global system behaviour. Therefore a procedure, also known as policy generation and refinement, is needed that coming from a high level goal assists the policy designer to systematically derive system enforceable policies. In that area is worthy to mention the work of Rubio et al. (2005) that was later formulated as a holistic refinement approach and validated in a QoS management environment (Rubio, J. et al., 2006). This approach could be clearly adopted for the definition of pricing policies.

From a complementary point of view, pricing policies for a network providing ubiquitous services can then be defined using the policy management paradigm, so that when a potential client "walks" into the coverage area of a provider a basic exchange can inform the client about the active policies for accessing the network facilities. Policies may include price structures (tariffs), security restrictions (who is allowed in), and resource allocation schemes (e.g. bandwidth). The potential client (or an agent on her behalf) would analyze those policies which will be expressed on open format (XML) and standard technologies (such as J2EE and Web services; see Agrawal et al (2005)) and decide whether she would like to use the services.

3. FUTURE WORK

In the context of Next Generation services, is worthy to mention pervasive services for their impact on the final users. Nevertheless, deploying such services requires the convergence of several technologies; among those we highlight policy-based network management and pricing. In principle, the flexibility of the policy-based management paradigm is very promising and makes it a candidate for service management, but in a very dynamic and distributed context, not only in terms of the number of users but also in the environment diversity, as it is the case of generalised computing, is not possible to rely on human managers to undertake updating changes in the bulk of policies used in order to adapt to new services or

devices connected to the network, or to be able to cope with any potential policy conflict. Therefore, it is mandatory to make use of mechanisms, not yet available today, for automatic policy generation and refinement as well as for policy conflict detection and resolution.

On the other hand, deploying ubiquitous services requires that users and providers collaborate in order to assign prices to these services. The key factor in the pricing mechanisms in the context of such services is the dynamic adaptation to the environment (context awareness) and henceforth their temporal evolution as a function of the context. Then, we require pricing models that take into account the services context and particularly the availability of resources in a non-cooperative business model. Also, pricing must consider the mechanisms to make the users aware about the evolution of the current prices.

Our research aims to tackle four challenges related to the above described ideas: To develop an automatic generation model for service management policies intended to deal with a variety of devices and services not known beforehand; To develop a formal method to bring and automatic method for policy conflict detection and resolution; To establish dynamic pricing models to represent the real cost of context-aware services; To propose the necessary mechanisms to ensure that the user is aware of the price evolution and hence he/she can react in consequence.

Personal Information Privacy: The World Has Changed

Sue Conger, University of Dallas, Irving, TX 75062, USA; E-mail: sconger@aol.com

ABSTRACT

Individuals can no longer manage their own personal information privacy. Rather, corporations and organizational entities with which individuals interact must recognize vulnerabilities and actively manage their data to guarantee known data sharing and to prevent data leakages. A more complete model of consumers' personal information privacy that includes not only data gathering, but also data sharing and data leakage is presented and defended here.

1. INTRODUCTION

Daily, we read of some new data loss of millions of individuals' personal information [1, 17, 32]. As losses amass, the realization that personal information privacy (PIP) is no longer manageable by individuals becomes clearer. Yet, research to date proposes that PIP is the responsibility of individuals' forging contracts with corporations for protection of their data [28], that it is the responsibility of government to protect the individual [29], or the responsibility of corporations to manage internal use [27, 28]. These views are all corporate-centric but threats have expanded beyond the corporation to its data-sharing partners. This shortcoming appears due, in part, to an incomplete view of corporate vulnerabilities. In this research, we build on past privacy research to develop a model of data sharing from the individual to the corporation and from the corporation to its data-sharing partners.

The premise of this research is that the individual-to-corporation link, while still needing research, is well understood. However, what businesses *do* with the data, once collected, is less understood and is becoming more important to privacy maintenance [cf. 1, 32]. Corporations, having spent billions creating secure corporate silos, do not operate in a silo-like vacuum. Rather, corporations routinely share data with business partners and legal entities that in turn, share that data with other organizations. In this data-sharing environment, we develop three types of data sharing *partners* with which corporations interact and the need to actively manage or prevent different types of data access and use. Once the full extent of data movement is understood, it is clear that corporate policies and procedures need extension and regulation to control multi-party access. In the next sections personal information privacy (PIP) research to date is summarized, the expanded model and data supporting it are presented, and suggestions for further research are developed.

2. PERSONAL INFORMATION PRIVACY MODELS

Two distinct periods of PIP research are summarized. Pre-Web maturity research concentrated on organizational data gathering, usage, and access practices, seeking to articulate the issues relating to PIP and organizational data gathering and use. Post--Web maturity research shifted focus to Internet transactions that generate more and different data, use more and different methods of data collection, and have different persistence issues. Through these discussions we argue that the World Wide Web (Web), a new technology 13 short years ago, changed many of the issues relating to PIP and furthermore, the Web and emerging technologies enable new abuses of data that require corporate relationship and data management.

2.1 Personal Privacy Before Web Maturity

Research published before Web capabilities matured had few references to Web information gathering practices [cf. 10, 28]. Much research in the 1990s sought to determine the scope of the privacy problem and how to frame privacy issues [8; 11, 18, 28,]. Privacy, at a minimum, concerns collection, unauthorized secondary use, ownership, accuracy, and access [18, 28].

Culnan & Armstrong's [10] privacy leverage model relates corporate use of consumers' collected personal data to the trust that either leads to retention or defection of customers. Culnan's model demonstrates an understanding of the issues in organizational data collection and use but assumes solid control over all use and also assumes firm's have some policy (whether explicit or not) on PIP protection. Transaction decisions are based on a 'privacy calculus' that is an idiosyncratic trade-off between trust, risk, cost/benefit, and other consumer assessments [2, 3, 10; 14, 20, 24, 25]. Further, this research assumed that 'demographic' and transaction data were the types of data gathered; this is no longer the case.

2.2 Personal Privacy After Web Maturity

Research published after 1998 (when Web transaction technology matured) demonstrates that the Web enables novel methods of obtaining information on individuals, some of which is unrelated to transactions between consumers and corporations. Web privacy issues include where and how information is collected, whether or not the collection is known or unknown by the consumer, trust in the vendor (see Figure 1) [15, 20], the life and breadth of information collected [13], perceived benefits and risks of information sharing [12], methods of storing and using the information and corporate privacy policies [13]. Web purchase transactions research includes consumer, product, medium, merchant, and environment characteristics [2, 3, 5, 6, 13, 14, 15, 19, 20].

The research summarized in Figure 1 addresses part of the transaction chain and tends to omit feedback from a transaction as paramount to future transactions though some research includes feedback [cf. 3, 10]. Omitting feedback implies similarity of evaluation for any transaction with a company whereas evidence supports the notion that every transaction is affected by all past transactions and transactions with other companies as well [21, 22]. There is conceptual confusion on whether the individual's assessment of a potential transaction results in perceived risk or perceived trust, or both [6, 13, 14, 15, 19, 20]. Most research never states what data is collected, or describes a limited domain of data that oversimplifies breadth of data that might be collected [cf. 13, 14, 20].

3. AN EXPANDED MODEL OF INFORMATION PRIVACY

This section builds on past privacy research to present a more complete view of the current state of PIP. The expanded model of information privacy has as its basis, the past research on how an individual, the 1st party, comes to transact with a company, the 2nd party vendor/provider (5, 10). Each unshaded box in Figure 2 and the arrows depicting the relationships between them represent areas in which significant research has already been conducted and incorporates the bodies of work summarized in (10) and (5). Part of the individual's decision includes what data to provide to the 2nd party based on the expected life and use of that data, perceived reasonableness of the data collected, expected benefits, and expectations of corporate use of the collected data (9). These new concepts are in Figure 2. The shaded boxes and arrows depicting their interrelationships represent areas in which little or no research has been published.

The type of data requested leads the consumer to draw conclusions about the perceived reasonableness of data being collected. Perceived reasonableness of data is a new construct in the decision calculus that arises from corporate use of smart technologies that can surreptitiously collect such data as click streams, personal movements, food and medicine usage, genetic markers, DNA, health, or other biological data, and criminal, genealogical, or financial history [9]. The decision calculus results in an assessment of trust and risk, to either consummate or cancel the transaction and, if consummated, which data to share and the sharing duration.

Figure 1. Summary model of Web transaction issues (Adapted from 5)

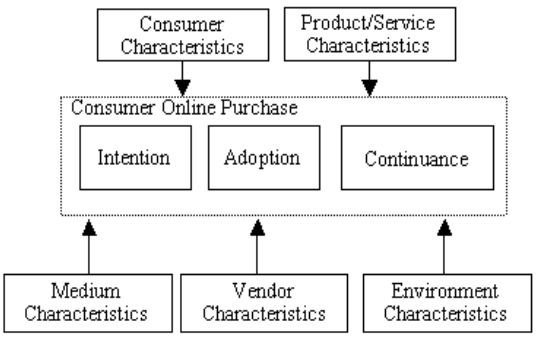

Figure 2. Expanded privacy model (Adapted from 9)

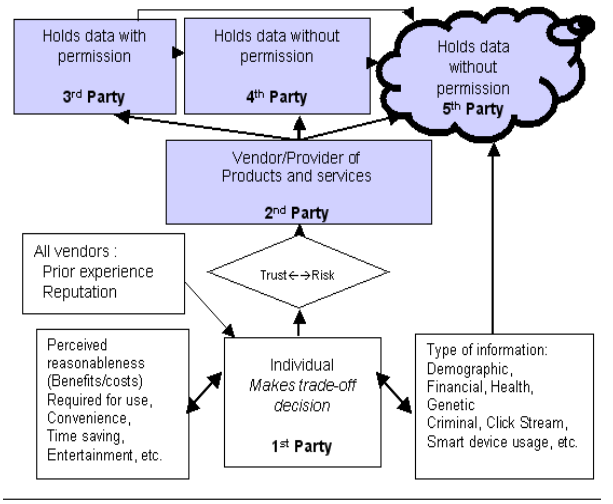

Data may be collected before; during, or after an actual business transaction and the data collection may be known or unknown by the consumer. Combined with other transactional and post-transactional data, this data enables the building of a consumption profile for a family that could affect their insurance or medical coverage. Combined with the other purchase information, a decision profile for the household might be developed and used for discrimination [9].

Consumers appear ignorant of corporate privacy policies and rely heavily on organizations that vouch for the trustworthiness of the vendor (20). The proposed model incorporates real policies and procedures (P&P), perceptions of those P&P, and indications of trustworthiness on Web or other sites.

After a transaction is complete, the information is shared with any number of legal data-sharing entities, the 3rd-party data user who is a known external data-sharing partner, for example, a credit reporting company such as Experion who shares data with 2nd-party permission. Companies, such as Experion, generate their revenues by matching consumer information to transaction information, profiling consumers, and reselling the expanded information. The Experions of the world are not necessarily the problem unless their use or access to data violates their legal and contractual agreements. The greater vulnerabilities arise from Experion's data sharing partners, the 4th parties.

Third-party organizations resell or provide their information to 4th-party organizations through legal requests. Problems arise when 4th-party partners use data without 1st-party and/or 2nd-party permission. Such partnerships might be governmental pre-emption of data (8) or legitimate data-sharing partners of the 3rd-party who violate the terms of their agreements. There is no actual way for, for instance Experion, to ensure proper use since compliance is self-reported. Further, government cooption of data has come under increasing scrutiny as violating constitutional rights to privacy provisions (32).

The nebulous cloud with fuzzy boundaries identifies the last category: 5th-party data users. This category of 5th-party users, are unintended, unwanted, and often unethical and/or illegal users of vendor data. Fifth-party usage results from non-compliant employee behaviors that result in leakages or from illegal activities. Fifth-party data users obtain data without permission or knowledge of their sources, which may be 1st, 2nd, 3rd or 4th parties (4, 17, 32). People who steal computers and who leak names, addresses, and, e.g., financial information, are in this category (32).

From ChoicePoint's infamous identity theft in February, 2005 through 2006, there have been 438 thefts, hacks, or leakages of consumer information of which 335 organizations reported losses over 181 million individual accounts with social security information (33). The 103 organizations either not reporting or not including SSNs, would approximately double the number of transgressions (33).

4. DISCUSSION AND FUTURE RESEARCH

Leakages of data by corporations and governments, while serious, are only evidence of inadequate or unmanaged policies and procedures. This section discusses research needs to determine both a more accurate scope of these problems and how to obtain equitable, workable solutions.

As much as the individual decision process has been researched, there is no known research on parties three through five, nor is there research on the impacts of data leakages or data sharing, in general. While there is a growing body of research on privacy policies and procedures [e.g., 22, 26], no evaluations to date include the impact on consumer decisions. Sample hypotheses for evaluating companies' data sharing management practices might include the following:

- The extent to which the individual's experience with this company's and other companies' data leakages affects the current decision.
- The impact of vendor policy and procedure management for internal users on actual data access and use, and the related impacts on consumer decisions.
- The impact of vendor policy and procedure management for data sharing with known 3rd-party and 4th-party companies on the consumer's beliefs about the company trustworthiness, and related impacts on consumer decisions.
- The impact of vendor policy and procedure management for preventing data leakages to 5th -party users on consumer beliefs about the company trustworthiness, and related impacts on consumer decisions.

The expanded model of personal information privacy described should become the basis for future PIP research.

5. SUMMARY

The expanded model of personal information privacy builds on past research to address emergent issues relating to heretofore unprecedented information demands of governments, unacknowledged corporate information sharing, and the spate of leakages of information from business organizations. The model describe five type of information users from the original owner to the vendor with which they conduct business transaction, to the data vendor, to legal fourth parties, to illegal fifth parties. Individuals are incapable of managing five sets of relationships. Rather, each vendor collecting any customer information must become responsible for actively managing the same criteria with its data-sharing partners *and* their data-sharing partners. Further, all organizations need to improve their management of data leakages to stem the deluge of data losses.

Towards an Integrated Framework of Project Performance

Corlane Barclay, University of the West Indies, Mona Campus, Kingston, Jamaica W.I.: E-mail: corie_corie@yahoo.com

ABSTRACT

Successful management of projects is an important value-creating activity for organizations worldwide. Billions of dollars are invested annually in the creation of new systems and processes to ensure some level of sustained competitiveness. These projects are usually assessed based on the "triple constraints" variables; scope, time and cost. This model is championed by the project management (PM) bodies worldwide and is widely adopted within industries. As the project landscape changed over the last couple of decades due to factors such as globalization and increased competitiveness, it has become increasingly evident that this level of assessment is incomplete, as both researchers and practitioners have raised questions. In response, researchers have begun to evaluate alternative measurements of project performance. Despite this trend, the academic literature on alternative performance metrics remains limited. This paper proposes a measurement framework; the Project Performance Scorecard that incorporates information systems (IS) success perspectives and the Balance Scorecard approach. Six dimensions of assessment are proposed: Project Process, Stakeholder, Learning & Innovation, Benefit, Quality and Use perspectives. It is believed that this approach may provide a more cogent perspective on project performance while providing industry analysts with an alternative measurement tool to value project contribution.

Keywords: project; project success; project performance; IS Success; project management; project performance scorecard; balanced scorecard

INTRODUCTION

Projects and the successful management of projects provide strategic benefits to organizations. Trillions of US dollars are invested in information systems (IS) related projects worldwide annually (Seddon et al., 1999). With these significant investments, organizations have a vested interest in the successes of these ventures. Furthermore, it is prudent to have an accurate depiction of the state of project activities and outcome to assist in the strategic management process. Despite this apparent need, there has been a conundrum within the field on the best, most appropriate method to assess the performance of these projects. Empirical studies have unearthed severe problems with of IS projects (Ewusi-Mensah & Przasnyski, 1991; King, 1997; Standish, 1994, 2004) and successful IS projects are quite rare (Agarwal & Rathod, 2006).

The widely cited 1994 Chaos Report revealed that a staggering 84% of IS projects have failed, or are challenged, and only a meager 16% succeed (Standish, 1994). However, there was a slight improvement in 2004 with a 29% success rate (Standish, 2004). These failures have given rise to the perception of a "software crisis" (Duggan, 2004; Glass, 2006). As a consequence, researchers and practitioners moreso have been struggling with providing a remedy for these failed systems. Researchers have contended that there are apparent disparities between research and practice (Glass, 2005, 2006) and have called for a "new theory of project success" (Glass, 1999). This phenomenon presents some interesting questions. *Do these studies depict an accurate picture? Are the current performance measures accurate or sufficient? Will alternative measurements provide a different outlook?*

This paper seeks to address the latter question by providing an integrated framework for measuring project performance, the *Project Performance Scorecard*. This will be achieved through the integration of multiple perspectives of performance measurement, including IS Success models and the Balanced Scorecard. Based on empirical evidence, the "triple constraints" methodology has been widely accepted in practice as the de facto standard for measuring project performance for decades. While there is merit in this approach, projects involve complex and dynamic activities, and evaluation of IS investments is a notoriously difficult area (Fitzgerald, 1998), thus performance criteria needs to take into consideration all aspects of the project (Wateridge, 1998). Additionally, as the dynamism of organizations evolves due to factors such as increased globalization and institutional pressures; questions have been raised as to the sufficiency of this method for the complex and dynamic project process. In an effort to extend the cumulative tradition in project management (PM) research, a multi-dimensional approach is proffered to provide a parsimonious assessment that can be adopted by practitioners.

Several alternatives to the triple constraint methodology have been explored in the literature (Atkinson, 1999; Bryde, 2003, 2005; Morris & Hough, 1987; Nelson, 2005; Wateridge, 1998) yet the adoption in practice is not yet widespread. Additionally, researchers have primarily focused on identifying critical factors for providing some level of assurance in achieving a predetermined level of project performance, e.g. (Cooke-Davies, 2002; Ewusi-Mensah & Przasnyski, 1991). This research therefore adds to the extant literature through the provision of an integrated and cogent perspective grounded in IS theory. The seminal contribution of Delone and McLean (1992) and subsequent studies (DeLone & McLean, 2003; Seddon, 1997; Seddon et al., 1999) are considered a strong theoretical pillars for the *Project Performance Scorecard*. The models posit that service quality, information quality, system quality, information use and user satisfaction are dimensions of IS Success. Empirical evidence supports that these dimensions provide strong theoretical support (Rai et al., 2002). The well cited balanced scorecard presents an approach to measuring organizational performance (Kaplan & Norton, 1993). It is aimed at providing a comprehensive view of the performance of the organization through four perspectives: financial, customer, business process and learning. One can therefore conjecture that these models may be used as the basis for evaluating IS projects.

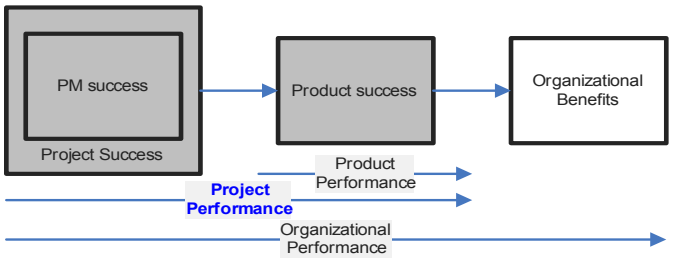
Performance measurement involves the processes of assessing the progress against predetermined objectives (Bourne et al., 2003). Project performance can therefore be considered as the process by which the project progress is measured against predetermined objectives to determine "success" or "failure" of which the triple constraints methodology is the standard. Atkinson (1999) suggested that it is time to move on from time, cost and quality criteria of success due to its limitations. Despite this advice, empirical evidence suggests that the triple constraint assessment is largely adopted by PM bodies such as Project Management Institute (PMI) and Association of Project Management (APM). The evaluation, more so the accurate evaluation of project performance is of strategic importance; according to (Ewusi-Mensah & Przasnyski, 1991), evaluating information systems is increasingly becoming a major concern among senior management.

The perspectives of project success are briefly discussed in the following section as it is important to understand success in order to provide an accurate view of performance. This is followed by a summary of the literature on project performance/success along with the perspectives on performance/success criteria. The exploratory framework, the *Project Performance Scorecard* is then explicated to provide an alternative integrated measurement tool and the paper ends with some concluding remarks including research limitations and research directions and implications.

DEFINING PROJECT SUCCESS

Projects bring about change and project management (PM) is seen as the most efficient way of managing these changes (APM, 2006). The management of projects ranges from unstructured to highly structured initiatives. The inclusion of PM best practices provides credence to the structure and organization of the projects managed by organizations. Project is defined by the PMI as *a temporary endeavor*

Figure 1. Project performance



undertaken to achieve a unique product, service or result (PMI, 2004), or a *unique, transient endeavors undertaken to achieve a desired outcome* (APM, 2006). PM is therefore defined as *the process by which projects are defined, planned, monitored, controlled and delivered such that the agreed benefits are realized* (APM, 2006) and *the application of knowledge, skills, tools and techniques to project activities to meet project requirements* (PMI, 2004).

The realization of these project benefits or requirements is necessary for the achievement of strategic objectives. There is very little agreement in previous studies as to what really constitutes project success (Shenhar et al., 2001) as researchers have put forward various views on project success. Project success is measured against project objectives while PM success is measured against the triple constraints criteria (Baccarini, 1999; deWit, 1988). Baccarini (1999) further outlined project success as consisting of two components: PM success and product success, where product success is seen as the effects of the project's final product. The divergence in perspectives has resulted in a lack of consistent definition of project success, it is therefore uncommon to present both processes as a single homogenous group (Baccarini, 1999).

It is apparent that there are three distinct processes that are considered in the project success discourse; *PM success, project success and product success*. (Wateridge, 1998) suggests that there is need to address the process and the outcome in assessing project success. The paper's interpretation supports the perspective the processes are intrinsically linked and considers that project success may be seen as an outcome of PM success. This complex interrelationship culminates into product success and organizational benefits over time (see figure1). Thus, project performance is based on PM success (*measured against PM objectives, inclusive of triple constraints*) and project success (*measured against overall project stakeholders objectives*) and product success (*measured against the value of the project outcome to the project and client organizations*). Therefore in analyzing this phenomenon the paper will consider the full spectrum of the project performance components.

PERSPECTIVES ON PERFORMANCE CRITERIA

Project being a complex and dynamic endeavor has numerous objectives, therefore criteria for measuring project success must therefore reflect different views (Struckenbruck, 1986). A survey (Sofian, 2003) of 142 respondents confirmed that project stakeholders have various perspectives on project success. The majority agreed that cost, schedule, quality, functionality and customer satisfaction were good assessment of project success. The creation of organizational learning, effectiveness and efficiency performance, and ability to execute changes were other consideration. Similarly (Agarwal & Rathod, 2006) research among software projects found that cost, schedule functionality and quality were important criteria while customer satisfaction, unique priorities being relatively minor considerations.

Several other researchers have formulated perspectives on success and performance criteria with the common theme being triple constraints. Atkinson (1999) suggested that practitioners should try to prevent type II error by moving away from the triple constraints criteria assessment. (Linberg, 1999) suggested that substantial learning which can be applied to future projects was the critical criteria from the developer's perspective. Organizational value, benefit or profitability were also considered (Morris & Hough, 1987; Nelson, 2005; Turner, 1993; Wateridge, 1998). Atkinson (1999) formulated the Square Root model that incorporates Deleone & McLean's IS success factors and organizational and stakeholder benefits. Organizational benefits include improvements in efficiency, effectiveness, profitability and learning. Benefits to stakeholders consider satisfaction of project results, learning impact to environment. (Nelson, 2005) used similar measures with the dimensions being value, use and learning from the project, and suggested that these be a part of the project retrospectives process. (Bryde, 2003) considered the quality perspectives based on the EFQM Excellence model in developing the PMPA, Project Management Performance Assessment. The model includes tools used to measure the level of performance amongst project including leadership, team, policy and strategy, partnerships and resources, KPIs. Additionally, eight quality dimensions should be considered for organizational leveraging; performance, features, reliability, conformance, durability, serviceability, aesthetics, and perceived quality (Garvin, 1987). Especially, for IS projects, these criteria are important in assessing not only the project but the project outcome.

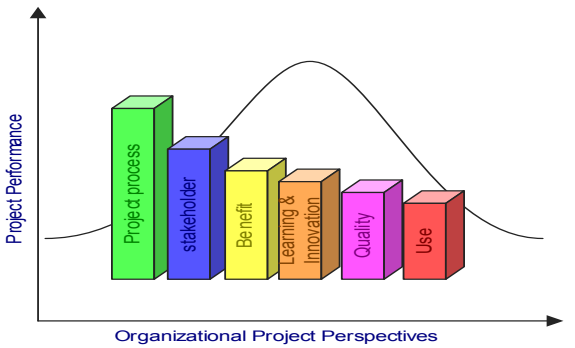
It is widely accepted that IS success is the principal criteria for IS assessments (Rai et al., 2002), with multiple perspectives. Delone & McLean (1992) found through extensive literature review that IS success could be explained by six dimensions: information quality, system quality, information use, user satisfaction, individual and organizational impact. The framework was extended to include service quality (DeLone & McLean, 2003) while Seddon (1997) posits that IS use is a consequence of IS success. Another performance measurement, the balance scorecard posits that the business process, client, financial and learning perspectives are the balanced approached to measuring performance within the organization (Kaplan & Norton, 1993).

PROJECT PERFORMANCE SCORECARD

In extending the literature, an exploratory framework is constructed that is primarily underpinned by IS Success and Balance Scorecard. It is put forward that this approach provides a cogent perspective as it accounts for the complexity and dynamism of projects. The *Project Performance Scorecard* seeks to theorize a perspective that span the realms of the project processes while taking into consideration the expectations of all the stakeholders. Based on the context, each dimension may play greater importance. The six dimensions interact as each has an influence on its counterpart, for example the stakeholder requirements may include quality and usability items. The dimensions are:

1. **Project Process perspectiv**e. Measures indicating key project processes, including triple constraints criteria. The key knowledge areas of integration, scope, time, cost, quality, human resource, communication, risk and procurement management (PMI, 2004) are assessed to measure the extent that they were adopted throughout the project.
2. **Stakeholder perspective**. Measures indicating stakeholders' expectations and objectives. It is essential that project managers obtain consensus from all stakeholders on the criteria for success (Wateridge, 1998). Based on the nature of the projects stakeholders may differ. The major stakeholders include the customer, client/sponsor and project team. The defined expectations, objectives, requirements and specifications are considered against actual outcome.
3. **Benefit perspective**. Benefits indicate the gains or advantages garnered throughout the project process. This involves measures indicating the financial and non-financial performance of the project outcome. Such an assessment may be over a period of time as the results may not be seen immediately.
4. **Learning and Innovation perspective**. Measures indicating project learning from the perspective of the project organization and/or client organization. Additionally incorporating formal and informal knowledge management practices of the project process may provide short and long term benefits to the organization, e.g.(Barclay & Osei-Bryson, 2006). Tiwana (1999) suggests that organization may face additional expenditure and challenges through repeated mistakes. Therefore, it important to manage learning and knowledge in such a way to have it accessible for the current project and future projects
5. **Quality perspective**. Garvin's (1987) discussion on dimensions of quality is applicable within this perspective. Depending on the nature of the project, environmental context and the stakeholders' requirements particular variables may be more applicable than others.
6. **Use perspective**. Measures indicating the use and usability of the project outcome. TAM (Davis, 1989), the seminal adoption model criteria, which also formed the basis of IS success models, are applicable instruments in accessing the performance of projects.

Figure 2. Project performance scorecard



A conceptualization of the six dimensions of the *Project Performance Scorecard* to depict the dynamism of the measurements based on the project and organizational context is shown (see Figure 2).

CONCLUDING REMARKS

The research is at its embryonic stage and is limited in its coverage of other alternative performance measurements. Future research directions involve the extension of the breadth of the study and the inclusion of other domain perspectives to refine the assessment framework. The identification and explication of goals and measures for each dimension are also recommended. Empirical case studies to improve the understanding of the how the *Project Performance Scorecard* will perform under different organizational project contexts and the investigation of alternative measurements under similar contextual framework also offer interesting research.

Possible research direction include two main paths; a consistent taxonomy on project success, and additional project performance metrics that are aligned to organizational strategic objectives. A consistent taxonomy is sought as the PM discipline evolves which will help in providing practical solutions, consistent with Delone & Mclean's (1992) view that if IS research is to make a contribution to practice then well defined measurements are important. Projects differ on various endogenous and exogenous factors such as complexities, purpose, organizational context, skill complement, it is therefore important to consider multiple perspectives and related disciplines to help explain this phenomenon.

Realistic performance measurements and assessments are becoming increasingly important as organizations continue to face internal constraints and institutional pressures. The research asserts that *Project Performance Scorecard* will provide a different outlook on project performance. It is a tangible tool for practitioners to adopt and assist in the management and assessment of their projects. Additionally the research adds to research through the provision of an additional perspective to help measure project performance.

An Approach for Rapid Creation of a Virtual Software Development Team

Damjan Vavpotic, University of Ljubljana, Trzaska 25, 1000 Ljubljana, Slovenia; E-mail: damjan@fri-uni-lj.si
Marjan Krisper, University of Ljubljana, Trzaska 25, 1000 Ljubljana, Slovenia; E-mail: marjan.krisper@fri-uni-lj.si

Nowadays, companies dealing with software development are often facing problems related to cadre as a consequence of rapid technology changes and varying project requirements. Knowledge of the companies' software engineers is quickly becoming outdated and it is virtually impossible for a single developer to master all the latest technologies and approaches in his field of expertise. Consequently older technologies often remain in use. Yet another difficulty is that cadre requirements of software development companies change from project to project. Frequently, when a new project is commenced additional workforce is required, but after the project is finished these additional employees are not needed anymore.

The usual solution would be to (temporary) employ more people and to additionally educate some of the existing employees. However it is often difficult to find enough people locally that have suitable knowledge and expertise and therefore additional training of new employees is required also. If these additional employees are not needed after the project is finished, educating them only for the needs of a project is a costly solution.

An alternative solution might be to form a virtual team. The main advantage of such solution is that team members can be selected form a large pool of people having appropriate skills and knowledge (Furst, Reeves, Rosen, & Blackburn, 2004). Nevertheless, different problems have been reported that arise in such teams (Johnson, Heimann, & O'Neill, 2001) and many projects relying on a virtual team failed (Furst, Reeves, Rosen, & Blackburn, 2004). The most exposed problems in virtual teams were related to communication (Gould, 1999) and different human factors (Townsend & DeMarie, 1998). Researchers suggest that people working in virtual teams need special social and communication abilities and should be trained to work in such teams (Gibson & Cohen, 2003).

The goal of our research is to create methodological approach that would enable a software development company to instantaneously start an ad hoc virtual team when required. A company should be able to use such virtual team to implement a whole system or only parts of a system. As most of the problems in virtual teams arise due to communication and human factors our aim is to lessen their impact. A backbone of the approach comprises of core system architecture, project management, core development process and human resource management. The purpose of the backbone that is managed centrally is to enable synchronisation of virtual team members.

- **The core system architecture** facilitates construction of the system from relatively small system parts. The backbone of the architecture is a system framework that connects these parts into a functioning system. Each system part is precisely defined by a detailed description of its functions and a definition of its interface. To support such architecture we intend to use existing technologies and architectures like SOA (Erl, 2005).
- **The project management** is modified in a way that it minimises human factor risks. Work is divided into small independent tasks. Each task is defined in a way that it can be executed by a single team member in a relatively short period of time and that its execution is as independent as possible to minimise needs for communication between team members. This way the progress can be monitored precisely and problems detected more easily. To further minimise the risks more critical tasks are assigned to more dependable team members and less critical tasks to new or less dependable team members. Because tasks are relatively small it is also possible to assign highly critical tasks to more than one team member and after two or more developers completed such task only the best solution (system part) is selected for inclusion in the final system.
- **The core development process** gives detailed instructions on how to perform different types of tasks. To lessen communication problems each team member is given only the instructions that are necessary to perform the type of task he was assigned. Furthermore, instructions are adapted to the skills and knowledge of each team member. The adaptation is based on principles of situational method engineering (Brinkkemper, Lyytinen, & Welke, 1996). Program support will be created that will automate the creation of adapted task instructions. It will be based on our existing research (Bajec, Vavpotic, & Krisper).
- The intention of **the human resource management** is to create a large pool of potential team members and to monitor of the performance and skills of current team members. Search for new team members is performed via internet. Recruitment of team members is based on their previous work record, on reported knowledge and skills and on task requirements. We intend to create program support that will automate search for new team members, team members monitoring and recruitment. The automation of human resource management will be based on existing approaches that automate formation and management of virtual teams (Norman et al., 2004), (Suter, 1999), etc. Although these approaches do not focus on software development they bring many interesting ideas in the field of virtual teams' management.

Figure 1 shows the model of the proposed approach.

In our opinion, the proposed approach could offer interesting advantages as it would enable software development companies to quickly assemble a virtual team when additional workforce is needed. It would also minimise the needs for special communication and social abilities of virtual team members, as each member would be given precise instructions on how to perform the task he was assigned and tasks would be as independent as possible. However, we are aware that there are many difficulties that will have to be resolved. The main question is whether it is possible to assemble a functioning system from system parts created by many different developers and there is also the problem of maintenance and efficiency of such system.

So far we have delineated the backbone for the approach and identified its basic properties. In the next step we will detail parts of the backbone and develop the required program support. To test the approach we intend to create an experimental team comprised of university students. The purpose of this test will be to identify weak parts of the approach and to gain experience. The results of the test will enable us to improve the approach. Finally, we plan to test the approach in a real life environment.

Collaboration Models or What Does It Take for Collaboration to Become a Common Asset?

Barbara Flügge, CEC St. Gallen/Switzerland, Blumenberplatz 9, 9000 St. Gallen, Switzerland; E-mail: b.fluegge@sap.com

1. INTRODUCTION

The topic that is subject to the paper is the standardization and interoperability of Enterprise Architecture Frameworks with respect to cross-border and cross-country trade in selected EU member states. The topic fits into the EU wide initiative of the European Commission to implement electronic customs. The expected outcome is the reduction of the administrative burden for governmental authorities and business partners, the compliance of logical, data and product flows as well as assuring secure trade lanes.

The paper will give in the first part a background to the field of collaboration and its elements. In the second part it will discuss the research area, introducing some research questions and the research methodology.

1.1 Traditional Context of eCommerce Initiatives

Traditionally academic research in collaborative topics started with a specific focus on the individual elements of collaboration. The relevant elements that have been investigated are Enterprise Architecture Frameworks, Business Process Management and eCommerce, namely B2B, as well as eGovernment standardization initiatives.

1.2 Enterprise Architecture Frameworks

Interoperable solutions and standards are in the focus of research since the first introduction of an Enterprise Architecture Framework by Zachman[1]. Since then various different aspects of interoperability and building elements have been added to apply, adopt and promote interoperable enterprise architectures.

One example of interoperable enterprise architectures is HL7[2], conceptualized by Blobel. Another example is the development of the client-server architecture and application standardization, conceptualized and engineered by SAP[3].

Complementing the research of enterprise architectures, the analysis how these frameworks set the ground rules for cross-organizational collaboration is not fully explored yet. Part of the analysis has been carried out in the work of Henriksen (Henriksen, 2002).

1.3 Cross-Organizational Business Process Management and Modelling

This topic focuses on the business process and cross-organizational perspective. Starting with business process re-engineering and the integration of workflow and BPR companies gained deeper understanding of their cross-departmental business processes and enhanced their internal process management capabilities. Having set the ground in a basic understanding of business process management, the cross-organizational perspectives are being extensively discussed in research projects like ATHENA[4] and PICTURE[5].

1.4 Standards and Standardization Efforts

In the arena of standardization efforts, the nature of the research was mainly focusing on individual standards and their usability to companies. With the introduction of marketplaces and the web itself, organizations got an accessible tool that enabled the proliferation of their own business models. Governmental institutions themselves commenced with eCommerce scenarios by publishing information and later forms and documents on the web.

Gathering counterparts and sparing partners from a range of alike companies and industry sectors, standardization organizations and initiatives (for example UN/CEFACT[6], AIAG[7], RosettaNet[8]) evolved the eCommerce commencements by setting ground rules for the composition of standards in their specific business / research field. They allowed companies to contribute to cross-organizational business models and process management by providing standardized processes and / or data schema. Today, we encounter more than 200 standards that are offered in the market.

1.5 Collaboration in Present and Future Perspectives

With respect to global trade, collaboration is a critical success factor where business and governmental institutions meet. Through the entire supply chain, the connected document flow and back-and-forth-approvals there are public process elements, commonly relevant for each of the business partners. They play the role of providing a common denominator to collaborative business scenarios.

Historically, collaboration research analysed the nature of networks (internal and external networks), business as well as cultural relationships. Through the introduction of local networks like the *keiretsu* phenomenon in Japan (Satoshi Hamaya, 2004) eCommerce and collaboration moved towards IT enabled collaborative scenarios for many to many relationships and away from the one to one focus in eCommerce. As *keiretsu* is specifically linked and limited to the Japanese cultural and business environment, the research will introduce the term ecosystem. The ecosystem illustrates participants and contributors in a pre-defined business environment such as the trade environment and their interactions.

2. RESEARCH APPROACH

2.1 Research Problem

The collaboration elements that have been discussed above still leave a (growing) community of business and governmental partners who seek for constant and reliable effects of collaboration beyond the traditional one to one solutions. In the area of electronic customs for example, business and governmental partners are confronted with an increasing demand for secure trade, compliant and accessible data at any time for any business partner participating in trade processes. Today's trade business is also characterized by new business partners entering existing and already collaborating ecosystems.

A substantial effort in proper and necessary business process re-engineering has been made in the past years. They aimed to analyse existing process scenarios, identified potential process breaks and resulted in a number of best practice approaches. One of the major achievements in research is the development of business process re-engineering models and their visualization through modelling techniques. These emerged from the usage of Petri nets, unified modelling language (UML) activity diagrams, business process modelling notation (BPMN), event triggered process chains (EPC), business process execution language (BPEL) to business process modelling language (BPML). Donath among others is introducing the evolvement of these modelling techniques.(Donath, 2006) Another major achievement has been made by integrating process modelling techniques with workflow modelling. (Wittges, 2005)

Proprietary IT solutions and industry standardization facilitate collaboration within industry sectors (MATTHEW L. NELSON, 2005; Sanna Maria Kallioranta, 2002; Sissonen, 2002). These efforts eased the ground of commencing discussions and research on appropriate collaboration (Wittges, 2005).

However, process modellers, IT developers and technical providers as well as business partners still see standards dynamically changing. Various studies and research projects have been conducted on standards and their evolution. They reviewed different aspects such as standards dynamics like in the research project NO-REST[9] under the sixth framework. Studies have been conducted on the evolvement and usability of standards in specific industries, specific scenarios like B2B or B2G and their diffusion (The European e-Business Report 2005, Studie eBusiness-Barometer 2006/2007, Global E-Government Readiness Report 2005, et.al.)(Commission, 2005; Myriam Fricke, 2006; Nation, 2005; NIELS BJØRN-ANDERSEN, 2004).

Due to high investments in IT, skill development and interface development, organizations find it still difficult to manage proprietary standards on the one hand and to limit the restrictions in collaboration caused by proprietary solutions and caused by the smaller number of personnel that is trained and capable to deal with standardization in ICT. Investments however have been made. Business and governmental partners seek a way to build upon their existing software solutions applying proper standard. They envision successfully deployable standards for collaborative business scenarios where companies and governmental institutions are not limited to any lack of skills, IT budgets or time constraints.

The expectation in the market is to overcome any effort that is needed to transform collaboration into a common (accessible, understandable and available) asset. Collaboration should be an out-of-the-box or better built-in-characteristic of any solution being offered in the market.

Accompanying the previous discussion there is a number of research questions that may be formulated:

- *What are the main elements of collaboration in the traditional context? Why is electronic collaboration still not a common asset to support daily business operation?*
- *What are the main factors driving collaboration needs in present and future business operations? How does the content and purpose of collaboration evolve in the context of the ecosystem?*
- *How could we invite technically, content and document wise a new business partner to join a trade ecosystem?*
- *Which standards related to technology, content and documents would the business partner need to apply or adopt to do business?*

2.2 Research Approach

Based on the various angles of collaboration the dissertation will map the research approach to various research methods.

Table 1 describes the main activities

The on-going research, relevant to Phases 2b and 3, is mainly linked to ITAIDE (ITAIDE, 2006) and further activities in Europe focusing on the Living Lab approach as a research method to investigate in ecosystems. ITAIDE is an integrated project funded by the IST 6th Framework Programme of the EU which has been initiated at the beginning of 2006 to address some of the key issues related to cross-border trade. Since I am involved in ITAIDE and the Living Lab approach, I will take the opportunity to carry out the various assessments, interviews and case studies in co-operation with these projects.

Phase 4 will draw assumptions of the key findings of Phase 3. Assumptions derive from three dimensions, the technical, the cultural and the process dimension.

To verify (heuristically) the assumptions, they will be confronted with a set of contradictions. In addition, the assumptions will be applied to future sub-sets of the ecosystem. There is no certainty for example that collaboration based on the UN/CEFACT methodology will not work tomorrow, although past experience (in the sub-sets of the ecosystem) would make such an occurrence seem unlikely. Phase 5 verifies the collaboration approach of UN/CEFACT in additional sub-sets of the ecosystem.

2.3 Research Progress

The following activities are currently carried out:

- Interviews with governmental institutions in the area of global trade and customs processes in the European Union
- Study about the ecosystem for the Finnish paper industry including the involved business and governmental partners and their interactions
- Study about the ecosystem for the Dutch beer manufacturing industry including the involved business and governmental partners and their interactions
- Study about process drivers for cross-organizational business with relevance to global trade, filtering public process views and assessing key performance indicators for successfully conducting customs and trade related processes
- Study about value drivers for each of the individual participants in the ecosystem, starting with small and medium sized enterprises and the customs authorities.

Further accompanying activities are the following:

- A questionnaire to form the basis for structured interviews on both process and value drivers is drafted and currently under review.

Table 1. Overview of research activities

Phases	Research Method	Means	Focus Area
Phase 1	Qualitative Research	• Literature Study • Unstructured and structured Interviews (with experts in the focus areas)	• Evolvement of Enterprise Architecture Frameworks • Business Process Management • eCommerce Development (early stages of collaboration, interoperability and standardization)
Phase 2a	Qualitative Research	• Case Studies	• Ecosystem Trade and sub-sets of the ecosystem throughout the research project
Phase 2b	Qualitative Research	• Literature Study • Unstructured and structured Interviews (with ecosystem participants and contributors in the focus area)	• Ecosystem Trade and sub-sets of the ecosystem throughout the research project
Phase 3	Qualitative Research	• Case Studies applying the collaboration scenario • Scenario study applying the standardization and collaboration methodology (UN/CEFACT)	• Ecosystem Trade and sub-sets of the ecosystem throughout the research project • UN/CEFACT standardization methodology as common denominator for collaboration

- The analysis of the state-of-art literature is an on-going process and will be done in parallel to the activities outlined above.
- Structured interviews are an on-going process. Knowledgeable interview partners are coming from the academic, governmental and business area.

The result from the activities described in this chapter will form the basis for a PhD dissertation concerning collaboration models and the research questions what it takes for collaboration to become a common asset.

3. CONCLUSIONS

Companies and governmental institutions are more and more forced to lower process definition efforts and diminish transaction costs. Time is running and companies as well as their counterparts in governmental authorities are faced with a growing competitive business environment that urges them to dynamically adapt and extend their process models. A research work like this will support both the research community and the European business and governmental ecosystem in introducing on the one hand research techniques to assess complex standardization efforts and to transform that feedback on the other hand into feasible technical, process and academic concepts.

Recognizing Constraints on Project Success

Theresa A. Steinbach, DePaul University, 243 South Wabash Avenue, Chicago, IL 60604, USA; E-mail: tsteinbach@cti.depaul.edu
Linda V. Knight, DePaul University, 243 South Wabash Avenue, Chicago, IL 60604, USA; E-mail: lknight@cti.depaul.edu

ABSTRACT

The Standish Group (2004) claims only 29% of IT projects are completed on time and on budget, with all features and functions originally specified. The use of a development methodology as long ago as 1970 has been considered critical in project success when building systems, however, the choice of which methodology is best suited for these projects is still under debate (Glass, 2004). This research-in-progress begins to identify the relationships between organization, project, and team variables that lead to project success.

INTRODUCTION

System development methodology was first formalized by Royce in the 1970s (Royce, 1970). It provided a consistent and reproducible approach in the analysis, design and delivery of data processing systems. This complex process was divided into plausible and coherent, linear steps that applied techniques and resources at appropriate times. Boehm (1986, 1988) introduced an iterative approach with the primary focus of reducing project risk associated with long implementation times. Aoyama (1993) documented a parallel methodology where concurrent development focused on the simultaneous execution of multiple processes to shorten cycle time. Agile development models developed most successfully by Beck (1999) had the primary goals of rapid value and responsiveness to change (Boehm & Turner, 2003). However, none of these methodologies is best suited to system development of all information systems, and Web Information Systems appear to demand a different methodology than that which has been used for traditional Information Technology projects (Steinbach & Knight, 2005). This study explores the relationships among a variety of organization, project, and team variables with the goal of better understanding the relationship between these variables, system development methodology, and project success.

METHODOLOGY

The variables to be studied were based on an extensive literature review of existing system development methodologies. These methodologies were analyzed for situations where they were most likely to be beneficial. For example, when there is need for rapid implementation of the project, an iterative methodology may be more suitable than a parallel one. See Steinbach and Knight (2005) for the complete analysis. Using the variables from this analysis, a Web-based explanatory survey was conducted using a purchased, opt-in mailing list purchased from a major Website frequented by information system developers. Respondents were asked to rank qualitative variables related to organization, project, and team variables.

SUMMARY OF RESULTS

One hundred thirty-one self-qualified IT project managers responded from a mailing list of 5,750 for a response rate of 2.29%. The majority of the organizations represented by the respondents were large (greater than 5,000 employees) entities from service, financial and government sectors (*Figures 1 and 2*).

DATA ANALYSIS TO DATE

At this point, ten hypotheses, out of a total of 15 hypotheses in the entire study, have been tested using **the chi square test of independence which measures the strength of associations between variables**. Of these ten, five provided unexpected results and are highlighted by bold type in the list below.

Figure 1

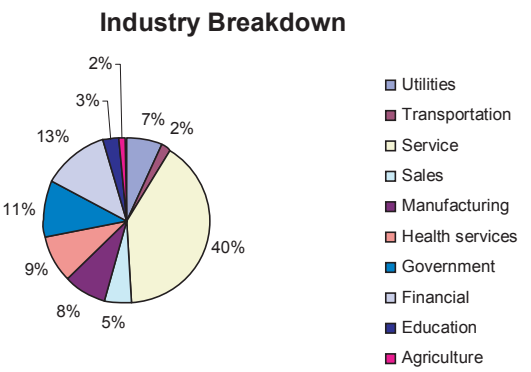

Figure 2

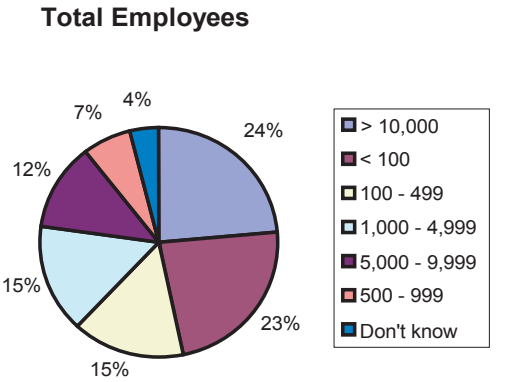

Users' Objectives

H1: *If the users' objectives for the project were clear, the project requirements were clear.* As expected, there is a strong association between the variables.

H2: ***If the users' objectives for the project were clear, the project's users were satisfied.*** There is no association between users' objectives and satisfaction. This is an unexpected result and warrants further discussion.

H3: ***If the users' objectives for the project were clear, project approvals were not required.*** There is no association between users' objectives and approvals. This is an unexpected result and warrants further discussion.

Project Approvals

H4: ***If project approvals were required, the culture in the organization is controlled.*** There is no association between project approvals and the culture in the organization. This is an unexpected result and warrants further discussion.

H5: ***If project approvals were required, the strategy of the organization is clearly defined and committed.*** There is no association between project approvals and the strategy of the organization. This is an unexpected result and warrants further discussion.

Knowledge of Users

H6: *If the users were known to the project's managers, the users' objectives were clear.* As expected, there is a strong association between the variables.

H7: *If the users were known to the project's managers, the project requirements were stable.* As expected, there is a strong association between the variables.

Project Risk

H8: *If project risks were well identified, the project was completed on time.* As expected, there is a strong association between the variables.

H9: *If project risks were well identified, the project was completed within budget.* As expected, there is a strong association between the variables.

H10: ***If project risks were well identified, the project was completed with expected features and functionality.*** There is an association between the variables, but not as strong as expected.

DISCUSSION

Discussion of these results and other results that are analyzed between now and the final paper deadline will be included in the expanded submitted paper.

Business and IT Strategic Alignment and Strategic Use of IT in Small Firms

Chia-an Chao, Indiana State University, Terre Haute, IN, USA; E-mail: cchao@indstate.edu

ABSTRACT

In businesses large and small, information technology has become an integral part of operation. To compete with large businesses, IT savvy small firms are at an advantage (Beheshti, 2004; Lin, Vassar, & Clark, 1993; Schaefer, 1995). Studies have shown positive impact of IT on small businesses, from helping small firms enhance their operational efficiency (Beheshti, 2004; Penhune, 1998) to driving business growth (Eckhouse, 1998), to integrating marketing operations with marketing strategies (Roge & Chakrabarty, 2002). In addition to the operational and strategic importance of IT, given small businesses' limited financial resources (Small Business Administration, 2000), small firms must invest wisely by making sure that their IT resource allocation properly reflects their business priorities. In other words, they must ensure their IT strategies are inline with their business strategies. This study examines the impact of IT and business strategic alignment in small firms, their business strategic orientations, and owner characteristics on the strategic use of IT.

LITERATURE REVIEW

Information technology strategic alignment is the fit between business strategy and IT strategy (Chan, Huff, Barclay, & Copeland, 1999; Hussin, King, & Cragg, 2002). According to Henderson and Venketraman (1993), strategic alignment involves strategic fit and functional integration. Chan et al., (1999) extended Henderson and Venketraman's work and developed instruments to measure strategic alignment. They studied the impact of strategic alignment on business performance and perceived IS effectiveness. They found that IS strategic alignment was a better predictor of business performance and IS effectiveness than either business strategic orientation or IS strategic orientation. Focusing on small businesses, Bergeron, Raymond, and Rivard (2004) studied 110 firms and found that firms with conflictual coalignment pattern of business strategy, business structure, IT strategy, and IT structure exhibited lower levels of business performance.

IT use in small firms is often characterized as tactical and lacking in sophistication (Bridge & Peel, 1999; Hassan & Tibbits, 2000; Igbaria, Zinatelli, Cragg, & Cavaye, 1997; Lin & Wu, 2004). Temtime, Chinyoka, and Shunda (2003) found that small firms more frequently used microcomputers for operational tasks—such as accounting, payroll, budgeting, production and sales planning, and stock control activities—than for managerial activities such as strategic analysis, investment appraisal, market research, and cash flow and profit forecasting. The tendency of small firms to focus on short-term operational efficiency instead of using IT for business planning, supporting business strategies, monitoring business performance, and improving competitive advantage could be attributed to several factors. Kyobe (2004) compiled a list of factors inhibiting strategic utilization of IT in small firms including lack of top management vision, lack of computer experience/expertise, and poor planning and inability to identify strategic use of IT. Among the inhibitors, management vision and support is clearly an important factor. The importance of management/owner influence is corroborated in studies that show small firms' owners' innovativeness, knowledge and perception of the relative advantage of IT played a critical role in IT adoption decisions (Cragg & King, 1993; Igbaria et al., 1997; Lee & Runge, 2001; Thong &Yap, 1995). The relationship between small firms' IS investment and strategic context was studied by Levy, Powell, and Yetton (2001). They found that small firms' IS use was a reflection of their strategic focus (cost reduction vs. value added) and market positioning (high or low customer dominance).

STUDY FOCUS

The purpose of this study is to examine IT and business strategic alignment in small firms by comparing aligned and not-aligned small firms' IT use, business strategic orientations, and owner characteristics. Specific research questions and hypotheses include the following:

- Do aligned and not-aligned small firms differ in their IT use? Are aligned firms more strategic in their IT use?
  - o H1: Aligned firms use IT for strategic analysis and planning more than non-aligned firms.
- Do aligned and not-aligned firms' owners differ in characteristics? Are aligned firms' owners more knowledgeable in IT? Are they more involved in IT implementation and management?
  - o H2a: Owners of aligned firms are more knowledgeable in IT than their non-aligned counterparts.
  - o H2b: Owners of aligned firms are more involved in IT implementation and management than their non-aligned counterparts.
- Do aligned and not-aligned small firms differ in their business strategic orientations? Are aligned firms more divergent in their business strategies such as focusing beyond cost and quality and on product/service differentiation also?
  - o H3: Aligned firms are more divergent in their business strategies than non-aligned firms.

By comparing characteristics of small firms with aligned and not-aligned IT and business strategies, this study seeks to determine the impact of strategic alignment, owner characteristics, and business strategic orientations on IT use in small firms.

RESEARCH METHOD AND EXPECTED STUDY OUTCOMES

Data for this study is based on input from small business owners (businesses with fewer than 500 employees) in several Midwest states in the U.S. While the study adopts the standard categorization of small-medium enterprises (500 or fewer employees), the survey included a "number of employees" question to aid classification of firms based on firm size in data analysis. The data collection instrument is a two-page questionnaire on the small firm's business and IT strategies, types of IT currently adopted, and business owner's IT knowledge and involvement in IT implementation and management.

To answer the research questions, several statistical analyses will be performed. First, cluster analysis will be used to identify firms with similar strategic alignment. Once clusters have been identified, additional analysis will be carried out to validate the clusters: t-test or analysis of variance will be used to determine whether significant differences exist between/among the clusters in the extent of IT and business strategic alignment of each cluster. Types of IT used and owner characteristics of firms in various clusters will also be compared. In addition, factor analysis will be used to detect existence of underlying dimensions of business strategies employed by small firms; the business strategic orientations of small firms in different clusters will then be compared. Finally, multiple regression analysis will be used to develop models for predicting small firms' strategic IT use based on various independent variables.

Expected findings from this study should enhance current understanding of IT utilization in small firms and its relationship with several variables (including

strategic alignment, owner influence, and business strategic orientation). While IT use in small firms has been a popular research topic, particularly studies that focus on e-commerce adoption in small firms (e.g., Grandon & Pearson, 2003; Martin & Matlay; 2003), this study explores the relationship between business and IT strategic alignment and IT use (including e-commerce), and examines the impact of mediating variables (business strategic orientation and owner characteristics) on strategic IT utilization. Such findings should add to existing literature on IT use in and strategic value of IT for small firms

The Quality of Human-Centeredness in CRM for SFA

Hannakaisa Isomäki, Information Technology Research Institute, University of Jyväskylä, Finland; E-mail: hannakaisa.isomaki@titu.jyu.fi
Carl-Erik Wikström, CRM Solutions Division, Mepco Ltd & University of Tampere, Finland; E-mail: carl-erik.wikstrom@pp.inet.fi

RESEARCH PROPOSAL

At present relationship marketing is increasingly geared towards the development and utilization of information systems (IS), which sets a new domain of interest also for the viewpoint of human-centered use and development of IS. However, after several years of implementing information technology to support relationship marketing, up to 55% of all Customer Relationship Management (CRM) projects do not produce expected results (Rigby et al. 2002). In CRM success literature one can find several human related factors as potentially affecting a successful CRM implementation. Incentive alignment, resistance, commitment, and the fear for change of power relations are just a few (Wikström 2005; Fjermestad and Romano 2003; Ba et al. 2001; Morgan and Inks 2001).

CRM has been defined in many ways. CRM is seen as processes and technologies that support the planning, execution and monitoring of coordinated customer, distributor and influencer interactions through all channels (Wilson et al. 2002). CRM is also defined as any application or initiative designed to help an organization optimize interactions with customers, suppliers, or prospects via one or more touch points for the purpose of acquiring, retaining, or cross-selling customers (Goodhue et al. 2002). In order to manage a relationship with an individual customer, the company must be able to see the relationship with the customer as a whole (Ryals and Payne 2001). Seeing the relationship with the customer as a whole involves all the interactions the customer has with the firm, regardless of the channel the customer uses. In order to achieve the whole view of customer relationships it is necessary to collect, store, and manage data on every interaction with them whether the data comes from a salesperson, a call centre, or the Web.

Ryals and Payne (2001) in their empirical study explicate several barriers to successful implementation of CRM. The human being is intertwined in at least three of these barriers: lack of skills, low awareness of benefits and functional boundaries. An example of the sensitivity of the personal relationship between the human being servicing a customer and the customer herself is depicted in Colgate and Danaher (2000), who show how the customer perceived satisfaction of a personal banker had a significant effect on the overall perceived satisfaction of the company as a whole. Essential from the human perspective in their list of the "four perils of CRM" (Rigby et al. 2002) is the apparent need for changes in an organization to match the chosen customer relationship marketing strategy. This potential need for change affects human beings in as well the sales, marketing as the service organization. The need for change may affect employees' job descriptions, performance measures, compensation systems, and training programs (Rigby et al. 2002).

Chen and Popovich (2003) explore the critical components that can enable (or hinder) the successful implementation of CRM initiatives and introduce a CRM implementation model that integrates the dimensions of people, process, and technology. In the category of "people" the authors note that "implementation of enterprise technology, such as CRM, requires changes to organizational culture". Customer-centric management requires top management commitment and support to CRM throughout the entire CRM implementation. The importance of a project champion is mentioned as a person who can persuade top management for continuous change efforts. In addition to enhancing employee skills and knowledge Chen and Popovich (2003) argue that education boosts motivation and commitment of employees and reduces employee resistance.

The above definitions of CRM explicate some of the most common organizational roles of the human being in the CRM context: as a member of the company's sales or service organization. Sales-oriented CRM applications, (sales force automation (SFA) applications) refer to salespeople's use of computer hardware, software, and telecommunication devices in their selling and/or administrative activities (Morgan and Inks 2001). To be specific, we focus in this study on human beings as users of SFA applications.

According to Zablah et al. (2004) the CRM phenomenon is best conceptualized as "an ongoing process that involves the development and leveraging of market intelligence for the purpose of building and maintaining a profit-maximizing portfolio of customer relationships". Thus, they introduce knowledge and interaction management as the two major sub processes of the CRM macro level process. Therefore, the interaction management process is highly dependent upon the human resources of a firm. In particular, the market intelligence of a salesperson plays an essential role in the process of transferring customer knowledge to the firm's portfolio of customer relationships. The salesperson's capability of understanding human qualities and recognising the factors essential to maintaining customership is the significant micro process establishing market intelligence. Then human qualities should be reflected against a holistic point of view concerning the very nature of the human being. In our holistic view, we draw on philosophical anthropology and the works of John Dewey and Michel Polanyi. We reflect humans in terms of physical, cognitive, emotional, social and cultural modes of being. Human knowledge creation is then seen to occur within two intertwined elements: knowledge and knowing, which include the tacit and explicit dimensions in human action.

We argue that for CRM to be successful a CRM system should be implemented and used in such a way that the users – in our research the salespeople – are empowered, motivated, committed, and willing to utilize the CRM system for knowledge management. In successful CRM culture salespeople gather and store essential information from crucial interaction episodes with their present and potential customers in order to collect into the CRM database information of customers' needs and wants. The tacit knowledge, which salespeople possess, can be made more explicit and thus help the organization to better utilize it. This knowledge may help the company in retaining its present customer relationships and enhance their profitability by enabling more targeted and effective cross-selling and up selling activities.

In our analysis, we take into account definitions of CRM as they arise in related research works, and the implications of the non-instrumental role of the human being (Isomäki 2006) as it appears in diverse application domains of CRM. We argue that research concerning CRM success should focus more on human-centered issues. The central argument is that humans should be understood in a holistic manner to fulfil the demands of human-centredness. Our analysis is carried out with the following aims: 1) to illustrate the importance of human qualities in implementing CRM successfully, 2) to be specific of the nature and delineation of the human qualities in CRM, 3) to explicate the nature of the image of the human being in CRM success, and to make visible the variety and limitations of human-centeredness in CRM.

To establish the concept of human-centeredness within the domain of CRM, we carry out a conceptual analysis (as presented by Järvinen 2001) with a normative orientation that draws on the previous findings of CRM research. In this way our analysis emphasises the utility aspect of the concept of human being in understanding the underlying assumptions rather than representing different interpretations of human-centeredness (cf. Järvinen 2001). Concepts are of utmost importance in theory formulation, since they establish, first, the boundaries that define a theory's domain of interest, second, the key constructs and their relationships within that domain, and third, the values or contents those constructs can take on (Järvinen 2001). To establish sound concepts, it is necessary to carry out conceptual analysis. This is especially important in new emerging domains that draw on earlier research drawing on different disciplines with varying underlying epistemological

and ontological notions. The recent research on CRM applications is a typical example of this kind of new research area in which concepts are applied from one domain to another. We aim to bring to the fore and discuss the nature and qualities of people in CRM theorization, and thus offer new explications of the construct to serve as means for further research and also development of CRM applications. We use the following framework to accomplish the analysis:

Questions/Means	Objectives/ Ends
1) What is the role of the human being in the context of CRM?	1) to clarify the specific role and activities of people in CRM
2) How the notion of the human being appears as a success factor in CRM?	2) to illustrate the importance of human qualities in implementing CRM successfully
3) What is the framework for a holistic view of people in CRM?	3) to be specific of nature and delineation of the human qualities in CRM
4) What are the human qualities present in the previous research on CRM success?	4) to explicate the nature of the image of the human being in CRM success, and to make visible the variety and limitations of human-centeredness in CRM

In our analysis, we set the boundaries that define a theory's domain of interest by first defining the prevailing image of the human being in CRM, and specify the significance of the notion of the human being as a CRM success factor. Further, we establish the framework for outlining the nature of the human being by drawing on a metamodel illustrating what kind of quality assumptions may be connected to humans in the CRM context, and continue by analysing what kind of human qualities there is within the domain of CRM. In this way we explicate the contents that the concept of human-centeredness can take on within this domain.

Can We Codify Professional Knowledge?

Chandra S. Amaravadi, Western Illinois University, USA; E-mail: C-Amaravadi@wiu.edu

INTRODUCTION

The management of organizational knowledge has become an issue of immense strategic and economic importance. There are many types of organizational knowledge including administrative, professional, structural and relationship knowledge (Roos and Roos 1997). Here, we will mostly confine ourselves to the issue of *professional knowledge* (PK) which we define as the knowledge required to perform a professional task such as auditing a company, designing a shock absorber or preparing a contract. There has been little research in this area and our understanding of such knowledge is still vague (Haider 2003).

Most of the knowledge management literature is concentrated on the soft techniques of managing knowledge such as KM strategies, knowledge transfer mechanisms, cultural issues etc (Amaravadi 2005). But as IS professionals, it is also incumbent on us to address the issue of technology support. A study of KM practice by the American Council on Productivity concluded that without an information technology model, KM efforts will end up in chaos (Amaravadi & Lee 2005). Most of the available KM technologies provide passive support in the form of ability to store knowledge, but they fall short in retrieval. Query capabilities based on keywords are contingent on entering the correct keywords. In addition, precision and recall could be affected by large volumes that are expected in KM systems. Ontological methods are intended to address this problem, but have several limitations. They are tailored to a particular domain and have limited ability for question answering (Anonymous 2007, Davies et al. 2003). Artificial Intelligence based approaches are more promising in this respect, but here also there are classic stumbling blocks, the most challenging of which is knowledge codification. Codification has been addressed primarily in the context of knowledge-based systems which use rules and frames. The domain models are classified as shallow rather than deep. For example, an expert system for stock selection will be able to explain rules used to select stocks, but will not know the difference between a common stock and a preferred stock. To properly manage PK requires deeper models for which we have to rely on logic or semantic nets. A representation scheme known as AEI-3 to manage administrative knowledge has been proposed in the literature (Amaravadi 2005). In this paper, we will first discuss the nature of PK, introduce AEI-3 and use it as a platform to model professional knowledge.

THE NATURE OF PROFESSIONAL KNOWLEDGE

There is a paucity of literature concerning organizational knowledge and especially more so in the case of professional knowledge. Lacking empirical evidence, we will hypothesize some characteristics based on samples from Luthardt et al. (2005). In their foreword, they state "The American Institute for Chartered Property Casualty Underwriters and the Insurance Institute of America are committed to *expanding the knowledge of professionals* in risk management, insurance, financial services, and related fields through education and research." Thus their comments establish the rationale for using the text as an example of explicit professional knowledge. A few representative samples are illustrated in *Table 1*.

Instances of PK in the insurance domain appear to exhibit one or more of the following characteristics:

a. They elaborate or define the concept as (*item#5)*, The concepts are both *concrete* such as "automobile," "property," and "underwriter" as well as *abstract* such as "loss" "depreciation," and "indemnify" but tend to be predominantly abstract. Abstract concepts are usually defined in terms of other concepts. For example, *mortgaged asset* is defined in terms of *asset.*.
b. They elaborate or define the concept with additional conditions or restrictions,
c. They describe structural relationships (*item#1*).
d. They describe axiomatic, mathematical or logical relationships (*item#4*).
e. They describe abstract and complex relationships such as an obligation to act in a certain way (*item#7*), f) They describe events, actions, objectives or policies.

It is the arbitrary and complex manner in which concepts, relationships and conditions are combined that makes knowledge engineering for PK a daunting task.

KNOWLEDGE ENGINEERING FOR PROFESSIONAL KNOWLEDGE

The objective of the representation is to serve as a foundation to manage professional knowledge. Since visual representations facilitate this task, we are committed to one that has a graphical notation. Additionally, the representation ought to provide sufficient storage mechanism or *expressivity* so that knowledge may be stored and queries, answered (Davies et al. 1993). Here, we will focus only on intensional or conceptual knowledge. The ability to *draw inferences* is a potential ancillary benefit.

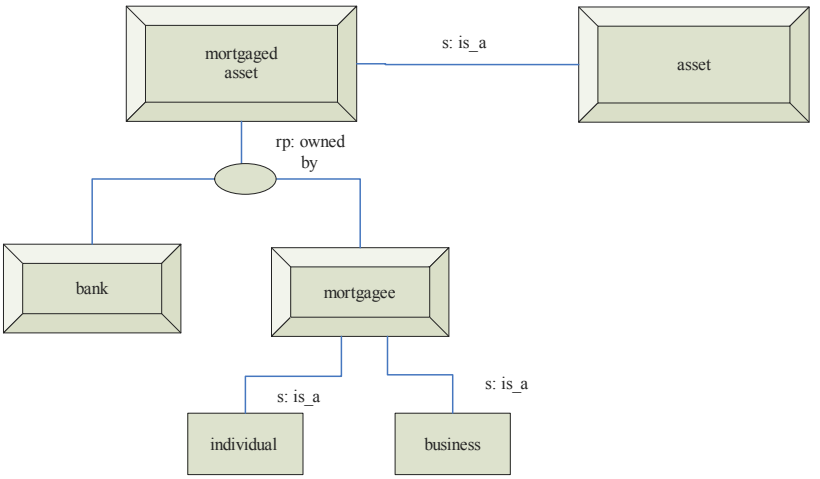
A method to represent administrative knowledge known as AEI-3 was recently proposed. AEI-3 is based on semantic networks and makes use of two node types

Table 1. Samples of professional knowledge (Luthardt et al. 2005)

Item#	Example
1.	Property includes real property and personal property. Real property is land, buildings and other property attached to it. §1.6.
2.	A liability loss exposure is any condition or situation that presents the possibility of a claim alleging legal responsibility of a person or business for injury or damage suffered by another party. §1.6.
3.	Types of insurers include stock insurers, mutual insurers and reciprocal exchanges. §1.11.
4.	Underwriting expenses include acquisition expenses, general expenses, premium taxes and licenses § 3.8
5.	Contingent commission is a commission that an insurer pays, usually annually to an independent agency based on premium volume and profitability of the agency's business with that insurer § 4.15.
6.	Depreciation is allowance for physical wear and tear or technological or economic obsolescence §6.14.
7.	A contract of good faith is an obligation to act in an honest manner and to disclose all relevant facts §7.7.

Note: "§" refers to section numbers, there are no page numbers in the cited reference.

Figure 1. Modeling concepts with AEI-PK



("class," "instance") and two link types ("structural," "descriptive.") to represent administrative knowledge. In this respect, it is similar to protégé a public domain ontological project (anonymous 2007). AEI-3 is designed to represent large volumes of routine knowledge such as "Manugistics is a client of BSS" or "the van leaves BSS at 11:00 am." It overcomes some of the traditional limitations of semantic nets such as tractability, separation of descriptive and structural knowledge and the ability to handle large volumes (Amaravadi 2005) but is a minimalist design owing to the relative simplicity of administrative knowledge. The basic ability echoed in all conceptual models including AEI-3 is to model concepts and relationships. In view of the nature of PK we will impose further requirements on the representation scheme.

Complex concepts such as premium are defined in terms of other concepts such as insurance coverage which may themselves be complex. Therefore it is convenient to refer to such concepts without having to redefine the entire concept, leading to the requirement of *supporting abstractions*. Abstractions support modularity and reuse. Another issue that arises is the *multiplicity* of definitions. A single concept has alternative definitions making this a requirement as well. For example, the value of an asset could be defined by its market value or by its book value. *Relationships* among concepts can be simple (concrete) or complex (abstract). A class-subclass relationship is an example of a simple relationship. Abstract relationships are complex because they are qualitative, involve multiple concepts and involve complex conditions. Thus the second requirement is to model both simple and complex relationships. We will not attempt to model mathematical and logical relationships (>, <) here because they do not lend themselves to visual schemes. Using AEI-3 with enhanced semantics, we will explore the question posed by this research.

AEI-PK

We will refer to our scheme as AEI-PK. Following the discussion from the previous section, the scheme will have constructs to model concepts and associations. Unlike in AEI-3, we do not have classes and instances. Instead we have concepts which are either atomic or complex. The former are depicted by rectangles while the latter by double-walled rectangles. At the present time, there does not seem to be any satisfactory way to demarcate concept boundaries except by drawing dotted lines around it. AEI-3 supported only one type of structural relationship and any number of descriptive relationships. In contrast, AEI-PK has an additional type of structural relationship for "part-subpart" relationships, abbreviated as "p-sp." Instead of descriptive relationships, we have "p:" links to depict properties of a concept and "rel" links to depict non-structural type of relationships. Some properties are required properties. Consider, *the board of directors consists of elected officials*. Here the required property is that officers must be elected. Such properties are depicted by "rp:" link types.

Testing AEI-PK with examples of knowledge indicated that well defined knowledge items are readily modeled. For example a mortgaged asset is defined as an asset for which some percentage is owned by a bank i.e. rest is owned by the mortgage. As shown in Figure 1, *mortgaged asset* is connected by "s:is_a" structural link to *asset*. It has the required condition that it should be partially owned by a bank. There is an "rp: owned by" link between the *mortgaged asset* and *owners* which in this case are both the *bank* and *mortgagee*. Note the use of ellipse for multiple arguments. A more abstract concept such as *insurance coverage* is difficult to represent. *Insurance coverage is the legal obligation of an underwriter to compensate the insured in the event of a loss.* The concept is challenging because it involves a number of abstract concepts such as "legal obligation," "compensate," and "loss." It needs to be represented as three assertions:

Event1: insured suffers loss
Event2: underwriter compensates insured
Axiom: If Event1 then Event2 with the restriction that compensation <= loss amount.

The representation can deal with depicting Events1 and 2 individually, but cannot deal with the idea that Event1, 2 and the axiom together define insurance coverage. It also fails if we have to define conditions. The issue becomes even more important when there are other ideas such as *salvage rights* that require using part of the knowledge about insurance coverage: Event1 with the restriction that it is a property loss and Event 2 and an additional fact that underwriter owns damaged property.

CONCLUSIONS

We have started with AEI-3 and attempted to add additional link types such as "p:" "s:p_sp" "rp:" in order to enhance the semantics. Even with certain simplifications, the modeling task is awkward. The main stumbling block is that abstract ideas are inherently complex and cannot be easily represented. The challenge arises from ideas being defined in terms of other complex ideas and having conditions/relationships, both of which can also be complex and interrelated. It is also difficult to represent PK without mathematical and logical foundations both of which are difficult to achieve in graphical form. The answer to the question posed by the research, "can we codify professional knowledge," is "not yet." Further research is required in understanding the nature of abstract ideas and in expressing conditions.

ERP Contribution to Long-Term Financial Performance and the CIO's Membership in the Top Management Team (TMT)

Carlos Alberto Dorantes, The University of Texas at San Antonio, One UTSA Circle, San Antonio, TX 78249, USA; E-mail: Carlos.Dorantes@utsa.edu
Myung Ko, The University of Texas at San Antonio, One UTSA Circle, San Antonio, TX 78249, USA; E-mail: Myung.Ko@utsa.edu

ABSTRACT

The difference in the contribution of Enterprise Resource Planning (ERP) systems to financial performance between firms that have a Chief Executive Officer (CIO) in the top management team (TMT) and those without a CIO in the TMT is investigated. A new and robust method to measure this contribution is proposed. Preliminary results showed that the mean contribution of ERP for firms with a CIO in the TMT is higher than those without a CIO but did not show any statistical significance.

INTRODUCTION

Although it is generally believed that the relationship between the CIO and the TMT is an important factor influencing the performance impact of information technology (IT), empirical support for this belief is nonexistent. Since IT has increasingly been an important enabler of business strategies and innovation in organizations (Karahanna and Watson[6]), IT leadership becomes critical especially when implementing and maintaining large-scale ERP systems. The inclusion of IS executive in the TMT might help to make the effective decisions needed to reap the maximum benefits of the technology. According to information Systems (IS) leadership research, the role of CIO is crucial in the assimilation of ERPs through his or her IT and business knowledge (Smaltz, et al.[13]) and also critical in enabling IT to enhance business performance (Karahanna and Watson[6]). However, this suggestion comes more from anecdotal cases than from empirical research.

This paper addresses two issues. First, drawing from upper echelons theory, the study argues that CIO in the TMT significantly influences the contribution of the ERP to long-term business performance. Second, a robust and innovative method to measure such contribution is proposed.

LITERATURE REVIEW AND RESEARCH HYPOTHESIS

Several studies have investigated the ERP impact on organizational performance (Hunton, et al.[4], Nicolaou[9]). These studies have examined important organizational factors such as financial health, firm size, industry, number of ERP modules, vendor choice. However, the influence of the CIO on the ERP contribution to business performance has not been researched.

The effect of top management support on ERP implementation has been consistently found to be one of the most critical ERP implementation success factors (Nah, et al.[8]). In addition, the close CEO-CIO relationship is key to get top management support to IT initiatives (Jarvenpaa and Ives[5]). On the other hand, the upper echelons perspective views the organization's actions and outcomes as reflections of its top managers (Hambrick and Mason[2]). Thus, we believe that composition of the TMT influences the extent of top management support on the level of ERP contribution to business performance. TMTs with more technological savvy should be more effective on resource allocation, ERP implementation, and post-implementation. Thus, those TMTs with a CIO might help make the assimilation of ERP systems more effective. Accordingly, the following hypothesis is proposed:

H1: organizations whose CIO is a member of the TMT will experience a higher ERP contribution to business performance than organizations whose CIO is not included in the TMT.

METHODOLOGY

Data Collection

Firms that already implemented any type of enterprise system in the period between 1995 and 2001 will be identified through media announcements using wired news from Lexis Nexis. Annual financial information for each firm will be pulled from Compustat. The composition of the TMT will be examined using the ExecutiveComp database, which includes the highest top five executives..

ANALYSIS

Previous research has used both market (Hayes, et al.[3], Ranganathan and Brown[12]) and accounting metrics (Hunton, et al.[4], Nicolaou[9], Poston and Grabski[11]) to measure the extent to which the ERP contributes to business value. However, few of these studies have controlled for important factors such as firm performance and industry. The studies that have used accounting metrics simply compare financial ratios before and after the ERP was adopted.

This study investigates the contribution of the ERP in two steps. First, an expected financial performance of the firm will be computed at the year t+3, being t the year when the firm finished the ERP implementation. The ERP business value literature has suggested that the ERP benefits are more likely to be observed after two or three years after the implementation (Poston and Grabski[11]). This estimate will be based on both past firm performance and past performance of companies from the same industry and similar size. To do this, regression analysis using a composite score based on accounting fundamentals (Lev and Thiagarajan[7]) for t and t-1 will be used. The dependent variable will be the financial performance at t+3 measured by return on assets (ROA). The method to compute this composite score will be the F-score version of Piotroski (2000) (see Appendix A). Components of this score include annual improvements of firm profitability, financial leverage, and inventory turnover. The F-score measure has been found to be significantly associated with future firm performance (Piotroski[10]).

In order to control for firm size, industry and industry tendency, the following regression model is proposed for each firm in the sample:

$$ROA(i)(j, t+3) = \beta o(i) + \beta 1(i) * FScore(i), (j, t) + \beta 2(i) * FScore(i)(j, t-1) + \varepsilon(j)$$

Where:

ROA i (i, t+3) = ROA of firm j from the sub-sample i at t+3; t= year of implementation
FScore (i), (j, t) = F-Score at t for firm j from the sub-sample i
FScore (i), (j, t-1) = F-Score at t-1 for firm j from the sub-sample i
i = [1.. N]
N = Number of firms

To compute the β parameters for the regression function i, one sub-sample composed of firms that are similar to the firm i in terms of size and industry will be extracted from Compustat, which is consistent with previous research that have used the matching sample method (Barber and Lyon[1]).The error term of the function i, which is the difference between the actual future ROA and the predicted future ROA, will be the ERP contribution to performance for firm i.

Finally, an ANOVA analysis will be performed to test which group has higher ERP contribution to long-term financial performance.

PRELIMINARY RESULTS

The following results are based on the period from 1995 to 1999. Descriptive sample statistics are shown in Table 1.

From 276 announcements, public firms with a CIO right after the implementation were reduced to 16. A matching sample of 16 cases was selected out of the remaining firms considering firm size, industry, and number of modules implemented. With these 32 cases, 32 sub-samples where constructed. Then, regression analysis was performed to calculate the ERP contribution to business performance using the error term of the regression for each sub-sample. Table 2 describes the mean differences between two groups.

Although the mean of ERP contribution for firms with CIO is higher than those without a CIO, this difference was not significant. We believe that it might be due to the small sample size. Once we include announcements from year 2000 to 2001, we can validate our findings.

To further explore this result, we did another analysis using all firms without CIO and those without a CIO.

We can see that the mean of ERP contribution for firms with CIO was still greater than those firms without a CIO. This might be a sign of a possible significance difference once we finalize the analysis.

EXPECTED CONTRIBUTION

This study will contribute to the IS leadership research by extending upper echelons theory to the context of ERP systems. Results will shed some light about whether CIO in TMT can influence ERP contribution to financial performance. In addition, the study will contribute to the IT business value literature by providing a robust methodology to measure the financial impact of ERP systems that might be generalizable to other types of large-scale IT systems.

APPENDIX A. CONSTRUCTION OF F-SCORE.

Piotroski (2000) considers nine accounting fundamentals posited to capture annual differences in firm's profitability, financial leverage/liquidity and operational efficiency. The profitability fundamentals are ROA, cash flow from operations, change in ROA and accruals (Earnings – CFO). All variables are scaled by beginning of the year total assets. The financial leverage/liquidity variables are long-term debt to average total asset ratio, current assets to current liabilities ratio, and equity. The operational efficiency fundamentals are gross margin ratio and current year inventory turnover. For each component, if there is an improvement from one year to another, it is assign 1, and 0 otherwise. The composite score is the sum of these binary variables. FScore can range from 0 to 9.

1. INTRODUCTION

Organisational knowledge include a documented part – as tools and documents – and a tacit component, which resides in individual skills, understanding and collaborative social arrangements (van Baalen, Bloemhof-Ruwaard, & van Heck 2005). Knowledge is always a result of the interpreter, which depends on the entire previous situation and on its position in a tradition (Winograd & Flores, 1986). When we focus on work practices, actors' social situation and traditional environment are formed in the work place and its community of practice. Knowing is not a stable disposition of actors, but rather an ongoing social accomplishment, constituted and reconstituted as actors engage the world of practice (Orlikowski 2002). Likewise, the community's shared knowledge and beliefs are constantly under construction (van Baalen et al., 2005).

In this paper, we focus on the use of information technology (IT) in a community of practice. The use of technology (or technologies-in-practice) is connected to the actors' experiences of awareness, knowledge, power, motivations, time, circumstances, and the technological artifacts (Orlikowski, 2000). We study the use of data flows in shaping organisational knowledge. The term "data" is used to refer to objective data items which can be documented, such as name or date. "Information" refers to interpreted data; for example, the data of the number of customers becomes information for the one who prepares lunch for them. Furthermore, "knowledge" refers to skilful to do something with information; for example, modifying menus.

The specific case which we focus on is the data flows in professional kitchens. The term professional kitchen is used here in reference to private catering companies, such as restaurants and personnel canteens, or institutional kitchens, such as those of schools, day-care centres and hospitals. The use of IT has reached almost all areas of working life; professional kitchens have been some of the last to exploit it. There is a variety of IT applications available for the needs of professional kitchens, which may be exploited for food production planning and instruction provision purposes: to design recipes and menus, to assess nutritional content, to manage raw material stocks, purchasing and cash register functions, etc. (Tuikkanen, Taskinen, Riihikoski, & Työppönen, 2005; Feinstein, McCool, & Cobanoglu, 2005; Cobanoglu & Heiberger 2003). Technology related trends in the restaurant industry are customer feed-back mechanisms, management of repeated business, management of marketing and service, IT and restaurant operations management, human resource management, (Oronsky & Chathoth 2006), nutritional analysis, cost-control techniques and systems, menu-mix management (Keiser, DeMicco, Cobanoglu, & Grimes 2007), and data mining (Collins, Cobanoglu, , & Malik, 2003).

We study data flows in professional kitchen processes. In this study, the professional kitchen processes were examined in two dimensions: (1) the iterative character of information, which means that information shaping is happened gradually within a repetition process, and (2) those reasons why iterativity is typical for professional kitchens. The current low level of exploiting technology makes professional kitchens an interesting case to study technology shaping in daily practices. Our focus is on how information is built iteratively through kitchen processes. This is partly achieved through planning tasks but is fully accomplished through the practical implementations of food production.

2. CASE: PROFESSIONAL KITCHENS

The practical objective of this study was to provide a holistic picture of data flows relating to the food production processes in Finnish professional kitchens, focusing on practical situations. The empirical information was gathered from professional

Table 1. Differences between the studied professional kitchens

Features of action		Professional kitchens							
		k 1	k 2	k 3	k 4	k 5	k 6	K 7	k 8
Scale	Local				x	x	x	x	x
	Nationwide	x	x	x					
Form of enterprise	Municipal organisation						x		
	Municipal unit					x		x	x
	Business	x	x	x	x				
Line of business	Institutional food service					x	x	x	x
	Profit making business	x	x	x	x				
Type of kitchen	Central kitchen						x	x	x
	Kitchen	x	x	x	x	x			

kitchens and aimed to generalise the results, pointing out those processes and data flows which are shared by all kitchens, and which recur in an identical form in food production planning, implementation and monitoring, thus enabling the formulation of a model at the general level. An additional objective was to establish what information is required to implement the processes in question, what type of information the processes produce, and what type of interactive communication there is between the said processes.

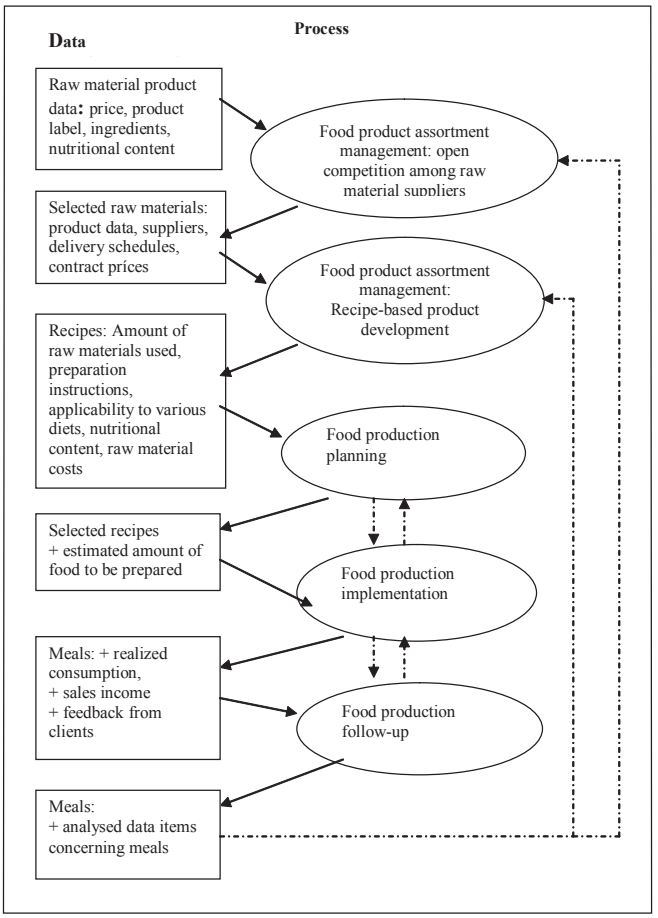
Eight professional kitchens were chosen as research objects, whose food production processes and related data were modelled. The research objects represented networking food service organisations operating in Finland. The research objects were selected so that there are differences between operation scale, form and function of enterprise (see Table 1). Due to their large size and special information management needs, these organisations rely on IT in their information management applications. The research objects consisted of national and local organisations that operate as businesses, municipal business units or municipal organisations. The research objects' kitchens were responsible for food production in personnel canteens, student canteens, restaurant chains, a la carte restaurants, health care institutions or hospitals. A number of these research objects operated as central kitchens, which means that they supplied food to several distribution kitchens. Some prepared meals to be served to their own clients, others combined both functions. On a daily basis, the number of food portions prepared varied from 300 to 7,000.

Empirical material for the study was collected by using theme interviews (based on Kvale 1983). The objective is to describe the kitchen data flows based on practical needs and that the kitchen workers know them in their own work situation. The interview themes were selected from views presented in recent Finnish professional literature on food production processes (Heikkinen 1995, Saarela, Hyvönen, Määttälä, & von Wright, 2005).The interviews focused on the following themes: food production planning, raw material acquisitions and storage, food preparation, food production monitoring, and food-related communication.

The interviewees were selected from among supervisors responsible for planning at the executive level, and food productions supervisors. They were interviewed since they are responsible for the progress of entire food production processes, their comprehensive view of the entire communication process and related information requirements and for their ability to verbally express their views and observations. The research material was collected from the eight research objects through 12 thematic interviews during 2005 -2006 with 17 interviewees. Most studied kitchens had more than one person who was responsible for planning and implementation of food production. Several informants in each of the research objects improve the quality of the interview material (see e.g. Rock 2001). The duration of each interview was approximately 90 minutes.

The analysis aimed to modelling the information flows, process-required information, and process-generated information of various professional kitchen types' food production processes. The modelling language consisted of UML 2 activity diagrams.. Modelling was based on a process division that was applied to the diagrams by the interviewers. Based on these, a maximum number of processes were drafted which the research objects had in common. To achieve a uniform level of abstraction, some processes were combined into higher level functions or divided into lower level functions. Modelling was used as a tool to find out similarities and differences between processes and used information.

Figure 1. The processing and specification of raw material data flow during the food production processes



3. COMPLETION OF THE INFORMATION USED IN PLANNING PROCESSES

Food production operations are usually viewed as series of stages consisting planning, purchasing, storage, production and service (Jones & Lockwood 1995, Saarela et al., 2005; Sivonen & Työppönen 2006). In this study the focus was information related to processes and the main food production processes were generated as: planning of offered food service activities, food product assortment management, food production planning, implementation and follow-up., This study indicates that decentralised kitchens need a large amount of planning work with plenty of information. The planning process was geared towards ensuring the profitability of food production, plus the high quality of food, throughout the organisation, under centralised instruction provision. A typical outcome was that information was edited and specified during the planning process. Planning took place in intertwining periods of varying durations.

The raw material information, as an example of one data flow, was essentially dependent on food production planning, instruction provision, implementation, and follow-up data collected from production. Figure 1 sets out a simplified example of how the various raw material data items are processed and specified during the food production process. The raw material data consists of items that the kitchen receives from various suppliers, for example. The kitchen combines the raw material data items into recipes. The recipe data items undergo changing specifications up until the food preparation moment. The recipes are converted into meals during the food production implementation phase. Following this, the raw material data items constitute a portion of the follow-up data that is collected based on the meals prepared.

4. ITERATIVE CHARACTER OF PLANNING PROCESS

The information obtained is processed and handled in an iterative manner in professional kitchens' food production processes. Some of the information flows reverted to the beginning of the process in a specified form, constituting additional information for the subsequent planning round. During food production implementation, the plans were adjusted in accordance with changing situations and more detailed information (See Figure 1). The kitchens use an iterative approach on two levels: in long-term planning on the one hand, and almost simultaneously during food preparation, on the other hand. The kitchen personnel participate in the food production planning and implementation processes in the capacity of an information provider.

The nature of the food service industry, as a service industry, requires that the production processes are very flexible. Flexibility is needed throughout the food production process. It has to be possible to adjust the production process to fit the changes: e.g. menus have to be modified in cases of customers' feedback and the recipes have to be brought up to date.

5. DISCUSSION

One of the principal findings of this study was that professional kitchens' information flows are built though interaction between people and processes. Process-generated information, people's skills and competence are used to steer the subsequent process cycle, to make the processes increasingly effective in accordance with the clients' needs and requirements. The generation of information flows requires people's skills and competence, as well as their tacit knowledge to a significant degree. These skills and competencies are partly converted into a visible form with the aid of information systems. In addition, the implementation of an iterative food production process requires the use of tacit knowledge, as well as its manifestation into a visible form. Regardless of the fact that the personnel play an important role, they convey their expertise-related knowledge face-to-face to the management, not through the IT systems. Furthermore, it is the supervisor who can decide how to apply the employees' knowledge to the process.

As information technology in kitchens is an almost unexamined area, our study opens several interesting study lines. For example, the focus on financial issues and management of information in professional kitchens requires further research. Besides focusing on hospitality and business issues, studying technology shaping by using professional kitchens as a empirical field, is also promising; for example, a deeper study of technology-in-use by using ethnography and the theory of ICT domestication (Silverstone, Hirsch, & Morley, 1992).

INTRODUCTION

National guidelines in Finland call for nationwide access to electronic patient data by 2007 (1, 2). Most of the technical infrastructure to meet this demand has been implemented, in particular all health care providers (Health Centres) in PHC have utilised electronic patient record (EPR) systems for some time. In addition to the technical infrastructure itself, however, it is also necessary to develop management, support and training required for EPR systems to function as efficiently as possible.

A long term project was started in the Finnish region of South-Ostrobothnia in 2003 to study the impact of EPR systems on availability and flow of information between public PHC and secondary care. As part of this major project, it will also be evaluated how well EPR systems in PHC can meet the needs of general practitioners (GPs) and other health care professionals for specific information. Previous studies have indicated differences in quality of data in EPR systems (3). Previous research has also indicated differences in performance and ranking of patient data for different EPR systems (4).

The focus of this study is to investigate further what reasons govern the performance or utility of EPR's in use in PHC, and in particular to investigate the role of IT management and user training in the overall performance of these systems.

METHOD

This study was conducted in the South-Ostrobothnia region. The total population of the region is 196 000; PHC is provided by 16 Health Centres. Secondary care is provided by Seinäjoki Central Hospital (560 beds) and Ähtäri hospital (28 beds).

In the first phase of this project, GPs from the research group identified all patients who received anticoagulant (AC) treatment on 1st April 2004 from the EPRs of eight Health Centres (population base 132 621). The GPs were requested to access 20 specific types of agreed-on information from patient journals (EPR). This patient group was deemed appropriate for this type of study because the information dealt with is specific and thus relatively easily quantifiable, for instance: start date of treatment, main reason for treatment, Internationalized Normalized Ratio (INR) target level, last INR value. The INR value is an indication of blood coagulation, and thus a important idex that must be determined for patients receiving anticoagulation (AC) treatment.

After analysis of information accessibility from EPR's for this patient group was completed, feedback and discussion sessions were carried out with GPs participating in this study (4). Reports on IT management and staff training practices in the Health Centres were requested initially in a non-structured format. Based on these reports, a more detailed and structured questionnaire compilation has been started. The collection and analysis of this data is currently taking place.

RESULTS

The Health Centres participating in this study used three different types of EPR, with one system being utilised in 5 Health Centres. The EPR systems had been operational for a relatively long time: up to 9 years. The total number of AC treatment patient cases analysed was **2 389**. All of the 20 specific types of agreed-on information requested was available via the EPR for 73% of all the cases, ranging from 52% to 93% for different Health Centres (table 1). There were major differences within individual EPR system performances which did not correlate with the period of use of the system.

It is expected that the additional information currently being gathered from the Health Centres will shed more information on the correlation between data quality and general IT management practices.

DISCUSSION AND CONCLUSIONS

The feedback and discussion sessions conducted with GPs participating in this study indicated that there were few if any purely technical reasons why certain information was or was not available in the EPR. It appears that user behaviour and general aspects of how the IT systems were managed were significant. Factors like number of staff substitutes that were previously untrained in the use of a particular EPR, and the training and delegation of tasks within professional groups seemed to have an impact on how the EPR systems were used and on the quality of data entered in these systems.

Table 1. Accessibility of specific information from EPR for AC treatment patients in 8 Health Centres in South Ostrobothnia, Finland

Health Centre	EPR system	Years in use	Proportion of cases for which all information requested obtained (%)
a	x	2,2	86
b	y	4	55
c	y	4	61
d	y	9	93
e	y	8	71
f	y	7	80
g	x	1,8	74
h	h	6	52

Initial results also indicated that the workflow in all Health Centres might not be optimal for EPR use. This study implies that in addition to the direct expenditure in EPR systems, more emphasis should be placed on IT management, training and "best practices" dissemination.

Component Based IT Software Project Management: A New Paradigm Shift

Ravi Agarwal, Infosys Technologies Limited, Plot No.24, Rajiv Gandhi Infotech Park, Phase-II, Village-Man, Taluka-Mulshi, Pune 411057, India; E-mail: ravi_agarwal@infosys.com

ABSTRACT

Component based IT Software Project Management – a new Paradigm Shift is a critical need for Information Technology Software Projects. Can we focus on small individual components which in turn can ensure a smooth and successful project implementation? Can we use these components to build a healthy portfolio or a group of projects? In a project world, the customer is at the core without which a project cannot exist. An organization is the primary component surrounding the core without which there can be no way a project can be executed. Small secondary components which revolve around the primary component and interact and contribute to each other together ensure that they can win the customer delight and contribute to the organizations goals. This paper provides details to these thoughts.

Keywords: Software Project Management, Component based IT Software Project Management, Paradigm Shift, Component, Primary component, Core component, Secondary components)

1. INTRODUCTION

The world is changing at a very rapid pace. With the advancements in Information Technology (IT) and the ever increasing need for IT professionals, constantly increasing project size and complexity, shrinking turnaround times – the focus needs to shift today from handling multiple aspects of Project Management to Component based IT Software Project Management.

By focusing on the individual components of IT Software Project Management, and then ensuring that they feed into and onto each other, we may assure the success of the project. The key here is to handle one component at a time from the perspective of the area of work.

The Project World can be likened to the solar system (Figure 1). There is a single core component, which is the **"Customer" –** can be internal or external. The core component is surrounded by the **primary component** – this primary component is the **"Organization"** which fulfills the requirement(s) of the core.

The primary component is surrounded by the **secondary components** for a project. These secondary components, along with the primary and core component, if built successfully and improved upon, may result in a successful project. The components need to communicate with each other at all times.

Knowledge, Configuration, Defect Prevention, Tools, Technology, System, Business, Events and Project Management are the secondary components.

These components need to complement each other before, during and after that component has been developed in the project.

2. COMPONENT DETAILS

There are three key components when we talk of component based IT software Project Management.

2.1. Core Component

Logical functional grouping governed by a single expert entity which ensures the existence of the project world.

This component (customer) is essential for the very existence of a project.

2.2. Primary Component

Logical functional grouping governed by a single expert entity which can ensure the build of this project world.

Why do we treat organization as the "Primary Component" The secondary components cannot thrive without the primary component. The focus of an organization is to set trends and provide management support for the core and the secondary components.

Without the organization resources, support and willingness, trying to maintain secondary components may not be feasible.

On one hand the organization supports the secondary components and on the other it helps build a shield of confidence around the core component.

Figure 1. Project world – solar system

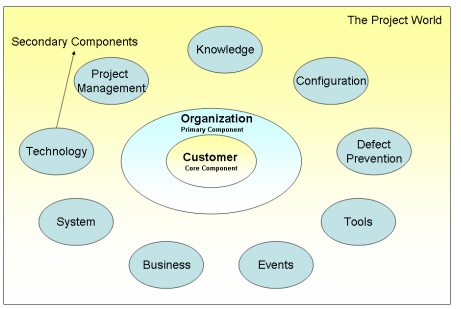

Figure 2. Building a component

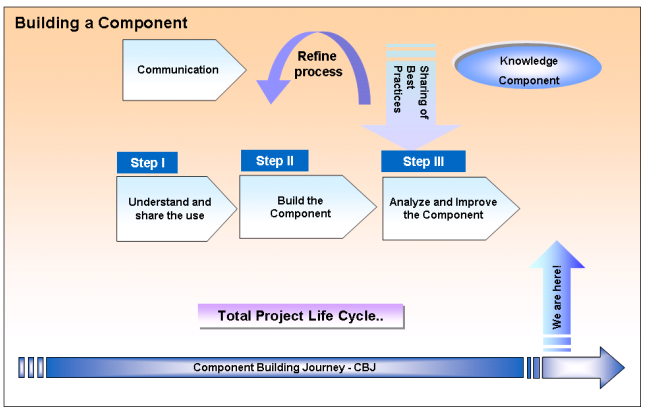


The core component ensures that a project is created while the primary component ensures that the project is build. The maturing of the organization component may help in stabilizing and improving the organization.

2.3. Secondary Component

Logical functional grouping of the individual tasks and activities that need an expert entity towards governance.

In any project there are multiple logical functions which need to be performed to attain the final deliverable.

Independent of the nature or the type of the project, the secondary component can be handled by an expert of that area.

As defined in 3.1 of [2] "The main idea of the component-based approach is building systems from pre-existing components"

These components will communicate with each other in one way or the other – with the focus always being on meeting the needs of the primary and the core component and be complimentary to other secondary components.

3. THE BUILDING OF A COMPONENT

Each component is built and made robust by a continuous improvement cycle of Understanding, Building, Analyzing, Improving and Communicating (UBAIC). A failure in successful building of a single component is a potential failure of the project.

The advantage of componentization is an enhanced and committed focus towards a specified area at any given point in time.

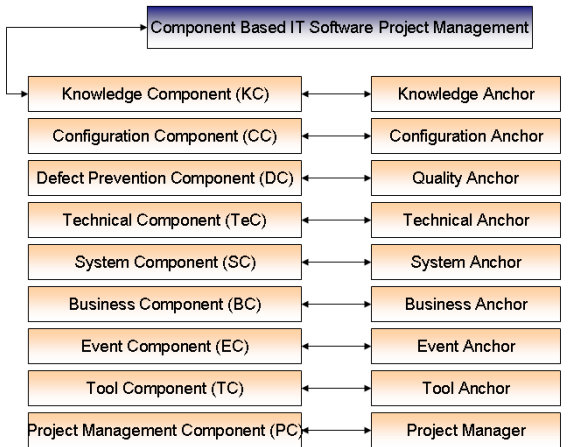
4. APPROACH: GOVERNANCE MODEL

The multiple secondary components can be streamlined in a project by defining a proper structure towards defining and building the individual component (Figure 3). An anchor is identified for each component. The anchor is a person who has expertise and is a Subject Matter Expert in that particular component. One person can play multiple anchorship roles and depending on the nature and size of the project the scope of the component can be defined at the project level. This person can be a member of the existing team or a member outside the current project team as well. This anchorship is vital towards building the component.

The anchor can guide the current project around building and utilizing the component most effectively.

A query is posed in [3] "Would an individual own a component or would a team of engineers own a component?" Our approach is there would be no separate owner but only an anchor. The final owner would be the organization.

Figure 3. Governance model



#	Nature of Project	Size	Secondary Component								
			KC	CC	DC	TeC	SC	BC	EC	TC	PC
1	Maintenance	<6 months	M	M	M	M	M	M	C	C	M

5	Consulting		M	M	M	M	M	M	C	C	M
	M	Mandatory									
	C	Customizable									

5. VALIDATION IN FIELD AND IMPLEMENTATION EXPERIENCE

Because of the basic observable premise that the building of different components is similar in nature but may vary in terms of the end use at the individual component level, the component based approach has been validated on three different projects within two different portfolios. "Cost, benefit and risk are the factors that need to be balanced and should be reassessed in order to maximize competitive advantage" [6]. The implementation experiences in the next two sub-sections will highlight the advantage of building a component in one project and will follow with the usage of multiple components to the benefit of two different projects.

5.1. Implementation Experience A

The knowledge component was build for a project in our Communication Service Provider division. This project was associated with maintenance of a set of applications by a team with varied experience.

Team Size: 22
Nature of Project: Maintenance
Project Time Size: >6 months
One subject matter was identified to anchor the Knowledge Component. Every knowledge bit was retained towards successful building of the knowledge component. The component comprised of multiple building blocks:

- Documentation of the understanding
- Best practices
- K-Tips
- Presentations
- Inter/intra team sessions

Moving an experienced team member to another module became very easy without impacting the project and with a minimal transition time. This was possible due to the knowledge component in place. Additional benefits were realized in terms of taking up more work equivalent to 1FTE (One Full Time Employee) with the existing team.

5.2. Implementation Experience B

The component concept was implemented in two projects working for the same client within the same portfolio in Communication Service Provider division. Each project developed the secondary components.

Team Size (Project 1: 18)
Team Size (project 2: 9)
Nature of Projects: Maintenance, Production Support and Testing
Project Time Size: >6 months
The experience from implementation of the System Component is shared.

The systems for two different applications were documented, their interfaces identified and the data within the application analyzed. These two components were shared between the two projects. The teams identified that the outputs from one project were actually an input to an interface of the other project. This enabled the teams to work more closely in terms of understanding the system flow and using that knowledge in preparing the data flows. This gave both the project teams a much better understanding resulting in catching some underlying defects in the system and fixing them to the delight of the client.

6. CONCLUSION

Following is what we conclude based on our implementation experience.

To ensure the success of a project for a customer and for an organization, we should focus on improving the business, technical and system skills of the team. There should be effective knowledge, configuration and quality management. There should be events in the project to make the project lively. The work should be supported by tools to make it automated and of course there should be effective project management. Each of these functional groups should be built upon and improved as components to derive the maximum benefits.

The component based approach can have multiple benefits:

- Across the organization – each component can be reused. Best practices towards building each component can be shared.
- Successful project world – delighted customer.
- Focused areas of attention at any point in time.
- Expert availability
- Enhanced precision and accuracy
- Easy forecasting
- Higher probability of success

On a comparative study, as [6] specifies that "The success of a project will depend critically upon the effort, care and skill you apply in its initial planning". Component based Project Management extends this to continuously building on the components identified during initial planning. In [7] – Models in perspective on CMMI "The model tells you what to do, not how to do it" – the component approach gives a thought on how to do it. Where [2] analyzes the component based development process and component life cycle, and [8] highlights a component based knowledge management system – component based IT software project management tries to look at components from a project perspective.

7. ACKNOWLEDGMENT

Infosys's Delivery Head, Srikantan Moorthy for Communication Service Providers Business Unit and Delivery Manager, Prashant Sinha for their continuous guidance and motivation.

Thanks to Bhaskar Chakravarty, Group Lead – Corporate Planning for his feedback. Thanks also to Infosys Project Managers and my Project Teams with whom I could get together to try these concepts on the live project.

Thanks to Aman Kumar (Quality), Dr. Vivekananda Kochikar (Education and Research) and Prixitraj (Quality) for their review feedback.

Managing IT Development Collaboration

Teemu Paavola, LifeIT Plc and Seinäjoki Central Hospital, Koskenalantie 16, 60220 Seinäjoki, Finland; E-mail: teemu.paavola@lifeit.com

Kari Mäkelä, Tampere University of Technology, Korkeakoulunkatu 10, 33720 Tampere, Finland; E-mail: kari.2.makela@tut.fi

INTRODUCTION

Ten hospital districts in Finland have joined forces in the 'Proxit' project to develop common health care IT solutions. The participating organisations include half the national health districts that cater for the health care needs of roughly a third of the national population.

Previous attempts at national health care IT development have resulted in a large number of independent, relatively small IT projects. These individual approaches were later replaced by a single regional IT effort in 1998-2002 - the 'MacroPilot' project in Pori region. This project attempted to create a unified information solution for regional needs covering most levels and organizations of health care (Nissilä, 2002). The MacroPilot project suffered the same fate as similar attempts in many countries previously: due to unrealistically large expectations and limited resources, the project did not meet its goals. Subsequently the Ministry of Social Affairs and Health resumed funding of regional or municipal health care IT projects, but in contrast to the strategy of the mid 1990's, large development projects were favoured. This emphasis on larger, joint ventures culminated in the Proxit project described in this report.

METHOD

Ten hospital districts decided in late 2004 to start a joint IT development project to meet Finnish health IT targets. These call for national integrability of hospital IT systems by 2007 and require adherence to common health record structuring and common standards such as HL7/CDA-R2 and DICOM (Ministry of Social Affairs and Health, Finland, 2003).

The health districts that decided to start a joint development project were installing, developing or considering to purchase the same healthcare EPR and HIS platform, the 'Effica' system by TietoEnator Plc. By launching a joint project, it became possible to share development work and best practices between all participants. The Proxit project started in 2005 and will continue until 2007. This is the largest single health care IT project in Finland to date: the total estimated budget is 10 million euros. Approximately 50% of these costs are covered by the Ministry of Social Affairs and Health, and the rest is covered by individual participating organisations. All the health districts participating in Proxit are public sector organisations. Overall project management and support is provided by LifeIT Plc.

Proxit consists of four main development and implementation sub-tasks or work packages:

- Structured electronic patient record system (EPR)
- Patient and hospital administration software (administration)
- Exchange of data between organisations (referrals, reporting)
- Joint IT project management

The first three modules are primarily IT development tasks specifically geared toward meeting national goals of intercommunicability between organizations in health care. The last module, joint IT project management and support for hospital districts on this scale, has not been achieved in Finland until now. 'Proxit' is the first time such a large consortium has embarked on a joint project by mutual consent.

RESULTS AND DISCUSSION

All main Proxit modules have shown significant progress. A new highly structured EPR version has been installed in most participating hospital during 2005 and early 2006. Common structuring and choice of formatting and datafield labelling has resulted in development of a single operational EPR version that can be adjusted to take into account the different needs of individual hospitals.

Somewhat more difficult has been changing hospital's working practices and workflow to accommodate a common EPR and administration system, but so far this work has also shown signs of progress. Data exchange solutions in the form of referrals and reports that can be sent between primary and secondary health care as well as between participating hospitals in Proxit, have also advanced to implementation stage by early 2006.

The progress achieved in all individual modules will be tracked and evaluated during this project. The level of national health IT target compliance of the solutions implemented by Proxit participants will be evaluated and compared to the situation in hospital districts that did not participate in this project. In this way it is hoped to show the benefits and gains achievable by common IT project management and collaboration in large scale health care IT development.

CONCLUSIONS

Development of joint solutions needs a joint development approach. It can be argued that the time for this type of national project was ripe: the benefits of a common effort were seen clearly enough by all participants, and definite national IT targets set by the Health Ministry set precise goals.

Changing working practices within individual organisations or hospitals is not easy, but if the benefit to all participants is seen as outweighing the problems caused to individual organisations, the work will none the less be carried out (Berg, 2001; Littlejohns, Wyatt & Garvican, 2003). Through common management of the project it is easier to demonstrate the rationale for this type of change. Learning to work together in this type of project has in itself been a significant achievement.

1. INTRODUCTION

Information and communication technologies offer sophisticated approaches to optimize the e-Business processes including financial services between companies. However, these services are often not integrated, which can increase costs and decrease options to exploit flexibilities. This was not of great importance as long as companies and customers were close geographically, but it has become critically important in today's "globalized" world. In this paper we give a short overview of the results of the field study of two European IST projects, „FLUID-WIN" and „SEAMLESS", in the context of financial services.

The FLUID-WIN project is the process of implementing an innovative, interdisciplinary and dynamic business model. This model will enable the European manufacturing companies to achieve quick response and competitive prices by integrating their suppliers whether international or domestic. This model is supported through readily adoptable e-commerce applications. The objective is to develop a means for a B2(B2B) service, adapting services into a complete existing network instead of manually creating individual relations to the network members. The scope of the FLUID-WIN project covers the material flow among a supply network as well as logistic and financial services flows associated with this flow.

The SEAMLESS project studies, develops and tests an embryo of the Single European Electronic Market (SEEM) network, where a number of e-registries are started in different countries and sectors. The SEEM vision is towards a web-based marketplace where companies can dynamically collaborate without cultural, fiscal and technological constraints.

Considering this background, we will discuss a bank's view on doing business with the participants on a web-based platform. The main activities of both projects are to define a collaboration framework and proper business models, to realize evolving ontology, to develop a technological infrastructure and a number of related applications and services. Distinctive features are addressing companies through their respective mediators (chambers of commerce, entrepreneurial associations, local development agencies, etc.) and in establishing interactions based on a collaboration framework.

Financial service providers are essential in any supply chain relationship. Among financial service providers one can also find insurance and other institutions providing transaction services related to handling large business volume in manufacturing and distribution. As customers still perform transactions, e.g. sales, outside of the closed supply chain platform economic trends are likely to impact even on a closed system. This is to be expected as the output from a closed system is still being marketed "externally". Though being integrated into a closed supply chain, financial service providers may still encounter competition as producers and suppliers can theoretically be provided with financial instruments from ex-platform or company sources. Therefore, the financial service provider market is of dual character and can't be exhaustively defined. The potentials to improve financial services in the web-based platforms as FLUID-WIN and SEAMLESS will be considered.

2. FINANCIAL SERVICES

Financial service providers would have to determine what financial instruments to offer when entering a closed supply chain or e-market. We list here some potential to improve their performance. On the other hand, we present the requirements for the services offered through the platform. The finance domain within web-based platform is certainly the most challenging area. However, it is one that can reap real benefits once it is integrated or interfaced within the B2(B2B) marketplaces. It is important to state here that finance is at the bottom of all real commercial endeavors and traditionally this has been a sector mostly ignored in many aspects. In fact large departments within companies are required to deal with the sheer volume of papers and documents that the financial area requires.

2.1 Potentials to Improve Financial Performance of Financial Service Providers Within Web-Based Platforms

Banks and lending/factoring institutions mostly give access to financial instruments and price their services according to the perceived risk element involved. The single item that gives confidence to banks is accurate and detailed information. This is however extremely difficult to deliver to the institutions. It is very normal for financial service providers (FSPs) to mostly receive historical reports or optimistic potential figures. Banks and other financial services institutions would have to collect information by running respective information mining and monitoring processes to guide financial instruments such as loans and trade financing documents for instance. The integration of finance and documentation processes enables manufacturers, suppliers, and financial service provides to perform trade and financing more efficiently and quicker. It is apparent that bureaucracy is still the name of the game when it comes to collate documents for trade financial instruments, and each bank has its own subset and version of how it requires these documents to be provided. The platform has sustained potential to streamline, to increase transparency, and to simplify document creation and related processes as an additional value to SMEs that want to trade within the internal market.

2.2 Requirements from the Financial Providers Point of View

There seems to be a certain concerted view when it comes to the requirements and wishes of the financial service providers. These can be summarized as follows:

Positive stance on potential B2(B2B) networks: All FSPs said that if they can have a group of SMEs that are integrated within each other, and normally carry out trade between them, they would be willing to offer services to the group. Banks have asked whether the transactions could be somehow guaranteed and this could actually be possible if there is an insurance company interested in taking up this role.

More information = less risk: All Banks and Factoring Houses mentioned that the more real time and not historic information can be give to them, the greater the willingness to lower costs to the companies. They all requested a sort of "window" where they can view real-time data on their clients and potential clients.

More automation where possible: It would be interesting for the FSPs (all types) to have direct interfacing, report generation and where possible transfer of data in order to speed up requirements for giving/sending information to and from manufacturers

More education to SMEs: It seems vital that manufacturers are trained and informed on the various services on offer by their own and other banks and

financial service providers since this speeds up initial proceedings and avoids errors and delays later on. Many small companies are not aware of Factoring Houses, or Credit Guarantee Institutions and they keep forging on in a much more difficult environment just because of not knowing about the existence of these financial services.

Potential cross-border financial business - In a European perspective this is extremely interesting due to the Internal Market enabling free movement of capital, goods, and labor.

Wish for more Trust and Confidence - All parties (FSPs and Manufacturers) need to have much more confidence in the security offered by web-based platforms (see also Section 3).

2.3 Potentials from the Financial Providers Point of View

The following potentials will follow the requirements:

Access to view data by FSPs: a system needs to be put in place where managers assigned to particular clients can be given a view only access to transactions and information on their clients. An approval system needs to be put in place for both sides.

Direct Data interface gateway: All FSP's information systems need to be interfaced to send/receive data from the platform to make sure that information is complete in a FLUID-WIN context.

e-Learning for SMEs: A simple guide how to the use financial instruments offered by banks, factoring houses and credit guarantee or insurance institutions needs to be developed resulting in a sound preparation and smooth transactions when inquiring and making use of financial services. By offering e-Learning financial services can experience additional quality and effectiveness as the knowledge is being spread among FSPs customers and decreases "frictional losses".

Increase Financial Performance: Doing business within the platform is likely to affect the financial performance of financial service providers. Financial service providers are to obtain increased capability to anticipate financing and investment needs and enhance their portfolio financing and investment decisions. They will still be able to generate interest income and fee income from traditional banking activities, and being sustainable profitable by providing tailor made solutions at competitive rates to known business partners.

3. TRUST ISSUES IN FINANCIAL MEDIATION ON B2B MARKETPLACES

Though operating within a closed supply chain system, locally spread information technology destinations (users of manufacturer, suppliers and financial services institutions) need to be linked, which brings up the need for trust, privacy and security. It is to be expected that security is at least of equal importance than in an open system as limitation of access plays a vital role. Within project Seamless, we have realized research regarding the trust issues on B2B e-marketplace based on P2P architecture. As input to the implementation of the P2P business platform was to examine the trust level of relevant trust building mechanisms (TBM) which will be supported by different types of mediators. The purpose of such analyze was to identify the most suitable and also minimum sets of TBM for Seamless platform and analyze potential future shifts in trust perception, acceptance and requirements according to e-experiences. The TBM was divided according to several contractual phases. One of the required trust services was identified escrow services (ES). For P2P platform we had analyzed three strategies how to solve providing such a service. First was model (1), where internal mediator (verifying information about participant, member of project team) will provide service integrated on the platform with other contractual phase (searching, negotiation, contract execution support). In the second model (2), ES provider was the bank (as the strategic alliance), which will cooperate with platform but will be not fully integrated. Last model (3) provided possibility to use services by specialized outsourced company, as for example Escrow.com. Every model has different implementation and business claims. For example, bank can be more expansive as specialized company and can refuse escrow service for the platform participant, if this company will be not trusted for them. We have examined, which model is most suitable according to different factors. The implications are as follow:

- Generally, companies preferred as a minimum necessary model (2) in 46% against (1) 38% and (3) 29%.
- Generally, companies trust more to banks as mediator for ES (57%).
- Companies which are dominantly focusing on one side business (selling or buying) prefer (1) or (2) 30% as the model with specialized company 8,7%
- The more e-skilled company, the higher trust to the bank or specialized company and lower trust to internal service (1). Together, most e-skilled companies requires in 83% bank for ES provider as a necessity.
- Micro sized companies trust more to (1) in 40% as to other models (26%). Within small and medium sized companies are not significant differences in trust between all models. Large companies definitely prefer (2) in 85%. (more detailed analyses will be published on Seamless webpage or papers by R. Delina)

From mentioned analyses and projects results, the bank as a dominant financial institution play a significant role also on web based business platform for B2B relations. Although, for the initial phase of some e-marketplace, where most participant have low skills in electronic commerce, the internal model where known mediator provide ES is appropriate. The main benefit against other models is maximum acceptance of e-marketplace participant by such a mediator. After achieving some level of skills, participants tend to trust and require more bank or specialized company as a trusted third party for escrow services. These results together with positive stance of banks on potential B2(B2B) networks and automation shows future best practice scenario in the field of escrow services on B2B networks.

1. ABSTRACT

This paper reflects on the organizational consequences when introducing Business Process Management methodologies in the organization. As Business Process Management (BPM) is a stage by stage approach of continuous improvement, it will influence the way integration efforts are organized in an optimal way. This paper considers the importance of centralized and decentralized governed integration efforts, and the evolving balance between them. A prescriptive model is suggested and followed by a validation, based on literature review and case study research.

2. INTRODUCTION

In contemporary organizations we see more often that several methodologies, combined in the general term *Business Process Management* (BPM), are studied and applied in order to gain efficiency and effectiveness, and with that competitive advantage (Davenport, 1993; Rummler & Brache, 1995; Hammer, 1996). BPM focuses on integrating and cross-linking the organization's departments, business units, sub-groups, etc. by actively managing the organization through defining end-to-end value creating processes (Paul Harmon, 2003). Research has proven that the development of a business process oriented view in organizations to integrate the differentiated and fragmented subsystems, leads to positive outcomes (McCormack, 2001).

Evolutions in the business needs such as the creation of more product lines, bigger geographical markets, a larger number of functional specializations, etc. necessitate more differentiation of organizations into sub-units and -systems. By differentiating the organization in homogeneous sub-systems (business units, departments, specialists teams, etc.), the organization becomes more efficient in their collaboration with specific sub-environments (Lawrence and Lorsch, 1967; Galbraith, 1995). This rising necessity for differentiation, in combination with a more demanding customer, the development of global collaboration mechanisms and the growth of technology opportunities, induces more than ever increasing integration needs. In this, the success of the BPM movement, which is focusing on sustained integration, without diminishing the efficiency and effectiveness of homogeneous subsystems, can be situated.

The switch in the early nineties in popularity from Business Process Reengineering, with specific one-time process improvements as subject, to Business Process Management, with the focus on continuously improving business processes (Hammer, 1996; Davenport 1993) induces a more formalized set-up of this specific management function. Depending on difficulty and time required for certain management tasks, different integration levels can be distinguished, from informal and ad hoc collaboration (e.g. frequent meetings) to highly procedural mechanisms (e.g. obliged collaboration policies or integrated ICT-systems) (Galbraith, 1995). As organizations currently evolve to more sustainable and longer term integration, an important impact on the way integration efforts are managed, can be expected. For that reason organizations need insight in which integration efforts optimally impact the organizational performance. An important consideration here is the role of *centralized* versus *decentralized* integration efforts. *Centralized integration* focuses on integration efforts applicable to all organization's departments, sub-divisions, etc., while *decentralized integration* focuses on efforts that obtain integration on a lower level and based on a particular and well defined processes or sub-processes.

3. PROBLEM SETTING

This paper investigates the effect of integration efforts and the evolving balance between centralized and decentralized integration efforts. From own empirical case study research, the authors have seen that the relative balance between centralized and decentralized integration efforts varies for different organizations. Next to more traditional contingency variables, such as company size, environment, strategy, technology (Birkinshaw et al., 2002), the level of yet accomplished process integration, due to cumulative integration efforts, seems to influence the balance between central and decentralized integration.

4. RESEARCH METHODOLOGY

Based on empirical findings and related case study research a general prescriptive model is proposed (see figure 1). Conceptually, the *level of integration efforts* influences (1) the *impact on the organizational performance* and (2) the *balance between centralized and decentralized integration efforts.*

To measure the *level of integration efforts,* a survey, based on previous work of McCormack (2001) and Gemmel et al. (2006), was conducted in 20 organizations, each represented by a significant selection of employees. To have comparable data, the survey probes extensively for the presence of sector and industry independent process characteristics, which collectively indicate a certain 'state of maturity' in obtaining benefits from accomplished integration efforts. A distinction is made between specific organizational characteristics (*'organizational state of maturity'*) and overall process characteristics, considered from different perspectives, i.e. customers, performance, strategy, suppliers, employees, technology, etc. (so called *'overall state of maturity'*).

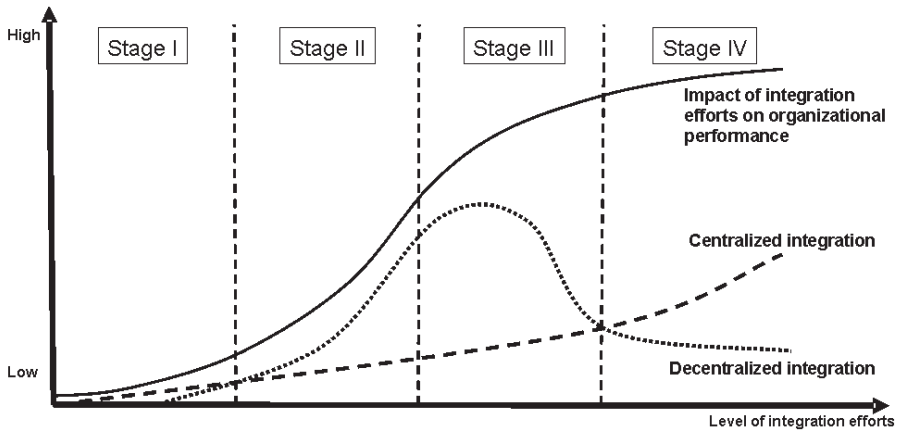
In addition to that, for each company semi-structured and peer checked interviews with several key persons in the organizations were conducted to gain insight in the present integration mechanisms. This is measured by means of total number of full-time equivalents (FTEs) dealing with process management, both centralized and decentralized.

5. A PRESCRIPTIVE MODEL ON INTEGRATION EFFORTS

Figure 1 describes three variables:

- **Impact of integration efforts on organizational performance:** In a strongly differentiated organization, there is an increasing need for compensating measures to encounter this differentiation with integration efforts. These efforts vary for each company and within each company over time in focus and size, depending on the accomplished benefits of previous integration efforts. In complex organizations these efforts have a positive impact on the organizational performance (Lawrence and Lorsch, 1967).
- **Centralized integration:** From empirical case study research the authors notice that for the execution of such centralized integration efforts, many organizations appoint a dedicated staff team with high-level responsibility, often called a *'business process office'* (BPO). Nevertheless the exact working modus, degree of control, empowerment and services provided by this central office vary from company to company, they share the central and company wide character. Other variants and names have been proposed in literature (Burlton 2001; Smith & Fingar, 2003; Kaplan & Norton, 2005)

Figure 1. Centralized and decentralized integration efforts, and their combined impact on the organizational performance



- **Decentralized integration**: For the execution of decentralized efforts in contemporary organizations, employees are more and more empowered to take up this responsibility. Specific process roles, such as process owner, process responsible, process facilitator, process coach, etc. are created. In addition complementary integration mechanisms are installed such as Process Improvement Teams (Harrington, 1991) and regular interdepartmental meetings.

Further the evolving role of both centralized and decentralized integration efforts will be discussed through 4 arbitrary stages, indicated on figure 1.

- In the first stage, mainly ad hoc initiatives to integrate differentiated departmental units are done on several levels, in an informal and discretionary way, for smaller and also quick-win type tasks (Galbraith, 1995).
- In the second stage, there is an emergence of centrally allocated initiatives with an impact on the organization as a whole, grown from previously installed and dispersed activities. To aggregate these initiatives consequently, a more formalized and high-level approach is required. In this stage a BPO is usually initiated to manage strategically linked integration tasks, such as process strategy formulation, definition of general process metrics, standardization of methodologies, etc. to analyze and redesign business processes.
- In the third stage, important centrally managed activities are set up to get the whole company involved in deploying a full-blown process oriented strategy, as it as it was initiated in stage 2. Centrally, the BPO takes up a more participating role to manage and deploy a full program of improvement projects enhancing on large scale the integration capabilities of the organization. Due to a large investment in centralized integration efforts, both the quick rise in *the impact on the organizational performance*, and the large volume of *centralized integration efforts* is explained. In this stage, the BPO influences and works together with some people more decentralized in the organization, who start taking up some responsibilities over certain (parts of the) processes.
- In the last stage, when costs for central integration efforts have become higher and when additional investments only give marginal results, the role of the BPO becomes more governing. Due to the improvement program deployed in stage 3, business process management has become a shared responsibility which is now more decentralized and dispersed throughout the whole organization. In this final stage the BPO takes a more coaching role with regard to methodologies, techniques and tools and manages the complete process knowledge repository.

6. FIRST RESEARCH FINDINGS AND DISCUSSION

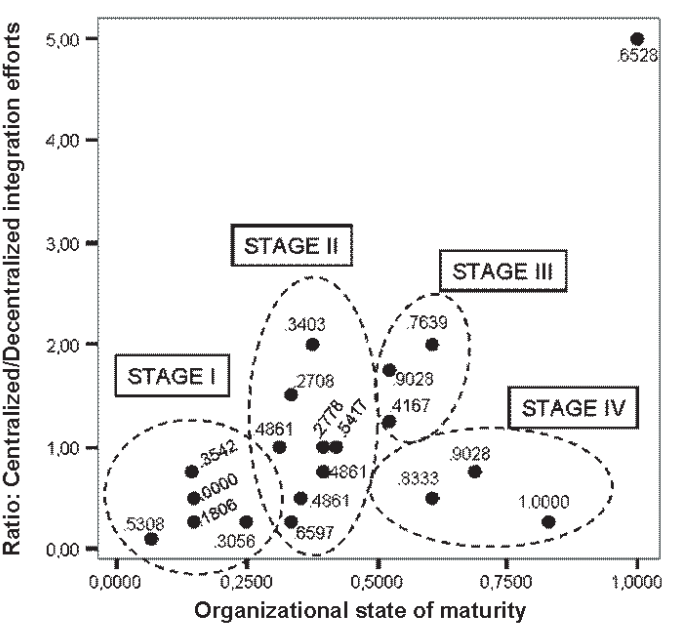
While the model in figure 1 has a more prescriptive character, figure 2 represents a descriptive situation comparing 20 different organizations, scattered graphically for two dimensions:

- The balance between centralized and decentralized integration, based on FTE allocations, shown as a *ratio: centralized over decentralized integration efforts*.
- The specific '*organizational state of maturity'*, calculated from the survey results based on the presence of specific organizational process characteristics.

Further for each organization, the '*overall state of maturity'* is shown (score between 0 and 1), based on the presence of process characteristics in all relevant domains (see methodology).

The substantial difference between the prescriptive character of the model in figure 1 and the descriptive character of the representation in figure 2, forces the authors to make a distinction between on the one hand the organizations which are in a situation represented by the prescriptive model of figure 1, and on the other hand

Figure 1. Scatter plot (20 organizations) centralized/decentralized integration efforts versus the "organizational state of maturity"



organizations which can be classified as exceptions. To estimate the value of the model, a thorough case study analysis comparing exceptions with the 'main stream' organizations, based on their integration performance, is necessary. This to ensure that what the model prescribes really leads to 'good/best practice', while for the exceptions valid indications of a sub-optimal approach should exist.

From figure 2 the varying trend between centralized and decentralized integration efforts can be distinguished. Most organizations can be roughly classified in one of the 4 groups confirming the prescriptive model of figure 1. Most clearly are the groups validating stage I, III, and IV, while for stage II, the balance between centralized and decentralized integration efforts is less clear. Further in-depth research must reveal the variables causing variance between different cases, especially for cases currently classified as stage II.

One clear exception is the case in the right upper corner of figure 2. This company has the highest score concerning '*organizational state of maturity'*. And contrary to the prescriptive model, the relative amount of central steering is noteworthy higher than other companies. However it is noticeable that the 'overall state of maturity' is lower than any case classified in stage IV. This suggests that this organization's additional investments in centralized integration efforts have less marginal impact on the overall state of maturity. Therefore in order to obtain the optimal impact on organizational performance, a more balanced set of integration efforts also in other relevant domains, such as e.g. cultural and technological integration efforts, is proposed.

Also here further research must disclose more detailed insights in the actual contribution on the organizational performance of both specific and combinations of certain integration efforts.

Integrating Stability and Dynamics of Organizational Capabilities Through Informal Knowledge Transfer

Ines Mergel, Harvard University, 79 John F. Kennedy Street, Cambridge, MA 02138, USA; E-mail: ines_mergel@harvard.edu
Harald F. O. VonKortzfleisch, University of Koblenz, Germany; E-mail: Harald.von.Kortzfleisch@uni-Koblenz.de

In the knowledge management literature it is widely accepted that organizational core competencies are the basis for competitive advantages because of their stable and reliable inimitable character (Prahalad/Hamel, 1990; Grant, 1996). Due to increasing dynamics of the global environment, however organizations are forced to integrate changing demands and adapt or develop new competencies to be able to stay flexible and dynamic (Lei/Hitt/Bettis, 1996). The challenging question remains how to integrate the advantages of stability and the advantages of flexibility, simultaneously.

Answers to this question are already given by authors like Teece, Pisano & Shuen (1997) as well as Eisenhardt & Martin (2000). What is missing however is a discussion from the perspective of knowledge management based on a precise definition of explicit and non-explicit knowledge. Another missing link is the importance of informal knowledge transfer through social networks as a possibility to balance between the stable and dynamic dimension of core competencies and capabilities. We will focus on both aspects in this paper.

TRADITIONAL KNOWLEDGE MANAGEMENT STRATEGIES

"*Knowing who*" and also "*knowing who knows what*" is an important pillar when it comes to knowledge management strategies. According to empirical results of Hansen et al., (1999) two different strategic directions for knowledge management can be followed: In some companies, the strategy centers on the computer. Knowledge is carefully codified and stored in databases, where it can be accessed and used easily by anyone in the company. We call this the codification strategy. In other companies, knowledge is closely tied to the person who developed it and is shared mainly through direct person-to-person contacts. The chief purpose of computers at such companies is to help people communicate knowledge, not to store it. We call this the "*personalization strategy*" (Polyani, 1962:17). Also Dennis and Vessey (2005) identified these two strategic orientations for knowledge management as a result of their empirical study. They call the first one "knowledge hierarchies" and the second one "knowledge markets".

KNOWLEDGE COMMUNITIES AS SOCIAL NETWORKS

Both traditional knowledge management strategies as mentioned before undergo an extension if the focus on communities displaces the focus on the individual. This third strategy can be called "socialization strategy", or – with the words of Dennis and Vessey (2005) – "knowledge community". The aim here is to get access to explicit and non-explicit knowledge of non-hierarchical communities by tapping into their informal social trust-based network relationships.

When looking at knowledge communities we are taking on a social network perspective. Social network theories are the basis for social network analysis in which people and collective actors (e.g. organizations) are regarded not as "social islands" who are primarily be described by specific characteristics or attributes of single actors. Rather, a network approach looks at pairs of actors who are characterized by their relations with other actors: „A social network consists of a finite set or sets of actors and the relations defined on them." (Wasserman/Faust, 1994:20). Radcliff-Brown (1940) calls it the "social structure" of networks.

Besides the above described structural components of social networks, where researchers mainly study the impact of different positions within the overall network on network outcome – it is also important to understand the actual content that flows through the network ties. In terms of knowledge management, the content of a tie represents the knowledge in form of resources and information that is being transmitted through the network ties. Relationships can therefore also be described as an "opportunity structure" through which connected actors have access to explicit or non-explicit knowledge. Besides the formal reporting structures in form of hierarchy through which mainly explicit or codified knowledge is transported, the informal aspect of information flow is important when it comes to knowledge networks. The structure enhances access to explicit as well as non-explicit knowledge that would otherwise not be accessible if the relationship does not exist. The network constrains as well as supports the diffusion of knowledge.

INTEGRATION OF STABLE AND DYNAMIC CAPABILITIES THROUGH SOCIAL NETWORKS

Social (knowledge transfer) networks as discussed above are informal in nature with regard to their character – they usually evolve bottom-up and overlap the formal and intended organizational structure. They allow for informal access to explicit as well as non-explicit knowledge.

Knowledge comprises cognitive-emotional capabilities as well as body-related skills, both in the sense of existing capacities in order to be able to take action (Senge 1990: 9). In so far, knowledge can be understood as "*knowing how and why*". The "tacit dimension" of knowledge can be theoretically demarcated from the "explicit dimension" of knowledge by pointing to the fact that "(w)e can know more than we can tell" (Polanyi 1962: 5). Polanyi's thesis is that all knowledge is rooted in tacit knowledge (Polanyi 1966: 195). The difference however is that explicit knowledge is articulated, documented, directly accessible and relates to what is called "declarative knowledge" (Squire 1987) or "discursive consciousness" (Giddens 1984).

If explicit knowledge is exchanged or the procedural part of non-explicit knowledge (operational routines) is made explicit, social networks draw back on the "architectural competences" of corporations (Henderson/Cockburn, 1999; 2000). These competences stand for the advantages of stability and reliability.

If non-explicit knowledge in terms of creative expertise is made explicit within the social network, new problems drive the explication and as a result dynamic capabilities are the outcome of respective learning processes especially in the sense of double-loop and deutero-learning and deutero-learning (Argyris/Schön, 1978).

Therefore, social networks can either contribute to organizational core competencies or to dynamic capabilities of organizations. In so far, they are potentially an informal way of balancing the advantages of both concepts.

RESEARCH DESIGN

We suggest applying a multi-method research design: a quantitative survey of networking activities among members of an IT department, accompanied by interviews to prepare the questionnaire and understand the findings. We have chosen IT departments as an area where the tensions between stability (due to technological standards) and change (due to permanent technological evolution)

are very characteristic. We conducted preliminary interviews in a single company to be able to identify the relevant actors within the chosen IT department, consolidate common vocabulary used in the company, and to pretest our survey items. The quantitative survey was sent out to all employees within the IT department and we had a 90% response rate. One employee refused to answer questions regarding his professional ties.

In the questionnaire, we included two pairs of questions regarding the perceived information sharing (-> knowing that and what; explicit knowledge and procedural operative routines) and advice networks (-> knowing how and why; special creative expertise), asking for bidirectional ties for both networks types: "Who do you turn to for information/advice regarding IT Governance?; and "Who turns to you for information/advice regarding IT Governance?". This allowed us to understand both the reciprocated ties as well as the uni-directional ties.

The main result of our research study is that the two different types of informal knowledge networks really exist and are overlapping the formal organizational hierarchy of the company. In addition to that, the informal information sharing network contributes to the stability of the IT department's capability with regard to the usage of ITIL. It stands for the explicit, declarative knowledge the department members share between each other about more than presently 30 ITIL volumes. Through this process of reinforcement, knowledge about ITIL is incrementally tuned and a common stable and reliable understanding of ITIL developed.

The informal advice network contributes to the dynamic capabilities of the IT department's knowledge about ITIL. Problems are seen as the source for detailed discussions about ITIL and further developments with regard to IT Governance. Respective advice takes place on the level of special creative expertise. The members of the department cannot simply remind themselves of routines but have to initiate creative processes of problem solving. Questions which have to be answered here are for example "How do I implement this with what consequences for whom?". Non-explicit knowledge except what was elaborated as "unconsciousness" is made explicit and shared between the members of the IT department. This dynamic process guarantees for the needed flexibility in the area of IT Governance.

Both explanations were confirmed by the department head when we presented our results and discussed the findings in the company.

Assessing IT Strategy with the STEP Model

Theophilus B. A. Addo, San Diego State University, San Diego, CA 92182, USA; E-mail: taddo@mail.sdsu.edu

INTRODUCTION

It has now become abundantly clear to most business organizations that any so-called "IT strategy" must encompass more than just IT (i.e., the technology) *per se*. Having the "latest and greatest" technological gadgetry (i.e., computers) does not necessarily translate into an effective IT strategy without sufficient attention being paid to the *people* who will be using the technology or the *business processes* for which the technology will be used. To gain competitive advantage in today's turbulent and highly competitive business environment, organizations need to be prepared for continual transformation in order to be successful and be able to respond quickly and effectively to changes in the environment. This includes, among other things, transformation in structure, processes, culture, and philosophy. Additionally, they need to be able to exploit relevant information technologies for their advantage—indeed IT is a major driving force for many organizational transformations and competitive positioning. The focus of this paper is primarily on the technology, process, and staff dimensions of IT strategy.

Increasingly, IT's contribution to a firm's bottom line has come under scrutiny by CEOs, who have invested significant resources into IT systems and projects (Haag et al., 2006, Luftman, 2004, Applegate et al., 2003, Wen and Yen, 1998; Axson, 1996) and are now beginning to seek results and accountability from these investments. While there have been many business successes reported in the literature about corporate IT investments (e.g., Stratopulos, 2000, Hitt and Brynjolfsson, 1996), there has also been an impressive number of failures resulting from unsuccessful IT projects. According to a survey by the Standish Group, 73 percent of corporate America's IT projects in 1996 were late, over budget, or canceled. Project failures cost an estimated $145 billion per year (Thorp, 1999). Notable among the reasons given for IT project failures are the following: a lack of alignment of IT projects with business strategy (Luftman, 2004, Boar, 1994, Floyd and Woodridge, 1990) and a lack of integration of IT into the activities of the people who use it (Bates, 1999). Both of these factors can be mitigated by an IT strategy which incorporates technology, people, and business processes, all within the context of overall corporate business strategy.

The need for a multi-dimensional approach to IT strategy has been articulated by other authors. For example, Bartlett and Ghoshal (1994, 1995) proposed the dimensions of *Purpose*, *Process*, and *People*. The present study uses another model, the STEP model, proposed by Wysocki and DeMichiell (1997), which looks at IT strategy along the dimensions of *Technology*, *Process*, and *Staff (People)*. Specifically, the 'STEP' in STEP model stands for ***S**trategy for **T**echnology **E**nablement through **P**eople*. This model recognizes that organizations cannot rely on technology, by itself, for competitive advantage but, rather, need to have an information-empowered staff which is able to utilize information technology effectively, as well as efficient business processes, all working together in concert. Using the STEP model, an organization can assess its standing on each of the model's three dimensions of technology, process, and staff to give an indication of how well it is positioned with respect to its ability to exploit IT opportunities for competitive advantage. Such an assessment can also help organizations in the formulation of an effective IT strategy (or the revision of current strategy) by focusing attention on the dimension(s) most in need of improvement.

RESEARCH OBJECTIVE

The objective of this study is to utilize the STEP model to determine how well various organizations are addressing the important performance dimensions of technology, process, and staff. This assessment gives an indication of the ability of these organizations to effectively utilize information technology for competitive advantage and for overall corporate performance.

METHODOLOGY

The STEP model, as proposed by Wysocki and DeMichiell, was strictly conceptual. Therefore, to convert it into a useful and practical assessment tool, it was operationalized as a questionnaire which could be administered to organizations. The questionnaire was created by developing a set of questions that addressed each dimension of the model (technology, process, and staff) as well as a few additional questions seeking demographic and other relevant information from the respondents; approximately 40 questions were developed in total. For those questions pertaining to the model's dimensions, respondents were asked to assign a numerical score ranging from 1 to 10 to each question. Before sending out the questionnaires to the actual respondents, a pilot study was conducted, in which the questionnaire was first sent to eight senior IT and business executives in various organizations in southern California for their comment, feedback, and suggestions with respect to the appropriateness of the questions, the length and duration of the questionnaire, etc. Based on the feedback received from these executives, the questionnaire was refined and mailed to about 350 senior IT and business executives in a variety of companies in various industries in the United States.

DATA ANALYSIS

Some completed questionnaires have been returned and data analysis is still ongoing. The plan of the data analysis is to:

a. determine the relative score on the technology, process, and staff dimensions of the STEP model for each organization (respondent)
b. see if there are any significant differences in the responses given by IT professionals and business professionals
c. see if there is any correlation between the given scores and various demographical factors such as company size and industry.

ABSTRACT

Previous researchers have cited a number of plausible explanations for the under-representation of women in the Information Technology (IT) field. However, there has not been a comprehensive study of the barriers women face in this field or the facilitators that encourage them toward IT, and the studies we have do not provide a cohesive picture of the situation as a whole. The primary reason for this deficiency is the broad nature of the problem. Studying such a wide-reaching problem requires careful, guided segmentation into manageable and logically cohesive slices. Toward this end, this research proposes a model of the IT Career Lifecycle that can be used both to categorize the work of prior researchers and to design future studies.

INTRODUCTION

Over the past two decades, numerous researchers have reported on the diminishing number of women interested in IT careers. In this research, IT is defined as the broad subject concerned with all aspects of accessing, managing, processing, and transmitting information, especially within a large organization or company (Webopedia, 2006). IT careers consist of occupations that require designing, developing, and implementing software and hardware systems, providing technical support for software and hardware systems, and creating and maintaining network or database systems (Creamer et. al, 2004). Camp (1997) in her classic article, *The Incredible Shrinking Pipeline,* emphasizes, "The ratio of women involved in computer science from high to graduate school has been dwindling at a startling pace over the past decade" (p.129). Sanders (2005) states that with the growing role of technology in the world at the beginning of the 21st century – in education, communications, occupations, and entertainment, and as a tool for solving the world's problems – American women's low and decreasing representation is a major concern. Furthermore, the percentage of women receiving bachelor's degrees in the Science, Technology, Engineering, and Mathematics (STEM) disciplines in the United States has increased in every category except Technology (National Center for Educational Statistics, 2005). From 1984 to 2004, the percentages of women receiving bachelor's degrees in the Physical Sciences ranged from 27.6% to 41.7%, Biological/Biomedical Sciences from 46.7% to 62.2%, Engineering from 14.1% to 20.5% and Mathematics from 44.3% to 46.0%. Technology started strong in 1984 with 37.1% women receiving bachelor's degrees; however, 2004 brought a dismal decrease to a low of 25.1%, near the level of three decades ago. The proliferation of computers and information technology in our society, businesses, schools, and homes would have suggested an increase in the participation of women in technology bachelor's degrees, but instead we are faced with a state of clear and continuing decline.

IT CAREER LIFECYCLE MODEL

Carlson (2006) reports that women who want to pursue a career in IT face barriers as early as grade school, in high school, through college and into the work world. Ahuja (1995) developed a model that depicted the factors that constrained women throughout multiple aspects of their recruitment and advancement in the IT field. Ahuja grouped factors influencing women's professional IT career choice into three stages: 1) Early Educational 2) Career Choices and 3) Career Advancement. In Stage I, Early Educational, Ahuja referred to positive and negative experiences that may have influenced a child's attitude and perception toward computers. Stage II, Career Choices, consisted of factors that influenced the critical career choices women made during their university education experience and initial entry into the job market. Finally, in Stage III, Career Advancement Stage, Ahuja considered factors that impede promotions to higher-level IT careers.

Ahuja's model, put forth over ten years ago, is updated by the model proposed here. This new model recognizes that young women begin to make their career choices before Stage II, and it distinguishes more clearly between the university experience and entry into the IT field. In addition, it includes career retention along with career advancement. The new model, proposed here, is shown in Table 1. This model, entitled IT Career Lifecycle, expands Ahuja's three stages into four: 1) Stage I - Contemplating choice of IT major, 2) Stage II - Validate or redefine IT major, 3) Stage III - Initial entry into IT field, and 4) Stage IV - Retention and advancement in IT field.

Table 1. IT career lifecycle model

Stage	Description	General Timeframe	Selected Researchers
I	Contemplating a decision of IT major	Early Childhood to juniors and seniors in high school	AAUW report (2000), Bleeker (2006), Jepson and Perl (2002)
II	Validate or redefine IT major	College	Cuny and Aspray (2000), Pearl et al. (1990), Margolis & Fisher (2002)
III	Initial entry into IT field	One to three years in IT profession	Teague (2000)
IV	Retention or advancement in IT field	Three or more years in IT profession	Trauth (2006)

The arrows in the new IT Career Lifecycle (See Table 1) represent the ability for women to enter or exit the model at any stage. The entry arrows illustrate potential barriers in recruitment of women in each of the four stages of the model, whereas the exit arrows illustrate potential barriers in retention. As the model indicates, a female high school student could decide to major in IT in Stage I of the IT Career Lifecycle Model, and leave the IT field during college in Stage II, due to the long hours in the computer lab and the perception of not having enough time to have a life outside of school. On the other hand, a woman could major in another discipline and enter into the IT Career Lifecycle in Stage III, as a self-taught IT professional. This same woman could leave her IT career in Stage IV due to a lack of opportunities for advancement. Thus, the IT Career Lifecycle model facilitates the ability for the IT community to concentrate and focus their research in a specific stage where girls/women may encounter barriers in their IT careers and target their intervention recommendations in either recruitment strategies, retention strategies, or both.

RELATING KEY STUDIES TO THE MODEL

Stage I consists of barriers a young girl may encounter from her early childhood years to the later years of her high school experiences. The American Association of University Women Educational Foundation report (2000) explains that many girls have a concern with the computer culture and express a "we can, but I don't want to attitude toward computer technology" (p.7). Jepson and Perl (2002) surveyed 652 high school students. Their study revealed several reasons why girls did not choose IT careers: not enough role models in the IT field, other interests, lack of knowledge of the industry, limited opportunity or access to computers, and the image of IT people as nerdy. Bleeker's (2006) study of 460 high school students concluded that the boys surveyed reported a significantly higher expected level of success and interest in IT jobs than the girls. The barriers that create this IT disinterest for girls must be examined to obliterate pipeline leakage in the beginning of the career lifecycle.

In Stage II, a young woman who has decided to major in an IT discipline may encounter barriers while she is validating her major during her college experience. Pearl et al. (1990) focused on the shrinkage of women in the IT pipeline from the pre-college level through graduate school; however, their primary focus was at the college level. Pearl et al. determined three primary barriers for women attempting to enter the field: "difficulties with self-esteem, lack of role models and gender discrimination." Cuny and Aspray (2000) reported on a workshop that developed 20 intervention strategies to increase women's participation in IT graduate programs across the United States. Margolis and Fisher (2002) conducted a study at Carnegie Mellon to investigate computer science education and the experiences of computer science students at the university level. As a result of their research, Margolis and Fisher discovered various differences in computer career decisions, interests, attitudes, and experiences of men and women at Carnegie Mellon. The goal of their research was to understand the differences and develop strategies to increase the participation and retention of women in IT.

Stage III barriers could restrict a young woman's growth and development of her IT career during her initial years in the IT industry. During Stage IV, an experienced IT professional woman may encounter barriers in the industry that impede her opportunity to advance her career. Trauth conducts research on women in the information technology workforce. Teague (2000) studied 15 IT women professionals to explore their reasons for entering the IT industry, what they liked about the industry, and what they didn't like. Some of the explanations for disliking the computer field were being in a male-dominated environment, lack of mentors, and discrimination in salaries. Trauth's research (2006a) examines the "Individual Differences Theory of Gender and IT." This Individual Differences Theory depicts the variation of how IT professional women from different backgrounds perceive and respond to the IT environment, computing culture and societal influences. Moreover, Trauth's contribution as Editor-in-Chief of the Encyclopedia of Gender and Information Technology is an international compilation of over 200 articles highlighting the emerging research and trends on men and women in IT (Trauth, 2006b).

CONTRIBUTIONS AND FUTURE USES OF THE MODEL

By breaking the broad area of women's under-representation in the IT field into more easily studied stages, this model provides both a way of categorizing, relating, and identifying gaps in prior work, as well as guidance for future research.

ERP Conception to Completion: Issues Experienced by Indian SMEs

Seema Sharma, Open University Business School, UK; E-mail: s.sharma@open.ac.uk

1. INTRODUCTION

Enterprise Resource Planning (ERP) system comprise a suite of software modules that lets an organization share common data and practices across the enterprise to access information in real-time environment(Marnewick and Labuschagne, 2005). ERP if implemented successfully can have a significant impact on organizational performance through automation and integrating the majority of business processes (Davenport 1998) on small, medium and large sized organizations.

Small and medium sized enterprises (SMEs) have become a major contributor to the economies of the countries throughout the world (Fillis *et al.,* 2004). Not only in developed countries but also in the developing countries like India, during the past 50 years, the small-scale sector has played a very important role in the socio-economic development of the country. It has significantly contributed to the overall growth in terms of the Gross Domestic Product (GDP), employment generation and exports (Economic Survey, 2003-04). This is the reason in studying these enterprises in this research and more importantly to understand how their efficiency can be increased through successful ERP implementation.

All over the world, a number of SMEs have begun to recognize the significance of ERP. In recent years, many ERP system developers and vendors have begun developing ERP software modules especially targeted at SMEs. For example, SAP, a market leader in ERP solutions has recently launched All-In-One package for 23 industrial practices for Asia –Pacific SMEs (SAP, 2006). However, examples of successful ERP implementation in the Indian SMEs sector are limited. ERP systems are complex. They require large investments in terms of capital, staff and management time (Adam and O'Doherty, 2000) and SMEs usually have limited financial resources, and less technological expertise and management skills (Blili and Raymond, 1993) compared to large enterprises. These constraints make it even more important for SMEs to implement ERP successfully because compared to large enterprises, it would be very difficult for them to survive a failed implementation (Muscatello *et al.,* 2003). Therefore, SMEs need to identify and understand the factors that will lead to successful implementation and those factors that may inhibit such success.

The literature review clearly indicates that most of the reported studies on these systems have focused on large ERP installations with individual investment costs of well over $ 100 million (Muscatello *et al.,* 2003). A literature review had revealed a gap in explaining ERP implementation issues faced by SMEs. In particular, there is very limited research on such implementation in the specific context of Indian SMEs. Given the importance of such firms to the Indian economy and, in turn, the importance of the Indian economy to the global economy, this is a significant gap, which this study seeks to address.

2. CONCEPTUAL FOUNDATION AND RESEARCH METHODOLOGY

The ERP systems experience cycle model (Markus and Tanis, 2000) has been adopted to classify implementation issues experienced by Indian SMEs during various phases of the implementation process. This process theory approach developed by Markus and Tanis (2000) focuses on the sequence of events leading to implementation completion.

The literature provides evidence that the definition of a SME generally depends on one or more than one factor (for instance, number of employees, sales turnover,

Table 1. Firm profiles

	Firm A	Firm B	Firm C	Firm D	Firm E	Firm F	Firm G	Firm H
Year of firm establishment	1999	1994	1985	2000	1986	1988	1997	1990
No. of employees	100	120	200	175	95	100	100	50
Industry	Retail	Retail	Retail	Manufacture	Manufacture	Service	Manufacture	Manufacture
Year of ERP installation	2004	2000	2006	2001	2006	2005	2005	2005
Implementation duration	9 months	6 months	6 months	8 months	8 months	8 months	6 months	1 year

Interviewee	IT Head	IT Head	IT Manager	Manager IT	Manager -systems	General manager	IT Manager and user	Chief information officer and user

investments in assets, and so on) and it is country specific. For the purpose of this study, the Government of India definition of SMEs has been used. According to this, small enterprises are those with an investment of not more than Rs. 50 million(approximately 0.6 million pounds) and medium enterprises are those with an investment of over Rs. 50 million but less than Rs. 100 million(approximately 1.2 million pounds) in plant and machinery(Ministry of Small-Scale Industries, 2004).

The research questions of the study were investigated through qualitative methods. Fieldwork was carried out in India through semi-structured face-to-face and open-ended interviews with IT managers/Head/Deputy General Manager in eight SMEs in India. In addition to this, data was also collected through company reports and documents. All interviews were recorded digitally. The duration of each interview was about 60-80 minutes. The particulars of the SMEs interviewed are presented in Table 1.

3. SUMMARY OF FINDINGS

The section 3.1 explains the issues that Indian sample SMEs faced during the implementation process. The process of ERP implementation, the stages and their corresponding critical success factors have also been studied in this research. Based on the findings, an integrated model for successful implementation has been developed and presented in section 3.2. Due to the constraint on the words limit, the findings are discussed briefly.

3.1 Issues Faced by the Sample Firms

The major issues faced by sample firms in the implementation process has been examined and are then linked to the stages of implementation process based on ERP systems experience life cycle model(Markus and Tanis, 2000).

A. Chartering Phase

Detailed business requirements: During project planning stage, detailed business requirements based on business growth for the future were not looked into by most of the sample SMEs. Due to this, ERP customization was required later on and this increased ERP implementation costs. To tackle this challenge, SMEs should plan carefully what kind of changes in the business processes might occur in the next few years.

Financial support: Though ERP installation was a management decision in the entire sample of SMEs most of the IT Managers found it difficult to get the budget sanctioned. One respondent suggested that management has to be influenced and explained about return on investments for both short and long term.

Dedicated team: Dedicated team for the entire duration of the implementation process was among most common challenge faced by SMEs. The reason for this was the team members were given these additional responsibilities while they were still performing their earlier duties. Therefore, they had to perform extra work for the duration of ERP implementation. This can be tackled if team members can be allowed to work only on ERP implementation. This will lead to successful implementation within time limit.

Vendor selection: Most of the SMEs were not aware of the fact that appropriate vendor selection is an extensive process and it took more time to select vendor than as initially planned.

B. Project Phase

Mindset of users: Changing mindset of users to have ERP was pointed out by all the interviewees. This can be handled only if senior management gives a clear decision that everyone in the company has to accept it.

Update on project progress: Lack of effective communication on the part of management to update the progress of ERP project led to incomplete information with the employees of the firm. This resulted in the resistance from the employees at the later stages.

Training to team members: Lack of systematic and comprehensive training has been raised as one of the main issues. Respondents suggested that initial training should be conducted in different city where all the training members will be completely involved in training. Then, in-house training can follow as and when required.

C. Shakedown Phase

ERP benefits: Management and end users expect ERP benefits from the day one. It was a major task for IT managers to make them understand that it takes few months for ERP benefits to be realized.

Users feedback: Once ERP is implemented, users feedback plays an important role. Users generally do not give complete feedback. Due to this, it takes more time to make the corrections.

D. Onward and Upward Phase

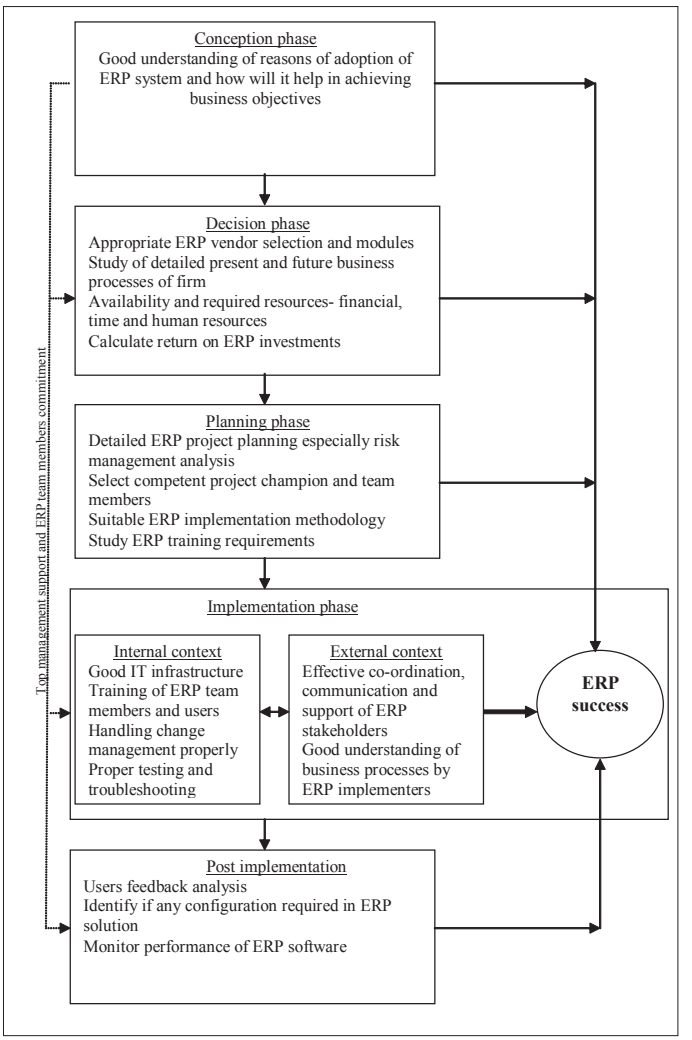
Performance measurement: The respondents recognize that there was no performance measurement technique accepted by the firm at various stages of implementation process. This would have helped the team members to know the status of implementation process as compared to planned initially.

Adaptability of new solution: Even when the system was in place, end users have to be convinced of the importance of the new technology from time to time.

3.2 An integrated Model for Successful ERP Implementation Process

Based on the results of the interviews, an integrated model for successful ERP implementation has been developed that is particular to Indian context (figure 1). This model summarizes and highlights only the most common factors leading

Figure 1: An integrated model depicting ERP installation stages and associated key success factors in Indian SMEs



Source: Compiled by the authors

to implementation success as identified by the respondents. All the interviewees emphasized the important role of top-level management during the implementation process. However, IT managers/consultants and users have a more significant role to play in implementation and post implementation phase respectively. Another interesting factor pointed out by most of the interviewees was that top management has to follow a firm approach to make ERP successful in Indian SMEs. This is mainly because resistance of users was found to be of major concern in most of the SMEs. The brainstorming sessions, training, involvement of users from the very beginning were some of the suggestions given by interviewees as ways of addressing the concerns of users. Other critical success factors have been mentioned in the figure 1.

4. CONCLUSION AND FUTURE RESEARCH

The findings of the study will assist ERP researchers and practitioners to be aware of challenges that can come while implementation process, and how these can be handled for ERP success. Specifically, an integrated model can be used by SMEs to gain knowledge of systematic stages and their corresponding critical success factors specific to Indian SMEs.

This work represents work in progress. In the near future, case studies will be conducted for further developing the framework based on the perceptions of senior management, IT managers and end users. In addition to this, quantitative surveys will be conducted to validate the findings.

A Dynamic Capabilities Theory Assessment of E-Learning in Jamaica

Christine Charlton-Laing, University of the West Indies, Mona Campus, Kingston, Jamaica, W.I.; E-mail: cclainguwi@yahoo.com
Gerald Grant, Carleton University, Ottawa, Canada; E-mail: gerald_grant@carleton.ca

ABSTRACT
Many governments are looking to e-Learning to foster the growth and further development of their educational systems. Despite the potential of e-Learning as a development tool, there are no guidelines given as to the capabilities necessary for the successful implementation of e-learning infrastructure within a developing country and how these capabilities should be shaped. This research examines how Jamaica plans to use e-learning to address the educational problems faced in the country. Several factors, deemed necessary, are identified within the literature and are used initially to outline the capabilities that may be necessary for e-learning infrastructure implementation success. Applying a dynamic capabilities lens and drawing on the lessons learned from the case study this paper will propose a framework for e-learning infrastructure implementation success in a developing country context.

Keywords: e-learning; dynamic capabilities; education; developing country.

1. INTRODUCTION

As economic and social disparities emerge between the countries of the world, most developing countries struggle to find a path to development. The literature has identified varying options for developing countries to achieve economic and social benefits. Some of these include IT-enabled services (Davis et al 2002), software exports (Carmel 2003) and e-government (Ndou 2004; Sipior et al 2005). However in order for a developing country to offer these services or benefit from them it is reasonable to assume that it will need people with the requisite level of education. Drucker (1996) argued that in this knowledge-based era "there would not be poor countries but only ignorant ones". The development of a country's human capital is essential in a global and knowledge based economy. Knowledge is recognized as the driver of productivity and economic growth. Kante & Savani (2002) further emphasized the importance of developing countries acquiring and enhancing knowledge as a competitive tool.

Kaplan-Leiserson (2001) defines e-learning as "a wide set of applications and processes such as Web-based learning, computer-based learning, virtual classrooms, and digital collaboration. It includes the delivery of content via Internet, intranet/extranet (LAN/WAN), audio- and videotape, satellite broadcast, interactive TV, and CD-ROM". Although it has been argued that technology does not improve the delivery of pedagogy, it can promote understanding by individuals with different learning styles (Zhang et al., 2004). E-learning as defined by Kaplan-Leiserson 2001 includes various delivery media that cater to differing abilities and learning styles of students.

E-learning has been identified as one of the contributors to a country's development (Kante and Savani 2002). Various governments have employed e-learning to assist in the education of their people. Some of the countries in which e-learning has been implemented at a national level include the Philippines, Thailand and Singapore. In 2001 Singapore implemented a national e-learning strategy which included using e-learning to enhance the delivery of education in schools but also a component which dealt with the use of e-learning within the corporate and government entities for staff training. By 2003, the majority of Singapore households had access to a computer and the Internet. In fact, The World Economic Forum and other indices rank Singapore as one of the most network ready countries in the world.

Despite the evidence that e-learning can propel a country on the path to development, there are no guidelines given as to the capabilities necessary for the successful implementation of e-learning infrastructure within a developing country and how these capabilities should be shaped. Countries have put e-learning infrastructure in place without full knowledge of all that is needed (Trinidad 2002, Pagram and Pagram 2006). A prescription for successful e-learning infrastructure implementation is needed for developing countries striving to become competitive as a result of increasing the educational level of their population.

The case of e-learning infrastructure implementation in Jamaica will be examined. The objectives of this initiative by the Jamaican government are:

1. Improve the quality of education
2. Enhance the learning experience
3. Ensure high levels of passes in the CXC Exams (a standard set of examinations taken by Caribbean high school students).

The questions that this research will answer are: What are the necessary capabilities for a successful e-learning infrastructure implementation? How does Jamaica develop these capabilities? Examination of this Jamaican case study will add to the body of knowledge on e-learning and provide insights to other researchers on the type and nature of capabilities that are needed in the implementation of similar projects in a developing country context.

The rest of the paper is organized as follows: section 2 gives background on the case study, section 3 proposes to use a dynamic capabilities theory lens to assess the project, section 4 proposes a work plan to engage in the research, section 5 looks at the preliminary findings and section 6 concludes the article.

2. JAMAICAN CASE STUDY

Jamaica has made great strides in integrating technology within its society, particularly voice telephony. The Economist Intelligence Unit's e-readiness rankings for 2006 ranks Jamaica as 43rd out of 68 countries while the Networked Readiness Index for 2005-2006 ranks Jamaica as 54th out of 115 countries of the world. There is access to the Internet and data related services but the use of these technologies is greatly inhibited by the low level of education of the nation's people. Several challenges are identified in the educational system. There are wide disparities in standards among schools, absence of standard instructional materials for teachers and students, an absence of a standard assessment system, inadequate equipment in schools to enhance teaching and learning using modern technologies and an inadequate remedial programme to enable weak students to cope with high school work (Feasibility Study - www.mct.gov.jm\elearning).

The e-learning project, executed mainly through e-Learning Jamaica, a government corporation, in collaboration with two government ministries, was developed with the goal to improve the quality of education in high schools. It proposes using technology to enhance the educational experience. Students in Jamaica's High Schools will benefit from a mix of formal methods with informal approaches to stimulating learning. Proponents of the e-learning project envision applying a blended learning approach that would see e-learning technologies complementing traditional classroom teaching.

The Jamaican e-learning project will be implemented in two phases as indicated in Table 1. The research phase will be "the testing ground for the project design, approach to implementation, the use of teaching and learning materials, the technology applications and software as well as the support systems that must

Table 1

Phases of the E-Learning Project	
1. The Research Phase – The Pilot Programme	• September 2006 – August 2007 • Grades 10 and 11 • 28 selected schools • Includes 5 subjects • Three teachers colleges will be included in the pilot
2. The Implementation Phase - All Island Access to e-Learning	• September 2007 – August 2009 • Includes all eleven (11) subjects in the high school CXC CSEC syllabus • Implementation will take place from grades 7 – 11 in remaining 166 high schools

Adopted from www.mct.gov.jm

Table 2

E-Learning Project Objectives
• To develop a comprehensive set of standard ICT-based instructional materials for teachers and students, in 11 CXC CSEC subject areas
• To provide schools with ICT equipment and software for use in the teaching and learning process • Establish a Central Repository for the Educational Materials (CREM) at the Ministry of Education
• To enhance the skills of teachers through training programs in the use of software and equipment and in modern methodologies for delivery of the high school CXC syllabus;
• To provide modern technologies to existing remedial programs in high schools to ensure that all children keep pace with the schools' programs
• To institute standard examinations that will measure and track the performance of students in each grade in high schools, as well as, measure performance among schools.

Adopted from www.mct.gov.jm.

be in place" (www.mct.gov.jm\elearning). The project has various objectives as shown in Table 2.

3. THEORETICAL FOUNDATION

Teece et al. (1997) define dynamic capabilities as 'the ability to integrate, build, and reconfigure internal and external competencies to address rapidly-changing environments'. Dynamic capabilities theory has been applied within various contexts. Ayuso et al. (2006) used two case studies to identify important capabilities necessary to successfully integrate stakeholders' insights into innovations. We have reviewed e-learning literature and this has suggested the existence of several factors necessary for a successful e-learning infrastructure implementation success (see Table 3). This will be our starting point for identifying the necessary capabilities. The dynamic capabilities theory can be effectively used to analyze the processes employed within the e-learning project.

4. RESEARCH DESIGN

The research approach that will be used in this initial assessment of e-learning in Jamaica will be qualitative. The use of a qualitative methodology is appropriate because it may be difficult to identify dynamic capabilities through quantitative research (Eisenhardt & Martin 2000). We will use an exploratory case study research strategy (Eisenhardt 1989).

A longitudinal study will be performed from 2006 to 2008. Interviews will be conducted. The personnel at the various entities, e-Learning Jamaica, the two government ministries involved in the initiative and at the schools where implementation will take place will be interviewed. This will be done at various intervals during the study. The initial interview instrument will include several open ended questions so that the feedback from the respective parties can be as rich as possible. Documentation from a variety of secondary sources will be examined. The different dynamic capabilities emerging will be identified through a review of the information that is gathered. A framework will be developed. It

Table 3

Factors Identified by Literature Review as Contributing to E-Learning Infrastructure Implementation Success
Adequate IT infrastructure and Equipment Implementation(Trinidad 2002)
Trainer Training (Crichton & Labonte 2003, Trinidad 2002)
Pedagogy Development (Pagram & Pagram 2006)
Matching of social and cultural issues to the delivery of the pedagogy (Pagram & Pagram 2006, Edmundson 2003)
Government and Private Sector Support (Trinidad 2002)

is expected that these capabilities will be linked to the factors identified in table 3, among other factors.

5. PRELIMINARY FINDINGS

There are no preliminary findings as yet since the project and our research into it are in their early phases. With regards to the project, the development of instructional materials is currently underway. The equipment will be supplied by a world-renowned company. Orientation and training of teachers in using ICT to train is also currently taking place.

6. CONCLUSION

There is no research on the implementation of e-learning in a Caribbean country. This research will examine the implementation issues related to Jamaica's e-learning project. E-learning has been used as a developmental tool in countries such as Singapore. It will be useful to learn more about successfully implementing e-learning infrastructure in a developing country.

The Role of Citizen Trust in the Success of E-Government

Benoit Jeanson, University of Sherbrooke, Canada; E-mail: bjeanson@videotron.ca

CONTEXTUALIZATION

When it began over a decade ago, e-commerce quickly encountered difficulties preventing it from reaching the potential level of success regarded as possible by specialists of the field. After having identified trust as being an important factor of success for e-commerce, both researchers and online retailers were quick to put emphasis on the mechanisms and software that make online transactions possible, and on the need to study and improve security of the Internet infrastructure. At first, researchers were interested in the various mechanisms that enable secure transactions, and also in the visual signs imbedded in web sites that convey security to consumers and let them gain the level of trust necessary for online transactions. But after a while, they came to realize that a secure infrastructure, though essential, was only one factor of success among many others. Additionally, they became aware of the necessity of simultaneously taking into account the trustworthiness of the organizations behind the Web sites as well as the risks that users perceive in using them.

Thus, according to IS literature, the lack of trust users have towards both the internet infrastructure of e-commerce, and the organizations that provide the products and services, counts much for the slow adoption (Wang et al, 1998). Trust and its influence (Chatterjee et al., 2002) on e-commerce have been the subjects of several studies, some of which have in the last few years investigated what influences the degree of trust (Gefen, 2000) and the success of information systems (DeLone and McLean, 2003).

PROBLEM FORMULATION

After retailers, governments of all levels are now showing a growing interest towards setting up various online relations with their citizens, and this mainly for reasons of cost reduction and quality improvement of services rendered. A significant part of e-government projects are related to the implementation of various systems of online transactions that allow citizens a fast and easy access to services that were previously accessible only by mail, phone or in person. The setting up of these online governmental services is facilitated by the expertise that e-commerce specialists acquired during the last decade, particularly in the usability and security of systems. And because governments, for various reasons, feel pressured to do so, they assign major resources for the implementation of these online services while making sure that they meet the highest standards of usability and security.

Citizen trust towards information systems such as applications of e-government has until now not been studied much, Warkentin et al (2002) and Carter and Bélanger (2005) being some of the few authors in IS literature who have published on the subject of user trust building in e-governments. We find that the dynamics of trust building and the adoption of governmental web transaction processing systems are still poorly understood.

OBJECTIVE

Taking these problems into account, the main goal of this research is to provide a better understanding of the opinions held by different stakeholders of the role citizen trust has in the success of governmental web transaction processing systems in the province of Quebec (Canada). Success is expressed here through the six interrelated dimensions DeLone and McLean (2004) define for e-commerce success: system quality, information quality, service quality, use, user satisfaction, and net benefits.

METHODOLOGY

In an exploratory study carried out in the province of Quebec (Canada), interviews are done with e-government specialists of both the municipal and provincial civil service and of non-governmental organizations with a strong interest in e-government, such as citizen groups, e-government information system solutions suppliers, and university researchers. Table 1 below presents a brief portrait of the stakeholders met so far.

Table 1. Identification and role of stakeholders

stakeholder	type of organization	role in that organization
# 1	provincial government	e-government planning
# 2	provincial government	e-government planning
# 3	provincial government	e-government operationalization
# 4	provincial government	e-government operationalization
# 5	municipal government	e-government planning
# 6	municipal government	e-government planning
# 7	municipal government	e-government planning
# 8	e-government IS solutions provider	general management, sales
# 9	e-government IS solutions provider	strategic planning and marketing
# 10	university	research, commercial law on internet
# 11	university	research, ethics in IS
# 12	IS research institute	management, research
# 13	community and citizenship development organization	management
# 14	community and citizenship development organization	management

Because of the exploratory nature of the study, the interviews are semi-structured qualitative interviews done according to the methodology proposed by Rubin and Rubin (1995). On account of the flexible design of these interviews, they are considered guided conversations using a questionnaire built to facilitate the exploration of main themes and the comparison of answers. This type of interview allows for the examination of themes that emerge during the conversation and for the use of follow-up questions when there is a need to clarify certain topics. Interviewed individuals are selected to reflect different points of view. This is done in accordance to their knowledge of the dynamics of e-governments and their having developed, through their professional activities, a founded opinion concerning the way in which citizens react to governmental web transaction processing systems. The number of individuals interviewed is not pre-defined. Rather, interviews are carried out until attaining saturation of data.

Once saturation is attained and interviews are over, a content analysis using the methodology proposed by Krippendorf (1980) will be carried out on the information collected during the interviews in order to identify emerging new results.

PRELIMINARY RESULTS

Preliminary results show a real divide in the opinions of the different stakeholders that were interviewed. Indeed, e-government specialists that participated so far in this exploratory study perceive citizen trust as having a role of variable importance to the success of governmental web transaction processing systems. First, municipal e-government specialists consider trust as being a minor factor of success of e-government applications that municipalities have put on the web. In fact, according to them, the trust that citizens have in municipal governments or in an e-government application has very little effect on the level of success encountered by e-government applications. They perceive that citizens trust municipalities and municipal organizations, and therefore have no reason not to trust the governmental web transaction processing systems they have put in place. They also attribute the non-attainment of the anticipated level of success of e-government applications to citizen's lack of knowledge in their advantages or even their existence.

This perception of citizen trust as not being an important stake for the success of municipal e-government might be explained by the fact that they consider that citizens have no reason to mistrust governmental web transaction processing systems since the infrastructure is secure and that they are dealing with governmental authorities. Furthermore, it might also be explained by the nature of the transactions between citizens and their municipalities, even large ones, since these transactions do not usually imply an exchange of sensitive data, hence a relatively low perceived risk by these citizens.

At the provincial level, the situation is slightly different. Indeed, some of the provincial e-government specialists participating in the study perceive citizen trust as absolutely not an important stake for the success of provincial government web transaction processing systems. For some others however, citizen trust is undeniably an important factor. Just as their municipal e-government peers, those who think trust is not a big stake consider that citizens have no reason to mistrust governmental web transaction processing systems because the infrastructure is secure and that they are dealing with governmental authorities. As at the provincial level where exchanged information is more sensitive and perceived risk higher, some other e-government specialists consider a secure infrastructure as not a sufficient condition to guarantee user's trust and perceive citizen trust is a major concern. For these specialists, it is important that the government and the individuals responsible for the setting up of on-line government applications be conscious of the importance of the trustworthiness of e-government and that they work to increase and to ensure it. It deserves to be noted here that among the specialists met, those for whom citizen trust is not an important stake are those whose task is to plan the setting up of e-government and have thus a more macro vision of it. Whereas those whose task is more closely related to the operationalization of e-government, thus closer to citizen concerns, regard citizen trust an important stake and one which they have to work on in order to ensure the success of e-government applications.

The other stakeholders involved in the study are e-government specialists working for non-governmental organizations with a close interest in e-government. They are university researchers, representatives of citizens groups, and suppliers of e-government information system solutions. Though these specialists have very different interests in e-government, they nevertheless share the same opinion about the importance of citizen trust. They all think it is a factor of success of e-government not to be ignored. According to these e-government specialists, it is a lure to think that a secure infrastructure and the general confidence people have in governments will easily make citizens adopt e-government. In fact, they consider these factors insufficient because, rightly or wrongly, and in spite of the posted security of the systems put online, citizens keep certain fears and express a certain level of mistrust towards governmental web transaction processing systems.

According to these e-government specialists, this lack of trust is articulated particularly around concerns related to security, confidentiality, ethics, and the integrity of the data transmitted to governments or held by them. As their peers who are responsible for of the operationalization of provincial e-government, they consider that emphasis must be put not only on the infrastructure of governmental web transaction processing systems but also on its general trustworthiness. In fact, in their opinion, e-government specialists who do not consider citizen trust an important stake are at the same level as the e-retailers who a few years back considered that the main factor of consumer trust was security.

CONTRIBUTION OF THE RESEARCH

In IS, the study of e-government is still new and this field of research has not yet reached its maturity, so a certain number of problems still remain to be studied in order for the knowledge pertaining to the IS field to be more complete. One of these problems in particular is the important role trust has in the success of governmental transactional web sites. Still very little studied, these applications, which evolve in a context distinct from that of traditional e-commerce where governments are the providers of services, seem to induce a different dynamics of user trust building. The contribution of this research will thus consist of a better and essential comprehension of this dynamics from the perspective of the various stakeholders that are e-government specialists.

A Study into the Critical Success Factors When Implementing Business Process Management Systems

Pascal Ravesteyn, University for Applied Science Utrecht, Institute for Process Innovation, Nijenoord 1, 3552 AS Utrecht, The Netherlands; E-mail: pascal.ravesteijn@hu.nl

1. INTRODUCTION

Nowadays the interest in Business Process Management (BPM) and Service Oriented Architecture (SOA) is rising enormously. There are a lot of software developers and consultancy firms that are jumping to the occasion and are selling Business Process Management Systems (BPMS) that are based on these concepts (Hill, 2006). Hearing these companies talk, it is mostly about 'What' the BPM and SOA concepts are and 'Why' companies should start projects. Often the aim of such projects is turning a company's current application portfolio to a Service Oriented Architecture that can make the business more agile by using Business Process Management concepts and putting the business in the lead where it concerns the use of IT.

Business Process Management Systems are based on developments in both the business and IT domain (figure 1). First, two major business trends that relate to BPM are Total Quality Management (TQM) and Business Process Reengineering (BPR) (Deming 1982, Hammer and Champy 1993). Second, we can identify a rise in the implementation and use of new types of information systems like Enterprise Resource Planning (ERP) systems, Workflow Management (WFM) systems, advanced planning systems and so on. What once started as the automation of a company's internal processes has now become digitization of supply chains (Davis and Spekman 2003). One of the key contributors to this has been the Internet and the associated network standardization.

Because existing methods to implement management concepts were not equipped to handle complicated IT developments as part of a project (Kettinger et al, 1997), and IT implementations started to impact the way in which business were run more and more, all these trends slowly converged into new types of information systems, that some (Smith and Fingar 2003) call Business Process Management Systems (BPMSs). A BPMS can be defined as "a generic software system that is driven by explicit process designs to enact and manage operational business processes" (Weske et al. 2004).

Due to the fact that both BPM and SOA are relatively new concepts, for the business as well as the IT world, the before mentioned emphasis on the 'What' and 'Why' is to be expected. But looking from a customer's perspective, i.e. a company that wants to start a BPM and SOA project and is gathering information for this purpose, the 'How' is most important. Especially if we keep in mind the list of failed ERP implementations during the fifteen or so years. Unfortunately most vendors and resellers largely neglect the implementation aspect, and companies that do claim to have an implementation methodology on BPMS are scarce. In most cases regular software development methodologies or project management principles are used to implement BPM and SOA. The reason for this is that most software developers and consultancy companies regard the implementation of a BPMS as a software development project; which even from a SOA perspective is no longer true (Krafzig et al. 2005). These companies use existing methodologies for software development such as the waterfall method, rapid application development (RAD) or rational unified process (RUP). By doing this, they ignore the business side of a BPMS implementation such as process analysis, performance measurement and continuous (quality) improvement. To cope with this, companies regularly use the Prince 2 project management methodology. Although this may sound like a good implementation approach it is far from tested and validated.

Figure 1. Emergence of business process management systems

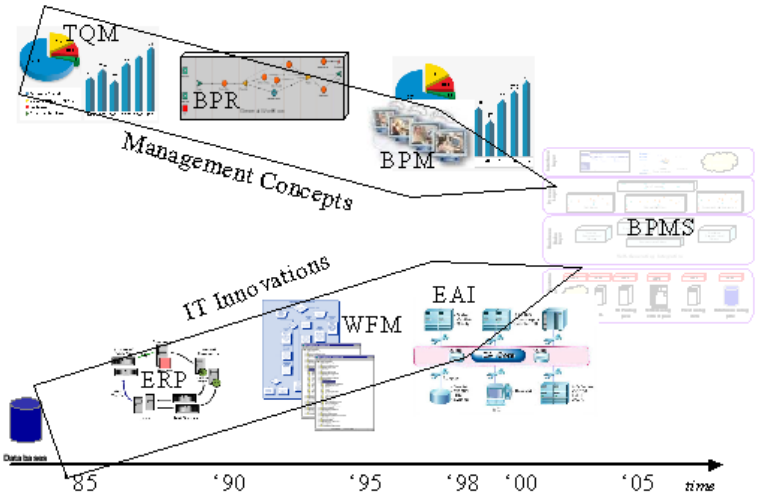

Figure 2. BPMS implementation framework

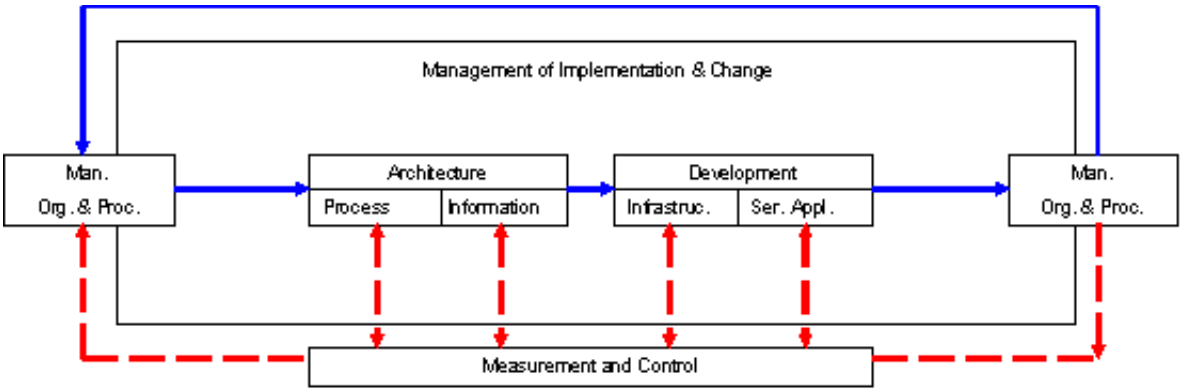

2. RESEARCH APPROACH AND PRELIMINARY FINDINGS

Based on what we have seen so far, it is possible to state that currently there are no proven implementation methods for a BPM and SOA project. In this paper it is argued that a different implementation paradigm is needed for the implementation of a Business Process Management System. A literature study of 104 articles and books[1] was conducted and based on a meta-analysis of the literature a list was compiled with over 337 critical success factors from the different background principles of BPMS (as depicted in figure 1). This list was based upon the principles according to the following composition: 3.86% of the factors came from TQM, 17.51% from BPR, 29.97% BPM, 11.57% WFM, 12.76% EAI, 2.08% BAM, 12.17% from the BPMS domain and 10.08% from various other related areas. Factors relating to SOA are not mentioned separately but as part of the EAI and BPMS.

Based on the list of critical success factors, a distinction is made between factors that are mentioned in only one domain, and factors that are common among more domains. For example, quantitative measuring and use of statistics to control the effectiveness of improvement actions is only mentioned in relation to TQM, while the importance of top management support is mentioned throughout almost all domains. Next, the frequency a success factor was mentioned is recorded to determine if a ranking or weight can be attached to the factors. Finally, a clustering is made in the following 5 themes that are partially based on the business and IT alignment model of Scheper (2002).

1. Management of Organization and Processes;
2. Architecture Design;
3. Developing an IT Solution based on SOA;
4. Management of Implementation and Change;
5. Measurement and Control.

Within these themes the 'architecture design' is subdivided into designing a process model and an information model, and the 'developing an IT Solution' consists of the realization of an infrastructure and the development of services oriented business applications.

Based on the ranking of the critical success factors a top three per theme can be given:

1. Understanding the BPM concept, management involvement, and strategic alignment;
2. Understanding the process, quality of modeling technique, and quality of data sources;
3. Managing process integrity, granularity of services, and integration of existing applications via services;
4. Quality of project management, change management, and involving people;
5. Defining performance metrics, availability of data, and organizing for continuous optimization.

3. IMPLEMENTATION FRAMEWORK

Based on the outcome of the literature study a BPMS implementation framework is developed that shows the most important aspects that should be part of a BPMS implementation methodology (see figure 2). When implementing a BPMS it is important to understand the underlying principles of Business Process Management and Service Oriented Architecture. It should also be clear that a BPMS implementation is a continuous process consisting of many different projects. This continuous character is shown in the framework by the blue line.

Furthermore the framework distinguishes three different areas, (1) the ongoing domain of the business organization itself, (2) the measurement and control function and (3) the BPMS implementation project area. In most cases a business that wants to implement BPMS will already have an established organization with running processes, which then will be the starting point for the implementation. Also, any business that is already in operation will have some type of measurement and control function. For small businesses this will probably be only the accounting function. For medium and large organizations other functions will provide information about the organization and processes, such as a quality department etc. To succeed in implementing a BPM and SOA there should be sufficient measurement information available about the processes that are going to be modeled. If this is not the case, the implementation should not be started. Metrics on processes are important to be able to continuously measure the effects of any changes.

The BPMS implementation area consists of two phases, the 'architecture design' phase and the 'development phase'. In the first phase a process and information architecture should be developed, i.e. the business process management part. Subsequently, this can be used in the realization of the technical infrastructure and creation of service oriented business applications, both part of the second phase. The two phases are supported by project and change management simultaneously because applying the BPM and SOA paradigm implies that while working on a project there can already be changes in processes and IT applications. The BPMS implementation can be regarded as a project or series of small projects as long as it is understood that both the organization and its processes and the measurement and control function are in fact just a small part of the project.

4. CONCLUSION

The first findings from this study suggest that a BPMS implementation should take into regard both the different management concepts and IT Innovations on which it is funded. To do so, BPMS implementations should start with the business objectives, processes and the metrics by which they are measured from the management side. These processes should then be aligned to a company's strategy and if necessary be (re)designed before starting to identify and develop services as part of a SOA.

The critical success factors that are derived from the different background principles to BPMS are expected to influence the outcome of a BPMS implementation. Based on these factors it is advocated to use aspects of both implementation methodologies for management concepts such as TQM and BPR, and software

development principles. The proposed framework shows the continuous nature of BPMS and is based on the concepts from both business and IT.

5. DISCUSSION AND FUTURE RESEARCH

In this paper a first attempt at is made at describing how a BPMS implementation is different than the implementation of a management concept or the development of an IT application. It can be argued whether such an implementation is really different from any other software implementation. Therefore further research should be done to have this notion validated.

Also the constructed framework is based mostly on the outcomes of the literature study. Comparisons to other implementation frameworks should be done to determine if there is no better-validated alternative already available.

At this stage the research focusing on comparison of the developed framework to others. Simultaneously a series of interviews (approximately 25) are held at Dutch consultancy firms, software developers and organizations that have implemented a BPMS to validate both the critical success factors that were found and the proposed framework. When an improved framework is available several case studies will be held to further validate and test the practical applicability.

Surviving Domestic Violence: Seeking Support in Cyber-Space

Lynn Westbrook, University of Texas at Austin, 1 University Station, D7000, Austin, TX 78712, USA; E-mail: lynnwest@ischool.utexas.edu

RESEARCH PROBLEM

Domestic violence (DV) continues to be a substantive criminal issue with profound personal, health, and economic consequences for survivors as well as a complex impact on society at large. Almost 5.3 million victimizations by intimate partners occur every year among U.S. women age 18 and older (Centers for Disease Control, 2003). These attacks include stalking, verbal abuse, sexual assault, rape, beating, and murder. Although women who live below the poverty line and young women are more likely to be abused, domestic violence crosses all social, economic, educational, racial, and cultural boundaries (Heise & Garcia-Moreno, 2002). In households with children, forty to sixty percent of perpetrators also abuse their children (Goelman, 2004).

Numerous studies confirm that DV survivors prefer using informal support networks rather than official legal, medical, or social service support (Grayson & Smith, 1981; Bowker, 1983; Harris, 1988; Harris, Stickney, & Grasley, 2001). Cyber-based social networks, such as discussion lists, exemplify this preferred type of support. They can provide, therefore, a unique window on the information needs and resources shared among DV survivors.

RESEARCH CONTEXT AND LITERATURE REVIEW

Although the Internet is certainly not universally available, used, or accessible, it is increasingly commonplace in the homes of even lower income American families. For DV survivors, the electronic bulletin boards of the Internet provide opportunities for support that can be, quite literally, life-saving. People who are reluctant to approach formal support systems (e.g., police, doctors) or informal support systems (e.g., pastors, family, friends), may feel safe enough in the Internet's digital anonymity to express their concerns and seek answers on critical questions of survival within a community of peers. Issues of cyber-safety, notwithstanding, the affective and cognitive experiences of sharing concerns in an online community can be of tremendous value to survivors, particularly those whose abusers force them into social isolation.

Little substantive examination of the nature and efficacy of information structures used to support DV survivors has been conducted since the advent of the Internet. The only nationwide, overarching analysis of formal information support systems that serve DV survivors was conducted in Canada in, essentially, a pre-Web environment, i.e., Roma Harris and Patricia Dewdney's *Barriers to Information: How Formal Help Systems Fail Battered Women* (1994). Those findings indicate that information was needed on 18 separate problems including housing, emotional support, professional counseling, money, protection, medical attention, children's needs, and transportation (Harris & Dewdney, 1994, p. 79). A total of 23 different agencies or services were expected to be able to provide help in solving these problems including women's shelters, police, pastors, the Salvation Army, community centers, taxi companies, and the YMCA (Harris & Dewdney, 1994, p. 80).

Survivors actively seeking assistance must move through at least three layers of service providers: emergency aid (e.g., police and ER staff), DV assistance centers (e.g., shelters and referral centers), and then an array of specialized support services (e.g., WIC, victim's assistance, mental health services) (Harris, Stickney, & Grasley, 2001). To make these steps, women use an array of information supports. For example, women involved in safety planning (i.e., structuring a plan to use in case of immediate physical danger) sought information from religious organizations, health care providers, shelters, hotlines, counselors, and families (Goodkind, Sullivan, & Bybee, 2004, p. 520). In certain situations, moving into the formal social service system as a victim of domestic violence results in "less control over their lives and being required to attend counseling, parenting classes, or go into a domestic violence shelter" and even the possible loss of their parental rights (Postmus, 2004, p. 113).

Reijo Savolainen's work on the "Everyday Life Information Seeking" (ELIS) model serves as the theoretical framework for this study. ELIS posits that active information-seeking behavior can be used with varying degrees of success to support problem-solving that maintains or develops a mastery of life (Savolainen, 1995; Savolainen & Kari, 2004). The ELIS model notes that "people commonly look first for advice and information from interpersonal sources, especially those similar to themselves" (Wathen & Harris, 2006, n.p.).

RESEARCH METHODOLOGY

This study is the first to examine the information issues of DV survivors functioning in an online environment. It seeks to identify the information needs and resources noted by participants in an active bulletin board community over the course of a single year. The anonymous community under study has been functioning for 2.5 years, includes 1,326 threads, and 7,566 responses to those threads. Only screen names are used and the community self-regulates to encourage solid cyber-safety practices; the members appear to feel comfortable expressing their concerns.

The analysis was completed in three phases. First, a stratified random sample was taken to cover 20% to 30%, depending on the traffic level, of every month's threads from October 2005 through September 2006. Second, the sample postings were prepared for coding by removing potentially identifying information. Finally, the resultant postings were analyzed (using HyperResearch to record the codes and their applications) to delineate information needs (e.g., legal, medical, social) and resources (e.g., web sites, safe houses). Using the constant comparison method of content analysis, the researcher noted, defined, and applied the codes which emerged from the data (Krippendorff, 1980; Miles and Huberman, 1984; Strauss, 1987). The final coding scheme employed 121 codes which were applied to 341,382 words in 1,793 separate postings.

The limitations inherent in any qualitative study pertain to these findings. The individuals who posted on this forum are not statistically representative of any full population so the findings only apply to these individuals. While this moderated forum uses common techniques to eliminate artificial postings, there is no way to guarantee the authenticity of any particular post. Certainly other coders may identify additional codes but these codes reached saturation (i.e., a point at which no new codes were added) at the end of the tenth month; two additional months were completed to insure that all critical items had been recognized.

FINDINGS

The community norms influenced the intent and focus of the postings and, therefore, the codes applied to them. Open to anyone, the forum is housed in a web site which provides extensive resources on domestic violence; the forum and the overall web site include cyber-safety information. In that relatively safe space, the most common pattern for posting is the identification of a problem, need, or acute situation by a single individual followed by a series of responses from community members who provide emotional support and concrete advice regarding tactics, resources, and referrals. Since some posters were just starting to verbalize their abusive situations, their descriptions did not always explicitly identify information needs; nevertheless, obvious examples of such need were coded appropriately.

INFORMATION NEEDS

Information needs fell into five broad categories: finances, law, mental health, domestic violence, and logistics. Understanding bankruptcy options, separating checking/credit card accounts, breaking apartment leases to move away from a stalker, and loans are a few of the financial issues explained in postings. The following post is typical: *He left all of our bills with me, including a loan that's in my name and his dad's name. The last thing he said before he left was that he'd kill me if I ruined his dad's credit.* Financial needs were generally viewed as a by-product of abuse, much like a black eye; there was little sense that anything could be done to improve the situation.

Closely tied to the financial needs are the following legal issues: legal protection from the abuser (193 instances such as *After I left for good he continued to stalk, assault, and tried to kill me and our children*), child custody/visitation (81 instances such as *No judge is going to take your boys away from you based SOLELY on your going to a shelter*), property/income law (66 instances such as *I left with only my clothes and my laptop*), documenting abuse (36 instances such as *Remember when you go to report an incident sometimes the bruises don't show up for a day, especially ones from being choked or restrained by the arms...go back the next day and have the cops take pictures*), divorce (26 instances such as *When I asked him for a divorce, he put the house on the market the very next day*), and other less common needs. Legal information needs often focused on making the system work or dealing with its failures.

Mental health needs pertained to the survivors themselves (*my deepest depression to date. Pills and the river looked so very inviting*), their children (*it's esp important to treat your son right now so you can help overcome his habits that he's picked up from the father*), and their abusers (*He had never been to serious therapy to deal with his childhood of abuse*). While the value of counseling for survivors was a common theme in discussions of mental health information needs, a great deal of effort was expended in discussing the mental health needs of the abuser, including the possibility of effective "treatment" for DV behavior, as well as addictions which were seen as the root cause of violence. *He said he'd go to anger management and counseling. Where can I seek help for that?*

Domestic violence information needs were less common but quite fundamental to progress. In eleven of the twelve months, a few individuals asked for confirmation of their perception that they were indeed being abused. Without an understanding of that basic fact, they had little chance of moving forward. (*He makes me feel ... no matter what I say or do it is never right. After looking at some of these websites I've realized that maybe this could be a form of abuse but when I talk to him about it he feels that it is not and that since he does not leave any physical bruises on my body that it is not abuse.)* Experienced forum members responded to these information needs with definitions, examples, and clarifications in an effort to demonstrate the fact that abusive behaviors run the gamut from isolation to murder.

Finally, information needs pertaining to the logistics of communication, relocation, employment, and other survival concerns surfaced regularly. People sought and gave advice on postal addresses (*Get a post office box for a forwarding address so you can be untraceable*), phone access (*change your phone number*), safety planning (*secretly pack documents, clothes, money etc so that when you leave you won't be empty handed if you have to go in a hurry*), documentation (*Me and my children have new names and ssn so there is no way to trace us*), and finding local social service agencies (*I have searched for local help but have not found anything*). The cyber-safety concerns often revealed a limited understanding of the degree of privacy available on the Internet (e.g., *My abuser managed to find me via lycos email and yahoo email*).

Information needs started with an understanding of what behaviors constitute abuse and then moved on to understanding the process of growing strong enough to separate. The act of separation included legal protections, property division, child custody, and divorce. The final stage, however, was the most common and difficult, that of staying away from the abuser despite emotional connections, fiscal problems, legal issues, and physical threats; mental health needs characterized this stage. Individuals joined the forum at various stages in the escape/survival process so no single pattern of information needs encompassed all users.

INFORMATION RESOURCES

The array of information resources offered in response to these needs included the Internet, services, and individuals. No single resource or type of resource dominated the postings. Instead, the resources were often described as useful but difficult to obtain in that they required a great deal of emotional energy, planning, and persistence to maximize their effectiveness. This patchwork quilt of information resources was rarely seen as sufficient but a long-term combination of resources could be life-saving.

The most common resource was information-seeking (120 instances); the value of seeking information in general (21) and reading specific self-help books (18) combined with general use of the Internet for information and/or emotional support (81). The act of seeking information was viewed as inherently therapeutic and empowering while the resulting understanding of DV and additional resources were viewed as tools with which to build change.

Formal and informal help systems were often recommended, particularly to those whose abusers isolated them. Counseling (81 instances) was useful throughout the escape process as beyond as survivors dealt with Post-Traumatic Stress Disorder. A shelter or DV service (60) was often recommended as at points of acute need while telling or moving in with someone trustworthy (59) could provide emotional support at any time. Although not universally trusted, the police (55) stood as a bulwark against physical danger.

Various activities designed to distract survivors from their urge to return to their abuser (e.g., taking classes, volunteering) or used in support of their overall healing (e.g., exercising, relaxation breathing) were suggested in 48 postings. Other resources were less commonly mentioned including abortion providers, support groups, the media, lawyers, a dog, a gun, and the ACLU.

Several resources were specifically described as problematic including the police (28), court officials (16), mandatory classes for abusers (8), and shelters/DV services (8). Although details were often lacking, some problem scenarios indicated an inaccurate understanding of what the resource could do, such as expecting police to function as body guards.

In this online community, domestic violence survivors are actively, regularly, and deliberately identifying a wide range of information needs and resources. They share affective concerns, pose cognitive problems, and share tactics on behavioral issues. As might be expected of individuals posting online in times of stress, they value both their online community and related resources, such as web sites. Legal, mental health, and social work resources are called for and recommended extensively. Certainly context-specific recommendations could be constructed from careful data-mining of state, county, and local service resources. Further examination of this type of support network for domestic violence survivors may reveal further commonalities which could serve as the basis of a service template. The complexities of the problem definitely requires such work just as the pain of the problem warrants a viable solution.

Information Systems Internships: Student Perceptions and Outcomes

Alan A. Brandyberry, Kent State University, Kent, OH 44242, USA; E-mail: abrandyb@kent.edu
Catherine Bakes, Kent State University, Kent, OH 44242, USA; E-mail: cbakes@kent.edu

INTRODUCTION AND BACKGROUND

It is not difficult to find sources that espouse the virtues of internships (e.g. Anonymous, 2006). However, little valid data can be found to demonstrate the positive outcomes that are generally assumed for internships in any portion of the business curricula. In addition, there is little information available to describe students' perceptions of internships and their decision process associated with making the decision to pursue (or not to pursue) an internship as part of their academic experience.

This research is an attempt to illuminate this issue. During the spring and summer of 2006 an online survey was administered to all business students at a large Midwestern university concerning internships. This research focuses on describing information system (IS) students' perceptions and outcomes related to internships. In addition, it will investigate differences in perceptions and outcomes of IS students when compared to their non-IS business student colleagues.

The Theory of Planned Behavior (TPB) (Ajzen, 1991) was determined to be the most appropriate means of modeling the process of students forming the intention to participate in an internship (see Figure 1). The TPB was simplified so that only students who had not yet engaged in the behavior were included in this model and actual behavior was, therefore, not measured. The relationship between intention and future actual behavior is presumed in our analysis. This is well supported by many TPB studies though the conversion rate of intention to behavior varies according to various factors. This conversion rate is unknown and left to future research (this would most likely require a longitudinal study to determine this rate). It is certainly reasonable to suggest that, if one has the goal of increasing the percentage of students who undertake an internship, developing students' intent to engage in internships is a necessary step. However, the need to encourage and facilitate the student in following through on the intent should not be underestimated. Other general questions were also incorporated into the questionnaires to determine what tools students utilize to find internships, where and when they participated in internships, whether they did or will take other coursework during the term of their internship, what skills were most developed, and what the most positive and negative aspects of their internships were, among others. Finally, demographic and employment information were gathered.

METHODOLOGY

Two surveys were designed. The first was designed for those who had not participated in an internship. The second was designed for those who had completed or were currently engaged in an internship. The survey instruments were created by a committee responsible for managing and promoting IS internships at the university. This committee was composed of the faculty internship coordinator, three industry representatives (IS/IT managers), and two members of the university's career services center (placement). This broad set of views created representative instruments that were then validated by presenting the questions to an oversight committee composed of approximately 30 industry and faculty representatives (approximately 70% industry). Valuable suggestions for improvement were gained and used to augment the instruments. Finally, the instruments were pilot tested on a single class of undergraduate students. The pilot test was completed by 27 students. Most of the instruments' constructs were adapted from pre-validated

Questions	Mean	Sig. (2-tailed) - that students are *indifferent* (=4.00).
I believe that participating in an internship would be a positive experience. (ATT)	1.646	.000
I believe that participating in an internship would be stressful.	3.417	.000
I believe that participating in an internship would be beneficial to my education. (ATT)	1.563	.000
I believe that participating in an internship would be enjoyable. (ATT)	2.563	.000
I believe that participating in an internship would be challenging.	2.229	.000
I believe that participating in an internship would be beneficial to me in achieving my career aspirations. (ATT)	1.688	.000
Fellow students would encourage me to participate in an internship.	2.917	.000
My instructors would encourage me to participate in an internship. (SN)	2.417	.000
My family and friends would encourage me to participate in an internship.	2.583	.000
People I admire would encourage me to participate in an internship. (SN)	2.500	.000
If I decide I want to participate in an internship I will be able to. (PBC)	2.833	.000
Finding and obtaining an appropriate internship position would be easy. (PBC)	4.125	.322
There are factors beyond my control that could keep me from participating in an internship.	3.833	.415
I intend to participate in an internship. (INT)	2.604	.000
I would participate in an internship if an appropriate opportunity presented itself.	1.875	.000
I intend to actively seek out an internship position. (INT)	2.563	.000

sources (TPB) and the pilot test was used to confirm these measures. The committee review and pilot study demonstrated good face, content, convergent, and discriminant validity.

The data collection was completed via an online web-based survey utilizing email with a link to the survey as the means to solicit responses. This research endeavor received unusual special permission to solicit students via email since experiential learning has been identified as a strategic direction of the university. A total of 387 valid responses were obtained. Of these, 65 responses were from majors or minors enrolled in the information systems (IS) curriculum. The number of responses to the survey for students who had not had an internship were 277 total with 48 IS students. The survey for those who had engaged in internships yielded 110 total and 17 IS students. The sample size for IS students, especially those who had completed internships, does limit the types of analyses that can be performed. However, we believe useful information has been obtained from the available data. The results reported here are only for IS students. Those interested in the full study are referred to Brandyberry (2007).

RESULTS AND ANALYSIS

The TPB items analyzed are from the survey of students who had not completed an internship. The latent variables utilized in the analysis were validated through a confirmatory factor analysis utilizing structural equation modeling (SEM) for the entire sample of business students. Conservative respecification of the model resulted in a good fit (X^2=39.029, DF=31, P≥.152, GFI=.970, CFI=.979, RMSEA=.031) (see Brandyberry, 2007). The results reported for IS students utilized these measures validated for the larger group. A SEM analysis for only IS students was not possible due to sample size limitations, however, bivariate correlations suggest that there are significant positive relationships between the three independent variables (attitude toward the behavior (ATT), the subjective norm (SN), and perceived behavioral control (PBC)) and the dependent variable (intention to pursue an internship (INT)). These correlations are shown in Figure 1.

Table 1 shows the individual items included in the measures as well the results of testing the hypothesis that the students are not indifferent (= 4.00). In addition, the items that were included in the TPB latent variables after model respecification are designated by having the item followed by the latent variable abbreviation. Each of the individual items was also tested for differences between IS students and other business students in the overall sample. The results showed no significant differences between these two groups on any of the variables.

Other selected results from the survey for students who have not had an internship will now be summarized. The students reported preferences for tools that they would use to find an internship. In order of preference these were: the university career services center job postings (64.6%), faculty assistance (60.4%), university sponsored job fair (50.0%), internship or employment websites (45.8%), family/friends (45.8%), and newspapers (22.9%). Students had a strong preference for receiving course credit for their internship in addition to the work experience (75%). Only 6.3% reported no desire for course credit while the remainder was uncertain. Students also thought an internship should be required for the major (47.9% required, 20.8% not required, 31.3% uncertain or not answered). Additionally, students are willing to commute to their internships with 100% reporting they would travel 15 miles and 68.9% reporting they would travel up to 30 miles.

For the students who completed internships selected results will now be summarized. Students used the following tools to locate their internships: internship or employment websites (29.4%), the university career services center job postings (23.5%), faculty assistance (17.6%), family/friends (17.6%), and the university sponsored job fair (5.9%). The majority of students took other courses during the time of their internship (70.6%) and 58.8% received academic credit for their internship.

Students were asked to list up to five skills that their internships helped develop. In rank order of occurrence, these were:

1. Technical/programming skills (82.4%)
2. Ability to work as a contributing/cooperative member of a team (70.6%)

3. Professionalism (58.8%)
4. Oral communication skills (58.8%)
5. Problem solving skills (52.9%)
6. Initiative and self-directed work habits (47.1%)
7. Ability to learn (47.1%)
8. Ability to adapt to organizational rules, policies, and culture (41.2%)
9. Dependability (41.2%)
10. Written communication skills (35.3%)
11. Ability to work accurately and with attention to detail (23.5%)
12. Research abilities (23.5%)
13. Creativity (17.6%)
14. Leadership abilities (11.8%)

DISCUSSION AND CONCLUSION

Some of the most important results of this research could not be reported here due to space limitations. These include the open-ended question results concerning the most positive and negative aspects of their internships as well as what information interested students would like to have available and what the internship program should offer to best serve students. These will be discussed in the associated presentation and are included in the full paper.

The results presented here show that IS students' perceptions and interest in internships is not significantly different from other business students. Modeling the intention to pursue internships with the Theory of Planned Behavior was supported for business students as a whole in a separate related study and correlations from the present study also suggest that TPB would hold for IS students as well. Individual TPB item analysis show that these IS students have positive attitudes towards internships, believe that others are supportive of the value of internships, but are less certain that they have control of whether they can successfully find and acquire an internship. Students that have completed internships report very positive skill sets being developed. In addition to the expected technical skills they also report frequent development of teamwork, communication, professionalism, and problem-solving skills among others.

ACKNOWLEDGMENTS

The authors wish to thank the membership of the Center for Information Systems at Kent State University for their invaluable input into developing the survey instruments employed by this study. Particular thanks go to the members of the Center's Internship Subcommittee who each spent significant time towards the survey's development. These individuals were (excluding authors): Rick Davenport of AllState Insurance, Ami Hollis of the KSU Career Services Center, Michael Litt of McKinsey & Company, Steve Morris of The Rallus Group Inc., and Ann Motayar of the KSU Career Services Center.

Note: This paper is a significantly reduced version of the complete paper due to conference word count restrictions on research-in-progress submissions (2000 words). The complete paper is available from the authors.

Enhancing the Effectiveness of Knowledge Management Systems: Using Grounded Models of Knowledge-Intensive Work Processes

Joachim Jean-Jules, University of Sherbrooke Business School, Canada; E-mail: joachim.jean-jules@usherbrooke.ca

INTRODUCTION

This paper aims to present the author's research interest and plans in relations to his doctoral studies. His research work focuses on the modelling of knowledge-intensive work processes for guiding the design and development of knowledge management systems (KMS) that fit an organization's particular knowledge flow pattern. Research will be undertaken as a multiple case study using knowledge-intensive organizations as an empirical setting.

THE CONTEXT

The changing business environment and the globalization of exchanges have greatly contributed in modifying the economical landscape. Consequently, the way in which organizations operate is becoming an ever-changing process resulting in the emergence of new business models.

Presently, because capital intensive and labour-intensive firms are moving to emerging countries like China, India, and Brazil, western countries are increasingly relying on knowledge-intensive organizations (KIOs) in order to maintain their competitive edge.

In knowledge-intensive organizations (KIO), as opposed to capital intensive and labour-intensive firms, knowledge is more important than other inputs, and exceptional and valuable expertise dominates commonplace knowledge (Starbuck, 1992). KIOs are more likely to be service firms or production firms with a strong service orientation (Roberts, 1999).

Ranging from global consulting firms to technology companies, KIOs are mainly composed of highly qualified experts. The work done by these experts consists primarily in gathering information, know-how, and feedback from three sources: from interpersonal exchanges; from reading, analyzing and applying this knowledge; and in delivering written and oral conclusions to their colleagues and clients (Haas, 2006).

Given the complexity of the projects that they undertake, these experts need to integrate knowledge that comes from either their colleagues or from external sources. To facilitate this integration, KIOs have invested substantial resources in knowledge management initiatives, typically in the development of information systems intended to capture, store and share knowledge about specialized topics (Haas, 2006). The systems that are designed specifically to facilitate the sharing and integration of knowledge are referred to as knowledge management systems (KMS) (Alavi and Leidner, 1999). They usually include the three following components: storage and retrieval, collaboration, and communication technologies.

THE PROBLEM

Despite the massive investments in KMSs, these systems do not always result in project teams performance improvements (Haas, 2006). Because KMSs are just beginning to appear in organizations, little research exists to guide the development and implementation of such systems or to set expectations of the potential benefits of such systems (Alavi and Leidner, 1999).

In fact, KMSs are conceptualized along the traditional information-processing model that promotes knowledge management that emphasizes convergence and compliance in order to achieve pre-specified goals (Malhotra, 2000). However, this model's underlying objective of obtaining greater efficiencies through optimization and routinization of pre-specified goals is increasingly not suitable for organizations that experience discontinuous environmental change, ambiguity, overload and politics (Haas, 2006; Nadler et al., 1995). Thus, KMSs modeled on the information-processing paradigm could be inappropriate for capturing the specificities of knowledge-intensive organizations such as: non-routine work processes, lateral coordination prevalence in work teams, constellations structure of value-creation processes, blurred boundaries determined not by formal structure but by interaction patterns, self-organization, etc.

In addition, systems in the information-processing view are mostly designed around organization information flows. But where teams of knowledge specialists from different disciplines are required to perform non-routine work, the flow and processing of knowledge becomes at least as important as the flow and processing of information (Nissen et Levitt, 2002; Allen et al., 1990). Given that KMSs are systems dedicated specifically to facilitate the sharing and integration of knowledge, it would be better to design them around knowledge flow rather than data flow. Indeed, there are a large number of knowledge management models found in the literature. Each one of them uses its own terms (sharing, transferring, disseminating, etc.) to label knowledge processes. But beyond the diversity of terms used to describe them, these processes all express the idea of knowledge flowing from one entity to another. Consequently, knowledge flow seems to be a pivotal concept to harness different knowledge activities. In other words, in order to design a robust KMS that fits the needs and specificities of knowledge-intensive organizations, we must have a profound understanding of how to represent and simulate knowledge flow processes in modern enterprises (Nissen et Levitt, 2002). The fast emerging knowledge economy provides strong impetus for such an undertaking since knowledge-intensive work now represents the principal means of attaining a competitive advantage across most industries and economic sectors (Drucker, 1995).

However, little is presently known about the phenomenology of knowledge flow. Though many scholars have been interested in studying knowledge-intensive organizations, mainly computational organization theorists, such as the Virtual Design Team (VDT) research group, address the phenomenon of knowledge flow. The VDT research project was launched in the late 1980s with the objective of developing language, theory and tools capable of formalizing work-process modeling. Initially the VDT chose to focus on organizations engaged in routine project oriented task. Research by and Cheng and Levitt (2001) extended the modeling and simulation techniques to address less routine project oriented tasks. Even this extension of VDT has had difficulty in simulating the kind of knowledge-intensive work that is becoming increasingly important in the modern enterprise (Nissen et Levitt, 2002). These last authors, in a collaborative research, built upon the VDT research stream to incorporate emerging work on the phenomenology of knowledge flow using agent-based simulation. Despite the wealth of contribution of these research streams, they do not succeed in capturing the social interactions underlying and shaping knowledge flow patterns. As yet, there is no grounded model of knowledge-intensive work processes that organizations with non-routine work processes can use as a basis to design and implement their KMS. Thus,

we need field research to increase our understanding of how to model the flow and processing of knowledge related to knowledge-intensive work. This new understanding needs to be grounded in data. This is mandatory not only to better design KIOs, but also and particularly to develop and implement robust KMSs that can deliver the tangible benefits expected from them.

RESEARCH GOALS AND QUESTIONS

The general purpose of the research is to describe the knowledge flow patterns associated to the emergent knowledge processes that take place in knowledge-intensive organizations. From this broad purpose are derived the following more specific purposes:

- Understanding the mechanisms underlying the emergence of the observed knowledge flow patterns.
- Modelling different knowledge flow patterns that are typical of complex adaptative processes.
- Developing a KMS design theory, including the formal model, the management philosophy, and the model of organizational relations that define any managerial technique.

In short, the research aims at both describing and understanding the factors that influence the structures of knowledge flow patterns associated with complex adaptive work processes like those that take place in knowledge-intensive organizations.

More precisely, this research plans to address the following questions:

What are the characteristics of the different knowledge flow patterns observed?

What are the environmental, structural, cognitive, political and other factors that shape the knowledge flow pattern observed?

How do these factors interrelate in structuring the flow patterns?

RESEARCH APPROACH AND STRATEGY

Two broad research approaches are generally cited in the litterature: quantitative and qualitative. These approaches include mixed methodologies (Creswell, 1994) and may be conducted under three epistemological assumptions generally named paradigms: positivist, intepretive and critical. Since the goal of this work is to acquire a deep understanding of the phenomenon of knowledge flow in organizations, a qualitative approach will be used. This implies constructing reality through language, cultural location and actions of the people involved. In other words, this work will use a qualitative interpretive approach. Then, the understanding of the phenomenon will be induced from data which are grounded in its context.

RESEARCH DESIGN

In the literature, case study is referred to as a research methodology (Creswell, 1998) or as a research strategy (Yin, 1984; Robson, 1998). A multiple case study in the former sense will be used in this work.

The research design will be twofold.

First, within the multiple case study a grounded theory methodology will be used to identify knowledge flow patterns in at least eight different KIOs, including healthcare organizations, hi-tec organizations, global consulting firms and engineering firms. This will then be followed by an attempt to build a susbstantive theory of knowledge flow in organizations by using multiple stages of data collection through an interactive process of refinement and interrelation of concepts. Doing so, this research will propose grounded models of knowledge flow process, as opposed to those derived from numerical simulation. These grounded models are anticipated to capture the essence of the social interactions governing the knowledge flow patterns. By identifying the contextual factors used to explain the observed knowledge flow patterns, the theory is expected to show sufficient predictive capacity to guide knowlege management systems design and development.

Secondly, considering that the goal of this research is ultimately to guide the design and development of KMSs and that a pure descriptive study would not be sufficient to do so, we will also need to understand how interrelate the different factors that structure the knowledge flow patterns. This implies adopting a systems approach. Moreover, it is worthy to note that KIOs are hybrid systems since they have both bureaucratic and human components. The main characteristic of such hybrid systems is the plurality of viewpoints held by different human components concerning the system's objectives, and even in what the system itself consists of (Lidell and Powell, 2003). Consequently, the systems approach needs to provide not only a practical means of capturing dynamic processes of knowledge flow from data collected in the multiple case study but also needs to inform on the degree to which the actions of the people involved affect the dynamics of the knowledge processes. Thus, to complement the descriptive analysis of the grounded theory, this research plans to use a non-numerical approach of system dynamics known as Qualitative Politicised Influenced Diagrams (QPID) (Powell and Bradford, 1998) .

Systems dynamics use cause-and-effect loops, and influence diagrams to represent processes within a system. By the means of these diagrams, one could visualize the way in which factors or variables affect one another in a dynamic system. These variables need not to be numerical (Powell and Bradford, 1998). Causality is expressed in the form of arrows connecting these factors. Being a non-numerical approach, qualitative system dynamics (QSD) reveals itself to be practical in capturing dynamic processes from responses given in a group environment. «*It avoids the necessity for numerical representation while retaining the causal information contained in influence diagram*» (Liddell and Powell, 2003).

QPID is a recent extension of QSD that works by ascribing agents and actors to the arrows of an influence diagram, allowing the examination of both the roles and motivations in a managed system (ibid). This could be useful not only to understand and predict the dynamic underlying specific knowledge flow patterns but also to put forward effective managerial actions that could enhance the adoption of KMS in the organisations.

SIGNIFICANCE OF THE PROPOSED STUDY

My research will make significant contributions to both theory and practice. First, I expect it will provide the knowledge-based view of organization with models that can help to understand the underlying logic of the dynamic of knowledge-intensive work processes. Second, it will serve as a framework not only for IS designers but also for executive managers to ensure that knowledge management systems they are building suit the needs and the work process nature of their organizations.

Note: The following references are those cited in the text above. For the purpose of this research, we mention that there exists a more comprehensive set of references that covers the different themes that our research touches upon.

Are Schools Ready to Go Online? A Case Study of Ten Secondary Schools in the Sydney Metropolitan Area

David John Smith, Catholic Education Office, Sydney, 5/393 Alfred Street, Neutral Bay, NSW 2089, Australia; E-mail: david.smith@ceo.syd.catholic.edu.au

INTRODUCTION

Much has been written and said about the use of technology to engage students in the learning process. This research is founded on the premise that technology in a school environment is more than just the number of computers in a classroom. According to a recent British Education report (Dfes, 2004), students are manipulating technology and information with dexterity that is not adequately catered for. This research explores the current impact that computer technology has on learning in a secondary school context by examining student and teacher perceptions about the use of computer technology in secondary school including the use of the Internet. The research also collects data about the skill and usage patterns of students and teachers in the use of computers, computer applications and the Internet. The research links these perceptions and usage data to the online presence of each school and examines from 2004 to 2006 the development of learning material posted on the school web pages.

RESEARCH DESIGN AND QUESTIONS

The research design needed to capture the school setting with the various realities of students, teachers and principals. The adoption of a case study approach, utilising quantitative and qualitative methods, provides the necessary liaison between the individual elements as well as capturing the substance of the research. The inclusion of a quantitative analysis allows the researcher to develop a richer understanding of the complexities between student and teacher perceptions, the impact of technological development and the implications for an online presence. The quantitative analysis provides robustness to the results collected from the surveys administered to students and teachers in the survey schools. The analysis is also used to develop a scale of online use. The qualitative analysis provides contextual information as well as a level of perspicuity to the quantitative analysis.

The questions underpinning this research needed to capture school practice, with its underlying pedagogy and individual rationales, along with technical data and use patterns. The eight specific questions that are addressed by this research design are listed below:

1. What is the relationship between teachers' computer skills and the integration of computer technologies into education programs?
2. What infrastructure has been established at schools to assist teachers in (a) increasing their information technology skills and (b) integrating technology into their teaching?
3. If the school has an infrastructure of networked computers, (a) what influences were responsible for its establishment and (b) what goals were serviced by establishing that infrastructure.
4. Does student age or gender have any relation to (a) their level of computer skill or (b) their interest in using computers?
5. Is there a perception amongst (a) students or (b) teachers that computer based programs will improve student achievement and is this view consistent across all schools whether it be single sex, co-educational or lower secondary?
6. What impact, if any, do students perceive that online learning can have on their education?
7. Is there any evidence of an on-line delivery of educational services in schools or a movement towards one?
8. Do schools or the participants surveyed see any advantage in adopting a greater stake in the use of computer technologies in the learning process?

The information needed to provide answers to these questions was gleaned from two questionnaires, one each for the students and teachers, and interviews with the Principals of the participating schools.

METHODOLOGY

Students in two particular year levels and teachers in the ten secondary schools were surveyed. Overall 2023 student and 243 teacher responses were received. Nine principals agreed to be interviewed and the web sites for each school were accessed and evaluated for their learning content for the period 2005 to 2006.

From the student and teacher data, after a factor analysis, six specific scales were formed: computer use, computer application, relevance, positive learning, online readiness and online usefulness. Online readiness and online usefulness were identified as the two dependent variables. In order to evaluate the impact of the dependent variables a linear regression analysis was applied. The linear regression also assisted in curbing the other variables.

The qualitative data from the interviews with principals served two purposes. The principal's specific knowledge of the school operating model was able to add a complementary layer of understanding to the quantitative data for each school. Secondly the principals provided an insight into the particular school's rationale and direction for learning and technology development.

Connecting the six scales to the school's web presence required the learning material on each page to be analysed and an eFactor be calculated. Various models of eLearning exist that do discriminate between the amount of physical presence as well as web interactivity. However the models did not adequately distinguish between the learning purposes of each posting. Using a model developed by the Organisation for Economic Co-operation and Development (OECD, 2005) as a foundation, existing constructs of eLearning were modified and adapted to this particular research. Six constructs of eLearning were defined; supplementary administration, supplementary augmented, supplementary directed, supplementary formative, dependent and mixed modal. Each of the constructs was categorised and weighted according to the following criteria:

- **Learning**
  - **Linked**: A hyperlink or directive to a website or hardcopy material.
  - **Encased**: Structured or staged work usually comprised of a variety of materials and stimuli. This material would be able to replace instructional time in the classroom.
- **Context**
  - **Related**: Material for use by students at their discretion
  - **Additional**: Further pertinent material for the students to use or investigate at their discretion due to the lack of accompanying instruction.
  - **Essential**: Accompanying instruction renders this material a necessary part of the learning sequence and requires the student to interact with the material.
- **Formal Interaction**: Addresses the flow of material that has been documented for each posting. Where there is a lack of documentation, a one way flow has been assumed.

The web presence of each school was then scored according to the categories of the postings, see table 1, school size and the number of teachers posting material.

Table 1. Categorisation of e-learning constructs

Categories	Learning	Context	Formal Interaction
Administration		Related	One Way
Augmented	Linked	Related	One Way
Directed	Linked	Essential	One Way
Formative	Encased	Additional	One Way
Dependent	Encased	Essential	Two Way
Variable	Encased	Essential	Multi

RESULTS

The study provides descriptive data about the access to computers away from school for students and the number of home computers that are connected to the Internet. This dispelled some notions that there were not enough students with computers at home with Internet connections. It also augments available data about student computer use patterns away from and at school, showing that year rather than gender influences the use of some computer applications. The study provides data about the level of a teacher's computer skills and the influence of gender, years of experience and subject background on the data. The study also provides a teacher opinion rating on the use of computer applications as they apply to learning.

This understanding is then matched by the regression analysis to the ways that computers are used at school by teachers. The regression analysis shows the levels of operation and understanding between students and teachers and that the students and teachers are clearly operating from different levels. The teacher linear regression variance for Online Readiness and Online Usefulness was R^2=0.199 and R^2=0.144 respectively whereas for students' the linear regression variance for Online Readiness and Online Usefulness was R^2=0.18 and R^2=0.36. Teachers are waiting to be ready for online use, model 1, whereas the students are past being ready, model 2.

The web site analysis provided some confirmation of the regression analysis as well as giving some insight to the progression by teachers in their use of school website in the following year. The resultant eFactor for the ten schools placed the schools in three distinct groups. The schools in the top category were distinctive not only by the number and interactivity of each posting but the underlying technology philosophy of the school principal. This was despite some of the schools focusing on the technical skills of the teacher and underpinning those skills as part of a total school program.

Finally the case study provides on overall perspective as to the understanding by individual leaders as well as educational systems of their commitment to and understanding of technology integration with the learning process. Clear evidence exists to demonstrate that school leaders who have a sound understanding of the benefits of technology coupled with an inspirational learning vision have instituted appropriate school development.

Organizational Project Management Maturity Model (OPM3): A Case Study

Sanjay Desai, GE Corporate, USA; E-mail: Sanjay.Desai@ge.com
Jakov Crnkovic, University at Albany (SUNY), Albany, New York, USA; E-mail: yasha@albany.edu
Peter Ross, University at Albany (SUNY), Albany, New York, USA; E-mail: pross@uamail.albany.edu

ABSTRACT

The degree to which an organization practices the project management effectively is referred to as Organizational Project management Maturity (OPM). Organizational project management is defined as the application of knowledge, skills, tools, and techniques to organizational and project activities to achieve the aims of an organization through projects. Effective project management helps organizations to achieve the strategic goals. OPM, by aligning projects to business strategy, fills the gap between organization's strategic planning process and accomplishing successful projects. The objective of this research case is to understand and apply the current OPM framework (OPM3) in context of the company IProcure Systems Inc (ISI).

1. SETTING THE STAGE

IProcure Systems Inc. (ISI), an internet based procurement service provider company, started offering web based procurement services with the vision to host I-Procurement application and offer indirect sourcing services to many small, medium and large companies giving users a self-service purchasing web experience. This strategy intends to offer numerous benefits to many organizations such as standardization of procurement processes, shared technical and functional expertise, and use of common infrastructure, accurate and comprehensive information gathering and reporting. A variety of projects have been executed to bring number of companies on this centralized IProcurement system as well as to introduce efficient processes, which could be used by all companies. This environment is used by number of companies for performing procurement activities using SSP (Self-Service Purchasing) worldwide. ISI continues to provide a very dynamic, innovative and very critical sourcing environment to many companies.

2. CASE DESCRIPTION

Our case will focus on the understanding the OPM3 model and its concepts in ISI organization's functioning, process and environment. The next step was to carry out the assessment of the organization. Two techniques were used to complete the survey - (i) group members individually complete survey independently from his/her operational point of view (ii) discuss the questions and answers of the survey in a group setting and then consolidate the results. The final stage is to generate and analyze results. After feeding answers to the survey questions, OPM3 model returns with the results of the preliminary assessment. It includes total four graphs that visually indicates ISI's organizational project management maturity placement on a continuum of maturity, ISI's attainment of Best Practices against the domains of PPP and the stages of process improvement (SMCI). These results are shown in terms of percentage points. It also identifies the detailed OPM3 components—Best Practices, Capabilities, Outcomes, Key Performance Indicators. The list then generated was analyzed in the areas exposed by the self-assessment as 'Areas requiring improvement'.

Establishing a well-planned project management process, OPM3 demands that projects, programs and Portfolio management processes are controllable. In order to establish a controlled system four steps are meaningful i.e. Standardize, Measure, Control and continuously Improve (SMCI).

3. OPM3

OPM3 is comprised of three, interlocking elements: Knowledge, Assessment and Improvement.

The **Knowledge Element** includes an executive summary, the narrative explanations required for the user to understand organizational project management, its definition and its application toward organizational project management maturity; an explanation of terms specific to the OPM3 Standard; the explanation of the OPM3 steps and an example of application, the appropriate appendices; the OPM3 Glossary; and the OPM3 Index. The **Assessment Element** includes the OPM3 self-assessment, an interactive database application. After completion of the self-assessment, the results include various graphs (spider diagrams) that visually depict an organization's attainment of Best Practices against the domains of Project, Program and Portfolio (PPP) management and the stages of process improvement: Standardize, Measure, Control, and continuously Improve (SMCI). When combined, these values produce a percentage point representative of the organization's organizational project management maturity placement on a continuum of maturity. The OPM3 components—Best Practices, Capabilities, Outcomes, Key Performance Indicators and the relationships across and among Best Practices–are warehoused within a database comprising the **Improvement Element**. This database will include each component's unique identifier, name, and description. Because different organizations might apply OPM3 in differing ways, this database will allow the user to filter specific criteria and parameters important to their organization to obtain various lists of Best Practices and/or Capabilities.

Thus, OPM3 provides answers to very important questions related to the organization's current project management maturity and allow organizations to further improve on the same. OPM3 is a roadmap, a well-structured and detailed guide to the Best Practices that the organization needs to implement to achieve its strategic goals through projects while conserving organizational resources. It promotes organizational maturity awareness among senior management and attributes organizational success to project management.

The detailed aspects and functioning of the company from the subject standpoint, by applying the framework, terminology and concepts used by OPM3 in the company ISI will be discussed at the conference and in our paper which will be submitted to JCIT for possible publication.

4. OTHER MODELS FOR ASSESSING THE PROJECT MATURITY OF A FIRM

Among the project managers, the PMBOK ® Guide [7] is widely accepted as a de-facto standard for PM. In Europe, and more recently in Japan and in US, there are competing standards, showing that there is not established unique standard in PM. The short list of standards in PM is in Table 1., below:

This variety of standards opens the possibilities for development different models for Project Management Maturity apraisals. In this paper, we are examining three other models.

4.1. PMMM

The **Project Management Maturity Online Assessment Survey** is a formal tool developed by PM Solutions and Primavera Systems used to measure an organization's project management maturity. Authors (from PM Solutions) claim that the online model will answer next important questions (PM Solutions (2006)):

1. How well does my organization manage projects?
2. What are the strengths and weaknesses of my organization?
3. How does my organization stand in comparison with others?

Table 1. International PM standards

Standard Name	Country
Open Standards Project Management & Consulting Services	Open standard
A Guide to the Project Management Body of Knowledge(*PMBOK Guide*)	USA
APM Body of Knowledge 5th ed. (*APM - Association for Project Management*)	UK
PRINCE2 (*PRojects IN a Controlled Environment)*	UK – (government sand commerce)
P2M (*A guidebook of Project & Program Management for Enterprise Innovation*)	Japan
V-Modell	Germany
HERMES	Switzerland, Luxembourg

4. What can I do to improve the project management maturity of my organization?

The list of questions for the survey is presented in Appendix 1 (Top 10 CSF (2004)). After taking the survey, PM Solutions offer two-stage pathway using their PMMM (Project Management Maturity model) with 65 questions (Rayner, P. & Reiss G. (2000)), based on Software Engineering Institute Capability Maturity Model's (CMM®) and in compliance with OPM3. Model examines PM maturity level in 5 stages: Initial Process, Structured Process and Standards, Organizational Standards and Institutionalized Process, Managed Process and Optimized Process. User needs to position all PM activities in one of those stages. This extended list of PM activities covers Management of Project Integration, Scope, Time, Cost, Quality, HR, Communications, Risk and Procurement/Vendors.

4.2. $(PM)^2$

The Project Management Process Maturity or $(PM)^2$ maturity model (also known as the Berkley model) is developed by Young Hoon Kwak, Ph.D. and C. William Ibbs, Ph.D., from the Department of Civil Engineering, University of California at Berkeley. This model "measures, locates, and compares an organization's current PM maturity level… The model is continuously being refined to reflect advances in their PM knowledge. Some of the most recent improvements include evaluating replicability of project success" (Kwak, Y.H. William, C. (2000)). This model is in sink with PMI principles and the process is organized in 5 levels (Table 2).

4.3. CMMI

The Capability Maturity Model Integration (CMMI®, CMMI 2006) is developed in 2001 and updated in 2006 by Carnegie Mellon University. The model is based on a premise: " Process, people, and technology are the major determinants of product cost, schedule, and quality". Use CMMI in process improvement activities: as a collection of best practices, framework for organizing and prioritizing activities, support for the coordination of multi-disciplined activities that might be required to successfully build a product, means to emphasize the alignment of the process improvement objectives with organizational business objectives. A CMMI model is not a process, but it describes the characteristics of effective processes. The Standard CMMI Appraisal Method for Process Improvement (SCAMPI) is designed to provide benchmark quality ratings relative to Capability Maturity Model Integration (CMMISM) models. It is applicable to a wide range of appraisal usage modes, including both internal process improvement and external capability determinations (see Appendix 2). Model defines 3 Classes of Appraisal Methods (SCAMPI family): SCAMPI C (provides a wide range of options, including characterization of planned approaches to process implementation according to a scale defined by the user); SCAMPI B (provides options in model scope and organizational scope, but characterization of practices is fixed to one scale and is performed on implemented practices), and SCAMPI A (the most rigorous method, and is the only method that can result in ratings.) The SCAMPI requirements are presented in Table 3.

Table 2. Five levels in the $(PM)^2$ model

Levels		Major characteristics
1	Ad Hoc	Basic PM process
2	Planned	Individual Project Planning
3	Managed	Systematic Project Planning and Control
4	Integrated	Integrated Multi-Project Planning and Control
5	Sustained	Continuous PM Process Improvement

Table 3. SCAMPI requirements

Requirement	**SCAMPI A**	**SCAMPI B**	**SCAMPI C**
Types of Objective Evidence Gathered	Documents and interviews	Documents and interviews	Documents or interviews
Ratings Generated	Goal ratings required	No ratings allowed	No ratings allowed
Organizational Unit Coverage	Required	Not required	Not required
Minimum Team Size Appraisal	4	2	1
Team Leader Requirements	SCAMPI A lead appraiser	SCAMPI B and C team leader	SCAMPI B and C team leader

5. INITIAL CONCLUSIONS AFTER USING THE OPM3 MODEL IN THE COMPANY ISI

In conclusion, applying the OPM3 model, we are able to announce that a percentage point representative of the ISI's organizational project management maturity placement was 68%. Model also provided ISI for the purpose of analysis and focus the improve areas, the list of Best Practices and Capabilities that are currently being observed in ISI and also the ones which need to be focused for further improvement. More details will be available in the JCIT paper.

APPENDIX 1. TOP 10 CRITICAL SUCCESS FACTORS FOR A PROJECT MANAGEMENT OFFICE (FOR THE ON-LINE PM MATURITY ASSESSMENT)

Rating scale for all questions:	
3 - We've got it covered. 2 - It's OK, but could be better.	1 - Needs some serious improvement. 0 - Couldn't be worse.
Questions	
1. The PMO has senior executive-level support.	6. Training of project managers is competency-based (rather than purely academic).
2. A superior process for selecting project managers and teams has been established.	7. Project management methodologies, tools and templates are standardized.
3. Project teams include participants from multiple business functions and disciplines.	8. A useful knowledge library of best practices is maintained as part of the PMO.
4. A high standard of truthfulness and integrity exists within the PMO.	9. The PMO is involved in all projects from start to finish.
5. The PMO serves as an "ambassador," communicating with all internal and external stakeholders.	10. The organization's project portfolio is managed by the PMO.

APPENDIX 2.

Phases and Processes in SCAMPI appraisal

Diffusion of RFID in Organizations: A Perspective Based on Risk Perception

Sanjay Goel, University at Albany, SUNY, 1400 Washington Avenue, Albany, NY 12222, USA; E-mail: SGoel@uamail.albany.edu
Jakov Crnkovic, University at Albany, SUNY, 1400 Washington Avenue, Albany, NY 12222, USA; E-mail: yasha@albany.edu

ABSTRACT

There are very well known advantages of implementing RFID technology in many industries. For example, if RFID tags are embedded within drugs it becomes very difficult for counterfeit drug makers who will have to replicate the RFID tag as well. However, there are several reasons for lack of adoption, including: rapidly changing technology, high costs, and poor reliability of tags. Even required mandates from partners and senior management may not be sufficient drivers to ensure penetration of RFID technology in other organizations. The "Diffusion of Innovation Theory" or DoI is used to explain the delay in the adoption of the technology in businesses. There has been significant work on computing the ROI for RFID based on technology risks and the cost of technology. The focus in this paper is on the significance of atypical risks in the adoption of RFID technology. This research is using the survey method to reject two suggested hypotheses. The innovative approach is in expanding the DoI in the organization into the process of planning the adoption of RFID technology and to continue using DoI during the implementation process.

INTRODUCTION

Radio Frequency Identifiers (RFIDs) are computer chips that can be tracked from a distance. They are slated to become one of the most significant business innovations in this century with far reaching implications in supply chain management, real-time location monitoring, and asset management. Since RFID allows a product to be tracked without line of sight, a greater level of automation in business processes is possible leading to reduction in labor costs and improved efficiency. In addition, RFID enables improved accuracy and closer integration with business partners. RFID tags are typically affixed onto the goods that they are supposed to track, however, they can also be embedded within the product thereby preventing proliferation of counterfeit goods with fake RFID tags or at least making it much more difficult. For instance, if the RFID tag is embedded within drugs counterfeit drug makers will also have to replicate the RFID tags. There are limitless possibilities for use of RFID tags, however despite all these advantages, their adoption remains painfully slow. There are several reasons for this lack of adoption, including: rapidly changing technology, high costs, and poor reliability of the tags. The infrastructure supported by different vendors is also often incompatible due to conflicting standards, incompatible frequencies, and different power levels for RFID tags and readers. Even required mandates from partners and senior management may not be sufficient drivers to ensure penetration of RFID technology in other organizations. In addition, there are other risks that have not been explored adequately which can skew the ROI equation for the adoption of RFIDs. We examine the risk perception of adopters to determine its impact on the penetration of the technology in organizations. The diffusion of innovation theory is used to explain the delay in the adoption of the technology in businesses. This work builds up on the initial work on RFID risks (Goel & Crnkovic, 2005). There has been significant work on computing the ROI for RFID based on technology risks and the cost of technology. However, there are several factors that have been ignored in this equation which we believe will be the key to the adoption of this technology, including, health, environment, security, privacy, and business uncertainty. The focus if this paper is on the significance of atypical risks in the adoption of RFID technology. Our hypothesis is as follows:

H1: Non-technology perceived risks are a significant factor in adoption decision on the RFID technology in organizations.

H2: Organizations are still mired in the first two stages (relative advantage and compatibility) of the Roger's Diffusion of Innovation Theory (DoI) in RFID adoption.

We use DoI to explain our hypothesis. In addition, we conduct a survey to collect the data to examine the hypothesis. The rest of the paper is organized as follows: Section 2 provides the theoretical foundations of this work; Section 3 presents the data collection methodology and preliminary results, and Section 4 presents conclusions and directions for future work

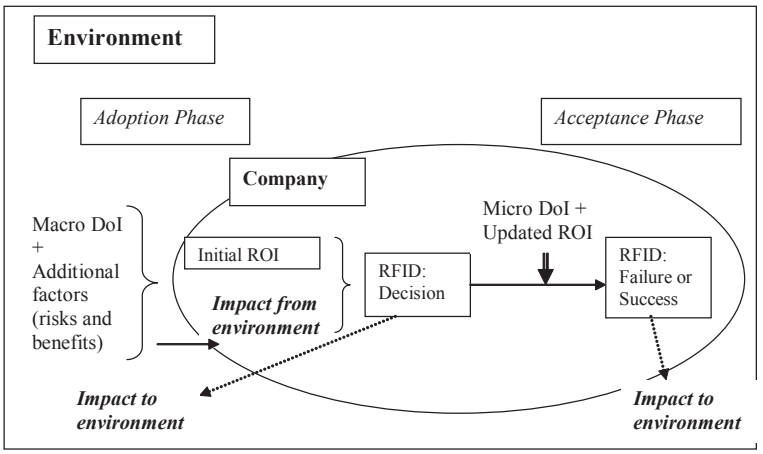
2.0 THEORETICAL FOUNDATIONS

There is often inertia in adoption of innovations by organizations for a variety of reasons such as: lack of clear understanding, aversion to risk, and general apathy to create changes in the organization. In the past, problems of diffusion and adoption of new ideas, processes, and technologies have been studied under the rubric of DoI. Rogers and Shoemaker (1971) have defined diffusion as the process of communication of a new idea to a person, group, or organization. Rogers and Shoemaker (1971) defined the adoption as the process of acceptance of an idea or technology after initially learning about it. The basic tenet of DoI is that innovation is communicated through certain channels over time within an organizational context. Individuals have different degrees of willingness to adopt new ideas or technology and the percentage of individuals adopting innovation is distributed normally over time (Rogers, 1995). The rate of adoption of innovations is impacted by five factors: 1) relative advantage, 2) compatibility, 3) trialability, 4) observability, and 5) complexity. The first four factors are generally positively correlated with rate of adoption while the last factor, complexity, is generally negatively correlated (Rogers, 1995). Mustonen-Ollila & Kalle Lyytinen (2003) in a recent study show that several DOI factors strongly influence adoption of innovations in organizations, however, innovation adoptions follow no discernable pattern.

The rate of adoption is governed by both the rate at which an innovation takes off and the rate of later growth. Low cost innovations may have a rapid take-off provide a quicker breakeven point for investment, while high cost innovations require a larger time to amortize the initial costs. RFID falls in the latter category where the initial investment is very high and the amortization time is fairly long. Given the high degree of uncertainty in the current business environment companies are reluctant to make the huge investments in an unproven technology (Collins, 2004; Schrieber, 2005).

Innovation adoption rates can also be impacted by other phenomena such as civic, social, and ethical concerns of the adopters. Some of the risks are real while others are based on paranoia emanating from lack of knowledge and understanding. The key factors influencing management decisions include health, security, privacy, environment, and business ethics. The key health issue is the possibility of radio frequency waves having carcinogenic effects. However, recent research by the cell phone industry refutes these claims. Current emission levels of WLAN and RFID tags are below RF emission levels from cell phones (CISCO, 2005). In addition, RFID uses low-end of electromagnetic spectrum from which the waves are not dangerous for general public (ILO, 2006). The other areas of legitimate concerns are security (Goel & Crnkovic, 2005) and privacy (EPIC, 2005), are currently being addressed through encryption and other security technologies. There are significant environmental concerns primarily related to disposal of millions of tags including batteries for active RFID tags. However on the other

Figure 1. Model for exploring acceptance of RFID using the DOI model



hand, RFID tags also allow trash to be tagged and tracked, which provides some ecological advantages (Thomas, 2003). A growing concern about adoption of RFID technologies will have huge labor implications (Gonsalves, 2004; Jaques, 2004; ILO, 2006).

This study examines the impact of the factors suggested in the DoI model as well as the civic, social, and ethical concerns of decision makers.

In this research, we are expanding DoI outside from simply organizational settings to discuss the planning of implementing this new technology. There is a very strong network externality associated with the adoption of the new technology since the supply chain can only be automated if all vendors and suppliers in the chain have adopted the technology. However lack of standardization in the technology and protocols associated with RFID mitigates the impact of network externality. Nevertheless, in the current network environment where company supply chains are intricately linked, a group of companies operate as a single organization with adoption decision made at the level organizations in the supply chain. Typically DoI is applied to individual companies where adoption is considered as an individual level. In view of a network environment we extend the DoI theory to a group of firms linked together via a supply chain. We consider the adoption within the organization as micro level diffusion and the adoption by the firm as the macro level diffusion.

Our research model is presented in Figure 1 which shows that DoI is applicable at two levels: 1) the macro level (adoption by multiple companies in a supply chain), and 2) the micro level (acceptance of RFID within a single organization). Our focus in this paper is the adoption of RFID among companies in a supply chain or in other words, at the macro level. To obtain the reasons for adoption it is important to understand the perspectives of the management and we choose to employ the survey methodology as described in Section 3. We attempt to determine the factors preventing the implementation of the technology and to identify the stage of diffusion that organizations are by evaluating their perceptions of the technology.

3.0 DATA COLLECTION METHODOLOGY & PRELIMINARY RESULTS

3.1 Participants

The participants in the study are executives of companies that work full time and attend the Part-time MBA program at the University at Albany, State University of New York. These employees have a diverse background in areas such as engineering, finance, sales, accounting, medicine, and manufacturing. They all have a good understanding of the technology, but differing levels of interest in RFID deployment.

3.2 Procedures, Analysis, and Results

The survey questions were developed for the elements of DoI (relative advantage, compatibility, trialability, observability, and complexity) as well as ethical considerations (health, security, privacy, environment, and business ethics). The initial set of questions was created based on review of previous relevant literature in risk (Armitage et al., 1999; Goodhue & Straub, 1991) and refined via pretest interviews. An initial set of respondents was solicited to further demonstrate content validity and clarify the wording for each item. A pilot study will be conducted with a set of graduate students to ensure the initial reliability of the scales and the general mechanics of the questionnaire, such as instructions, completion time, and wording. The revised questionnaire will be used with the primary pool of respondents that are industry executives participating in the Part-time MBA Program. A small set of demographic questions (Appendix 3) will be used at the aggregated level. One of the authors administeres each of the surveys in person. Participants will be briefed of the study, and informed that participation was voluntary and had nothing to do with their normal MBA course work. In lieu of financial incentives as suggested by Dillman (2000), participants were promised a summary of the study. Data gathered from the pilot study and from completed survey will be examined using traditional statistical methodology. All results from the pilot study will be presented at the conference.

The Effect of the Combination of Business Characteristic with ERP Implementation Strategies on Firm Performance

INTRODUCTION

This study focuses on the effect of the combination of business characteristic with ERP implementation strategies on firm performance. Implementing ERP is not simply purchasing software. Each ERP system represents the best practice for business processes selected from the vendor's point of view. Therefore implementing ERP means that the company implementing the system accepts the vendor's assumptions about the business and changes its existing business processes as required by the vendor (Umble, et al. 2003). Accordingly, it is reasonable to assume that business characteristics of a company and the implementation strategies may affect the benefits resulting from the implementation of the systems. To do this, we employ a cluster analysis to identify different group behaviors among companies and examine the differences in performance between the groups of companies. The results of this study show that what kinds of groups exist in terms of the combination between business characteristic with ERP implementation strategies and how their performance differs.

The current study contributes to literature in two ways. First, this research identifies the basic strategies for ERP implementation and their relationship with business characteristic that in turn affects firm performance. Second, this study empirically tests the role of the combination of the business characteristic with ERP implementation strategies in explaining firm performance. In so doing, this study sheds light on the factors that affect the successful implementation of ERP.

BUSINESS CHARACTERISTICS: MAKE-TO-ORDER/MAKE-TO-STOCK

For manufacturing companies, business requirements such as customization, volume flexibilities, production volume, set-up and production schedules, number of suppliers, and labor skills may determine their business orientations (Yen and Sheu 2004). Typically, this orientation is categorized into two continuums: make-to-order (MTO) and make-to-stock (MTS) (Gupta and Benjaafar 2004). Under MTO approach, a production order is released to the manufacturing facility only after a firm demand has been received, while under MTS approach, products are manufactured in anticipation of future orders and stored in the finished goods inventory (Youssef, van Delft, and Dallery 2004). The MTO production method is good for customization and volume flexibilities (Yen and Sheu 2004) when products are low in volume but high in variety. On the other hand, when products are high in volume but low in variety, the MTS strategy is better than MTO. That is, when there are requests for high production volume, long set ups, stable production schedules, relatively small number of suppliers, lower labor skills, and a functional organization, companies need to implement MTS strategy to obtain immediate reactivity to external demands at the cost of inventory holding costs (Yen and Sheu 2004, Youssef, van Delft, and Dallery 2004).

Recently, an increasing variety in production variety with varying logistical demands (e.g., short due dates, specific products) and production characteristics (e.g., capacity usage, set-up) leads to a combined strategy of both MTO and MTS (Gupta and Benjaafar 2004, Soman, van Donk, and Gaalman 2004). One widely used approach to the combination of these two strategies is the assemble-to-order (Lu, Song, and Yao 2003). Under this strategy, the upstream part of the manufacturing system is controlled through MTS, whereas the downstream part of the manufacturing system is controlled via MTO (Youssef, van Delft, and Dallery 2004). This approach is effective when finished products have high variety but components have low variety. This approach enables mass customization and quick response by using advanced information technology (Lu, Song, and Yao 2003). However, It is noteworthy that very different managerial actions than those required in MTO and MTS strategy are necessary in a combined MTO-MTS production situation where important issues need to be addressed such as which products should be manufactured to stock and which ones on order and, how to allocate capacity among various MTO-MTS products (Soman, van Donk, and Gaalman 2004).

Initially the primary benefits of ERP implementation have been expected to be in the production processes (i.e., better inventory management and faster order processing). These benefits are very important factors to run MTS types of organization. However, practitioners and researchers now generally agree that the real benefits of ERP are its ability to standardize business processes, build a clean database and minimize data complexity (Connolly 1999). This will affect the business process of MTO types of organization, increasing the level of communication with their suppliers and partners. Based on ERP's origin, it is a better view how ERP impacts different types of manufacturing firms. ERP only increases business process efficiencies or it boosts other business areas beyond business process efficiencies.

ERP IMPLEMENTATION STRATEGIES

In IT implementation, organizations have to either customize the software packages and/or change their existing business processes (Amrani et al., 2006). This is natural process when organizations implement information systems because different organizations, department, and users require costumed systems based on their needs derived from different approaches to task (Pawlowski et al., 1999). In this study, we use two terms to conceptualize those processes: software customization and process re-configuration. Software customization occurs when an adopting organization will not or cannot change its business process, instead it modifies the application to meet business requirements. On the contrary, business re-configuration is defined as an adoption of business processes embedded in ERP application without modifying the application, which leads to business process reengineering for the adopting organization. An ERP is the enterprise-wise software in which all business functions (such as financial, manufacturing, human resources, distribution, and order management) are tightly integrated into a single system with a shared database. While customization is not impossible, the broad scope and close connectivity of all related functions make customization very costly for any ERP implementation (Davenport 1998, Davis 1998).

The high cost and lengthy implementation process persuade most organizations to align their business processes with the functionality provided by the ERP, rather than customizing the ERP to match their existing processes. According to Forrester Research, only five percent of the Fortune 1000 companies that had purchased an ERP application customized it to match their business processes (Davis 1998). Implementation of an ERP typically entails using the business models included in the ERP software package (Slater 1998). While some companies opt to customize ERP to fit their organizations, the majority of organizations prefer

to install off-the-shelf ERP implementations as a way to avoid customization by altering their business processes. The important fact is that the cost of customization is formidable, and there is a trade-off between convenience/functionality and customization.

Customization and re-configuration are not discrete but on continuum. Thus, organizations, with ERP implementation, have opportunities to define, identify, and improve their business process through business process re-engineering (BPR) approach to enhance business process over different functionalities (Hammer and Champy, 1991).

ERP IMPLEMENTATION APPROACHES

ERP implementation is no easy task. Once started, there is no way of going back due to the considerable expense of ERP implementation (Bingi 1999). Accordingly, companies have developed various approaches to the implementation. Parr and Shanks (2000) categorized ERP implementation approaches based on the number of implemented modules. First, comprehensive implementation, so called 'big bang' approach, refers to a total effort to implement all modules of the ERP package to their organizations with the tremendous efforts targeted for business process reengineering (BPR)." This approach is the option frequently used by multi-national companies. The second approach is called Vanilla. This approach is for less ambitious companies which want less BPR and few ERP functionalities in probably one site only. The last approach is middle-road, which is in-between the comprehensive and vanilla approaches. This approach can be defined as a phased approach (Parr and Shanks 2000). The phased approach can be further divided into two types, one proceeds module-by-module and the other goes site-by-site (Boudreau, 1999). Recently, companies have followed more structured ways of implementing ERP based on their degree of need for integration. This partial implementation is possible due to the modularity of ERP. Companies may decide to adopt financial accounting module without changes in it process but make significant changes in materials management module.

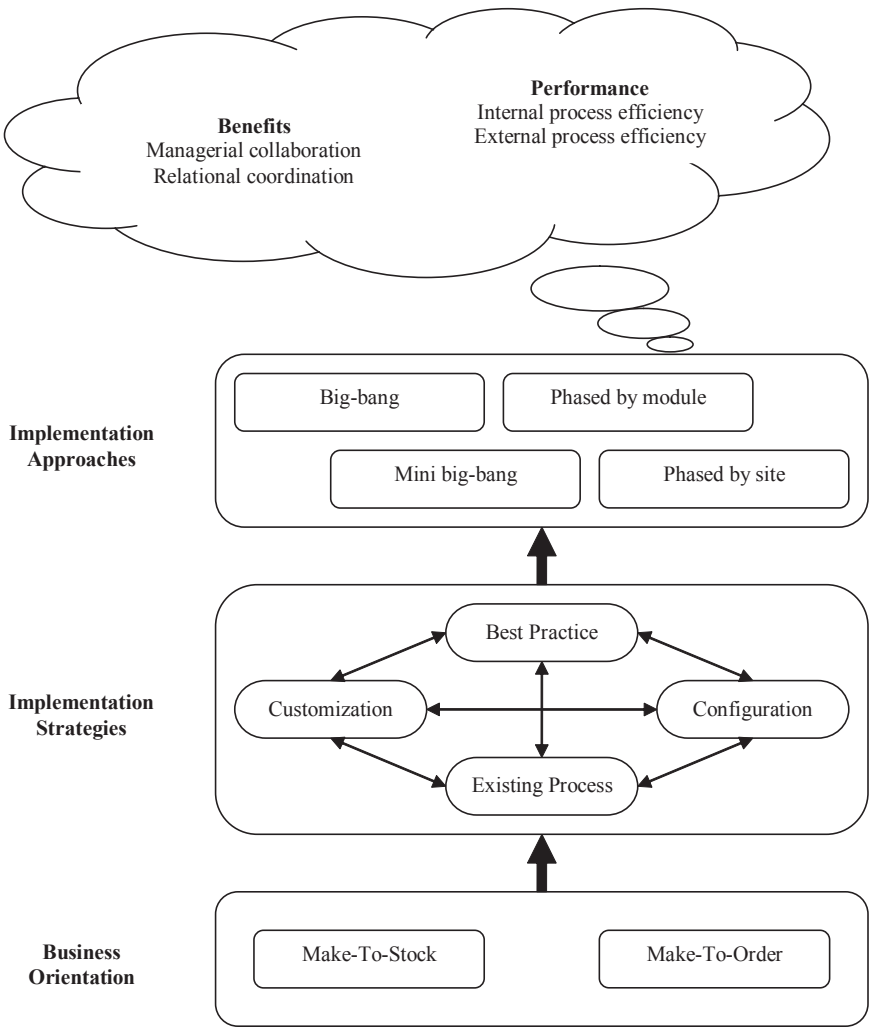
Based on companies' business characteristics and inter-relationship between functions, a variety of mixed implementation approaches can be used together. Companies can take a big bang approach to go live all ERP modules at a single period of time or they can open several modules at different dates, mini big bang. For phased approach, companies can set each phase based on ERP modules or companies' sites.

Figure 1 illustrates the relationship between the production orientation in manufacturing companies, ERP implementation strategies, and implementation approaches. It is assumed in this paper that business orientation affects the selection of ERP implementation strategies which subsequently influence the choice of the implementation approaches. We discuss this relationship in the next section.

RESEARCH HYPOTHESES

In the previous sections, we discussed production orientations in manufacturing companies, ERP implementation strategies and approaches. As discussed earlier, a different business orientation leads to a different resource allocation system

Figure 1. Business orientation, ERP implementation strategies and approaches



and distinctive communication systems to align the downstream, midstream, and upstream processes to customer needs (Prasad, Tata, and Madan 2005). For example, compared to the more traditional MTS orientation, the MTO strategy requires managers to answer for the added complexity resulting from the increased production complexity including product range, more detailed specifications on batch sizes and due dates (Prasad, Tata, and Madan 2005).

As such, the business orientation affects the subsequent implementation strategy of and approach to ERP application. This relationship between the orientation, implementation strategy and approach can be understood in terms of organizational configuration referring to "commonly occurring clusters of attributes of organizational strategies, structures, and processes" (Ketchen, Thomas, and Snow 1993, p. 1278). The basic premise of the configuration theory is that identifying groups different from others but similar within the group allows the better understanding of the relationship between organizational characteristics and performance (Ketchen, Thomas, and Snow 1993). In this study, we define the clusters of the companies based on three configuration variables: business orientation, ERP implementation strategy and implementation approach. We believe that making clusters of companies that have similar business orientation and pursue similar implementation strategy and approach is a better way of understanding the differential effect of ERP implementation on firm performance. That is, if the implementation strategy and approach well fit the business orientation of a company, the company may achieve a better performance.

Therefore, we hypothesize:

Hypothesis 1: The performance of companies pursuing different combination of business orientation, ERP implementation strategy, and implementation approach is significantly different from that of others.

CONCLUDING REMARKS

In this study, we will investigate what kinds of clusters exist in the ERP implementation context and how the clusters affect firm performance. We will do so using cluster analysis and drawing on the concept of the fit between business orientations and ERP Implementation strategy and approach (Ketchen, Thomas, and Snow 1993). The major implication of this study lies in the finding that where there is discrepancy in business orientation, i.e., production strategies, there may be a gap in the firm performance. Another contribution of this study will be the observation made regarding the role of ERP implementation strategy and approach in determining the types of configuration of groups. This observation will allow the understanding what kinds of firms can be classified as a group and what kinds are not.

Conceptualization of a Secure Agent Based Network Management System

O B. Ajayi, University of Agriculture, Abeokuta, Nigeria; E-mail: tayoajayi@yahoo.co.uk

ABSTRACT

As configuration of network services is faced with wide-spread deployment problems requiring considerable human efforts and involvement, Plug-and-Play (PnP) services become a central concern. Moreover, the recent developments in the area of mobile agent based network management and ever improving Java Programming language have provided important tools for designing Secure Mobile Agent based PnP Protocol (SMA-3P). Again, a roaming agent on a network consumes significant network bandwidth which implies that their frequency and number must be regulated. In a sensitive and intelligent network where the PnP behaviour can be altered dynamically during the lifetime, the proposed system must be genuinely secure. So, it is necessary to design secure protocol using the elliptic curve based multi-signcryption for the purpose of efficiency.

Keywords: Mobile Agent, Security, Plug-and-Play, Protocol, Network, Configuration

1.0 INTRODUCTION

The current network is characterized by its increasing distribution, its dynamic nature, and the complexity of its resources, due to the increasing requirement of different services (Yang, 2003). Network management essentially involves monitoring and controlling the devices connected in a network by collecting and analyzing data from the devices (Stallings, 1999).

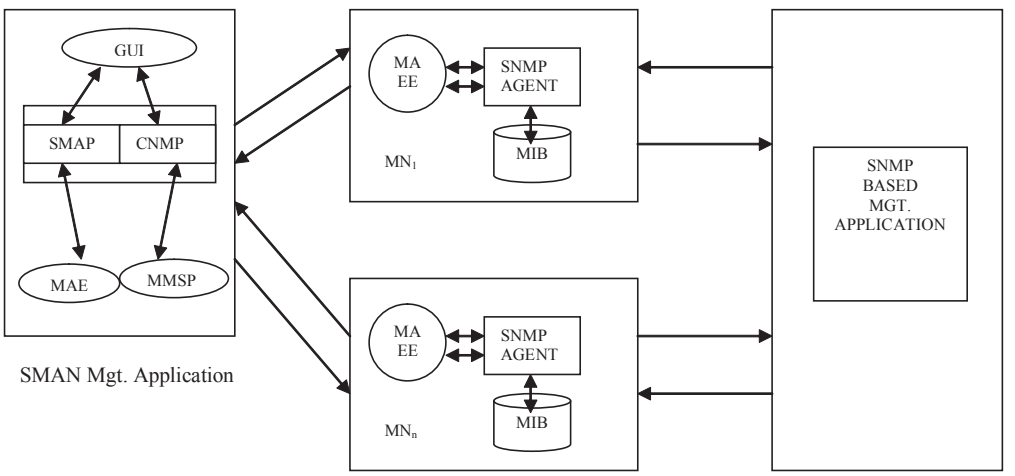
The current trend is to deploy mobile agents to manage large heterogeneous networks. Mobile agents are special software objects that have the unique ability to transport itself from one system in a network to another in the same network (Feng, 2002).

One of the possible approaches is to automate the installation and configuration steps using a mobile-agent based Plug-and-Play (PnP) architecture for service configuration.

2.0 RELATED WORKS

As networks are growing and becoming more distributed, the need for better management through available distributed technologies is being realized. According to Kona (2002), mobile agent technology has long been pursued but its applications in network management are still rudimentary. Bieszczad et al. (1998) described theoretical views on application of mobile agents for network management that lack concrete implementation. Gavalas et al. (2000) presented the application of mobile agents in bulk transfer of network monitoring data, data aggregation and acquiring atomic SNMP table views. They analyzed the usage of mobile agents in network management with regard to the bandwidth utilization. The work addresses the issue of mobile agents for network monitoring, but did not consider provisioning services. Pinheiro et al. described a conceptual model which collects management related data across a changing set of networked components and periodically compute aggregated statistics using mobile agents. More concentrated towards aggregation of network monitoring data and exploring mechanisms for agent adaptation.

Figure 1. Hybrid SMAN model



Keys:

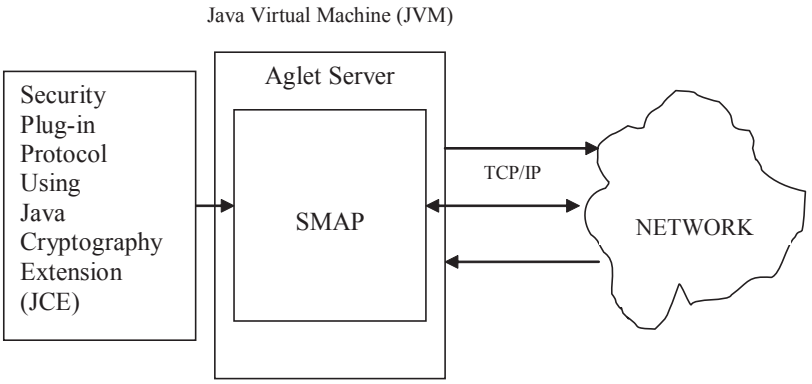
MIB – Management Information Base
MNi – Managed Nodes where i = 1 to n

Figure 2. SMAN station



3.0 OBJECTIVES

1. To provide a comprehensive review of mobile agent architectures, development tools and emerging agent technologies
2. To develop a prototype application system that will allow the development of the network management system using a secure mobile agent oriented approach
3. To employ the use of discrete logarithm based multi-signcryption for the secure protocol.

4.0 SMAN ARCHITECTURE

SMAN station assumes responsibilities of a client. All managed nodes are servers, which has mobile agent execution environment and respond to SNMP queries from mobile agents when they visit the servers and manipulate data locally. When the client in the SMAN needs access to data in a network-connected device, it does not talk directly to the server over the network but dispatches a mobile agent to the server's machine. On arriving at the servers' machine, the mobile agent makes its request and return to the management station with the results.

The SMAN architecture consists of the following major components:

- Management application (MAP)
- Mobile Agent Execution Environment (MAEE)
- Secure Mobile Agent Producer (SMAP)
- Mobile Agents (MA)
- Modified Multi-signcryption protocol (MMSP)

The mobile agent development environment is the Aglet Software Developer Kit (ASDK), which provides a modular structure, easy-to-use API for programming of mobile agents and excellent documentation.

Figures 1 and 2 show the hybrid model of SMAN and architecture for network management using secure mobile agents. The administrator/manager is given the flexibility of deciding whether to use SNMPv3 or mobile agents.

6.0 CONCLUSION

This paper has demonstrated that it is possible to develop a secure mobile agent network management system using Java components and cryptography. To this end, the paper has presented reasonable detail on design level view.

The Contagion of Corporate Social Responsibility in Networks: From a Technical Competition to a Social Competition

Valerie Paone, Centre Thucydides, Paris, & CCIP, Negocia, Paris; E-mail: valerie.paone@afri-ct.org, vpaone@negocia.fr
Yongren Shi, Huazhong University of Science and Technology, China; E-mail: yongren_shi@163.com

Keywords: CSR, contagion, networks, distribution, agent-based model, Corporate Social Responsibility, Transnational Corporations, contagion, drivers.

Corporate Social Responsibility (CSR) combines microeconomic aspects (firm level) and macroeconomic aspects (environment level) and has become a main issue worldwide for well-being. At the micro-level, the social capital can be defined as a set of social norms, and organization behaviours through "trust" that shapes and reshapes the collective and individual production in order to maximize the well-being. At the macro-level, this social capital could be envisioned as a dynamic networks that might accelerate or impede the economic growth.

Within a few years, CSR, which relies on voluntary adoption, has paradoxically become a predominant governance model. Moreover, due to stakeholders' pressure, CSR has also emerged as a societal mode and recently in Europe as a "protectionist" tool to face the Developing Countries Transnational Corporations (DCTNC). The strong emergence of national champions from developing countries, in particular Chinese and Indian with a huge potential economic development has accentuated the technical and economic competition among Western and Developing Countries Transnational Corporations(WCTNC vs. DCTNC). For years the emerging countries have been passives (or not) recipients of technology and knowledge accumulation, and foreign direct investments (FDI). CSR was one of the strong components of these transfers for the last years. Two opposing CSR strategies are in fact at work, and the current CSR contagion observed among the Western-based TNCs may be facing a much stronger resistance than the current literature anticipates. Labor forces or consumers in the developing countries are gradually exposed to CSR and Western-type management via Western-based TNCs. However, at the same time, the Developing Countries TNCs (DCTNCs) are now settling in Western countries, notably by means of corporate acquisitions.

The purpose of this paper is to examine the phenomenon of CSR contagion and to understand the possible implications of strategies of the Western-based TNCs and Developing countries TNCs through competition in the area of CSR through networks. We propose an agent based model (ABM) for CSR contagion through global supply networks based on classic BASS model (Bass 1969) and on the recently emerging Complex Network theory (Newman 2003).

BACKGROUND

Since the early 90s, most Transnational Firms controlled by Western-based parent companies (WTNCs) have modified their development strategies. As markets in developed countries became saturated and less profitable, WTNCs started to target the developing countries, not only as a source of cheap labor and raw materials, but also as an important growing market. For years the emerging countries have been passives (or not) recipients of technology and knowledge accumulation, and Foreign Direct Investments (FDI). CSR was one of the strong components of these transfers for the last years. However, as these WTNCs and their brands became increasingly transnational, so the risk to their reputation increased. It is notably to tackle the growing risk of "reputation" and in accordance to the "Nexus of Stakeholders' pressure," that a number of major Western transnational corporations (WTNCs) have decided to integrate Corporate Social Responsibility (CSR) principle in their operating procedures worldwide. The voluntary adhesion to CSR principles has raised skepticism and criticisms, but the non-adhesion to it is judged even more severely by stakeholders. In spite of controversies about the motives of the firms' adoption, loose self-regulation boundaries and no evidence of its social performance, CSR evolved no longer as marketing tool but it became a growing issue for companies. But CSR became also a social issue in the Western civil society for it has a perspective to relieve the conflict between self interest and atruism. So it has rapidly become a standard model of management by a sort of contagion phenomenon in networks. This evolution seems now beyond the control of the Western transnational corporations (WTNCs) which adopted it through worldwide competition and under the stakeholders' pressure. Most observers considered that this phenomenon is global. At the meso-level the corporations are more and more involved in CSR, and the macro-level (States and international organizations) and micro-level (Stakeholders) claim for the CSR as a social capital and need. It seems that CSR has some drivers in networks worldwide to spread the contagion beyond the WTNCs.

The literature has heavily focused on the Western TNCs strategies and how they approach, and might impose, worldwide, the contested concept of CSR (Moon 2002, Crane et al. 2003, and Davies 2002). But the strong growth of developing countries' TNCs might counterbalance this trend, after a century of domination by Western countries standards. Recently, researchers have turned to the Asian arena to conceptualize and benchmark CSR in corporations in emerging countries. For Blowfield (2004), the success of CSR in Asian corporations will depend on the Asian capacity to manage a global supply-chain. Does it mean that Western global management of CSR is still efficient or shall it fail facing Asian corporations? In addition, if CSR is a model that was designed for industrialized corporations and States (Khanna and Palepu 1997), what should be its global development? So far, what could be the approach of Asian corporations to CSR and where could CSR find growth drivers?

Two opposing CSR strategies are in fact at work, and the current CSR contagion observed among the Western-based TNCs may be facing a much stronger resistance than the current literature anticipates. Labor forces or consumers in the developing countries are gradually exposed to CSR and Western-type management via Western-based TNCs. However, at the same time, the Developing Countries TNCs (DCTNCs) are now settling in Western countries, notably by means of corporate acquisitions.

As globalization creates homogenization, will CSR find out strong new drivers in the Asian corporations or it will experience a severe breakdown? Is CSR today under control or beyond control worldwide? And if CSR is a model designed for industrialized corporations and States (Khanna and Palepu 1997[1]), what its global development could be?

RECENT CHANGES IN THE MARKET DYNAMICS

Until recently, global competition involved mainly WTNCs or TNCs with a western background (from Japan, Korea, Singapour, Hong Kong and Taiwan). However, the rapid and strong growth of TNCs in developing countries (DCTNC[2]), supported

by steady growth rates and by their governments, has generated an unexpected economic and cultural shock. Nowadays, WTNCs are competing with other WTNCs and also with their challengers from developing countries (DCTNCs) to attract consumers, best competitive labour-force and investments drivers.

In the last years and particularly since 2003, market dynamics highlights[3] a heavily underestimated economic strength of the DCTNCs. Several takeovers were carried out in industrialised countries by DCTNCs (in particular Chinese and Indian), as for example IBM's PC division by Lenovo, Thomson by TCL, Teleglobe by Tata, RPG, a branch of Aventis and Ohm Laboratories by Ranbaxy, Bayer's generic medicines branch by UB Group, MG Rover by Nanjing Auto, one Arcelor's plant by Mittal Steel, Marionnaud by Hutchinson Whampoa. These takeovers have been possible and welcome by the governments as these firms were unprofitable or non strategic for the future of the Western corporations and States. However, Mittal Steel's takeover bid on Arcelor and its latest development, or CNOOC's bid on Unocal and the subsequent Western governments intervention are even more representative of the rising economic power of DCTNCs. In order to prevent such takeovers, Western governments focused on the alleged lack of social responsibility of DCTNC in both environmental and social terms. Becoming aware of this phenomenon, the industrialized States and their firms started almost immediately to implement national defense strategies based mainly on "economic patriotism" and underlined corporate social responsibility enhancing, for both WTNCs and DCTNC to redefine their strategies.

The emergence of national champions, in particular Chinese and Indian, has accentuated the competition and the degree of "patriotism" of industrialized countries towards their corporations, claiming the lack of social responsibility of the DCTNCs. They have thus implicitly underlined and reinforced their own CSR. Indeed, since 2000 most WTNCs have introduced Sustainable Development or Corporate Social Responsibility at least as communication, management or strategic tool. Yet, a closer look at the last five years shows that CSR has become a competitive advantage between WTNCs but lately even more strongly between WTNCs and DCTNCs.

THE ASIAN DRIVER

The three main theories explaining the emergence and the development of DCTNCs are the learning cycle theory (Wells 1983[4]), the technological accumulation theory (Lall 1983[5]) and the investment cycle development theory (Dunning 1988 & al 1997[6]). These theories are rooted in the TNCs theories and combine microeconomic aspects related to the firm and macroeconomic aspects related to the environment (Beausang 2003[7]).

FINDINGS

CSR in Perspective Today: A Global Trend Beyond Control?

As we explained, over the last five years, many WTNCs present in industrialized and emerging countries, were particularly exposed to a risk to their reputation. They incorporated elements of corporate social responsibility into their international development strategies, in response to internal or external pressures or stimuli (Ansoff 1979, Agle et al. 1997). Even though their motives continue to fuel criticism and reflection, it seems that they have had a number of consequences.

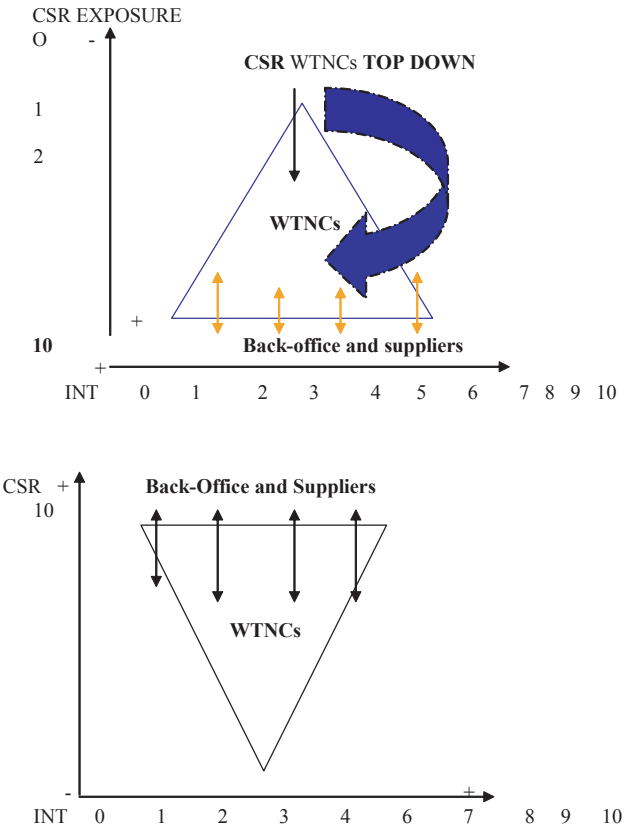
Firstly, they brought to light the corporations seeking to avoid taking a stance on CSR.(need some change) Secondly, they generated the quest for intra- and extra-sector social performance (De Bry 2001) by corporations in industrialized countries. Lastly, they imparted on CSR an internal momentum and maturity via the adoption of CSR in the front office and back-office networks of these corporations in their national territories and in emerging countries (Paone and Mangalagiu 2006). For Abernathy and Clark (1985), anything innovative, at any point in a commercial chain, has repercussions on the entire sector (on the existing technologies and on the players in the sector) and even has voluntary and involuntary repercussions outside the sector. We have seen how over recent years, and particularly since 2000, under the pressure of public opinion, of the financial markets and of insurance companies, furthermore due to the convergence of standards and legislation around the world, some WTNCs adopted CSR as an element of strategic management and as a competitive advantage to be developed and improved.[8]

CSR afford the firms to define their own boundaries of responsibility to maximize the benefits to their stakeholders. Voluntary CSR has led corporations to modify, to a greater or lesser degree, their management, communication, methods, and organization in developing countries. Either they now compete to secure the sources of supply best able to satisfy CSR criteria, or they work together in competition. By working together and pooling their needs in the eyes of their worldwide front office and back-office networks, they harmonize their demands over methods and criteria, reducing the cost of this competition. Whilst the costs generated by the implementation of CSR are easily quantifiable, the costs and losses linked to the risk to reputation are more difficult to estimate.

In order to understand CSR' global contagion from west to east, we have to rank the company's exposure rate by the adoption timing, as we have listed some of them in table**. Here we can see the most exposed sector is the Retailing Sector. It should endure most of the reputation pressure from the stakeholder side in order to compete with other retailers. On the supply side, the retailers have to shape the suppliers' product standard to meet their CSR criteria and this effort spread through the supply chain in a top-down way, as we defined from the most exposed sector to less exposed sector. But is this top-down western mode fit for the eastern emerging market? What is a general mode for the contagion of CSR from regions to regions? We examine this theme in both empirical and computational approaches.

Empirical approach: We have seen that the rationale behind the internationalization of WTNCs and DCTNCs is similar but that the difference resides in their competitive advantages and in the nature of their national markets. Because of the difference in the characteristics of competitive advantages and markets, the emerging market cannot spontaneously appear a top-down CSR adoption, partly for the unawareness of the social issue on the stakeholder side, and partly for the pressure from the economical globalization. More and more companies across western and eastern traded, collaborated and even merged. These intense interactions of western and eastern world truly facilitate the adoption of organization practice, including CSR, through the global supply networks. But in contrast to the Western adoption, most of the companies that adopted CSR early in emerging market are

Figure 1



less exposed DCTNCs. Although they do not have to face the pressure from the retailers or stakeholder in country, they must be aligned with the criteria that casted by WTNCs. So this spread mode is not the top-down pull mode, but a bottom-up push mode. Many data have been collected and some pre-results have shown the trend of this pull mode in contagion of CSR from Western to Eastern.

Computational approach: For confirming this "bottom-up"contagion phenomena, we will model CSR contagion phenomena from WTNC to DCTNC and contrarily the influence of DCTNC to WNTC in an Agent-Based Model for the future work. We combine the classic BASS diffusion model (Bass 1969) with the emerging Complex Networks theory (Newman 2003) into an ABM simulation. We propose the CSR contagion from WTNC to DCTNC through global supply networks, which follows a Scale-Free fashion. Firms in this global supply network have their own decisions on the adoption of CSR, but this decision would be influenced by two factors, the external factors from characteristics of the national environment or pressure of stakeholder side (i.e. mass media, the law) and the internal factors from the transnational supply network ties. The internal factor is given by the local network connectivity. More local firms that have direct transaction relation with the central firm adopt the CSR criterion, more possibility the central firm would adopt it for the higher risk and cost to trade with these CSR firms. And the contagion phenomena exhibits an S shape in the basic model setting, that means if the number of CSR firms gets to a critical mass, the contagion speed would be much more quick than the beginning. More results will be explored in the future work.

INTRODUCTION

Team activity has long been a core aspect of organizational life. Traditional teams have primarily interacted in a face-to-face setting. However, due to globalization and advances in technology, it is no longer necessary for team members to be located in the same place and meet at the same time in order to perform at a high level. Instead, it is possible for "virtual teams" of people supported by electronic collaboration technologies to meet in a distributed setting and collaborate across distance, time and organizational boundaries (Lipnack & Stamps, 1997). Due to the operational and competitive advantages associated with using virtual teams, the virtual team approach is rapidly being adopted in organizations. For example, high technology companies and consulting firms have relied on virtual teams for several years to reduce costs, reduce project time, and enhance decision making and communication (Duarte & Snyder, 1999; Townsend, DeMarie & Hendrickson, 1998).

The "virtual" environment can impose new types of challenges for the management of virtual teams (Pauleen, 2003-04). The development of trust among virtual team members can be a particularly important factor associated with team performance (Jarvenpaa & Leidner, 1999). While the development of trust in a virtual environment may not be easy, it can be a critical component for virtual team success (Duarte & Snyder, 1999; Handy, 1995; Jarvenpaa, Knoll, & Leidner, 1998; Paul & McDaniel, 2004). One potential way to enhance trust in teams is through effective leadership. Research on effective leadership in traditional, face-to-face teams is voluminous. Recently, however, a model of effective leadership has been proposed by Avolio and colleagues that argues for authentic and transformational leadership as most effective (Avolio, Gardner, Walumbwa, Luthans & May, 2004). They view effective leadership as, among other things, motivational, participative, inspirational, and authentic (Avolio, et al., 2004; Bass & Steidlmeier, 1999).

Leadership in virtual teams requires the ability to inspire and motivate others without face-to-face interaction. Research on virtual team leadership supports the Avolio, et al. (2004) model of an inspirational and understanding leader as most effective in that context (Kahai, Fjermestad, Zhang & Avolio, 2007). For example, in their field study of 13 virtual teams, Kayworth & Leidner (2002) found that the most effective virtual team leaders acted as mentors for other team members, motivating them through a participative and authentic style.

For our "research in progress," we will describe a study in which we investigate the role of emergent leadership on the facilitation of trust in virtual teams. Research questions to be addressed by the study include: Are emergent leaders in virtual teams considered to be more trustworthy?; If so, in what ways? Do trustworthy leaders help to enhance trust within a virtual team? For purposes of this manuscript, the three factors of trustworthiness suggested by Mayer, Davis & Schoorman (1995) – ability, benevolence, and integrity – will be explored using a survey instrument designed by Bigley (1996). The data for the study has been collected and is in the process of being analyzed. The next section provides a brief overview of the study, followed by brief summaries of preliminary results and the potential contributions of the research.

OVERVIEW OF STUDY

Sample: The research study has employed a case study approach to learn more about the perceived characteristics of emergent leaders in virtual teams. Participants in the study included 101 students who were members of a distance-learning executive MBA program operated by a university in the United States. The mean age of the participants was 33 years old and 70% were male. The participants were distributed throughout North America and typically had several years of managerial experience.

Teams and Tasks: The participants were randomly assigned into 26 distributed groups consisting of four members each (three teams had three members). Over the duration of the class term of fifteen weeks, each team performed ten graded team assignments associated with an introductory Information Systems course. To provide each team member with an opportunity to apply and demonstrate leadership skill in a virtual team setting, each member was randomly assigned to serve as the "team leader" for two of the team's assignments. The team leader's role was to oversee the work tasks associated with the team assignment. Team leaders were allowed to implement their own approach and style in leading the team. After each team member had rotated through two stints as a team leader, then the teams were allowed to select a leader for the remaining assignments. (The group size was selected to be four members to allow each to allow each team member to serve as a team leader for at least two of the ten assignments and to allow the teams to have the opportunity to select a leader for the later assignments.) The team tasks included five business case analysis assignments (i.e., Harvard Business School cases) and five "summary paper" assignments involving a report on a technical or managerial topic in information systems. To complete the tasks, the team members communicated via e-mail and phone. Based on the reports of the participants, no team members for any team met face-to-face.

Data Collection: The data collection included weekly self-reported communication behavior logs, a post-study survey questionnaire, and performance evaluations. The communication logs were used to determine the extent to which the team members interacted with one another and the type of communication media used. The survey questionnaire included several items aimed at assessing perceptions of trust. In part, trust was measured using a survey developed by Bigley (1996) based on work by McAllister (1995) and Mayer, et al. (1995). This 18-item instrument was used to measure perceptions regarding three types of trust: role performance trust (based on task performance), affective bond trust (based on close relationships, such as friendship), and ethical integrity trust (based on a belief in the ethical integrity of the individual). Each team member was also asked to assess the other members with respect to perceived leadership effectiveness using a 4-item scale. (Survey instruments used for this study are available upon request.) Ninety of the participants completed the final survey for a response rate of 90%.

PRELIMINARY RESULTS

A regression analysis was conducted to address the research question of whether or not emergent leaders in virtual teams are considered to be more trustworthy. The means, standard deviations, and correlations of the regression variables are shown in Table 1. The scale reliabilities for the measurement scales were good. Although the correlations among variables was high, based on a review of the variance inflation factor (VIF) indices for the regression coefficients (Cohen, Cohen, West, & Aiken, 2003), multicollinearity did not appear to be a problem. A factor analysis of Bigley's (1996) trust survey instrument confirmed that the trust measures clearly loaded as three distinct factors.

Table 2 shows the unstandardized regression coefficients and intercept, the standardized regression coefficients, and R^2 for the regression analysis. The overall R^2 for the regression model was high (0.85). For this model, the significant coefficients corresponded to the role performance and affective bond trust factors, with role performance trust most strongly related to perceived leadership effectiveness. Ethical integrity trust was not significant. Drawing from the preliminary findings of this study, it appears that the ability and benevolence factors of trustworthiness identified by Mayer, et al. (1995) were most strongly tied to perceptions of leadership effectiveness. In particular, those who rated high with respect to the trust that others had in their demonstrated ability to perform were also considered to be effective leaders.

Table 1. Correlations of trust variables with respect to perceived leadership effectiveness

Variables	1	2	3	4
1. Leadership Effectiveness	–			
2. Role Performance Trust	.91 **	–		
3. Affective Bond Trust	.71 **	.68 **	–	
4. Ethical Integrity Trust	.68 **	.72 **	.78 **	–
	1	**2**	**3**	**4**
No. of Items in Scale	4	6	7	5
Scale Reliability	0.90	0.94	0.89	0.85
Mean	2.96	3.13	2.57	3.05
Std Deviation	0.59	0.56	0.46	0.50

Notes:
1. Scale reliability calculated using Cronbach's Alpha.
2. All scale items were on a Likert scale ranging from 0 ("Strongly disagree") to 4 ("Strongly agree"); higher values reflect a more favorable perception.
*3. *p < .01, **p < .001.*
4. N = 90.

Table 2. Regression analysis for variables related to perceived Leadership effectiveness

Variable	B	SE B	β
Constant	-.020	0.16	
Role Performance Trust	0.87	0.07	0.82 **
Affective Bond Trust	0.29	0.09	0.23 *
Ethical Integrity Trust	-0.10	0.09	-0.08
R^2 for total equation (Adjusted R^2)	0.85 (0.84)		
F for total equation	156.2		

Notes*:*
*1. *p < .01 , **p < .001.*
2. N = 90.

POTENTIAL CONTRIBUTIONS

Based on our preliminary results, this study has the potential to contribute to the growing body of research on virtual team effectiveness by enhancing our understanding of the role of leadership in the development of trust for virtual teams. Previous literature suggests that virtual teams with higher trust may perform at a higher level (e.g., Jarvenpaa & Leidner, 1999). The trust relationships in any team are complex and variable. In our study, we found that role performance trust and affective bond trust in the leader were strongly related to perceptions of leadership effectiveness. Through a trustworthy leader, trust in a virtual team might be developed and enhanced. Perhaps virtual teams with lower trust levels would benefit from having a leader who was perceived by the team as more trustworthy. We plan to continue our analysis of the study data to gain more insights into the characteristics and implications associated with trust and leadership in virtual teams.

The Disconnected Customer: An Exploratory Study Toward a Model of Call Center Effectiveness

Anthony Francis Rodi, California University of Pennsylvania, California, PA, USA: E-mail: trodi1@yahoo.com
Robert Joseph Skovira, Robert Morris University, Moon Twp, PA, USA; E-mail: skovira@rmu.edu

ABSTRACT

The call center plays a significant role in the development and retention of customer relationships in all industries. Organizations have become more complicated, and the ability to get personal service and satisfaction has become more difficult. Technology and its use in processing a customer phone call to a call center are changing the quality of communication. The customer often experiences a combination of touch- tones, transferred calls and frustration. Loyalty centers on the customer and failure to provide good customer service results in lost revenues and customers. This paper discusses the effectiveness of banking call centers. Several categories affecting call center effectiveness are elaborated; these include automated call handling technologies, corporate cultures and attitudes, management styles and outside forces. Another aspect or factor of customer satisfaction can be extracted from the mission statement. The mission statement of the call center reflects corporate attitudes and perceptions from the company to the customer. These relationships are the heart and soul of every corporation and can be based on future success and failure of a call center and possibly of the corporation.

INTRODUCTION

Framing the Discussion

Cost efficiency over customer service is the main reason for the use of technology in call centers. In order to lower costs and improve profitability and efficiency, customers are forced to interact with automated systems until they are finally given the option to speak with a live representative.

Bank customers tend to be the pickiest and most diverse customer (O'Herron 2004). The call center is one of the most essential tools that banks possess. The strategies used in handling the many thousands of customer calls involve using Interactive Voice Response (IVR) systems (keypad input) and call handling technologies. Interactive Voice Response (IVR) is defined as an automated telephony and computer system that allows customers to interact with the system through touchtone response or voice response. This interaction allows the call center to gather customer information and filter or route calls to the appropriate agent or area (Thomas, 2003; Ammenheuser, 2004). Even with all of the latest technology, the banks interviewed in the above article noted that a live human voice was still the most effective tool. Internal operations provide strong influences on good customer relations and experiences. Attitudes, cultures, perceptions and motivations within the institution can be transferred outward to the customer and directly reflects the internal structure of the organization (Spradley and McCurdy, 1988).

Customer frustration is rapidly turning to anger and is reflected in their loyalties with a bank or company (Clark, 2003). The challenge for banks and corporations is to operate a call center efficiently and at the same time provide superior customer service. The research indicates that reliance on technology is not the answer to customer satisfactions and provides a quick path to customer frustration.

The financial services corporation used for this research displayed a true reflection of satisfactory customer service once a person was reached. The process of getting to a person seemed to cause frustration and poor customer service. Banks and corporations struggle with the balance of providing good customer service and maintaining a cost effective, efficient call center.

For a financial services institution, in order to retain customers and develop ongoing relationships, there must be a balance of good use of technology and human interaction in the call center. Customers have become very impatient with poor service of any kind and will switch loyalties to where they are treated well. An innovative bank or company will understand that customer satisfaction is a key element of their success. The ability to blend the mission statement objectives with the customer expectations should be a standard practice. Adherence to the mission statement and clear communication of its importance provides consistency in customer relationships and good business practices (Bart, 1999).

The three key elements that should be blended to provide a good customer experience are the mission statement, technology, and customer service. By blending these three elements, the barriers between the customer and the call center are lowered and provide the ability for superior customer service (Phillips, 2004). Particularly important is the balance of technology used to direct and filter the incoming customer phone call. Technology in the form of Interactive Voice Response (IVR) systems can be adjusted to be more customer- friendly by enabling the customer to reach an agent in the first menu (Swann, 2003).

The analysis encompasses the role of the call center, corporate perspectives and philosophies detailed in its mission statement, value of the customer, effect of technology on customer relations and effectiveness of the call center. Success and effectiveness of the call center will be determined by the customer response to the call center mission statement. The call center mission statement is an important asset in this analysis because it is used as the basis of determining if corporate perspectives of customer service are reflected to the customer.

CALL CENTERS: THEIR USES AND ABUSES

Why do companies and customers like call centers? They are still the main source of communication between customer and company. Customers get immediate results and resolution to problems when dealing with a person over the phone (Dausilio, 2005).

As companies consolidate and offer more products and services, there is a greater dependency on call centers to provide the complete customer experience. There is the advantage of up- selling products to customers. Companies are constantly searching for ways to increase productivity and reduce costs. There is a cost advantage of using technology when handling inbound customer telephone calls and a slow acceptance that customers have towards automation (Bills, 2004).

In their attempts to cut costs, companies constantly try to improve efficiencies by using new technologies while creating customer dissatisfaction in the process. The installation of trendy technologies is not the best way to keep up with rising customer expectations (Monegain, 2001; O'Herron, 2004).

A TYPICAL EXAMPLE

While conducting this research study, the researcher discovered a distance towards customers that call centers create either through poor use of technology or poorly directed corporate initiatives. Several test calls were made to the bank call center to determine the how easily an agent could be reached. Upon dialing the toll-free number, the main menu was accessed giving five options. The remaining option was a "zero out" option to reach an agent. The menu encompasses the sequence

of prompts as the call travels through the menu. The bank call center does offer the ability to request an agent at the first menu. As with most call centers, the time it takes to actually speak to a person would depend on call volume and time of day.

DISENCHANTMENT

The research details customer distaste for being forced to interact with technology, when the need for human interaction is necessary. People want to interact with other humans and not with an automated response system. Enterprises must provide consistent quality communications at each touch-point (Swanson, 2004).

Customers are revolting against companies and their impersonal approach to customer service. Customers will slowly and silently defect to a competitor and the company loses the opportunity to learn what went wrong. They will not complete surveys after they left and automation cannot detect emotions or frustration of customers (Dawson, 2005).

There is a consumer movement and website named "gethuman.com" headed by Paul English, who seeks to improve the quality of human communication in U.S. call centers (gethuman.com, 2006). This emergence indicates that customers have grown weary of navigating through endless menus while trying to reach a representative. The ratings of company call centers are based on ten standards set to determine overall quality of customer experiences including ease of navigation, ability to reach a human immediately, response to frequent customer service complaints and logical information flow. Currently, there is a list of 500 companies named on the "gethuman500" list (www.gethuman.com, 2006). In a recent article, only 9 out of 500 companies earned a high rating. Some companies included are Hertz, Dillard's, Land's End, and L.L. Bean (Houtz, 2006). The website also displays IVR shortcuts and override codes for a large list of companies.

THE PROBLEM

After nearly 19 years of call center experience, a recurring problem of misuse and overuse of automation seemed to be the main cause of customer complaints and dissatisfaction. Customers are much happier to deal with human interaction on a phone call. In addition, the company may realize additional revenue from opportunities that arise during the conversation. In an ethnography conducted by the researcher, low value and tightly scripted phone conversation, combined with dependency on technology, impairs the communication process in a call center (Rodi, 2004; Monegain, 2001). This research seeks to discover the effectiveness of people, process and technology and discover how customer relationships are impacted. The goal of the research is to explore if mission statements, corporate beliefs and perspectives are channeled through to the customer (Bartkus, et al 2000). This is call center effectiveness. Call center effectiveness is defined as effectively providing good customer service, using efficient, user- friendly technology, and customer relationships and satisfaction. What is the impact of the call center on the customer perceptions and attitudes when forced to interact with automated technologies in comparison to dealing with a live agent? Are call centers channeling corporate perspectives of good customer service through to the customer?

METHODOLOGY

The focus of this exploratory study is represented using qualitative methods, in particular, focus groups. Through the use of focus group discussions, participant observation, and personal experience, ethnographic analysis will be utilized (Morgan, 1997; Morgan and Krueger 1997; Spradley, 1980). Personal experience was used to compare and contrast the researcher's knowledge and experiences with those from the participant group experiences. The focus group discussions seek to reflect customer and corporate attitudes, behaviors, cultures, failures and successes at the customer telephone call level and effectiveness of the call center.

Qualitative research uses thick or rich description where value is placed on deep detail in order to see all possible meanings and to dig deeper in the understanding of things (Geertz, 1973). In a similar case study by Gilmore (2001), participant observation and focus groups were employed as main sources of data collection (Gilmore, 2001).

SOME RESEARCH FINDINGS

The first classification named Getting to a person, reflects the level of frustration that exists throughout the customer base. Each focus group revealed strong emotions towards the issue of speaking with a person. The results of the focus group discussions indicate that customers have lost their patience with banks that do not place importance on customer relationships. These same customers are willing to switch their loyalties to a bank that is more customer- friendly.

The second classification is using a cell phone. The cell phone has become the primary form of communication as a result of our mobile society. Using a cell phone complicates the communication process because of the parameters that exist with cell phone usage. These parameters include peak usage times, weak or lost signals and service, low battery causing disconnected calls that would not normally happen when using traditional telephone communications.

The third classification, Reliance on technology, revealed customer importance with the banks that rely heavily on an Interactive Voice Response (IVR) system to filter or screen their customers away from speaking to a person. The results revealed that customers feel that they are purposely routed through the Interactive Voice Response (IVR) to discourage them from speaking to a person and is used for the bank's convenience. Customers are tired of being routed through endless loops of touchtone and voice responses and feel disconnected from the ability to develop good human communication with a live person. Good customer service means providing satisfaction and the ability to provide user- friendly technology.

Classification four dealt with providing good customer service. The focus group discussions revealed that customers are weary of poor customer service and demand better treatment. People are looking for the personal touch in customer service. When customers do not get treated well for any reason, they will switch to a competitor with no remorse, regardless of their previous relationships with that bank. Like other industries, banking has similar products and what sets them apart is the quality of the service that is provided.

In contrast to reliance on technology, classification five addresses the advantage of using technology. The focus group participants felt that technology has its place and can be beneficial when used to check balances or make simple updates where a live agent is not needed. They felt that a customer needs a choice whether to interact with the Interactive Voice Response (IVR) or to go directly to a person.

As a final classification, adherence to the mission statement proved to be important in the group discussions. The mission statement is the basis of the operation and should be projected to the customer. A consistent response throughout all of the groups was that the participants felt that their bank did not stand out above the other banks with their innovative technology. The participants felt that similar technologies existed and the difference between banks is their approach to the customer.

SUMMING UP THE FINDINGS

An important classification discussed in the research was getting to a person. The call center is usually the first point of contact for many banks and the first impression is developed from this experience. In many cases, the call center is the only point of contact for a customer. The research indicated the customer impatience with call routing technologies and the negative perception of these technologies. When accessing a call center, bank customers generally have a need to speak to a person to resolve an issue. The reliance on automated response systems has created a barrier between the customer and their bank call center (Dawson, 2005). This barrier became apparent during the focus group discussions where customers felt isolated when navigating through the Interactive Voice Response (IVR) systems. The customer perception discovered from the research indicated that the focus of a call center is on saving money and creating efficiency at the cost of good customer service.

Discovered through this research is the fact that banks must be focused on their customers. The products are so similar in banking that the difference between good and bad banks is determined by their focus on the customer. This focus encompasses the call center experience and the ability to provide user-friendly call center initiatives.

CONCLUSION

The goal of this research project is to explore and discover if the call center is meeting its customer's expectations. The impact of technology on customer relationships and adherence to the mission statement plays a key role in operating a successful call center. A good example is L.L. Bean. They are famous for their outstanding customer service and superior call handling in their call

centers (L.L.Bean Company, 2006). This researcher has called L.L. Bean on several occasions and has consistently reached a phone representative on one ring, regardless of the time of day. Running a call center strictly by the numbers creates a distance with customers and limits the ability to build and develop good customer relationships. Good, consistent customer service is what attracts and retains customers. The emergence of websites such as "gethuman.com" proves that call center customers are weary of interacting with technology when their need is to speak with a live person. The goal of a successful company would be to provide choices to interact with technology or to speak with a person. By providing these simple choices to call center customers indicates that they are still important and are valued.

Performance Based Testing: Can a Web-Based, Simulated Environment Assessment Tool Measure Student Ability in Application Software Programs?

Kathleen Voge, University of Alaska Anchorage, 3211 Providence Drive, Suite 224, Anchorage, AK 99508, USA; E-mail: afklv@uaa.alaska.edu
Minnie Yi-Miin Yen, University of Alaska Anchorage, 3211 Providence Drive, Suite 224, Anchorage, AK 99508, USA; E-mail: afmyy@uaa.alaska.edu

INTRODUCTION

The College of Business Administration (CBA) offers a comprehensive business computer literacy and application software skills course. This MIS 110 course is required for our Business Administration (BBA) degree. The course covers hardware, the information processing cycle, ethical computing practices, and problem solving using popular business application software. The applications covered include Excel, Access, Word, and PowerPoint.

Eighty percent of the course is focused on using the computer as a tool to solve business problems. Developing intermediate-level application software skills is an important course goal for two reasons. First, the course is a prerequisite for other upper-division BBA required courses. As computing topics and software usage in these other courses becomes more extensive and required tasks more complex; a higher prerequisite knowledge and problem-solving skill level is mandatory for success. Second, CBA faculty members believe that businesses hiring BBA graduates place high value on computing skills proficiency.

Our University is an open enrollment institution and MIS 110 faculty members have witnessed increasing diversity of incoming student skill levels. To help identify students needing a more introductory course, we have investigated using simulated environment assessment programs such as SAM, SimNet, and TAIT for course placement purposes.

We believe that to use a tool as a means to measure performance, there must be an established correlation between the tool's outcome, or student score, and actual performance (Witnah, 2004). Performance-based testing (PBT) methods which "show us what you know by showing us what you can do" (Childers, 2000), are how we prefer to approach skills measurement in this course. PBT was originally designed to assess whether students can put knowledge to use, or demonstrate application of knowledge (Vaglio-Laurin, 2006). In other words, according to industrial psychologist Ruth Clark, "To establish that a person can use a procedure, the person must be able to actually perform it." (Stolovitch & Keeps, 1999)

PERFORMANCE-BASED TESTING METHODS

There are two popular methods for testing performance in software: simulation and live application. Each is an alternative to the most authentic means of measuring performance – on-the-job evaluation. (Vaglio-Laurin, 2006)

Simulation

A simulation approximates the live application environment--often by presenting a series of screen captures in response to the student's keystrokes / mouse clicks, thereby giving the appearance of actual interaction with the software. Simulations typically do not approximate the entire functionality of a live application, and required examination tasks are completed *independently* of each other.

Live Application

Live application approaches have students using actual software and/or hardware to perform a series of required tasks. Using the live application method, required tasks are *dependent* upon each other. The correct result of one task is needed for successful completion of subsequent tasks, much like on-the-job situations.

Though the labor and time intensive nature of developing and evaluating our live application examinations may seem excessive, we believe that simulated assessment environments do not adequately measure a student's ability to use these tools in real-world, on-the-job environments. However, resource shortages and an ever-expanding curriculum are forcing us to reconsider using simulated environment assessment tools as not only a placement mechanism, but possibly a way to reduce the time-intensive nature of our current assessment environment. If we can demonstrate that:

1. simulated environment test results are positively correlated with live application project-based test results, and
2. these results measure the learning outcomes we expect from our students, then

simulated environment assessment tools should be included as a part of our course curriculum / delivery and should be used for student performance evaluation.

EXPERIMENT DESIGN AND DATA ANALYSIS

Subjects for this study will be MIS 110 students in spring 2007. Subjects will be freshmen or sophomores and will belong to one of three sections taught by the same instructor. Each section may enroll up to 35 students. In this study phase, we will focus on two applications: Microsoft Excel and Microsoft Access. These two applications are the most important components of MIS 110. The simulated environment tool we will use is TAIT (Train and Assess IT), a Prentice Hall product. The live application examinations (LAE) are developed in-house by experienced instructors. Our formal design with three subject groups combines a factorial design with repeated measures and counterbalancing. Group 1 subjects will take a TAIT examination before taking the LAE examination. Group 2 will take the LAE examination before the TAIT examination. Group 3 is our control group and will take only LAE examinations.

At the beginning of the semester, subjects in all three groups will complete a survey gathering general demographic data such as gender, age range, self-reported current GPA range, level of comfort with Microsoft Excel and Microsoft Access, and years of computing experience.

For Group 1 subjects, after both Excel examinations have been scored and feedback received, a survey gathering feedback on the perceived benefits of completing TAIT prior to the LAE examination will be administered. Group 2 subjects will receive a similar survey gathering feedback on the perceived benefits of taking the LAE examination before the TAIT examination. Group 3 subjects will take only the LAE examinations and will have no exposure to the TAIT environment. This process will be repeated for the Access examinations.

Individual student examination scores will *not* be identifiable. Only categories of students and their score data will be collected, analyzed, and reported on. Score analysis for different tasks in each group will be made to determine whether the TAIT examinations enhanced student performance on LAE examinations, or vice

Table 1. Research activities

		Excel Examinations			Access Examinations		
Group 1	**General Demographic Survey**	**TAIT**	**LAE**	**Excel Perceptions Survey**	**TAIT**	**LAE**	**Access Perceptions Survey**
Group 2	**General Demographic Survey**	**LAE**	**TAIT**	**Excel Perceptions Survey**	**LAE**	**TAIT**	**Access Perceptions Survey**
Group 3	**General Demographic Survey**	**LAE**			**LAE**		

versa. Our data analysis can also be used to test the hypothesis of whether the simulated environment tool – TAIT, can be used as a viable student performance assessment tool. See Appendix A for a comparison of sample TAIT and LAE task instructions.

CONCLUSION

We believe this research will assist us in determining whether simulated environment assessment tool results can provide sufficient evidence of student ability within a live application. Given increasing emphasis on measurement of student learning and attainment of student learning goals, the identification of more efficient, reliable, time-saving, and cost-effective assessment methods will benefit both CBA faculty and students.

APPENDIX A

Sample of TAIT Examination and LAE Task Instructions

	NOTE: TAIT tasks are *independent* of each other and may be presented to students in random order.	**NOTE**: LAE tasks are *dependent* on each other and it is recommended that students perform each task in the order presented.
Excel Software Function / Task	**TAIT Sample Task Instruction**	**LAE Sample Task Instruction**
Open correct workbook	Open the "Judson Ford Realty.xls" spreadsheet.	Locate the Excel_HO_2_Template.xls file located on the H: drive. Open the workbook.
Merge and center cells	Merge cells A1:D1 and center "Expenses" in the merged cells.	Merge and center the heading in row 1 across columns A through E.
Sorting	Perform a multiple sort on the spreadsheet: first by Description and then by Member Company (both in Ascending order).	Using the appropriate menu command option, sort the list by both Destination (in ascending order) and Trip Cost (in descending order).
AutoFilter	Apply an AutoFilter to this sheet, and show only figures from the year 1850 or later.	Using AutoFilter, display the data for trips with a Trip Length of 7 Nights and a Trip Cost greater than $2,300.
Average function	In cell B20 of the current worksheet, create a function by typing in cell references to display the Average Monthly Sales for the six-month period covering January to June.	In cell E23, determine the average of Trip Cost for the displayed data. Use the appropriate Excel function to accomplish this.

The Influence of Contribution Visibility on Participant Satisfaction in Electronic Brainstorming

Alex Ivanov, Simon Fraser University, Canada; E-mail: aivanov@sfu.ca
Dianne Cyr, Simon Fraser University, Canada; E-mail: cyr@sfu.ca

ABSTRACT

Electronic brainstorming (EBS) was developed to overcome limitations of face-to-face brainstorming, and can be particularly useful in distributed idea generation sessions. However, EBS adoption in organizations has been sluggish, and its benefits beyond productivity—such as participant satisfaction—are equivocal. Applying the recently advanced theory of satisfaction attainment by Briggs, Reinig, and deVreede, our research explores if EBS participant satisfaction can be increased by innovative visualization of participants' contributions. This paper outlines our research model, and reports on the pilot deployment of one of our proposed EBS user interfaces.

INTRODUCTION

Idea generation is the process of deriving new concepts that may be useful when addressing a problem or opportunity [20]. Group brainstorming—a key ideation method in organizations—is characterized by deferring judgment, including even wild ideas, striving for quantity, and building on the ideas of others [16]. *Electronic* brainstorming (EBS) was developed to overcome limitations in face-to-face brainstorming, such as delays from taking turns speaking and withholding ideas for fears of a negative reaction. EBS eliminates these limitations by allowing simultaneous and anonymous input of ideas from distributed workstations, especially relevant in today's global teams [6, 18].

Despite the potential of EBS to boost productivity, its adoption in organizations has been sluggish—not unlike other e-collaboration technologies [7, 11]. *LotusNotes*, for instance, was not well accepted in a consultancy, due to lack of incentive to share one's best ideas if they were going to be seen as common property [17]. Other group support systems have left managers emotionally unfulfilled, for lack of that affective atmosphere inherent to some face-to-face meetings [21]. At the design firm IDEO, for instance, brainstorming sessions serve as 'prestige auctions' among employees, whose status is affected by reactions within the group [23]. While such explicit evaluability is not the point of EBS, complete anonymity, on the other hand, has been known to decrease motivation and participant satisfaction [5, 9, 14]. Anonymity may refer to *process* (inability to tell who is contributing) or *content* (inability to associate comments to contributors) [19].

CONTRIBUTION VISIBILITY

A recent EBS study by Jung, Schneider and Valacich [14] took a middle-of-the-road approach to anonymity. Their user interface (UI) included a bar chart that plotted the idea generation rates of each of the five participants, identified by pre-assigned pseudonyms. This treatment increased participants' motivation, compared to the control UI with no such performance feedback. The study, however, did not measure participant satisfaction. In addition, the authors note, some participants had realized the chart was displaying the number of contributions, and so lowered the *quality* of their ideas. Our study fills these gaps by investigating whether higher satisfaction with EBS outcome and process would be reported in conditions of identifiability and contribution visibility.

Only a handful of EBS studies address the issue of information visualization in EBS [8, 12]. Despite the compelling work by Erickson and Kellogg's on social translucence and social proxies in digital systems [10], the value of visualization

Figure 1. Our research model, with an iconic representation of the EBS interface conditions on the left, instantiating three levels of contribution visibility (our independent variable). Perceived goal attainment is the causal construct, while meeting satisfaction is the consequent construct. Dependent variables are reported scores on the various items (shown with the smallest type)

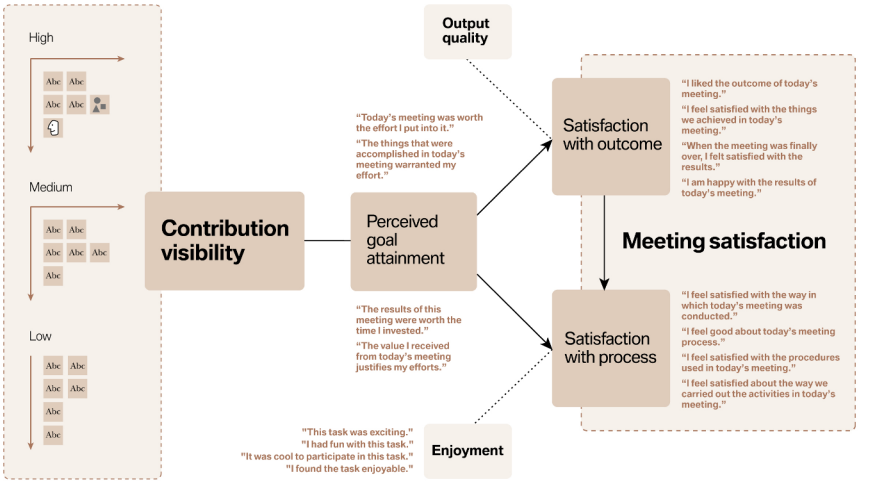

Figure 2. A screenshot taken near the end of the pilot session. Participants have submitted ideas as in a threaded discussion, except that text appears in rectangular cells. New ideas are arranged horizontally. Refinements or elaborations of already generated ideas are arranged top-down

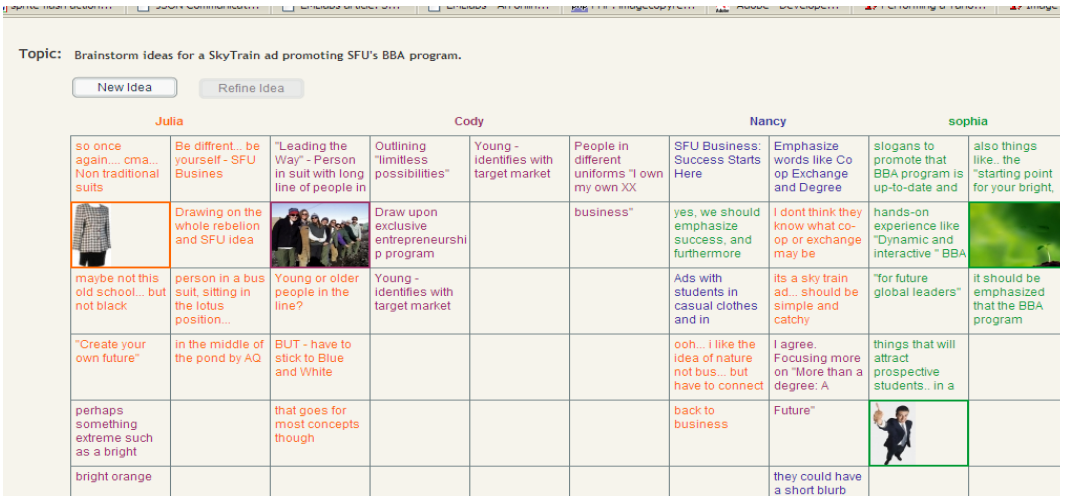

Table 1. Mean responses for each construct from the five participants in the pilot test.

	1 Strongly Disagree	**2** Dis-agree	**3** Some-what Disagree	**4** Neutral	**5** Some-what Agree	**6** Agree	**7** Strongly Agree
Perceived goal attainment					**5.3**		
Satisfaction with outcome					**5**		
Satisfaction with process				**4.85**			
Enjoyment				**4.75**			

for interfaces of collaboration technology has yet to be realized. The most popular system on the market and in the labs, GroupSystems.com, is mostly based on text and tables, and relies on trained facilitators to wield its rich computational functionality. But the scope of our research does not include facilitated meetings. For political and economic reasons, reliance on facilitators in companies has become impractical [3]. Instead, our experimental manipulation is varying the design of our web-based EBS interface.

MEETING SATISFACTION

There is a dearth of research on what causes satisfaction in technology-supported meetings. Yet insufficient satisfaction can undermine the adoption of otherwise productive systems [2, 22]. Briggs and his colleagues observed many instances of users abandoning systems they *judged* to be useful and easy to use, but with which they nonetheless *felt* dissatisfied [2, 21]. These researchers have since then defined meeting satisfaction as an affective arousal with a positive valence on the part of a participant with respect to the outcomes or procedures and tools used in a meeting [2, p. 588]. We apply the validated instrument that stems from this definition, but in addition include items for *enjoyment*, which has influenced technology acceptance in more general IT contexts [24]. Its inclusion will help us better understand the link between extrinsic and intrinsic motivation in EBS.

Effort towards a goal is generally determined by our subjective assessment of its *value* and the *likelihood* of its attainment [2]. Yet this effort is reduced when individuals work collectively and combine their inputs, according to the collective effort model [15]. This reduction is strong when individuals feel unlikely to get credit for their contributions, or when these are not instrumental towards attainment of the group goal. In one study of an online community, for instance, members were reminded of their unique position to rate a specific movie that only they had seen. This intervention increased their participation [1], and similar increases in EBS have been achieved based on social comparison [14, 21]. Indeed most of us compare ourselves to others due to some degree of uncertainly about our abilities, which we seek to resolve through positive confirmations [19, 23]. Uncertainty occurs in EBS given the flurry of incoming ideas, as some participants even confuse their own ideas with those of others [9].

While all hypotheses have yet to be derived, our main expectation is that EBS participants who brainstorm in conditions of high contribution visibility (CV) will report higher meeting satisfaction than participants who brainstorm in the conditions of low CV. Further, since the condition of highest CV supports uploading of image thumbnails alongside text, we expect participants, who do take advantage of this feature, to report the highest levels of satisfaction. This is because—simply put—pictorial representations are more impressive than text [4, 13]. Pictures can also be used as avatars instead of usernames, but this feature was not enabled in our pilot.

METHODOLOGY AND PILOT TEST RESULTS

Consistent with the EBS literature, our methodology is the lab experiment with students. In a between-subjects design, 240 students from a second-year business course will brainstorm on how to advertise the University's undergraduate Business program in the local mass transit. Each participant will receive course credit, and teams with the best ideas will further receive $100 ('best' being determined by independent coding from domain professionals). All 5-person teams will brainstorm for 15 minutes in distributed settings, using one of the three web-based EBS interfaces. The post-experimental questionnaire, with items on a 7-point Likert scale (shown in Figure 1) will be administered at the end online.

A pilot test was already conducted with five participants using the high contribution visibility condition. The quality of participation (Figure 2) and survey responses (Table 1) were promising. Some usability problems that emerged will be fixed for the upcoming main data collection. For instance, participants needed more and wider cells, so an algorithm will rescale and optimize the canvas aspect ratio. The outcome also alleviated our concern whether participants would take the trouble to find and upload pictures with relevant content. All five participants submitted a picture. The elaboration structures were not so clear, unfortunately, but on the plus side, participants reported they found the color-coding meaningful. The next step is conducting a second pilot test for instrument validation and finalizing all three EBS interfaces.

KM in Higher Education: Modeling Student Help-Avoidance Behaviors and Performance

Derek Ajesam Asoh, Southern Illinois University, Carbondale, IL 62901, USA, & University of Yaounde I, Cameroon; E-mail: dasoh@siu.edu

ABSTRACT

The application of corporate knowledge management (KM) practices such as customer relationship management (CRM) within the academic environment is considered within the sphere of student relationship management (SRM). By engaging in SRM, key issues such as student help-avoidance behaviors can be proactively addressed to ensure academic achievement and success.

This study describes the development of a structural model to investigate how student help-avoidance is related to perceived academic performance. We based our model on one developed by Butler (1998) which includes autonomous orientation, ability-focused orientation, and expedient orientation as three dimensions of the help-avoidance construct. Preliminary results of a survey of 130 undergraduate students taking an IT course indicate that besides the three dimensions of help-avoidance, students have other student- and instructor-specific perspectives of help-avoidance also exist.

Keywords: Knowledge management, higher education, student help-seeking, help-avoidance, academic performance, student relationship management, structural equation model.

1. INTRODUCTION

Knowledge management (KM) is a relatively new management activity which many companies have embraced in an attempt to meet the challenges of an increasingly global business environment to compete over customers. Even though some have questioned the view that educational institutions can be and indeed are in business (Bishton, 2005), the competitive wave is being experienced in educational institutions. More than ever before, higher educational institutions now have to compete for students. Competition is particularly fierce among those institutions that are moving away from research and putting more emphasis on teaching. For teaching-oriented institutions, the student is the focal entity. While the debate about the view of students -- as customers, products, or partners (Clyason & Heley, 2005; Obermiller, Fleernor, & Raven, 2005) is far from being over, for institutions that consider students as their "raison d'être," the predominant view is that students are their customers.

The view of students as customers brings two expectations. First, students are expected to seek help in the course of their studies to ensure the best academic achievement and success just as customers would seek help in the course of using a product or service for maximum benefit. Second, since the value proposition of KM in the corporate world includes innovation, customer intimacy, and operational excellence (Kindwell, Vander Linde, & Johnson, 2000), teaching-oriented institutions are expected to embrace KM with a vested interest in student intimacy. Student intimacy can be attained through the establishment of student relationship management (SRM) programs just as companies have established various customer relationship management (CRM) programs for the same parallel purpose. The foregoing expectations remain largely unmet. For example, whereas most customers will readily seek help from company help-desks, the same is not true of most students, who do not often approach instructors ("university help-desks") to seek help in the course of their studies. Equally, with every effort is made to recruit and retain students, few or no educational institutions have any SRM programs in place to help understand student help-avoidance or promote help-seeking behavior. SRM will foster help-seeking behaviors of students for two potential benefits -- instructors are able to fill gaps in student knowledge and adapt teaching, both of which should contribute to student achievement and success.

This purpose of this study is develops a structural equation model to delineate factors that account for student help-avoidance behaviors, and subsequently relate it to academic performance. We base our model on a previously developed model to investigate the relationship between help-avoidance and style of help-seeking behavior (Butler, 1998). As we apply the model in the higher educational setting, we attempt to answer the following questions: (1) why do students avoid seeking help when doing their academic assignments?; (2) how does help-seeking behaviors relate to academic performance?

2. LITERATURE REVIEW

KM can be used to learn about students' needs and behaviors just as is done in the corporate world with respect to customers. In this review, we examine the nature of the relationship between students and educational institutions (referred further as universities) as well as discussion on the student help-avoidance and help-seeking behavior.

2.1 Student-University Relationship

The nature of the student-university relationship is highly debated and three orientations of how students should be considered have been discussed in the literature. The first orientation considers students as customers, the second as products, and the third as partners to universities. Many institutions do not explicitly state their orientations of students as customers (Clyason & Heley, 2005). These authors cite evidence that have shown that indeed the customer-oriented view of student implicitly exists in most universities. For example, marketing material for future students resembles marketing material for customers in the corporate world, the urge by university departments to write marketing plans, the requirement for students to complete customer-like surveys about their educational experiences including evaluation of instructors.

In an empirical study involving instructors and students, Obermiller *et al*.(2005) found that instructors preferred referring to students as products while students preferred being referred to as customers. However, both instructors and students "believe the other orientation prevails" (p. 27). In an earlier study students were more deterministic about being called customers, and the researchers concluded that the operation of higher education was consumer-driven (Delucchi & Korgen, 2002). The use of both customer and products orientations has been advocated (Conway & Yorke, 1991). Other think referring to students as customers or products is not appropriate (Franz, 1998; Bay & Daniel, 2001; Bishton, 2005; Clyason & Heley, 2005).

An emerging view of students as partners has been proposed (Bay & Daniel, 2001). Although we support this view, we contend that KM practices associated with CRM can be applied to the partnership under the appellation of SRM as previously discussed.

2.2 Student Help-Avoidance and Styles of Help- Seeking Behaviors

When faced with a problem, between the alternatives of giving up or persisting unsuccessful alone and seeking help, it has been recommended that seeking help is the most valuable thing to do (Newman, 1991). Failure to heed to the foregoing

recommendation may be due to several factors, including consideration that the cost of help-seeking outweighs the benefits of help-avoidance (Nadler, 1997), striving for independent mastery (Butler & Neuman, 1995), culture; where students tend to avoid embarrassment (Hambrecht, 2006), and reward; where high achieving students seek help for personal difficulties related to course work (Taplin, Yum, Jegede *et al.*, 2001).

Other studies have pointed out that seeking or avoiding help, especially in computer mediated environments is dependent on the nature of learner-oriented factors such as help facilities (Bartholome, Stahl, Pierschl *et al.*, 2006). Cognitive tutors have been developed in an attempt to help students learn to seek help (Aleven, McLaren, Roll *et al.*, 2004). Evidence suggests that those who seek help have better learning outcomes, whereas those who really need help are less likely to seek help (Ryan, Gheen, & Midgley, 1998).

Help-avoidance have been characterized as a multidimensional construct and studied in relationship with the style of help-seeking behaviors (Butler, 1998).The help-avoidance construct has three dimensions – autonomous orientation, ability-focused orientation, and expedient orientation. The author defined autonomous help-avoidance orientation as striving for independent mastery; ability-focused as desiring to mask incompetence, and expedient orientation as reluctance to seek help attributed to the perception that asking for help will not expedite the task. The author used the model to investigate the relationship between help-avoidance and styles of help-seeking behaviors (autonomous –first trying to solve a problem before asking for help, executive – request help relatively early, and avoidant-covert – requesting little overt help). In an experimental study in a K-12 environment, it was found that autonomous help-avoiders are likely to engage in autonomous help-seeking style; expedient help-avoiders used the executive help-seeking style; and ability-focused help avoiders used the avoidant-covert help-seeking style (Butler, 1998).

3. HELP-AVOIDANCE AND PERFORMANCE RESEARCH MODEL

We adapted the help-avoidance model proposed by (Butler, 1998) to the context of a university environment and investigated the relationship between the various orientations and perceived academic performance. The research model is shown in figure 1.

4. METHODOLOGY

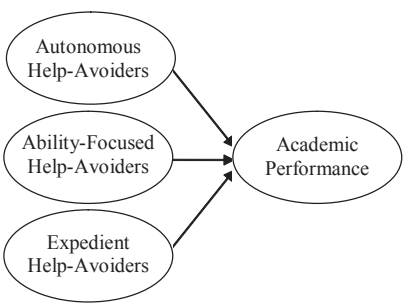
4.1 Instrumentation and Sample

To measure help-avoidance, we used a modified version of the 17-item instrument proposed by Butler (1998). The modified instrument was reviewed by four instructors for clarity and consistency. Perceived academic performance was measured using the six items below. One hundred and thirty students from eight sections of an undergraduate IT course were surveyed to collect data for the study. Each student was asked to rate his/her performance compared to fellow students in the class using a five-point scale (SD –Strongly Disagree, D-Disagree, N-Not Sure, A-Agree, and SA-Strongly Agree):

"Compared to your fellow students taking the course, you: ..."

1. *Have or will have a better grade in the course*
2. *Are more satisfied with the class organization*
3. *Are more satisfied with the course material*
4. *Are more satisfied with the way the course is taught*
5. *Are more satisfied with the course instructor*
6. *Have a higher Grade Point Average (GPA)*

Figure 1. Help-avoidance and performance model



Besides the reasons pointed out in the research instrument, students were asked to identify one other reason why they believe may explain why students do not ask for help. Demographic information was also solicited, including number of credit hours and working status.

5. PRELIMINARY RESULTS AND FUTURE WORK

Preliminary analysis of the responses to the qualitative question requesting students to state one reason they believe students do not ask for help indicate some student-oriented reasons such as students being lazy, students not wanting to learn, not caring if they get it right, scared and preserve self-respect, think attention being bad, and not wanting to slow progress. Instructor-oriented reasons cited include expectation of students to know certain things ahead of time and sometimes, instructor tells everything but the answer to the question asked.

Future work will focus on analyzing the data and examining the results to see if the same three dimensional model of help-avoidance is applicable to higher educational environments. Results from the study would provide management indicators for the establishment of SRM programs geared at understanding and eliminating help-avoidance. SRM will foster help-seeking behaviors of students for two potential benefits -- instructors are able to fill gaps in student knowledge and adapt teaching, both of which should contribute to student achievement and success.

ABSTRACT

The question of student retention remains one of the main preoccupations of university administrators. As the interplay of several factors often causes students to withdraw from university at various levels, pro-active administrators are in dire need of analytical tools to help predict student academic persistence. By knowing which students are likely not to persist after a given semester, administrators are able to take measures to help reverse the trend.

We report on an on-going data mining project to develop and deploy models to predict student persistence in the first year of undergraduate studies following their participation in a specialized pre-undergraduate program at the Center for Academic Success at Southern Illinois University, Carbondale. Preliminary results from the first run of the models have validated predicted persistence at 75 percent accuracy. These results are very encouraging compared to previous work at this level.

Keywords: higher education, knowledge discovery, data mining, GPA, prediction, academic persistence.

1. INTRODUCTION

Data mining, which has predominantly been carried out by private sector organizations is gradually emerging as a routine endeavor in the academic environment because of its potential benefits of improving the quality of education (Ma, Liu, Wong *et al.*, 2000; Luan, 2002). University administrators, instructors, students, and parents often want to have some idea ahead of time, regarding the performance and persistence of students. Being able to predict performance and persistence offers the opportunity for better planning and better decision-making processes.

This report highlights our current work of applying data mining on academic data and is organized in five sections: background information, research model, methodology, results and discussion, and a conclusion highlighting the limitations of the research, management recommendations and direction for future work.

2. LITERATURE REVIEW

Although data mining is an emerging practice within the academia, it has been used as technique to answer many challenging questions. Mining of student data has been eloquently compared with mining of customer data (Luan, 2002). The author outlines several customer-related data mining questions and provides an analogy for student data-mining. For student data mining, such questions include knowing those students that are unlikely to persist, take many credit hours, or transfer. In a case study of using clustering techniques and neural networks to model academic persistence, an initial prediction accuracy rate of 65% was obtained. Modification of the models resulted in an improvement up to 85% prediction accuracy (Luan, 2002). A system has been developed to identify weak students for remedial classes with 67% accuracy (Liu, Hsu, & Ma, 1998). A more recent system for the same purpose performed at a higher accuracy level (91%) but the task was attainable at 93% accuracy using traditional methods (Ma *et al.*, 2000)).

3. PROJECT BACKGROUND AND RESEARCH QUESTION

The Center for Academic Success (CAS) is a pre-undergraduate preparatory at Southern Illinois University Carbondale (SIUC) that offers target students the opportunity to prepare themselves for better performance in their first year at the university. Procedurally, CAS admits new students during the Fall and Spring semesters, with the greatest number of admissions (300 - 500) in Fall and the least in Spring (typically 20). As these students spend only two semesters at CAS (Fall and Spring or Spring and Summer), their persistence is verified at the end of the second week of their third semester at SIUC, in the academic unit of their choice.

Although the data mining project is geared at providing actionable data for administrative support to address several questions, this first question we are attempting to answer is: who are those CAS students that persist at SIUC after their time at CAS?

4. DATA MINING PROJECT MODEL

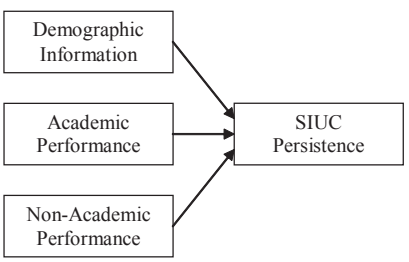
Given the problem at hand, our project uses the predictive data mining approach. Student persistence is a categorical variable with two levels (YES or NO). Therefore, we develop a predicting data mining classification model, i.e. a model that will predict the value of the persistence attribute of a student as either YES or NO, based on a number of input variables. The model being investigated to respond to the research question at this stage of our project is shown in figure 1.

5. METHODOLOGY

5.1 Data Mining Approach

The data mining approach adopted for the project is based on the Cross-Industry standard Process for Data Mining (CRISP-DM) model (Chapman, Clinton, Kerber *et al.*, 2000) which reflects the real-world experience of how data mining should be conducted in a standard and systematic way. We have implemented key elements from all six steps of the CRISP-DM methodology (Business, Understanding, Data Understanding, Data Preparation, Modeling, Evaluation, and Deployment) and obtained a prototype system whose performance is very encouraging.

Figure 1. Persistence research model



5.2 Dataset and Variables

The dataset included demographic, academic, and non-academic information on the students. **Demographic variables** included gender, age, and race. **Academic variables** included *ACT scores*: English, Mathematics, Reading, Science, and Composite; *High School-related*: Rank, Percentile, and High School GPA; *CAS-performance*: Term1 GPA, Term2 GPA, Term1 Standing, Term2 Standing, Year1 GPA; and *SIUC-related*: Term3 Persistence. ***Non-academic variables*** included *CAS-Semester related*: Term1 Semester (e.g. Fall 2004), Term 2 Semester (e.g. Spring 2005), Term 1 Mentoring, Term2 Mentoring, Term1 Tutoring, Term2 Tutoring, Positive Self Appraisal, Positive Self Confidence, Long Range Goals, and Gender Sensitivity.

For the prototype system develop at this point, we have not used non-academic variables since these are not available across the entire dataset. Nine of the other variables were retained for the prediction of Fall 2005 persistence (T3 Persistence). These include five continuous variables: age, ACT composite score, High School GPA, Term1 GPA, and Term2 GPA; and four categorical variables: gender, race, Term1 Standing, and Term2 Standing.

Within the dataset with demographic and academic variables, the data mining dataset was further screened to include only those students who had effectively spent two semesters (Term1 and Term2) at CAS. Given the objective of developing a model to predict Fa2005 persistors, two final datasets were maintained for this stage of the data mining project. The first dataset (**dataset1**) spawns the period of Fall 1998 to Spring 2004 (2279 records) and the second dataset (**dataset2**) included Fall 2004 and Spring 2005 (384 records). We used **dataset1** to train and test the data mining models. The models were then applied to **dataset2**, to predict persistence status for Fall 2005. The data mining project is being carried out using Statistica Data Miner (Statsoft.com).

6. RESULTS AND DISCUSSIONS

6.1 Preliminary Investigations on the Training and Testing Datasets

Preliminary investigations were conducted on the training and testing dataset regarding risk of wrong estimate and standard error. The training set had a risk estimate of 0.15 and a standard error rate of 0.01 and the testing dataset had a risk estimate of 0.13 and standard error rate of 0.02. Given the standard errors for the training and testing datasets, we estimated prediction accuracy to be between 83 and 91 percent at the 95% confidence level. Since the training and testing datasets had different risk estimates and different standard errors, we compared their performance using the approach of comparing supervised models (Roiger & Geatz, 2003). We found that the two models were not significantly different from each other. This alleviated any worries about the accuracy of the final results when persistence was to be predicted using the target sample (**dataset2**). We investigate the relative importance of each predictor variable and found that Term2 GPA was most influential, while gender had the least predictive importance (Table 1).

6.2 Performance of the Data Mining Algorithms/Models

Eight data mining algorithms/models were used, referred to here as CTrees2, CCHAID3, CECHAID4, CBTrees5, Logit6, Probit7, CMLP8, and CRBF9. The performance of an algorithm was judged by examining goodness of fit or misclassification rate, the degree to which predictions disagree with actual cases in the testing dataset. Low percentage disagreement (% Incorrect) of an algorithm meant lower misclassification, and hence better performance in prediction. The performance of each algorithm of incorrectly predicting Term3 Persistence (T3Persist) in the test dataset is shown in Table 2. The percentage disagreement among all eight algorithms of incorrectly predicting Term3 Persistence as either Yes or No is shown in Table 3.

6.3 Fall 2005 Persistors and Non-Persistors Predictions: Vote of Three Best Predicting Models

Three of the 394 records in dataset2 (Fall 2004 and Spring 2005) were deleted because of "excessive" missing values in some of the fields. As a result, 391 records were used in the subsequent analysis. In line with extant research, the results of the eight data mining algorithms were subjected to a vote. However, only the results of the best three performing algorithms were considered in the vote. The results indicate that **48 students** (12% of Fall 2004/Spring 2005 students) **may not** persist while **343 students** (88 %) **may persist** in Fall 2005.

Table 1. Predictor ranking and importance in predicting T3 persistence

Predictor Variable	***Rank***	***Importance***
AGE	25	0.25
ACTCOMP (ACT Composite Score)	27	0.27
HSGPA (High School GPA)	48	0.48
T1GPA (Term1 GPA)	95	0.95
T2GPA (Term2 GPA)	100	1.00
GENDER	8	0.07
RACE	39	0.38
T1STAND (Term1 Standing)	55	0.55
T2STAND (Term2 Standing)	79	0.79

Table 2. Percentage disagreement of individual algorithms in predicting observed persistence

#	*Data Mining Algorithm/Model*	*Fall 2005 Persist* (% Incorrect for Yes and No)	
		Yes	**No**
1	CTrees2	14.30	5.26
2	CCHAID3	13.85	18.88
3	CECHAID4	13.85	18.88
4	Logit6	13.88	12.30
5	Probit7	14.04	11.11
6	CMLP8	11.42	59.76
7	CRBF9	12.64	57.34
8	CBTrees5	12.37	34.76

Table 3. Percentage disagreement among algorithms in predicting observed persistence

#	*Data Mining Algorithm/Model*	*Fall 2005 Persist* (% Incorrect Yes or No)
1	CTrees2	13.27
2	CCHAID3	14.57
3	CECHAID4	14.57
4	Logit6	13.67
5	Probit7	13.67
6	CMLP8	31.86
7	CRBF9	28.74
8	CBTrees5	17.07

Table 4. Fall 2005 persistors and non-persistors

#	Predicting Algorithm/Model	Fall 2005 Persist	
		Yes (%)	No (%)
1	CTrees2	343 (88)	48 (12)
2	CCHAID3	349 (89)	42 (11)
3	CECHAID4	349 (89)	42 (11)
4	Logit6	343 (88)	48 (12)
5	Probit7	343 (88)	48 (12)
6	CMLP8	240 (62)	148 (38)
7	CRBF9	249 (64)	142 (36)
8	CBTrees5	325 (83)	66 (17)
	Best3Voted	343 (88)	48 (12)

6.4 Fall 2005 Persistors and Non-Persistors Predictions: Individual Algorithms/Models

Prediction results of all eight models were compared with that of the vote from the three best models and presented in Table 4. We note that three algorithms (CTrees2, Logit6, and Probit7) won the vote as these three had identical predictions.

6.5 Fall 2005 Persistors and Non-Persistors Actual Persistors

Actual persistence assessed using Fall 2005 data indicated that 294 students persisted (as opposed to 343 predicted) and 97 students were non-persistors (as opposed to 48 predicted). The actual persistence rate obtained is 75% (as opposed to 88% predicted) while the non-persistence rate is 25% (as opposed to 12% predicted).

7. CONCLUSION AND FUTURE WORK

Compared to previous similar work at this level (e.g. Luan (2002) and Liu, Hsu, & Ma (1998)) the results obtained are very acceptable. The 75% prediction accuracy are quite encouraging, giving that this is the first run of the models; and it is our expectation that better results can be obtained with the improvement of the models. Nevertheless, the results are being exploited with caution since most of the parameters have not been incorporated into the models. We found an interesting pattern in the prediction of persistors and non-persistors. The differences in accuracy for both predictions are about the same -13%. This result could be coincidental but it does raise some curiosity which we are exploring, especially because we consider the 13% difference to be very large.

Future work includes drilling down to identify whether individual students predicted to persist indeed were the ones who persisted and vice versa. Subsequently, we will proceed to refine the models

The results of our project will be useful to management as an aid in making decisions regarding resource allocation to accommodate the number of persistent students, i.e. those who will return to continue their undergraduate studies after the pre-undergraduate preparatory year. The results are also useful in exploring different channels to ensure high persistence rates.

ABSTRACT

In this study, we address a new efficient robust optimization approach to large-scale environmental RSSS reconstruction/enhancement as required for remote sensing imaging with multi-spectral array sensors/SAR. First, the problem-oriented robustification of the previously proposed fused Bayesian-regularization (FBR) enhanced imaging method is performed to alleviate its ill-poseness due to system-level and model-level uncertainties. Second, we incorporate the dynamic filtration paradigm into the overall reconstruction technique to enhance the quality of the imagery as it is required for decision support in environmental resource management with dynamic RSSS behavior.

Keywords: Environmental Remote Sensing, Dynamic Filtration, Resource Management, Decision Support, Regularization.

I. INTRODUCTION

Nonlinear reconstructive processing/enhancement of large-scale environmental imagery provided with modern multi-spectral array sensors/synthesized array sensors/radar (SAR) are extremely computation and time consuming. The crucial aspects here are problem-level and system-level model uncertainties that complicate severely the implementation of any adaptive nonlinear large-scale image enhancement techniques based on descriptive or statistical regularization paradigms [1] - [4]. The aggregated regularization inference-based treatment of the problem was initially undertaken in [3] and developed in recent papers [7], [8] in the scope of the inverse problem methodology for coherent SAR image restoration. Some recent publications in this field use the maximum entropy (ME) approach but again in a context of descriptive regularization that simply alleviates the ill-posed nature of the corresponding scattering pattern estimation or image restoration inverse problems [5].

The key distinguishing feature of the new paradigm considered in the present study is that the inverse problem of estimating the particular remote sensing scene signatures (RSS) from the available measurements of random realizations of the data field is stated and treated in the framework of the robust regularization strategy aggregated with the dynamic filtration. We address a new efficient robust optimization approach to large-scale environmental RSS reconstruction/enhancement as required for remote sensing imaging with multi-spectral array sensors/SAR. First, the problem-oriented robustification of the previously proposed descriptive regularization (DR) enhanced imaging method is performed to alleviate its ill-poseness due to system-level and model-level uncertainties. Second, we incorporate the dynamic filtration paradigm into the overall reconstruction technique to enhance the quality of the imagery as it is required for decision support in environmental resource management with dynamic RSS behavior. The new proposed method is addressed to as the dynamical aggregated robust regularization (DARR) technique. Finally, we report and discuss some simulation results of enhancement of the real-world 1024-by-1024-pixel format 256-scaled environmental RSS indicative of the efficiency of the developed DARR method. In the simulations, the advantage of the RSS reconstruction using the derived DARR-optimal and suboptimal estimators over the case of the conventional matched spatial processing technique [6] based on the use of the matched spatial filtering method is evident. The resolution is substantially improved; regions of interest and distributed object boundaries are much better defined, while ringing effects usually observed with filters based on inverse operations are substantially reduced.

II. PROBLEM PHENOMENOLOGY

According to the mathematical statement [1], [2], [4] to perform the image enhancement via processing the remote sensing data employing the descriptive regularization (DR) approach one have to solve the optimization problem

$$\hat{\mathbf{v}} = \underset{\mathbf{v}}{\operatorname{argmin}}\, E(\mathrm{v}|\lambda) = \underset{\mathbf{v}}{\operatorname{argmin}}\, \{(1/2)\,\lambda_1 J_1(\mathrm{v}) + (1/2)\lambda_2 J_2(\mathrm{v})\} \qquad (1)$$

of minimizing the cost (energy) function $E(\mathrm{v}|\lambda)$ with respect to the desired K-D image vector v for the assigned (or adjusted) values of the regularization parameters $\lambda = (\lambda_1, \lambda_2)^{\mathrm{T}}$. The proper selection of λ is associated with parametrical optimization of the DR process. In (1), $J_1(\mathrm{v}) = \|\mathrm{u} - \mathrm{F}\mathrm{v}\|^2$ represents the error function for corresponding sensing system, and $J_2(\mathrm{v})$ represents the conventional Tikhonov's stabilizer [5].

The data acquisition model is defined, as in [7], by the equation, $\mathrm{u} = \mathrm{F}\mathrm{v} + \mathrm{n}$ where F defines the corresponding system's degradation operator usually referred to as the imaging system point spread functions (PSF) and n represents the noise in the actually acquired image, respectively.

Next, the particular RSS is formed applying corresponding nonlinear signature extraction operator Φ to the enhanced image $\hat{\mathbf{v}}$, i.e.

$$\ddot{\mathbf{E}} = \Phi(\hat{\mathbf{v}}). \qquad (2)$$

Note, that in our particular study of the hydrological RSS, the Φ is specified as corresponding weighted order statistics (WOS) computing operator [1].

It is important to mention that the DR solutions for $\hat{\mathbf{v}}$ and $\ddot{\mathbf{E}}$ exist and are guaranteed to be unique for a given λ because the surfaces of all functions that compose $E(\mathrm{v}|\lambda)$ given by (1) are convex. But one can deduce that in the case of incorporating any additional dynamic information on the evolution of the RSS $\ddot{\mathbf{E}}$ in time, the non-linearity of the aggregated optimization problem (1), (2) will require extremely complex computations and will result in the technically intractable scheme if solve this problem employing the standard direct minimization techniques [1], [3]. For this reason, we propose here to apply the iterative computing paradigm for implementing the proposed DARR method.

III. DYNAMIC RSS RECONSTRUCTION WITH DARR METHOD

The crucial issue in application of the modern dynamic filter theory [1] to the problem of reconstruction of the desired RRS in current time is related to modeling of the RSS as a random field (i.e. spatial map developing in discrete time i) that satisfies the dynamical difference state equation [1]

$$\begin{aligned}\mathbf{z}(i+1) &= \ddot{\mathbf{O}}(i)\mathbf{z}(i) + \tilde{\mathbf{A}}(i)\mathbf{x}(i)\\ \ddot{\mathbf{E}}(i) &= \mathbf{C}(i)\mathbf{z}(i)\end{aligned} \tag{3}$$

specified by the linear dynamic model formation operators (matrices) $\ddot{\mathbf{O}}(i)$, $\tilde{\mathbf{A}}(i)$ and $\mathbf{C}(i)$, respectively. The dynamical estimation strategy for such optimal RSS prediction procedure can now be defined as follows [1]

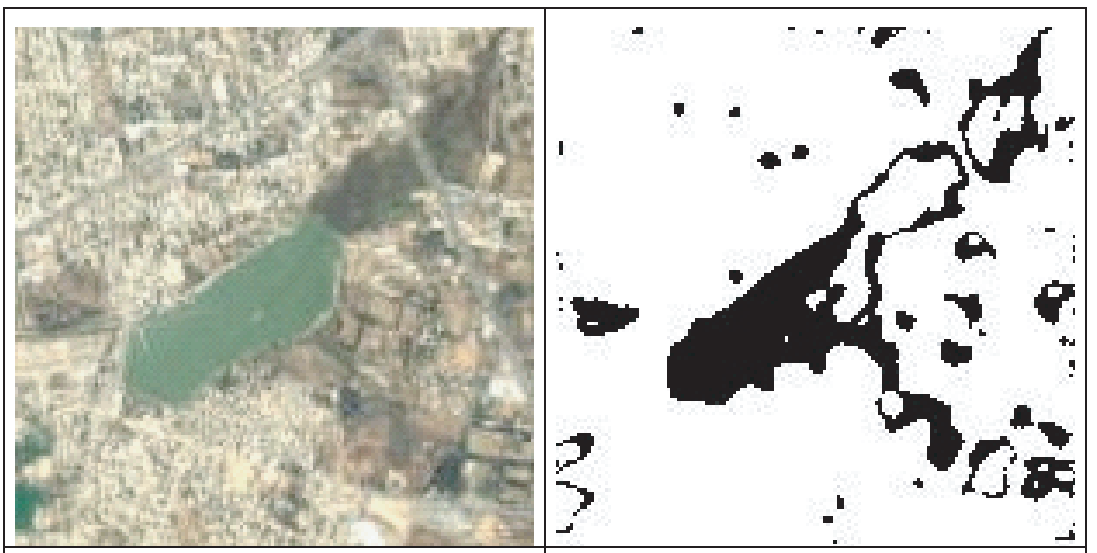
$$\begin{aligned}\hat{\mathbf{z}}(i+1) &= \left\langle \mathbf{z}(i+1) \middle| \hat{\mathbf{z}}(i),\ \hat{\mathbf{v}}(i+1) \right\rangle;\\ \ddot{\mathbf{E}}(i) &= \mathbf{C}(i)\mathbf{z}(i)\end{aligned} \tag{4}$$

Routinely solving the dynamical RSS filtration problem (4) for the current $(i+1)$-st discrete-time prediction-estimation step, we obtain the desired DARR technique

$$\begin{aligned}\hat{\mathbf{z}}(i+1) &= \mathbf{m}_{\mathbf{z}}(i+1) + \acute{\mathbf{O}}(i+1)\left[\hat{\mathbf{v}}(i+1) - \mathbf{H}(i+1)\mathbf{m}_{\mathbf{z}}(i+1)\right];\\ \ddot{\mathbf{E}}(i) &= \mathbf{C}(i)\mathbf{z}(i)\end{aligned} \tag{5}$$

where $\mathbf{m}_{\mathbf{z}}(i+1)$ represents the predicted mean vector and the optimal dynamic filter operator $\acute{\mathbf{O}}(i+1)$ is defined as follows,

Figure 1. Simulation results of hydrologic electronic map (HEM) extraction from the original super-high-resolution image reconstructed with the proposed DARR method.



(a) – Original super-high-resolution image.

(b) – HEM-W extracted from the original scene image reconstructed with the proposed DARR method.

(c) – HEM-WH extracted from the original scene image reconstructed with the proposed DARR method.

(d) – HEM-WHD extracted from the original scene image reconstructed with the proposed DARR method.

$$\begin{aligned}
&\acute{O}(i+1) = \mathbf{K}_{\acute{o}}(i+1)\mathbf{H}^{T}(i+1)\mathbf{P}_{i}^{-1}(i+1)\ ;\\
&\mathbf{K}_{\acute{o}}(i+1) = \left[\emptyset_{\acute{o}}(i+1) + \mathbf{P}_{z}^{-1}(i+1)\right]^{-1}\ ;\\
&\emptyset_{\acute{o}}(i+1) = \mathbf{H}^{T}(i+1)\mathbf{P}_{i}^{-1}(i+1)\mathbf{H}(i+1)\ .
\end{aligned} \tag{6}$$

Last, using the derived filter equations (4), (5), we finally obtain the DARR optimal filtering procedure for dynamic reconstruction of the desired RSS map in the current discrete time $i = 0, 1, \ldots$

$$\ddot{E}(i+1) = \ddot{O}(i)\hat{z}(i) + \acute{O}(i+1)\left[\hat{v}(i+1) - \mathbf{H}(i+1)\ddot{O}(i)\hat{z}(i)\right];\ i = 0, 1, \ldots \tag{7}$$

with the initial condition, $\ddot{E}(0) = \Lambda\{\beta(0)\}$. The crucial issue to note here is related to model uncertainties regarding the particular employed dynamical RSS model (2), hence the corresponding uncertainties regarding the overall dynamically reconstructed RSS (7). These issues require more investigations and are the matter of further studies.

V. SIMULATION EXPERIMENT AND DISCUSSION

The results of the simulation experiment are summarized in Figure 1. The Figure 1.a shows the original super-high-resolution image, displaying the dam named "Las Pintas" in the Metropolitan area of Guadalajara in Mexico.

In Figure 1.b, 1.c and 1.d we present the simulation results of dynamic reconstruction-filtration of a particular RSS that represents the so-called *Hydrologic Electronic Map* (**HEM**) extracted from the reconstructed images $\{\hat{v}\}$. The HEMs are specified as follows:

1. **HEM-W** (Water content) map that represents the water content zones extracted from the original super-high-resolution image reconstructed with the proposed DARR method. The watered zones are shown in black. All white regions represent non-classified zones.
2. **HEM-WH** (Water and humidity content) map that represents the water content zones (black regions) and the humidity content zones (gray region) extracted from the original super-high-resolution image reconstructed with the proposed DARR method. All white regions represent non-classified zones.
3. **HEM-WHD** (Water, humidity and dry content) map that represents the water content (black region), the humidity content zones (gray region) and the dry content zones (gray region) extracted from the original super-high-resolution image reconstructed with the proposed DARR method. All white regions represent non-classified zones.

The purpose of this research was to investigate the possibility to perform the dynamic RSS filtering in the realistic conditions of minimum prior model knowledge regarding the dynamical behavior of the particular RSS. The dynamic HEM information was used iteratively applying the DARR algorithm (5), (6), (7).

The reported results qualitatively demonstrate that with proper adjustment of the degrees of freedom in the general DARR algorithm (5), (6), (7), it is possible to predict the dynamic behaviour of the HEMs. The detailed investigation of application of the developed DARR method to resource management is the matter of the perspective studies.

V. CONCLUDING REMARKS

In this paper, we have presented the dynamical aggregated robust regularization (DARR) approach for solving the nonlinear inverse problems of high-resolution dynamical reconstruction of the SSP and RSS of the remotely sensed scenes via processing the finite-dimensional space-time measurements of the available sensor system signals as it is required, for example, for enhanced RS imaging/scene mapping with imaging radar/SAR. We have developed the dynamical RSS post-processing scheme that reveals some possible approach toward a new dynamic computational paradigm for high-resolution fused numerical reconstruction and filtration of different RSS maps in current time. In future work, we intend to develop a family of such dynamical versions of the DARR-based algorithms for updating the relevant RSS maps in current discrete time.

Ensuring Equal Access to Technology: Challenges of Providing Assistive Technology Service for Individuals with Disabilities

Hwa Lee, Bradley University, 1501 W. Bradley Avenue, Peoria, IL 61614, USA; E-mail: leehwa@bradley.edu
In Lee, Western Illinois University, Stipes Hall 431, Macomb, IL 61455, USA; E-mail: I-Lee@wiu.edu

With the passages of landmark laws such as the Americans with Disabilities Act (ADA) and the Individuals with Disabilities Act (IDEA), equal access to technology for all individuals regardless of their abilities or disabilities has been getting increasing attention in the field of education and rehabilitation. The Technology-Related Assistance for Individuals with Disabilities Act (Tech Act, 1988), and the Public Law 105-17 the IDEA amendments of 1997, define assistive technology (AT) device as any item, piece of equipment, or product system that is used to increase, maintain, or improve the functional capabilities of a child with a disability (IDEA 1997). AT devices are typically categorized as no technology, low technology, medium technology, or high technology depending on the existence and level of sophistication in the included electronic components. An AT item can be as low-tech as the Dycem mat, which is a non-slippery material used to prevent objects from tipping or slipping, or as high-tech as the Pathfinder which is a highly sophisticated communication device. AT devices can also be classified into a number of categories based on how they assist individuals in meeting the tasks that are demanded by different environmental settings (i.e., computer access aids, communication aids, daily living aids, education and learning aids).

Considering a continuum of assistive technology items and services for individuals with disabilities is a recommended practice in the field of rehabilitation and education. However, due to the vagueness of the current laws and lack of clear guidelines on how the service should be provided, service providers at education and rehabilitation agencies are faced with challenges of developing effective AT service delivery system on their own. While funds for AT has been decreased, it is still the intent of the laws that school professionals consider AT as an option for students with disabilities. Once professionals identify the needs for the use of any AT item on the Individualized Education Plan (IEP), they must provide the item at no cost to parents (IDEA 1997). School and rehabilitation professionals are faced with additional challenges of evaluating the technological needs of individuals with disabilities and identifying the appropriate AT items that will increase their functional capabilities in the settings of home, school, and community. In other words, AT items can function as an equalizer that will enhance the independence and freedom of individuals with disabilities.

Given the fact that rehabilitation and education agencies attempt to fulfill the intent of the laws regardless of these challenges, the purpose of this case study is to examine how a number of rehabilitation and education agencies provide assistive technology services to individuals with disabilities. An instrumental case study method (Stake, 1995) will be used to examine how AT service delivery system is developed and functions. Case study research method is widely used to investigate a phenomenon in its real-life context (Yin, 1984). Using a purposive sampling method, five to ten agencies in a Midwestern metropolitan city have been identified for the case study. These agencies provide AT services for individuals with disabilities between the ages of birth to 21. A professional who is responsible for coordinating AT service at each agency will be contacted. Data sources include interviews, site visit, and document review. A face to face interview will be conducted using a semi-structured questionnaire that contains items including the population served, funding sources, staffing pattern, evaluation procedure, purchase/lease procedures, technology training, inventory, device/equipment lending policy, and challenges and barriers to providing effective assistive technology services. In addition, documents such as evaluation models and AT inventory will be collected with the consent of each agency. Data will be analyzed using both quantitative and qualitative methods. Findings from this study will shed lights on the development of effective AT teams by education and rehabilitation agencies where the administrators are either in the process of or at the planning stage of developing AT service team. In addition, it is expected that the findings from this study will enable researchers to develop a structured survey for a larger scale research to examine the factors that are associated with effective AT service delivery and utilization.

MIS Shaped by Business Process Models

James Perotti, Rochester Institute of Technology, USA; E-mail: jperotti@cob.rit.edu

Many of today's dominant global businesses have achieved their successes by being better integrated, better coordinated, better focused than their competitors. Many of their leaders attribute these characteristics to a process orientation; top management explicitly designed an organizational structure reliant upon integrated processes to coordinate the efforts of the organization. That coordination and that process structure are built upon and reliant upon software process models.

Business colleges can ill afford to ignore this growing phenomenon. The integrated business structures and practices should be reflected in an integrated, process focused curriculum. This paper will attempt to justify the business process focus and will then propose a model curriculum based on that process focus.

THE PROCESS FOCUS

During the last decade, management emphasis was directed to adding value (Boulton, Libert, Samek, 2000). Bolstering that emphasis was the relatively recent definition of a business model which included a value proposition, the market segment, the value chain structure, revenue generation, and the position in the value network. This business model, in other words, included a larger process view of business. It forced managers to consider the importance of their relationships with partners, to think about how best to coordinate the whole supply chain process to maximize adding value.

The e-business phenomenon also created an emphasis on business process and on process models. The ideal e-business ventured on being completely automated, e.g., Ditech.com, PriceQuote.com. Web-linked businesses are commonplace; they are now categorized as Business to Business, business to consumer, portals, auction sites, etc. Business authors clearly noted and commented about automated business processes in which : "the systems…don't just track the process, they contain and perform it" (Treacy & Wiersma, 1995). The re-engineering craze brought further notoriety to the process approach—although, in the end, re-engineering quickly faded from the management scene.

The supply chain management process has achieved such prominence that, by itself, it is largely the justification for a process focus. Thanks to publicity from organizations such as AMR research, the benefits of that approach can to be noticed and widely adopted. AMR research annually publishes a list of the "Top 25" businesses using supply chain management software; the criterion for making the list is market performance for that year. For 2005, the top five were Dell, Proctor and Gamble, IBM, Nokia, and Toyota. The list is impressive. Here are some of the reasons why businesses feel it imperative to adopt supply chain management, a process approach to their business:

- The top 10 percent of SCM performers in any industry use half the working capital per unit of sales than their median competitors (Source: University of Maryland Supply Chain Management Center)
- The fraction of U.S. GDP tied up in inventory and SCM costs has dropped by 40 percent (The Economist). The amount tied up in distribution and transportation has halved, from 19% to 9% of GDP.
- "Supply chain excellence" companies use 15% less inventory, have 35% shorter cash-to-cash cycle times and 60% higher margins than the average large firm (AMR Research).

What is distinctive about some of the best businesses in the world is how well coordinated they are. Dell, for example, has excellent synchronization of it supply chain, resulting in the fastest possible inventory turns. Wal-Mart, too, has a tightly integrated supply chain/demand chain that extends from customers back to a multitude of suppliers. Southwest airlines, competing in a horribly unprofitable industry, makes money by its standardization of operations and its highly choreographed processes. All three use information technology to coordinate their operations, culture, and knowledge base; all three are designed to focus every employee on the big coordinative strategy delivery. Finally, Peter Keen emphasizes that all three "have an explicit enterprise coordination design, owned by top management" (Keen, 2004).

AMR is quick to point out, these are more than supply chain models, they are "Demand Driven Supply Networks" (DDSN).(Caruso, Cecere, & O'Marah, 2006) The business process is embedded in the process model software; the model is a network which links the complete flow, from suppliers to customers. "The demand signal, " i.e, customers' demand for new features or products, is monitored with dashboards, scorecards, alerts and reports which are shared with all partners. With these process models companies can influence and shape demand, not just respond to it. Product innovations are based on a deep understanding of the customers; feedback from customers—AMR terms the software a "supply network" to indicate the partners' collaborative efforts to seize market opportunity (Caruso, Cecere, & O'Marah, 2006).

PROCESS MODELS

According to Peter Keen. "A business process is an organizational routine with clearly identified tasks and responsibilities that is: recurrent, replicable, consequential, leveragable, and well coordinated" (Keen, 2004). A process model is a representation of that entire process with its suppliers, producers, distributors, partners, and customers clearly displayed, and with outcomes and costs measured at each step in the workflow. Process models which feature dashboards measuring performance, graphic displays of performance trends are a great help to the process teams and to supporting managers.

The better models include visual displays of parts or all of the model; the lesser models rely on metrics only.

There is a growing body of practitioners, software vendors, and researchers who have created a business cognate area called Business Process Management (BPM). Here is the definition posted at Wikipedia.com:

Business Process Management *(or* **BPM***) refers to activities performed by businesses to improve their processes. While such improvements are hardly new, software tools called business process management systems have made such activities faster and cheaper. BPM systems monitor the execution of the business processes so that managers can analyze and change processes in response to data, rather than just a hunch. BPM differs from business process reengineering, a technique popular in the 1990s, in that it deals not just with one-off changes to the organization, but long-term consequences.*

Note the emphasis that BPM places upon the BPM software which enables the process-focused business. To fill out this coverage of process modeling, here is a description of a leading BPM vendor's software suite. Note that Savvion's software does much more than build process models; it integrates other software, integrates the process workflows, monitors them, controls the process, and provides a platform for improving the process.

A comprehensive Business Process Management platform provides an organization with the ability to collectively define their business processes, deploy those processes as applications accessible via the Web that are integrated with their existing software systems, and then provide managers with the visibility to monitor, analyze, control and improve the execution of those processes in real time. (Savvion's Web Site)

Process Models have become very sophisticated. Software vendors, such as IBM and Savvion, sell process model software that does much more than mirror the process. The best supply chain software models not only monitors the flow of activities, the software "executes" or runs the process, meaning by that the process model orders the supplies (and pays the vendors), schedules production, arranges distribution or shipping, and verifies delivery at the retail outlets. That ability to run the process has been extended to the capability to simulate improvements to the process model—and this is how process innovations can occur. Since both time and cost are measured at each step of the process, trading off resources for time savings can be simulated and decided upon.

Toyota is the most publicized example of a process-based business. Toyota's profits are greater than Ford, GM, and Chryslers' combined income over the previous five years (Liker, 2004). While Toyota's "Lean Manufacturing" is its best known process, it is one of many process models. Toyota is spending an estimated $1 billion to implement a massive information technology system that will model every aspect of the cars' designs, production sequences, just-in-time parts availability, and the distribution to the dealers. This shared process model platform is the foundation for the collaboration and coordination to which Toyota's managers attribute its success. Volkswagen's CIO tells us:" The vehicles and factories are all digital—all based on digital models." (Hoch & Laartz, 2006).

The automotive industry is fully committed to process modeling, indeed manufacturing as a whole has long understood itself as a process. Now most managers understand the message of supply chain management, i.e., that linking suppliers, partners, producers, and customers is the accepted way. But there are many tasks that can be turned into organizational routines and, as they are streamlined and standardized, they become processes. Here are examples: travel and expense reporting and processing, employee benefits management, procurement, any handling of forms or contracts. Defining and modeling these routines, then creating software applications can make them much less bureaucratic, much simpler and faster.

PROPOSING CURRICULA BASED ON A BUSINESS PROCESS APPROACH

Again, the major premise here is that the curriculum should reflect current business practice. And it has been shown that a business process approach is a distinctive competency of many, many excellent businesses. Colleges need to prepare their students for this evolving business context. What follows is a suggested MIS curriculum which could pilot the concept. The training in Web Services, Rules Engines, and Process Design are easily generalizable into many different careers. Should this MIS curriculum become accepted, it could lead to the fully integrated business college curriculum described below. The business accrediting agency, AACSB, has long urged colleges to integrate their functional departments and curricula into a coherent whole. Here is one way.

SAMPLE MIS MAJOR: ARCHITECTING AND DESIGNING A PROCESS-MODEL DRIVEN BUSINESS

1. Overview of business processes, process models, and vendors' suites
2. ERP: Web Services to deploy data from ERPs to new apps
3. Definitions and Design in a process model: XML, SOA, WSDL, Schema building, Ontology
4. Web Services (WSFL) to integrate workflows & design Process Models
5. Designing Processes & building Process Models using donated software
6. Creating Business Rules in a donated "Rules Engine"—Business Decision-making in context.
7. Adding Monitoring tools: metrics, dashboards, alerts
8. Seminar: Strategic directions in MIS enabled businesses

SUGGESTED BUSINESS COLLEGE CORE CURRICULUM

1. Conceptual Bases: Re-engineering, Business Process Management, Demand Driven Supply Networks, Management Innovation(Hamel & Keen), using studies of Toyota, Dell, e-businesses
   a. Strategic Management
   b. Operations Management
   c. Entrepreneurship
   d. Management of Innovations
2. Managing the transition from functional jobs to process teams
   a. Management
   b. Human Resource Management
3. Learning from the models: Building Metrics, dashboards, alerts.
   a. marketing research from the demand signal on price, shaping demand
   b. Accounting studies of trade-offs of cost vs resources, added value
4. The Process Model as a workbench for analyses and simulations
   a. Decision Sciences
   b. Marketing,
   c. Accounting
5. The Rules Engine shapes the process and gives the business its edge
   a. Management and business rules
   b. Decision Sciences
   c. Accounting

International Research on Web Accessibility for Persons with Disabilities

Terry Thompson, University of Washington, USA; E-mail: tft@u.washington.edu
Sheryl Burgstahler, University of Washington, USA
Elizabeth Moore, University of Washington, USA
Jon Gunderson, University of Illinois at Urbana-Champaign, USA
Nicholas Hoyt, University of Illinois at Urbana-Champaign, USA

ABSTRACT

The current research establishes a global benchmark for web accessibility by evaluating 8557 higher education home pages and 6872 national government web pages for 181 United Nations member states. Results show that overall, web pages around the globe have room for improvement on all rated dimensions of accessibility. Fewer than half of the items assessed on any criterion received a "pass" rating. There is very little difference overall between education and government pages on accessibility. However, there are significance differences by country. Cluster analyses revealed a group of 39 countries whose web pages are significantly more accessible than others, and a subgroup of ten countries whose pages are especially more accessible. The correlation between web accessibility and demographic variables provides insights into the characteristics of the more accessible countries.

Keywords: Internet, International, Web, accessibility, accessible design

INTERNATIONAL RESEARCH ON WEB ACCESSIBILITY FOR PERSONS WITH DISABILITIES

Researchers undertaking disability-related studies across nations and cultures face fundamental challenges. First, there is no universal concept of disability. Although physical, sensory, cognitive, and psychological impairments occur universally, there are differences in how nations and cultures explain these impairments and respond to them (Ingstad & Whyte, 1995; Retish & Reiter, 1999; Iwakuma & Nussbaum, 2000). Some languages include labels for individual disabilities, but have no single term that encompasses all disabling conditions (Ingstad & Whyte, 1995). World Health Organization (WHO) has created a common cross-cultural classification system that attempts to address this problem by expressing disability in terms of body/impairment-related functions and the effect of social and environmental factors (WHO, 2001). WHO estimates that 10% of the world's population (approximately 600 million people) meets this definition (WHO, n.d. 1).

For cultures that have embraced or are beginning to embrace technologies such as the Internet, the ability of persons with disabilities to participate is significantly impacted by the accessibility of these technologies. Technology is made accessible in part by people with disabilities using assistive technologies—specialized tools that allow people with disabilities to perform functions that they otherwise would be unable to perform at all or without extreme difficulty. Assistive technologies related to computer access include screen-reader software for people who are blind or dyslexic and speech input systems for people who are unable to operate a mouse or keyboard. There are tens of thousands of assistive technologies available (ABLEDATA, n.d.), and those that process language (either as input or output) are available in dozens of languages and dialects. However, there are still significant gaps in availability of assistive technology for poorer nations and in smaller language markets. WHO estimates that only 5-15% of people who require assistive devices and technologies in low- and middle-income countries have access to them (WHO, n.d. 2).

A second requirement for technology accessibility concerns the actual design of the technology device or system. On the Web, visual images are inaccessible to blind users unless the images are encoded with alternate text, which is read by screen readers and Braille output devices; multimedia content is inaccessible to users with hearing impairments unless captioned; and features that require a mouse are inaccessible to users who are unable to use a mouse.

The problem of web accessibility becomes larger as the web itself becomes larger and plays a growing critical role in commerce, education, and the dissemination of information and services worldwide. The Computer Industry Almanac (2006) estimates that over one billion people worldwide use the Internet, expected to top two billion by 2011. At the start of the new century, approximately 50 percent of economic production in Organization for Economic Co-operation and Development (OECD) countries was generated by knowledge-based industries (United National Development Programme, 2001). The Internet also plays a key role in the inter-country transfer of beliefs, knowledge and experiences, including those related to disability (Mitchell, 1999).

The Internet has potential to provide enormous benefits to individuals with disabilities worldwide, allowing them to communicate, learn, work, and participate in society in ways that might otherwise be unavailable. However, it can also become a significant barrier. To address the problem, the World Wide Web Consortium (W3C), an international organization that develops interoperable specifications, guidelines, software, and tools for the web, has developed the Web Content Accessibility Guidelines (WCAG). Version 1.0 of the WCAG (W3C, 1999) provides definitive guidance on how to develop accessible websites, and is comprised of 14 guidelines, each of which is further explained using specific checkpoints. There are a total of 65 checkpoints, with each assigned a priority level of 1, 2, or 3, where Priority 1 checkpoints are the most critical for accessibility. The WCAG provides the basis for many policies, guidelines, and laws related to web accessibility worldwide. The W3C maintains a growing archive of national laws and policies, which as of January, 2007, includes 19 countries/regions (W3C, 2006).

The United Nations has worked for decades to promote accessibility, and has recently extended these efforts to include technology accessibility. On December 13, 2006, the United Nations General Assembly adopted a Convention on the Rights Of Persons With Disabilities (United Nations, 2006), which prohibits discrimination against persons with disabilities in all areas of life. Article 9 of the Convention specifically calls for State Parties to ensure that persons with disabilities have access to information and communications technologies and systems.

Despite the leadership of the United Nations, the availability of international web accessibility standards, and national laws and policies related to web accessibility, published studies have reported widespread inaccessibility of websites across a variety of societal sectors, including postsecondary education institutions in the United States (e.g., Jackson-Sanborn, Odess-Harnish, & Warren, 2002; Odess-Harnish, 2001; Opitz, Savenye, & Rowland, 2003; Walden, Rowland, & Bohman, 2000; Zaphiris & Ellis, 2001; Schmetzke, 2001, 2002a, 2002b, 2002c, 2004; Thompson, Burgstahler & Comden, 2003; Williamson, 2003; Hacket, Parmato, & Zeng, 2003), Australia (Alexander, 2004), the United Kingdom (Kelly, 2002; Witt & McDermott, 2004), and Ireland (McMullin, 2002); as well as government websites in Taiwan (Chen, Chen, & Shao, 2006) and the United States (Hacket, Parmato, & Zeng, 2004); and websites across all sectors in Cyprus (Zaphiris & Zaphiris, 2001).

The United Nations commissioned the first global report on web accessibility (Nomensa, 2006). The survey was "not intended to be exhaustive", and sought to obtain a "snapshot" of global web accessibility from a sample of 100 home pages across 20 countries. Only three of the pages in the sample met all Priority 1 WCAG 1.0 checkpoints, and 93% did not provide adequate text descriptions for graphical content, thereby creating barriers for people using screen reader software. The present study seeks to extend this effort with a more extensive global assessment of web accessibility, focusing specifically on higher education and national/federal government web pages worldwide and identify demographic predictors of web accessibility.

The following specific research questions are addressed in the present study:

1. Are there significant differences in the accessibility of web pages across countries?
2. Are there significant differences between higher education web pages and national/federal government web pages on accessibility?
3. Are there demographic predictors of web accessibility that might help us to understand why some nations are more inclined to address web accessibility than others?

METHOD

Selection of Countries and Web Sites

Countries included in this research represent the 192 member states of the United Nations (United Nations, 2006b). Home page Uniform Resource Locators (URLs) from 8557 universities within 162 of these countries were collected from the website Universities Worldwide (Förster, 2006). Additionally, 6872 national/federal government websites from 181 of these countries were collected from the website Worldwide Governments on the WWW (Anzinger, 2002). Of the 15,429 URLs collected, researchers were able to connect to 12,520 pages—7239 higher education pages (57.8%) and 5281 government pages (42.2%).

Selection of a Method for Evaluating Website Accessibility

Most web accessibility studies have used an automated web accessibility evaluation software tool. A few others (e.g., Thompson, Burgstahler, & Comden, 2003) have used a manual evaluation method for greater detail and accuracy. A manual method was not practical given the sample size in the present study, so researchers used the Functional Accessibility Evaluator (FAE), a tool developed by the University of Illinois at Urbana-Champaign (UIUC, n.d. 1). FAE evaluates web resources for markup that is consistent with Web Accessibility Best Practices identified by UIUC researchers (UIUC, n.d. 2). FAE focuses on functional requirements that improve access to all users, including people with disabilities, rather than limiting its scope to a set of technical accessibility standards. This approach helps to address issues of usability as well as accessibility.

Selection of Demographic Variables

The World Bank (2006) annually publishes 900 World Development Indicators (WDI). For the present research, a subset of 355 indicators was selected that included measures related to economics, health, education, and technology.

Hofstede (2001) has developed five independent dimensions of culture, and has scored 40 countries on each of these dimensions. The dimensions include a Power Distance Index (the degree to which less powerful members of society expect there to be differences in levels of power), Individualism vs. Collectivism, Masculinity vs. Femininity, Uncertainty Avoidance (the extent to which a society attempts to cope with anxiety by minimizing uncertainty), and Long vs. Short Term Orientation.

Procedures

Using FAE, each web page was automatically evaluated on 31 rules across the following five categories:

Navigation and Orientation: Inclusion of structural markup that facilitates navigation and contextual orientation, e.g., including an HTML title element, HTML headers, and appropriate accessible markup on forms and data tables

Text equivalents: Proper use of images for interoperability across web-enabled browsers, platforms, and devices; inclusion of text descriptions of non-text content for accessibility to non-visual users

Scripting: Avoidance of scripting techniques that compromise accessibility and interoperability

Styling: Use of cascading style sheets (CSS) to separate content and structural information from styling and presentation.

HTML standards: Conformance to the W3C HTML specification, to improve interoperability.

For each category, each web page received scores reflecting the percent of rules passed and percent of rules failed. FAE also outputs a third score, reflecting the percent of rules for which accessibility can not be programmatically determined, and therefore requires manual inspection. Since manual inspection was not practical for the present study, these values were not used in analysis.

RESULTS

Overall, web pages worldwide have room for improvement on all rated dimensions of accessibility (see Figure 1). Conformance to HTML Standards is the criterion that received the highest rating overall, but the average proportion of "pass" ratings on this criterion is slightly less than half of items evaluated. The criteria on which web pages rate most poorly are Navigation and Orientation (only about one-quarter of the items assessed on this criterion received a "pass" rating) and Scripting (nearly all of these items failed on accessibility).

A cluster analysis was conducted to explore which countries are more similar in their web accessibility ratings. The analysis produced two clusters, one with 39 members and another with 119 members. Figure 2 shows the average "pass"

Figure 1. Overall level of accessibility

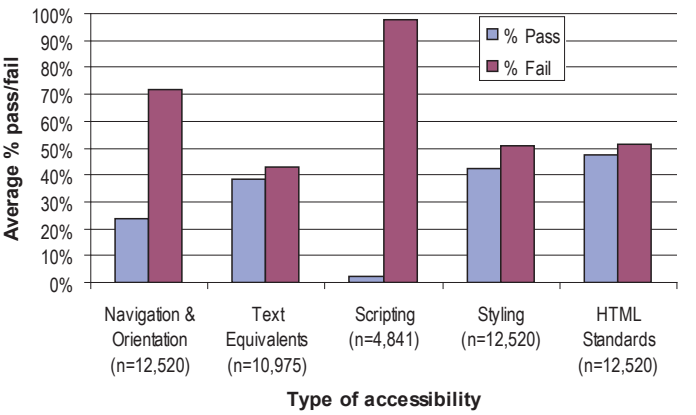

Figure 2. Average "pass" rate on each criterion by cluster group

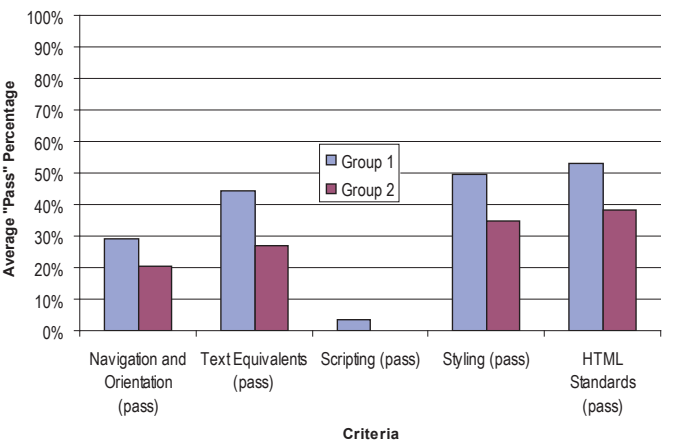

Table 1. Accessibility data for the "Top Ten" group of countries

					% Pass rating				
	# EDU pages	# GOV pages	Total pages	# with Scripting	Nav & Orientation	Text Equivalent	Scripting	Styling	HTML Standards
Australia	50	113	163	53	39%	64%	2%	59%	63%
Czech Republic	24	40	64	13	37%	60%	0%	61%	61%
Congo, Dem.Rep.	3	0	3	2	46%	67%	0%	55%	44%
Ireland	21	78	99	27	31%	51%	22%	48%	60%
Marshall Islands	0	1	1	1	75%	50%	0%	40%	66%
New Zealand	8	84	92	33	46%	62%	0%	53%	64%
Spain	74	70	144	33	34%	52%	8%	64%	59%
Sweden	32	122	154	36	41%	40%	3%	54%	68%
Switzerland	35	65	100	28	41%	44%	5%	54%	65%
United Kingdom	156	290	446	99	43%	64%	11%	57%	71%

rate of the countries in cluster groups 1 and 2 on the criteria used to classify the groups. The group of countries in the first cluster has a higher percentage of "pass" ratings on each of the accessibility measures. Detailed assessment results for each country, including cluster group membership, is available at http://staff.washington.edu/tft/research/international.html.

Additional analysis with country demographic information creates a profile of the countries that have greater accessibility. Group 1 countries, those with more accessible web pages, are countries with more money and with more investment in information and communication technology both publicly and in individual spending. More of the people in Group 1 countries have personal computers and more use the Internet. According to Hofstede's cultural ratings, Group 1 countries have Power Distance Index (PDI) ratings 29% lower than in Group 2, and ratings on Individualism vs. Collectivism (ICI) twice that of those in Group 2. A low PDI rating indicates a strong belief in equal rights held by all members of the society (Group 1 countries also have a higher percentage of women holding a seat in a national parliament). Group 1 countries also have a larger urban population (and a much smaller percentage of the labor force works in agriculture). These countries spend more money on health care and education, and their population lives longer and are more likely to complete school.

A second cluster analysis was performed on Group 1 countries, which further broke this group into two clusters based on web accessibility, revealing a "Top Ten" group of countries which received a higher percentage of "pass" ratings on all accessibility criteria except for scripting. Two of the countries in this group had very low numbers of web pages in the sample. However, the remaining eight countries are the accessibility leaders as measured by this study. Table 1 provides detail on the top ten countries' web accessibility ratings.

Analysis of the demographic factors used above to describe differences between Groups 1 and 2 did not reveal statistically significant differences between the Top Ten and other Group 1 countries in these characteristics. This could reflect the small number of countries included in the analysis, or it could mean that the factors that account for these differences are not embodied in or related to the items included in the analysis. Some factors that could be important but not represented here might include web accessibility initiatives promoted by the national government, or an active organization working to heighten awareness of the needs of people with disabilities, or school curricula that teaches students to consider varying perspectives and varying needs.

Comparison of Higher Education and Government Web Pages

Higher education and government web pages are similar in their accessibility. Government pages performed slightly better in Navigation and Orientation and education pages performed slightly better in HTML Standards. There is little difference in accessibility of Scripting. However, 43% of higher education web pages use scripting, as opposed to only 33% of government pages. This may imply that educational institutions are showing leadership in the adoption of scripting technologies, but without corresponding leadership in accessibility.

Correlations Between Accessibility and Country Demographics

Correlation analysis yields similar results to those attained in the above profile of the Group 1 cluster of countries. A higher "pass" rate across all web accessibility criteria (except in a few cases Scripting, which is suspect because of its poor distribution) is strongly and positively correlated with GDP per capita sales; number of bank branches per 1000 people; value of commercial service imports and exports; both expenditures and receipts on international tourism; per capita expenditure on information and communication technology; per capita health expenditure; female life expectancy; percent of population 65 and above; percent of urban population; use of electricity per capita; number of personal computers, secure Internet servers, and telephone mainlines per 1000 people; number of Internet users; number of mobile phone subscribers; price basket for residential fixed line; and Hofstede's Individual vs. Collective Index (high individualism is associated with greater accessibility). Correlation statistics on these variables range from $r=.29$ to $r=.69$ at $p<.001$. Hofstede's Power Distance Index was strongly negatively associated with web accessibility, which means that more hierarchical countries (less equality) tend to perform more poorly on accessibility (statistics range from $r=-.24$ to $r=-.59$).

Strong and positive correlations were found between secondary and tertiary school enrollment and accessibility. However, surprisingly, few other education demographics correlated significantly with web page accessibility.

DISCUSSION
