The correlation findings in the present study suggest that two types of conditions may promote attention to accessibility. One is the level of media use, influenced by the type of commerce important to the country, such as those requiring international communication (tourism, commercial service imports and exports) or by the sheer prevalence of electronic devices among the people. These factors may be related to other correlates of web page accessibility, such as the country's wealth and investment in information and communication technology. The other type of condition these data suggest may promote attention to accessibility is a culture's and government's values regarding individual rights, and the social contract stipulating the relationship between the government and the people. These can be seen in the relationship between Hofstede's PDI and ICI indices and accessibility, as well as the relationship between public health care expenditures and accessibility.

The present study also identifies countries that may employ promising practices. Given the performance of the "Top Ten" countries relative to other countries, a deeper exploration of each of these countries is a logical next step, although even these countries' results show considerable room for improvement.

At least six of these countries (Australia, Ireland, New Zealand, Spain, Switzerland, and the United Kingdom) have laws and/or policies protecting the rights of individuals with disabilities and/or requiring accessibility of electronic communications (W3C, 2006). However, other countries have similar laws, yet did

not perform as well in the current assessment. Further research is required to gain a deeper understanding of the legal, political, social and cultural factors that contribute toward a nation's embracing web accessibility.

This study provides a starting point for understanding the global state of web accessibility. Hopefully a deeper understanding will stimulate dialog and international collaboration, as all nations work toward creating a World Wide Web that is accessible to everyone, including the estimated 600 million people who have disabilities.

Antecedents of Online Trust and Acceptance of E-Commerce

INTRODUCTION

The impact of computer technology has transformed business practices and creation of e-commerce, such as online retailers. However, consumers tend to be reluctant to provide personal information to Web sites because they are unsure if they can fully trust online merchants. Consumer tends to feel uncomfortable engaging in a transaction over the internet with unfamiliar vendors (Gefen and Straub 2002). Previous research has also found that 95% of the consumers have declined to provide personal information to websites because of the lack of trust on those collecting the data (Hoffman at al. 1999, p. 82). McKnight et al. (2002) assert that there is another perception of technology beyond the widely accepted technology acceptance model (TAM). Hence, the trust issue is rooted in security and privacy which has been labeled a key concern of e-commerce by consumers (Miyazaki and Fernadez, 2000). In this study, we build upon the research proposed by McKnight et al. (2002) on understanding the antecedents of trust. We explore factors such as consumers' perceptions of information security, privacy, trust, and their acceptance of e-commerce. Specifically, we are examining the effects of having a third party organization/web seal, and also privacy and security statements on the adoption behavior of electronic commerce.

THEORETICAL BACKGROUND

Trust, according to Pavlou (2001), in electronic transactions context is defined as the subjective probability that customers believe an organization's technology infrastructure and control mechanisms are capable of carrying out transactions that are meeting customers' expectations. Other researchers have included trust as an additional construct in TAM and their findings demonstrated the relationship between trust and adoption intention (McCloskey, 2006; Dahlberg, Mallat, & Oorni, 2003; Pavlou, 2003; Suh & Han, 2003; Keat & Mohan, 2004). McKnight et al. (2002) discusses various forms of trust issues e.g. initial trust, institutional-based trust, trust-related behaviors including trusting intentions and trusting beliefs. Trusting beliefs is defined as the confidence perception that a vendor has attributes that are beneficial to the consumer. These beliefs are competence, benevolence and integrity (Battacherjee 2002, Gefen 1997, Mayer et al. 1995). Trusting intention on the other hand, refers to the willingness to depend on the vendor. There is an element of "volitional preparedness" to make a consumer vulnerable to the vendor (McKnight et al. 2002).

The objective of e-commerce security is information assurance, which means to maintain confidentiality (privacy), integrity, and availability of information resources for authorized organizations and users (Warkentin, Davis, & Bekkering, 2004). Ensuring security and confidentiality are the fundamental prerequisites before any electronic transactions involving sensitive information can take place (Jayawardhena and Foley, 2000). Many researchers have discussed the element of e-commerce security control requirements (Hutchinson & Warren, 2003; Suh & Han, 2003; Kesh and Ramanujan, 2004). These security elements can be summarized in five categories. They are: authentication, non-repudiation, data integrity, confidentiality, and privacy protection.

Researchers have also found that stable situation-specific personal characteristics such as personal innovativeness in information technology (Agarwal and Prasad, 1998) and risk tolerance such as perceived risk (Lu, Hsu, and Hsu, 2005) influence how individuals perceive information technology. Agarwal and Prasad (1998) define personal innovativeness in the domain of information technology (PIIT) as the "willingness of an individual to try out any new information technology." (p.206). They argue that inclusion of personal innovativeness with respect to information technology acceptance model would help to further understand how perceptions are formed and the subsequent role they play in the formation of usage intentions.

Another personality characteristic, perceived risk has been described as comprising the subjective perception of two components: (1) the amount at stake and (2) the degree of certainty about possible negative consequences. Perceived risks can take many forms, depending on the product and consumer characteristics. Lu, Hsu, and Hsu (2005) incorporated perceived risk in their study about intention to use online applications and concluded that perceived risk plays the key factor in influencing the determinants of online applications adoption.

CONCEPTUAL DEVELOPMENT

Figure 1 shows the proposed research model. We are examining the effects of perceived security, the use of privacy and security statements and third part organization seal while controlling the effects of personal characteristics and organization characteristics on trusting beliefs. Then, we study how these trusting beliefs will affect consumers in engaging e-commerce transactions.

Third Party Organization/Web Seal

To address issues of privacy and trust related to on-line transactions, e-commerce assurance services were created in the 1990s (Wakefield & Whitten, 2006). Third party organizations such as Better Business Bureau®, TRUSTe®, and VeriSign ® are organized to promote trust in e-commerce. Studies found that third party web seal promotes consumers feelings of trust (Palmer, Bailey, & Faraj, 2000; Schneiderman, 2000; Wakefield & Whitten, 2006) and confidence in their e-commerce transactions. Thus, the following hypothesis is proposed:

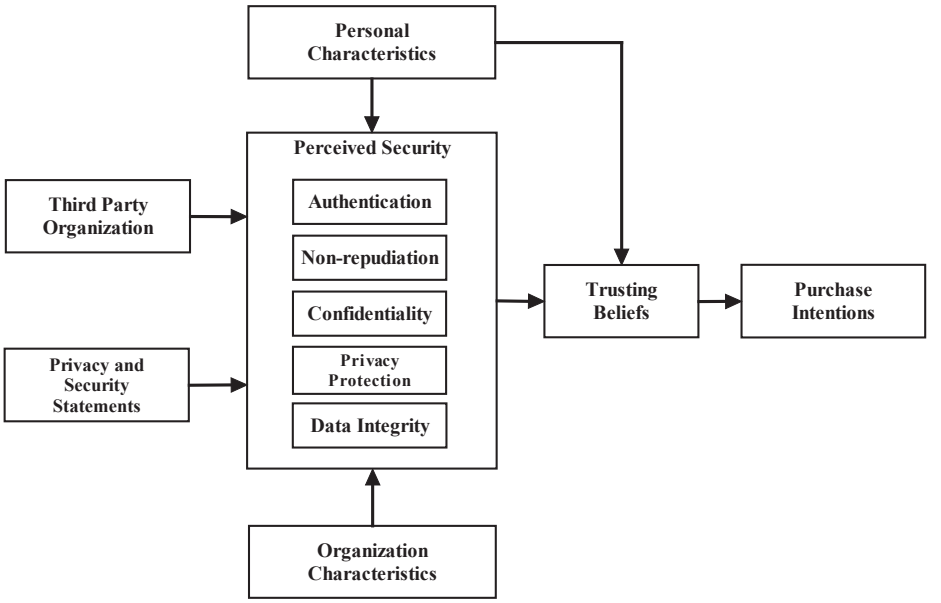
H1: The presence of third party web seal logo has a positive effect on consumers' trust in e-retailer.

Privacy and Security Statements

The ability to monitor and record Internet users' personal information has raised fears about online privacy. According to Federal Trade Commission (FTC) 2000 survey about online privacy, the survey result indicates that 97% of the random sample websites and 99% of the most popular websites collect an e-mail address or some other type of personal information (Federal Trade Commission, 2000). Companies have the ability to collect and follow users' every movement on the Internet by using "cookies" and advanced browser technology. Consumers are concerned about the type of information that is gathered and how this information is being used, and by whom.

Unlike the European countries, where there are laws governing and protecting consumers from being victims of privacy-violating businesses, the United States advocated self-regulation for the Internet. It suggested that businesses should develop and post clearly written policies that inform consumers about who is collecting their personal information and the intended purpose for the collected information. Businesses should also provide consumers with a readily available, simple, and affordable option for exercising their choices with respect to whether and how their personal information is used (Privacy in electronic communications, 1998). Thus, the following hypothesis is proposed for investigation:

Figure 1. Proposed research model



H2: Displaying a privacy and security link on an on-line retailer's home page has a positive effect on consumers' trust in e-retailer.

Perceived Security

Kesh et al. (2002) and Gupta et al. (2004) describe the need of authentication is to "ensure that the origin of an electronic message is correctly identified" (p. 150). The essence of authentication is to make sure the sender of the message or originator of the transaction is the person who he/she claims to be. Authentication reduces the risk of identity theft and fraudulent activities. Non-repudiation refers to the need to ensure that the customers can be certain that they are communicating with the genuine merchant, or vice versa, and each party involved in a transaction will not later falsely deny the transaction (Gupta et al., 2004; Hutchinson & Warren, 2003). Data integrity ensures that only authorized individuals can make changes to the documents transmitted over the network. Integrity ensures the content of the sent message or transaction is the same message or transaction when it is received. Information confidentiality refers to protecting customers' private and personal information to ensure the information is secured and hidden wherever the information is stored, as well as in transit through the Internet. Thus, the following hypotheses are proposed for investigation:

H3: Perceived strength of security has a positive effect on consumers' trust in e-retailer.

Methodology

Instrument Development

Data was collected using a self-administrated questionnaire. Each item presented a statement to which respondents were asked to weigh their level of agreement. All items were measured on a seven-point Likert scale. The measurement items used in this study were derived from validated scales found in previous extant literature, with modified wording to be specific to this study.

Measures for the sub-dimensions of perceived security (SECURITY) were taken from Suh and Han (2003) with modified wordings to adapt the items to the current topic. Measures for antecedents to perceived security were built upon relevant literature. Perceived reputation (PREP) and firm size (PSZE) were derived from Jarvenpaa and Tractinsky (1999). Third-party seal (PTP) and privacy statement perception (GPSS) were modified from Wakefield and Whitten (2006), the privacy statement availability (PPSS) was newly developed items. We differentiated the two based on perception of importance of privacy statement and the availability and presence of such statements. Computer self-efficacy (SEFF), or the confidence and capability of the respondent to use the Internet to make a purchase, was derived from Taylor and Todd (1995). Personal Internet innovativeness (PINN), or the level of respondents' enthusiastic trying out new information technologies and Internet features, was originated from Agarwal and Prasad (1998). Perceived risk (PRSK) was assessed with four items following Jarvenpaa, Tractinsky, and Vitale (1999). These items measured the respondents' perception of there being risk in participating in using online website to make purchase. The measures for trust (TRUST) were based on Pavlou and Gefen (2004). The measures for purchase intention (PINT) sub-dimensions were borrowed and modified from Schlosser, White and Lloyd's (2006) research about online purchase intention.

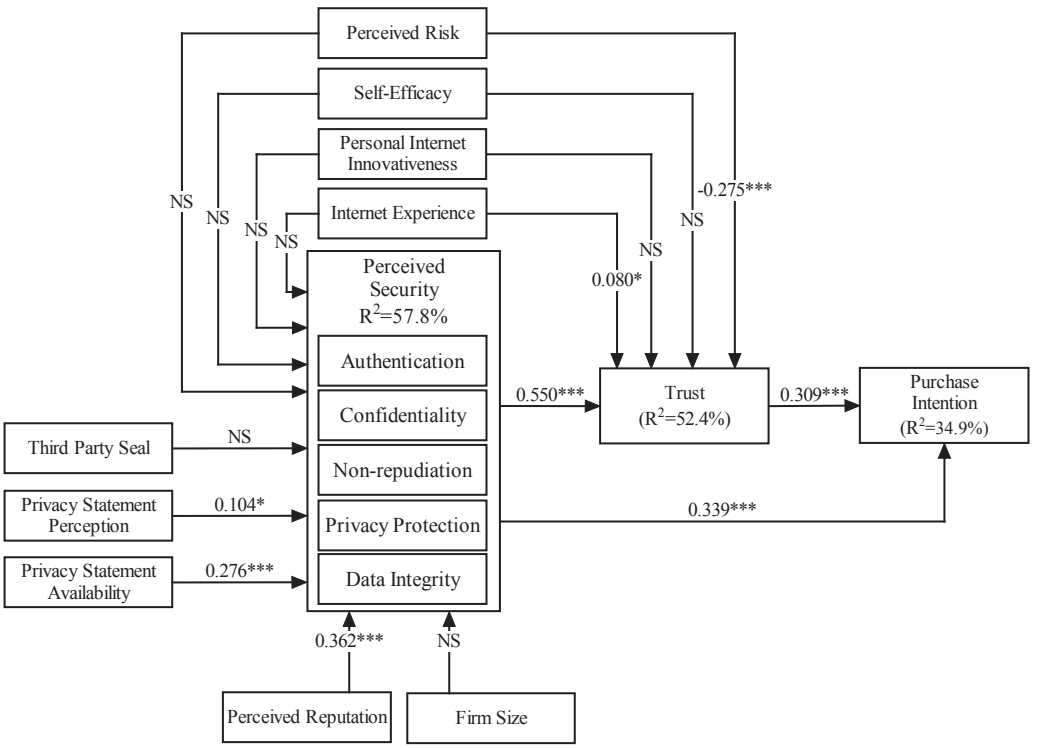
Data Collection

The pool of respondents came from a panel maintained by an online marketing research firm. Invitations were sent out to 4000 panel members. The survey first asked participants to enter the names of three online retailing websites from which they have made a purchase in the past. We randomly picked one entered website and asked participants to answer a series of questions about their impressions of that website. The survey was left open for 14 days. After removing incomplete surveys and surveys that were completed at impossible speed (< 5 minutes), 330 responses were deemed usable giving 8.25% effective response rate. One possible explanation for the low response rate was that there was no reminder e-mail send out to the panel members to remind them to complete the survey. Overall demographic profile of usable respondents: 56% are male with average income of $48,000.

DATA ANALYSIS

From the path model shown in Figure 2, we were able to show strong significance of the availability and presence privacy statements in the perception of security. McKnight et al. (2002) refers to this perception as institutional based trust. Moderate significance was found instead for the perceptions of the importance of these statements. This implies that even though consumers indicate that privacy statements were fairly important, their actions were otherwise, i.e. given the presence

Figure 2. Integrated results of path model



and easily available statements on privacy, it affected their security perception. Perceived reputation is found to be significant in affecting the respondents' perception of perceived security while the presence of third party seal did not influence in their perceptions. The combination of the reputation and third party seal lead us to believe that it is still very important for new websites to develop their reputation and simply putting "artifacts" such as third party seal will not increase the perception of security.

In examining the antecedents for TRUST (Trust in retail website), it is interesting to note that personal characteristics such as innovativeness and self efficacy do not affect TRUST while SECURITY was found to be strongly related to TRUST. In examining the antecedents of purchase intention (PINT), we found significance of both TRUST and SECURITY.

We were able to use Baron and Kenney (1986) method in examining mediating effects. We found that personal characteristics such as perceived risk and internet experience are both mediated by TRUST in purchase intention. Furthermore, we found that signals of privacy statements (GPSS, PPSS) are also mediated by SECURITY to TRUST.

CONCLUSIONS

Based on the data that we analyzed, our research improves on the model suggested by McKnight et al. (2002). We show the antecedents to the institutional based trust model represented by perceived security. We are also able to show the mediating effects of both perceived security and trust for personal characteristics and privacy signals in explaining purchase intention.

E-Commerce and Health Care Web Site Quality: Comparing and Contrasting End-User Perspectives

Cynthia LeRouge, Saint Louis University, USA; E-mail: cynthialerouge@mac.com
Gianluca DeLeo, Saint Louis University, USA; E-mail: gdeleo@odu.edu
Reuven Levary, Saint Louis University, USA; E-mail: levarypr@slu.edu

ABSTRACT

In this study, we explore and compare the importance of various quality dimensions for health care and e-commerce web sites and to identify drivers (e.g. features) of health care web sites that managers can use as levers to improve their web sites. The results show that the importance of various quality drivers for all except two of ten quality dimensions studied differ between health care and e-commerce web sites and that in general, the call for quality among the dimensions studies is higher in health care web sites. On-going work will identify feature and operational drivers associated with customer ratings of e-commerce and health care site quality ratings and illuminate difference in identified drivers between each type of web site.

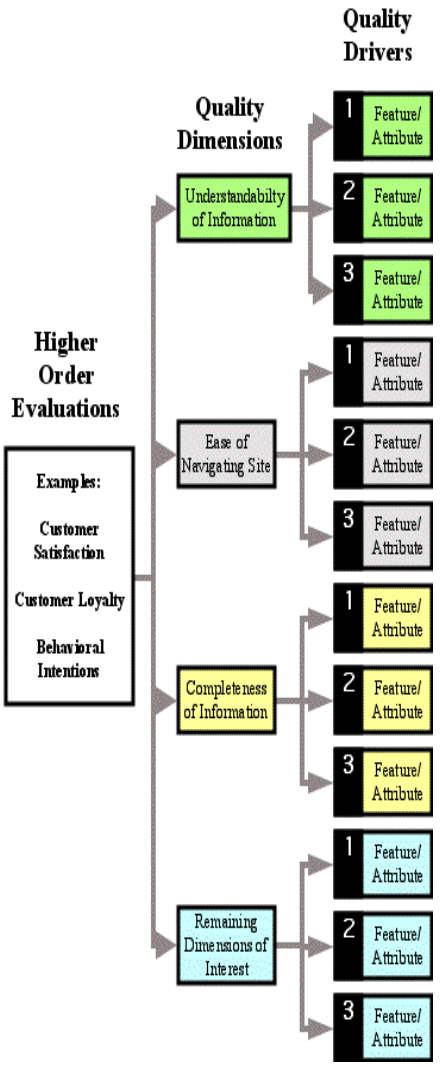
INTRODUCTION

Eysenbach and Kohler (2003) estimated that approximately 4.5% of all search queries submitted to Web search engines are health-related, which is equivalent to a global minimum of 6.75 million health-related searches on the Web every day. With medical professionals referring patients to health care web sites and health organizations initiating the development and management of these sites, some understanding of consumer perceptions of how consumers evaluate the overall quality of such sites is relevant and necessary. Web site designers are traditionally grown from technology fields, such as information systems and are often seasoned in e-commerce environments. Such developers may miss potential nuances in consumer quality perceptions in transporting their skills to new contexts.

Health care site sponsors and developers are increasingly challenged to ensure high quality and good design in their electronic services with tangible guidelines and processes. Research does not seem to provide needed guidance. Piccoli, et al. (Piccoli, et al., 2004 p. 423) lamented the "dearth of research-based insights and guidelines concerning the roles, functionalities, and effective design of Web sites". Zeithaml, Parasuraman, and Malhotra (2002) suggested future research in e-service quality should focus on "… investigat[ing] questions about the importance of different dimensions and perceptual attributes to overall electronic service quality and its consequences" and "… understand[ing] which dimensions are most responsible for driving electronic service quality". Though many researchers have studied how perceptions of individual quality dimensions (e.g., ease of navigation) relate to perceptions of higher order evaluations of overall web site quality (e.g., customer satisfaction), few have studied which features of a web site drive these common quality dimensions (see Figure 1).

Wolfinbarger and Gilly (2003 p. 21) recognize the need to consider site context when they state, "future research should investigate how characteristics of various product categories may affect the importance of the four factors [in their eTail Quality measure] in predicting quality." Research in marketing and information systems (IS) literature on web site quality (e.g. WebQual) does address consumer preferences, but has not typically included application to health care web sites. Existing studies of web site design and quality in the medical literature do focus on health care web sites, but rarely use end-consumers to investigate health care web site quality and often rely on the perceptions of seasoned medical professionals. In summary, current literature does not seem to provide insight on the perceptions of consumers in specifying health care web site quality and attempts to reconcile, bridge, and extend the two literatures is needed.

Figure 1. Web site quality hierarchical model



The overall goal of this study is to understand and improve the design and acceptance of health care web sites based upon consumer perceptions of quality. The study uses e-commerce web sites as a point of comparison. To address this goal, we attempt to (i) determine the priority of various quality dimensions of web site quality for e-commerce and health care web sites (ii) identify specific attributes (drivers) that affect e-service quality dimensions, thereby identifying potential levers for improving web site quality and (iii) examine significant differences between e-commerce and health care sites both in terms of quality dimension ratings and quality attributes identified for each quality dimension.

METHODOLOGY

This study employs quantitative and qualitative methods. Attributes of interest were determined through three group interviews (approximately ten students per interview) with upper division and graduate students in response to the question, "What quality dimensions a health care or e-commerce web site would lead to (visitor satisfaction/promoting desired behaviors by the site sponsors/ consumer site loyalty)." Interviewees were then asked to comment on potential attributes found in the literature that were not included in their responses. The final attribute list was a cross section of the attributes identified by all three groups (see Table 2).

A quality assessment exercise was developed with a focus on the attributes identified. 116 upper division and graduate students in colleges of business, allied health, and public health at two universities completed the exercise. Participants rated the general importance of the ten quality attributes for health care and e-commerce web sites on a low importance to high importance scale of 1 to 5 with 5 anchored as, "*This characteristic is very important to my assessment of this type of web site*". Participants then visited two web sites of each genre and rated the respective web sites according to the ten importance dimensions to provide a focus on context. After rating a quality dimension, participants answered the question, "What would cause you to rate an *e-commerce/health care* site with a high score of 5 for *name of quality dimension* (may be either something present or missing from the site)?

The research team used basic statistics (e.g., means and standard deviations to compare importance ratings of quality dimension) for each type of web site and ANOVA to compare ratings of importance criteria among the web site types. Qualitative open-ended coding procedures to identify drivers (e.g., specific features) that support the quality attributes under study for each type of web site through participant's open-ended commentary is underway. In addition, the team plans to use basic statistical procedures (i.e., means, percentages) to report responses within each group and overall responses evaluating each web site visited and for general insight.

RESULTS AND DISCUSSION

We first identify, compare, and contrast the importance of nine common quality dimensions consumers use to evaluate the quality of web sites applied to both health care and e-commerce sites. An assessment of consumer rankings of these attributes for each type of site is provided in Tables 1 and 2.

The most important dimensions noted for the health care web sites were content related, namely participants want complete, understandable, and relevant information with sufficient detail. On the e-commerce side, consumers seem to want complete and understandable information, but also look to ease of navigation and site reputation as key indicators of site quality. It is interesting that aesthetic aspects of the site (e.g., visual appeal) were among the lower scoring of our ten key attributes, though sensitivity to consumer feelings was more important for the health care site as demonstrated by the .80 statistically significant difference in mean scores.

The range of means across dimensions for health care web sites was generally higher than that of e-commerce web sites perhaps indicating that designers may have a greater call to quality for such sites. Ease of navigating the site and visual appeal of the site showed no significant differences between the genres. However, the mean importance scores for the health care sites were statistically higher than the e-commerce site for all other quality dimensions.

Qualitative analysis is in process. Early results indicate unique aspects of feature drivers for each type of site. For example, for completeness of information, links (to product information, other parts of the site, other items in the general category of goods) was frequently mentioned as a driver for e-commerce sites. In contrast, links were not mentioned as a quality attribute for completeness of information for health care sites. Instead, participants indicated they look for comprehensive, topical article that included information from many sources. Completeness was defined by one participant as, "all a person should know without going to a doctor" which may include the following content mentioned by participants: symptoms, procedures, diagnosis, prevention and treatment content.

In looking at the sensitivity to consumer feelings dimension, e-commerce site drivers included comments such as "geared to all levels of customers", whereas health care site comments indicated they should be "direct, simple to understand term, geared to nonprofessional visitor" and include message boards and live events. With respect to graphics, multiple comments for sensitivity in e-commerce sites indicated e-commerce designers should include pictures of "real members" of the target audience using products. Comments about health care site graphic content, with respect to sensitivity, indicated sites should show photos should represent a target audience, but also be "non-offensive, non-discriminating, non-personal, and non-judgmental." Our final results will further identify feature drivers associated with consumer ratings of e-commerce and health care site quality ratings.

Table 1. Importance ratings of e-commerce and health care quality dimensions in order of highest rating

E-Commerce	Mean	Std. Deviation	Health	Mean	Std. Deviation
Understandability of Information	4.57	±0.514	Completeness of Information	4.90	±0.295
Ease of navigating Site	4.50	±0.640	Understandability of Information	4.85	±0.380
Completeness of Information	4.37	±0.655	Relevancy of Information	4.59	±0.661
Site Reputation	4.04	±0.921	Level of Information Detail	4.51	±0.691

CONCLUSION

The overall goal of this study is to understand and improve the design and acceptance of health care web sites based upon consumer perceptions of quality. We provide guidance for the development and assessment of quality e-commerce and health care web sites by highlighting differences in the importance of key quality dimensions for each type of site showing. In fact, results show that there are statistically significant differences in mean score ratings of the importance of eight of the ten quality dimensions studied, with health care web sites having a higher call to quality for all dimensions except site reputation. In addition, on-going analysis of qualitative data indicates difference in the feature set (i.e., attribute) leading to these quality drivers.

Contributions from this study will help decision-makers design and evaluate health care (and e-commerce) web sites with a better understanding of the ultimate consumer and context. On-going work to expand this study will identify features (attributes) that drive each of these dimensions of interest in both health care and e-commerce contexts that can be used as levers to improve web site quality in both contexts to complete the theoretical model.

ABSTRACT

This paper proposes the utilization software meta-process theory in a factory context. A case study verifying the adherence of the proposal to the factory in operation also is presented.

1. INTRODUCTION

Brazilian software industry has been constantly working for increasing its quality and productivity. This information can be verified by analyzing the incentive programs promoted by Science and Technology Ministry (MCT) in which Brazilian government established that software is a priority (Software, Semiconductors and Industry). One of these programs is the SOFTEX (Society for Promotion of the Excellency of Brazilian Software). The objectives of SOFTEX are: to place Brazil into the top 5 biggest world software exporters and producers and to reach international standard of quality and productivity in this sector.

Beyond of those programs, the Ministry develops, periodically, a research to verify quality and productivity attributes of Brazilian software development sector. In Brazil exists about eleven thousand companies with activities related to the development and commercialization of software, employing about 160.000 workers, 25% of these companies have a quality program defined, and other 26% feels the need to establish this kind of program. This fact shows that Brazil is conscious about the need of improving the quality of its products in IT sector, in this case, the software sector. (www.mct.gov.br/sepin - November, 2006).

Parallel to the these facts, COSTA (2003) presents a research involving the 31 most significant companies, which work at Brazilian market using the Software Factory model. From these, only 41% apply a software development complete cycle; 45% apply proper methodology; 16% use projects control tools; 14% possess CMMI certification; 13% use CASE tools and 10% apply quality metrics.

Based on the context presented above, it is possible to affirm that to reach the objectives traced by SOFTEX, it is necessary an effort of the UNIVERSITIES, COMPANIES and of the GOVERNMENT with the intention of becoming aware of the market about the existence of the quality and productivity models for the theme software factory.

So, the objective of this paper is to propose a meta-process for the production of a software process. The meta-process will be used in the modeling of the process of UNITECH[1] Software Factory.

2. THEORY ABOUT META-PROCESS

Sommerville (2003) defines that a software process has activities, methods, practices and transformations set which, partially, reach a determined objective.

Reis (2002) indicates that the meta-process provides the development of executable processes for the software production.

Feiler and Humphrey (1993) propose a group of activities to configure the basic structure of a meta-process:

- Analysis of process requirements: social and technological aspects of a certain environment configure the process requirements.
- Process modeling: results in a process abstract model that should be materialized by a process modeling language (PML).
- Instantiation: in that meta-activity the process engine is configured. That engine should act, directly, into the software process and it has the following functions:
  - to support and to monitor the cooperative development of the stakeholders in the process;
  - to register data generated during the execution process;
  - to guarantee the composition of the defined activities in the process;
  - to manage the versions of the information generated by the process;
  - to collect, automatically, the metrics generated with the process execution;
  - to make possible the process changing during its execution and;
  - to manage the resources allocation inside the process.
- Simulation: allows to foresee the problem and to esteem the process duration when it is under production. If problems are detected in that activity, the process planner should return to the previous phases so that fittings can be done.
- Execution: a real project is executed with the process created.

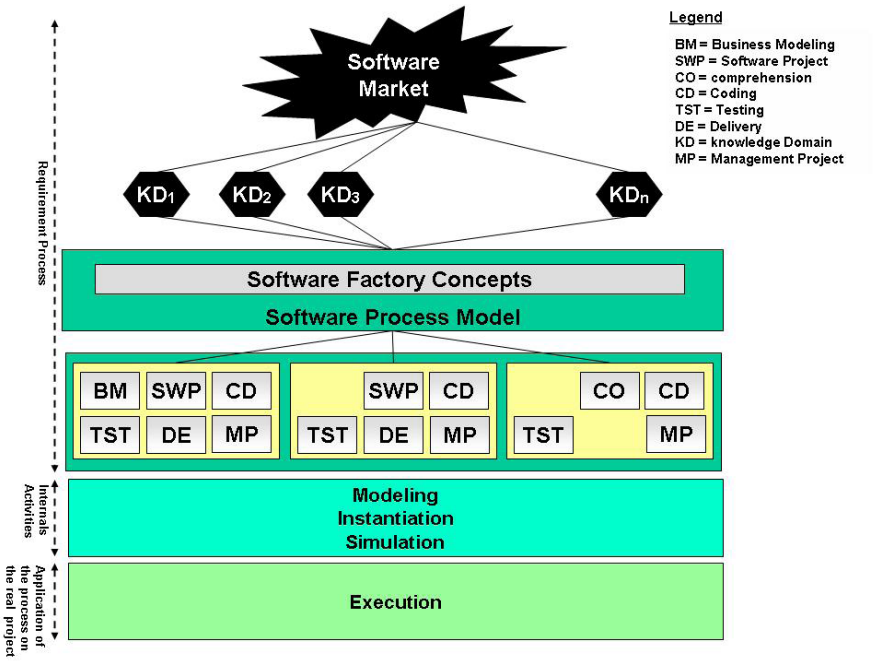
3. THE META-PROCESS PROPOSAL

The meta-process proposed by this paper is divided into five meta-activities: requirements, modeling, instantiation, simulation and execution.

In the requirement meta-activity it is necessary to define:

- Production cycle: The cycle presents the type of products generated by the factory. It can be classified as:
  - Long: The software factories which are framed in this concept should accomplish the business modeling, software project, coding, testing (modular or unitary, integration), project management and, finally, the software delivery (installation and training, for example). The long cycle factories should have a strong standardization to the activities of business modeling and software project. It is important to point out that activities depend on the creativity of system analyst and software architect.
  - Medium: The software factories which are on this cycle do not care about the business modeling; the responsibility of the factory begins with the execution of the activities of software project. It also accomplishes code, tests and project management.
  - Short: The software factories which are on this cycle make the activities of comprehension (the comprehension has the objective to verify if the

Figure 1. Structure of the meta-process proposal



project specifications is correct, consistent and intelligible, in order to reduce the stop risks in the production or the breaks of productivity), coding, testing (component and integrated) and project management. The business modeling, the software project, should be accomplished by long cycle software factory.

- Knowledge domain in which the factory will operate: the definition of domain is, specifically, the line products concept. Which products will the factory produce? This question should be answered.
- Process model (waterfall, incremental) that the factory will operate: The definition of the model will influence the dynamic behavior of the software process, knowing that the model defines the activities relations about the temporary optics.

The modeling, instantiation, simulation and execution activities are described on Section 2.

Figure 2 represents the meta-process used in the modeling of a software process. The figure shows the software development market divided into several segments (knowledge domains), the cycles (long, medium, short) and the conceptual aspects about software factory which are used taking into consideration the chosen model. The modeling, instantiation, simulation and execution activities, also, are contemplated in the figure.

4. ADHERENCE OF THE META-PROCESS TO THE SOFTWARE FACTORY: THE UNITECH CASE

The information presented in this section has been based in a case study realized in the UNITECH Software Factory.

Figure 2. UNITECH process modeling: PML used: IDEF-0 notation

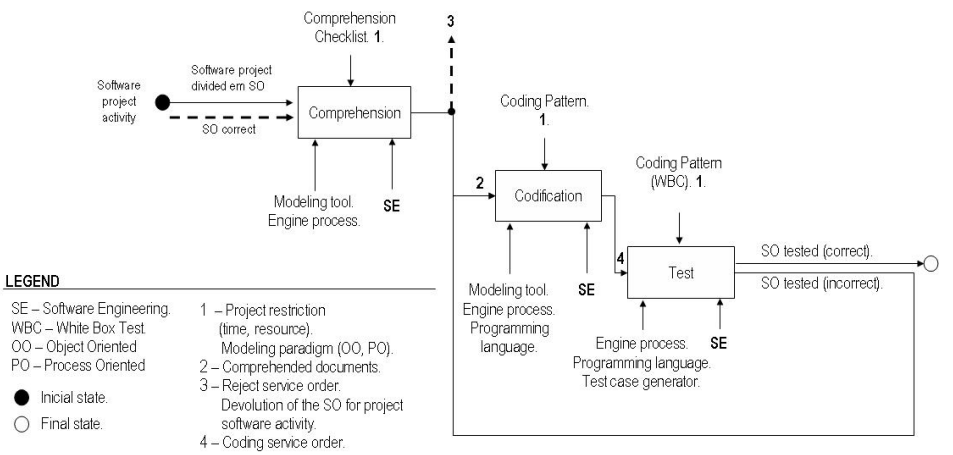


Figure 3. An instance of the real execution of the UNITECH process

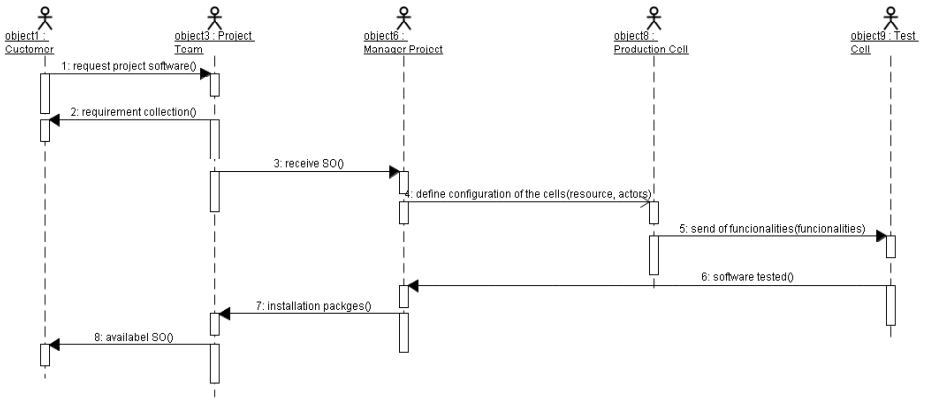

The UNITECH was created in 1995 and, nowadays, has about 1266 professionals. In 2002, the company had 584 employees and annual revenue of 18 million dollars. The forecast for 2007 is to reach the 1500 employees with revenue of 50 million dollars. The UNITECH growth rate has been maintained in the last years around 25%. In relation to the quality certification, UNITECH got CMMI level 3.

The company produces software for the following segments: telecommunications, administration of engineering companies, customer relationship management (CRM) and tributary administration for municipal districts.

The process model used by the company is characterized as incremental. The software factory production cycle of UNITECH is defined as short, which is, the comprehension, coding, and testing activities are executed.

After the process requirements are defined, the next activities of the meta-process are modeling and instantiation. The first of them can be verified in Figure 2.

The instantiation demands the configuration of the process engine. In UNITECH such machine has these following functionalities:

- To maintain[2] the production process activities;
- To maintain the service orders, derived from the software project;
- To maintain the stakeholders of the software process;
- To maintain the customers and their software projects;
- To maintain the developed products, which are related to the services orders;
- To store the stakeholders, errors and the development time for each product in each version;
- To relate the products developed to the customers' projects.

Finally, it is important to point out that the UNITECH software process is already under execution, and so, it is not possible to execute a meta-activity simulation. An instance of the real execution of the process is presented in Figure 3, (in case of multiple instances, this is necessary to develop new diagrams). Through the illustration, we can observe that a **Customer** requests a software project to the **Project Team**. This **Team** begins the collection and analysis of the requirements, as well as logical and physical project. The **Project Manager** verifies if the Software Factory has conditions, specially, in relation to time and technology, to produce the requested software.

At this moment, the production cycle of the factory begins. The **Project Manager** receives the SO and defines the configuration of the **Project Team**. The specification comprehension is led; the software production begins and the functionalities implemented are sent to the tests activity. Tests are executed and, if there are no errors, the SO is liberated for delivery to the customer. The **Project Manager** packs such SO, sending it to the **Project Team**. Finally, the Project Team delivery the product requested in the SO to the customer.

5. CONCLUSIONS

This paper presented the possibility of using the meta-process theory for the definition of a software process.

We could verify that the requirements meta-activity has a great importance to the process definition, because it is where is defined the knowledge domain, production cycle and process model.

In the modeling meta-activity was used like PML, the notation derived of the technique IDEF-0, it is important to point out the efficiency of this notation for the modeling process.

The instantiation and simulation meta-activities were not verified, because UNITECH already has a software process implanted.

Finally, as future work authors intends to verify the meta-process under the view point of new cases.

ABSTRACT

This paper presents the use of IDEF-0 in the modeling of a production process of a Brazilian software factory. The information used in the modeling were captured through a case study.

1. INTRODUCTION

The development of the Brazilian software market is constantly searching for quality and productivity. This information can be verified analyzing the incentive programs promoted by Science and Technology Ministry (MCT) which the government established software is priority (Software, Semiconductors and Industry). One of these programs is SOFTEX (Society to promote excellence of Brazilian software). The objectives of SOFTEX are: to ranking Brazil between the 5 biggest software exporters and producers of the world and to reach international standard of quality and productivity in this sector.

Beyond of those programs, the Ministry develops, periodically, research to verify quality and productivity attributes of Brazilian software development sector. In Brazil exist near 11.000 companies with activities related to the development and commercialization of software, those companies hire 160.000 employees, which 25% of them own a quality program defined, and other 26% fell necessity to establish this type of program. This fact shows Brazil is conscious of the necessity of improving its products quality in the IT area, software sector, in this case. (www.mct.gov.br/sepin - November, 2006).

Parallel to these facts, COSTA (2003) presents a research involving 31 most significant companies, which act in Brazilian market using the Software Factory model. Only 41% of these companies apply a complete cycle software development; 45% apply its own methodology; 16% use projects control tools; 14% own CMMI certification; 13% use CASE tools and 10% apply quality metrics.

Based in the presented context, we can affirm: to reach SOFTEX objectives is necessary an effort of Brazilian UNIVERSITIES, COMPANIES and GOVERNMENT, with the intention of becoming aware the market about the existence of quality and productivity models to software factory. In this point of view, this paper has objectives: 1) To present the use of IDEF-0 in the software process modeling of a Brazilian software factory, showing it is perfectly possible to work with production scale in this sector. 2) To verify the adherence of this notation in the software process modeling in a factory context.

2. BIBLIOGRAPHIC REFERENTIAL USED FOR THE DEVELOPMENT OF THIS PAPER

This section presents software factory and IDEF-0 concepts, witch are the base of this paper.

2.1 Definitions about Software Factory

Cusumano (1991) tells: the term software factory was used on the first time in 1960 at Japan. Even so, several companies associate the term software factory with the software development. However the software company witch doesn't assist characteristics of the software production in mass and in wide scale and doesn't own tasks and control standardization, work division, mechanization and automation can't be considered a software factory. For Cusumano the software factory development implies in the good practices of the software engineering systematically applied.

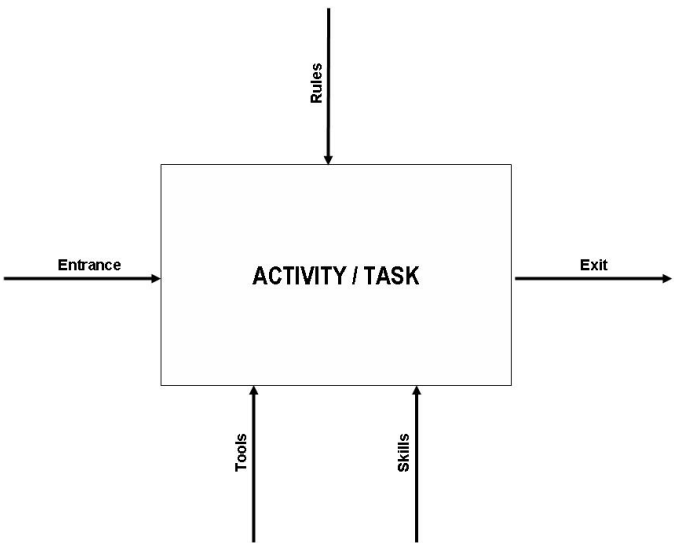
Fabri et. al. (2004) show that is possible to understand a software factory like a structured organization, gone back to software production totally building on the engineering and with strong features of work organization, to capacity modular components and to product in high scale. Software factory may have project management environment and tools, standard process, metrics to estimate cost, term and staff size and quality product guarantee policy.

2.2 Definitions about IDEF-0

The IDEF-0 was developed by American Air Force. In 1972 the SADT (Structered Analysis and Design Technique) was developed by Douglas T. Ross of SoftTech. The SADT was used in AFCAM (Air Forces Computer Aided Manufacturing) project, witch resulted on ICAM I (Integrated Computer-Aided Manufacturing I). The second version of ICAM was developed, documented and renamed as IDEF-0.

The IDEF-0 is a collection of activities, represent by ICOMs (Input Control Output Mechanism). An ICOM doesn't include only data and information but also everything that can be described about the process (scheme, estimate, regulations, products, etc). The ICOM in Figure 1 is a graphic representation of a task or a tasks group witch have "terminals". The terminals feed or are fed by an ICOM. An ICOM has raw material (entrances); rules and restrictions; people/skill; tools/mechanism

Figure 1. An ICOM representation



and products (exit). The entrance receives the data to be converted by an activity (or process), the rules and restrictions present how and when the entrance should be processed and executed, the mechanisms/tools represents who should execute this activity (can be an equipment, machine or others organizations) and the exit presents the result of as the entrance was processed (a product).

3. THE SOFTWARE PROCESS IDEF-0 MODELING A BRAZILIAN SOFTWARE FACTORY

The information presented in this section is configured through of a case study made at a Brazilian software organization with production characterized as factory. To organize this study, the authors used the bibliographical referential proposed by YIN (2005). (Note: the organization is certified with the quality model CMMI level 2). The authors of this work doesn't possess a formal authorization to publish the name of the company, this fact took them to denominate it as FÁBRICA BR.

FÁBRICA BR was founded in 1996 and provides IT solutions on data communications, internet and business process consulting areas. Nowadays, FÁBRICA BR has 600 collaborators on highlight areas.

Inside its production process, FÁBRICA BR does requirement mapping activities, business modeling, software project, comprehension (the comprehension objectives to verify if the project specifications are correct, consistent and intelligible, in order to reduce stop risks production or productivity breaks), codification, test (unitary and integrated), delivery and maintenance. Figure 2 presents the relationship among the software process activities of FÁBRICA BR. Note: process activities won't be detailed in this paper.

Analyzing Figure 2 is possible to verify the presence of process activities, rules and mechanisms that execute it, and two production units: the projects and the software factories. The first one is responsible to execute activities of requirements mapping, business modeling, project and software implantation. The comprehension, codification and tests activities are under the software factory responsibility. In the production process representation is possible to verify the process engine (characterized as a tool) is related with all activities.

Schaefer et. al. (1999), affirm the process engine can be classified as software with the objective of aiding in the communication and coordination of activities accomplished by process involved. One of the process engine objectives is to control the documents production (for example: requirement document), from requirements till delivery activities. FÁBRICA BR process engine possesses the follow functionalities:

- To maintain[1] production process activities;
- To maintain service orders, derived from software project;

Figure 2. FABRICA BR Process Modeling used IDEF-0

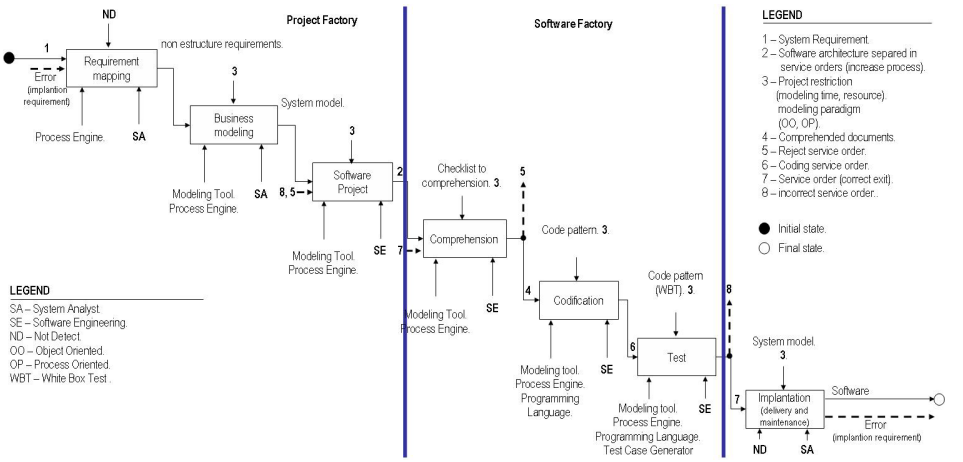


Table 1. Information produced with process engine

FÁBRICA BR Process Engine Production Control				
Client – Company XYZ				
Project – ABC				
Service Order: Date Code 00/00/00	Order: 1	Product – 1.1 St: OK	Actors: John (Leader) Mark	Activity: Codification: Started: 00/00/00 Finished: 00/00/00 t: 3/4 Testing: Started: 00/00/00 Finished: 00/00/00 t: 1/2
		Product – 1.2	Actors: Mary Peter	Errors: Err A Err B
	Order: 2			
	Order: 3			
Legend: St: Product State = In development or OK t: n/n1 = t – development time: n forecast, n1 accomplish.				

- To maintain involved with the software process;
- To maintain customers and theirs software projects;
- To maintain developed products, these related to services orders;
- To store involved, errors and development time for each product in each version;
- To relate developed products to the customers' projects;

With functionalities listed, the management information presented at Table 1, it can be inferred with process engine.

It is perceptible that project manager of factory receive a productivity estimate of each project and management reports. These reports are also supplied by process engine.

FABRICA BR software process possesses an incremental systematic because the inherent functionalities to software architecture document are separated in service orders (these orders aggregate one or more functionalities). The orders are understand, codified and tested by software factory and implanted by projects factory, one by one.

4. CONCLUSIONS

This paper presented the IDEF-0 software process model of a Brazilian software factory. The modeling notation used details the process in following aspects: process activities; activities information flow; rule and tool (the paper emphasize the process engine) applied to activities and to software process actors.

The process theory establishes the process modeling should assist some visions, among them: workflow; skill; tools; dataflow and rule.

The notation IDEF-0 used on process modeling (Figure 2) assists all the visions presented, this fact proves her efficiency.

Finally, as future work, the authors intend details about production process present in this paper, using IDEF-0 as a modeling technique.

Social Networking in Web-Enhanced Courses

Karen S. Nantz, Eastern Illinois University, USA; E-mail: ksnantz@eiu.edu
Norman A. Garrett, Eastern Illinois University, USA; E-mail: nagarrett@eiu.edu

INTRODUCTION

The use of the Internet for delivering courses has become a pervasive influence on undergraduate and graduate curricula. Current figures indicate that fully 12% of Internet users in the United States use the Internet to take an online course for credit toward a degree of some kind (Pew/Internet, 2006). That number is indicative of the rapid proliferation of online courses over the past several years.

Classifying web courses becomes problematic because the web-enhanced course is a blend with the components of the traditional class and course management software, a course listserver, instructor-student e-mail, collaborative activities using RSS feeds and related technologies.

Navarro (2000) suggests that faculty are far more likely to start by incorporating Internet components into a traditional course rather than directly offering web-based courses. These web-enhanced courses might be considered the transition phase to the new paradigm of Internet-based courses. Rich learning environments are being created, with a shift from single tools to the use of multiple online tools, both to enhance traditional courses and to better facilitate online courses (Teles, 2002).

Lee Rainie, Director of the Pew Internet and American Life Project notes that the role of experts, such as teachers, has changed. The Internet has empowered amateurs. New teaching models and methods have developed as educators try to adjust to changing student attitudes (Rainie, 2006). The new educational model becomes "the net-savvy, well-connected, teacher-independent end-user" (Castells, 2000).

Approximately 96% of undergraduate students at a midwestern, public university come to school equipped with at least one computer with university-supplied high speed Internet access. (Nantz, unpublished research, 2006). Researchers at Ball State University found that 30% of a waking day is spent with media as the sole activity with an additional 39% spent with media combined with some other activity. Part of the expectation of the current college population is that two-way technologies are the norm (instant messaging, weblogs, and online journaling, for example) and that online communities provide a rich environment for information sharing ("Average Person", 2006). According to Pew data, almost half of Internet users access list servs, RSS feeds and bulletin boards to stay engaged.

Clearly, there are many compelling reasons to use web-based resources in a course, including greater efficiency in the delivery of materials, providing up-to-the-minute content, enhanced status for the course and faculty, fostering student-to-student collaboration, and the use of technologies with which the students are increasingly familiar and comfortable.

RESEARCH VALIDATION

We have implemented the learning community paradigm in a variety of classes using several RSS technologies (RSS feeds, blogs, and wikis). Anecdotal evidence suggests that this approach enhances the instructional experience for students and exposes them to a wider variety of ideas than is possible with only the instructor as a source.

The learning community is, essentially, a social network. Social networks are based upon network theory, which focuses on the connections in the network. Any given social network has n(n-1) connections possible, where *n* is the number of nodes in the network. In a classroom, that includes all students plus the instructor and any other relevant individuals (graduate assistants, etc.). That is not to say that all connections will be used in any network. This is just the number of possible connections. In reality, each potential connection may be used in one of four ways:

- No connection exists
- Unidirectional connection, with interaction flowing primarily from node A to node B
- Unidirectional connection, with interaction flowing primarily from node B to node A
- Bidirectional connection, with interaction flowing in both directions

For example, the relationship between a teacher node, X, and a student node, Y, might be primarily unidirectional, from X to Y. A relationship between a student Y, and another student, Z, might be bidirectional.

Further, there is the strength of the connection to consider. It is likely that the strength of the connection between an instructor and a student will be high. The strength of a connection between students will likely vary greatly.

To analyze the efficacy of peer-driven learning communities in the classroom, it is necessary to examine the social networks that result from such communities and to compare them with the social networks that exist in classes wherein the learning

Figure 1. Instructional communication matrix

	Non-interactive	***Interactive***
Synchronous	Lecture Webcasts Videos	Discussion Managed Meetings IRC Chat Internet Messaging (IM) Webinars
Asynchronous	Podcasts / Vodcasts Webcasts Wikis	Discussion Boards Weblogs RSS Feeds / Syndication Cellular Text Messaging (SMS)

community has not been formally established, or is operating on an ad-hoc basis. To do this, a network diagram must be established for both the control and the experimental groups. In order to do this, we intend to establish network maps for each class, both for those participating as experimental groups and for those not participating (controls) by asking students about their learning relationships with other students and instructors in the class. In so doing we will establish:

1. The number of potential connections actually in use in the network
2. The nature of those connections
3. The strength of the connections that are in use

We will undertake a statistical analysis of the differences between the control and experimental networks to see if the difference is significant and if the resulting experimental network can, indeed, be enhanced by stronger and more plentiful peer-to-peer interaction.

Finally, the authors will discuss using synchronous and asynchronous communication with both non-interactive and interactive components as indicated in Figure 1 (Garrett, 2006). This model can enhance web-delivered instruction and meet student expectations for two-way communication and online communities.

ABSTRACT

As a result of our R&D efforts, we have developed an integrated telemedicine application "e-Diabetes" in accordance with the vision of Govt. of India to provide multi-specialty healthcare to all at an affordable cost. Its primary aim is to develop a world-class telemedicine technology solution for providing health care to all at affordable cost. This paper describes the potential benefits made available by this technology in diabetes care, and how this new E-Diabetes solution complements the daily care of diabetic patients. This Telemedicine Diabetes Application will deliver diabetic care to the patients of under-served rural areas of India at very low cost.

Keywords: E-Diabetes, Tele-Radiology, Tele-Cardiology, Tele-Pathology, Internet Information Services (IIS), Electronic Medical Recorder (EMR)

I. INTRODUCTION

Diabetes in India is increasing in prevalence, and now considered an epidemic. The World Health Organization (WHO) has concluded that India, which has the largest number of diabetic patients (32 million in 2000), is expected to have nearly 80 million patients by 2030. E-Diabetes is an emerging technology for the delivery of patient care in diabetes through telemedicine. Telemedicine has the potential to improve the delivery of health care in India by bringing a wider range of services such as radiology, pathology, cardiology, mental health services and dermatology to underserved communities and individuals in both urban and rural areas. At present, the position of diabetes care in the rural areas of India is not good. The number of primary health care centers in the State is less and thus vital medical facilities necessary for the population are not provided.

In rural areas of Northern India there is a high prevalence of curable diabetes disease, which remains untreated due to lack of resources. E-Diabetes can help the population of Northern India by providing specialized medical care, services and treatment to the patients in the far flung, remote and inaccessible areas from the specialty hospitals. Thus to provide effective solution to such an increasing number of diabetes cases, Center for Development of Advanced Computing (C-DAC), Mohali, India has taken an initiative in designing a web based E-Diabetes solution.

Deployment of "e-Diabetes" will help the poor and needy sitting at remote and rural places where specialized treatment is not available. With this the poor can easily have the advice of the specialists and suffer less.

II. VISION

I. Primary Stage

The purpose of this research work was to design and implement a Web-based e-Diabetes system tailored to provide an expert advice in the intake of insulin dose.

Initially following design goals were set:

1. The system should be tailored to support the workflow of the developed store-and-forward telemedicine software 'Sanjeevani'.
2. The system should be Web-based for true Internet operation.
3. The system should be built upon Open Source components and support multiple platforms for the ease of adoption.
4. The system must be secure and user friendly.

II. C-DAC & Telemedicine

Centre for Development of Advanced Computing (C-DAC), Mohali (Erstwhile CEDTI) is a premier Institute of Ministry of Communications & Information Technology, Govt. of India. CDAC is working in the field of Telemedicine since 1998 and has successfully developed state of the art telemedicine application packages namely, Sanjeevani and e-Sanjeevani that complies with the International telemedicine Standards.

We have established telemedicine sites at various locations in India. Our first endeavor was establishing telemedicine sites at AIIMS, New Delhi, PGIMER, Chandigarh, and PGI Lucknow. We expanded it in the second phase to connect three more medical colleges namely, IGMC, Shimla, Medical College in Rohtak and Cuttack.

Our second effort is to establish telemedicine sites at different states of Himachal Pradesh, and in rural areas of Punjab.

III. Objectives

E-Diabetes is a web-based application and its beta version is hosted on a central server for trial purposes at present. It can be opened with common Internet browser being bundled with any operating system software installed on the computer. The most sophisticated technology on date for developing web based solutions, namely ASP.Net has been used.

By integrating e-Diabetes with our existing Telemedicine software we hope to prevent diseases related to diabetes like cataract, kidney failure, Heart attack, BP, Neuropathy in those areas of Northern India where basic health amenities are not available.

The telemedicine diabetes care procedure aims:

1. To make available the expertise of the specialists at institutes like PGI Chandigarh, to common people at remote places.
2. To improve communication of the patient with the hospital-based diabetologist, in between the patient's visits to the specialized clinics.
3. To allow doctors to assess the patient's condition on a frequent basis.
4. No need to move the diabetic patient from remote areas to specialty hospital at far away places unnecessarily.

IV. Features of E-Diabetes

1. User-friendly interface facilitating doctors to navigate through the database.
2. Comprehensive Electronic Medical Recorder (EMR) with unique patient ID.
3. Structured investigation using clinical reports.
4. Secured environment through encryption and hashing algorithms.
5. Standard communication protocols.
6. Single point entry for operation through user name and password.

7. Multi-point, Multi-referral access to a number of Tertiary Institutes.
8. Central repository to keep the large patient data for backup.
9. Cost effective as no system softwares are required.
10. The application is designed for supporting client server Internet environment.

This e-Diabetes application uses forms authentication for the purpose of security. Every hospital that intends to use this application is provided with an administrative level user name and password. The administrator need not be a computer knowledgeable individual. Their duty is confined to creation of user names and passwords for the doctors employed in their hospital. Only the administrator is allowed to create accounts for doctors for security reasons. The user information passwords have been stored in encrypted form in the database table carrying users' information.

Other than e-Diabetes following modules are also part of E-Sanjeevani application software. Provision of inclusion of other modules is also there which can be implemented as per the requirement of the site.

1. Tele-Radiology
2. Tele-Cardiology
3. Tele-Pathology
4. Nephrology

III. WORKING MODEL

The system's architecture comprises of following main components: the Medical equipment, Workstation, Application software, Video-Conferencing to be used by rural based physicians and nurses at Health Centre in rural areas, and a telemedicine workstation, Multi-Videoconferencing Kit used to provide consultation to multi hospitals at same time at specialist centres in urban areas.

A dedicated internet website, allows the physician to monitor daily blood glucose information of the patient, and allows the patient to access his own blood glucose patterns. With the use of the developed e-diabetes software the doctor or other paramedic staff present at remote area health centers will enter the patient's diabetes data. Then the expertise doctors at institutes like PGI Chandigarh, will provide consultation to the common people at remote places. In the Software, analysis of Diabetes values can be made on daily, weekly or monthly basis by these expert doctors to provide feedback on the amount of insulin intake.

The basic functions of e-Diabetes application software include:

- Telemonitoring of patient's blood glucose data.
- Self-management actions, and
- Remote care from doctors to diabetic patients.

The developed software can handle up to four of 16 possible insulin types. Patient details like Carbs intake, Blood sugar, Protein, Cholesterol, Calories and weight values are filled in his EPR (Electronic Patient Record). The daily Average Line and Bar Graph of all these test figures is available to the doctor present in remote area as well as to the specialists in the urban area hospitals, which helps them to provide an expeditious care to the diabetic patient. Line graphs (Fig 1) and Bar chart graphs and the Print Colors option added to the Graph provides a visual effect to the readings and thus helps in better analysis of the patient data.

The telemedicine diabetes care procedure aims:

1. To make available the expertise of the specialists at institutes like PGI Chandigarh India, to the common people at remote places
2. To improve communication of the patient with the hospital-based diabetologist, in between the patient's visits to the clinic
3. To allow doctors to assess the patient's condition on a frequent basis
4. No need to move the diabetic patient from remote areas to specialty hospital at far away places unnecessarily.

Through consultation between two or more geographically separated physicians and with the availability of accurate and updated patient's diabetes data, an improved patients' glycemic control is achieved. Hence the use of telemedicine diabetes will allow diabetes case management of patients at remote distance and in those cases, where an in-person case management visit is not available or not feasible.

Work flow of the e-Diabetes solution once it is implemented at Health centers of rural areas in Northern India is as shown in Fig.2

Figure 1. Line graph using dummy diabetes values

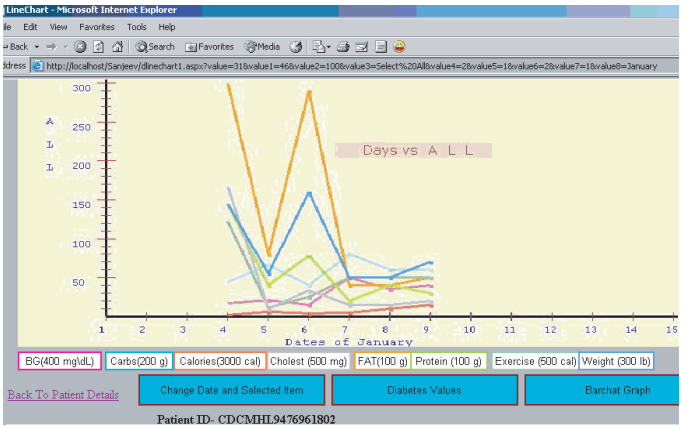

Figure 2. Work flow of e-diabetes

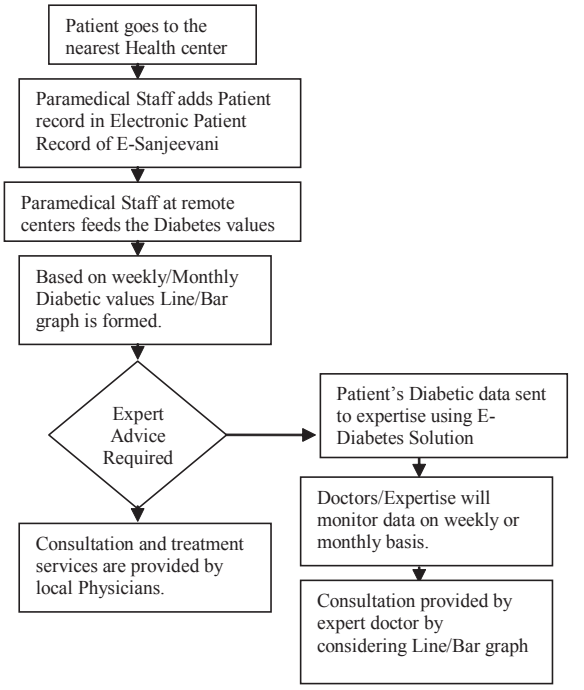


IV. APPLICATION ARCHITECTURE

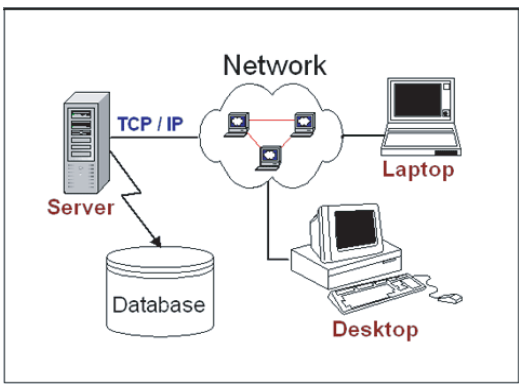
Web applications use client/server architecture. The Web application resides on a server and responds to requests from multiple clients over the Internet, as shown in Figure 3.

I. Client/Server Interaction in a Web Application

The Web application composes responses to requests from resources found on the server. On the client side, a browser hosts the Web application. The application's user interface takes the form of HTML pages that are interpreted and displayed by the client's browser.

On the server side, the Web application runs under Microsoft Internet Information Services (IIS).

Figure 3. Web application architecture



IIS manages the application, passes requests from clients to the application, and returns the application's responses to the client. These requests and responses are passed across the Internet using Hyper Text Transport Protocol (HTTP).

Web applications are much like traditional Web sites, except that the content presented to the user is actually composed dynamically by executable, rather than being served from a static page stored on the server.

The executable portion of the Web application enables you to do many things that you can't do with a static Web site, such as:

1. Collect information from the user and store that information on the server
2. Perform tasks for the user such as placing an order for a product, performing complex calculations, or retrieving information from a database
3. Identify a specific user and present an interface that is customized for that user
4. Present content that is highly volatile, such as inventory,

pending order, and shipment information

What makes a Web application special is that the client/server interaction takes place over the Internet.

II. Platform Chosen

ASP.NET is the platform that we have chosen to create Web applications that run under IIS. ASP.NET provides a high level of consistency, easy to create, debug, and deploy across Web application development.

V. CONCLUSION

During the ongoing trial period, large set of feedback records from the expert doctors and effect of remote Doctors and patients will be studied to develop novel measures of diabetes control in Northern India. Simultaneously many more specific measures will now be considered to update the presently developed beta version of e-Diabetes.

Thus this paper describes the potential benefits made available by this technology in diabetes care, and how this new e-diabetes solution complements the daily care of diabetic patients. This telemedicine diabetes application will deliver diabetic care to the patients of under-served rural areas of India at very low cost.

Effects of Color and Gender on the Perceived Attractiveness of Websites

Constantinos K. Coursaris, Michigan State University, USA; E-mail: coursari@msu.edu
Sarah Swierenga, Michigan State University, USA; E-mail: sswieren@msu.edu

INTRODUCTION

As the World Wide Web continues to grow in popularity, currently estimated to exceed 1.2 billion users (Nielsen 2005), websites have become core extensions of a business practice rather than a consideration of a new channel (Ravi 2005). Companies seek new insights on how to create more effective websites and entice online customers. Extensive literature exists on the acceptance of a new technology, but the former has centered on utility-related dimensions that drive this acceptance. Limited research exists on the hedonic dimensions of HCI and their relevance to usability and an even smaller set of this research is empirical in nature (Zhang and Li 2005). Furthermore, it appears that there are gender differences regarding perceptions of attractiveness, usability, and the consequent affective state of satisfaction, in website design. However, more research is needed to understand the nature of such differences as in most past studies there were many confounded design variables. Thus, this research-in-progress aims to address the above gap by studying the effects of color and gender on the perceived attractiveness of websites.

LITERATURE REVIEW

Hedonic Effects of Color

Hedonic, derived from Greek where "hedonism" means pleasure, dimensions include factors such as color, graphics, animation and other design elements that either implicitly or explicitly cause an affective state of pleasure. Zhang and Li (2005) argue that the more pleasing or attractive a website is, the easier it will be for the individual to learn how to use it and the more likely that this individual will continue to use it. Past studies have primarily looked at website design as the aggregate product of these hedonic dimensions and the users' consequent affect. However, a closer look at the impact of each hedonic dimension on affect is warranted.

Empirical studies on the impact of color on the perceived attractiveness and usability of websites are extremely limited. Most studies focus on the role that aesthetics play in usability and treat color in an overly subjective and qualitative manner. However, based on the limited number of empirical studies on the subject, it appears that color (and more specifically color combinations and schemes) have a significant effect on the perceived attractiveness and aesthetic appeal of a website. Brady and Philips (2003) suggested that users found a site with a Triadic color scheme more usable and more aesthetically pleasing than a site with a non-standard color scheme. Their study was limited by its design in that it did not differentiate the users' perceptions of usability and attractiveness between the variables of color and balance, both of which make up *visual balance*. Papachristos et al. (2005) suggested that color combinations and schemes resonate with users in a particularly emotional manner. Their research shows that user's tend to predictably attach specific emotional descriptors, such as fresh, modern, friendly, and aggressive, to specific color schemes and color combinations. Results of their research further suggested that the design attribute with the strongest effect on the website's perceived attractiveness is the *brightness* of the dominant color, followed by the *brightness* of the secondary color and its type (warm or cold), the *number of colors*, and the *contrast* between hues.

Based on the limited past empirical research, it is plausible to suggest that color, color schemes, and color combinations are variables dependant on other areas of design such as balance and contrast. It is also possible to suggest, based on the work by Papachristos et al. (2005) that the perceived "temperature" of a color impacts a website's perceived usability and aesthetics. Thus, the following hypothesis is proposed for this study:

H1. There will be differences between designs in relation to users' perceptions of the website attractiveness for each color combination.

Gender Differences in Hedonic Effects

Effects of web design on affect have also been studied in the context of the users' gender. While most studies explored gender differences for credibility, trust, and satisfaction with websites, a few studies focused on the relationship between gender and perceived attractiveness of websites. In the realm of visual design, men had more favorable impressions of how product information was presented. Women were more attracted by the colors on the site, and men by animations and the interactive, 'flashy' aspects of the site (Cyr & Bonanni, 2005). Simon (2001) found that women preferred sites that were less cluttered, having few graphics, as well as sites that avoid multiple levels of sub-pages to drill through. Men liked sites that used extensive graphics and animation. Additionally, in a study of gender and Web usage among college students, significant gender differences emerged with respect to evaluative criteria and use patterns, with men liking some of the "bells and whistles" and women using academic Web sites more (Mitra et. al, 2005).

It appears that there are gender differences regarding perceptions of attractiveness, usability, and the consequent affective state of satisfaction, in website design, but more research is needed to understand the nature of such differences. As with past studies on hedonic dimensions and usability/acceptance, gender differences were explored in terms of website designs as an aggregate of multiple design elements instead of a more controlled design regarding these aesthetic factors. Thus, the following hypothesis is proposed for this study:

H2. There will be differences between men and women in relation to their perceptions of website attractiveness for each color combination

METHODOLOGY

This study employs a 2 x 2 research design, where color is manipulated on two levels: warmth and scheme. Specifically, two sets of colors are selected from the color wheel, each being categorized as either "warm" or "cold." Color scheme indicates whether a warm color, for instance, is selected as the primary or secondary color choice for the particular website design. Implementation of this design resulted in the following four treatments or color combinations for the test website: i) Warm Primary – Warm Secondary (i.e. Red – Orange); ii) Warm Primary – Cold Secondary (i.e. Red – Light Blue); iii) Cold Primary – Warm Secondary (i.e. Blue – Orange); and iv) Cold Primary – Cold Secondary (i.e. Blue – Light Blue). All other design elements (e.g. text, images, background) were held constant across the four designs.

Tasks invoked participants to browse through the website in search of specific information. Participants were informed that the tasks were only meant to offer them an opportunity to explore the website and its design, instead of measuring their performance with it. Having evaluated the website design randomly assigned to them, participants were then asked to rank four different website designs in terms of perceived attractiveness.

A Structural Equations Modeling (SEM) technique, Partial Least Squares (PLS), is used in testing the validity of both the structural and measurement model. Data analysis will speak to the two aforementioned hypotheses, but also on any interaction effects between color and gender on the perceived attractiveness of websites.

A total of 130 subjects were recruited for this web-based voluntary study via email announcements on various databases and listserv. All participants used the same website, but each treatment involved the use of a discriminant color design described above. The minimum sample size for the selected method, PLS, is 10 times the number of the most complex construct. In this study endogenous constructs consist of five items, thus our sample size far exceeded the needed 50 cases. The sample exhibited an even split between males and females, an average age of 39, was entirely college-educated, 84% described themselves as Caucasian/White, and had an average experience of 18 years with computers and 11 years with the World Wide Web respectively. ANOVA tests found no significant differences for subjects in the various treatment groups in terms of these control variables, thereby ensuring the successful randomization of assignment across groups.

Two scales developed by Lavie and Tractinsky (2000) were used to measure the users' perceived attractiveness of websites through assessments of "classical aesthetics" and "expressive aesthetics." These 7-point Likert scales (anchored "Strongly Disagree/Agree") measured responses to the shared question "My perception of this website is that it is…" for each of the following items: Clean, Clear, Symmetric, Aesthetic, and Pleasant for "Classical Aesthetics", and Original, Creative, Fascinating, Sophisticated, and Uses Special Effects for "Expressive Aesthetics".

RESULTS

An item is significant if its factor loading is greater than 0.5 to ensure construct validity. Adherence to this criterion required the modification of the Classical Aesthetics scale by removing two items (i.e. Clear and Symmetrical). Each item was then re-validated by testing its item-to-total correlation measure, where all items had higher measures than the 0.35 threshold and finally reported in Table 1. It should be noted that the loading for Clean was 0.673 before the removal of the other items.

Results of tests for convergent, discriminant, and construct validity can be found in Table 2. Both constructs had adequate reliability and internal consistency well above the 0.7 threshold. Cronbach α-values were satisfactory for our two constructs and constructs' AVE exceeded the 0.5 benchmark for convergent validity. The square root of the variance shared between a construct and its items was greater than the correlations between the construct and any other construct in the model suggesting discriminant validity. Discriminant validity was confirmed by verifying that all items load highly on their corresponding factors and load lowly on other factors.

The structural model tested using PLS demonstrated mixed explanatory power for perceived attractiveness of websites. With an R-square of 0.43, 43% of the variance in Expressive Aesthetics was explained by the color manipulation in this study. Only 3.2% of the variance for Classical Aesthetics was explained by this manipulation, suggesting that there are other dimensions not captured by the scale (in part explained after the removal of two items) and/or by the exogenous construct's effects.

From the two hypotheses, only the effects of color manipulation were supported. Both paths from Site Design to Classical Aesthetics and Expressive Aesthetics were significant to the 0.05 level (t=2.149 and t=2.484 respectively). Gender was not shown to have a significant effect on either Aesthetic construct.

The last measurement pertains to the ranking of the different website designs. Regardless of which website a participant was first exposed to, the ranking was not significantly affected. Rankings were significantly different (one-sample T-test) suggesting a preference for "blues" or the cold-cold color design (see Table 3).

DISCUSSION

The findings of the present study support and extend prior research regarding the effect of color combinations on aesthetics (Brady and Philips, 2003; Papachristos

Table 2. Validity test results

ITEMS	**Classical Aesthetics**	**Expressive Aesthetics**
Clean	**0.590**	-0.036

Cold-Cold	130	1.68	0.998	0.088	19.16219	129	1.49208E-39

et al., 2005). The triadic color schemes that utilized a cold primary color (blue) for the top or global part of the page and then used either another cold color (medium blue) or a warm color (orange) for the secondary page components provided the balance that users found most aesthetically pleasing. In contrast, the site that combined both a warm primary color (red) and a warm secondary color (orange) was the least preferred site, likely because the color pairing did not balance out the rest of the page. Additionally, research has shown that the cool blue color schemes are associated with higher perceived credibility and trust levels, which would be important for a travel booking website (Fogg et. al, 2001; Lee & See, 2004; Zhang & Li, 2005). The current results suggest that designers need to carefully consider color choice as the combinations will convey information about the quality of the site that may not be intended.

While other research has found gender effects in several computer-related contexts (Cyr & Bonanni, 2005; Simon, 2001), the current study did not indicate that gender impacted perceived website attractiveness. However, the small sample size may have been a factor, and the effect may be revealed as more responses are obtained. Similarly, women tend to employ more exhaustive information processing strategies than men do, which means that gender differences may have been masked by the lack of detailed content in the prototype website; the content was not as extensive as users expected from a travel website. We plan to expand and hone the website content to create a more realistic level of detail on each page, as well as having more content pages, which would enable users to better assess perceived usability within the context of the multiple color schemes. Additionally, future research efforts will seek to broaden the focus to assess the influence of culture on perceived website attractiveness and usability through a global multi-country study.

Virtual Learning Evaluation for the Development of Core Competences in Integrated Management of the Chemical Industry

V. B. Carmo, Fatec-SP, Brazil; E-mail: vadson@mpc.com.br
K. Tannous, State University of Campinas, Brazil; E-mail: katia@feq.unicamp.br

INTRODUCTION AND OBJECTIVE

The challenge of the companies to get economy of large scale production has taken the integration and development with the companies that follow the productive supply chain by means of management and technological innovation.

The integration of the productive supply chain is an important conquest for a competitive differential. This integration will be able to happen of diverse forms, since the upright of the activities, how to the acquisition of companies throughout the even though competing supply chain, or still, alliances and partnerships with customers and suppliers.

So that this possible integration either, the best experience and dissemination practical accumulated throughout the time are necessary, for the accomplishment of the critical processes, either by means of knowledge of its collaborators either by means of explicit organizational learning.

The advances of the technological innovation and the models of management have allowed successive profits in the productivity of the companies through reductions of costs and improvement of performance of the processes, products and services offered for its force of work.

This search of alternatives leaves to have an isolated focus and starts to have a vision extended of all the productive supply chain by means of resources renewed. The productive supply chain of the petrochemical sector exactly represents a significant parcel of the Brazilian internal production with 23,1% of the BIP (Brazilian Internal Production), producing raw material for other productive sectors, as for example, automobile, electro-electronic, packing and the textile sector, having that to face diverse factors that increase the production costs and hinder one better performance of the productive supply chain.

Amongst the factors that make it difficult the improvement of the productive supply chain could be: the sprayed productive structure, not existing supplements integrated, distant supply chain of the polar regions of production and the biggest consuming markets, the bad quality of the logistic infrastructure, high tax burden, high raw material costs, high capital costs and of the energy used in the sector, raising the production costs (NAKANO, 2006).

Although the essential importance of this productive supply chain, this one has a critical disadvantage that is the dependence of source non-sustainable. In this direction, it is each more frequently the resources of renewable fuels sources.

As alternative for this study, the sugar and alcohol productive supply chain was chosen, that inside represents an importance of the Brazilian potential, in special, for increasing attendance of the energy demand fuel. The challenge is in the generation of bigger combustible alcohol production to replace the gasoline, which is proceeding from the petrochemical sector (OLIVERIO, 2004).

Nevertheless, this productive chain can manufacture fuel from agricultural sources sustainable, as ethanol, which Brazil is world-wide the producing greater with the lowest cost of alcohol production from the sugar cane-of-sugar. To illustrate this competitive advantage, for example, in terms of costs, one liter of ethanol manufactured from the sugar cane costs $ 33 cents against $ 43 cents equivalent made of corn.

The alcohol production in Brazil was of approximately 16 billion liters in 2005, counting on 335 plants and the estimate is of 36.8 billion liters for 2015, being that more 89 plants are currently in project or construction, conducted for operation in 2012, representing an investment of 12 million dollar. Another important factor is that almost whole 335 plants in the country generate the proper energy from the burning of the residue of the proper consumed sugar cane, generating 1.642 megawatts (MW) of electricity from agricultural source sustainable, enough to supply an area with 3.2 million inhabitants, equivalent to the population of Uruguay, generating except for sales (VEJA MAGAZINE, 2006).

This work has the objective to understand the advances of the technological innovation and its impacts in the management of the inserted companies in the sugar and alcohol productive supply chain evaluating the essential abilities for improvement of its competitiveness in the market.

METHOD AND RESULTS EXPECTED

In this study it will be used a specific software for survey and management of the competences, the e-HCDM software, in a virtual learning, the TelEduc, as facilitator of the evaluation process and development of the essential competences. The chosen environment was the TelEduc, environment for distance education, developed for the Nucleus of Computer Science Applied to Education (NIED) of the State University of Campinas. This software is of public domain, being able to be redistributed and/or to be modified under the terms of General GNU Public License version 2 (Free Foundation Software).

For the survey of the data the models of management as ROSS (1997) that it contains four periods of training of management of the productive chain and the classification of the abilities (business, technician-professional and social).

The competences found will be classified as ZARIFIAN methodology (1999) *apud* FLEURY and FLEURY (2001) in abilities of the business, in which will have the strategic vision of the organization inserted in its strategic planning.

Employees must have to know about the external and internal environment for identification of the chances and threats. In this context, they have the knowledge of corporative values and objectives as well as its planning adjusted for the necessary changes.

The technique-professional abilities must have to the specific knowledge in the business core area for the performance in the activities inherent.

The social abilities involve abilities to communicate, negotiation and work in a team which its will allow that the organization can express and transmit ideas and direction with synergy for the employees get the corporative objectives.

For the accomplishment of the competences survey, the e-H-CDM software in the TelEduc will be carried through a diagnosis in the critical processes for evaluation front to the competences, relating the abilities necessary for the development. The competences will be compared with a model of competitive performance of the companies in the productive supply chains and would be to frontier for the learning development of core competences management.

Table 1. Diagnosis of the performance of productive supply chain

Diagnoses	Productive Supply Chain Sugar and Alcohol
Organizational Model	Not yet structuralized; few special companies in this market, functioning as buffer for companies that act in other chains
Requirements of competitiveness of the productive supply chain	Knowledge about the market, design, quality, price, gradual increase of importance of the innovation.
Critical factors of successes of the companies	Technological qualification, qualification for negotiation, prospecting of markets, development of products/systems, fast engineering of processes, answers to the market and search of information to make possible production

Table 2. Core competences for the productive supply chain

Core competences	**Objetive:** Increase of the capacity of sugar cane processing
business	management of the performance of the manufacture processes
Technician-professional	equipment development and engineering of processes
Social	multifunctional, work team and collaborative

An example of the application is shown in the Tables 1 and 2 where the diagnosis of the performance competitive and the essential abilities for the productive chain according to FLEURY and FLEURY (2001).

The analysis of this survey company it will be able to reach its corporative objectives, elaborating a plan for the development and acquisition of abilities improving performance and competitive advantages.

THE FINAL CONSIDERATIONS

The evaluation of the essential abilities of a company by means of a virtual environment of learning will allow, beyond a plan for the development of the abilities, to direct resources for to enrich of the company being considered its competitiveness. A time known to the deficiencies and the competitive advantages, the management front to the strong points of the company will have to be potential and of the neutralized weak points.

It can still, to be fortified and integrated other methods of management, in the search of competitive advantages. From this knowledge, a plan for the development of these abilities could be created, being visualized, of individual and systemic form, by means of reports and pointers in a repository of information for the management of the development of these abilities.

This repository of information will be available in the virtual environment of learning, which will facilitate the integrated management of the chosen productive chain, allowing the improvement of the demand forecast, reduction of costs of supplies and the productivity throughout the supply chain.

ABSTRACT

Despite a substantial literature concerning the impact of computer-mediated communication (CMC) on decision-making, the potential interaction with an organization's management control system has received little attention. In this study, we use social presence, media richness and media naturalness theories to develop hypotheses concerning the interactions of communication medium with the incentive schemes, a ubiquitous aspect of management control systems. Hypotheses concerning the intended interaction of increased profit and unintended interaction of reduced cooperation will be presented. The results of a laboratory experiment examining the effects of using face-to-face negotiations versus virtual negotiations where buyer-seller dyads determine the price and quantity of transferred goods will be presented. Preliminary results indicate that there is a significant interaction between communication medium and incentive scheme on the measured outcomes.

Keywords: Computer-mediated communication, virtual negotiations, transfer pricing.

OVERVIEW

New communication technologies are offering options that are impacting many aspects of intra-organizational communication. As organizations rely more heavily on virtual interactions, it is important to more fully understand the interactions between virtual communication and the management control system. The purpose of this study is to compare the outcomes of face-to-face negotiations with the outcomes of computer-mediated communication (virtual) negotiations in an intra-organizational transfer pricing scenario.

TRANSFER PRICING

Transfer pricing negotiations for the price and quantity of an intermediate good are a particularly interesting form of negotiation because they contain aspects from both ends of this spectrum. The larger the **quantity** of goods transferred, the larger the profit to be divided between divisions. This aspect could lead to cooperative behavior from the negotiators. But the transfer **price** determines the portion of the profit that goes to each division, which could lead to competitive behavior. Organizations have a stake in the quantity transferred since it determines the profit to the organization. Negotiators have a stake in both the quantity (larger pie to be divided) and the price (size of the slice). Therefore, negotiated transfer pricing is considered to be a mixed-motive situation.

COMPUTER-MEDIATED COMMUNICATION

The computer-mediated communication literature draws on theories that are concerned with social aspects of communication, e.g., social influence (Fulk, et al., 1990), on theories that are concerned with technology, e.g., task-technology fit (Zigurs and Buckland, 1998), and on theories that integrate both aspects, e.g. media naturalness (Kock, 2004, 2005). Social presence theory (Short et al., 1976) predicts that communication is more effective when the medium has the appropriate level of social presence for the level of interpersonal involvement necessary for the task. Media richness theory (Daft and Lengel, 1986), which extends social presence theory, classifies communication media according to its ability to convey nonverbal cues, immediate feedback, personality traits, and natural language. Under media richness theory, the criterion for matching the media to the collaborative task is based on the need to reduce uncertainty. Face-to-face communication is the richest medium. Most intranet- and internet-based media are near the other end of the spectrum and are classified as lean. These theories emphasize using the appropriate medium for the task at hand.

The media naturalness theory (Kock, 2004) proposes that there is a negative causal link between the "naturalness" of a computer-mediated communication medium, which is the similarity of the medium to the face-to-face medium, and the cognitive effort required for an individual using the medium for knowledge transfer. This theory is integrative in that it encompasses previous theories, and it examines the *reasons* why face-to-face and CMC can lead to different outcomes. The task is an aspect of this theory, but the focus is on the cognitive effort required by the difference between 'natural' medium (face to face) and lean CMC mediums.

INCENTIVES

Cooperation and competition can refer to the interdependence between goals. In cooperative situations, the achievement of one person's goals is positively related to the achievement of another person's goals (one person's movement toward their goal facilitates the other person's movement towards their goal). In competitive situations, the achievement of one person's goals is negatively related to the achievement of another person's goals (one person's movement toward their goal interferes with the other person's movement towards their goal). Perceived interdependence of goals can affect group productivity and problem solving ability. One way to create cooperative or competitive situations is through the incentive scheme. Ferrin and Dirks (2003) found competitive versus cooperative reward structures influence actions (e.g., information sharing) and perceptions (e.g., perceived motives and perceived performance of others). Negotiation situations are of special interest because they can vary in the same manner as incentive schemes, from cooperative (win-win, also called integrative) to competitive (win-lose).

HYPOTHESES

Our hypotheses are concerned with the interaction of communication medium with the incentive scheme. Three outcomes are measured and tested, organizational profit, efficiency of the negotiations, and the negotiators' attitudes.

PRELIMINARY RESULTS

Preliminary results indicate that there is a significant interaction between communication medium and incentive scheme on the measured outcomes.

Project Portfolio Management: An Analysis in the Brazilian Market

Leandro Alves Patah, Polytechnic School of the University of Sao Paulo, Brazil; E-mail: leandro.patah@siemens.com
Marly Monteiro de Carvalho, Polytechnic School of the University of Sao Paulo, Brazil; E-mail: marlymc@usp.br

ABSTRACT

The definition of portfolio for project management states that portfolio is a collection of projects and or program and other work that are grouped together to facility the effective management of that work to meet strategic business objectives (PMI, 2006). It is necessary to select the right projects to be conducted; otherwise too much effort and money will be invested in wrong projects. The main objective of this paper is to analyze the theory of portfolio management for projects and check its applications in the Brazilian market. Three companies in the Brazilian market were studied, an international bank, a Brazilian public company in the transportation market and a multinational electric manufacturer.

INTRODUCTION

The modern portfolio theory was first described by the Nobel Prize in economics Harry Markowitz in 1952. In brief, it describes how, for a given risk level, there is a specific mix of investments that will achieve an optimal return (LEVINE, 2005). Portfolio management is formally defined as a dynamic decision process, whereby a business list of active new product (and development) projects is constantly updated and revised (COOPER et al., 1997). In this process, new projects are evaluated, selected, and prioritized; existing projects may be accelerated, killed, or reprioritized; and resources are allocated and reallocated to active projects.

The portfolio concept applied to projects comes from economics and management. Some research has been developed in the last years about project portfolio, as the integrated framework for project portfolio selection proposed by Archer & Ghasemzadeh (1999) that states that the task of selecting project portfolios is an important and recurring activity in many organizations and proposes a framework that may be implemented in the form of a decision support system and a prototype system to support the decision making activities.

Portfolio for project management is a collection of projects and/or program and other work that are grouped together to be managed in an easily manner. Morris and Jamieson (2004) arguments that project and program management are widely used as a means of implementing corporate and business strategy and that strategies should be aligned and moved from the corporate level through portfolios, programs and projects in a systematic and hierarchical manner.

The main objective of this paper is to analyze the theory of portfolio management for projects and check its applications in the Brazilian market. The research is basically structured in two parts: project and portfolio management theory and practical application of portfolio management including three case studies.

PROJECT MANAGEMENT

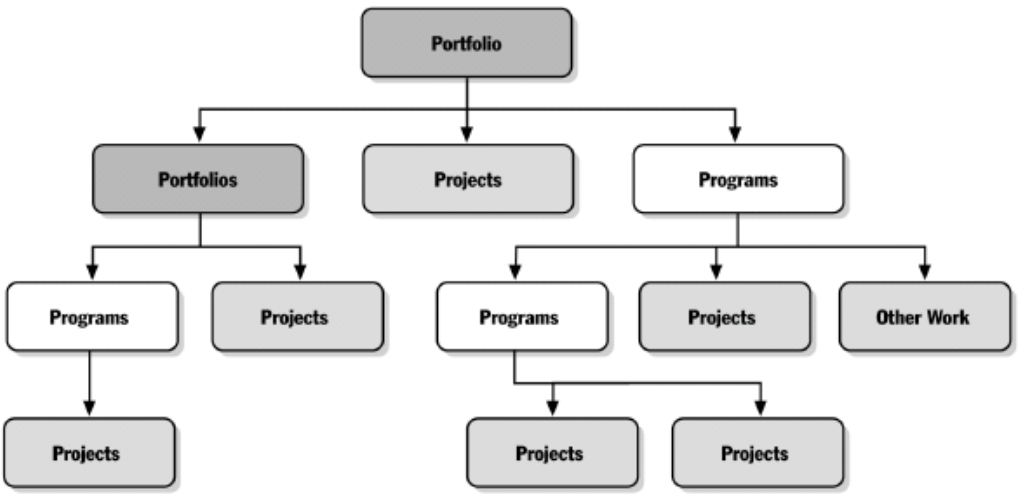
The project management was developed as a leadership concept of interdisciplinary activities with the objective to solve a temporary problem. This characteristic permits the project management to reach a high degree of innovation in the presented solutions to more complex's works (LITKE, 1995).

In the most significant areas of application, new products and services are created through projects, what could be demonstrated by the increasing number of companies that are adopting the project management methodology (KERZNER, 2001).

According to the PMI (2004) a project could be defined as a temporary endeavour to create a unique product or service and project management could be defined as the art of coordinating activities with the objective to reach the stakeholders expectations.

Rabechini Jr and Carvalho (2003) argue that in all the project definitions it is possible to realize two intrinsic concepts: temporality and uniqueness. The temporality

Figure 1. Portfolio and its components (PMI, 2006)



means that all projects have a well-defined beginning and end. The uniqueness or singularity means that the product or service created by a project is different from all the others already made.

PORTFOLIO MANAGEMENT

The portfolio concept applied to projects comes from economics and management. But just recently a standard was properly defined for project management. The definition of portfolio for project management states that portfolio is a collection of projects and/or program and other work that are grouped together to facility the effective management of that work to meet strategic business objectives (PMI, 2006). In the same way, PMI (2006) defines portfolio management for projects as the centralized management of one or more portfolios, which includes identifying, prioritizing, authorizing, managing, and controlling projects, programs, and other related work, to achieve specific strategic business objectives.

Figure 2. Portfolio process (PMI, 2006)

The Figure 1 presents an example of a portfolio and its components.

All of the components of a portfolio present some common characteristics:

- They are investments made or planned by an organization;
- They are aligned with the goals and strategic objectives of the organizations;
- Typically they present some specific characteristics that allows an organization group them in order to a more effective management;
- The components of a portfolio are quantifiable, that means, they can be measured, ranked and prioritized.

The portfolio should also be aligned with the strategy of the company. It should be the way the strategy is implemented by the company. It components must come from the strategic objectives and goals of the company. The output of the portfolio must increase the project and program activities authorized by the company. This process is presented in the Figure 2.

PMI (2006) also presents the phases of the portfolio management. They are organized in two groups:

1. Aligning Process Group:
   - Identification;
   - Categorization;
   - Evaluation;
   - Selection;
   - Prioritization;
   - Portfolio Balancing;
   - Authorization.
2. Monitoring & Controlling Process Group:
   - Portfolio Review and Reporting;
   - Strategic change.

Figure 3 presents the phases of the portfolio management.

There are lots of tools that the theory presents to evaluate and manage the portfolio. One of the most used is the bubble chart. The Figure 5 presents one example.

BRAZILIAN PROJECT MARKET

The Brazilian market for projects could be defined as a big one, considering the number of big projects in the ongoing phase and the value of each one, and all of

Figure 3. Detailed phases of the portfolio process (PMI, 2006)

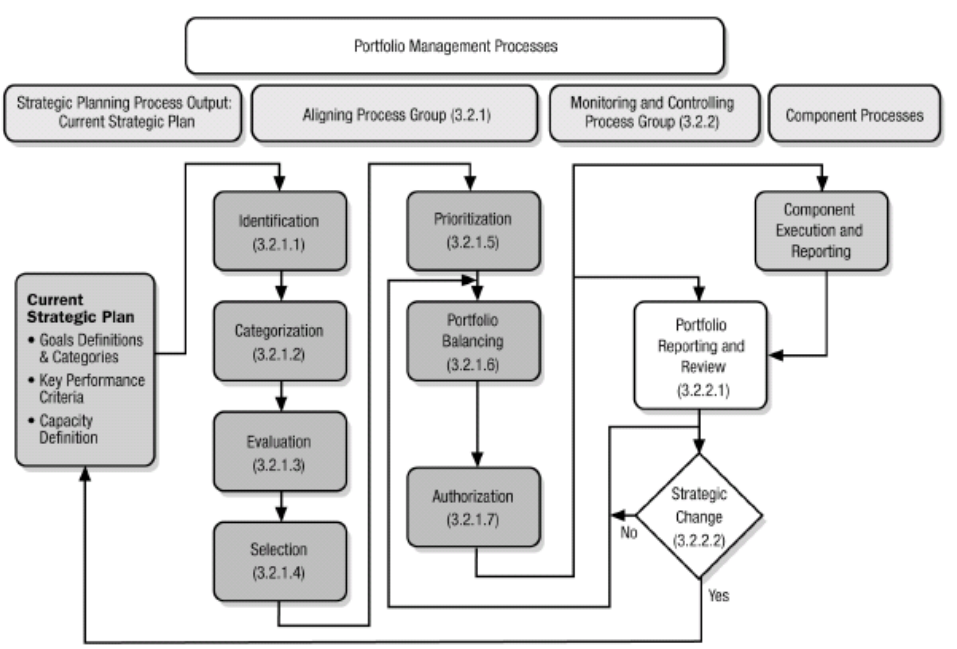


Figure 4. Bubble chart (PMI, 2006)

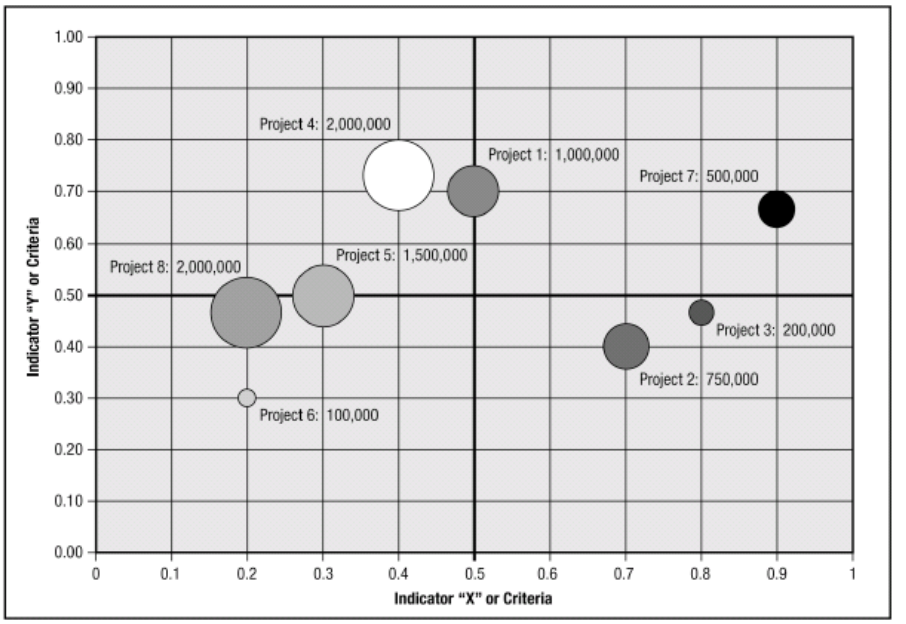

Table 1. Brazilian project market (EXAME, 2005 and EXAME, 2006)

	2005	2006
Total Number of Projects	403	707
Total Value of Projects (millions of US$)	83,574	99,600
Avarege Value of Projects (millions of US$)	207	141

Table 2. Tool for evaluation of projects from a bank

Criteria	Project 1	Project 2
	Grade	Grade
Revenue	5	2
Cost	5	5
Importance	2	1
Final Results	12	8

them. The market is also increasing. In the last year, the total value of the projects increased in 19%, from US$ 83.6 billion to US$ 99.6 billion, as presented in the table below.

The data presented below represent the following economy sectors:

- Energy;
- Oil and gas;
- Water;
- Telephone;
- Transportation.

METHODOLOGY

For the analysis of the practical application of portfolio management, three case studies were selected. For the cases studies, three companies in the Brazilian market were studied, an international bank, a Brazilian public company in the transportation market and a multinational electric manufacturer. The cases were selected to compound a multi-varied scenario were the portfolio management could be evaluated.

CASE STUDIES

International Bank

The analyzed bank has more than 170 years and started its operations in Brazil in the beginning of the last century. The main area that uses project management in the bank is the information technology. This area owns 95% of the projects of the bank.

The method used to select the projects for the portfolio of this company is based in spreadsheets with three defined criteria: revenue to be obtained after the implementation of the project, cost of the project and strategic importance. For each criteria there is a grade related to some specific values defined by the top management. Table 2 presents a simple example of two projects evaluation.

Brazilian Public Company in the Transportation Market

The public transportation company analyzed in this study works simultaneously in three metropolitan regions, which includes 67 cities and a population of 23 millions of inhabitants. It attends 1.5 millions of passengers per day.

It portfolio includes 12 projects and totalize US$ 383 millions. The tool used by the company to select the projects and control the portfolio is the bubble chart as presented in the Figure 5.

Multinational Electric Manufacturer

The electric manufacturer is a Europe based company, with more than 150 years, with 400,000 workers, placed in almost 200 countries. The company produces and installs a great variety of electrical and electronic equipments, in the great majority delivered to customers through specific projects adapted to the necessities of each one. The products innovation tax is extremely high and the products actually sold were developed maximal three years ago. Basically the company sells customized solutions to their customers.

Figure 5. Portfolio of a public transportation company

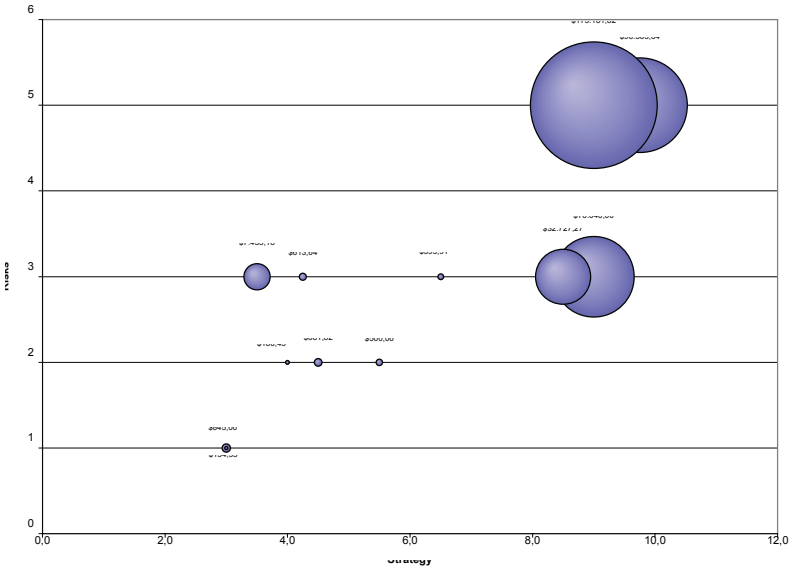

Figure 6. Portfolio of an electric manufacturer

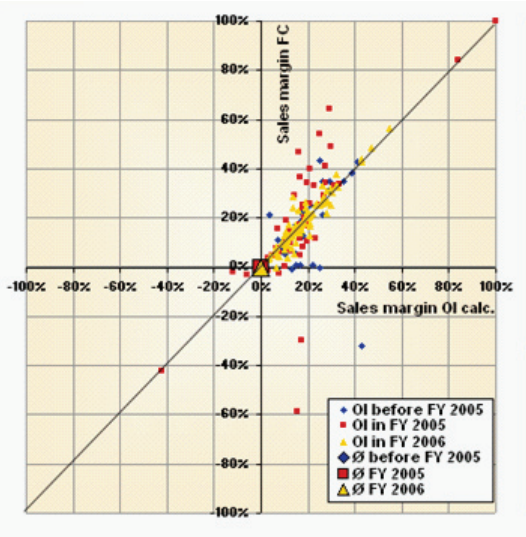

In Brazil more than 50% of its gross sales are managed as projects. In the fiscal year of 2005/2006 this represents almost US$ 1.2 billion. This demonstrates the importance of a good project management for this company. The tool used by the company relates the margin of the projects in the beginning of them and the margin in the closing of the project. This information is crossed in a graph as presented in the Figure 6, where the 220 major projects of the company are placed.

CONCLUSIONS

The conclusions obtained from this study could be grouped in two sections: adoption of portfolio management and tools used by the companies.

- The companies realized the importance of the portfolio management for projects and programs and are starting initiatives in order to implement methodologies to administrate the portfolio;
- There is not a standard tool used by the companies and the tools used by them are made inside the companies and not developed by a specific software provider.

Although the companies in Brazil are realizing the importance of portfolio management in the management of their business, there is some room of improvement for them in the portfolio management topic, for example, the selection methods are not as objective and systematic as presented in the theory.

The great challenge for the companies in general is to do more, better and faster, always with less. To achieve these objectives, the companies must be able to measure what they do, and how well they do. And it is here that portfolio management could help the companies.

ABSTRACT
MetaTool for educational platform design (METOD) is a general computer supported educational development paradigm comprising special framework and flexible tools combined in MetaTool that enables even non-skilled ICT users to develop or adapt educational platforms that suit their needs. In METOD several learning theories and contemporary intelligent system design are integrated to introduce innovative educational methods and to improve the quality and accessibility of training and educational processes.

Keywords: *e-learning, adaptive learning*

1. INTRODUCTION
The rapid advancement in ICT enabled the development of computer supported educational platforms (CSET) which can improve the quality, user friendliness and accessibility of training, education and lifelong learning. Computer supported platforms are the basis for supporting or even developing new innovative types of learning, like problem based learning and evidence based learning [1].

However, literature overview and recent research results and results of some pre-studies [2, 3, 4] have shown that there are various disadvantages of current CSETs,: (i) that after the novelty effect of drill and practice wears off the motivational power is lost, (ii) the platforms are static - the educators or trainees can not adapt them to specific environments (e.g. people with special needs), changed educational requirements, new educational programmes and (iii) normally the educators or trainees can not develop such platforms by themselves.

We identified increasing demand for open and all-accessible training and learning and the need for prospective platforms enabling teachers, trainers, educators and even parents to build their own ICT educational platforms without ICT development and design knowledge. These initiatives led to the development of a special paradigm and development framework – MetaTool for Educational platform Design (METOD) within the Leonardo da Vinci Programme[5].

2. THE METOD PARADIGM AND METATOOL
The METOD paradigm is a collection of theoretical and practical findings and the repository of: various training environments, description of trainees' characteristics, possible pedagogical goals, different pedagogical and communication strategies and learning materials (implemented in MetaTool). It comprises numerous learning theories like adaptive learning, adaptive testing, and item response theory and contemporary intelligent system design [6]. The METOD paradigm concepts are implemented in MetaTool and specialized plug-in for learning management system.

MetaTool enables professional and non-professional educators (parents and other family members) to create e-learning platforms which can be imported into METOD-compatible viewer, e.g. Moodle [7], an open source content learning management system (CMS). After importing e-learning platform student can access materials and exercises of available courses. Each student has a different learning path, which is a sequence of materials and exercises that are displayed. The learning path is defined by student type and learning style of the student and it is adapted to if student type or learning style changes.

3. METOD EVALUATION
The evaluation for e-learning is very important. It includes user evaluation, which is divided into evaluation of the instruction and learning environment and evaluation of learning materials, and the evaluation from the developers of e-learning materials which includes evaluation of the instruction and learning environment. Several evaluation studies have been performed in order to get a real feedback about MetaTool and it's applicability in practice.

3.1 Test Site Evaluation Study: Faculty of Electrical Engineering and Computer Science)
The first testing of the users (trainees) response to the e-learning with Metod enhanced Moodle was performed on Faculty of Electrical Engineering and Computer Science, University of Maribor. E-materials for studying Checkland's soft system approach were prepared. The materials were imported in ordinary Moodle. The same materials were also imported in MetaTool and a Metod project was created. The Metod project was imported into Metod enhanced Moodle. From this small experiment we can conclude that e-learning with Metod enhancements in Moodle contributes to the learning ability but the results would be probably better when blended learning would be used.

3.2 Test Site Evaluation: University College of Nursing Studies
The efficiency of learning with e-learning materials can be tested when prior-knowledge and the knowledge after taking an e-learning course are compared. The difference in successfulness of solving pre-exam and post-exam shows the gain in trainee's knowledge.

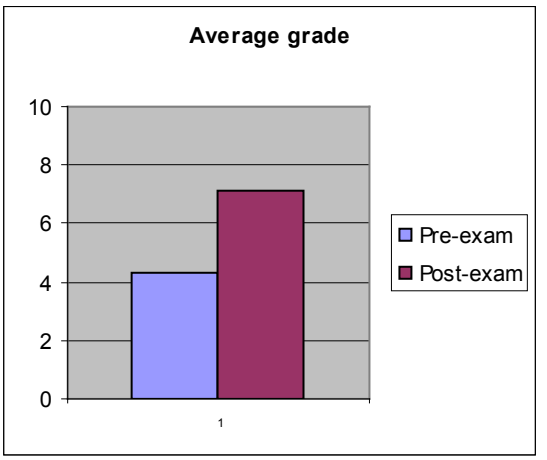
In this study students were using the e-learning materials created with MetaTool during classroom lectures. Before taking an e-learning course in Metod enhanced Moodle they performed a pre-test for evaluating their prior-knowledge. After learning they performed a post-test to establish how much they learned with e-course. The results showed that e-learning was successful.

3.3 Test Site Evaluation: E-Course on Learning Computer Skills
In this study students were using Moodle platform with Metod extensions. E-learning materials for learning basic computer skills were created with MetaTool. The following content was covered: Information Network Services, Basic Concepts of IT, Using a Computer and Managing Files and Word Processing.

The people with special need were also included. The e-learning materials were adapted for them in the following way: (i) the e-learning materials for heard of hearing people and deaf included video with the interpreter and (ii) weak-sighted people had the possibility to use software magnifiers. We tested the efficiency of learning and the trainees satisfaction with e-learning materials and platform.

3.4 Pilot Sites Evaluation
Pilot sites were included in the project with the purpose of testing the MetaTool. The teachers in the schools that were included as pilot sites prepared e-learning materials using MetaTool and they used the materials with their students in their classes. The studies showed that the creation of e-courses with MetaTool is not too demanding. The course creators were satisfied with the help from import and export wizards; however some minor flaws had to be fixed.

Graph 1. The results of test site evaluation at the School of Nursing



The trainees found learning with e-courses very interesting. Their response to e-courses and platform was mostly positive. However, we have to aware that e-learning is not suitable for everyone. The Metod enhanced platform was also tested with people with special needs. The survey results show that deaf and heard of hearing people learned a lot in adapted e-courses. They were satisfied with the courses but since their prior knowledge was generally lower compared to other trainees, they had to spend more time for learning how to manage the course.

4. RESULTS

Because of the space limit we can not present all the results so we will describe only the results for Evaluation study no. 2: Test site evaluation: University College of Nursing Studies.

Fifty-three students at the University College of Nursing Studies were involved into the study. As we mentioned above, the pre-exam and post-exam method was used to evaluate their knowledge. The results showed that e-learning was successful since the average gain in student performance was 27.9% (Graph 1).

At the end of course the students filed out the questionnaire for evaluation of e-course and e-materials. The results are presented below:

- **Question 1**: What is your learning style [8]?
  Most of the students (50%) involved in the survey think that they learn most through seeing. Others learn most with listening (30%) or if they are actively integrated in the process of learning (20%).
- **Question 2**: Were the materials in the course well adapted to your learning style?
  Most of the students have the opinion that their learning style is well represented in learning materials (around 90%).
- **Question 3**: Are you satisfied with the comprehensibility of the text in e-learning materials?
  Most of the students think that the text in e-learning materials is simple and understandable (around 80%).
- **Question 4**: Are you satisfied with the number of practical examples in e-learning materials?
  All except one of the students think that e-learning materials include enough practical examples.
- **Question 5**: Are you satisfied with the number of visual materials?
  E-learning materials should include more visual materials by the opinion of most of the students (55%). Others think that there was sufficient number of visual materials.
- **Question 6**: Are you fond of e-learning and would you like to try it again?
  The analysis showed that more than 50% of students were fond of e-learning and would like to try it again.

From the results of the questionnaire we can conclude that students were generally satisfied with e-course and that all learning styles and learning types were well represented in e-course. The Metod enhancements were well accepted by students.

5. DISCUSSION AND CONCLUSION

Several evaluation studies have been performed in order to get a real feedback about MetaTool and it's applicability in practice. The studies showed that the creation of e-courses with MetaTool is not too demanding. The course creators were satisfied with the help from import and export wizards; however some minor flaws had to be fixed. The trainees found learning with e-courses very interesting. Their response to e-courses and platform was mostly positive. However, we have to aware that e-learning is not suitable for everyone. The MetaTool and Metod enhanced Moodle proved to be very useful for trainees of different ages and also for trainees with special needs. However, the tool will be extended and updates (according to the practical needs) will be available on the project web page in the future.

ABSTRACT

This study is to investigate the process of innovation capability effects on both technological innovation adoption and firm performance directly and examine the intermediate effect of technology implementation process model and its impact on firm performance.

1. INSTRUCTION

Senior managers have paid attention to focus on whether the process of innovation can directly influences firm performance and implements IT properly in organization. The innovation studies have studied the relationship between nature, type, and process of innovation in organization and its innovative adoption and performance effect. However, in spite of a variety of innovation researches have been carried on, this mainstream of innovation has been little research on the process of innovation capability how this method affects technological innovation (Benner and Tushman, 2002; Edmondson et al., 2001), in turn, whether the technological innovation leads firm performance (Garvin, 1995; Harrington and Mathers, 1997; Harry and Schroeder, 2000). The objective of this study is to investigate the process of innovation capability effects on both technological innovation adoption and firm performance directly and examine the intermediate effect of technology implementation process model and its impact on firm performance.

2. LITERATURE REVIEW

The Process of Innovation Capabilities

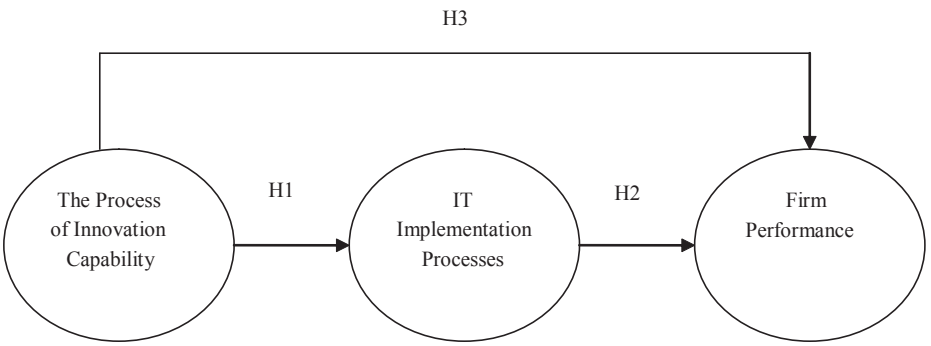
The process of innovation is occurred through fourth phases: idea generation, problem solving, response and implementation. (1) organization-wide generation of technical, product, process, and administrative kinds of innovative idea toward current and future organization need (Van de ven 1986). Ideas are generated by monitoring activities such as political, social, competitive and cultural elements that influence the needs and preference of its organization. (2) Organization-wide dissemination is the innovation into organizations by pushing and leading over time (Van de ven 1986). Rogers (1985) argues that an innovation mainly occurred through communication channels and messages through near peers, salespersons or advertising. Interfunctional coordination gives a chance to communicate or exchange regarding new idea. (3) Organization-wide responsiveness. Decision process can formulate positive attitude or negative attitude the innovation and lead directly a possible choice of adoption or rejection. (4) Organization-wide application actual usage, which means practically flow the innovation into physically implementation.

A Model of the IT Implementation Process

The IT implementation process is developed by Zmud and Apple (1989) and examined empirically by Cooper and Zmud (1990). The IT implementation process proceeds as follows:

- Initiation process: Search or scan problems or opportunities in organization and suggest IT solution. Initiate technology innovation from the organizational needs and wants.
- Adoption process: Implement IT application by political and rational negotiation entailing organizational support and assistance.
- Adaptation process: Developed, installed, test, and maintained the IT application. Revised organizational procedures and re-developed with the IT application. Then, train employees for the procedures and the IT application.
- Acceptance process: Employees accept the IT application and use it
- Routinization process: The IT application is used as a normal base.
- Infusion process: Organizational process effectiveness is achieved by the IT application usage.

Figure 1. Research model



3. RESEARCH MODEL AND HYPOTHSES

Based on the process of innovation theory, we suggest the process of innovation capability model shown in Figure 1.

Process of Innovation Capability and IT implementation Processes

The process of innovation capability helps firms to explore and recognize the significant of external innovation (Iansiti and Clark, 1994), subsequently, lead new technology adoption (Cohen and Levinthal, 1990; Edmondson et al., 2001). Several studies have found the positive relationship between innovation characteristics and implementation processes (Cooper and Zmud, 1990, Premkumar et al., 1994). Therefore, we assume that the process of innovation capability positively influences the IT implementation processes. Thus, we hypothesize as follow:

H1: The process of innovation capability will positively influence the IT implementation processes.

IT Implementation Processes and Firm Performance

Hitt and Brynjolfsson (1994) also found a mixed result of IT investment. Firm sales are positively related to the IT investment, whereas the total shareholder return, ROA, and ROE is not found any significance level. Controversially, Several studies have found that IT investments and firm profitability appear mixed results in IS literatures (Alpar and Kim, 1990; Barua et al., 1995; Bharadwaj et al., 1999, Cron and Sobol, 1983, Weill, 1992). In this study, again, we investigate the relationship between IT implementation processes and firm performance. Hence, we hypothesize as follow:

H2: IT implementation processes will positively influence firm performance.

The Process of Innovation Capability and Firm Performance

Benner and Tushman (2003) stressed the importance of process management and activities of process are positively related to organizational effectiveness in their conceptual paper. Ittner and Larcher (1997) found that process management is positively related to the firm performance in automotive industry. Thus, the process of innovation including organization learning, process management, and market orientation appears to be robust into firm performance. Therefore, we provide the following hypothesis:

H3: The process of innovation capability will positively influence firm performance directly.

4. RESEARCH METHODOLOGY

Sample and Data Collection

We collected data using survey questionnaire for a wide range of firm and industries from South Korea. We took three months for gathering data based on Web survey and paid 1, 500 U.S dollars for the collection. A total of 160 useable surveys were collected, and a response rate is 16 percent.

Analysis

We will analyze this data by structural equations methodology. We will check for the presence of a mediating effect, first, the direct relationship between process of innovation and firm performance, second, the process of innovation and IT implementation process, third, IT implementation process and firm performance. IT implementation will be a mediator between the process of innovation and firm performance.

5. EXPECTED RESULTS

Our study has focused on the process of innovation toward IT implementation and firm performance. We expect the capability of innovation lead IT innovation as well as firm performance. Most importantly, IT implementation by the process of innovation will affect positively firm performance.

Evaluating Usability Factors in Three Brazilian Portals

Wabner Alves de Souza, Faculdade Natalense para o Desenvolvimento do Rio Grande do Norte – FARN, Brazil; E-mail: wabnersouza@tjrn.gov.br
Luiz Augusto M. Mendes Filho, Faculdade Natalense para o Desenvolvimento do Rio Grande do Norte – FARN, Brazil

ABSTRACT

The usability of a system is a concept that relates to the quality of the interaction of systems with the users and depends on many aspects. The objective of this article is to carry through an evaluation of usability in three of the biggest portals of information and service of Brazil. A usability test was carried out to reach this objective. It was used users with and without experience in computer science, for the development of specific tasks to test the efficiency of the portals analyzed. The evaluation was made through standards of usability described for Nielsen.

1. INTRODUCTION

The importance of the interfaces of computational applications has been increasing in the last few decades. Thus the necessity to interact with computers is more present in the life of all. The innovation in the field of the Information Technology (IT) has caused changes in the form of living of people that must adjust themselves to this reality. For this reason it is necessary easy information systems that allow to get and to supply information to the users in easy and intuitive way.

Hence, the usability acts to stand out the importance of thinking ahead about the people who are in the other side of the video, and the reaction of them about the use of the computers, systems and interfaces. According to Leite (1998), the usability of a system is a concept that relates to the quality of the systems interaction with the users and depends on many aspects.

At a time where it verifies the emergency of terms as interactivity and usability, it is well-known the function each more critical played by IT, being distinguished the Internet. In this environment, each second worth a lot in the time to conquer users or to offer services. Therefore, the interfaces of the websites must be friendly and easy of use. This account so much to whom uses the Internet for the most different ends.

IT has proportionate a variety of new resources for the development of interfaces with the user. The adequate use of these resources becomes the websites sufficiently friendly and attractive, making with that the access to the information and the resources are efficient and pleasant for the user. It doesn't matter the great resources spend in technology if the user satisfaction isn't reached.

Portals of information and service are used in day-by-day of the Brazilians, since the former supplies notice and information of the most varied types and updated every second. So, the objective of this study is to evaluate the usability factors in three of the biggest portals of information and service of Brazil.

2. METHODOLOGY

This research used a usability test as form to evaluate the usability factors of the three portals. A usability test is a process in which representative participant evaluate the degree that a product is in relation to the specific criteria of usability (Rubin, 1994).

The evaluation of usability of the interfaces was carried out in three of the biggest portals of information and service of Brazil. According to Folha Online (2006), the three portals more cited by internet users were: UOL with 21% of the interviewed ones, whereas Terra and IG (Internet Group) were with 10% and 9% respectively.

The usability test used 12 users for the development of specific tasks to test the efficiency of the portals analyzed, being that nine work with computer science and the other three use the Internet only in the day by day.

The test used standards of usability described for Nielsen (2000), and that they focus the following aspects:

- Design of the page: Land of the screen, Time of reply, and Links;
- Design of the content: Adequate formatting of the texts;
- Design of the site: Metaphor and Navigation.

3. DATA ANALYSIS

3.1 Design of the Page

The first factor to be analyzed is the Design of the Page, divided in three items: Land of the screen, Time of reply, and Links.

3.1.1 Land of the Screen

In the first question related to the land of the screen, 66.67% of the users affirmed that the available space to the content is fine. However, with respect to priority given to the comparative content to the use of the land of the screen to show other resources or services, the analyzed portals still need to improve in this aspect.

It was verified in the second question referring to the land of the screen, that 80.56% of the users said that the spaces blank in the screen of the portals are few, showing that they are using appropriately the available spaces in the screen for the content, navigation or other resources well.

The question of number three asked to the users about if the announcements and propagandas are taking too much space in the portals. According to 52.78% of the respondents, they consider that the announcements are in excesses and confuse the visualization of the site. In such a way, the portals would have to diminish the amount of advertising in their sites, thus it makes possible a better usability for the user.

3.1.2 Time of Reply

As for the reply time, the evaluated portals demonstrated a good performance. Only 5.56% of the users answered that the site did not react fast to the commands, and 36.11% of those found that the time of reply of the portals is enough. The others 58.33% affirmed that the time of reply of the portals is satisfactory.

With regard to the time of download of file of the portals, for 33,33% of the users these portals almost never inform the size of downloads. Only 16,67% said that the portals always inform the size of downloads. Therefore, these portals need to inform to the user the size of the file, and then one can decide if will download it at that moment or not.

3.1.3 Links

The research verified if the portals offered a resource that showed one brief explanation of link before the user clicks on it. The results show that 38.89% affirmed never the portals show the headings of links to facilitate the navigation of the users, and only 22.22% of the respondents answered that always the portals inform the heading of links. Thus, it expects that these portals always inform some information about the link before the user clicks on it.

3.2 Design of the Content

For 55.55% of the users, the content available for the portals is satisfying the necessity of them with regard to the quality and brevity of the texts. The others

44.45% were indifferent as regards to the adequate formatting of the texts in the site. Therefore, as the result was not satisfactory for the great majority of the respondents, it is expected that the portals try to develop more objective contents, dividing the subjects in topics, facilitating and providing to the user a clearer and direct reading.

3.3 Design of the Site

In respect of the use of metaphors in portals, 47.22% of the users demonstrated indifference to this aspect, affirming that the use of metaphors does not harm and nor contributes for a good navigation. No informer answered that the metaphors helped a lot in the navigation, and 38.89% said to be satisfactory the use of metaphors in the portals.

In the aspect of the navigation, referring to the identification of where the user is in the site, 61.11% of the users said that is satisfactory or very satisfactory the navigation of these portals. This information proves that the portals are informing the localization of the users whenever possible, facilitating to get the information in any place of the site, and not leaving them to lose during the navigation.

4. CONCLUSION

The results in general showed that the users have a good impression as regards to the usability of the portals. The purpose of this research was exactly to show the reality of the main Brazilian portals since all internet users currently access theses sites at least once per day. In such a way, verifying the usability of these portals and identifying possible deficiencies in them, it can solve them, and consequently to facilitate the access of the information for any type of user, from the least to the most experienced in the Internet.

The majority of the developers and Brazilian companies still invest very little in usability, and usability tests still are something rare. Therefore, it must be had in mind that the elaboration and accomplishment of tests to evaluate the usability, applied to a product, as it was the focus of this work, is a good pointer to display problems in potential. This sufficiently minimizes the risk of offering an unstable product and of difficult learning in the market.

This work did not intend to analyze all the existing problems with the usability of these portals since the research would be much more ample. As recommendation for future research aiming at practical results, it is suggested a work deepened in this subject using more professional without experience in computer science, in order to get a set of suggestions for the improvement of the usability in the sites of the Web. This set of suggestions can be carried through one checklist or developing a method of evaluation for portals of information and service.

The Role of ICT in Organizational Knowledge Sharing Processes: An Exploratory Study

Marieke Wenneker, Raboud University Nijmegen, The Netherlands; E-mail: M.Wennecker@maw.ru.nl
Paul Nelissen, Raboud University Nijmegen, The Netherlands
Martine van Selm, Raboud University Nijmegen, The Netherlands
Fred Wester, Raboud University Nijmegen, The Netherlands

This research is funded by The Netherlands Organization for Scientific Research (NWO), project number 014-43-702.

In modern societies knowledge is considered to be an important factor to stimulate organizational development [4,5,7]. Scholars suggest that information and communication technology (ICT) tools such as email and intranet, in which telecommunication and information technology are integrated [1,8,14] support knowledge sharing and thereby enhance organizational development [2,5,7]. However, in several empirical studies, organization managers often complain that the opportunities for knowledge sharing provided by ICT tools are underutilized, or even ignored [3]. Accordingly, the question arises how knowledge sharing processes take place and which role ICT tools have in these processes. The purpose of this study is to examine the role of ICT tools in everyday knowledge sharing processes related to the primary process in organizational teams.

Knowledge sharing is often described as an interaction between individuals in which they mutually exchange knowledge used in their jobs [2,5,11]. This characterization of knowledge sharing implies that a knowledge sharing process consists of both donating and receiving knowledge. Three types of knowledge sharing are discerned: knowledge storage, knowledge retrieval and knowledge exchange [4,5]. In this study, the role of ICT in the sharing of knowledge in (small) teams is examined. We registered and interpreted all communication acts in which we assume knowledge to be shared.

The role of ICT tools in knowledge sharing processes is assumed to be different under various conditions [13]. Based on previous research [6], we expect ICT use to be more prominent in knowledge sharing processes in relatively large, dispersed teams than in relatively small, collocated teams.

METHODS

In an exploratory case study (study 1) and a comparative study of three cases (study 2), we assessed knowledge sharing processes under varying conditions. Each case represents a project team involved in knowledge intensive work. The critical project team size was eight to ten persons [12]. Geographical dispersion was measured by the presence of other team members in their environment [10]. All teams were selected from large, knowledge intensive organizations in both profit as well as non-profit branches. As Table 1 shows, we expected ICT use to be more prominent in knowledge sharing processes in relatively large, dispersed teams (case 2) than in smaller, less dispersed teams (other cases). Moreover, we assumed that ICT tools have a more important role in small, dispersed teams (case 3) and medium sized, less dispersed teams (case 4) than in medium sized, collocated teams (case 1).

STUDY 1: EXPLORATORY STUDY

In study 1 we examined ICT use in knowledge sharing processes by means of diaries in which team members recorded their communication activities during two days (n = 12). In addition, we carried out follow-up interviews with project team members (n = 5) in order to furnish contextual information about the registered communication acts and to check the representativeness of the registered communication acts in their daily work.

To examine knowledge sharing processes, we observed the topic and persons involved in a communication act. In addition, for the use of ICT tools and other communication channels we looked at the use of communication channels and persons involved in a communication act.

Analysis was focused on describing the nature of knowledge sharing processes. While analyzing the communication acts, we found that different forms and subforms of knowledge sharing could be distinguished. These forms were found by observing the topic and persons involved in a communication act in the context of the other communication acts.

STUDY 2: COMPARATIVE STUDY

In study 2 we examined whether the forms and subforms of knowledge sharing distinguished in study 1 could be identified in the other cases as well. Data were

Table 1. Conditions of cases and expectations regarding ICT use

	Size (number of members)	Geopgraphical dispersion	Expectations regarding ICT use
Case 1 (exploratory)	12	--	-
Case 2	45	++	++
Case 3	6	+	+
Case 4	12	-	+

Note. Differences in 'geographical dispersion' and 'expectations regarding ICT use' between cases are relative and range from '--.'(collocated respectively low on ICT use) to '++' (dispersed respectively high on ICT use).

obtained through diaries (n = 27) and interviews (n = 10) in the same way as in study 1. In order to examine forms of knowledge sharing, communication acts were categorized in clusters, such as communication activities around meetings, or a couple of days of work. Furthermore, in the interviews we presented the team members with a list and asked them to indicate which forms and subforms of knowledge sharing they used. In addition, we asked for a ranking of the prominence of communication channels.

Accordingly, we analyzed the diaries and interviews. Analysis was focused on describing forms of knowledge sharing and the use of ICT tools and other communication channels in clusters of communications activities. Comparisons between cases were made in order to formulate generalizations on the role of ICT tools.

RESULTS

Study 1: Exploratory Study

Firstly, we discovered that communication activities could be distinguished into three different forms of knowledge sharing: donating, acquiring, and exchanging knowledge. If a communication act carried out in the context of an interaction, knowledge was exchanged, otherwise knowledge was donated or acquired. These forms seemed to be interesting because they shed light on the nature of knowledge sharing processes and stand for ways in which knowledge could be shared. As knowledge sharing is often described as an interaction between individuals, we would expect that knowledge is mainly exchanged in two-sided, mutual interactions. However, one-sided processes could be identified too. Secondly, zooming in on these forms of knowledge sharing, various subforms of knowledge sharing could be discerned. Examples are brainstorming, giving advise, or receiving an answer. Thirdly, ICT tools did not have a prominent role in knowledge sharing processes of the team. They were mainly used in one-sided activities like donating or acquiring knowledge. Face to face communication was the most prominent channel for the exchange of knowledge.

Study 2: Comparative Study

Firstly, three forms of knowledge sharing distinguished in study 1, donating, acquiring and exchanging knowledge, were recognized in study 2 as well. Secondly, in addition to study 1, six new subforms of knowledge sharing were disclosed, adding up to a total of 23 subforms (see Table 2).

Some of these subforms seem to contribute to the development of knowledge, for instance giving advise or brainstorming. Other subforms seem to deal with information, like giving a remark or spreading information.

Thirdly, we examined how various ICT tools are used in donating, acquiring respectively exchanging knowledge (see Table 3 for summary).

In general, Table 3 shows that email is the most important ICT tool, except for case 4. However, email is not the most prominent tool for exchanging knowledge. Face to face communication plays an important role as well; in case 1 and 3 face to face communication is the most important communication channel.

Table 2. Forms of knowledge sharing

Forms of knowledge sharing		
Donating knowledge	Acquiring knowledge	Exchanging knowledge
making information available	*inquiring information*	*exchanging information*
making mentions available	*inquiring mentions*	*fine tuning*
spreading information	*acquiring information*	*brainstorm*
giving advise	*acquiring mentions*	*evaluation/reflection*
giving an answer	*acquiring advise*	*monitoring*
making mention of things	*receiving an answer*	*exchanging experiences*
giving a remark	*receiving a remark*	
asking a question	*receiving a question*	
writing down information		

Table 3. ICT tools and face to face communication channels used in knowledge sharing processes in teams

Forms of knowledge sharing	Case 1	Case 2	Case 3	Case 4
Donating	**email** shared drive virtual work space face to face	**email** virtual work space	email shared drive intranet face to face	email **workflow system** face to face
Acquiring	**email** shared drive virtual work space face to face	**email** intranet knowledge base virtual work space	**email** shared drive intranet face to face	email intranet **knowledge base** **workflow system** face to face
Exchanging	**face to face**	**email** **phone** conference calls face to face	**phone** **face to face**	face to face

Note. Prominent ICT tools and face to face communication channels are in bold.

Regarding the conditions, knowledge exchange through ICT tools could be identified in dispersed teams (case 2 and 3). In collocated teams knowledge exchange through ICT tools was not identified. Furthermore, ICT tools are used in large teams (case 2) in order to exchange knowledge. However in small teams (case 3) the phone is also used in order to exchange knowledge. Accordingly, dispersion seems to be the most important condition for exchanging knowledge by means of ICT tools. Concerning donating and acquiring knowledge the conditions seem not to matter. Knowledge is donated and acquired through ICT tools in all cases.

Furthermore, the results show that in teams high on ICT use (case 2 and 4) different forms of knowledge sharing are dominant. The team's task seems to offer an explanation for this. In teams involved in developing products or services (case 2), exchanging knowledge through ICT tools was dominant, whereas in teams applying rules (case 4) donating and acquiring knowledge was dominant. In development teams low on ICT use (case 1 and 3), ICT tools are used for donating and acquiring separately.

DISCUSSION

In this study, different forms and subforms of knowledge sharing were empirically derived from organisational teams that differed according to size and geographical dispersion. As knowledge sharing is often described in terms of an interaction between individuals [2,5,11], we would expect that knowledge is mainly exchanged in two-sided, mutual interactions. However, one-sided processes, i.e. donating and acquiring knowledge, could be identified too. Accordingly, in addition to the characteristics mentioned in literature [2,5,11], knowledge sharing is not only characterized by two-sided interactions, but one-sided processes as well.

The starting-point of this study was to empirically examine knowledge sharing processes through observing communication activities. Accordingly, we registered and interpreted all communication acts in which we assume knowledge to be shared and focussed on the process of knowledge sharing. However, there are indications that knowledge is not shared in all communication activities. Some subforms seem to deal with knowledge, whereas other subforms seem to deal with information. With regard to the types of knowledge sharing discerned in literature [4, 5], subforms dealing with information seem to be related to knowledge storage and knowledge retrieval, whereas subforms dealing with knowledge are related to knowledge exchange. We will further investigate when knowledge is shared in communication activities.

Moreover, regarding the subforms, we have to mention that they are not mutually exclusive. Further research into the distinctions between subforms is needed.

With regard to ICT tools, in previous research [6], ICT use seemed to play a more dominant role in relatively large, dispersed teams. Since in our study relatively small teams had a high score on ICT use too, size seems not always to be a critical condition for ICT use. Moreover, in literature it is assumed that ICT could play a dominant role in knowledge sharing [9]. However, this study shows that face to face communication seems most important.

Missed Call Use Across Cultures

Ishraga Khattab, Brunel University, UK; E-mail: Ishraga.Khattab@brunel.ac.uk
Steve Love, Brunel University, UK; E-mail: Steve.love@brunel.ac.uk

ABSTRACT

With the ubiquitous use of mobile phones everywhere, mobile phone users constantly invent new ways to use their mobile phones to satisfy their communication needs. An example of how technology sometimes is used in a way that was not anticipated is the use of "the missed call". The missed call is an intentional action whereby a person places a call and disconnects the call before the recipient on the other end answers the call. Despite the popularity of the missed call, to date the missed call as a form of communication has not been considered in mobile phone design. Therefore, the aim of this research is to propose a solution that employs an icon-based missed call service (IBMCS) to help users interpret the different meanings of the missed calls. Two contrasting cultures were selected for this study; the UK as a representative for the mature mobile technology market and the Sudan as an emerging market for mobile devices. The results from the study indicated that the IBMCS allows for better interpretation of the missed calls. The Sudanese had more positive attitude towards the developed service than the British participants. However, the British deemed that the icons were self explanatory and more informative and expressive than the old missed call service. The Sudanese were satisfied with the new IBMCS but they suggested adding more icons to the IBMCS. .

INTRODUCTION

The use of the missed call is grown popular especially in Africa. Samuel, Shah and Hadingham (2005) observed missed calls or *beeping* among users in Tanzania and South Africa. Gamos consultancy (2003) found that 38% of participants used payphones and telecentres in Uganda, Botswana, and Ghana to beep mobile phone users.

Donner (2005c) found that users in sub-Saharan have produced elaborated codes and social messages to be exchanged over the network without bearing any cost or at least not from those who are in a less secure financial position. Donner (2005c) found that the missed call/beeps is used mainly to mean 'call me back'; where the caller's intention is to request the recipient to bear the cost of the call. Missed call is also used as 'instrumental message', or 'relational sign' such as "pick me up now", "I am thinking of you" respectively

Chakraborty (2004) observed the missed call phenomena in Sitakund, Bangladesh. Here, users invented ways to communicate through the network without paying for the call. An example for the missed call code is: one ring = 'I am at home, where are you?' two rings = 'I'm at your house, where are you?'

Understanding the intended meaning of the missed call is a challenge that faces missed call users. To eliminate the ambiguity related to the interpretation of the missed calls an icon-based missed call service (IBMCS) was developed.

AIMS OF THE STUDY

- To investigate whether an IBMCS will clarify the meaning of the missed call in comparison to the traditional missed call system
- To investigate the impact of culture on users' perception of an IBMCS.

PARTICIPANTS

Eighty participants took part in this study. 35 British (16 male, 19 females) and 45 Sudanese (18 males and 27 females) ranging in age from 13-34 years old, with the average of 20 years old. All participants were mobile phone users. Experience of mobile phone use for the Sudanese participants ranged from 2-5 years whereas the British participants had used mobile phones for 4-12 years.

DATA COLLECTION

A Likert-type scale (Likert, 1932) was used to ascertain people's perception of using the IBMCS. The questionnaire was a fully revised version of the Computer System Usability Questionnaire developed for IBM by (Lewis, 1995) the scale had a 7 point format with responses ranging from strongly disagree to strongly agree with a neutral mid point. An example of the format is given below in Figure 1.

In addition to the Likert scales, a semi-structured interview was completed to get richer data about the users' perception of the IBMCS.

PROTOTYPE

Flash 8 Macromedia was used to create the prototype used in this study. The prototype consists of set of screens that enable the user to place/receive an icon-based missed call. Figure 2 shows an example of the missed call icon based service.

PROCEDURE

Participants were briefed about the purpose of the experiment and provided with the task instructions.. Examples of typical tasks participants were asked to complete is given below:

- Place a missed call that means "Reminder for prior arrangement"
- Place a missed call that means "After sending sms"

Following this, participants were asked to complete the Likert questionnaire statements. Finally, participants were interviewed for one hour regarding their experience of using the service.

QUESTIONNAIRE RESULTS

A Mann Whittney test indicated that significant differences were found between the British and the Sudanese in relation to the sending and receiving missed calls using the IBMCS.

For sending, Sudanese participants showed a more positive attitude in all measures in comparison to the British. For example the likeability and the overall satisfaction of using the service to send missed calls measures indicated the Sudanese willingness to use the service in comparison to the British ($U= .000, p<0.001$), ($U=.008, p<0.01$).

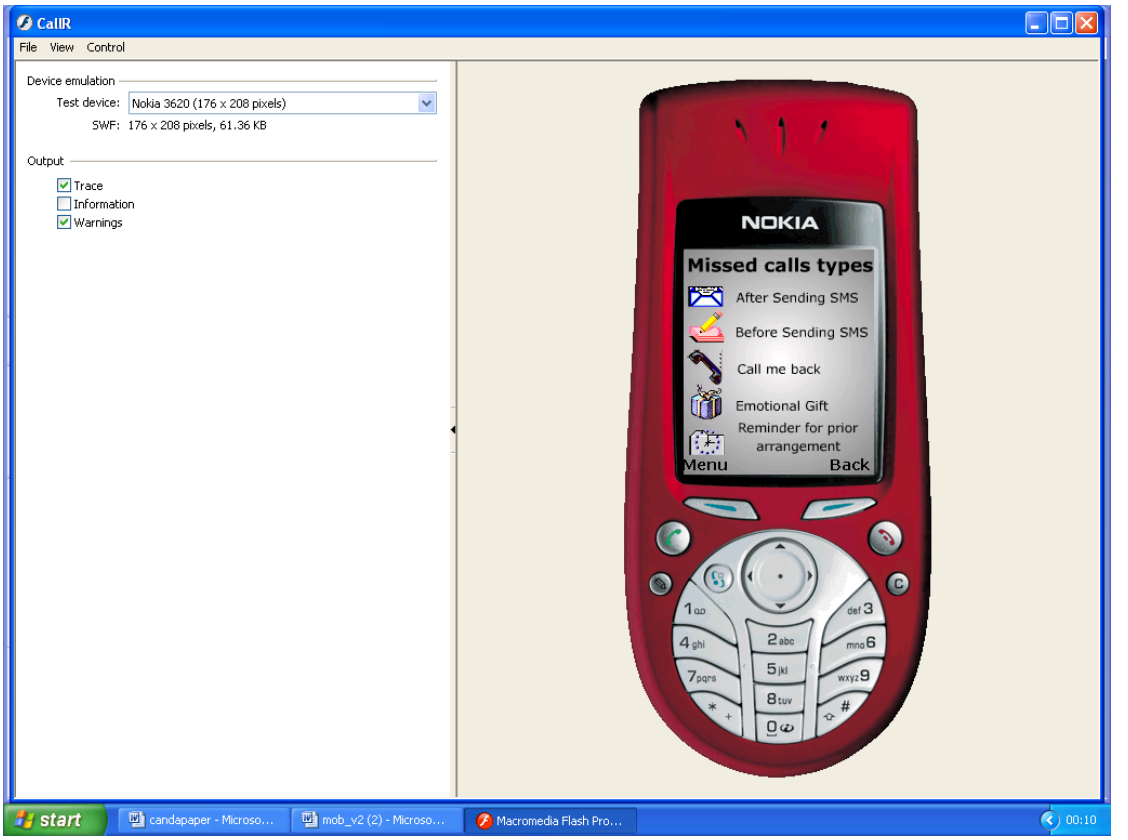
For receiving, again the British were less enthusiastic about using the IBMCS to receive missed calls. For example the enjoyability measure and the ease of use

Figure 1. Example of attitude statement used in the study

It was easy to learn how to send a missed call using the IBMCS.

Strongly disagree	Slightly disagree	Disagree	Neutral	Agree	Slightly agree	Strongly agree

Figure 2. Shows an example of the missed call icon based service



both indicated the Sudanese positive attitude (U=.001, p<0.001), U=002, p<0.001). Please see Table 1 for a summary of the main results.

INTERVIEW RESULTS

The interview results also reflected the Sudanese positive attitude towards the developed service in comparison to their British counterparts. Participants from both cultures appreciated the ability of the new service in conveying missed call messages in a quick and clear way as one of the British interviewee commented:

"I like the new missed call service, on the old system it was tricky to figure out the meaning of the missed call sent."

The British and the Sudanese differentiated between the sms and the IBMCS. The cost element was the main theme that was highlighted by the British and the Sudanese. They believed that using the IBMCS to convey social messages is more cost effective than using sms. The IBMCS enable users to scan and understand the message quicker than the sms message where the user needs to read through the whole text to perceive the intended meaning. As one of the interviewee commented:

"You need to read the entire text to understand the meaning of the message where with the missed call just one quick scan at the icon will explain the message"

DISCUSSION

The results on this study highlighted the importance of missed call rituals as a developed mode of communication that facilitates social interaction. The IBMCS seems to offer users a unique form of mobile phone interaction possibly that is not offered by phone calls or text messages.

The Sudanese were found to be more positive about enjoying and using the new service than the UK participants. Measuring these results against Hofstede's typology (1980) the enthusiasm of the Sudanese towards the IBMCS can be viewed through their collectivistic way of living, where they expected to look after each other, care for others social interests and stay connected. Apparently the IBMCS enable users to fulfil their social commitment with less effort, time and cost.

Both the British and the Sudanese identified differences between the sms and the new missed call. The Sudanese appreciated the ability of the new missed call service in conveying social meanings using the icons. The Sudanese also perceived the IBMCS as a better channel of communication in comparison with the sms in terms of cost, time and effort. One justification for the Sudanese attitude might be related to the difficulty they experience when using sms. For example, the maximum limit of the sms is 160 characters but in Arabic it is only equivalent to around 78 characters. Therefore, a single message might need to be written in 2-3 different sms. Some of the Sudanese mobile phones do not have comprehensive support for Arabic language or the Arabic alphabet may be absent on the key board, as a result, writing an sms may require memorization or a workaround texting and thus they perceive the IBMCS as more of a simple and clear way of communication.

CONCLUSION

The rationale for using the missed call has unmistaken economic and financial connotations. However, diversity in the users' perception of the IBMCS between the two cultures implies that the conventions of the missed call perhaps are shaped by cultural differences. For example, the British perceived the IBMCS as an entertaining mode of communication to fill empty times, whereas the Sudanese

Table 1. Users' attitudes towards the new missed call service in the UK and Sudan

Theme	Country	N	Mean Rank	Asymp sig 2 tailed	Sig level
It was easy to use the IBMCS to send a missed call.	Sudan	45	45.20	.031	*

**P<0.05, **P<0.01, ***P<0.001*

with their limited financial resources tied with their social and cultural obligation has made the new missed call service an appealing channel of communication that supports their personal and business communication. The Sudanese actually sought further solutions to maximize their communication opportunities and to develop a sophisticated missed call service that satisfies more personal communication needs.

Dealing with Data Warehouse Transaction Processing Truncated Data: Case Study of SQL Server 2000

Carin Chuang, Purdue University North Central, USA; E-mail: cchuang@pnc.edu
Kuan-Chou Chen, Purdue University Calumet, USA; E-mail: kchen@calumet.purdue.edu

ABSTRACT

In this paper, the cause of truncated data in the transaction processing will be discussed. Specifically, the main goal of this paper is to demonstrate the function of recovery model in the SQL Server 2000. In the paragraphs to come, we will discuss in a little more detail, the truncated data that can take place, along with the importance of data integrity. Afterwards, we will discuss two scenarios cases to implement the recovery model. In the case, we will begin by discussing the transaction processing in between data warehouse. Afterwards, we will discuss the potential causes of truncated data. The last part of this case details configuration of each recovery model; more specifically what types of functions are available in this particular setting, what requirements those functions place on to deal with specific problems and few of the benefits that come with having experience. This paper has the potential to provide the recovery model needs to database administrator to do advanced support task.

Keywords: CIS majors, math course, course design.

INTRODUCTION

Transaction management is one of the most crucial requirements for enterprise application development. Most of the large enterprise applications in the domains of finance, banking and electronic commerce rely on transaction processing for delivering their business functionality. Given the complexity of today's business requirements, transaction processing occupies one of the most complex segments of enterprise level distributed applications to build, deploy and maintain.

Enterprise data warehouse often require concurrent access to distributed data shared amongst multiple components, to perform operations on data. Such applications should maintain integrity of data (as defined by the business rules of the application) under the following circumstances:

1. Distributed access to a single resource of data, and
2. Access to distributed resources from a single application component.

In such cases, it may be required that a group of operations on (distributed) resources be treated as one unit of work. In a unit of work, all the participating operations should either succeed or fail and recover together. This problem is more complicated when a unit of work is implemented across a group of distributed components operating on data from multiple resources, and/or the participating operations are executed sequentially or in parallel threads requiring coordination and/or synchronization. Truncated data would be easy to be occurring in the process in either case. It is required that success or failure of a unit of work be maintained by the application. In case of a failure, all the resources should bring back the state of the data to the previous state (i.e., the state prior to the commencement of the unit of work).

In this paper, the cause of truncated data in the transaction processing will be discussed. Specifically, the main goal of this paper is to demonstrate the function of recovery model in the SQL Server 2000. In the paragraphs to come, we will discuss in a little more detail, the truncated data that can take place, along with the importance of data integrity. Afterwards, we will discuss two scenarios cases to implement the recovery model. In the case, we will begin by discussing the transaction processing in between data warehouse. Afterwards, we will discuss the potential causes of truncated data. The last part of this case details configuration of each recovery model; more specifically what types of functions are available in this particular setting, what requirements those functions place on to deal with specific problems and few of the benefits that come with having experience. This paper has the potential to provide the recovery model needs to database administrator to do advanced support task.

DATA WAREHOUSE AND TRANSACTION MANAGEMENT

Every operation involves data occurs within a transaction. The way in which a database handles transactions is a critical to the database industry as the aerodynamic curve of a wing is to the aircraft industry (Nielsen, 2003). Transaction processing is a reliable and efficient of large volumes of repetitive work. Database management systems ensure that simultaneous users do not interfere with each other and that failures do not cause lost work. There are three problems that can result because of simultaneous access to a database: [1] lost update, [2] uncommitted dependency, and [3] inconsistent retrieval (Mannino, 2004).

Data warehouse is a central repository for summarized and integrated data from operational databases and external data sources. In a data warehouse, data must be organized for rapid access to information for analysis and reporting, as this is the purpose of the data warehouse. Data integrity and performance of transaction processing requires that operational database be highly normalized. In contrast, data warehouses are usually demoralized from Normal Form to reduce the effort to join large tables. Most data warehouse processing involves retrievals and periodic insertions of new data. Because of difference processing requirements, different data models have been developed for operational data warehouse database. In general, the different processing may cause the truncated data.

DATA WAREHOUSE IMPLEMENTATION

Dimensional modeling is used in the design of data warehouse database to organize data efficiency of queries that analyze and summarize large volumes of data. The data warehouse schema is usually much simpler than the schema of an OLTP (On-Line Transaction Processing) system designed using entity-relation modeling. The verification tables used in OLTP systems that are used to validate data entry transactions are not necessary in the data warehouse database because the data warehouse data has been verified before it was posted to the data warehouse database and the data is not expected to change frequently once it is in the data warehouse (Agosta, 2000). Backup and restore strategies also differ in a data warehouse from those necessary fro an OLTP system. Much of the data in a data warehouse is unchanging and does not need repetitive backup. Backup of new data can be accomplished at the time of update, and in some situations it is feasible to do these backups from the data preparation database to minimize performance impact on the data warehouse database.

Data to be used in the data warehouse must be extracted from the data sources, cleaned and formatted for consistency, and transformed into the data warehouse schema. The data preparation area is a relational database into which data is extracted from the data sources, transformed into common formats, checked for

consistency and referential integrity, and made ready for loading into the data warehouse database. Performing the preparation operations in source database is not an option because of the diversity of data sources and the processing load that data preparation can impose on online transaction processing systems. Furthermore, attempting to transform data in the data source systems can interfere with online transaction processing (OLTP) performance, and the reconciliation of inconsistencies in data extracted from various sources cannot be accomplished until the data is collected in a common database, at which time data integrity errors can more easily be identified and recited. The data preparation area is a relational database that serves as a general work area for the data preparation operations. It contains tables that relate source sat keys to surrogate keys used in the data warehouse, tables of transformation data, and many temporary tables. It also contains the processes and procedures that extract data from source data systems.

The data preparation area should also contain the processes that are used to extract the data from the data sources, the processes that transform and cleanse the data, and the processes that load the data to the data warehouse. The processes may be in the form of SQL quires, stored procedures, DTS packages, or documents of manual instructions. As in the development of any database system, the objective is to automate as much of the process as possible and to mange and maintain the automated tools developed. Storing and maintaining the transformation processes in the data preparation area permits the use of standard database backup and restore mechanisms to preserve them. The database schema must support complex data representations. Database must contain data that are aggregated and summarized.

CASE STUDY OF SQL SERVER 2000

Scenario

As an administrator of a SQL Server 2000 computer, the job responsibility is to create a database to use an intermediate data store for a data warehouse. Each night the administrator must import daily sales data into the database from SQL Server 2000 computers in 120 locations. After the data is moved into the data warehouse, the tables are truncated. The database schema is shown in the Figure 1. For the purpose of minimizing the time to import the sales data and administering the database, there are several procedures for an administrator to configure the data import processes.

Implementation

We want to optimize or speed and at the same time keep administration down. We accomplish this by

1. Use the simple recovery model and the FOR LOAD option to create the database. Use the simple recovery model. It will avoid logging of the bulk import process. This will increase speed.
2. Create a Data Transformation Services package that uses the BULK INSERT statement to copy the sales Data. Create a DTS package with BULK INSERT to copy sales data. BUL INTERT is fast way to import data and a DTS package can be reused and requires little administration.

A SQL Server 2000 provides three recovery models that can be used to recover database data in case of hardware failure or other eventualities that may compromise data integrity. These recovery models are: the Simple Recovery model, the Full Recovery model and Bulk-Logged Recovery model. With the Simple Recovery model, the database can be recovered to the point of the last backup but not to the point of failure or to a specific point in time. To do that, choose either the Full Recovery or Bulk-Logged Recovery model. Furthermore, the FOR LOAD clauses of the CREAT DATABASE statement are used for compatibility with earlier versions of SQL Server. The database is created with the dbo use only database option turned on, and the status is set to loading. The simple recovery model fits this scenario well since the tables are truncated every night.

An Overview of the Role of Math Courses for CIS Majors

Kuan-Chou Chen, Purdue University Calumet, USA; E-mail: kchen@calumet.purdue.edu
Carin Chuang, Purdue University North Central, USA; E-mail: cchuang@pnc.edu

ABSTRACT

In this paper, an overview of the math course contents, knowledge and skills and trends should be required for CIS majors will be presented. A variety of math course developments will be discussed. Appropriate math course development provides a systematic, problem-solving approach to planning and designing learning experiences for CIS majors. It is imperative to explain the benefits that result from mathematics, discuss how its practitioners work, and present the rationale for CIS majors.

Keywords: CIS majors, math course, course design.

INTRODUCTION

Since late 1970s and early 1980s, personal computer goes into individual working settings and family life. Computer utilization and operation has no longer for computer professional only. Since then, a sub-division of compute sciences (CS) department, called computer information systems (CIS), has been growing to be an individual academic unit. The computer information technology major is designed to combine the benefits of a traditional college education with the benefits of hands-on training in state-of-the-art computer technology. Students become technically competent, but also learn to write well-organized and clear memoranda and reports. The computer information technology curriculum integrates technical skill with communication skills, superior general education requirements, and breadth of knowledge in the computer information technology field. In other words, from teaching and research standpoints, computer information systems education focuses on more the design for product-oriented and market trends. Computer science education is the discipline that seeks to build a scientific foundation for providing the underpinnings for today's computer applications as well as the foundations for tomorrow's applications. To this extent, computer science requires strong math disciplines and foundations. Computer information systems program only requires minimum math education. Computer information systems majors may not need as many math courses as computer science students need. Mathematics is the language of technology. It is used to formulate, interpret, and solve problems. It is the bedrock for the computer revolution. Mathematics provides us with powerful theoretical and computational techniques to advance our understanding of the modern world and societal problems and to develop and manage the technology industries that are the backbone of our economy.

Mathematics is a living discipline. Some traditional subjects in pure mathematics have been studied for hundreds of years; other topics, developed during the last few decades from the study of industrial issues, form a body of applied mathematics closely tied to the understanding of practical problems and basic phenomena. There is remarkable synergy between these seemingly disparate fields of study; the abstract nature of mathematics supports important applications in an ever-growing number of areas. However, how much knowledge is need for CIS students? How many math courses should be required for CIS students? What math course contents are needs for CIS students?

MATHEMATICS

Mathematics is an abstract science concerned with level and structure. It is best seen as a highly interrelated set of abstract systems, the structure of which is well understood. As such, it is perhaps the most advanced science. Other sciences use the concepts and structures of mathematics as tools to study real world problems. By mapping real world systems into abstract mathematical systems, the researcher facilitates the application of powerful mathematical results and methods. The broader our understanding of different mathematical structures, the better we are able to select appropriate models to study information systems phenomena.

In addition to the fact that mathematics is the most highly developed and powerful science, there are two other characteristics which recommend it to the study of information systems. As noted above, all disciplines contributing to information systems research use mathematics to some extent. It thus provides a common language for cross-disciplinary communication. Finally, the clarity, precision, and conciseness afforded by quantification are essential to the study of complex phenomena like information systems. Whitehead, in regard to mathematics, notes that a good notation spares us the painful necessity of thinking; notation itself may generate ideas. Mathematics has the most highly developed systems of notation of any science.

Mathematics tends to be viewed in a limited and distorted way by non-mathematicians. There is therefore a need to first outline the field of mathematics. Information systems researchers tend to identify mathematics which statistics. Statistics is just one of nine major branches of mathematics (Table 1). Although this may be the only branch of mathematics to which information systems researches are exposed, it is certainly not the only branch of potential use to information systems researchers. The over-emphasis upon statistics in the training of information systems researchers has resulted in a corresponding over-emphasis upon hypothesis testing and inductive methods in information systems research, almost to the exclusion of modeling and deductive approaches. Content analysis of the information systems research literature bears this out (Van Doren and Heit, 1973; Smale, 1981).

The range of potential applications of each of these nine branches of mathematics is limited only by our understanding of these areas of knowledge and out imagination. While each branch of mathematics includes very complex concepts and structures, each also includes quite simple and basic concepts that are within the grasp of virtually any information systems researchers. A good example is set theory's Venn diagram methods, now taught to grade scholars. A more recent development is set theory is the concept of "fuzzy set" (Zadeh, 1973), which offers methods of dealing with the many "fuzzy concepts" in information systems and leisure. Matrix algebra is important in solving systems of equations and provides the basic structure for many applied models, such as linear programming, input-output, and Markov chains.

Table 1. Areas of mathematics

1.	Logic and Set Theory
2.	Algebra, Group Theory, Matrix Algebra
3.	Geometry, Topology, Network and Graph Theory
4.	Differential Calculus
5.	Integral Calculus
6.	Real and Complex Analysis
7.	Probability, Game Theory
8.	Statistics
9.	Numerical Analysis

The mathematics of spatial structure including network and graph theory has many applications to transportation and communication flows, two very important dimensions of information systems. The calculus is one of the most powerful inventions of mathematics. It is difficult for me to envision anyone studying change without an elementary understanding of differential calculus. I would liken it to studying movement without having heard of the wheel.

Stephen Smith reminds me that probability is one branch of mathematics that has its roots in play behavior, and yet most information systems researchers pass all too quickly over probability to statistics, only to learn too late that one cannot fully understand statistics without first mastering the basic laws of probability. Probability and game theory have been applied extensively to management and decision making (Von Neumann and Morgenstern, 1953). Numerical analysis includes many techniques for approximation and estimation that will become increasingly useful to information systems researchers as quantification progresses.

While it may be impossible for a creation researcher to master all of these branches of mathematics in a single lifetime, an exposure broader than statistics is surely needed. We especially need to train future information systems researchers more fully in mathematics. I would recommend the following as a minimum for undergraduate programs in information systems:

1. A course in logic, perhaps in conjunction with philosophy of science.
2. A course in finite mathematics. This would include introductions to logic, set theory, matrix algebra, and probability with applications to linear programming, Markov chains, and the theory of games and decisions. Such courses are offered at most universities at the freshman level, and are required in most business programs.
3. One course in calculus
4. One course in statistics

I must emphasize that this should be a minimum for anyone training for a position in information systems management, administration, planning, or research. Quantitative skills will not be learned on the job, and when neglected in undergraduate education usually results in a lifetime of inadequacy and fear of mathematics. I do not believe there is a single information systems program in North America that meets this minimum requirement. Until we raise our standards in the quantitative area, our graduates will operate under a serious handicap, especially if they must compete with management and business graduates. Few will be adequately prepared to begin graduate programs or understand research.

Second courses in calculus and statistics are desirable, along with a course in mathematical modeling. Operations research, management science, and systems courses at this point in time can fill modeling needs until information systems-related modeling courses are developed. I suggest introducing these at the graduate level.

MODELING

This concludes a brief overview of mathematics. I will now move on to quantitative techniques in general. There is one important area of quantitative applications in information systems: modeling.

The term "model" is synonymous with the term "theory." In use, "model" is generally applied to mathematical models, while "theory" is reserved for more conceptual models in logical or verbal form. A model is simply a representation within abstract mathematical systems, basically mappings from the real-world system to the mathematical system. To be useful, a model must be less complex than the real system and must abstract its essential features. Achieving these two goals is the art and science of model building.

There are four important aspects of modeling that information system researchers need to understand:

1. How does one develop and test a model?
2. What are the different types of models?
3. For which kinds of problems is each model best suited?
4. What roles does modeling serve in information systems research?

Table 2. Classification of abstract models by attributes

1. Treatment of Time	: Static, Comprehensive Status, Dynamic
2. Treatment of Space	: Point, Area
3. Measurement Scales	: Discrete, Continuous
4. Recognition of Uncertainty	: Deterministic, Stochastic
5. Aggregation Level	: Micro, Macro
6. Form of Equation(s)	: Linear, Non-Linear, Systems
7. Inclusiveness	: Open, Closed
8. Flexibility	: Canned, Custom Built
9. Best Solution?	: Non-Optimizing, Optimizing

There are a variety of different types of models, including verbal, physical, graphical, and mathematical models. Mathematical models may be classified along nine distinct dimensions (Table 2). Models that have been applied in information systems tend to be (1) static, (2) linear, (3) deterministic, and (4) "canned." Since most of the phenomena that we study are dynamic, non-linear, and stochastic there is a need to develop more custom-built models to better suit our needs. It is particularly important that we recognize the dynamic and probabilistic nature of the objects of our study and use methods more suited to these properties. Our static, linear, deterministic view of the world is reinforced by the lack of time series data or longitudinal research, and ignorance of non-linear, probabilistic, and dynamic models.

CONCLUSION

As view of information systems research as processes will require all learner to take a broader historical perspective on the field, to develop new measures that better lend themselves to a process approach, to look more to mathematics, modeling and theory, and to take a longer range perspective on information systems research. It is necessary to spend more time and effort integrating what has been learned and making information research a cumulative process. Mathematics and quantification more generally, can help CIS move in these directions.

Business and Technological Perspectives About Mobile Commerce

Rosarito Sánchez-Morcilio, University of Puerto Rico, P.R.; E-mail: parisrosa@gmail.com

ABSTRACT

This paper presents a research in process about the privacy and security issues regarding m-commerce (mobile commerce). In this research, privacy issues are viewed as the business perspectives and security issues are viewed as the technological perspectives. M-commerce is an alternative way for customers to be reached. The questions are: is customer privacy acceptable in the m-commerce environment? and is security (reliability and trustfulness of the mobile systems) acceptable in the m-commerce environment? A pilot study was conducted to University students to observe their opinion regarding those questions. The intention of this research is to conduct a formal survey that present possible strategic solutions to improve m-commerce environment. Findings from the pilot study suggests that students would like to be informed about the lowest prices of their favorite products and services and that actual stability of the system is acceptable.

1. INTRODUCTION

About 1.7 billion people in the world own a mobile telephone (Momo, 2005). This is approximately how big mobile commerce market can become. M-commerce (mobile commerce) is an extended branch of electronic commerce, indeed users interact in wireless environment, in which time and space issues are overcome (Coursaris, Hassanein, Head, 2003).

2. LITERATURE

M-commerce is an extended branch of electronic commerce (Coursaris, Hassanein, Head, 2003). Its user interaction is done wireless. This atmosphere provides information about time and space to facilitate the location of potential customers. Privacy and security in the wireless environment are still main issues since technology is continuously improving. Business and technological aspects of m-commerce are analyzed.

2.1 M-Commerce from the Business Side

The business perspective provides an inside about the utility and profitability of m-commerce. Gilbert and Kendall (2003) present that many users of mobile devices carry it wherever they go and are more careful about its incoming stream of calls and text messages. Definitely, this new channel to reach customers closely represents an opportunity of great value to businesses.

Strader, Tarasewich, and Nickerson (2004) emphasize on the relationship between quality of service perceived by customers and the quality of service that was really delivered by service providers in the m-commerce environment. Another issue that they mention that have an impact on the business standpoint is the experience and compatibility among different mobile devices technologies.

New business models need to be developed for the proper m-commerce integration in the market. Gjerde, Venturin, and Stordahl (2005) highlight that the new strategy should take into account the fact that time and content (location, terminal capabilities, personal preferences) are factors known by the provider for the focus of the business campaign.

2.2 M-Commerce from the Technical Side

M-commerce depends on its technical support. Zheng, Chan and Ngai (2006) point out that data should adapt in the highly dynamic wireless environment called adaptive system. An adaptive system consists of presenting real images and text in the m-commerce device by location, awareness or transparency, dynamic reconfiguration, compositions, mechanism, and description. They use a Java platform to promote maximum interoperability across the systems. Even though their system is highly efficient, scalability, security and heterogeneity are important areas to explore.

A centralized database model is proposed by Hu and Meng, B. (2005). Their system uses a database for saving computing time when the mobile equipment is watched and controlled at anytime/anywhere environment. This database is controlled by authorized personnel. This system is like an adaptive system that uses a centralized database. They state that this system is a viable and effective way of saving computing time.

Kato, Yamamoto, Hirota, and Mizuyama (2006) present a Linux based mobile phone to approach some issues in the m-commerce system. Those issues are memory size, stability, boot time/ response time, real time, and power consumption of the mobile device. However, Linux has more processing overhead than what a mobile phone requires. They explain that additional technical innovations should address the configuration of memory size, the stability, which ensures security, and the boot time (to reduce the startup time).

2.3 Summary

Given the current technological advances in m-commerce, business can take advantage of this opportunity by providing the perfect market campaign according to when and where potential customers are. However, customers' invasion of privacy can be adversely affected. Future research would be relevant in the area of privacy and security awareness in the m-commerce environment.

3. THEORETICAL FRAMEWORK

3.1 Research Design

The survey for the pilot study was conducted at the University of Puerto Rico in Aguadilla, and the sample consisted of students taking information systems courses with Dr. Sanchez. Forty-three pilot study surveys were completed. Students were chosen for the study because most of them own a mobile phone, they are typically more receptive to innovations (considering m-commerce as an innovation), and they were the most accessible sample.

3.2 Limitations

There are limitations to the reliability and validity of the data collection instrument and study design common to cross-sectional studies (Bourque & Fielder, 2003). Since the selection of the sample was not randomly selected, the external validity of this study was affected. The survey for the pilot study was not randomly selected for a target population of 200 students registered in information systems courses in the Department of Business Administration. The sample selected was convenience sample of only 43 students. Therefore, generalization of the findings of this study to the target population should be made with caution.

4. IMPORTANCE OF THE STUDY

This study is relevant to the emerging mobile commerce market, which offers a new media to reach for customers. The intention of this study is to present possible strategic solutions to improve m-commerce environment. This particular paper presents the results of pilot study survey that is expected to contribute to the enhancement of the real study that will eventually be conducted.

5. RESEARCH FINDINGS OF THE PILOT STUDY

Forty-three pilot study surveys were completed by students, with no missing values. Those were analyzed in order to develop an improved survey instrument for the real study. According to the pilot study findings, a new survey instrument will be developed. The Statistical Package for the Social Sciences, version 11.0 was used to conduct all data analysis.

5.1 Descriptive Statistics

The variables that have the lowest standard deviation (with less than .73) are "Lowest prices about favorite products and services" and "Feel well if receive unsolicited services no matter the location".

The variables that have the highest standard deviation (with more than .97) are "Carry a mobile phone everyday" and "Customer privacy is accepted".

5.2 Regression

Multiple regression was used to predict customer privacy and security issues regarding m-commerce.

HYPOTHESIS 1

Null Hypothesis: The linear combination of independent variables ("Nearest favorite business location", "Promotions based on time and location", "Lowest prices about favorite products and services", "Feel well if companies know where you are", "Feel well if receive unsolicited services at a specific moment", "Feel well if receive unsolicited services at a specific location", "Feel well if receive unsolicited services no matter the location") does not predict the variation in the dependent variable ("Customer privacy accepted").

Alternative Hypothesis: The linear combination of independent variables (mentioned in the null hypothesis) does predict the variation in the dependent variable ("Customer privacy accepted").

Table 1 shows that the most important predictor in the model is "Lowest prices about favorite products and services" with $\beta = .388$ ($t = 2.065$, $p = .046$).

The ANOVA for the regression model using the stepwise method, $F(7, 35) = 1.43$, $p < .225$, suggests that the linear combination of variables does not explain a significant amount of variation in the dependent variable "Customer privacy is accepted". Therefore, the null hypothesis is accepted. This is maybe due to the sample size.

HYPOTHESIS 2

Null Hypothesis: The linear combination of independent variables ("Stability or good reception of the system is accepted", "Power consumption or battery life is accepted") does not predict the variation in the dependent variable ("Security issues are accepted").

Alternative Hypothesis: The linear combination of independent variables (mentioned in the null hypothesis) does predict the variation in the dependent variable ("Security issues are accepted").

Table 2 shows that the most important predictor in the model is "Stability or good reception is accepted" with $\beta = .301$ ($t = 1.839$, $p = .073$).

The ANOVA for the regression model using the stepwise method, $F(2, 40) = 4.735$, $p < .014$, suggests that the linear combination of variables does not explain a significant amount of variation in the dependent variable "Security issues are accepted". Therefore, the null hypothesis is accepted. This is maybe due to the sample size.

Table 1

Coefficients[a]

Model		Standardized Coefficients Beta	t	Sig.
1	(Constant)		2.953	.006
	Nearest favorite business location	-.065	-.409	.685
	Promotions based on time and location	-.090	-.489	.628
	Lowest prices about favorite products and services	.388	2.065	.046
	Feel well if companies know where you are	.094	.588	.560
	Feel well if receive unsolicited services at a especific moment	-.302	-1.423	.164
	Feel well if receive unsolicited services at a especific location	.083	.361	.720
	Feel well if receive unsolicited services no matter the location	-.058	-.271	.788

a. Dependent Variable: Customer privacy is accepted

Table 2

Coefficients[a]

Model		Standardized Coefficients Beta	t	Sig.
1	(Constant)		3.488	.001
	Stability issue (good reception) is accepted	.301	1.839	.073
	Power consuption (battery life) is accepted	.202	1.237	.223

a. Dependent Variable: Security issues are accepted

6. DISCUSSION OF FINDINGS OF THE PILOT STUDY

Results show that "Lowest prices about favorite products and services" and "Feel well if receive unsolicited services no matter the location" are strong variables. This means that most students were in agreement with those items. Although, none of these variables refer to the m-commerce scenario in which the customer can be reached according to the time and location.

Next, "Carry a mobile phone everyday" and "Customer privacy is accepted" are weak variables since variation in the answers were very high ranging from strongly disagree to strongly agree.

In addition, "Lowest prices about favorite products and services" was the only variable that try to predict better the dependent variable "Customer privacy is accepted" for hypothesis 1. However, "Lowest prices about favorite products and services" is not a variable clearly related to the m-commerce environment.

Lastly, "Stability or good reception is accepted" was the variable that tries to predict better the dependent variable "Security issues are accepted". May be technological issues are not affecting students in the m-commerce environment.

7. CONCLUSIONS

This research in process presents a pilot study that is relevant to improve a complete study about m-commerce and its customer perceptions regarding privacy and security issues. The intention of this research is to conduct a formal survey that present possible strategic solutions to improve m-commerce environment. The lessons learned from this pilot study to apply to future research are very relevant. First, some questions in the survey should be rephrased to emphasize on the m-commerce perspective. Second, more questions concerning security (technical) issues to should be added. More literature review in this area is needed, as well. Third, improvement in the selection and size of the sample is important. This study can provide important implications to m-commerce, if the factors arise from the pilot study are taken into consideration.

The Information Steering in Government: Information Resource Managed by Administration in Welfare Sector

Jari Stenvall, University of Lapland, Finland; E-mail: jari.stenvall@ulapland.fi
Antti Syväjärvi, University of Lapland, Finland; E-mail: antti.syvajarvi@ulapland.fi
Risto Harisalo, University of Lapland, Finland; E-mail: risto.harisalo@uta.fi

INTRODUCTION

In government, the impact of information on organizations and humans has been under increasing scientific interest (e.g. Jones, Boushey & Workman 2006). Information can indeed generate fundamental changes both to the structure, processes and management of inter-government collaboration and to the choices of public policy. As research has been done about information processing, usage and sharing, however, there has not been enough research neither about the role of information as a steering method in governmental organizations nor about its effectiveness. In current study, the information is seen like a valuable asset and resource for the inter-government collaboration that the government must power as a public trust on behalf of local public organizations.

The questions rise about the instrumental roles of information (e.g. Sbragia 2000). Hence, it can be asked how the steering strategies and the forms of steering are build up or could be structured in order to coordinate quasiautonomous public organizations? Also, what is the effect of information when used as a steering mechanism? As a result, the information steering is seen as an approach to manage with the information resource. Information steering has an effect to the actor's behavior by sharing or transmitting the information (Stenvall & Syväjärvi 2006). In addition, the information management is seen as interdisciplinary procedures designed to provide, create, transmit and improve appropriate information systems and resources (Soeparman & Wagenaar 2006).

An information organization (e.g. Webster 1995) can be respectively recognized as a society of separate public unions either supported or not by the information. The organizations in public administration confront many challenges due to the information and technology. Information has indeed a direct effect on organizational behavior. Public organizations have to realize the role of information, for example, in the relation to other steering methods. In addition to information steering, there is steering by resources and steering by norms recognized in public sector (Stenvall & Syväjärvi 2006). Thus, information modifies or even challenges traditional organizational practices and further activates to scrutinize organizational processes (Syväjärvi & Stenvall 2006). The suitability of information steering is based on view that organizations operate at least partly according to the information. The success in information usage influences on organizational decision making and coordination (rf. Casson 2001; Adams 2004).

AIMS AND OBJECTIVES

This research aims to build up a theoretical framework or model for a successful information steering. In addition, the effectiveness of information steering is under investigation. The research has focus on the role of Central government as it carries out the information steering. More precisely, the research considers steering of the Ministry of Education and the Ministry of Social Affairs and Health in Finland. The purpose of steering, which coordinates the production of public welfare services, is to power local public organizations. The main research tasks can be set as follows

How information steering can be modeled from the perspective of inter-governmental collaboration?

How effective is information as a steering instrument and how it could be developed?

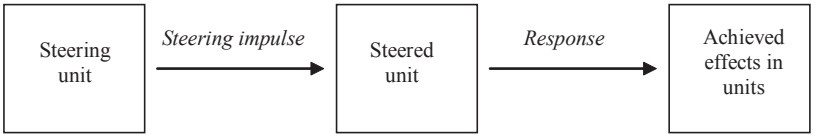
The research considers information as an instrument from the theoretical point of view, models information as a collaborative steering method, but also includes an assessment on the effectiveness of information steering. A comprehensive approach is needed when establishing information steering among inter-governmental organizations. This is partly because the autonomy and control of the public sector organizations affect the choice of coordination methods. We argue that information steering should be approached from the perspectives of traditional steering theory, communication theory, and knowledge and information management theory.

PERSPECTIVE OF STEERING THEORY

Steering is an inherent part in the implementation of public policies. It can be seen as a part of political processes. After a democratic decision-making processes, the steering can be used to direct administration in order to execute the public policy. *Steering power* means the right, power based on status or an expertise to influence on the behavior of another operating unit. Correspondingly a *steering impulse* means incentives or means, such as information, that the steering unit sends to the steered unit in order to produce desired behavior. (Oulasvirta, Ohtonen & Stenvall 2002, 16-21.)

The objective of information steering is to provide information that helps service producers to develop their own operations. Other objectives may be to increase expertise, to provide more general information, and to ensure the implementation of norm and resource steering and, more extensively, the public policy.

Figure 1. Components of steering



Research is indicating that information steering can produce effects, but often these effects on the behavior of the object remain with respect to the expectations minor or deviate from the objectives (e.g. Vedung 1998, 117-118). In addition, the effects of information steering may be difficult to detect. It is also possible that a steering impulse is lost or remains completely unnoticed by the steered unit. In conjunction to steering impulses we can talk about noise (i.e. organization or information noise), which means factors that weaken or prevent the free transfer of information. These factors have a distorting or disturbing effect on interactive operation, flow of information and confidential observations (Zaheer et al 1998; Ivancevich & Matteson 1999).

PERSPECTIVE OF COMMUNICATION

Communication has traditionally been considered to deal with the sending and receiving of messages. Typical communication research objectives include the question how people understand communicated messages, verbal and non-verbal communication as operating modes, and the study of changes in the contents when people exchange messages. Information steering is, indeed, quite naturally understandable and analyzable as a matter of communication. From the system perspective and combined with traditional steering ideas, the communication is a tool for management for achieving its objectives. From the viewpoint of objectives it is possible to set four different tasks to information steering: public information, promotion of objectives, bi-directional asymmetric communication, and bi-directional, symmetric communication.

Besides system perspective, the communication can be approached from a number of other directions that help in studying the success and nature of information steering. These are for example, the organizational communication (Craig 1999), the linguistic approach (Hood 1983, 38), the semiotic approach (e.g. Vedung 1998, 107-114; Oulasvirta et al. 2002, 29), and the approach of social psychology and sociology (e.g. Gibson et al 2003).

The communication principle means a process where information steering includes exchange of information. For instance, the actors in the central administration and at the local level take turns as equal senders and recipients. It should be noted now that the function and approval of information transfer and the related interactive nature seem to depend on the situation. Alternatively in long-term development operations communication and information should preferably have more bi-directional and dialogical nature (Waterhouse & Lewis 2004).

PERSPECTIVES OF KNOWLEDGE AND INFORMATION MANAGEMENT

Information steering is connected to the idea that organizations are increasingly dependent on knowledge and information. This has been studied in organization and management theories within the areas of information management, knowledge management as well as the management of so called expert organizations. Information can be loosely defined in public administration as knowledge of the facts, values, and ideas that help in the implementation of things. Some researchers (e.g. Adams 2004, 30) also include in information the separate information element of public politics, such as political programs. Information steering can, indeed, be used for strengthening organizations. Thus organizations can combine understanding, generate information, and develop decision-making.

Many questions that have been analyzed include the different elements of information and their relations to each other (e.g. data, information, knowledge, wisdom). The more advanced information steering is the more it has been developed in the direction of knowledge and wisdom, and the more the organizations also resemble information organizations that are able to comprehensively utilize the information potential. In this conjunction we also talk about information management, which means the overall management of information, operating processes, and information technology (rf. Sena & Shani 1999; Syväjärvi & Stenvall 2006).

It is essential that the conveyed information is true and accurate. Thus, the effective information must be reliable (Pfeffer & Sutton 2006). In this case attention is paid on, for instance, the fact whether the information also contains other factors than just those corresponding to the desired political will. One consideration of information quality is also the extent of its contents. Information is often conveyed solely on what should be done. Another, wider view is also that information steering should tell how things should be implemented. (Gelders 2005, 377)

METHODOLOGY

Both methodological and data source triangulation principles were applied (Patton 2002). More precisely, the research data was collected by interviews and by focus group meetings (Barbour & Kitzinger 1999). Totally 14 high-position officials from Central government were interviewed and eight experts attended to the focus group. All these were directed to people in Central government. In addition, a questionnaire (n=360) was implemented in local governments and a focus group meeting was arranged to eight managers representing Municipalities. The response rate was 45%.

MAIN RESULTS

Only the key results are shortly presented. Results are comparable throughout the public welfare sector. The findings also allow structuring a preliminary model of the information steering. It was found from strategic perspective of the central government that the information steering is not well organized. This viewpoint was shared by all stakeholders of the inter-governmental cooperation. Although the information steering was not found to be in a crisis, it needs development as it can be an effective method.

Firstly, the information steering was observed in relation to other traditional steering mechanisms like steering by norms and funds. It was showed that the information steering has not a clear or independent role as a governmental steering method. The information steering executed by the central government was indeed diverse and uncoordinated. The main reason for the abovementioned is probably in the implementation processes. It seemed that the information steering consists of a bunch of variable steering elements and it is not a single manner to steer as itself.

Secondly, there was a need for more suitable, functional and practical information steering. Local governments were after more coordinated and compacted steering as otherwise all the representatives of Central government were steering without clear goals. At the same time, the Local governments attempted to gain a more simplified and clarified information steering. This was required in order to get better usability for the general information resource. The lacks of interactive and communicative procedures were immense.

Thirdly, in Local government level as well as in Central government level people were after efficient public information management. As the information steering seems to be diverse and unorganized in many ways, it is obvious that its effects are quite modest. In welfare sector, the inefficient information management was manifested as large difficulties (or lack) with future visualization, coordination and implementation, as mistrust between inter-governmental operators, and finally as a lack of change pressure that emphasize the importance of information steering in inter-governmental collaboration.

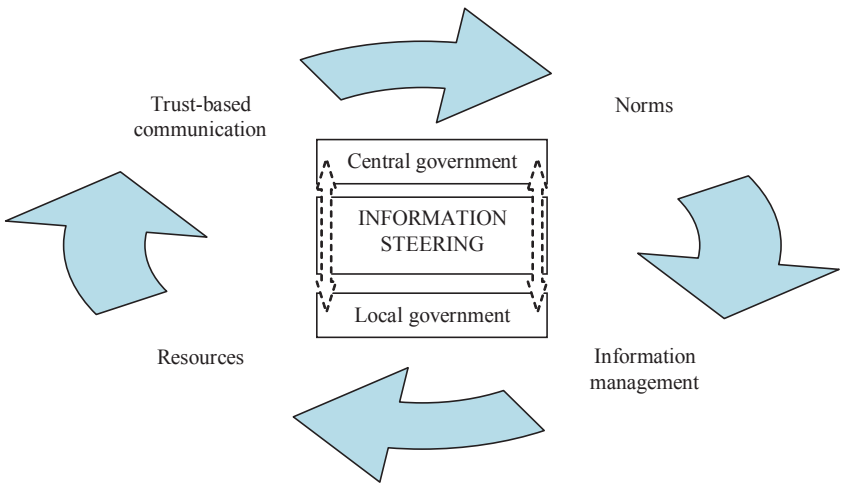
Fourthly, it was found that there are no systematic evaluations done about the effects of information steering. Awareness about the effectiveness of information steering was inaccurate as information steering has not had any stabilized models or perspectives. Steering has been executed by means of various evaluations, verifications and recommendations, which have not had any concrete position. It was recognized that huge information flows are produced, but usually those will not lead to parallel activity. However, the information steering has functioned finest in a quality-based local government work as it has assisted: to both recognize development challenges in Local governments, to increase the transparency of Central government activities and finally, to create knowledge about funding possibilities and norms.

CONCLUSIONS

In information steering, as respectively in other organizational activities, justified and meaningful procedures are needed in relation to what is attempted to accomplish. Research literature has quite well introduced the criteria and ideas of collaborative steering. These are, for example, clear and steady goals, capability to measure execution and results, and finally enough time for implementation (Gelders 2005). It seems evident that more interaction among steering participants and the viewpoints of effectiveness and productiveness should be emphasized in public policy.

Information steering requires communication that serves mutual trust. Trust is needed as an inter-governmental and interpersonal element for communication, but also as a feature of information quality (e.g. Harisalo, Stenvall & Syväjärvi 2006). The results indicate that in inter-governmental collaboration the trust capital

Figure 2. The information steering model in public inter-governmental collaboration



is not well taken care. Elements inducing trust and mistrust will reinforce each other. The information steering can be seen, together with its deepest goals, as an element to develop more interactive inter-governmental collaboration. The quality of information is also one critical factor. Sanderson (2002) has pointed out that a problem in public administration is the lack of information quality about social conditions in where the information will be applied.

The effectiveness of information steering in somewhat blurred as steering does not have a collaborative and strategy-based logic. The outcome is thus uncoordinated, unbalanced and unfiltered. In current research a challenge is to model information steering from the perspective of inter-governmental collaboration. The shaded arrows indicate how information steering consists of four major elements that interact and are in relation to each other. In addition, the dashed arrows indicate how information steering challenges to effective inter-governmental collaboration between the Central and Local governments.

Hence, the information steering can be developed and modeled by the means of information management, trust-based communication, and also in good synchronization to traditional steering methods like norms and a mixture of resources. Information as an instrument requires overall competence with information management (rf. Soeparman & Wagenaar 2006), it requires careful planning and action with two-way communication (Waterhouse & Lewis 2004), it requires the notion of trust and mistrust (Zaheer et al. 1998; Harisalo et al. 2006), and finally it requires well coordinated harmony that takes into account the deep nature and needs of various other steering methods (Sbragia 2000).

It was noticed that the information steering without logic and systematic is not very powerful approach. The information steering seems to have significance for two different levels of information processing that are individual and organizational levels. In order to gain the information steering as a useful part of public policy information processing should be modeled one way or another. In parallel to previous arguments Jones et al. (2006) have showed the information-processing approach of policy making, which focus on both complex environment of policy-makers and on their cognitive capacities.

Finally, organizations are always operating with more or less deficient information. This was noticed already in 1940 by Herbert Simon (1977) as he introduced the bounded rationality. Due to a number of situational factors, such as limited time or intelligence, it is not realistic to assume that any operation could be based on complete information. Information steering is thus inevitably accompanied by a shortage of information between the conveyed information and the demand. This argument is supported by the thematic of information and organization noise presented in conjunction to the theoretical framework.

Making E-Business Customer Focused: A Fuzzy Approach

B. K. Mohanty, Indian Institute of Management, India; E-mail: mohanty@iiml.ac.in
Sajjad Zahir, University of Lethbridge, Canada; E-mail: zahir@uleth.ca

ABSTRACT

In this paper a methodology has been introduced to make the e-business more customers focused by obtaining the preference ranking of the products as per the buyers' choice. The methodology takes into account the multiplicity of the product attributes and works in an integrated approach of fuzzy logic and Ordered Weighted Average Operator (OWA). The concept of OWA is used here to measure the optimism level of the customers in the given e-business system. This is most valuable information to make the e-business customer focused. Further, the OWA is applied here to articulate the targeted customers thereby making the e-business more customers' orientation.

1. INTRODUCTION

In any business whether it is online or traditional, a customer evaluates all available products as a whole before ranking them according to his or her own preferences. The ranking is specific to a particular customer and it normally depends on the number of products available to the customer in the market and how the product features satisfy to his/her likings. A customer's preferences for the products and hence their rankings are implicit in his/her mind and are difficult to express explicitly.

No doubt that each customer likes to have the fullest satisfaction on all the desired attributes of the products. However, the product attributes are in general conflicting, non-commensurable and fuzzy in nature and it is very difficult to satisfy all of them simultaneously. In this situation, a customer makes effort to satisfy most of the attributes rather than all of them. By the process, the customer is attaching some weights to the product attributes. These underlying weights are implicit in customers' mind. Articulation of these hidden weights will not only make the business more customers focused but also will help the business in analyzing the need of the customers in terms of the product requirements. The enunciation of these weights is a very complex and difficult task. In traditional markets, a sales person can assess these weights to some extent while interacting with the customers and through their body language. However, in e-business where no direct interaction takes place amongst the business partners, the identification of these weights is next to impossible. This problem becomes further complicated when the customers' requirements regarding the product specifications are imprecise or fuzzy in nature. In our paper we have introduced a methodology based on fuzzy sets to handle this problem in the e-business system.

In the literature, several papers refer to e-business sites. Jango and "Deal Time" (www.dealtime.com) are the earlier e-business market places. These sites collect information regarding the customers about their product preferences along with their prices and futures from the internet, and based on the information collected, suggest suitable products to the customers. However, it is difficult for the buyers to decide about an appropriate product in the vast Internet market. The agents such as "decision guide" by www.ActiveBuyersGuide.com assist the customers in identifying a suitable product. This e-business site requires the data from the buyers: the importance of the attributes numerically or in a range. The "decision guide" hardly accepts customer's fuzzily defined product specifications. These characteristics of www.ActiveBuyers.com fail to attract the customers.

A product classification problem in e-market is given in [5] and the classification of the products was based on their attributes. This procedure searches for a suitable product in the Internet, based on the customers' attribute wise requirements and if a product is found, the search ends. In case of non-availability, the procedure chooses a next available product closest to the targeted product. The drawback in the work [5] is the term attribute flexibility which was defined subjectively. The concept of attribute flexibility helps in classifying different products having different attribute values into the same preference group. The procedure given in [4] extends the idea of [5]. In [5], the subjective assumptions of the attribute flexibility are replaced by their objective counter parts. In [5], the available products in the e-business site are hierarchically classified based on their attribute values in a sequential manner. For example, in a CAR purchasing problem the possible attributes may be cost, maintenance-cost, and mileage. First the Cars are selected with respect to cost, then with respect to maintenance-cost, from the selected ones through cost attribute and finally by mileage from the Cars passed through the test of maintenance-cost. However, the deficiency of this approach is that the order in which the attributes are used to screen the products is arbitrary and does not reflect customers' anticipated priority about the attributes while making the final choice.

The present work addresses this problem by calculating the overall assessment of the products by using linguistic quantifiers [3] and OWA (Ordered Weighted Average) operators [6]. The procedure presented in this paper also helps to find the level of optimism of the customers and also the targeted customers. These are important aspect of e-business to make it more customers' focused. Optimism level of customers gives e-business companies become aware of the extent to which it is customer focused. On the other hand, the targeted customer determination helps the e-business system to focus on the valuable customers.

2. FUZZY CONCEPTS IN PRODUCT ATTRIBUTES

In any product purchase, normally a customer expresses his/her desire in multiple product attributes, which in general are fuzzy. For example in a car purchasing problem, the attributes may be price, re-sale value, mileage, maintenance etc. Very often a customer views these attributes fuzzily as shown in the italic words below:

Price should be *around US$ 2000*
The re-sale value should be *OK*
Mileage should be *normal*
Maintenance cost should not be *very high*.

We can define the above fuzzily defined terms as fuzzy numbers [1, 2, 4]. For example, the terms "*around US$ 20000*" and "*normal*" can be represented as fuzzy numbers as shown in figures 1 and 2 below.

Figure 1

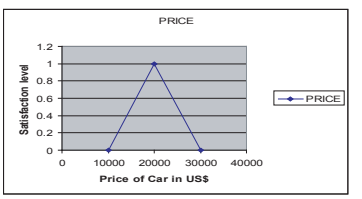

Figure 2

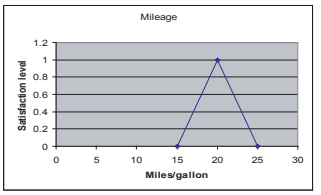

3. OWA OPERATORS IN E-BUSINESS

We have used OWA here to measure how far an e-business system is customer focused under a given product profile and what strategies are needed to improve the same. This is done by determining the preference ranking of the products as per the buyers' choice, optimism level of the buyers and through the identification of the targeted customers.

3.1 OWA Operator

An OWA operator of dimension n is a mapping f: $R^n \rightarrow R$ that has an associated *n* vector $(w_1, w_2 ..., w_n)^T$ such that $w_i \varepsilon [0,1]$ and $\sum w_i = 1$.

If $a_1, a_2 .., a_n$ are the elements to be aggregated (here they refer to product attribute levels) their aggregated value through OWA operator is:

$$f(a_1, a_2, ..., a_n) = \sum_j w_j b_j \quad \ldots \quad (3.1)$$

Where b_j is the jth largest amongst a_j.

The OWA operator uses the linguistic quantifier from the customers to derive the weights for the OWA operator. We consider the linguistic quantifier "most" following the [3] as follows.

$$\mu_{most}(x) = \begin{cases} 1 & x \geq 0.8 \\ \dfrac{(x-0.3)}{0.5} & 0.3 \leq x \leq 0.8 \\ 0 & x \leq 0.3 \end{cases} \quad \ldots. \quad (3.2)$$

The weights for the OWA can be obtained through the following equation [6].

$$w_i = Q\,(i/n) - Q\,((i-1)/n) \qquad \text{for } i = 1, 2, \ldots n \quad (3.3)$$

3.2 Product Ranking

Let us assume that K products (P_1, $P_2 \ldots P_K$) are available on the Internet. Let each product Pi (i =1, 2 …, K) has *m* attributes (A_{ij}) (i = 1, 2… K and j = 1, 2… m). A_{ij} represents the j^{th} attribute of the i^{th} product. Let $s_1, s_2 \ldots, s_m$ represent the customer's attribute-wise requirements in the form of fuzzy sets as:

$\{(s_1, \mu_{s1})\}, \{(s_2, \mu_{s2})\} \ldots, \{(s_m, \mu_{sm})\}$

Where μ_{sj} (j =1, 2, 3 …, m) represents the membership value of the customer's specifications on the attribute *j*.

Initially the e-business system presents the available products to the customers. After evaluating the products, generally customers form an overall opinion about the products fuzzily through linguistic quantifiers such as; mostly, more or less etc. The product rating of the product P_i can be derived through the OWA operator as given below.

$$F_Q(\mu_{s1}(A_{i1}), \mu_{s2}(A_{i2}) \ldots, \mu_{sm}(A_{im})) = \sum_i w_i b_j = R(P_i)\ i = 1,2, \ \ldots \ K \quad \ldots.(3.4)$$

where b_j is the j_{th} largest of the $\mu_{si}(A_{ij})$. The weights in the above equation are determined using equation (3.3).The value $R(P_i)$ is the rating of the product P_i.

Since these values are numerical numbers, they can be ranked from the best preferred product to the least preferred one. Note that the products are ranked here as per the buyer's choice.

3.3 Optimism Level of the Customers

The concepts of OWA operator and the weights therein provide a measure of or-ness [6] (optimism) and it is defined by the equation (3.5) below.

$$\text{Or-ness } (W) = \frac{1}{m-1} \sum_{i=1}^{m} (m-i) w_i) \quad (3.5)$$

The or-ness measure helps the e-business companies become aware of the extent to which it is customer focused in a given product profile. If the customers are absolutely optimistic we have

$$F_Q^*(\mu_{s1}(A_{i1}), \mu_{s2}(A_{i2}), \ldots \mu_{sm}(A_{im})) = Max(\mu_{s1}(A_{i1}), \mu_{s2}(A_{i2}), \ldots, \mu_{sm}(A_{im})) \quad (3.6)$$

The weights are here (0, 0, 0 …1).

Similarly if the customers are pessimistic about the products we have

$$F_{Q*}(\mu_{s1}(A_{i1}), \mu_{s2}(A_{i2}), \ldots, \mu_{sm}(A_{im})) = Min[\mu_{s1}(A_{i1}), \mu_{s2}(A_{i2}), \ldots, \mu_{sm}(A_{im})] \quad (3.7)$$

The weights are as (1, 0, 0 ….0).

3.3 The Targeted Customer Identification

It is very important for a business to identify its most valuable customers in totality. In the context of e-business, however, it is difficult to identify them. In the event of high demand and low stock level, it is an important issue. The purpose of this paper is to find strategies for the selection of these targeted customers under limited products. The procedure first evaluates different customers' ratings of the desired products. Then the customer corresponding to the maximum rating is selected as the targeted customer. The next higher rating determines the second-best targeted customer and so on. This methodology is explained in the following steps.

Step.1 If there are p numbers of customers, $C_2 \ldots, C_p$ and they require the products as follows (P=3, say) we have:

C_1: P_i, P_j, P_k

C_2: $3P_i$, P_j, P_r

C_3: $2P_i$, P_r, P_u, P_t

(The coefficient 3 for C_2 indicates the number of the product P_i as required by C_2)

Step.2 Take their attribute-wise satisfaction levels.

For C_1:

P_i $[(A_{i1}, \mu_{s1}(A_{i1})), (A_{i2}, \mu_{s2}(A_{i2})), \ldots, (A_{im}, \mu_{sm}(A_{im}))]$
P_j $[(A_{j1}, \mu_{s1}(A_{j1})), (A_{j2}, \mu_{s2}(A_{j2})), \ldots, (A_{jm}, \mu_{sm}(A_{jm}))]$
P_k $[(A_{k1}, \mu_{s1}(A_{k1})), (A_{k2}, \mu_{s2}(A_{k2})), \ldots, (A_{km}, \mu_{sm}(A_{km}))]$ (3.8)

For C_2:

$3P_i$ $[(A_{i1}, \mu_{s1}(A_{i1})), (A_{i2}, \mu_{s2}(A_{i2})), \ldots, (A_{im}, \mu_{sm}(A_{im}))]$
P_j $[(A_{j1}, \mu_{s1}(A_{j1})), (A_{j2}, \mu_{s2}(A_{j2})), \ldots, (A_{jm}, \mu_{sm}(A_{jm}))]$
P_r $[(A_{r1}, \mu_{s1}(A_{r1})), (A_{r2}, \mu_{s2}(A_{r2})), \ldots, (A_{rm}, \mu_{sm}(A_{rm}))]$ (3.9)

For C_3:

$2P_j$ $[(A_{j1}, \mu_{s1}(A_{j1})), (A_{j2}, \mu_{s2}(A_{j2})), \ldots, (A_{jm}, \mu_{sm}(A_{jm}))]$

P_r $[(A_{r1}, \mu_{s1}(A_{r1})), (A_{r2}, \mu_{s2}(A_{r2})), \ldots, (A_{rm}, \mu_{sm}(A_{rm}))]$

P_u $[(A_{u1}, \mu_{s1}(A_{u1})), (A_{u2}, \mu_{s2}(A_{u2})), \ldots, (A_{um}, \mu_{sm}(A_{um}))]$

P_t $[(A_{t1}, \mu_{s1}(A_{t1})), (A_{t2}, \mu_{s2}(A_{t2})), \ldots, (A_{tm}, \mu_{sm}(A_{tm}))]$ (3.10)

Step 3. For each customer add the attribute totals of every attribute. For customer C_1 we have the total attributes for the ith, jth and the kth products are as follows:

$$C_1(A_z) = \frac{1}{3}(m_i(A_i) + m_j(A_j) + m_k(A_k)) \qquad z = 1, 2 \ldots m \qquad (3.11)$$

The index z represents the z^{th} attribute. Similarly we can have $C_2(A_z)$ and $C_3(A_z)$ for the 2nd and 3rd customer.

Step.4 Use the aggregated weights from equation (3.4) and apply the OWA operator to $C_1(A_z)$ (z =1, 2… m); the product rating of customer C_1 is

$$R(C_1) = \sum_{z=1}^{m} w_z q_z \qquad (3.12)$$

Where q_z is the j_{th} largest among $C_1(A_z)$. Similarly, product ratings of second and third customers can be obtained as $R(C_2)$ and $R(C_3)$ respectively. Since these product ratings of the individual customers are numerical quantities, they can be ordered. In this approach the customer with the highest rating is considered to be the best customer in the customers' hierarchy. The next best customer in the hierarchy is accorded the second highest rating and so on.

4. NUMERICAL EXAMPLE

Let us assume that the customer's requirements for a product (e.g., a car) are expressed in terms of attributes cost, maintenance-cost (monthly) and mileage (miles/gallon). The attributes are in the form of fuzzy sets as shown below.

Cost = {0/10,000, 0.8/15,000, 1.0/20,000, 0.8/25,000, 0.6/30,000, 0.4/40,000, 0.1/50,000, 0/60,000}

Maintenance = {0/40, 0.4/50, 0.63/100, 0.65/150, 1.0/200,0.8/300, 0.4/400, 0.2/500}

Mileage = {0/9, 0.1/10, 0.4/12, 0.5/15, 0.6/16, 0.73/17, 0.8/19, 1.0/20, 0.9/21, 0.8/22, 0.72/25, 0.7/26}

Let us assume that there are eight types of cars available on the Internet. The data regarding these cars are given in Table 1.

Product Ranking

Using equations (3.2) and (3.3) the aggregated weights to the attributes are:

$w_1 = Q(1/3) - Q(0/3) = Q(0.33) - Q(0) = \mu_{most}(0.33) - 0 = 0.06$. Similarly, $w_2 = 0.66$ and $w_3 = 0.28$.

Now by using equation (3.4) we can get the product ratings are: $R(P_1) = FQ(0.6, 0.63, 0.8) = 0.632$.

Similarly, $R(P_2) = 0.419$, $R(P_3) = 0.792$, $R(P_4) = 0.492$, $R(P_5) = 0.5$, $R(P_6) = 0.7$, $R(P_7) = 0.368$ and $R(P_8) = 0.812$. From the above it can be determined that the customers' preference ranking of the products can be ordered as:

P_8, P_3, P_6, P_1, P_5, P_4, P_2 and P_7.

Level of Optimism

From equation (3.5) with aggregated weights as $w_1 = 0.06$, $w_2 = 0.66$ and $w_3 = 0.28$; $m = 3$, the or-ness or degree of optimism of the customers is:

1/2([(3-1)0.06 + (3-2)0.66+ (3-3)0.28] = 0.39

This demonstrates that the customers' level of optimism at the present system is approximately 40%.

Targeted Customers

Assume there are three customers who would like to purchase the products as given below

C_1: P_1, $2P_2$, P_3

C_2: P_1, P_3, P_5

C_3: $2P_1$, P_3, P_2

Let the company has one product each of type P_1, P_2, P_3, P_4, P_5, P_6, P_7, P_8. Now the question is how to choose the customers. First consider customer C_1. Using equation (3.11) the attribute totals of customer C_1 are

$C_1(A_1) = 1/3[0.6+0.4+1] = 0.67$

Note that for P_2 the second attribute's satisfaction has been added once, because the company does not have two P_2s.

$C_1(A_2) = 1/3[0.63+0.4+0.8] = 0.61$

Table 1. Sample data for products

Car type	Cost in US$	μ_{cost}	Maintenance Cost in US$	$\mu_{maintenance}$	Mileage in (miles/gal)	$\mu_{mileage}$
P_1	30,000	0.6	100	0.63	19	0.8
P_2	40,000	0.4	50	0.4	25	0.72
P_3	20,000	1.0	300	0.8	17	0.73
P_4	50,000	0.1	100	0.63	22	0.8
P_5	50,000	0.1	150	0.65	25	0.72
P_6	40,000	0.4	200	1	22	0.8
P_7	15,000	0.8	500	0.2	12	0.4
P_8	25,000	0.8	300	0.8	20	1.0

$C_1(A_3) = 1/3[0.8+0.72+0.73] = 0.75$

Based on the product requirements and the availability, we can obtain the customer's aggregated rating for the products can be obtained following the equation (3.17) as: $R(C_1) = 0.06(0.75)+0.66(0.67)+0.28(0.61) =0.658$. Similarly we have $R(C_2) = 0.66$ and $R(C_3) = 0.658$. This indicates that an e-business system should target the C_2 first and then C_1 and C_3 equally.

5. CONCLUSION

In this research, customers' imprecise judgments are treated in terms of fuzzy logic and their compromising attitudes are handled by linguistic quantifiers Then, OWA operators are used as excellent tools for producing an overall ranking of products in a fuzzy e-business environment. Such applications of these recently developed techniques are lacking in the literature. It has been demonstrated that this approach makes it possible to calculate levels of customer optimism or pessimism. Businesses on the Internet are expected to benefit from such a measure as it will help them become more customer-focused and gain competitive advantage.

A Marketing Model for Innovative Software Products (MISP): Research in Progress

Linda Hill, Unitec Institute of Technology, Auckland, New Zealand
Kay Fielden, Unitec Institute of Technology, Auckland, New Zealand; E-mail: kfielden@unitec.ac.nz

ABSTRACT

In this 'this research in progress' paper a model for marketing innovative software products is presented. This model, which has evolved from Moore's (2002) 'crossing the chasm' metaphor, is discussed. A case study method has been adopted to apply this model to a small innovative software organization in New Zealand.

Keywords: Marketing, Innovation, Software Products

INTRODUCTION

In this research project a model that has evolved from Moore's (2002) 'crossing the chasm' metaphor is used as an appropriate tool with which to identify catalysts required to move from: innovators to early adopters; and early adopters to early majority. The research questions asked are: what are the main factors that impact on marketing new innovative software products; and what are the interrelations among these factors. Applying the model developed suggests that these two sets of marketing catalysts (innovators to early adopters, and early adopters to early majority) may be different.

First the MISP model (Marketing Innovative Software Products) (Figure 1) is outlined. This is followed by a brief review of the literature on marketing strategies for innovative software products. The case study research method to apply this model to a small innovative software organization in New Zealand is then described. Significant findings that are expected to emerge are discussed.

The paper concludes with suggestions for future research and for implications for innovative software organizations.

THE MISP MODEL

Key to the adaptation of Moore's (2002) 'crossing the chasm' metaphor is the identification of catalysts required to cross the divide between different adopter groups. Catalysts are considered to be any factors that influence the uptake of an innovative software product in the case being studied. These catalysts are influenced by both the marketing context of the firm and the firm's characteristics that inform an appropriate marketing mix. Marketing plays a key part in realizing both transitions from invention to innovation and from innovation across the chasm to a commercial product by identifying and implementing catalysts. The MISP model extends Moore's (2002) model by providing a theoretical mechanism for identify marketing catalysts to cross the chasm.

LITERATURE REVIEW

Successful innovations require successful marketing. A marketing concept "holds that the key to achieving organisational goals consists in determining the needs and wants of target markets and delivering desired satisfaction more effectively and efficiently that your competitors " (Dalgic & Leeuw, 2006, p. 12).

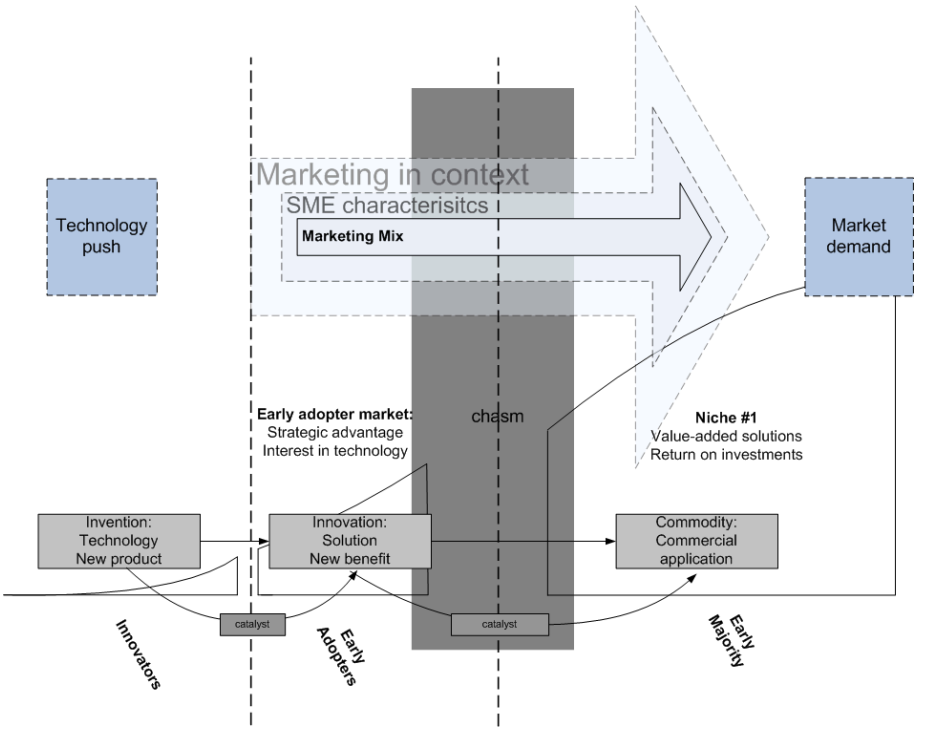
A different marketing strategy needs to be applied in moving from early adopter to early majority to accommodate different buying patterns. It appears that market entry can be achieved reasonably easily whereas survival cannot (Argarwal & Audretsch, 2001). The release of an innovative product to the mass market carries high levels of risk as well as manifold opportunities (Botting, 1997). The selection of a target market is a prerequisite to pursuing a niche marketing strategy within the early majority segment. As this has been identified as a main challenge in commercialising an innovative product, the capabilities of a firm should be aligned with the required strategies and tasks that are necessary to accomplish this goal (Slater & Mohr, 2006). A dilemma for small innovative software organizations is having an appropriate mix of marketing expertise in entering a mainstream commercial software environment (Dunn, Hulak, & White, 1999). Discovering the whole product solution including added-value and alignment with market needs (Cooper,2000; Davis & Moe,1997; Moore,2002) is necessary to establish and to isolate catalysts. Close customer relationships help to identify the needs of the target market. In SMEs this is most likely to be conducted through business networks. Dunne (1999) suggests that a direct sales approach is best suited to early adopters. Small firms often have limited resources for sales and marketing for commercialising products themselves. Marketing alliances through strategic networking therefore become important. Strategic alliances also encourage product promotion through word-of-mouth among industry consultants (Kohli,1999; Goldenberg, Barak, & Muller, 2002). To stimulate word-of-mouth communication, interpersonal communication and networking are important abilities that are required to actively promote the firm and the product to key contact points of the target group's network. Rowley (2004) describes three ways in which virtual marketing communication could be effective: creating presence, relationships and mutual value.

RESEARCH METHOD

An exploratory single case applying a deductive framework approach (Figure 1) has been adopted for this study. The case explored for this study was a small innovative software organisation whose core business is the design and implementation of a secure, spam-free interoperable grid infrastructure. This organisation is based in Auckland New Zealand. This organisation is the only one of its kind in New Zealand. The research questions were concerned with establishing an understanding of the factors that impact on the researched phenomenon and the interrelation between those factors. A holistic view of the research problem and the method applied was required in order to gain desired results. The phenomenon under consideration has been studied in its real-life context. In general, "how" and "why" questions help to investigate holistic characters of real-life events with its processes, life-cycles and relationships. Yin (2003) states that these are the forms of research questions that are posed in case studies. A "what" question can be also a "justifiable rationale for conducting an exploratory study" (Yin, 2003, p. 6). For instance, "What are the main factors that impact on …" clearly has an explorative character rather than an enumerative one.

A gap has been identified between scientific academic marketing theories, practitioner application and execution of marketing. Consequently, a more suitable approach is required that captures the dynamic and often chaotic growth, development and interaction of SMEs. An integrated approach that combines a post-positivist philosophy with a more interpretive approach is more suitable in the context of internationally operating SMEs according to Carson and Coviello (1996). Sinkovics Penz & Ghauri (2005) suggest a qualitative research approach that is flexible and open but that still follows conventional procedures of data

Figure 1. Marketing model for innovative software model (MISP)



gathering, analysis and interpretation. This research follows these recommendations for acceptance by academics as well as marketing practitioners.

EXPECTED FINDINGS

It is expected that the SME being studied will have a defined position on the MISP model and that marketing catalysts will not only be identified but also ranked in importance. Catalysts to move from innovator to early adopter are likely to be product information from external sources, acceptance by the innovator community, and evidence of functionality regardless of cost. Catalysts from early adopters to early majority pose a problem as there seems to be no effective cross-market communication between early adopters and the mass market of early majority adopters. Early majority adopters need to: solve an existing business problem with new benefits; minimise risk; and have sufficient trust and credibility in the new product. Results to date suggest that marketing innovative software products are dependent on the sector into which they are marketed. Because the existing interoperable infrastructure has such a dominant market position it would seem that the sales of this particular product are more likely to be made into companies operating closed grid systems – such as defence systems, systems requiring a high level of security or systems in which there currently is no such network in place. IT is not the network itself that will be the catalyst but rather products opera ting within the network.

FUTURE DIRECTIONS

Identification and rated importance of marketing catalysts should aid in developing a marketing plan for this particular SME. It is also expected that MISP will be applicable for further organisations. It is also envisaged that further evaluations of the model in other organizations will provide information to further fine-tune the model to make it more robust.

CONCLUSION

In this paper an evolutionary model (extended from Moore's (2002) crossing the chasm metaphor) for marketing innovative software products (MISP) has been proposed. It is expected that the completed research will identify the marketing catalysts required to move from innovator to early adopter and from early adopter to early majority. These catalysts will then facilitate the formation of a marketing place for this particular SME. These findings can not be generalised, however development of MISP adds to the body of knowledge for marketing innovative software products.

Social Learning and Self-Inclusion Through Women's Web Magazines

Els Rommes, Institute for Gender Studies, Radboud University Nijmegen, The Netherlands; E-mail: e.rommes@pwo.ru.nl

What do users/readers of women's web magazines learn and how do they learn this? In this paper, women's web magazines will both be seen as a source for repeating and reinforcing heteronormative gender differences and as a tool for empowerment of their users. Most of this paper will focus on the processes through which the female users of women's web magazines acquire digital skills, get self-confidence and learn that the Internet is a place where they can feel 'at home'. They learn this through processes of 'assisted inclusion': through the design of websites, self-inclusion and social learning can be encouraged. Learning is considered to be a process of co-shaping of user and magazine, which takes place at both a material and a symbolical level: what gendered subjects are being produced by women's web magazines and what computers/Internet are users of web magazines producing?

Traditional women's magazines target middle class, middle aged, white heterosexual women, using and reinforcing traditional stereotypes of the attractive heterosexual partner, the productive modern housewife, the caring mother and supportive friend. Whereas women's web magazines repeat and reinforce these same stereotypes, e.g. by offering information about beauty, fashion and relationships, they at the same time stretch the traditional stereotypes of women to include the modern, computer competent and independent woman. Hence, they may help in breaking down some of the traditional stereotypes of femininity. Similarly, they can challenge the gender binary of women/serious/functional use versus men/fun/pleasure use. Or by allowing women to discuss their everyday life interests on a public forum, traditional binaries of women/private place versus men/public space may be loosened up. Finally, these stereotypes could have been loosened up by for instance presenting such a traditional, female connotated medium as a women's magazine on a, certainly at the time of conception of these web magazines, male connotated computer and Internet environment, giving them the incentive to use the Internet and facilitate self-inclusion in that respect.

To study what users of women's web magazines learn, creators and designers were interviewed and sites and discussion-threads were studied of the Norwegian web magazines 'Femme', the Irish 'eVenos', the Dutch 'Libelle' and Italian 'Donna Moderna'. In addition, two self-help mailing lists were studied, the Dutch Women On the Web ('WOW') aimed at women who start their own business or who want to develop their ICT competences and the Italian 'Sensa Maschera', aimed at people with 'Lupus', a serious illness that is more common amongst women than amongst men. In addition, surveys were held amongst users of Sensa Maschera, Donna Moderna, WOW and eVenos and (online) interviews were held with users of the latter two. All magazines had an early web-presence as they came online between 1996 and 2000. We can assume that the early web presence of these websites targeting women has contributed to the image of the Internet as it is now, a place where a diversity of users can find information they like. Arguably, this image has contributed to more equal statistics regarding the number of men and women that use the Internet. In and of themselves, these web magazines certainly attracted variable but high numbers of women. Whereas, for instance, the Irish web magazine eVenos is accessed by 790 visitors per month (MacKeogh, 2003), the Italian web magazine Donna Moderna attracted for instance an estimated one and a half million readers (Fortunati, 2004: 235) and Dutch web magazine Libelle had 13 million page views in a year (Slooten, 2003). In all these cases, a majority of users was female.

SELF-INCLUSION: COMMERCIALITY WITH A TWIST

What were the motives and intentions of the creators of the women's magazines we studied to 'go on line'? All four web magazines operated commercially. They hoped to directly earn money through advertisements on the Internet and indirectly by going on line as that would give their paper magazine a more modern image, again leading to (new) advertisers aiming at a younger audience and possibly to more buyers of their paper magazine. The magazines were founded in the period before the dotcom crash, in the same period that in the US and Canada 'active courting of the 'elusive female audience' began in earnest' as a result of some studies that showed that women 'accounted for 55% of web shopping' (Shade, 2000: 220). Hence, the creators had high expectations of huge growth rates and possibly even 'rolling out over Europe', as the creators of the Norwegian web magazine 'Femme' called it (Hestflatt, 2003).

All web magazines except Femme were magazines that already existed on paper, so their target users were somewhat younger but basically similar to that of their paper magazine, whereas the Norwegian magazine aimed to look similar to Cosmopolitan. In short, they all aimed at middle to upper-class women, which is not surprising 'given that advertisers want the most bang from their bucks' (Shade, 2000: 221). They tried to attract these women by addressing similar issues as they addressed in their paper magazines. According to sociologist McRobbie (1991), rather than dividing their target group according to interest, as is done when the target audience is male, girl-magazines 'assume that all girls are interested in romance, make-up, physical fitness, cooking, and fashion' (McRobbie, 1991). Indeed, the designers based many decisions on stereotypes rather than on user-research: as a Norwegian designer said 'certain things just belong to being a woman and to being female' (Hestflatt, 2003). Some designers also followed the so-called 'reflective I-methodology', as they assumed that their own interests would reflect those of the target users (Rommes, 2006), but perhaps most of all, they made their choices based on what they thought their potential advertisers would want to be on their site, which in the case of the Italian web magazine 'Donna Moderna' explained the attention paid to beauty topics.[1]

One of the common perceptions expressed by the producers of web magazines was that many women needed assistance to become web users. Generally, this was not based on a perception of female users as poor with technology, but in most cases it was felt that either women had no time for technology (Donna Moderna, eVenos) or had the ability but lacked the confidence (Women on the Web). For whatever reason, all the producers approached the user with 'kid gloves'. In particular, producers felt that the technology had to be 'easy to use' or 'user-friendly'. For example, the editor of Libelle felt very passionately about the importance of ease of use, and suggested that navigation should be : 'super, super simple; always visible, always knowing where you are, always recognizable … I would give my life if necessary to make sure that those requirements were met' (Slooten, 2003: 179). Hence, for the web magazine sites clear, traditional, fixed frames were used, explanations about how to use the site were given and the sites were made accessible at multiple platforms, e.g. also by Macintosh users and by not using flash.[2] So even though they did not think about their female users as incompetent, their websites could easily give that impression, especially if it is compared with similar web magazines for men.

All in all, these magazines used and reinforced traditional heteronormative stereotypes of women being interested in private and household issues and who are incompetent and need help in their use of the Internet. Whereas the users of magazines that targeted men and that were founded in the same period of time learned about a wide variety of ICT gadgets (Hestflatt, 2003), female users of these web magazines learned about how to make themselves more beautiful, how to improve their relationships and how to make a good meal. This reproduction and reinforcement of traditional stereotypes by commercial websites, web magazines, soap operas and games for girls has been extensively criticized by feminist researchers (Brunsdon, 1995; Cassell & Jenkins, 1998). Although many women

were clearly interested in the topics presented in these magazines, the success of the non-commercial websites Sensa Maschera and Women On the Web shows that other topics, like health, computer use or starting an enterprise were at least as popular. For a long time, Women On the Web was even the largest Internet community in the Netherlands (Drost & Jorna, 2000). Moreover, it seems that one of the most successful parts of the web magazines was not the content produced by the creators, but rather the communication and information exchange between the users of these sites on the many discussion boards that these sites hosted.

Although there is a lot to say against the repetition and reinforcement of stereotypes by these women's web magazines, they can also offer support and recognition in dealing with everyday life events, including how to deal with a gendered unequal society, and validation for undervalued female-connotated characteristics (Lovell, 1980). From a feminist standpoint position and from a diversity perspective, there is every reason to encourage an increase in female connotated values and topics on the Internet, and the main problem with these web magazines is that these topics are so clearly directed at 'women', rather than 'for everybody interested in these topics'. In a sense, these web magazines helped in constructing the Internet as an object of desire for users with a wider variety of interests, something that was clearly needed, looking at the historical roots and development of the Internet as 'a toy for the boys'.

Moreover, women's web magazines give the message that you can be a computer competent and confident woman and at the same time adhere to heteronormative requirements for women in present day society. These websites may attract female readers by offering the motivation and the opportunity to become familiar with the use of the Internet, e.g. they encouraged learning by doing, and several web magazine sites offered help for instance by offering an alphabet of 'technical terms'. 'Self-inclusion' thus flows from the relevance of the content of the magazine, the motivation this creates to be online and by reducing the amount of 'inclusion-work' by the users by connecting closely to the situation in which the user is, in terms of their everyday life experiences and their access to technological facilities, knowledge and skills. But even the large majority of women that is disinterested in women's magazine topics may experience that the creation of such 'places for women' or the addition of explicitly 'feminine' topics on the Internet gives the (implicit) message that the Internet is a place for women as well as for men.

SOCIAL LEARNING: WARM EXPERTS WITH A TWIST

As we have seen above, web magazines may be important instruments for assisted inclusion by providing for some relevant content, by facilitating more diverse learning methods than just learning by doing, and in symbolically transforming the meaning of the Internet to something that women feels fits with them. In addition, websites may assist inclusion by providing interactive mail lists, chat rooms and discussion boards where technical matters can be discussed and where users may develop social bonds and communities. This latter way of assisting with inclusion we will call 'social learning'. As with self-inclusion, however, the skills and knowledge that is being passed on between people is only a minor part of what needs to be learned. The symbolical and identity-work is at least as important, through which not just the perception of women as computer competent is changed, but also the perception of computers and the Internet as being relevant, fun and interesting is transformed.

In general, social learning is one of the main ways in which people learn to use new technologies and especially interactive ICTs (Rogers, 1995). People learn not just skills but also the relevance or entertainment-value of new ICTs from so-called 'warm experts': family members, friends or acquaintances who already have experience with the technology (Bakardjieva, 2001). A warm expert can 'translate' the usefulness of the technology and the language and skills needed for it in a way that fits with the everyday life experiences of the new user and can gear information towards specific questions and level of skills of users on a 'need to know' basis. This is hardly possible in manuals or during more formal learning settings. As many of the users of the women's web magazines remarked, however, such a 'warm expert' can also create an unwanted dependency relationship. One of the users of WOW said: 'I want to manage and maintain my own computer without being dependent on others'. Having a warm expert help may in fact increase the feeling of incompetence by the person being helped and even reinforce gender hierarchies (Rommes, 2002). Moreover, warm experts may not have time when needed or they may give wrong or unhelpful information.

The help women gave each other on-line had all the advantages of warm expert knowledge without the disadvantages. Answers were being checked by many other users, who would often provide additional information and the information was seen as more 'trustworthy', as they did not perceive any hidden agendas of the helpers. (Gendered) power-relations were absent as they were not in a personal relationship with the other users of the boards and almost all users were women. Most importantly, reading about personal experiences with technology but also with other recognizable stories of dealing with illness, discrimination or a (male) partner gave many of them more self-confidence in life and in dealing with technologies: they felt 'at home' on the Internet. As a user of WOW remarked: 'It gives me the feeling that I belong to it and because of this, I have started taking myself more seriously in the area of computers. Nowadays, I follow a master education media design'. In short, women would empower each other by being role model to each other. As two users of the mailing lists remarked of WOW and eVenos remarked: 'I have become so stubborn, I think: if others can do it, then why should I not be able to do it?' and another user said: 'by reading how others deal with computer problems (…) I get the sense that I could also learn it!' As we have shown in earlier research, being a role model for each other is one of the main advantages of women-only education in general (Rommes, Faulkner, & Slooten, 2005).

All in all, as a result of the self inclusion and social learning that was facilitated by the women's web magazines, both the female users of these websites as well as (perceptions of) parts of the Internet changed. Women perceived themselves as being computer competent and 'belonging' to the Internet. Simultaneously, the perception and content of the Internet changed. The Internet was no longer seen as a 'toy for the boys', but also discussion boards and topics were added and interfaces were changed as a result of requests by female users. Moreover, the female users of the discussion boards and mailing lists changed the discussion culture of the Internet, the 'Netiquette', at least for the boards and lists they were using. Rather than pasting short answers inside another woman's mail or replying 'RTFM' ("read the fucking manual') to questions, which had been the dominating discussion style on many mailing lists before, the discussion style on all discussion boards and mailing lists we studied was one of supportiveness, 'there are no stupid questions' and one in which women took time and space to answer questions elaborately and often illustrate them with personal stories and experiences (Herring, 1994). This chapter has shown the importance of changing both gender and technologies as a way of including gender in the information society, and it has shown ways in which this can be done.

ENDNOTES

[1] Similarly, in the development of a new electronic toy for girls, the designers based their final decision about the color of the toy on what they expected the parents of the girls would like, rather than on what they knew the girls they had studied would like (Rommes, Stienstra, & Oudshoorn, 2003).

[2] This is an often underestimated aspect of software, as e.g. Star noted: 'It seemed the difficulty was not in the interface (…) but rather in infrastructure - incompatible platforms' (Star, 1999: 380)

Information and Communications Technology (ICT) as a Vehicle for Economic Development: Challenges Facing the Caribbean Common Market (CARICOM) States

Patrick I. Jeffers, Iowa State University, Rm. 4320, Gerdin Bldg., Ames, IA 50011, USA; E-mail: pjeffers@iastate.edu

Rhoda Joseph, Pennsylvania State University Harrisburg, 777 W. Harrisburg Pike, Middletown, PA 17057, USA; E-mail: ruj1@psu.edu

INTRODUCTION

This paper proposes to examine the potential of information and communications technology (ICT) as a vehicle for promoting the economic objectives of the Caribbean region and specifically those of the Caribbean Common Market (CARICOM) member states. Among the expressed objectives of CARICOM is "the strengthening, coordination and regulation of economic and trade relations in order to promote accelerated, harmonious and balanced development.(Palmer 2002)" Understanding and appraising the nature of the challenges to be faced in leveraging the potential of ICT for the economic development of the region is a critical contribution to this cause. The current standing members are: Antigua and Barbuda, The Bahamas, Barbados, Belize, Dominica, Grenada, Guyana, Haiti, Jamaica, Montserrat, Saint Kitts and Nevis, Saint Lucia, Saint Vincent and the Grenadines, Suriname and Trinidad and Tobago.

Just over 200 years ago, the Caribbean Archipelago was the economic cockpit of the world, supply European industries with the vital raw materials from cash crops such as cotton, sugar, tobacco, cocoa, coffee and spices. The island of San Domingue (Hispaniola), now comprised of the Republic of Haiti and the Dominican Republic, held center-stage then, as the most prosperous European colony of the New World(Williams 1970). The Hispaniola of old is no more, now a landscape of economic stagnation that stands testimony to the economic despair that has griped the region since the heydays of the eighteenth century.

The island is now comprised of the Spanish-speaking Dominican Republic, occupying the eastern two-thirds and Haiti to the west, which still retains a very strong French influence. Haiti became the first black republic, following a slave revolt in 1802 that won its independence from France. Today Haiti holds the unenviable status as the poorest country in the Western Hemisphere and among the poorest in the world (Verner and Egset 2006). The juxtaposition of these two divergent cultures that comprise the land mass of Hispaniola characterizes the challenge to be surmounted in attempting to foster economic cooperation.

Once jealously guarded by their colonial rulers, these former pockets of economic opportunity for European investors have since been plagued by persistent economic stagnation. Recent international trends such as globalization and the outsourcing of light industry to the Far-East have greatly exacerbated the spiral. Each island is a truly unique and complex micro-state bearing the distinct imprint of its European colonial heritage. This proposal outlines a path of future study to use ICT as a vehicle for development in the region.

ICT AS A VEHICLE FOR DEVELOPMENT

Information and telecommunication technology (ICT) holds many promises as a vehicle for addressing the economic and other challenges faced by CARICOM member states. Clearly fostering internal economic cooperation in this Galapagos-like setting would pose a phenomenally rich setting for research. On the surface it may seem that the cultural and ethnic divergence of the region is not unlike the challenges faced by other similar efforts at economic cooperation, such as the European Union. But there are profound differences. Steeped in a legacy of economic dependency, geographically and otherwise fragmented, the island nations of the Caribbean possess their own litany of challenges. In this paper we propose to address these issues, drawing parallels from other successful efforts at regional cooperation, but mindful of those issues that can only be fully comprehended when framed in the historical and social legacy of the region. We propose to examine the potential for ICT applications in the following functional areas as they relate to the fifteen member states of the Caribbean Community (CARICOM), as briefly outlined below:

1. ***Economic Development and Cooperation:*** Limited size and resources makes economic cooperation an imperative for the future economic viability of the region, especially in the face of globalization (Byron 2004). The problem is compounded by the fact that the economies of the region are by definition open and export-oriented, each island possessing closer economic ties with the European mother-country and very limited intra-regional trade. The concept of *supply chains*, which is firmly grounded in the application of modern information technology to foster economic collaboration across industries, is a fitting example of how ICT can promote economic cooperation in the region. Other possible applications will be explored, taking cues where possible from successful regional projects elsewhere.
2. ***Education:*** The proverbial "brain drain" is yet another persistent problem of the region. For many of its inhabitants who are afforded advanced education the urge to migrate, beckoned by the prospect of higher wages and living standards abroad, is overpowering. For those left behind there are the dim prospects of a lifetime of underemployment and lack of access to the few skilled jobs available. There exists an unending spiral: migration of skilled workers depletes labor reserves, which in turn reduces the ability to attract investments. Could ICT provide the means for mitigating this problem?
3. ***Tourism:*** ICT could assist in the development of the tourism industry, facilitating better planning and resource utilization at a regional level. For example, e-markets and e-changes could potentially assist in the marketing of fresh produce, fruits and vegetable to support the hotel industry, yet another problem that characterizes the region.
4. ***Other dimensions of cooperation:*** E-health, e-government, regional security; these are all aspects of Caribbean life that can be potentially addressed through the applications of ICT-based solutions.

SUMMARY

The task of charting a path for economic development can be aided by learning from efforts pursuing similar economic objectives elsewhere. The case of the European Union immediately comes to mind. There may be several parallels, but the unique historical and political legacy of the Caribbean demands that the application of ICT, while holding significant potential as a vehicle for development,

should be tempered by other relevant concerns that may not be readily apparent to the researcher. This paper proposed an insight into the nature of Caribbean societies addressing those issues that could have a significantly impact on ICT related projects.

E-Learning and an Implementation in Yildiz Technical University

Esin Ertemsir Berkin, Yildiz Technical University, Turkey; E-mail: ertemsir@yildiz.edu.tr
Esin Can Mutlu, Yildiz Technical University, Turkey; E-mail: emutlu@yildiz.edu.tr
Yonca Gürol, Yildiz Technical University, Turkey; E-mail: gurol@yildiz.edu.tr

In a globalizing world, the rapid advancements in technology affect education as well as the other sectors. To keep up with the innovations in information and technology, it is imperative to implement communication technologies within instructional settings. The use of internet and web in education is important especially for keeping the graduate curriculum that aims to equip students with modern trends in order to prepare them for the work force updated and for reaching more people without any time or location limit.

Today, most institutions draw on lecture-oriented methods. Traditional education has its limitations in terms of its engagement with students due to the inadequate use of audio-visual technology, causing a setback by not letting the learner to study in his/her own speed. (Inoue, 2004). Furthermore, there are other educational methods such as case study analysis, role-playing, conducting research, which provide students to have real life experiences. However, the insufficient funds together with the growing population of students require new alternatives to be employed by institutions as a means to complement the current instruction methods.

In this sense, technological advancements serve the educational institutions by both providing them with access to internet and to other communication technologies to help them create new learning and teaching opportunities.

E-learning is an example of the communication technology usage in higher education level. Some Turkish Universities follow "distance learning" and "e-learning" implementations by both practicing and blending it with other learning activities to attain to the modern education standards, to meet the increasing educational demand independent of any locational limits, with 7 days 24 hours access, and with less costs and more participants. In a supporting manner, the draft report of 2006-2008 Higher Education Strategy for Turkey, stipulates a %10-%30 percent increase in higher education programs via e-learning with the purpose of increasing the capacity of Turkish Universities. Also, the inter-university project; titled as "e-campus" supports the transformation of knowledge community in the higher educational level. (Yalabık, 2004)

Yildiz Technical University (YTU) , to which we belong, is also among the Turkish Universities which utilizes e-learning. 2006-2008 Strategic Plan of YTÜ attempts to make sure that each YTÜ student takes at least one e-course before graduation. In the strategic plan, the role and the short, intermediate and long term goals of YTÜ E-Learning Commission, decisions about the usage of blended learning model and the introduction of e-learning technologies to instructors and students have been emphasized.

The mission of the project titled as "e@yildiz"; is primarily to raise the quality of education, and secondarily to maximize the efficiency in facility management and human resources by applying distance learning technologies along with traditional models. For the effective usage of distance learning technologies, a preparation committee was constituted in May 2002. In 2003-2004 fiscal year, 5 courses from various disciplines have been offered on the web: Instructional Technology and Material Development, Micro Economics, Data Structure and Algorithms, Design Languages and Figuration Grammars, English-Listening courses. In the 2006-2007 fiscal year, three of these courses are still presented via web. A chart about YTÜ's e-courses is given below.

In addition to the courses presented in Table 1, the departments of Business Administration, Economics, Civil Engineering, Western Languages and Literature have suggested four more courses to be transferred to the web. This four courses including Human Resource Management course which is suggested by our division of Management and Organization in the Department of Business Administration have been endorsed by the commission as a part of the e-learning project.

This study involves the scenario work of the above-mentioned HRM course which has been prepared within the framework of Blended Learning Model.

E-learning can be described as an instruction in the electronic environment and has been defined by the American Society for Training and Development's e-learning glossary as "a wide set of applications and processes, such as Web-based learning, computer-based learning, virtual classrooms and digital collaboration" (Derouin, Fritzsche and Salas, 2004). E-learning provides synchronized and asynchronized education via computers, internet/ intranet, network, CD-ROM technologies.

Besides, blended learning is defined as an integrated model that unites the strengths of the face to face teaching activities in the classroom and online learning environments such as information and communication technology instruments (Hummel, 2006, 3). The notion here is that e-learning elements or modules are combined with traditional methods to make a hybrid learning experience (Kovaleski, 2004, 35; Coné, 2002, 19).

Each method and instrument has its own strengths and weaknesses in its own context. Today it is accepted that communication instruments should be mixed in best fit to be able to provide a more effective education.

Bersin identifies these instruments as classroom instruction, books, conference meetings, CD-ROMs, PPT presentations, handbooks/guides, education softwares, web pages, online simulations, web based discussion groups, mentoring programs and videos. He also mentioned that there is no need to use all of these materials to succeed in blended learning, but rather just two or three of them will be sufficient if they're consistent with the course content.

To be able to carry on HRM course in a more updated and affective manner, the courses presented in Table I have been investigated. HRM e-course had been adapted from the Instructional Design Model of Kemp, Morrison and Ross (Morrison, Ross and Kemp, 2001).

In this study, undergraduate students' readiness for self-directed learning and technical readiness (Chapman, 2004, 351), learning behavior of their age, size of the group, their interest and needs had been taken into consideration while setting the instructional objectives and constituting the content and the scenario. Differently from target audience analyze, course contents' predisposition to visuality and the appropriateness of showing most of the HRM applications on web were also affected the selection. Students take this basis and single course of HRM along their management education so the HRM functions and main concepts are intended to make known.

While configuring the HRM course content in the "instructional objectives setting" stage, the objectives indicated within the context of YTÜ EKSİP (Continual Quality Improvement Project in Education) were treated as the guidance.

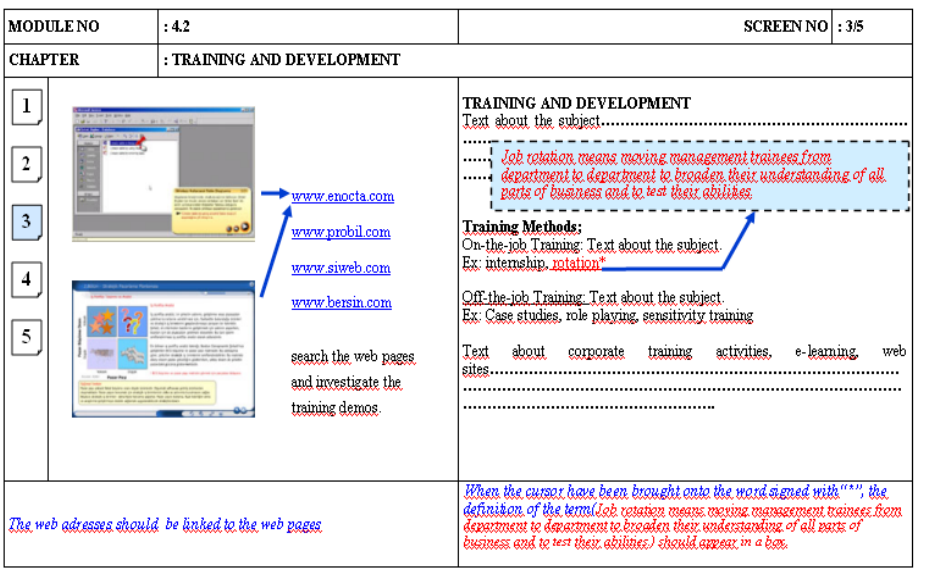
The knowledge had been separated in the modules that have integrity inside. The objectives for each module had been determined, some had been planned to be given in blended learning and the others in face to face instruction.

In the "instructional objectives organizing" stage, the learning behavior that will be introduced to students were prepared in accordance with Bloom's Taxonomy of Educational Objectives. Taxonomy consists of three domains of learning: cognitive, affective, and psychomotor. In addition; six levels of cognitive domain; knowledge, comprehension, application, analysis, synthesis and evaluation have been taken into consideration. The objectives in knowledge and comprehension level had been thought to fit to e-learning, the ones in application and advanced levels to classroom education.

For the purpose of informing students about the content of the course and to motivate them, the objectives of the new module will be presented in the first page of the module. By using the most appropriate language for the student, the new issues which will be introduced him by that module at the end of the session will be emphasized. By means of these, it is aimed for the student to be prepared and open for learning.

In the "module design" stage, some limitations have been assigned for both written texts part and visual expressions part. Allocating the subject into chapters, giving a heading to each chapter, allocating the chapter headings into subheadings, designating progressivity incisively, approaching a new subject under a new heading, scheduling the time table for module accesses and location selections(classroom or lab) for the courses, preparing an interactive visual material, writing the scripts

Figure 1. Interface sample



of animations, using maximum seven visual materials for a plain interface, not using horizontal scroll bar, using vertical scroll bar for the large charts, creating the texts and visuals for the 800x600 pixel resolution, disposing the written texts in the right side of the interface, never using an horizontal scroll bar in this written area and using the vertical one for maximum three times scrolling are basic standards.

YTÜ uses IBM Learning Space 5.0 in its project. The interface of the program has three main parts. Visual expressions such as figures, tables, charts, animations are found in the midst of the screen, thumbnails in the left part of the screen and the written texts of the course are found in the right side of the screen. (see www.e-learning.yildiz.edu.tr)

The visual expressions in the centre part can be changed easily to click on the links in the text or thumbnails in the left part. The thumbnails which are lined up one under the other represent the number of visual expressions in the module, the colored icon represents the actual visual material on the screen just in that moment.

In the scenario study of e-HRM course, visual expressions and written texts showed course content and screen flows is being arranged following the instructional texts are prepared in summarized formats. Scenario study is simply a plan that explains things that student will see, hear and do on screen during the e-course process.

In this study, an interface template of Learning Space 5.0 has been constituted to guide the web design team. In the lower-middle part of the template the verbal exposition about the visual material in the midst of the screen is found. If there's an annotation about the written text, this can be found lower-right cell of the template.

Furthermore a notation is created for facilitating the communication process between web design team and instructor and getting them understand the requests about the interface easily. Notation can be defined as a system of numbers and signs. Some notation examples are given in the Table 2.

In the "content constitution" stage, the objectives and contents of HRM courses in foreign universities are investigated and benchmarked to see the HRM relevant literature which is predominantly consisting of foreign sources as well as to be able to read the global implementations. The extent and classification of Dessler (2005) and De Chenzo(2001) in HRM were helpful while preparing of our own.

The HRM course contents of Melbourne Business School, AUSTRALIA; McGill University, CANADA; Nottinghom University Business School, UK ; Seattle University & Washington State University & Yale School of Management; New Haven USA; and the contents of Turkish Universities HRM courses; Marmara University, Yıldız Technical University have been benchmarked.

Some important differences have been detected in the course contents in terms of "speed of change" and/or "cultural diversities". To state as an example, although employer-employee relations, collective bargaining, racial and religious discrimination are frequent subjects in foreign and most notably in USA origin HR literature, the same subjects are emphasized less frequently in Turkey; and accordingly, they didn't take a place in our e-course.

We tried to show and give examples to the daily practices and business life experiences in the content preparation process. A self produced video about competency-based recruitment&selection and a 360-degree performance feedback test for the students' term project in which the evaluation of instructor, project team members, classmates and the student himself have been taken into consideration for his performance were specially created to be used in the modules. These are some examples for the most outstanding tools used in the program. On the other hand, the compensation management function of HRM had been left out of the content because it's difficult to build up the subject with audio visual stimulus in electronic media and also it's best fit to face-to-face learning. As a support for this elimination, a research of YTÜ Department of Economics puts forward some important evidences. The research showed that the students achievement has fallen after the web-assisted education; although previously an improvement had been expected. As one of the reasons behind these results, it was stated that the students were used to traditional style education, especially to the blackboard illustrations of technical issues (Eren&Donduran, 2005, 197), such as graphics or the compensation charts of HRM.

Student access scheduling and arrangement of the modules are modified in terms of opening each module just after the former module is worked up and being able to access the corequisite modules concurrently.

At the end of the process of "deciding on the instruction strategies", YTU decided to use Blended Learning Model during all the term, right along with the modules which have been followed through the web, and with the process of face to face instruction readings, discussions, case studies and workshops. Mid term and end-term evaluations will be done in class as it is in traditional education. The activities will be sent to the teacher or tutor by e-mail, the evaluations will be done at class, by that way the mutual interaction between the teacher and the student will be able to be provided.

The learning of lesson over web will be done by presentation. First of all the whole will be shown and explained by the method of deduction, then examples will be given. Every week after the students checked the modules, teachers and students will meet at the class, they plan to overview the details if needed, debate and summarize the subjects. The activities in the class should not be as a repeat of the subjects on the web; rather they should be in a complementary and supportive manner. The issues like student-student and instructor-student interaction and active engagement to the class have not been maintained in a satisfactory manner with virtual class and synchronized practices in e-learning and they are tried to be maintained with face-to-face education.

In "the design of modules" stage, IBM Lotus Learning Space 5.0. Program will be used. Learning Space 5.0 is a software with user-friendly interface that provides to constitute on-line courses, to manage them, to communicate the contents to students and to check out the courses. Finally, after preparing the summarized formats within the framework of the mentioned standards and limitations above, the scenario plan showing course content and screen flows with written texts and visual expressions has been arranged following the instructional texts. LMS (learning management system) will also provide glossary, notebook, reading room, print, download and help options. Glossaries and online dictionaries are the most preferred web-assisted functions in terms of perceived usefulness in the communities whose mother tongue isn't English. Notes, powerpoints and multimedia projects are following the glossaries. (McNaught&Lam, 2005, 610). In our project HR terms, reading room, print and download options are planned to be used in an efficient way.

The new information and communication technologies such as web journal/blog, podcasting, wiki, e/pop are supposed to be used in the near future of Turkey. The infrastructure and limited bandwidths are needed to be developed and the instructors need to be more enthusiastic with the instructional technology use both in and out of the classroom. Poscasting is a new concept and an alternative delivery for any content including the educational ones which can be thought as university lectures. It is a combination of *iPod* (Apple's popular audio player)

Table 2. Notation sample [1]

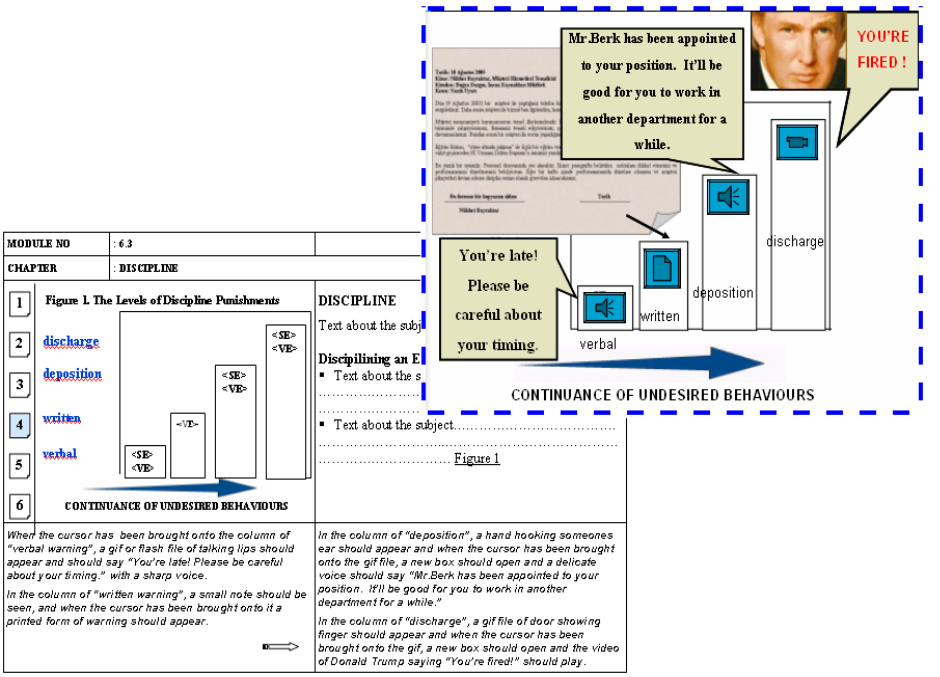
<1>	=	1 second blank

Figure 2. Scenario screen sample



and broadcasting (Elliott, 2006; Crofts, Dilley, Fox, Retsema & Williams, 2005; Jardin, 2005). Podcasts, audio podcasts, video casts can be played on any computer, and downloaded to almost any portable music player (Toole, 2006). E/pop is a new video conference method that lets instructors and students not only see each other but also lets them send documents and mails, see the others' desktops on their own screens and use it interactively. This technology is especially ideal for small group courses.

The HRM course is planned to be opened as an e-course in 2007-2008 fiscal year after the web design team transfers the scenario to web. The preparation process requires the interaction and exchange of ideas between instructor, subject field specialists and web design team so we're looking forward to hear the participants' contributions and criticisms.

E-Government and Its Impact on the Informal Sector in Turkey

Vichuda Nui Polatoglu, Anadolu University, Turkey; E-mail: nuip@anadolu.edu.tr
Levent Erdogan, Anadolu University, Turkey; E-mail: lerdogan@anadolu.edu.tr

INTRODUCTION

In recent years Turkey faced with large budget deficits. After the financial crisis in 2001, budget deficits had reached a critical level. In order to deal with the problem, Turkish goverment have taken some actions to increase its revenues and to reduce its expenditures. The government has been working with the IMF to bring about structural changes and governmental reforms. As a result, a stabilization program has been put in place under IMF directions. Also, Turkey is currently in the negotiation process for EU full membership. The implementation of e-goverment is seen as a large step in governmental reform and another step towards EU standards.

E-government was introduced as one of the ways to increase tax revenue collections, which has been a major problem causing the deficits. The study is focused on e-taxation which was introduced as a way to effectively collect taxes which are the most important revenue resources of the government. Another focus is on the informal sector of the economy (or underground economy). In Turkey, efficient tax collection system is needed because of non-collection from its large informal sector. Gerxhani (2004) reported the average size of this sector in developing countries to be as high as 44% of GNP in Africa and 35% in Asia. This sector has also been significant in the Turkish economy as well. Therefore, the target for higher rate of tax collections comes from this sector of the economy.

Informal sector is a very important area to investigate because it inhibits productivity, discourages business investment and has the potential to reduce economic growth (Capp et al., 2005). According to a study by OECD (2006) of Turkish economy, a major factor which caused a relatively low GDP per capita is its low level of productivity, especially in the informal enterprises. Informality therefore reduces the overall growth potential of the Turkish economy. We expect that the implementation of e-taxation has significantly increased tax revenue collections coming from the informal economy. The following section presents a brief review of informal economy.

REVIEW OF INFORMAL ECONOMY

The informal economy is a vague, multidimensional and interdisciplinary concept therefore, it is necessary to define the boarders of the areas under investigation. In this study, we take similar interpretations from the OECD report (2005) on informal economy as the unobserved economic activities that are driven by tax evasion or by attempts to avoid legal standards and procedures. Therefore, it excludes criminal activities and non taxed activities such as domestic labor. According to this definition, registered businesses in informal sector may keep substantial parts of their earnings unrecorded and evade substantial tax payments. This group includes, for example, self-employed businesses, restaurants and traders whose tax amounts depend on their declarations. Tax evation behavior exists in some businesses and in all sectors of the economy, however, the magnitude of informality depends on the special structure of that sector (Sarili, 2004). For example, in those sectors where auditing is difficult to implement such as small companies serving individuals and labor-intensive sectors, business owners are more likely to hide their real earnings.

There is a positive correlation between tax rates and the level of informal economy. The higher tax rates in developing countries, with respect to developed countries, lead to larger informal economies (anonymous, 2001). Another significant incentive for informal economy in Turkey is the presence of high value added tax rates. This often leads to undocumented trade by increasing the propensity of purchasers towards bargaining for not taking the receipts. Thus, it should be expected that such bargains will reduce when the VAT rates are lowered. The European Union, is planning to harmonize the VAT practice. In the process of joining the EU, the VAT rates in Turkey will have to be aligned with these regulations.

Some of the primary economic reasons to participate in the informal economy related to unemployment and inflexible formal labor market; high tax rates and low audit probabilities; a declining real price of capital; the governmental over-regulation of the formal or market sector; and the high cost of formal production (Gerxhani, 2004). In Turkey, a large number of employment opportunities has been in the informal sector because the formal sector has been unable to absorb the growing labor force, especially in the urban area. Also, the Turkish labor market is over-regulated with very high taxes on labor, both of which serve as a large disincentive to formal sector employment (OECD, 2006).

Additionally, weak legal and law-enforcement systems contribute to the high percentage of informal economy. Tax amnesty programs has been put in place several times over the years in Turkey. They seem to encourage tax evasion and informal economic activities. Under the expectations of the next amnesty, taxpayers postpone their tax payments. This has been possible because of lack of effective tax auditing. According to the Ministry of Treasury statistics, the number of tax auditors in the last 17 years declined by 68%. From 1985 until 2001, the population in Turkey grew from 50.3 million to 68.6 million, that is 36.4%. Thus, while the population grew, the number of auditors reduced, which implies that both the frequency of tax auditing and the number of audited taxpayers has been reduced. It can be concluded that the government has been unable to collect a large portion of tax revenues. Over the recent years, the Turkish government has concentrated on borrowing, thus, it indirectly encourages those taxpayers to continue their informal activities. As a result, the internal and external debt of the country has been large.

ANALYSIS OF E-TAXATION AND INFORMAL ECONOMY

Kertesz (2003) proposes that governments need to evaluate their e-government projects for the economic value using cost-benefit analysis (the net present value method) since hundreads of millions of dollars are spent on such projects. Picci (2006) propose a structural modelling approach to analyze the economic impact of e-government. Others such as e-government readiness report (available at http://www.unpan.org/e-government5.asp) assesses UN member states to ascertain how willing and ready the governments are to use ICT to improve the access and quality of basic social services to the people for human development. Curtin (2006) offers a framework for e-government model and measurement. In this research, the authors attempts to explore e-taxation issues and its impact on informal sector by using various measurement methods, for example, econometric models, monetary approach and production of electricity approach. Specifically, it is expected that there has been an increase in tax revenues collected by the government after the implementation of e-taxation, and the revenues have come from previously undeclared informal economic activities. Comparison will be made from data gathered before and after e-taxation implementation. The authors will offer analysis, conclusions and recommendations based on results from various measurement methods.

Pre-Mortem Factors for ERP Projects: Preliminary Findings

John J. Sullivan, Charleston Southern University, USA; E-mail: jsullivan@csuniv.edu
Mela Wyeth, Charleston Southern University, USA; E-mail: mwyeth@csuniv.edu
Wade M. Chumney, Charleston Southern University, USA; E-mail: wchumney@csuniv.edu

ABSTRACT

While ERP systems have the potential to provide significant benefits, they are often mismanaged, with unrealistic expectations, or fail outright. This research focuses on applying organizational reliability to ERP systems. Findings from preliminary analysis of exploratory interview data from a group of ERP implementation managers/consultants are examined within the context of Sullivan and Beach's (2004) model for how High Reliability Organizations (HROs) manage complex systems. The model is comprised of five broad categories: risk factors, expectations, resources, organizational competence, and consequences. ERP implementations and HRO systems share considerable commonality, and thus, it is anticipated that ERP implementations could adopt HRO techniques to improve outcomes. By understanding organizational readiness issues for ERP projects, areas of weakness can be identified, and project performance metrics can be forecasted. This would enable ERP project managers to understand project vulnerability better and strengthen areas of weakness before the project begins.

INTRODUCTION

This research addresses recurrent problems with ERP systems. Four ERP managers/consultants have been interviewed (so far) to obtain perspective of factors that are critical for success with their absence contributing to failure. Sullivan and Beach's (2004) model for High Reliability Organizations (HROs) provides a basis for understanding success in managing complex systems. HROs have one difference; failure is the exception rather than the rule. By understanding the successes of HROs and overlaying that against ERP failure factors, it may provide a basis for a pre-mortem framework for improving ERP system management. If successful, this research will provide practitioners the ability to:

1. assess organizational readiness for undertaking an ERP project,
2. identify areas of weakness, and
3. predict with a degree of confidence the outcome of the project in terms of common project metrics such as budget, schedule, and system capability.

EXPLORATORY RESEARCH: PRELIMINARY FINDINGS

ERP implementation managers/consultants rarely have authoritative roles however their close proximity to the authoritative core of these projects provides a insightful perspective into ERP project management. It is recognized that four interviews with this set of participants is not a representative sample of the entire ERP universe. However, these participants were chosen because of their experience in a variety of industries and organizations. A list of factors is provided (Table 1) along with the number of participants who identified those factors. These were considered necessary for success, yet were frequently absent and contributed to failure.

Missing, or misplaced, *accountability* is where project managers are not held accountable for managing projects effectively. Failure does not lead to consequences. Misplaced accountability occurred when the only people held accountable were, "outside the client's organization" (i.e., the consultant or vendor), "anyone but the in-house people." Overwhelmingly, the participants believed that if internal project managers were held accountable for the success or failure of a project, they would succeed far more often.

The consultants reported a lack of *organizational learning*, where organizations failed to learn from past mistakes or the mistakes of others. While there are critics of the effectiveness of organizational learning strategies (Anheier, 1999; Husted and Michailova, 2002; Mellahi, 2005), there are cases where it is commonly used effectively (Garvin, 1993; Laise, 2004), particularly in cases of organizational benchmarking or Total Quality Management (TQM) (Camp, 1993; Yasin and Zimmerer, 1995; Daniels, 1996). While transferring learning strategies may not be universally effective, there is evidence that some organizations can learn from others.

Table 1. Factors emphasized by ERP managers/consultants

ERP Factors	Participants
Accountability	4
Organizational Learning	4
Reward Optimization	3
Leadership	3
Risk Management	4
Personnel Alignment	4
Change Management	4
Performance Monitoring	3
Business Processes	3

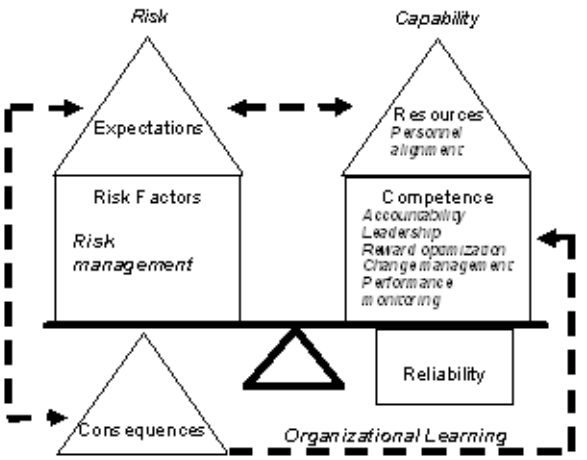
Reward optimization was another theme that emerged from the interviews. Three of the participants believed that organizations often reward behavior that improves the performance of a small component of the organization, at the expense of the greater organizational goals. "…this type of sub-optimization of an organization's overall goals occurs quite frequently. …subverts the overall goals for the maximization of their own personal goals." Thus, rewarding the highest *good* for an organization requires an understanding by its members of what that *good* is.

There is also a need for strong *leadership*. Managers "don't take ownership of the project" and that lack of leadership will allow problems to develop unmitigated. Ineffective or indifferent leadership sends a message to subordinates that the project is not viewed as important by senior management. Managers often delegate too much responsibility to consultants and vendors, and that lack of involvement results in a lack of understanding by internal personnel of the day-to-day management of the system.

Risk management was also reported as a problem for ERP projects. One participant said that many are aware of risk, but its affects are underestimate. Types of risk unaccounted for include, "amount of user acceptances, number and quality of resources assigned, data quality, willingness to change, and user skills, or lack thereof." Difficulties in large scale IT projects should be expected and contingencies should be available in such cases.

Organizational alignment means having the properly skilled personnel assigned to the proper job to avoid "people related problems." Further, "many of the reliability challenges you face with ERP do not deal with the system, but the business process and people instead." Having people assigned to jobs for which they are

Figure 1. Conceptual model for how HROs manage complex systems



not fully qualified develops weaknesses in the implementation process that persist over the duration (often years) of the project.

Another critical area of need is that of effective *change management*. ERP systems often require fundamental changes in the way an organization operates. One trap that some organizations fall into is excessive customization, "to make the ERP system look like our old system." As a result, they failed to recognize that ERP systems often require fundamental changes in the way the business operates.

Many of the participants mentioned that structured *business processes* were necessary. This process-orientation of ERP systems is a completely different perspective from the traditional functional orientation. Properly implemented business processes enhance the way departments interact. However, there appears to be considerable difficulty in getting managers to commit to the change in thinking from departmentalization to process orientation.

Finally, the organization must continuously monitor its performance. *Performance monitoring* provides feedback on the progress of the project. Participants recommended that a set of specific and measurable goals must be established, documented, and communicated among members of the organization. Key Performance Indicators (KPIs) that remove subjectivity are used as a standard set of metrics for measuring the performance of an ERP project. The Y2K problem is an example. When January 1, 2000 was reached, Y2K compliance was either achieved or not achieved, with the non-achievers being the more obvious cases.

DISCUSSION

While far from conclusive, there is considerable agreement in these areas. By aligning these areas with HROs, similar in terms of system complexity, budget size, project duration, and strategic importance of systems, much can be learned. Notably, accountability, leadership, and organizational learning are among the weakest. Understanding how HROs address these areas may provide insight into managing ERP systems.

Managing HRO Systems

HROs have been very successful in managing complex systems such as those controlling nuclear power stations, military operations, and chemical processes (Bierly and Spender, 1995; LaPorte, 1996; Britkov and Sergeev, 1998; Roberts and Bea, 2001; Weick, 2004). Yardsticks for HROs include, "How often could this organization have failed with dramatic consequences?" If failure could have occurred thousands of times, but did not, the organization is highly reliable (Roberts, 1990).

The ability to balance capability and risk in the presence of high consequence separates HROs from traditionally less critical organizations (Sullivan and Beach, 2004). The Sullivan-Beach Model (Figure 1) provides an illustration of the dynamics of managing complex systems in HROs using a scale to represent the weight of risk and the required weight of capability to counteract that risk. Failure occurs when risk, comprised of expectations and risk factors, outweighs an organization's capability, comprised of resources and organizational competence. In such cases the scale tips out of balance, and consequences follow. Bilateral relationships in this model exist between expectations and consequences, as well as expectations and resources. Additionally, a one-way relationship between consequences and organizational competence exists.

Expectations and consequences are related in that the consequences for failure are consistent with the degree of missed expectations. For example, a delay in launching the space shuttle by one day violates an expectation that the shuttle program stay on schedule. However, the consequences of failing to meet this expectation are minimal. Higher order expectations include returning the shuttle and its crew safely to earth. Failing to meet those expectations involves severe consequences (ibid). The relationship between expectations and resources is demonstrated when stakeholders provide resources to a project. Certain expectations, or a return on investment, accompany those resource commitments. Conversely, if resources are withdrawn, project managers will insist that stakeholders lower their expectations, or failure will result. Similarly, if expectations increase, managers will demand additional resources (ibid).

Finally, the one-way relationship between consequences and organizational competence is best described as organizational learning. When HROs fail, an investigation follows, and what is learned contributes to changes in policies and procedures that increase organizational competence so that the potential for failure is significantly reduced (ibid). ERP projects exhibit many of the same characteristics as HRO projects. The key to success for ERP systems might be found in the differences.

Comparing and Contrasting HRO and ERP Systems Management

Based on the Sullivan-Beach Model, HROs share considerable commonality with ERP implementations:

- complex, highly integrated, systems,
- significant resource investment,
- high expectations for success,
- risk factors that threaten success,
- significant consequences for failure (punitive, financial, etc.),

Managing ERP and HRO systems involve similar factors that influence their success. System complexity, resource commitments, high expectations, and risk all interrelate in their respective environments. However, there are differences. Preliminary findings from this research suggest one significant difference: the accountability and organizational learning connection between failure and enhanced competence. For example, losses of the space shuttles Challenger and Columbia involved significant consequences where NASA was held accountable. Consequently, they learned from their mistakes and became more competent. Even though the findings are not yet conclusive, it appears that accountability is frequently misplaced or absent in ERP implementations. Thus, an avoidance of certain types of consequences negates the benefits of organizational learning, and failures repeat.

CONCLUSION

Preliminary findings from ERP managers/consultants provided some insight into causes for failure. Using the Sullivan-Beach Model for how HROs manage complex systems, it provides understanding into how some organizations manage complex systems effectively and apply those techniques to those that do not. Additional data in the next phases of this research will build upon these preliminary findings.

Ultimately, this research seeks to develop a framework for practitioners to assess organizational readiness for undertaking an ERP project, identify areas of weakness, and provide the opportunity to correct weaknesses before the project begins. This pre-mortem organizational assessment model can be derived from prioritizing factors that contribute to success to provide insight into organizational shortcomings while there is time to correct them. Considering the immense resource commitments of ERP projects, opportunities to correct weaknesses in advance could be worth millions of dollars in wasted resources.

Organizational, Environmental and Technological Determinants of E-Commerce Adoption in Botswana

Faith-Michael E. Uzoka, University of Botswana, Botswana; E-mail: uzokafm@yahoo.com, uzokaf@mopipi.ub.bw
Geoffrey G. Seleka, University of Botswana, Botswana; E-mail: selekagg@mopipi.ub.bw

ABSTRACT

A number of studies have applied the technology innovation models to the adoption of ecommerce. However, it is observed that no singular model fits the contextual situations of developing countries due to country specific factors such as culture, technology competency, government policy, and educational level. This study proposes an interactionist model termed technology readiness model (TRM) in the study of factors negatively affecting the ability of businesses in Botswana to adopt e-commerce. The findings show that organizational, internet marketing and customer/logistic factors have significant influences on e-commerce adoption. Security factor was however not identified to impact significantly on the decision to adopt e-commerce. The second phase of the study determines the impact of each organizational variable on e-commerce adoption.

Keywords: E-commerce, e-readiness, developing countries, technology adoption, technology readiness model

1.0 INTRODUCTION

Majority of studies on e-commerce adoption were in developed nations (Hawk 2004), while predictions point to a significant growth in e-commerce in developing countries in the first decade of the twenty first century (McConnel 2000). Recent studies have attempted to identify factors that affect organizations in the decision to adopt e-commerce in developing countries (Aghaunor and Fotoh 2006, Uzoka *et al.* 2006). However, most of these studies have emphasized the influence of contextual impediments related to economic, technological, legal, and financial infrastructure as major determinants of e-commerce adoption

Botswana is one of the countries in the Southern African Development Community (SADC) with a good degree of e-readiness (World Development Report 2003), and one of Africa's best performing economies (World Economic Forum, 2003). A report by Ifinedo (2005) shows Botswana as having an e-readiness value of 2.47 (on a five point scale), only after South Africa with an e-readiness value 2.78, and an African mean of 2.2. A previous study (Uzoka and Seleka, 2006) identifies Botswana as having a low level of e-commerce adoption. This study seeks to identify the factors militating against the adoption of e-commerce in Botswana, and determine the effects (if any) of organizational factors on e-commerce adoption in Botswana.

2.0 THEORETICAL FRAMEWORK AND METHODOLOGY

Most innovation adoptions promote several dominant perspectives: managerial imperative, organizational imperative, technological imperative, and environmental imperative (Molla and Licker 2005). Technological imperative models include the diffusion of innovation [DOI] (Rogers 1995), technology acceptance model [TAM] (Davis 1989), and the theory of planned behavior [TPB] (Ajzen, 1991). This study leans towards the interactionism as the theoretical framework for the adoption model.

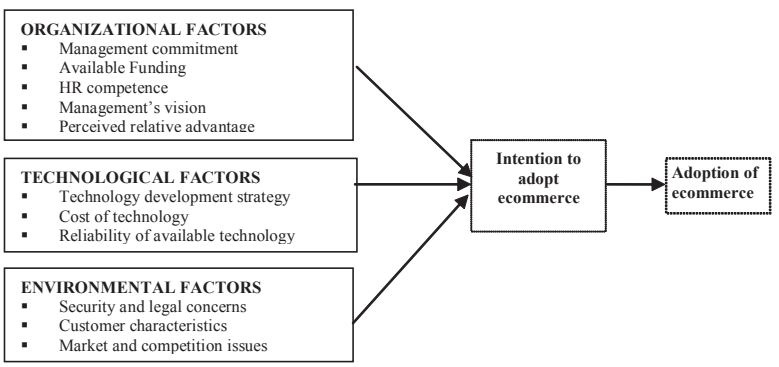
Some literature have adopted the interactionist models, which attempt to fuse the features of the managerial, organizational, technological, and environmental imperatives to technology adoption (Nelson and Shaw 2001, Molla and Licker 2005, Aghaunor and Fotoh 2006). This study leans towards the interactionism as the theoretical framework of adoption model. We posit that organizational, technological, and environmental factors can provide meaningful predictors of e-commerce adoption in Botswana. We refer to the model as *technology readiness model* (TRM) depicted in Figure 1.

Based on the TRM model, the following initial hypotheses were formulated:

H^1: There is a positive relationship between organizational characteristics and ability to adopt e-commerce.

H^2: Customer characteristics and logistics exert a significant influence on the organization's ability to adopt e-commerce.

Figure 1. Technology readiness model (TRM)



H^3: Internet marketing variables exert an influence on the adoption of e-commerce.

H^4: Security concerns significantly affect an organization's decision to adopt e-commerce.

Two hundred questionnaires were administered to product/service organizations in both public and private sectors of Botswana. Twenty four variables relating to ecommerce adoption were identified through literature search and utilized for the purpose of analysis (Appendix A). The first part of the analysis involves the use exploratory factor analysis to reduce the variables into few factors that could affect the adoption of e-commerce in Botswana. Following the factor analysis was the use of K-means cluster analysis in grouping the respondents into two clusters relating to the effects of the identified variables on the adoption of e-commerce. The reliability of the resulting data was measured using the Chronbach's alpha. Multiple regression analysis was further carried out in order to test the hypotheses relating to the effects of the factors obtained in the exploratory factor analysis.

3.0 INTERMEDIATE RESULTS

The exploratory factor analysis (Table 1) produced four extracted factors which were considered interpretable.

The following factors were extracted:

a. *Organizational factor (ORGANIZ)*, which relates to organizational influence on the adoption of e-commerce.
b. *Customer/Logistic factor (CUSTLOG),* which represents the influence of customer characteristics and logistics on the adoption of e-commerce
c. *Internet marketing factor (INTERMKT)*, which represents issues relating to internet marketing as they affect developing countries (such as Botswana). Such issues include credit card penetration, internet access, and technical reliability.
d. *Security factor (SECURIT)* relates to security concerns.

The cluster analysis shows that 69.84% of the respondents agree that the variables under consideration exert an aggregate influence on their ability to adopt e-commerce, while 30.16% do not. The regression analysis shows an adjusted R^2 of 3.02, which indicates the predictive capability of the model. The model has a low predictive capability because other behavioral variables were excluded from the model [having been previously tested in (Uzoka *et al.* 2006)].The regression analysis (Table 2) shows that ORGANIZ, CUSTLOG and INTERMKT exert a significant influence on the firm's decision to adopt e-commerce, while the security factor (SECURIT) is not significant in a firm's decision to adopt e-commerce.

4.0 DISCUSSION AND FURTHER WORK

The findings show that organizational, internet marketing and customer/logistic factors have significant influences on e-commerce adoption, thus H^1, H^2, H^3 are supported. Security factor was however not identified to impact significantly on the decision to adopt e-commerce, thus H^4 is not supported.

Organizational factor is a major determinant in a firm's decision to adopt e-commerce. Variables such as level of funding available for retail development on the Internet, senior management's level of commitment to e-commerce, company's Internet development strategy, level of human resources available, web design skills of company personnel, management vision of the usefulness of the Internet and conviction about the benefits of e-commerce are key organizational issues

Table 2. Regression statistics

	ORGANIZ	.464	.086	.405	5.375	.000	.984	1.016
	INTERMKT	.295	.087	.256	3.377	.001	.972	1.028
	CUSTLOG	.229	.087	.200	2.647	.009	.978	1.023

identified to affect e-commerce adoption. This agrees with the postulations of the DOI model (Rogers 1995) and the results obtained by (Aghaunor and Fotoh 2006). A key issue here is the negative attitude of management towards e-commerce (Orlikowski 1993). This attitude could be attributed to a number of factors, including the level of information systems (IS) literacy of top management. Until recently, IS courses have not been prominent in the syllabi of tertiary institutions, and when they were, at best, they were theoretical, leaving the students with no good level of appreciation of IS. Organizational culture is another factor, which could be influenced by xenophobia (Campbell 2003) that hinders innovations.

Internet marketing factor exerts some good level of influence on the ability to adopt e-commerce. This in line with the findings by (Aghaunor and Fotoh 2006) and is supported by the 'facilitating conditions' component of the theory of planned behavior (Ajzen 1991). In most developing countries, the internet market is not well developed with low credit card penetration (Hawk 2004). Often times, the costs associated with telecommunications and courier services to Africa and some parts of Asia are enormous. Some credit card companies even refuse credit card payments from Africa. This tends to alienate African countries from the digital market, thereby expanding the digital divide between the developed and developing countries. Customer characteristics also impact significantly on the firm's decision to adopt e-commerce. Key issues here are: customers' levels of access to the Internet, levels of computer literacy and internet awareness, gender of company's target customers, and age of company's target customers. Customer's characteristics are particularly instructive in developing countries where the access to internet is low and the level of IS awareness is equally low (Swami and Seleka 2005). Interestingly, the study reveals that security concerns does not significantly affect the firms decision to adopt e-commerce. This is in consonance with the results obtained in (Lawson *et al*. 2003), and could be explained by the reasoning that security only becomes an issue when the infrastructure and the enabling environment are in place.

Botswana is identified as one of the countries in Africa with a good e-readiness score. However, there is a low level of e-commerce adoption due to organizational and socio-economic structures. This study identified organizational, internet marketing and customer characteristics factors as impacting on the ability of organizations to adopt e-commerce. We have distributed questionnaires on the effects of the organizational variable on e-commerce adoption. We are currently analyzing the data using the method adopted in the preceding study, which is reported in the 'research in progress' paper.

Towards a Knowledge-Based Society: The Need for a Continuous Life-long Learning Programme – The PRILHE Project

Ana Maria Correia, ISEGI – Universidade Nova de Lisboa, Portugal; E-mail: acorreia@isegi.unl.pt
Anabela Mesquita, ISEGI – Universidade Nova de Lisboa, Portugal; E-mail: amt@iscap.ipp.pt

The development of a knowledge-based society requires the contribution of a technological infrastructure as well as a workforce with the necessary skills, knowledge and competences, supported by a well-structured initial education and a continuous learning program. The individuals in this workforce must be autonomous, independent and reflective learners, because this is the only way to take advantage of a life-long learning programme and, in so doing, remain in employment at a time of global change. How can we help our students to become more autonomous, reflective and independent? What kind of strategies should be used in the classroom? What are the best practices? This paper sets out to answer these urgent, contemporary questions.

Project PRLIHE – Promoting Reflective Learning in Higher Education [113869-UK-2005-G1] - developed under the framework of the European Commission Socrates Programme - aims to identify the learning processes which enable adult students in Higher Education to become independent and reflective learners, to identify how this process could be better supported, to examine the interface between learning from experience and academic learning and to identify models of good practice in higher education institutions across Europe.

To achieve these objectives, a consortium was formed, with partners from Germany, Sweden, Finland, Portugal, Spain, Poland and UK. The consortium developed a questionnaire and distributed it to students and lecturers; this was then backed up by face-to-face interviews. The answers and opinions obtained have been compiled into a Handbook for Students and a Toolkit for Lecturers.

Some of the results reveal that students learn better when they are able to build bridges between life / work experience and the topics to be learned, when they share different points of view, when they discuss with others, when the learning process occurs in a supportive environment, when there is teamwork / interaction, when they see the practical use of what is being taught. For some of them, the guidance or instructions are an important issue; for others, it is important to be on their own. They prefer to explore the topic alone. One can also say that some of the students prefer to work alone while some others prefer to be in groups and discuss the contents with their colleagues. Anyway, there are different routes to become an independent, reflective and autonomous learner. One step in the right direction involves the discovery by the student of his / her best way to learn (and be conscious of that) as well as the help of the lecturer in a supportive environment. Of course, we realize that this process is not easy. Lecturers are, generally speaking, aware of this problem. They try to bring the experience of the students into the curriculum and use it to make the learning process more successful. However, there are difficulties that prevent success. Some of these are:

- as students work, they do not have a lot of time (time to study, time to attend classes, to be with the family, …), they are not able to arrive on time to classes or they miss classes. They have some difficulties reconciling family, profession and studies.
- Difficulties related to their academic background – they have a lack of knowledge to understand the subjects, they have bad learning habits (acquired in the past) which prevent their progression, they are more sceptical in relation to what the teachers say and so they have more difficulty in changing their opinion.
- they have more enthusiasm than the traditional students but they give up more easily, it is difficult to help them to change their study habits, some have lack of motivation, lack of objectives. They work at different rhythms and have different objectives; the standardization of subjects and contents do not meet all the interests of each individual. It is difficult to initiate them into critical reflection.

Although we realize that some of these difficulties are real, we also observed that there are lecturers who do not try to change the way they lecture – maybe because they have a lot of work (lack of time to prepare new lessons) or just because they are lazy (they have been in this profession for so long that they just repeat the contents without updating it). Anyway, we feel that there are still a long way to go in preparing the workforce for the knowledge based society; this involves students, lecturers and the institutions.

In this paper, we present project aims, objectives and methodology. We also report the lessons learnt and best practices identified. We believe that the preparation of the knowledge based society starts at school, helping students to become autonomous and reflective learners.

Approaches to Valuing Information: Exploratory Research

Nicholas L. J. Silburn, Henley Management College, UK; E-mail: nick.silburn@henleymc.ac.uk
Jean-Noel Ezingeard, Henley Management College, UK; E-mail: jean-noel.ezingeard@henleymc.ac.uk

ABSTRACT

This paper introduces a piece of exploratory research carried out into issues around organizations 'valuing' their information resources. Academic and practitioner research over the past 15 years have identified issues around the use and appreciation of information as an asset by organizations. Drawing on this published information, an interview schedule was developed and used with ten individuals who used and/or were responsible for information. Initial analysis of the findings suggests that organizations still have difficulty with their approaches to information as an asset. The data also suggests that there are some serious cost and efficiency implications resulting from this difficulty. It is also apparent that being able to value information in some way may help to raise awareness of information as an asset and therefore improve the management of information. However an economic approach is not seen as necessarily the best way. Analysis of the interviews is continuing to explore non-economic methods of valuation.

APPROACHES TO VALUING INFORMATION: EXPLORATORY RESEARCH

This paper is an introduction to a piece of exploratory research being carried out as part of a doctoral research project on the attitudes and behaviors of project teams towards their information resources. It explores the background and context to the research and how we developed a semi-structured interview schedule. It then discusses some of the initial findings from this exploratory research and our next steps in the research project.

BACKGROUND AND CONTEXT TO THE EXPLORATORY RESEARCH

Academic and practioner research over the last 15 years has highlighted some key issues with the way organizations 'value' their information as an asset in the twin sense of seeking to estimate the worth of their information assets and expressing that worth, and ensuring that information assets are treated as worthwhile. In the same timeframe, the regulation, direct and indirect, of information and information management has changed significantly.

One of the first signs of change in the way the business world values information was the Hawley Committee report which published the results of an investigation by a group of companies into information management in large UK businesses. The report made several recommendations concerning the management of an organization's information assets, including its Board of Directors taking a "systematic approach to ensure appropriate policies and practices are in place and to check the adequacy of their arrangements for information assets." (Hawley, 1995, p.7).

Research into the use of the UK's FRS 10 accounting approach to valuing goodwill and intangible assets provided interesting insights into more recent thinking and practice on information as a valuable company asset. The researchers found that "very few companies held a register of their information assets or had taken steps to identify or assess them on an organizational level." (Wilson, Stenson & Oppenheim, 2000, p.13) This suggests that little had changed since the publication of the Hawley Committee report. Concerns about how much organizations and their top management teams value and protect their information assets have not abated since.

Over the last decade a variety of internationally recognized standards and codes of practice have emerged focusing on improving information management practices. In parallel, government legislation in most OCDE countries has modified the regulatory frameworks in which many businesses operate. The emphasis of these frameworks and legislation has been on the secure and good management of information whilst the information is of use to the organization and beyond the information's original value to the organization.

Recent research into information security and information assurance has highlighted shortcomings with the attention organizations pay to their information resources (Ezingeard, McFadzean & Birchall, 2005). The same research has suggested that aligning information assurance with organizational strategy can deliver a wide range of benefits including improved customer service, better governance, and better information usage.

THE VALUING OF INFORMATION

Tensions exist in an organization valuing its information assets. For example, information required for decision-making in a project is of use to the organization, and therefore of value, at the time the project is being undertaken. An information stakeholder, such as a regulator, may want access to the information at some future date, when the information is of value to the regulator but not the organization. Hence, despite this apparent lack of value, the organization still has to maintain the information securely and in good condition. However, the research discussed above, and anecdotal evidence would suggest that organizations do not value their information as well as they should. But how is information valued and how should its value be expressed?

Repo provided an extensive review of economic and management science research into the value of information (Repo, 1989). He concluded that the research was mainly theoretical and that two approaches could be taken to valuing information. Firstly that the "exchange value of information products (….) should be studied using 'classical' economic methods." Secondly, "value-in-use", should be studied using the "cognitive approach which takes the user, the use, and the effects of the use of the information into consideration." (Repo, 1989, p.81). An approach that could be described as cognitive is explored by the IS success model (DeLone and McLean, 2003), and the information orientation model (Marchand, Kettinger & Rollins, 2001). Both models reinforce that it is important for an organization, through the people that work for it, to exhibit the correct attitudes and behaviors towards their information assets.

THE EXPLORATORY RESEARCH

As previously mentioned, the Hawley Committee, Wilson et al, and Ezingeard et al suggest that there is a problem with organizations valuing their information assets and that there are implications for not treating information as an asset. These findings underpin the first question we tried to answer:

1. Are there shortcomings in the way organizations manage their information resources, and more specifically value that information (in both sense of the word 'value')? If so, what is the impact on these organizations?

Repo's analysis of economic methods and the complex picture he portrayed of this approach to valuation suggested a second line of questioning:

2. What would be the benefits of organizations ascribing an economic value to their information resources?

Lastly, Repo's cognitive approach to information valuation and the attitudinal and behavioural aspects of DeLone and McLean, and Marchand et al suggested a further line of investigation focused on the following group of three questions:

3. What kind of non-economic valuation mechanisms might be useful and what benefits might there be?
4. What policies and procedures might an organization employ to show that it valued its information and how might these help the organization look after its information?
5. What attitudes and behaviors might be appropriate to show that an organization valued its information resources?

These five questions formed a framework for a semi-structured long interview schedule. Ten interviews have been undertaken for this exploratory research. The interviews involved individuals who are responsible for information management in their organization and/or are significant users/processors of information. The interviewees were drawn from both public and private sector organizations. Eight individuals were interviewed face-to-face, one over the telephone and a tenth made a written submission using the interview schedule as a guide. Each interview lasted for approximately an hour. Eight of the interviews were recorded, with the permission of the interviewee. All recordings were transcribed. An initial analysis of the ten sets of data collected has been carried out using a manual thematic coding approach with seed codes developed from the literature and interview schedule. Subsequent analysis will be carried out using HyperResearch 2.7 (a qualitative software package) along with the seed codes and other codes generated from the interview data itself.

INITIAL FINDINGS

In this section we concentrate on two of the question themes identified above namely questions 1 and 2.

Is There A Problem, To What Extent, and What Is Its Impact?

The interview responses suggest that there is still a problem with organizations treating their information as an asset. Indeed evidence from the interviews suggests that little progress has been made since the publication of the Hawley Committee report. The evidence is threefold.

Firstly, the majority of respondents considered information to be "vital", "very important", "absolutely crucial – a differentiator" and "fundamental to the business". One interviewee argued that the importance of information to the business depends on the business context. It is clear though that information is a key component of most, if not all, organizations.

Secondly, most interviewees felt that organizations valued their information badly. Here value is used in the context of how well they look after their information, how well it is managed. In the words of one individual "people tend to worry about it a lot but [do] not do a lot about it". There were some arguments to suggest that data is managed better because it is more structured, and that the concepts and ideas behind the databases that usually manage this data are more embedded in the organizational psyche. One respondent felt that the lack of information value amongst senior management was down to the increasing invisibility of information caused by the move from information as physical paper to the more ethereal bits and bytes of databases and electronic document management systems.

The third strand of evidence focuses on how well organizations manage their information. Again the majority of interviewees felt that organizations managed their information poorly though there was an acknowledgement that there are examples of good practice. One respondent suggested that this poor capability was perhaps down to "an overemphasis on technology [and] underemphasis on business processes and values and behaviours.". Examples of the impact of poor information management ranged from unnecessary information re-creation to unnecessarily long periods of time taken to find information appropriate to the task in hand. All respondents argued that having some kind of mechanism for valuing information was of use. One interviewee did apply a caveat - the application of a valuation mechanism should depend on the category of information involved. Some information should be valued and some could be regarded as a commodity of little value (typically operational information or 'data'). This point raises issues around terminology – data versus information – and what drivers an organization might use to influence the valuation of its information.

The Economic Valuation Of Information

Most of the interviewees considered an economic valuation to be of use, especially as it would be a simple and easily understandable approach to convince organizations, particularly Western organizations, to invest in information and information management. It was also suggested that economic valuation is easier for some types of information and some types of organization. For example, an organization whose principal output is information, such as a consultancy, might benefit more from the exercise in so far as it would help it communicate with its staff, in particular around performance standards and desired outcomes. The exercise could also help in communications with investors.

However there is a recognition that due to the complex properties of information, an economic valuation would be subject to so many variables that the cost of developing a mechanism probably outweighs the benefits. For example, there is the notion of subjectivity: a piece of information that is valuable to a journalist is not necessarily of equal value to his/her readers. This is further complicated by the temporal nature of information – what is valuable today is not necessarily valuable next week.

Economic approaches suggested by interviewees tended to concentrate on the cost of production of information, the finding of information, and the subsequent maintenance of the information during its lifetime. A number of respondents described the real value of information in terms of its use or exploitation. In the words of one respondent "the value of information is really in the use you put it to and so having the information is not of value in itself". This, what can be called Latent value, was considered difficult to quantify in economic terms because of the variables, described earlier, which come into play.

NEXT STEPS

It is acknowledged that the work described here is exploratory research with no intention for the data presented to be generalizable. However it does give tantalizing glimpses into the state of information management in some organizations today. Based on the interview analysis carried out so far it is apparent that problems still exist with organizations' 'valuing' their information resources in terms of taking care of it, and in ascribing some kind of economic or other type of value to it. Through examples given by interviewees it also seems to be an issue worth pursuing to develop some practical answers and solutions.

Work is continuing to complete the detailed analysis of the collected exploratory data with the intention of answering questions 3 to 5 above. The next stage is to then use the insights gained from the exploratory data to create a more focused research strategy with the intention of gathering data from a wider range of sources. The outcomes from this wider data will then be used to help develop some practical solutions to aid organizational and individual management of information.

Knowledge Management Approaches and Knowledge Gaps in Organizations

Nastaran Simar Asl, Allame Tabatabaee University, Tehran, Iran; E-mail: Nastaran_simar@yahoo.com
Hossein Rahmanseresht, Allame Tabatabaee University, Tehran, Iran; E-mail: Hrahmanseresht2003@yahoo.com

ABSTRACT

Nowadays, knowledge has been recognized as an indispensable strategic resource in organizations. Therefore organization` s capability in acquiring, developing, sharing and applying knowledge is expected to lead to their sustainable competitive advantage. It seems that the first step to be taken in order to enter the world of knowledge management is to analyze different approaches that exist in the field. Then it would be essential to identify knowledge management gaps. Organization` s inability to identify and fill these gaps before implementing knowledge management programs will obviously have unwanted effects on implementation stage. This paper is aimed firstly at a review of knowledge management history from 1700 A.D till now. Then its approaches (Mechanistic, systematic, core competencies and behavioral-cultural) are reviewed and two models of knowledge management gaps are studied. The inefficiencies due to the implementation of knowledge management systems and also an investigation into the context of knowledge growth in Iran are correspondingly represented. It also encompasses a contrast between some developed and developing countries including United States of America, Japan, United Kingdom, Germany, France, India, Turkey and Pakistan denoting the criteria of their economic status and knowledge growth. In conclusion, the priority to adopt systematic, behavioral/cultural and core competencies approaches in contrast to traditional mechanistic approach will be emphasized. The first model of knowledge gaps which will be presented in this paper is based on individuals` socio-economic status and situation- specific factors. In the second model of knowledge management gaps, six gaps have been recognized due to perception, strategic, planning and implementation aspects. It will also be mentioned that the first model is appropriate to be applied at macro level whereas it will be appropriate to apply the second model at micro level.

Keywords: Knowledge management, knowledge gaps, Systematic approach, Behavioral/cultural approach, Core competencies approach

1. INTRODUCTION

Today, knowledge has been recognized as an indispensable strategic resource in organizations. Therefore organizations` capability in acquiring, developing, sharing and applying knowledge is expected to lead to their sustainable competitive advantage. The organizations which are equipped with knowledge resources are able to deliver superior value to customers by combining traditional resources in the new ways.

In fact, it is the organizations` knowledge that enables them to develop their resources and processes, to reinforce their core capabilities and to create sustainable competitive advantages.(sharkie, 2005)

Knowledge management systems, both from their strategic core capability point of view and also as vital resources, have gained increasing importance in organizations. (Ahn and Chang, 2004)

In order to exploit knowledge workers as organizations` intellectual assets and disseminate knowledge to promote organizational learning, decisions` effectiveness and improve their competitive position, many organizations have implemented knowledge systems and processes. (Rao, Muati and Bryson, 2006)

Of course, in this époque, the most important opportunity for organizations is the availability of new and web-based information technology and mobile communication services that enable organizations to overcome geographical and organizational barriers to communicate and transfer knowledge in discrete networks. (Corso, Martini & Pellegrini, 2006)

In the present article, short descriptions of knowledge management history and knowledge management approaches have been discussed and finally a review on existing models of knowledge management gaps in organizations have been developed.

With emergence of service society after the 2nd world war, the importance of the role of the employees` knowledge and innovation has increased. (Malhotra, 2000, p.5)

At present, in the era of globalization, collective learning, knowledge sharing and creating institutionalized networks beyond country borders, has become as an important subject for politicians, managers and citizens. (Zhu, 2004, pp.76)

These days, economy has become global and knowledge- intensive. In this economy, what a company knows is more important than traditional resources of economic power such as land, factory, equipment and workforce. Though, availability of natural resources does not lead to competitive advantages. In fact, prosperous companies are the ones who are able to perceive and organize their knowledge. Today, corporates` success is due to their ability to acquire, encode and transfer knowledge more efficiently than their competitors. It has been widely acknowledged by experts that during the last fifty years, developing companies have evolved so that knowledge. (Davenport, De Long, 1997)

Based on the results of the survey conducted by Darroch (Darroch,2003),the organizations which have developed behaviors and procedures of knowledge management, in contrast to other countries present more innovation and higher levels of performance. (Darroch, 2003, pp.52)

In fact, this organizational phenomenon complete and reinforce other organizational procedures such as TQM, process reengineering and collective learning by focusing on sustaining organizational competitive advantage. (Sharma, 2004)

2. KNOWLEDGE MANAGEMENT AND THE NECESSITY OF ITS IMPLEMENTATION

Some definitions of knowledge management developed by some scholars are as follows:

"Knowledge management is the process of knowledge creation and dissemination to effectively implement it in organizations." (Hoffman, Hoelschler and Sherif, 2005)

"Knowledge management is the conscious design of processes, tools, structures and etc… to increase, renew, disseminate and improve the utilization of structural, human and social knowledge."

Results of different researches and surveys demonstrate that nations which have superseded others in creating knowledge even have higher ranks according to competitive growth and economic power. Also, companies that suffer from inappropriate economic situation do lack appropriate knowledge infrastructures.

The following table demonstrates the significance of this debate.

Table1. Situation of knowledge in some countries

	U.S.A	Japan	U.K	Germany	France	India	Turkey	Pakistan
Rank (GCI)*	2	9	11	13	27	55	66	91**
Number of Scientific Products (2004)	450287	84395	90443	84266	57774	23748	14107	1048
Number of Knowledge Products (per one billion GNP)	41.14	19.22	53.84	40.43	39.05	41.67	71.32	13.51***
GDP per capita	39820	36205	36042	32862	30713	640	6700	2100****

**Growth Competitiveness Index*
*** These figures are related to GCI ranking (2004)*
****www.iranknowledge.irandoc.ac.ir*
*****World Bank Group(2004)*

In the table above, Growth Competitiveness Index (GCI) is measured by criteria such as quality of economic macro environment, conditions of public administrations and level of country's preparation to acquire technology. All the figures refer to the year 2004.

Scientific products refer to registered records in Information Science Institute, USA in any document or language.

In order to compare statistics, figures from five developed countries (U.S.A., Japan, France and Germany) and three developing countries (Pakistan, Turkey and India) have been acquired.

Also, according to relevant literature review, the quantity of scientific products and the quantity of knowledge production per 1 billion $ GNP, are amongst the index to measure knowledge development in different nations. (www. iranknowledge. irandoc.ac.ir)

In organizational context, the importance of knowledge management augments (Increases) when according to global competition; organizations are in excessive need to acquire knowledge about their potential business competitors in present and future, their clients and scientific and technological progresses which could be replaced by their goods and services.

It could be claimed that one of the reasons of existing problems and weaknesses in all levels of Iranian organizations, is the lack of systematic processes of knowledge management that leads to creating, sustaining and transferring knowledge. In case an organization lacks such processes, there will occur an extensive gap between its existing and required knowledge. Therefore, consequences such as occurrence of frequent errors, repetitive processes, increased costs, decline in the quality of goods and products, dissatisfaction of internal and external customers and lack of competitive power in national and international levels. Also, lack of systematic processes of knowledge management and emergence of knowledge gaps will lead to disappearance and devaluation of the great part of the organizational knowledge and automatically, a great deal of this valuable stock which has been acquired by allocating valuable resources of time and money, will be ignored and no solutions will be thought of.

3. HISTORICAL BACKGROUND OF KNOWLEDGE MANAGEMENT

As Ferdowsi (Ferdowsi, 940) – the Persian well-known poet- has introduced knowledge and wisdom in his well-known poem As the foundation of power, also Francis Bacon in his well-known statement , " Knowledge is power" has gained global fame. In his first publication, "In praise of knowledge"(1592), even defined the individual by his/her knowledge.

Nguen, quoting Peter Drucker in his well-known publication "The post-capitalist Industry" has described the historical trends of knowledge management. He believes that the social intentions of knowledge have evolved in three phases:

- Firstly, it has taken place before 1700 A.D. and the attitude of knowledge for knowledge, wisdom and enlightment has been pursued.
- Secondly, it has occurred during 1700 and 1800 A.D. In this era, by stressing on technology creation, knowledge has shifted to organized, systematic and goal-oriented entity.
- Thirdly, it has commenced from 1800 A.D. and has reached the peak by Fredrick Taylor's principles of scientific management. Scientific management was to make some attempts to formulate the skills and experiences of its employees to the scientific and goal-oriented knowledge which reflects the era of applying knowledge for knowledge.(Nguen,2002)

Although, Islamic Republic of Iran has no place among 117 countries of the world according to GCI, based on other statistics , Iran ranks 11 among sixteen countries including U.S.A. , U.K., Japan, Germany, China, France, Canada, South Korea, India, Turkey, Iran, Egypt, U.A.E, Kuwait and Iraq and its knowledge production percentage is 0.19 % (Ensafi,2006).

Therefore, all these figures demonstrate that in contrast to other developing and developed countries, Iran has a long way to effectively manage the knowledge and in order to be able to compete with its competitors; it has to acquire systematic techniques to manage knowledge and bridge the existing gaps between present knowledge and required knowledge.

In the relevant literature, poverty does not only signify the lack of economic resources, but also it includes lack of hygienic facilities, knowledge capabilities and appropriate management skills.

Before shifting to the knowledge-based economy in the post-modernist perspective, the major sources of economic value creation has been tangible assets namely factory, land, tools, machinery and raw material (which are identified as structural, physical and hard capital), whereas in knowledge-based economy, intangible resources are the strategic resources of value creation. Intangible assets include the informal knowledge embedded in organizational structures, processes, systems, work teams such as communities of practice, innovative networks and competencies. (Corson, Ranzjin & Mardsen, 2004)

It could be acknowledged that the historical origins of knowledge management are as follows:

1. Religion and philosophy to comprehend the nature and role of knowledge
2. Psychology to comprehend the role of knowledge in organizational behavior
3. Economics and social sciences to outline the role of knowledge in society
4. The business theory to conceive the role of knowledge in work and its organization(Wiig,1999)

4. KNOWLEDGE MANAGEMENT APPROACHES

In this article, four approaches of knowledge management, the mechanistic approach, the systematic approach, the core capability approach and the cultural /behavioral approach have been discussed. (Sharma, 2004)

4.1 The Mechanistic Approach

The mechanistic and hard approach to knowledge management involves applying technology and resources to do more of the same better. The main assumptions of this approach include:

Better accessibility to information is a key, including enhanced methods of access and reuse of documents.

4.2 The Systematic Approach

The systematic approach involves the systematic practices in order to disseminate knowledge and information among appropriate people in appropriate time, to create value.

A Knowledge management system involves the representation, acquisition, creation, usage and evolution of knowledge in its many forms and the modeling, analysis and design of technical systems for supporting all facets of knowledge management.

Some key assumptions of this approach are as follows:

The most important thing is to achieve sustainable outcomes but not the processes, technologies or definitions people present. Managing a resource without being modeled is not possible. However, many aspects of organizational knowledge could be modeled as an explicit and observable resource. Also, solutions could be found in a wide range of disciplines and technologies. It is also possible to re-investigate the nature of knowledge work and to solve knowledge problems by applying the traditional methods of analysis. Therefore cultural issues are important but their analysis should be done systematically. This probability exists that some changes occur among employees but definitely, policies and procedures require changes. It is also possible to successfully apply technology to resolve knowledge problems.

4.3 Core Competency Approach

One way to manage knowledge-based organizations is developing knowledge competencies. Core performance capability and core knowledge capability are two distinct concepts, though complementary but each of them is a component of organizational identity.

Core competencies approach is a mechanism to convert core knowledge capabilities to goods and services. Core performance capabilities are processes that enable organizations to deliver goods and services with high quality, speed and efficiency to customers. These capabilities include high-speed delivery of new products to markets, product customization for customers, optimal management of logistics, employing qualified employees, learning and vision dissemination and are regarded as a key for organization success.

4.4 Cultural/ Behavioral Approach

This approach which has its origins in change management and business process re-engineering, regards knowledge as a managerial issue. Based on this approach, although technology is necessary for the management of explicit knowledge resources, it is not the only solution for knowledge management. Based on this approach, focus is more on innovation, creativity and learning organization rather than focusing on manipulating explicit resources or knowledge creation.

The dissemination and sharing of knowledge is embedded in interactions and networks among people and their institutionalized groupings e.g. teams, organizations and etc… that enable us to access the diverse resources of intelligence.

The key assumptions of this approach are as follows:

In information-intensive environments where organizations are losing their efficiency and effectiveness according to the business objectives, implementing changes in organization's culture and behavior seems to be vital.

Organizational culture and behavior involves changes while traditional technologies and solutions have reached their boundaries of effectiveness.

At present, cultural factors which have an important role in organizational change, have been devaluated, therefore implementation of cultural/ behavioral factors will probably lead to profitability for organizations. (Sharma, 2004)

5. INCONVENIENCIES OF KNOWLEDGE MANAGEMENT SYSTEMS

After investing large amounts of money on implementation of knowledge management systems in organizations, they face inconsistencies between these systems and managerial and cultural philosophies and business processes. Therefore they feel being conceived. Some of these problems include:

- In most cases, the Idealist designers and implementers of knowledge management systems are isolated from the rest of the organization and instead of designing the systems, taking account of the priorities and organizational characteristics and processes; they design them according to their own perceptions and personal beliefs.
- Most of the knowledge management systems have unrealistic capabilities that in fact cause users to become annoyed and upset.
- Instead of focusing on business needs and opportunities, they regard knowledge management as a general capability and do neglect the value creation for organizations.
- Many attempts in the field of knowledge management lead to failure because of the allocation of inappropriate employees and other resources.

In the era of knowledge-based economy, organizations have realized that a key factor in their success is the application of appropriate knowledge management approaches.

Based on a survey conducted by Chong et al (chong, 2002) in twenty-five international corporations, it was revealed that the majority of the senior managers of the so-called organizations believed that they had lost many opportunities in business according to the adoption of weak and inefficient practices of knowledge management (Guang, 2006).

6. KNOWLEDGE MANAGEMENT GAPS

Knowledge gap is defined as the difference between the corporate`s present capability and the required capability in the field of knowledge management. (Hall & Andriani, 2002)

Various studies have been conducted to define knowledge gaps as " the difference between the corporate`s present capability and the required capability in the field of knowledge management." Lovrich and Pierce have identified two gaps namely: socio-economic factors and socio-specific situation that will be discussed later.

Tiwani (Tiwani, 2001) has also introduced some infrastructural gaps which hinder the creation of knowledge management systems.

Hall and Andriani (Hall and Andriani, 2002) have also identified the existing gaps between the current knowledge possessed by organization and the required knowledge while introducing new products and services.

Wild (Wild, 2002) has introduced knowledge gap as the qualitative and quantative difference between the existing and the required knowledge.

Also, a model has been introduced by Lin, Yeh and Tseng (Lin, Yeh and Tseng, 2005) to represent six gaps in strategic, planning, implementation and perception levels.

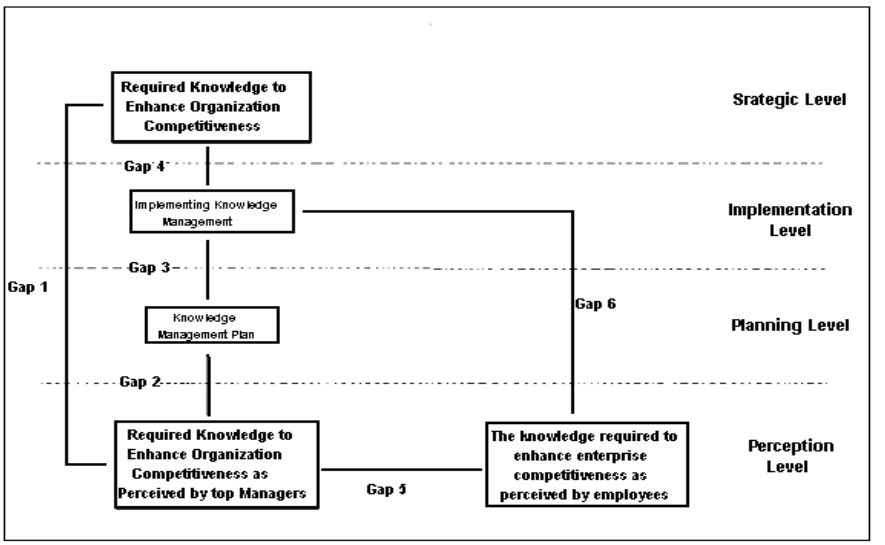
It is necessary to mention that any failure in identification and bridging knowledge gaps before implementing them will have unwanted effects on implementation stage, therefore actions such as knowledge requirements analysis, knowledge management systems assessment and the identification of obstacles seems to be essential. (Lin, Yeh, Tseng, 2005)

7. KNOWLEDGE MANAGEMENT MODELS

7.1 The First Model

Literature on the distribution of public affairs knowledge among citizens identifies a "knowledge gap" separating persons of higher and lowers socioeconomic status (SES). More precisely, lower SES persons typically exhibit lower levels of policy-relevant information. They also usually respond more slowly to mass media-infused attempts to increase the public's knowledge.

Figure 1. The model of the KM gap (Source: Lin,Yeh,Tseng,2005)



Ettema and Kline (1977) identify two types of explanations for the knowledge gap. One is rooted in "trans situational "conditions associated with living at lower SES levels. One of these conditions is a hypothesized lack of communication skills on the part of lower SES persons. In contrast to transsituational explanations, some scholars advance a situation-specific theory. This view suggests that gaps widen in those circumstances in which lower SES persons are less motivated to acquire the information or in which the information is less functional for them.

These two rival theories focus attention on the respective roles of SES and individual motivation in explaining individual holding of information. (Lovrich,Pierce,1984)

7.2 The Second Model

This model has been developed based on knowledge value chain (Holsapple and Singh, 2001) and knowledge spiral (Nonaka, 1991) to demonstrate the managerial gaps occurring during the implementation of knowledge management systems. As depicted in figure no….. , there are six gaps in this model that could be identified from four perspectives:

7.2.1 Strategic Perspective

In order to increase organizations` competitiveness, organizations must continuously scan their internal and external environment. Failure in doing so, will probably lead to the gap between the knowledge required to increase organization`s competitiveness (as perceived by top managers) and the real knowledge required to increase organization`s competitiveness. (Gap 1)

Failure to evaluate knowledge management processes leads to the creation of gaps between the outcomes of the implementation of knowledge management systems and the perceived outcomes of top managers.

7.2.2 Perception Perspective

It is probable that top managers do not have sufficient capability to identify the knowledge, organization requires to enhance its competitiveness therefore a gap appears between the top manager`s perception of the appropriate knowledge management plans and the existing knowledge management plans in the organization (Gap 2).

Also, in an organization, due to the differences between the role, position and the knowledge of top managers and employees, some differences may exist between their perceptions (Gap 5).

It is also possible that a gap exists between the organization`s required knowledge for enhancing competitiveness and employee's perceptions of the required knowledge while implementing knowledge management systems (Gap 6).

7.2.3 Planning Perspective

The appropriate internal and external environmental perception of top managers causes to plan appropriate programs for knowledge management. If top managers can not apply this acquired knowledge from environment during knowledge management systems implementation, gap 2 appears. If employees fail to comprehend knowledge management plans while facing them, gap 3 appears.

7.2.4 Implementation Perspective

If implementations of knowledge management systems are not congruent with its plans, gap 3 occurs. Also, it is essential that employees gain appropriate perception of the required knowledge to enhance organization`s competitiveness otherwise gap 4 appears.

7.3 Knowledge Gap Definitions

Generally speaking knowledge gap is defined as the difference between organization`s current capability and its required capability to manage knowledge. (Hall and Andriani, 2002)

The definitions of knowledge gaps according to the second model are as follows:

Gap 1: The gap between top manager`s perception of the required knowledge to enhance competitiveness and the real knowledge required.
Gap 2: The gap between top manager`s perception of the required knowledge to enhance competitiveness and knowledge management plans.
Gap 3: The gap between top manager`s proposed plans and the progress of knowledge management plans.
Gap 4: The gap between the acquired knowledge after implementing knowledge management systems and the required knowledge to enhance organization`s competitiveness.
Gap 5: The gap between top manager`s perception of the required knowledge to enhance organization`s competitiveness and employee's perception of this subject.

Gap 6: The gap between top manager`s perception of the required knowledge to enhance organization`s competitiveness and the acquired knowledge after implementing knowledge management systems.

8. CONCLUSION

In this paper, after a short review on the historical background of knowledge management, four knowledge management approaches including mechanistic approach, systematic approach, core competencies approach and cultural/behavioral approach have been discussed. It seems that in knowledge era, mechanistic approach that only focuses on physical tools and information technology infrastructures is not sufficient. In other word, it is better to adopt an integrated approach based on the systematic, core competencies and cultural / behavioral approaches in order to be able to take into account the people, physical and core knowledge competencies aspects of knowledge at the same time.

According to knowledge gap models, the 1st model is applicable in macro and country level regarding the socio-technical factors and people` s motivation to acquire knowledge and the 2nd model is applicable in organizational level regarding 6 knowledge gaps in strategic, planning, perception and implementation levels.

A Weighted Average Scale for Multi Stakeholder Evaluations of Enterprise System Success

Sharmistha Dey, Queensland University of Technology, Australia; E-mail: s.dey@qut.edu.au
Darshana Sedera, Queensland University of Technology, Australia; E-mail: d.sedera@qut.edu.au

1. ABSTRACT

An Enterprise System (ES), unlike a traditional Information System (IS), entails many stakeholders ranging from top executives to data entry operators. These stakeholders typically have multiple and often conflicting objectives and priorities and rarely agree on a set of common aims. The importance of gathering perceptions of IS-success at multiple levels in organizations has been discussed among academics for several decades. However, there is no universal agreement on what stakeholders should be canvassed and how to interpret results. This research attempts to design a weighted average scale to better interpret findings when gathering data from multiple stakeholders.

2. INTRODUCTION

Enterprise Systems entail multiple stakeholders. The importance of gathering perceptions of System success at multiple stakeholders within an organization has been discussed among academics for several decades (e.g. Cameron and Whetten 1983; Leidner and Elam 1994; Tallon, Kraemer et al. 2000; Sedera 2004). Contemporary IS-success (ES is an archetype of contemporary IS) studies have used various stakeholders making it difficult to generalize the findings and impossible to make comparisons. Moreover, there is no universal agreement on (i) what stakeholders should be canvassed, (ii) whether all stakeholders are adequately informed about every dimension of the system and (iii) whether differential weightage is required to interpret the results of success assessments.

Previous studies have treated multiple stakeholders and the data collected from them, without any distinction. Every stakeholder group would have a different perception of ES success but by grouping their responses together we are ignoring the difference in their perception.

In an attempt to minimize perplexity and to increase our understanding of interpreting multiple stakeholder responses when assessing ES-Success, this research attempts to develop a differential weighting scale. Such a weighted average scale is valuable for contemporary IS research to understand: (1) the views of multiple stakeholders, (2) the influences of the lifecycle phases when interpreting responses, and (3) whether certain stakeholders are better informed on certain success dimensions. The following section outlines the aforementioned objectives.

1. **Multi-Stakeholders:** An ES, unlike a traditional Information System, entails many 'users' ranging from top executives to data entry operators. These stakeholders typically have multiple and often conflicting objectives and priorities and rarely agree on a set of common aims (e.g. Cameron and Whetten 1983; Quinn and Rohrbaugh 1983; Yoon 1995). There is no Universal agreement on what stakeholders should be canvassed in an ES-Success study. Many IS success studies seek only a top-management perspective (Shang and Seddon 2000; Shang and Seddon 2002), yet research suggests that ES often succeed or fail at the operational level. In order to gain a 360-degree view of the ES, it is important to analyze ES-Success at all levels of the organization; from multiple perspectives. The proposed differential weighting method and instrument is designed explicitly for this purpose. Sedera et al (2006) demonstrated the evolution of employment cohorts in IS-success studies over the past decade by demonstrating a decline on data collection of *Operational* staff and a strong incline in *Strategic* and *Management* Staffs. Their study empirically identified four internal stakeholders of ES (i) Strategic, (ii) Management, (iii) Operational and (iv) Technical.
2. **ES-Lifecycle phases:** Ross and Vitale's (REFERENCE) ES lifecycle model identified a dip in organizational performance [ES-Success] post- 'Go Live', thereafter followed by steady improvement. Such a normative model and related ES-Success scores can aid organizations to better manage expectations of new ES, and to better plan mid- and longer-term for evolution of the ES. In example, it may be appropriate to place relatively greater emphasis on the Quality dimensions (Information & System) early in the lifecycle (during and soon after the 'dip' it is too soon for 'Impacts' to have been realized), and relatively greater emphasis on the 'Impact' dimensions (Individual & Organizational) later in the lifecycle. The different stakeholders place emphasis on different dimensions during the ES lifecycle phases. For example, during the implementation phase the managers may place emphasis on data accuracy and this could shift to a greater emphasis on system quality or process re engineering in the post implementation phase. Therefore there is need for these dimensions to be measured differently.
3. **The foci on multiple stakeholders:** Using the multiple stakeholders – Strategic, Management, Operational and Technical – researchers (Sedera et al., 2004; Sedera et al., 2006) have demonstrated that certain stakeholders tend to be better informed about, and more influenced by a particular ES-Success dimension(s). Not surprisingly, these employment cohorts place relatively greater emphasis on those dimensions that they are better informed about. For example, Strategic employment cohorts may place a greater emphasis on Organizational-Impact compared to Technical respondents' emphasis on System-Quality.

3. STUDY APPROACH

The stakeholder classification is developed based on the three kinds of knowledge that is required for an ES implementation (Davenport, 1998), the knowledge matrix (Sedera et al., 2003) and the four stakeholders (Sedera et al., 2006). Respondents' knowledge is assessed on the knowledge of the (i) system, (ii) business processes and (iii) the organization. The intended weighted average model would include the three aspects, in combination with traditional "job title" to determine the *degree of proficiency*, which extends over a continuum, from novice → intermediate → expert (Ericsson and Charness, 1994). The a-priori model will be tested using survey data.

This differential weighting scale would generate scores that provides in-depth information on the stakeholders (For example, Final Score = {Raw Score *[Factor of experience]*[Factor of Lifecycle Phase]}). Employing a differential weighting approach, organizations might place relatively greater emphasis on a particular stakeholder based on their proximity to a particular success dimension. Sensitivity analysis can yield the best overall measure of ES-Success. Analysis of survey data using the ES-Success approach, would seek to gauge how sensitive results are to variation in weightings across the dimensions, and thereby calibrate the model weights for a given organization-system context.

Table 1. Raw scores

Stakeholders (Designation)	Organisation Impact				Raw Score	System Quality				Raw Score
	OI_1	OI_2	OI_3	OI_4		SQ_1	SQ_2	SQ_3	SQ_4	
Director	4	5	4	5	4.5	4	3	2	4	3.25
Technical	6	4	6	4	5	5	3	2	4	3.5

Table 2. Proficiency scores

Stakeholders (Designation)	System	Business Process	Organisation
Director	4	5	6
Technical	6	4	5

4. RESEARCH METHODOLOGY

The study employs the ES-Success Measurement Model (Sedera et al., 2004; Gable et al., 2003) to measure the perceptions of employment cohorts[1]. The ES-Success Measurement Model employs 27 measures of success arranged under 4 dimensions (System-Quality, Information-Quality, Organizational-Impact and Individual-Impact). These 27 measures can be better interpreted using the intended scale. A survey instument will be provided to all the stakeholders in an organisation in order to collect this data. A separate instrument will be developed to understand the degree of profeciency of each stakeholder in the three areas: (i) system, (ii) business processes and (iii) the organization.

The following hypothetical example using the Organization Impacts and System Quality, together with extreme stakeholder group values (e.g. Director and Technical) demonstrate the value of such a weighted averaged scale. See details in table 1.

A separate survery instrument will be developed to understand the level of profeciency for each stakeholder group. The following example (table 2) demonstrates hypothetical profeciency scores measured in a 7 point Lickert scale. This example illustrates only the degree of profeciency and does not include the effect of weighted average score due to the lifecycle phase or foci of stakeholders on the raw scores.

Then for the final score:

Final Score = Raw Score * profeciency score / 7
Director OI = 4.5 * 6/7 = 3.9
Technical OI = 5 * 5/7 = 3.5

In the example, the Director's raw score for OI was 4.5 which was less than the Technical person's score of 5. By looking at only the raw score, one would then interpret that the technical person's evaluation of Organisation Impacts of ES is higher than the perceptions of the Director.

However, the raw score ignores the fact that one stakeholder group (i.e. director) is closer to the dimension that is under evaluation (i.e. OI) than the other stakeholder group (i.e. technical), thus the aggregation of stakeholders may provide misleading management information.

The weighted scores, using the level of proficiency, takes into account the knowledge that one would posses in the dimension that they evaluate. Having moderated the scores using the weighted averages by the profeciency level/score, the scores provide a more meaningful management information. In deriving the final score, for example, the Director would have a higher level of profeciency in the management or functioning of the organisation than the technical person.

Everyone Is Different! Exploring the Issues and Problems with ERP Enabled Shared Service Initiatives

Darshana Sedera, Queensland University of Technology, Australia; E-mail: d.sedera@qut.edu.au

1. ABSTRACT

In today's increasingly competitive environment, there is constant pressure for corporate leaders to add value to their organizations. These contemporary organizations are increasingly moving into business models that attempt to reduce duplicate supporting processes and staff by streamlining processes that are not central to the organization's operations and concentrating on strategies on strategic or core, business processes. This concept, known as Shared Services, attempts to bundle some of the supporting processes and non-strategic activities into a separate organization, which in turn treats those processes and activities as the core of its own business. Shared services consolidate and support redundant functions, such as accounts payable and procurement, for disparate business units. By leveraging economies of scale from a common IT infrastructure, such a group is able to market specific services to business units. Many organizations are employing Enterprise Resource Planning (ERP) systems, for example SAP, to facilitate shared service initiatives by aggregating backroom functionality across departments.

2. INTRODUCTION

Shared Services is defined as a concentration of company resources performing like activities, typically spread across the organization, in order to service multiple internal partners at lower cost and with higher service levels, with the common goal of delighting external customers and enhancing corporate value (Schulman et al. 1999). In a Shared Services, the disparate activities and operations (such as finance, human resources, payroll, and marketing) that have been seen by business executives as back office and secondary to the core business processes are treated as if they themselves were the core processes. A Shared Services Initiative typically expects tangible benefits such as expense reduction, increased productivity and economies of scale and skill. Intangible benefits range from enhanced customer service to standardized business process and consolidation of Information Technology.

Increasingly, organizations utilize ERP systems to facilitate Shared Services Initiatives by leveraging on such features like (i) process standardization, (ii) common information systems platform, (iii) common databases, (iv) process automation and (v) ERP workflow (Markus et al. 2003). Many such organizations are creating '*shared service centres*' that perform administrative transactions for numerous divisions or subsidiaries of the same company, rather than having those transactions conducted in every division or subsidiary. The shared services centres enable organizations to use ERP systems to retain control of core functions while maximizing cost efficiencies. The concept is simple bring-together functions that are frequently duplicated across divisions, subsidiaries or operating units and offer these services more efficiently and at a lower cost.

This study is motivated by the disparate reports on the success of shared services initiatives and the lack of discussion in academic literature. With the limited trade press reports it is clear that despite the positive objectives, evidence of shared services initiatives has been mixed with some organizations showing positive impacts to the organization, while others have shown nil or detrimental impacts. This paper specifically investigates the issues and problems of shared services initiatives from the point-of-view of ERP systems. The preliminary study results are derived secondary data from fourteen (14) private sector and five (5) public sector case studies published in trade press. The paper begins with a synopsis of objectives of shared services initiatives and the details the role of ERP systems in a shared services initiative. Next, the paper introduces key activities of an ERP enabled shared services initiative. The final section seeks to demonstrate the issues and problems with an ERP enabled shared services initiative.

3. OBJECTIVES OF SHARED SERVICES INITIATIVE

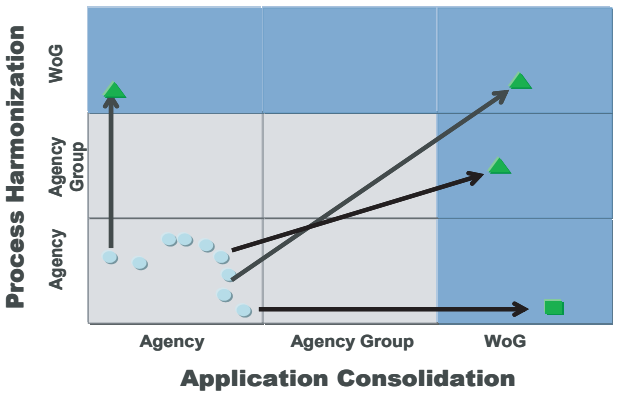
The overarching objective of a Shared Services initiative is to re-direct savings (and potential savings) to direct service delivery and also to better focus on the main business processes with an organization. Moreover, in a group of organizations – especially in public sector, where there are many organizations providing services to the community – shared services facilitate greater consistency of services. Similarly, shared services increase the transparency in costs of services between the organizations. It is believed that greater transparency increase healthy competitiveness within fellow organizations. Furthermore, a number of organizations embarking on a similar business processes for shared services facilitate better environment for skill development, training and career enhancement. From an information system viewpoint, shared services enable organizations to consolidate information technology assets. Especially, in relation to the ERP systems, shared services organizations could engage in shared maintenance of the system and other cost consolidation activities.

4. THE ROLE OF ERP SYSTEM IN A SHARED SERVICE INITIATIVE

Provision of adequate Information Technology infrastructure across the shared services organizations is one of the important aspects of a contemporary shared services initiative. An ERP system not just provides the necessary technical backbone, but also provides an environment with standardized business processes across many organizations. To get maximum benefit out of shared services, all the Information Technology operations in an organization need to have a common system platform so that the supporting business activities and processes are consolidated and standardized. ERP systems present an opportunity to do this from the technical perspective. Since an ERP system provides an integrated suite of applications which provide transaction processing and management information systems for the common core of business processes, consolidation becomes easier. Moreover, ERP systems provide comprehensive administrative systems and help to automate and streamline business processes. It is argued that ERP systems facilitate organizations to combine information from multiple, but disparate business entities to achieve a unified system and business processes.

According to a recent survey conducted by Accenture, '*having an ERP system*' has been regarded as the key enabler for successful shared services implementation. This is evident in recent examples of shared services initiatives in large number of *Fortune 500* companies, including Microsoft, Chevron Texaco, and HP. According to a survey conducted by the National University of Ireland, 30% of the companies surveyed identified '*lack of a common system*' as the biggest obstacle to facilitate functionality of a shared service center. Usage of an ERP system allows management of massive amounts of transactional information rapidly with minimum human interference and standardization of transaction data processing. This allows organizations to develop better contractual agreements with suppliers and consistent service to customers. Not having an ERP system to facilitate

Figure 1. The key activities of an ERP system enabled shared services initiative



a shared service initiative may require organizations to integrate a number of disparate systems and to consolidate data into a standard format.

5. KEY ACTIVITIES OF A SHARED SERVICES INITIATIVE

Using the ERP system as an enabler, the case organizations attempt to 'Harmonize' the business processes from the organization level to a 'Whole-of-Enterprise (WoE)' level. Similarly, the case organizations attempt to 'Consolidate' the applications from the organization level to a 'whole-of-Enterprise' level (See Figure 1)

The intended outcomes of process harmonization include: (i) reduce process variability across organizations, (ii) greater consistency of information across all organizations, (iii) economies of scale and skill, (iv) greater transparency in costs and services, and (v) promoting efficiency in internal business processes. The application consolidation attempts to achieve (i) permits infrastructure and support consolidation, (ii) economies of scale and skill in application maintenance and upgrade, and (iii) cost effective implementation of new technology.

6. KEY FINDINGS

Though the move towards shared services centers using Process Harmonization and Application Consolidation tends yield aforementioned benefits, it tends to compromise the individual needs of each organization. It is expected that for both the Shared Service Centers and the individual organizations require a major change management exercise to cope with the transformations in business processes and information technology. The importance of achieving the common business requirements for a range of organizations that engage in a range of different (organization specific) business objective has been identified as one of the key issues. Furthermore, the move towards application consolidation compromises the in-house applications that many organizations had developed to cater for the 'out-of-scope' SAP functionality.

7. ISSUES AND PROBLEMS WITH SHARED SERVICES

The preliminary findings identified several issues and problems that may hinder the potential benefits of shared services initiative. One of the main challenges of a shared services initiative is the amount of changes made to the business processes and systems. Since many organizations attempt embarking on shared services when the ERP applications in each organization are at the mature stage of the ERP lifecycle, converting 'intra-organizational' standardized applications to 'inter-organizational' standardized applications is harder. Secondly, as a result of achieving a common business practice, many compromises are made against organizational specific business requirements. In organizations where many ERP modules from many versions of the same ERP application are being used, it is debatable which version to consolidate the applications to and which modules to consolidate. Similarly, different hardware and operating platforms provide similar issues for shared services organizations. In many instances, organizations decide to upgrade into a higher version of the ERP application through the shared services initiative. Another issue that shared services organizations face is the out of scope functionality in the ERP software. With the introduction of 'common functionality' to facilitate shared services, many organizations reported 'out of scope functionality' in the ERP software as an issue for many specific functionality. Timing considerations were also reported as a problem in a shared services initiative. Many organizations have reported lengthy time delays in introducing shared services. A commonly stated issue in shared services was the difficulty of managing change within the organizations. With many specific system features and business processes compromised, tasks and roles changed for employees, shared services initiatives undergo intense resistance.

Determinants of Marketer Satisfaction with the Choice of Electronic Marketplace Type

Peter C. Knight, Carleton University, Canada; E-mail: pknight@connect.carleton.ca

ABSTRACT

An empirically testable model is suggested which improves understanding of supplier motivations for participating in various types of electronic marketplace structures and also how suppliers evaluate the performance of their electronic marketplace choice. Performance is considered as a multi dimensional construct. The theories of behavioural psychology, relational exchange, strategic networks, political economy, population ecology and transaction cost are synthesized to develop the proposed model.

Keywords: electronic marketplace, transaction cost theory, strategic network theory, relational exchange theory, performance as a multi-dimensional construct, asset specificity, market fragmentation.

INTRODUCTION

Electronic marketplaces are increasingly important to the organization of procurement and sales activities and analysts predict that, by the end of 2005, electronic marketplaces may account for more than 50% of all online B2B ecommerce, perhaps over 4 trillion USD volume worldwide (Zank and Vokurka 2003).

The growth of B2B marketplaces has also driven the evolution of a variety of newer market structures for conducting business through electronic markets. Le, Rao and Troung (2004) found that though 54% of 286 firms surveyed had utilized an electronic marketplace that only 31% of those users found them as having lived up well to their expectations. How do we then answer the crucial question of when and how to exploit electronic markets to maximally take advantage of their inherent value propositions?

The focus of this proposal is to suggest an empirically testable framework which significantly improves our ability to understand supplier motivations for participating in various types of electronic marketplace structures and also how suppliers evaluate the performance of their electronic marketplace choice. The extant literature indicates that ability to fit the electronic marketplace type with existing market structure, company size, prior experience, role (buyer or seller) all impact expectations for performance in electronic marketplaces.

Much of the research in this realm of study to date, however, has relied upon a transaction cost theory explanation (Malone et al. 1987, Bakos, 1991, Mahadevan 2003). In the spirit of the "blended" models of Barringer and Harrison (2000) and Christianaase and Markus (2003), the proposed model also allows consideration of the perspectives of behavioural psychology, relational exchange theory, strategic network theory and political economy perspectives as well as those of transaction cost theory. Mahadevan's (2003) proposed typology of market, competitive and product/service characteristics which favor various electronic marketplace types is used to provide a transaction cost perspective.

This model is also the first that in this area of research study that considers that marketers evaluate performance as a multi-dimensional construct, building on the work of Clark (2000). The sizeable body of literature on consumer and employee satisfaction is also employed to extend Clark's (2000) work to incorporate the relationship between the performance of and satisfaction with participation in electronic marketplaces.

In sum an empirically testable and comprehensive model is suggested which incorporates the rather diverse, embryonic and limited research in this area of study. The complete research model is shown in Figure 1.

SAMPLING AND DATA COLLECTION

The survey instrument to test the model has 80 questions including indicator questions . To achieve a desired return rate of at least 500 questionnaires required for structural equation modeling, an email list of 7654 Canadian B2B marketers has been compiled via Scott's directory and additional online verification.

I am currently collecting data by means of an electronic questionnaire. It offers some considerable advantages compared to mail surveys as it eliminates data re-entry errors while reducing the costs and the response cycle time (Dillman, 2000).

METHODOLOGY

Structural Equation Modeling will be used and Lisrel will be the software of choice given the criterion for analysis. Most variables will be measured by 4 to 6 questions or indicators based on both previously validated questions (Clark 2000, Arnemann, 1994) and newly constructed ones derived from an extensive review of constructs proposed by others (Mahadevan 2003, Rask and Krogh, 2004, Christianaase and Markus 2003). The proposed model, though complex is recursive and over identified. Though the model is complex, a piece wise approach (Garson, 2006) will be employed. Should overall model fit be poor, partial models which assess marketing performance evaluations as a multi-dimensional construct, the importance of market structure factors in satisfaction with electronic marketplace choice, and the effect of the specificity of expectations on the performance/satisfaction all can potentially make a contribution to electronic commerce and marketing literature.

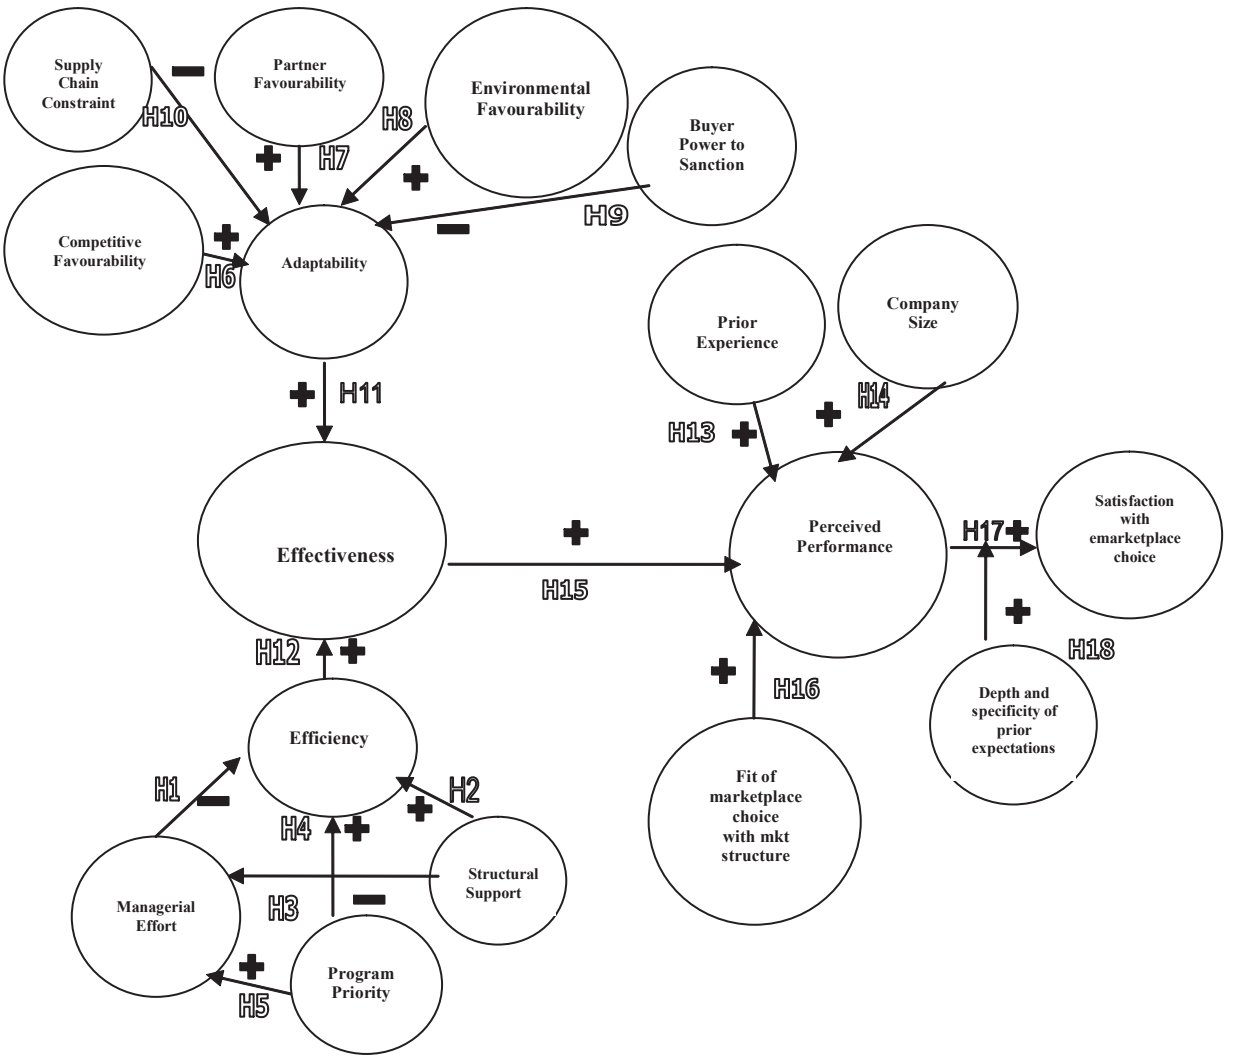
Hypothesis 18 requires the use of a moderating latent variable (depth and specificity of prior expectations) An interaction exists when the direction and/or strength of association between predictor (perceived performance) and outcome (satisfaction) variables are modified at different levels of interaction variables (moderators in this case high and low depth and specificity).

Data is currently being collected and data analysis and model verification should be complete by the date of the 2007 IRMA conference.

IMPORTANCE OF THE RESEARCH

Firstly this research makes a rather significant and unique contribution to the study of how marketers judge marketing performance. Clark (2000) found marketers use multiple performance measures. He found a mean number of 2.68 measures and with just 21% of respondents reporting one measure. I could find no paper since the publication of Clark's (2000) paper that incorporated more measures. It is surprising, to say the least, that a science such as marketing that is so strongly grounded in a plethora of underlying psychological and sociological constructs such as brand performance, consumer satisfaction and buyer expectations has not paid greater attention to similar determinants of its own practitioner's perceptions of these constructs. .

Figure 1. Determinants of marketer satisfaction with the choice of electronic marketplace type (Knight, 2005)



Academically Clark (2000) suggests that understanding how perceptions of performance are developed should be useful in two senses. First it is relevant to know what performance measures marketers attempt to maximize. Second, as marketing performance evaluation moves to multi-dimensional techniques such as balanced scorecards and executive support systems these systems should use measures that are reflective of how marketers judge performance in reality. Clark (2000) has provided a strong research framework by demonstrating that marketers judgments of performance are multidimensional but how do we begin to operationalize those dimensions to improve our understanding of specific marketing activities are judged?

The proposed research can perhaps provide a significant step in this regard. B2B transactions are often incredibly complex and to compound this effect electronic marketplaces are rapidly evolving in terms of structure and application (Mahadevan 2003). Participation in electronic marketplaces is fraught with uncertainty and risk and marketers would seem to make decisions about the type of participation based on a great deal of uncertainty in a highly dynamic environment. To operationalize Clark's (2000) typology of a generalized model of marketer's perceptions of success a setting is chosen which has few established norms. The often conflicting goals of market integration and brokerage, the risk of market power effects and the growth of complex interfirm networks (Christianaase and Markus, 2003) typify the environment of firms participating in electronic marketplaces. Though a variety of perspectives have just recently been posited as being explanatory of electronic marketplace formation and participation, the dominant explanatory theory has been that of transaction cost economics. This research topic and proposed model therefore provides fertile ground for greater understanding of how given bounded rationality (Simon, 1976), marketers set expectations, judge performance and achieve satisfaction in this dynamic environment. By providing a multidisciplinary and multidimensional operationalization of marketer's satisfaction in this environment, important research footprints could be laid down to further understand the construct of marketer satisfaction.

A second and less ambitious contribution, but one perhaps of more immediate interest to researchers of electronic marketplaces is also made by this research. This is the first research that I am aware that attempts to integrate transaction cost theory as well as other recently posited theories concerning the formation and adoption of electronic markets such as strategic networks theory, relational exchange theory, principal-agency theory, population ecology theory and behavioral psychology into an integrative and empirically testable model.

Understanding Gender Differences in the Use of Instant Messaging

Wenhong Luo, Villanova University, USA; E-mail: wenhong.luo@villanova.edu
Hao Lou, Ohio University, USA; E-mail: lou@ohiou.edu
Dahui Li, University of Minnesota–Duluth, USA; E-mail: dli@d.umn.edu

Increasingly, Instant Messaging (IM) has been accepted as a communication and collaboration tool in many organizations (Hu, Wilcox, and Hansen 2002). Ferris Research predicted that the number of IM users will reach 183 million by 2007. Unlike other communication tools such as email and groupware, however, IM was initially designed for home users as a social networking tool to connect families and friends via the Internet and only gained its popularity in business after individual users started using IM as a substitute for face-to-face communication with co-workers. Thus, the adoption and use of IM in organizations have some unique characteristics. First, many corporate users may have had prior experience with IM before they begin to use it for business purposes. Second, the inherent social features of IM may affect how business users interact with each other and possibly change the ways in which business tasks are accomplished. These characteristics could have significant implications for promoting and managing IM use in organizations.

Li, Chau, and Lou (2005) examined IM adoption and use in a social context. Based on the motivation and interpersonal theories, they identified perceived usefulness, perceived enjoyment, relationship commitment, attachment motivation, and perceived critical mass as antecedents to intention to use of IM. Perceived enjoyment was found to play a central role in predicting intention to use. Different from prior studies, perceived enjoyment was found to have as significant effects on intention to use as perceived usefulness. One explanation was that the activities supported by IM in that study were social interactions as opposed to work-related activities. The effects of relationship commitment and attachment motivation on intention to use were also mediated by perceived enjoyment. Furthermore, the study showed that perceived critical mass had direct effects as well as indirect effects through perceived usefulness and perceived enjoyment on intention to use.

Gender has been suggested as one of the moderating factors in using IM (Ilie, Van Slyke, Green, and Lou 2005). Studies in sociology have shown that men and women hold different attitudes towards social interactions and have different communicate goals and patterns. For example, women are more likely to enjoy social-oriented activities, value connection and cooperation, and share emotions. Men, on the other hand, tend to focus on task-oriented activities and communicate based on social hierarchy (Meyers, Brashers, Winston & Grob 1997, Wood and Rhodes 1992). Taking the diffusion of innovation approach, Ilie, and her colleagues (2005) examined how gender moderated the impact of innovation characteristics on intention to use. They found that men and woman are different in a number of ways. Ease of use and visibility were found to be more important to intention to use for women than for men. On the other hand, relative advantage, result demonstrability, and perceived critical mass were more important for men.

This research focuses on the role of gender in IM adoption from a social and interpersonal perspective. Specifically, we examine whether gender moderates the relationship between perceived usefulness, perceived enjoyment, relationship commitment, attachment motivation, and perceived critical mass and the intention to use of IM. Data was collected using a survey of IM users. Preliminary analysis shows that the impact of the above social factors on intention to use was very different for men and women. Final results will be presented at the conference.

Usability Attributes of the Celluloid Interface: Perceptions of Interactivity in the Age of "Blade Runner"

John Lenarcic, RMIT University, Australia; E-mail: John.Lenarcic@rmit.edu.au

A user interface can broadly be defined as being those attributes of a system that a user connects with. It is a conceptual structure made up of an input language for the client, an output language for the system and a modus operandi for choreographing interaction. The usability of an interface is defined as the efficiency and level of gratification with which users can accomplish tasks in a specific environment of a product. High usability means that a system is typically easy to learn and remember; efficient, visually and perhaps aurally satisfying and fun to use; as well as swift in its capacity to recover from errors (Nielsen, 1993).

Some media theorists view cinema as being a kind of cultural interface for society that acts akin to a collective consciousness (Manovich, 2001) but more generally the notion of the user interface is applied within the context of human-computer interaction. What is the mainstream public's view of the human-machine interface?

Cinema is a popular form of entertainment that implicitly shapes the belief of the masses on a wide variety of concerns. This art-form also has the capacity to mirror the predominant societal customs, issues and systems of the time. A film can contain a wealth of detail in its sub-text that when subject to interpretation can be transformed into new knowledge. Indeed, in this vein, academic studies have explored diverse topics ranging from the cinematic image of chief executive officers of non-profit organizations in the U.S. (Lee, 2004) to the pedagogic effects of motion picture depictions of analytical chemistry in action (Lucy, 2000). In the latter paper the author remarks that fictional representation can function as a mechanism to foster contemplation of an actual scientific technique's authentic potential for better or worse.

McMurdy (1973) argues for a closer relationship between imaginative literature and public administration scholarship, highlighting the significance of personal discernment in the evaluation of organizational phenomena and the beneficial role that fiction could have in testing existing theories and developing new insights. Academic interest in the fictional portrayal of some occupations such as the legal profession has grown appreciably in the past decade, a fact noted in a recent study of admiralty lawyers in popular culture by Jarvis (2006). Computer science and information systems, though, are lagging behind in this eclectic technique of mining popular culture for wisdom that could inform scholarly progress. The commentaries by Mathews & Reifers (1984) and Grupe (1996) are a rare exception as they examine nascent public attitudes towards the computer as reflected in cartoons published in print media since the 1940s. In a more applied outlook, the Institute for Creative Technologies (affiliated with the University of Southern California) is a research centre that is a partnership between the Hollywood entertainment industry, the U.S. military and academia (e.g., Gratch, Rickel, André, Cassell, Petajan & Badler, 2002). The goal of the centre is to create technical environments that evoke synthetic experiences for learning, training and other operational functions and it does so with input from film personnel such as cinematographers as well as traditional IT researchers.

Films of the science fiction and action genres often feature plots where computers are prominent devices (Vos Post & Kroeker, 2000). Clarke (1993) notes that the stories of science fiction author Isaac Asimov could shape the destiny of computer ethics. Aaron Marcus, a leading user interface designer, claims to have developed an early interest in his current field of expertise by being exposed to images of future technology at the movies and on TV (Marcus, 2006). Indeed, some scholars have advanced the notion that works of speculative fiction in general can act as an inspiration for future technological development in an actual sense (Boutillette, Coveney, Kun & Menides, 1999).

In terms of the technically literate audience, is the public perception of the usability of current and future computer systems being influenced by what is depicted in the cinema? In this study, examples of usability issues from films such as "Blade Runner", "2001: A Space Odyssey", the "Matrix" trilogy and "Minority Report", amongst others, will be investigated in terms of their technical validity, ethical rationale and potential cultural side-effects. An allied matter to be addressed is whether or not the creative inclinations of user interface designers are shaped by these genre-based forces. The usability attributes of the fictional interfaces depicted in films of the science-fiction variety will be classified in the long-term and arguments will be raised as to the effect these have on the expectations of users as they relate to actual human-computer interface technology.

"Blade Runner" is a science fiction film released in 1982 but it depicts a dystopian Los Angeles in 2019, a future where the technologies on display are a hybrid melange of the past, present and futue. There is a sequence in the story where the lead character Deckard (portrayed by Harrison Ford) is using a computer device known as an Esper. This apparatus is employed in this scene to manipulate photographic imagery in the search for a particular individual. Terse vocal commands of an alphanumeric nature control the mechanism in its operation, with the Esper providing feedback via high frequency sounds. A person viewing this scenario who is not an IT practitioner or academic may be oblivious to the technical minutiae unfolding at this juncture. Perhaps they may even be bored by the detail. Accumulated technological wisdom, however, may affect the experience of the viewing. With this background, the sequence could serve as a touchstone for debate about usability issues. To a computing academic experiencing this "Blade Runner" segment, what is the meaning of the Deckard-Esper interface as enacted on screen? This key question will initiate a novel phenomenological study to launch the overall research project.

Phenomenology is a research technique employed to obtain an intricate, richly textured understanding of human experience in a wide variety of contexts. In stark contrast to positivist enquiries, this practice concentrates on subjective experience as being the prime source of all knowledge defining objective phenomena. Akin to producing a complex piece of literature that juggles multifarious dominant themes interleaved with allusions, the output of this research approach succinctly describes observed commonalties in terms of ideas, issues and subject matter when individuals are confronted with a phenomenon that they experience. To achieve this goal requires the pursuit of four main stages of the phenomenological process: epoche, reduction, imaginative variation and synthesis of composite structural descriptions (Moustakas, 1994). Epoche is an idiosyncratic term coined by the originator of phenomenology Edmund Husserl and refers to the initial step of sweeping aside the personal bias of the researcher in order to accentuate a naïve interpretation of the human experience under consideration.

Once the state of epoche has been suitably negotiated, the reduction stage is undertaken by describing the phenomenon using richly textured language so as to obtain a deep level of comprehension. All statements rendered in the ensuing text are then inspected with the thought that they are of equal value, this being a procedure known as "horizonalizing". The aim is to extract a structural appreciation of the interweaving between person, conscious experience and the phenomenon that stimulates the latter. The third step, imaginative variation, revolves around speculative ruminations to explore possible experiential meanings through divergent thinking and systematic reflection. To conclude, synthesis assimilates the structural and textural vantages encountered in the previous stages into a coherent unified statement, which encapsulates the quintessential nature of the phenomenon.

West (1997) advocates the existence of a "hermeneutic computer science" to augment the formalist orthodoxy permeating the study of information technology. Such an approach can provide strategies to deal with the problems encountered with complexity. Hermeneutics is the study of interpretation, usually of texts but also of systems in general. Phenomenology is one strand of this paradigm and the concepts to be plumbed in the ensuing investigation will possibly include multiple-perspectives, cooperative and transient meaning, emergence, self-organization, variation, evolution as well as elucidation in general.

The "Blade Runner" film segment as described above will be employed as a phenomenological stimulus to be viewed by a number of academics from the domain of information systems. The interpretive research methodology as outlined above will then be adopted to gauge the subjective experience of this unique cohort. Conventional HCI research often involves the deployment of usability labs that consist of sophisticated video recording equipment and observation facilities such as one-way mirrors to permit fastidious scrutiny of users engaging with the interface of a product (Dillon, 1988). In an ironic sense, the motion picture sequence to be viewed in this research project will be akin to a cinematic usability lab, the one-way mirror here being the film artifact and the message that its viewers experience via the unilateral conduit of entertainment.

Improving Corporate E-mail Communications with Employees at Remote Locations: A Quantitative Study in Progress

Fairlie Firari, Capella University, USA; E-mail: ffirari@yahoo.com

INTRODUCTION

Today's company managers are under pressure to manage employees residing in different cities, states and countries, and are pressured to adapt to the changing definition of the workplace. Mayor (2001) describes the traditional 9:00-5:00, one office location, as archaic; advocates for having employees at remote locations; and advises managers to learn to effectively communicate without the luxury of in-person or face-to-face interaction. Companies are setting up remote offices so employees or telecommuters can work from or near home, are physically close to clients, and to cross boundaries of time, distance, culture, and geography. Melcrum (2000) wrote that the increase in the number of remote locations accommodates work/life balance of teleworkers by reducing travel and time away from home, and is supported and enabled by technological advancements such as computers, the world wide web, video conferencing, cellular phones, pocket-size computers, wi-fi, and electronic mail (email) - the predominant communication channel of teleworkers and the topic of this quantitative research project.

If Janove (2006) and Enemark (2006) are correct - knowledge, trust, and connectedness are critical to managing offsite employees, and a common success denominator of the three elements is effective communication, which has distinct performance challenges. Kuzma (2006) wrote that a prominent issue for companies managing teleworkers is the pervasive use of email and its associated communication problems. Enemark (2006), Kuzma, (2006), and Suler (1997) agree that the absence of verbal and non-verbal communication signals, present in face-to-face and telephone interactions, can lead to misconstrued email tones or meanings, miscommunications, disorientation, and lingering bad feelings. "While email may indeed smooth the load to some degree, it also carries a big potential for misunderstanding. The problem, however, is not email but communication skills. Employees who cannot communicate, whether orally or in writing, are less effective" (Gibbs, 1998, p.1). But managers of teleworkers in virtual communities often defer to this most popular corporate communication channel of email and therefore need tools to enhance the effectiveness of email communications.

STATEMENT OF THE PROBLEM

Email is a dominating corporate communication channel, replacing even the telephone (PcPheat, 2002). Email is an invasive, technological phenomenon that should be used proficiently. It can build or destroy relationships, and has the legal power of the printed word which cannot be taken back once the send button is pushed. Resources for writing effective emails are abundant but are limited in focus to netiquette, content, format, and proper/legal use. Interpersonal communication experts advise on the art of communication but the advice is written for face-to-face or phone interactions rather than for email interactions. Decker (1996), Hunsaker (2005) and others have written at length regarding the need for managers to build trust and relationships with employees by actively listening and sending encouraging verbal and nonverbal communication signals through the use of behavioral skills like appropriate eye contact, open posture, suitable facial expression, encouraging gestures, verbal prompts - all present in synchronous interactions but all nonexistent in an environment dependant on asynchronous interactions like email. "The inability to develop personal rapport over e-mail makes relationships fragile in the face of conflict" (Enemark, 2006, p.1). Seeley and Hargreaves (2003) wrote that email is the "DNA of communications," (p. 4) and that some managers receive an average of 68 emails a day. Managers need performance enhancing tools and techniques to act as surrogates for email's missing verbal and nonverbal signals to help build trust and relationships with telecommuters and offsite employees, and to enhance productivity and profitability.

Business communicators know that one way to improve communications is to first study and understand the various styles of communication (Wilson, 2004). Once the communication style of a client or employee is determined, then managers who have been trained to use the skill of adapting behaviors to mirror those of others can effectively learn to communicate in the native styles of a client or an employee (Alessandra & O'Connor, 1996). Managers who understand style differences and then learn to adapt to the styles of others benefit greatly and help reduce communication barriers and misunderstandings (Hunsaker, 2005), but these critical skills relate to face-to-face interactions. And an online poll of 1,013 Canadians conducted in the spring of 2006 revealed that face-to-face conversations account for 38% of daily interactions and are closely followed by email exchanges at 30% of interactions (mobile telephones account for 12%, and home telephones about 20%) which illustrates the need to develop tools and techniques for maximizing the effectiveness of email exchanges (Canadian Newswire, 2006).

Additionally, it is estimated that there are over eight million teleworkers in the United States and that the most popular channel of communication of these individuals is email. There are intrinsic problems with understanding the tone of email exchanges, recipients correctly interrupt emails only about 50% of the time, often leading to misunderstandings, ill will, flame wars, and a lack of trust and connectedness - all of which negatively impact production and profit. Enemark (2006) wrote of a study conducted by Kruger and Epley in 2005 that proved a link between email misunderstandings and egocentrism, meaning, that people tend to write and interpret emails solely from a single perspective and assume that email receivers understand exactly what the senders intended. Enemark (2006) further described the findings of this study to include the confirmation that the lack of verbal and nonverbal cues is a problem with emails; and that because emails are quickly transmitted and informal they imitate face-to-face interactions but are missing the critical paralinguistic signals of the spoken word. Jourdain (2002) reminds that only seven percent of a message interpretation is based on the actual written or spoken words and that the remainder of the message is subject to the receiver's filters. The Kruger and Epley research found in five separate studies that email senders believe they clearly communicate 78% of the time; that email recipients believe they properly interpret emails 89% of the time; and, in reality, the receiver only correctly interprets email 56% of the time, indicating room for miscommunication (Enemark, 2006). "To avoid miscommunication, e-mailers need to look at what they write from the recipient's perspective, Epley says" (Enemark, 2006, p.1).

RESEARCH PROJECT DESCRIPTION

Communication suffuses most everything in life therefore any and all improvements to communication process effectiveness is beneficial (Jackson, Dawson,

& Wilson, 2002). Identifying and adapting face-to-face communication styles is a process for improving communication effectiveness that is not new; it has been taught and successfully used in corporations for over 45 years (TRACOM Group, 2004), was created as a way to understand the perspective of message recipients and to demonstrate respect. What ***is*** new is the concept of applying the identification and adapting techniques to email interactions to determine email styles or e-styles. Before a technique or model for adapting e-styles can be developed, the hypotheses that e-styles exist, are predictable, and correlate to face-to-face styles must be researched. The researcher will work to prove or disprove the theory that communication styles manifest not just during face-to-face interactions but also in email communications.

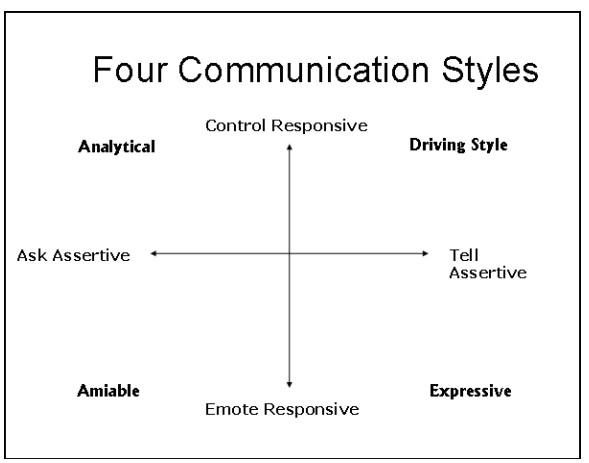
The TRACOM SOCIAL STYLES Model SM is based on the premises that there is no communication style better than another; there are four basic styles – analytical, amiable, driving, and expressive; styles are identified by analyzing physical and verbal behaviors that are measured on two axes or continua of assertiveness and emotiveness; and that the key to using this information to improve communications is in the ability of the person transmitting the message to style-adapt to the person receiving the message.

First is style identification and second is style adaptation. Benefits of adapting include learning to speak in a client's or employee's style language which will increase comfort, help make a difficult message palatable, and emphasize the content of the message rather than the delivery style of the message. Focus will remain on the message content and reduce misunderstandings or misconstrued negative feelings, attributable to style differences, which the manager may have unintentionally communicated to the employee.

The TRACOM Corporation's SOCIAL STYLE SM MODEL has well documented evidence of four basic communication styles and of the effectiveness of adapting. TRACOM has a tested and proven methodology for identifying styles by analyzing specific physical and verbal behavioral patterns such as eye contact, speech, and body movement (TRACOM Corporation, 2001). TRACOM places specific behaviors on two continua. One continuum is described by behaviors that determine a person's amount of Tell/Ask assertiveness or level of influence. About half the population is more tell- assertive, the other half is more ask-assertive (Bolton and Bolton, 1996). Driving style and expressive style are the two styles considered tell-assertive and analytical style and amiable style are ask-assertive (TRACOM Corporation, 2004). TRACOM's model determines assertiveness by analyzing specific behaviors.

The second continuum is described by behaviors that determine a person's amount of responsiveness or levels of evident emotion and are called Emote/Control responsive. About half the population is more emotionally controlled and the other half is less emotionally controlled and both are determined by examining levels of obvious displays of emotion and attention to people versus attention to numbers and statistics (Bolton & Bolton, 1996). Driving and analytical are the two styles considered more emotionally controlled, and expressive and amiable styles are less emotionally controlled. TRACOM determines emotiveness also by analyzing specific behaviors.

Figure 1. The four communication styles quadrant



The styles are then determined when the two continua are combined to form a quadrant with assertiveness on the horizontal axis and emotiveness on the vertical axis. People who are tell-assertive and more emotionally controlled are driving style. People who are tell-assertive and less emotionally controlled are the expressive style. People who are ask-assertive and less emotionally controlled are the analytical style, and people who are ask-assertive and more emotionally controlled are the amiable style. TRACOM's objective approach to analyzing behaviors for determining styles is captured in Figure 1 on a quadrant. The lines with the arrows are the continua and the combination of assertiveness and emotive behaviors when placed on the quadrant indicate style.

During this study a similar diagnostic tool using two continua and a quadrant will be created to capture and analyze the email writing behaviors that would define e-styles. The researcher will model the styles descriptors and the identification after TRACOM's SSP system but proposes the following titles for the four e-styles. The researcher's e-styles and TRACOM's in-person styles names are, respectively (a) logical/analytical, (b) supportive/amiable, (c) straightforward/driving style, and (d) communicative/expressive. Diagnosing styles is the first step to improving interpersonal communications and regardless of what the names of the styles are, once an employee's style is determined it is advisable for managers to take the second step and adapt behaviors in a way that emulates that of the employee's style. Adapting will result in fewer misunderstandings and encourage trust and open communication. The adapting technique is important to use for a variety of reasons including increasing the employee's receptivity to hearing a difficult or complicated message. But before adapting e-styles, comes analyzing and identifying e-styles, which is the focus of this study.

By proving the hypothesis that e-styles exist could result in the creation of a training solution for managers to: (a) identify e-styles; (b) craft effective emails by adapting to the e-style of others; (c) increase the recipient's understanding; and (d) decrease the potential for miscommunication. Second, the creation of e-styles predictor software has important applicability to corporations managing remotely. Additionally, if the research provides evidence that e-styles and in-person styles correlate, then the theories and practices regarding in-person styles identification can be applied to e-style identification. Managers who understand and value the premise of identifying in-person communication styles of employees may also see a value for identifying e-styles of employees however; research has not been conducted on predicting e-styles.

PURPOSE OF THE STUDY

The purpose of this study is to develop a tool to test the theory that e-styles exist, can be identified, and correlate to in-person styles. Once proven, training will be developed to instruct managers how to adapt to the e-styles of others. The research will require the development of a software model designed to analyze email characteristics and to identify data trends that can be categorized as e-styles. The characteristics are derived based on behavioral criteria similar to those used by the TRACOM SOCIAL STYLES Model SM. The researcher will analyze approximately 2,000 emails collected from 100 eligible participants and, to explore a second hypothesis, correlate the data with data collected on the participant's in-person styles. If the study proves the hypothesis that e-styles correlate to in-person styles then the literature and practices of in-person communication styles theories will apply to e-styles.

Two hypotheses have been formulated for this study. The first hypothesis is that e-styles can be predicted by analyzing email correspondence. The researcher will study email characteristics, or predictors, to identify trends in levels of emotiveness and assertiveness which when placed on continua indicate the writer's e-style. The second hypothesis is that e-styles correlate to in-person communication styles. If the second hypothesis is true then theories, research, practices, and literature on in-person styles can be applied to e-styles.

RESEARCH FRAMEWORK

The information gained during this quantitative research study will test the hypothesis that e-styles of employees can be determined by examining specific email characteristics that when placed on two continua describe how best to understand an employee's written e-style. Similarities and differences may surface during this study between email and in-person communication characteristics used to predict

the styles which will disprove or prove a correlation between the two. Information from this research study will provide new communication improvement resources for management to use in developing and improving relationships with employees at remote locations. Additionally it is expected that participation of 100 will be achieved because managers are interested in learning about communication styles and will be interested in receiving a free style profile assessment.

The study described is designed to test the hypotheses by (a) studying about 2,000 emails from about 100 participants to determine email communication style indicators; (b) by identifying participant's in-person communication styles, using the TRACOM SSP-E online profile method; and (c) by comparing e-Com styles with the in-person profile results to see if there is a correlation. The results of the study will be compiled into and communicated through a manager's training curriculum. The training will be designed to be used as a strategic internal communications plan component, will link improved email communication skills to corporate business operations initiatives, and may be a viable HPI training solution.

The researcher will use data mining and conduct a neural networks regression analysis driven by R-Software of which the predictors or independent variables are email characteristics and the response variables or the dependant variables are the 2,000 emails submitted by the participants. The characteristics will be reviewed and parameters extracted using a C++ language program developed by a data analyst for this project. The parameters will then be fed into R-Software which is the user interface for running the neural networks. Neural networks is a computational information processing model that will be trained, by using the TRACOM model as a basis, on what the appropriate relations between email attributes and e-styles are and will determine the probability that a set of emails comes from a person having a particular e-style. If a model that can relate email attributes to in-person styles can be built then e-styles exist. The e-styles will be categorized as communicative, logical, supportive or straightforward. The researcher's theory regarding e-style identification is that managers with communicative styles will issue more directives and make fewer requests and will refer more to feelings. Managers of the logical style make more requests, issue fewer directives and will refer more to facts. Managers who email in the supportive style will make more requests, issue fewer directives and refer more to feelings; and managers of the straightforward style will issue more directives rather than making requests, and will refer more to facts.

CONCLUSION

Improved email communications with employees at remote locations translates to improved relations, trust, productivity, and ultimately profitability. The development of an e-styles identification tool and training curriculum are timely, would offer companies a new HPI training solution for improving the performance of managers and others, and would be a viable component of a corporate internal communications strategy. The ability to identify e-styles will provide guidance to managers seeking a technique to write emails that are non-inflammatory, correctly interpreted, and that successfully and professionally disseminate information to peers, subordinates, supervisors, and clients of different styles. Given the importance of effective communication with clients, employees and others, and the fact that many companies have gone global and need tools and techniques to effectively communicate via email the timing and importance of this study are appropriate.

The Evolving Concept and Practice of Knowledge Management: Seeking a Common Understanding and Definition

Elizabeth Regan, Morehead State University, USA; E-mail: e.regan@moreheadstate.edu

ABSTRACT

This research traces the roots of knowledge management (KM) to assess how its origins relate to current variation in terminology, concepts, theory, and practice. The objective is to provide a framework for clarifying the relationships among these divergent views and move toward a more common understanding and definition of KM.

INTRODUCTION

The past two decades have witnessed the rapid evolution of knowledge management (KM) as a concept and as an area of study and practice. Some researchers suggest that KM has matured to a level to be recognized as an academic discipline in its own right (Jennex and Croasdell, 2005). However, the literature offers little agreement on a common definition of KM or its foundations and methods. In fact, almost every KM source offers its own unique definition.

The KM umbrella has, in fact, become very broad. It has introduced new concepts such as the knowledge worker, chief knowledge officer, knowledge economy, intellectual capital, and knowledge as a tangible asset. It has also evolved to encompass all or many of the following concepts, depending on the source: work flow, document control and distribution, e-mail, performance support, best practices, organizational learning, organizational memory, collaborative computing, data warehousing, data mining, and knowledge portals. Other sources also include Intranets, Extranets, e-business, customer relationship management, and business intelligence. All of these, and more, are discussed in various ways by different sources under the knowledge management umbrella.

The idea of the importance of knowledge is not new, of course. Yet as a concept and an organizational process, KM takes on an entirely different meaning, which has gained widespread attention on a global scale. At the same time, however, the concept has lacked unity, and its rapid popularization has made it difficult to sort out the hype from the reality. As often happens when a new concept becomes popular, there has been a rush to rename existing technologies or products to make them more marketable. As a result, systems that have been around for a long time, such as artificial intelligence, expert systems, workflow management, databases, document management systems, and most recently corporate Web portals, now are touted as KM systems.

This study hypothesizes that the lack of consensus around a common definition of KM relates to its divergent roots. The literature reveals that the origins of KM have not been well researched (Bertels, 1996; Sveiby, 2001). The purpose of this research, therefore, is to identify the various disciplines or threads in which KM has roots and to assess how these varying roots relate to the current variation in terminology, perspectives, and recommended approaches to KM. The objective is to provide a framework for clarifying the relationships among these divergent views and move toward a more common understanding and definition. This insight will be critical to defining KM as a discipline and clarifying its foundations, theories, and methods as well as validating its business value.

LITERATURE REVIEW

The literature provides a plethora of definitions for KM (Alavi & Leidner, 2001; Awad & Ghaziri, 2004; Ayerton, 1998; Gates, 1999; Grundstein, 2006; Konda & Steenkamp, 2004; Malhotra, 1999; Sveiby, 2001, Regan, 2007; Regan & O'Connor, 2002). The lack of agreement on a definition is problematic for an emerging discipline that traces its roots back at least two decades. Even the most recent textbooks spend an entire chapter just explaining what KM is and what it is not, and provide an entire page of definitions (Awad & Ghaziri, 2004; Regan & O'Connor, 2002).

Systematic analysis of the literature on knowledge management reveals at least seven distinct roots or disciplines related to the evolution of KM. While these different roots share common concepts, they also reflect sharp differences. The current status of KM appears to represent a convergence of these distinct roots—rather than a progression from any single discipline. The analysis suggests that this convergence of several different disciplines accounts, in large part, for both the disparity of viewpoints and what seems like an explosion of interest.* A very brief summary of each of these roots follows:

- *Best practice transfer*. One dominant theme of KM is the systematic transfer of best practices. According to a study conducted by the American Productivity and Quality Center (APQC, 1996), best practice management was the one strategy pursued by 100 percent of the firms implementing KM approaches. The use of benchmarking and best practices gained widespread industry acceptance in the early 1990s (O'Dell & Grayson, 1998). This perspective is represented in the O'Dell and Grayson book (1998), *If Only We Knew What We Know*, based on APQC's work with Fortune 500 firms.
- *Information and records(or resource) management (IRM)*. KM also has roots in document management, both paper and image. Both the Association of Information Image Management (AIIM) and ARMA, International, the former Association of Records Managers and Administrators, have a huge presence in the KM market. This approach reflects a strategic view of managing and safe guarding information resources from a corporate perspective. It also suggests the origins of the life cycle concept frequently applied to KM. IRM is the approach reflected in the book by Jan Duffy, *Harvesting Experience, Reaping the Benefits of Knowledge*.
- *Organizational learning and organizational memory*. The concept of the learning organization is generally associated with Peter Senge, author of *The Fifth Discipline*. It embodies the notion that organizations as well as individuals can learn from experience, and it emphasizes the need for information sharing and collaboration. Concepts such as organizational intelligence and self-organizing knowledge would fall within this tradition as well (Allee, 1997). Many researchers also consider *The Knowledge-creating Company: How Japanese Companies Create the Dynamics of Innovation*, by Ikujiro Nonaka and H. Takeuchi (1995) to be a seminal work in the area of organizational learning.
- *Electronic performance support systems (EPSS)*. One of the early precursors of KM is electronic performance support, the concept of just-in-time delivery of online reference, training, and help. During the 1980's hundreds of firms focused on creating online performance support and computer based training using new computer authoring and reference systems. Another related concept was Information Mapping, a process for analysing, organizing, and presenting information for reference, which originated for paper documents and was then adapted for electronic presentation. The EPSS approach is described in books such as *Designing Electronic Performance Support Systems* by Gloria J. Gery and *Designing and Writing Online Documentation* by William K. Horton. Another widely recognized pioneer in this area is Dr. Ruth Clark, author

of *Building Expertise: Cognitive Methods for Training and Performance*, and other books and articles on learning objects, online learning, workplace performance, and instructional design.

- *Technological methodologies*. Another perspective is based on technological methodologies related to data warehousing, data mining, and business intelligence. This thread has its foundation in information systems and technologies. It tends to focus more on knowledge taxonomies and to view knowledge more from the perspective of objects rather than process. One of the weaknesses of early data warehouses was that they tended "to create massive data and text archives of dubious value" (Sveiby, 2001, online). This approach is represented in works such as Thomas H. Davenport and Laurence Prusak, *Working Knowledge: How Organizations Manage What They Know* (1997)
- *The knowledge economy and knowledge as a corporate asset.* Another perspective is based on economic concepts related to productivity and measuring economic value in the new economy. Economists and business leaders today are concerned with whether traditional accounting and statistical models are capable of calculating the true productivity gains created by knowledge in the new economy. Intellectual capital, which has long been regarded as an intangible quality of individuals and organizations, is now gaining ground as a tangible line item on the corporate balance sheet. Recent works in this area include Paul A. Strassman, columnist on knowledge metrics for *Knowledge Management Magazine* and Thomas A. Stewart, author of Intellectual Capital: The New Wealth of Organizations (1997). Another example is found in Housel and Bell (2002), *Measuring and Managing Knowledge*.
- *Internet and Web Portals*. The Internet has created a common, relatively low cost networking platform that has opened access to information and greatly expanded the options for enterprises to share information both internally and externally. The influence of this approach has expanded more recently to include customer relationship management, business intelligence, and portal technologies. It is a major focus of *Knowledge Management Magazine*, subtitled Business Intelligence for Strategic Decision Makers, aimed at executives interested in organizational and technological knowledge-management strategies (Roberts-Witt, 1999).

We might also add the discipline of library and information sciences to this list, which is being transformed by digital technology and online access to information resources. Indeed some excellent practitioners in KM come from the library sciences. Astra Pharmaceuticals is among the documented case studies where enterprises made a decision to include people from the world of library and information sciences in key KM positions (Regan & O'Connor, 2002).

Sveiby (2001) seeks to explain the wide disparity in understanding KM concept s by analyzing what people in the field are doing—researchers, consultants, vendors, KM users, companies, and other practitioners. He suggests two difference tracks. An Information Technology (IT) KM Track that focuses on the Management of Information and a People KM Track that focuses on the Management of People. He suggests that researchers and practitioners in the IT KM Track tend to come from computer and information science backgrounds. They are involved in applications such as information management systems, reengineering, artificial intelligence, data warehouses, groupware, etc. To them knowledge equates to objects. On the other hand, researchers and practitioners in the People KM Track tend to come from business/management, psychology, philosophy, or sociology. They are primarily engaged around workplace performance, professional development, and organizational learning. To them knowledge equates to processes. Grundstein (2006, p1259) makes a similar distinction between two main approaches underlying KM: "(1) A Technological Approach that answers a demand of solutions based on the technologies of information and communication; (2) A Managerial Approach that integrates knowledge as resources contributing to the implementation of the strategic vision of the company."

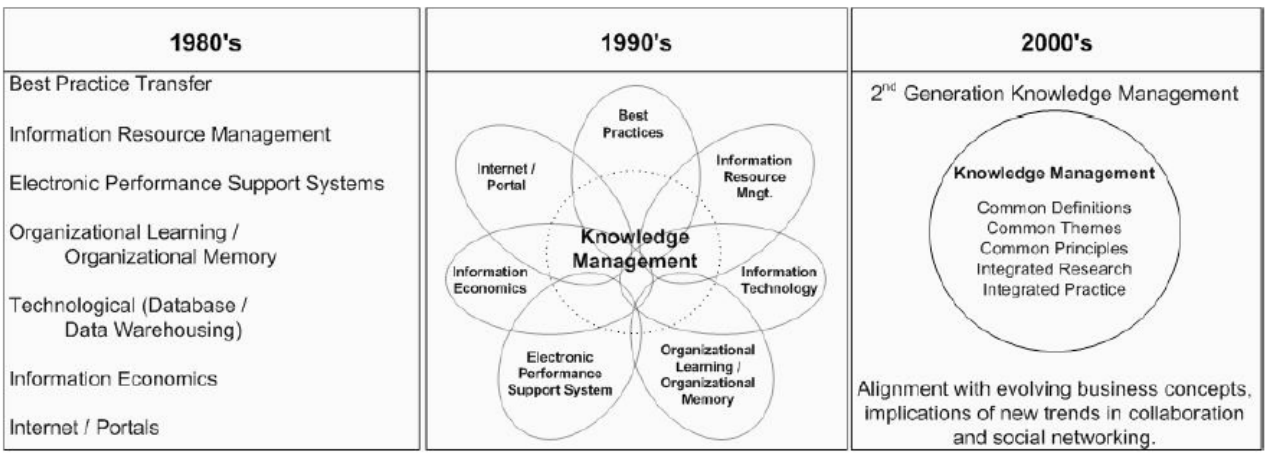
Consequently, according to Sveiby (2001, online), there are "paradigmatic differences in our understanding of what knowledge is." Researchers and practitioners who view knowledge as objects, tend to rely on concepts of information theory in their understanding of knowledge, whereas those who view knowledge as process tend to take their concepts from philosophy or sociology. "Because of their different origins, the two groups use different languages in their dialogues and thus tend to confuse each other when they meet" (Sveiby, online).

Konda and Steenkamp (2004) offer yet another approach to classifying the varying KM perspectives. These include the technological, organizational, process-based, product-centric (or asset-focused), and strategic perspectives. Researchers and practitioners have proposed several variations of knowledge life cycle models that emphasize one or more of these perspectives while neglecting others.

ANALYSIS

This legacy helps explain, at least in part, the contradictory views, inconsistencies, multiple perspectives, and plethora of definitions surrounding the concept and emerging discipline of knowledge management. Although the different threads share some common themes, they also reveal fundamental differences in our understanding of what KM is and is not. They represent different foundations and use different languages in their descriptions and approach to KM. They also differ in the types of applications and problems that they address and the approaches that they take to these problems. For example, technology approaches generally emphasize explicit knowledge and focus on how to create, store, retrieve, and use the explicit knowledge artefacts; whereas organizational learning approaches generally emphasize the importance of tacit knowledge and focus on personal, organizational, and inter-organizational learning and knowledge transfer. What is needed in practice is a more holistic or balanced approach that would ensure

Figure 1. Evolution of KM: A convergence NOT a progression from a single discipline (Source: Regan, 2007)



an optimal integration of tacit and explicit knowledge to serve the needs of the business (Konda & Steenkamp, 2004).

The research provides little evidence of a shared awareness among the communities of practice and research associated with each of these threads or traditions (Jennex & Croasdell, 2005). This silo effect is evident from the apparent lack of cross-referencing of research and practice in the literature of these different traditions. This silo effect suggests that the current state of KM represents a convergence of these different traditions with little integration of theories or methods. Although common themes have emerged around the concept of knowledge management, wide disparities continue to exist in theory, terminology, and practice. Thus, as suggested by Figure 1, the current status of KM as a concept, represents a convergence of multiple disciplines and approaches, which has not yet truly coalesced into a discipline in its own right. Kondra and Steenkamp (2004, p1383) also argue the need for an integrated KM framework that comprehends all the perspectives of knowledge to present a holistic approach. They propose an Integrated Knowledge Management Framework (IKMF) based on five perspectives: strategy, organizational entity, knowledge process, knowledge asset, and information technology. They suggest that, "No treatise on KM is complete unless it addresses all the issues arising out of a comprehensive view of entire KM domain" (Kondra & Steenkamp, 2004, p1384).

CONCLUSIONS AND FUTURE RESEARCH

This research focuses on the variety of traditions from which KM has its roots to assess how they relate to the current variation in terminology, perspectives, definitions, and recommended approaches to KM. Current evidence shows little shared awareness among these different traditions. This research suggests a need to work toward development of a holistic KM model that recognizes the entire spectrum of research and practice. Future research also is needed to validate common themes and practices among these separate traditions. If researchers continue to work in their own silos, KM will continue to be characterized by a general lack of agreement and congruence. More importantly, the opportunities for richness and insight of a more holistic, multi-disciplinary perspective will be missed. To be viable, it would seem that any movement toward establishing KM as a discipline must be inclusive and recognize the full range of research and practice.

ABSTRACT

Studies in Software Engineering (SwE) and Systems Engineering (SE) disciplines have alerted on the increasing complexity of software-intensive systems in the last 15 years. As a response to this phenomenon, it has been recognized the need to strengthen the SE and SwE curricula mutually through a unified Software Systems Engineering discipline. In turn, a common definition of the Information Systems (IS) discipline indicates that IS concerns with the study of Information Technology-based systems (IT) for managerial purposes as well as with the dual nature – technical and social- of its management. This paper, -product of a research in progress- develops the case for a Management & Engineering of IT-intensive Systems view under the following rationality: (i) the technical and social complexity of the issues related with the emergent information systems -built on software-intensive systems- that is demanded by organizations escapes of the scope of knowledge of the traditional IS discipline, (ii) the IS discipline has arrived to such degree of fragmentation that it has became in a set of knowledge islands, and (iii) an interdisciplinary –systemic- approach provides the adequate philosophical paradigm and methodological research tool to cope with this phenomenon through the systemic interaction of traditional IS, SwE and SE disciplines. In pursuit of this purpose, this paper reviews the origins, foci, objects of study, main disciplines of reference, and main research methods used in these disciplines, and uses a Systems IS research framework for theoretically justifying their integration. Discussion of benefits and barriers for its development are also finally reported.

Keywords: IT-intensive systems, Information Systems, Systems Engineering, Software Engineering, Interdisciplinary Research, Systems Approach.

INTRODUCTION

Studies in Software Engineering (SwE) (Andriole & Freeman, 1993; Sommerville, 1998; Boehm, 2000, 2006) and Systems Engineering (SE) (Sage & Cuppan, 2001; Keating et al, 2003) disciplines have alerted on the increasing complexity of software-intensive systems in the last 15 years. For the former case, this identification has been through the concepts of software-intensive systems (Andriole & Freeman, 1993; Boehm, 2000); socio-technical software-intensive systems (Sommerville, 1998) and software-intensive systems of systems (Boehm, 2006) while that for the latter case, through the emergence of the concepts of system of systems (SoS) (Sage & Cuppan, 2001; Keating et al, 2003) and complex systems (Senhar & Bonen, 1997; Mage & de Weck, 2004; Cleary, 2005).

As a response to this phenomenon, it has been recognized the need to strengthen the SwE (Sommerville, 1998; Hecht, 1999; Bate, 1998; Johnson & Dindo, 1998; Denno & Feeney, 2002) and SE (Brown & William, 2000; Rhodes, 2002) curricula mutually. Furthermore, a unified Software Systems Engineering discipline it has also posed by other studies (Andriole & Freeman, 1993; Thayer, 1997, 2002; Boehm, 2000). In turn, the SE disciplines per se, has been also required to wide its scopes to managerial duties (currently it is taught as Engineering Management, Industrial Engineering or Project Management topics) in order to SE provides the systems-view for managing the complete organization and only the traditional technical processes for engineering a product or provision a service (Farr & Buede, 2003; Arnold & Lawson, 2004; Emes et al, 2001).

Hence, while the SE and SwE disciplines have started to interact in the last 15 years to address the design of complex software-intensive systems -but composed of hardware components also like automotive systems, airspace systems, mobile telephone systems, etc-, a highly related discipline –*e.g.* Information Systems- has largely ignored such issues. Then, given a common definition of the Information Systems (IS) discipline as concerning with the study of computer-based systems –now called Information Technologies - for managerial purposes as well as with the dual nature – technical and social- of its management process (MIS Quarterly, 2006) and where the IS development (Nunamaker et al, 1991) and the IS design process (Hevner et al, 2003; 2004) are considered part of the practitioners duties and research paradigms, this paper -product of a research in progress- develops an initial case for a Management & Engineering View of IT-intensive Systems as discipline.

This perspective is developed under the following rationality: (i) the technical and social complexity of the issues related with the new information systems demanded by organizations escapes of the scope of the traditional monolithic view of IS, (ii) the IS discipline has arrived to such degree of fragmentation that it has became in a set of knowledge islands, and (iii) an interdisciplinary –systemic- approach (Ackoff, 1960) provides the adequate philosophical paradigm and methodological research tool to cope with the phenomena of interest to be studied through an unified view of IS, SwE and SE disciplines.

In pursuit of this purpose, the paper is structured as follows: in next section an extended review (Mora et al, 2006a) of the origins, foci, objects of study, main disciplines of reference, and main research methods used in these disciplines is reported. We continue -by using a systemic IS research framework (Mora et al, 2006b, 2007)- with the theoretical justification of the integration posed through an initial case. Finally, we conclude with a brief discussion of the benefits and barriers for its further development.

A SYSTEMIC REVIEW OF THE SE, SWE AND IS DISCIPLINES.

The concept of modern SE, SwE and IS disciplines –*e.g* as systematic generation and deployment of scientific knowledge- emerged historically during late 1930's for SE and late 1950s and 1960 for IS and SwE respectively. Some reports (Buede, 2000; Gonzalez, 2005; INCOSE, 2004) point out that SE principles have been used by urban architects or early civil engineers through the construction of large-scale systems such as: Egyptian pyramids, Roman aqueducts, bridges and buildings, and early mechanic and naval engineers with heavy industrial machinery, trains and ships. However, modern and systematic SE discipline is born with the integration

of a multidisciplinary engineering team in the British air defense systems in 1937, the first SE course at MIT in 1950, the establishment of a systems development division by RAND corporation in 1955, and the publishing of the first textbook on SE from H. Goode & R. Machol in 1957. At present, after 40 years, the existence of undergraduate and graduate programs discipline (Brown & Scherer, 2000), professional societies as INCOSE, worldwide conferences and scientific journals proves that SE is a well-recognized discipline.

The term of IS –originally named Management Information Systems- was coined in 1958 by Leavitt & Whisler (cited by Adam & Fitzgerald, 2000). The first textbook appears in late 1960s (Dearden & McFarlan, 1966; cited also by Adam & Fitzgerald, 2000) as well as the first graduate program in the University of Minnesota. As the same as the SE discipline, 40 years after, the IS discipline is well-recognized by the existence of the similar aforementioned indicators (*e.g.* programs, conferences, journals, etc). In turn, SwE concept was formulated in a NATO's Conference in late 1960s (Bauer, 1969; cited by Pressman, 1997) despite of the development of computer programs, languages and operating systems was done previously from the 1950s. However, these technological developments are related with Computer Sciences or Electrical Engineering disciplines. The first SwE textbook appears on the early 1970s, but is until the 1980s and the 2000s when the first graduate and specialized undergraduate programs in SwE are available respectively. However, despite of the delays in its evolution, the current existence of focused graduate and undergraduate programs, professional societies, conferences and journals in SwE supports evidences to consider the SwE as a discipline separate from its origins –*e.g.* Computer Sciences or Electrical Engineering-. Hence, the historical order of apparition of these disciplines suggests that SE is a more mature discipline –supported by the large-scale projects where it has successfully used as well as by the stability and standardization of its theories, methods and tools developed (Honour, 2004) -. In second place is the IS discipline and finally the SwE discipline. However, recent studies in the three disciplines –fostered by the increasing of IT-based systems and inherently complexity- are alerting on a required convergence or interdisciplinary curricula, research and praxis. In next section we develop an initial case for it, but it is required firstly to analyze the current foci, disciplines of reference and body of knowledge as well as the main research methods for each discipline.

According to Mora et al (2006a) there is not a standardized definition of what is SE, SwE and IS. Nevertheless, from several sources (INCOSE, 2004; SEI, 2003; MIS Quarterly, 2006), it is feasible to report the common definitions. Their systemic analysis is done with the construct <PQR-system> (Checkland, 2000) and exhibited in Table 1. From Table 1, it could seem that the systems of study for each discipline are disparate: a physical system, a software system and an IT-based system. However, the definition for SE implies the integration of several engineering disciplines as the physical system demands a special expertise for its development. In particular it has been identified a trend on the increasing development of systems coordinated by SE that are intensive in software (Andriole and Freeman, 1993; Bohem, 2000, 2006). Rhodes (2002) –nevertheless – remarks that software is other critical component like hardware and people involved in the entire man-made organizational system developed by systems engineers.

In turn, in the SwE discipline has been suggested that software systems must be considered as socio-technical software-intensive systems –e.g. "*systems where some of the components are software-controlled computers and which are used by people to support some kind of business or operational process … therefore, always include computer hardware, software .., policies and procedures and people … [and] operate in a systems-rich environment where different systems are used to support a range of different processes*" (Sommerville, 1998, pp. 115).

For the IS discipline, the new definition of software systems corresponds to what is considered an *Information System* (Mora et al, 2003). Furthermore, as it was already indicated, SE discipline is facing the challenge of design and development of more very complex and large systems where not only the technical or operational issues are relevant but also the political and economic ones. A specific new direction on these new demands is through the concept of System of Systems Engineering (SoSE) (Keating et al, 2003). Hence, then there are initial evidences of a required interaction between the SE, SwE and IS disciplines due to the common sub-systems or components based on software or IT in the whole systems addressed by SE.

Table 2 exhibits the relation of the three disciplines of interest with their reference disciplines through a qualitative 5-points scale from 1 (very low support) to 5 points (very high support). These disciplines shares common reference disciplines. Table 2 was populated from a conceptual analysis of several sources (Sage, 2000; Emes et al; 2005 for SE, SWBOOK (IEEE, 2001) for SwE, and Culnan & Swason, 1986; Vessey et al, 2003; Glass et al, 2004; for IS). A different grey intensity level is also used in the cells to emphasize the support score assessed for each discipline. From Table 2, some useful inferences can be supported. Firstly, SE and IS disciplines have been shaped by at least two fundamental disciplines (IE/OR and MS&OR for SE; B&OS, S&BS and IS self-referenced for IS). However, for the case of SwE seems to be a weak disciplinary reference support where only CSc (e.g. with a 5 points level) was fundamental in its original development. Furthermore, SwE was largely considered as a research stream and body knowledge of Computer Sciences (Denning et al, 1989). Nevertheless, in the last decade, it has been recognized in SwE the relevance of disciplines such as: SE, MS&OR, and B&OS (Kellner et al, 1991; Fuggetta, 2000). Secondly, despite of the Systems Science should be a common discipline (at least by the utilization of the concept *system* in the name of two disciplines and the emergent software-intensive system engineering discipline posed for SwE), only SE has kept it as strong theoretical foundations for the discipline.

In the case of IS, Systems Science was an original discipline of reference as main two IS research frameworks report (Nolan & Wetherbe, 1980; Ives et al, 1980). However, despite some proposals have been reported in IS literature to re-incorporate it (Mora et al, 2003; Gelman et al, 2005; Alter, 2006), few evidences of a reincorporation of Systems Science exist at present. SwE also seems to be an

Information Systems	●	●	●●●●●

isolated discipline with few interactions with Systems Science. New proposals to interact with SE could robust it. Thirdly, while SE and SwE disciplines have started to acknowledge the need to interact between them in order to study and develop better software-intensive systems, the IS discipline still ignores this fact. Few efforts have been reported and more related studies in IS research despite do not address the SE discipline directly, are focused on a Design/Engineering paradigm (Hevner & March, 2003; Hevner et al, 2004). However, from a systemic view it can be argued that the SE discipline is a clear reference also for IS and it has been largely ignored in IS research, teaching and praxis.

Table 3 exhibits the main knowledge areas and general research streams derived for these disciplines from several sources. From Table 3, a first inference is that SE and SwE disciplines –by its engineering heritage- are most likely to interact in next 25 years. The IS discipline, in contrast seems to be unaware of the dramatic changes and challenges that world organizations are demanding via the emergence of complex socio-technical systems. A second argument is that in the cells with very low interaction (value of 1 point) is required an increment in the interaction in order to the discipline reduces the lack of such body of knowledge and with it can have a entire and holistic view of the systems studied and intervened. This implies –according to the Systems Approach- that any system only can be understood if it is studied: (i) from two perspectives (like a unitary whole or a set of parts interdependent) and (iii) within its wider system and comprising internal subsystems (Ackoff, 1971; Gelman & Garcia, 1989). Details of the need of Systems Approach in IS discipline has been also reported (Mora et al, 2003; Alter, 2003; Gelman et al, 2005; Mora et al, 2006b). Finally, Table 3 shows that SE requires fewer missing interactions than other two disciplines. A strong implication of this situation is that systems engineers are more holistically trained to cope with the study and implementation of large-scale and complex systems than software engineers and information systems practitioners. It is also worth

Engineering Approach (Design of Artifacts)	●●●	●●●	● (Required)
Behavioral Approach (Survey, Case Studies, Social Experiments)	●●●	● (Required)	●●●●●

noting that IS frameworks and standards/models of processes (like CobIT, ITIL and derived) are scarcely researched and taught at present.

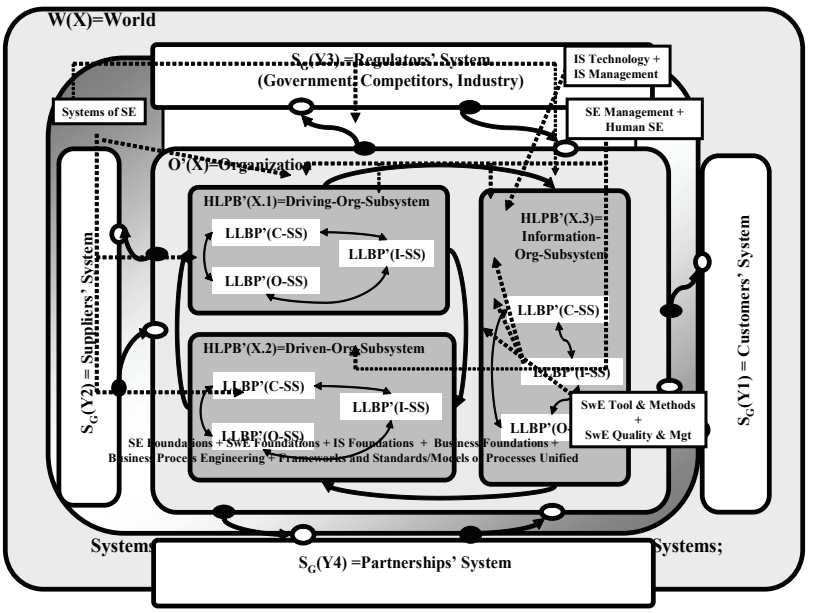
The Table 4 reports the levels estimated of types of research approaches mainly used in the three disciplines. Main categories of research approaches are adapted from Denning et al (1999), Hevner & March (2003) and Glass et al (2004). Theoretical and Modeling approaches can be considered pieces of conceptual research that study concepts, constructs, frameworks, methodologies, algorithms and systems without take data directly from real artifacts. Engineering and Behavioral approaches, in contrast, are pieces of empirical research that take data directly of artifacts, people or organizations.

The Table 4 shows that SE research is conducted mainly through a Modeling Approach–which is a core approach used in Systems Approach- but it also uses the other research approaches in a more balanced way than the other two disciplines. According to Glass et al (2004) theoretical/conceptual studies are more frequent than engineering studies in SwE. However, as a contrast with SE discipline, the modeling/simulation studies are few conducted. For the case of IS, due to its strong historical dependence of O&BS, most studies conducted are classified in the empirical approach (behavioral approach). The theoretical/conceptual studies are in second place and it is because of the B&OS influence. Recent studies have argued the necessity to use modeling/simulation (Mora et al, 2006b) and engineering approaches (Nunamaker et al, 1991; Hevner & March, 2003; Hevner et al, 2004) in IS discipline. In similar way, other studies have suggested that SwE must conduct empirical research (Kitchenham et al, 2002) and wide the few modeling/simulation approaches used.

THE MANAGEMENT & ENGINEERING OF IT-INTENSIVE SYSTEMS: AN INITIAL CASE

To complete this initial case, a description of how the integrated body of knowledge is required to cope with the management and engineering of complex IT-based information systems is reported by using a systemic IS research framework (Mora et al, 2006b; Mora et al, 2007a, 2007b). Figure 1, shows a mapping of knowledge streams reported in Table 3 into the main systems of interest for each discipline: the information organizational system for IS, the operational (information) subsystem for SwE and the driving, driven, information organizational systems or entire organization within the wider system called *world* and composed of the suppliers' system, customers' system, regulators' system and partnerships' system.

Figure 1. Mapping of SE, SwE and IS body of knowledge into the common systems of interest



Systems Thinking, Systems Foundations and Modeling/Simulation of Systems topics are suggested for being the most essential theoretical foundation for the common new integrated discipline. A systems thinking enables to practitioners and researchers to analyze any complex situation as a particular system of interest. In turn, the different conceptual systemic tools let them elaborate hierarchical models with the level of detail required for being studied or intervened. This holistic view of the situation can accommodate hard, soft and critical perspectives (Mora et al, 2007a), as well as quantitative or qualitative modeling. Fragmented and partial views of the systems of interest are reduced. Systems Thinking correctly applied also enables to formulate problems considering all stakeholders' rights.

In next level of common foundations, we suggest the integration of SE, SwE, IS and Business foundations as well as the topics of Business Process Engineering and Frameworks and Standards/Models of Processes. As it was identified, the most worldwide influential standard of processes (ISO 9000 series) has been founded in eight principles, two of them related with Systems Approach (Principle 5) and Process Approach (Principle 4). Furthermore, standards and models in SE and SwE have finally converged in unique view such as the CMMI-DEV, and ISO/IEC 15504 attest. A missing theoretical link between the concepts of *system*, *proces*s and *service* is missing but some initial efforts are being developed (Mora et al, 2007b).

The topic of SoSE (Systems of Systems Engineering) is also recommended as part of the body of knowledge of this integrated discipline because the emergence of large-scale and complex IT-intensive organizational and man-made systems. SoSE is an extension to classic SE methods to cope with systemic problems (negative emergent proprieties) generated for the composition of systems which subsystems works themselves as whole systems (Sage & Cuppan, 2001; Keating et al, 2003). In next level, the topic of SE Management and Human SE is suggested to address the organization as a system with your main three subsystems: the driving-organizational, the driven-organizational and the information-organizational subsystems. This view supports a modern cybernetic perspective based in control as a coordination act rather than a coercion act (Gelman & Garcia, 1989; Mora et al, 2003; Reyes, 2007). The IS Technology and IS Management topics are suggested to study and intervene on the information-organizational subsystem that is responsible to generate all IS/IT services in the organization (Mora et al, 2003; 2006a). Finally, to complete the mapping of the topics found in Table 3, the SwE Tools&Methods and SwE Quality & Management topics are required to study and intervene in the three sub-systems within the information-organizational subsystem. Each one of these subsystems, in turn, are composed of *systems* of tasks, personnel, tools&infrastructure, methods&procedures and socio-political issues (Mora et al, 2003; 2006a).

Hence, from the literature reviewed, the four tables of evidences generated and the mapping of concepts exhibited in Figure 1, we consider that an initial case for the interaction of SE, SwE and IS disciplines has been generated. Further research to refine and extend the knowledge and research topics will be conducted in next semesters by authors. Main benefits of this study are: (i) the novelty of the analysis on the body of knowledge of these disciplines that are required to interact in the short-term and be integrated in the long-term; (ii) the identification of the rationality for this interaction and integration suggested and (iii) the availability of a conceptual map of the systems of interest in the three disciplines for easing this interaction/integration. In turn, the main barriers for its acceptance are (i) the willingness for an interdisciplinary and systemic effort required and (iii) the lack of utilization, teaching and research based in Systems Approach in SwE and IS disciplines at present. In the meanwhile, however, we believe that IS and SwE community has been alerted of the emergence of these topics. A similar unified research effort is also conducted by the Service Science Management and Engineering initiative (Chesbrough & Spohrer, 2006). Its link with this research is required for further research.

ACKNOWLEDGMENTS

This research is being developed with the financial support of the Universidad Autónoma de Aguascalientes (Project UAA-PIINF-06-8) and the PROMEP support assigned to the Academic Group in Management and Engineering of Systems and Information Technologies at UAA.

Broadband Technology Services: A Survey of New Zealand ISPs

Nurul I. Sarkar, Auckland University of Technology, New Zealand; E-mail: nurul.sarkar@aut.ac.nz
Elaine Wong, Auckland University of Technology, New Zealand

ABSTRACT

Broadband technology services becoming increasing popular among home and offices users worldwide as the Internet access technology. This paper reports on a survey of New Zealand Internet Service Providers (ISPs) focusing on the current state of broadband services, the level of deployment, reasons for non-deployment, the scope of deployment, investment in deployment, problems encountered, and future plans. The study was conducted using a postal survey. A self-administered questionnaire was sent to some 40 New Zealand ISPs and a total of 15 replies were obtained from the respondents. Survey results show that New Zealand's pace in broadband technology services is still lagging behind the developed countries.

INTRODUCTION

Broadband technology services are becoming increasing popular for high-sped Internet access for both home users and businesses worldwide (Clarke & Kanada, 1993; Cloetens, 2001; Oh, Ahn, & Kim, 2003). More about Broadband services in New Zealand can be found in (Putt, 2006; *Wikipedia*, 2006; Williams, 2006).

In this paper, we report on a survey of New Zealand broadband technology services providers. The survey seeks to gauge the broadband technology awareness in New Zealand, including deployment of broadband services and users (type and the number of users adopting broadband services), ISPs' experiences with broadband technology and future plans (problems with deployment and maintenance). See Appendix for survey questionnaire.

To gain an insight into the broadband technology services in New Zealand, we compared our survey results with some developed countries. We found that New Zealand's pace in broadband technology is actually lagging behind a majority of the developed countries, including Australia and the USA.

COMPARISON

Digital subscriber line (DSL) is a popular broadband Internet access technology worldwide. Overall, 62% users are using DSL and its variants, 31% Cable modem, and the remaining 7% of users using other technologies, such as wireless and optical fibre.

Table 1 compares broadband subscribers per 100 inhabitants of 30 countries over 2001-2005 (http://www.oecd.org). It also shows OECD average and EU15. As seen in Fig. 1, New Zealand is lagging behind 21 developed countries in broadband subscribers and is below the OECD average. A summary of survey results are presented next.

SURVEY RESULTS

In this section we present the key results of the survey on broadband technology services provided by New Zealand (NZ) ISPs. All costs are in NZ$.

- **Deployment:** Twelve ISPs (out of 15) have indicated that they are currently providing broadband services. Three ISPs indicated that they are not currently providing broadband services, but are planning to offer them in the future. Those who are planning to provide broadband services either considered it too expensive or complicated, which is why they have not implemented broadband services yet.
- **Year of deployment:** The year that each ISP deployed broadband services ranged from 1996 – 2005. The larger ISPs have begun earlier, whereas some smaller ones may have only just began offering broadband services or planning to offer them in the future.
- **Technology:** Eleven ISPs have indicated that they are providing asynchronous digital subscriber line (ADSL) and wireless broadband services, two ISPs

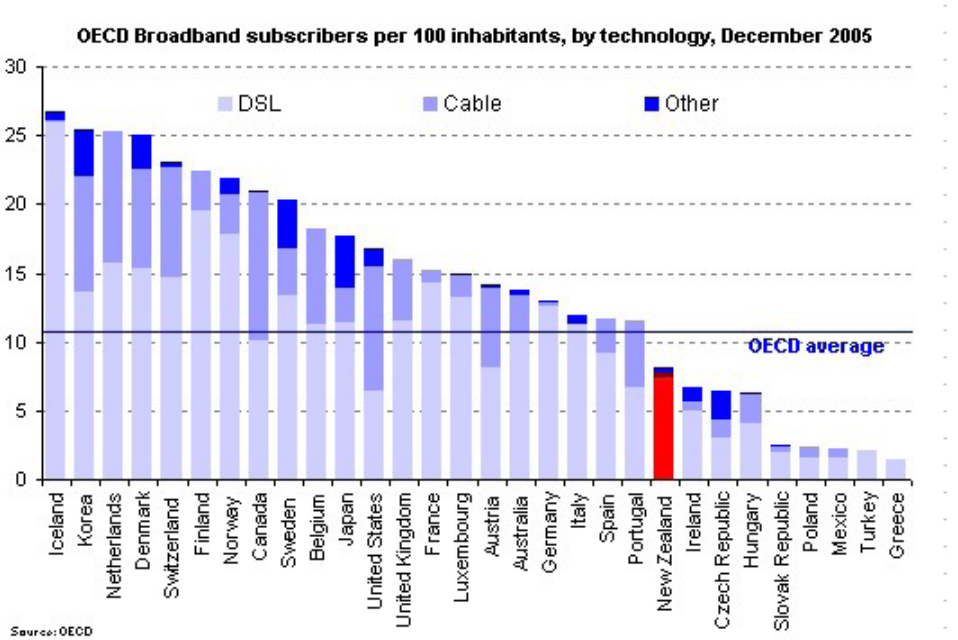
Italy	0.7	1.7	4.1	8.1	11.9	United States	4.5	6.9	9.7	12.9	16.8
Japan	2.2	6.1	10.7	15.0	17.6	**OECD**	**2.9**	**4.9**	**7.3**	**10.2**	**13.6**
Korea	17.2	21.8	24.2	24.8	25.4	**EU15**	**1.6**	**3.4**	**5.9**	**9.7**	**14.2**

Figure 1. Comparison of broadband subscribers in OECD countries (Source: http://www.digitalstrategy.govt.nz)



indicated that they are offering cable modem, and the rest, two ISPs providing fibre optic and frame relay services. Although some ISPs offering several types of broadband services, ADSL services appear to be the most popular in New Zealand.

- **Cost of deployment:** Six ISPs have indicated that they have invested over $100,000 for the deployment of broadband services. Five ISPs indicated that they spent less than $10,000, one ISP spent from $10,001 to $20,000, and the remaining three ISPs did not provide deployment cost.
- **Setting up broadband services:** Six ISPs have indicated that they have implemented broadband using in-house services. Two ISPs indicated that they have implemented broadband services using third-party, and the remaining seven ISPs did not provide this information.
- **Deployment time:** The deployment time ranged from one week to six years and beyond. This was also dependent on whether the ISP was deploying in-house or whether they were reselling services to other ISPs.
- **Type of users:** Most of the ISPs (12 out of 15) are providing services to both residential customers and businesses, whereas the rest three ISPs offering services to government and schools. More users tend to connect to ADSL at 256 kbps, but gradually moving towards higher speeds.
- **Problems encountered:** Main problems associated with broadband deployment in New Zealand including, too many constraints, no system in place, making everything to be done was manual, poor support, problem with changeover from one ISP to another, limited visibility of network infrastructure, resource management, integration of broadband, and not adhering to their own procedures, bad congestion of network and outages due to overselling of services, restrictions to speed and price, constantly changing or deleting plans, everyone having to follow Telecom's rules, and time delays with ISPs that were not Telecom's. Other problems encountered include some technical difficulties, users have problems with understanding what to do, difficulty in contact regarding installation, reliability of ADSL in some areas were poor, slow and cumbersome installation, lack of government regulation, capital costs for building own network, and difficulty to make a profit.
- **Future plan**: The future plans for the ISPs, including wireless broadband services, continue to provide all available broadband services with better deals, build their own fibre optic network, and concentrate on business customers.

CONCLUSION

We have surveyed 50 large New Zealand ISPs to identify the current state of broadband services, the level of deployment, reasons for non-deployment, the scope of deployment, investment in deployment, problems encountered, and future plans.

While there is an increase in users opting to use broadband services worldwide, New Zealand is still lagging behind in broadband technology services and usage compared to other developed countries, including Australia and the USA. This lagging is due to the lack of users' knowledge about broadband services, high services cost, and the Telecom NZ monopoly on local loop (Nowak & Thomson, 2006).

APPENDIX: SURVEY QUESTIONNAIRE

Section 1: Broadband Technology Awareness

All respondents complete this section.

1. What is the current state of the broadband services that you offer? (Tick one)
   We will not provide broadband services at all.
   We are planning to provide broadband services in the future.
   We are currently providing broadband services to customers.

2. If you are not offering broadband services, or has decided against it, why is this? (Tick all applicable)
   Unaware of it.
   Consider it too expensive.
   Consider it too complicated.
   Other (Please specify)

Section 2: Deployment of Broadband Technology

Only respondents that are providing broadband services complete this section.

3. Which year did you first offer broadband services?

4. What type of broadband services are you providing? (Tick all applicable)
   ADSL
   Cable
   Wireless
   Other (Please specify)_____

5. How much did you spend ($) for the deployment of broadband services? (Tick one)

< = $10,000	$40,001-$50,000	$80,001 - $90,000
$10,001 - $20,000	$50,001-$60,000	$90,001 - $100,000
$20,001 - $30,000	$60,001-$70,000	> $100,000
$30,001 - $40,000	$70,001-$80,000	

6. How did you set up or deploy broadband services? (Tick all applicable)
   In-house staff.
   Third-party specialist.
   Other (Please specify)_____

7. How long did it take to deploy broadband services? _____

8. Were there any problems that you encountered during the deployment of broadband services?

Section 3: Users of Broadband Technology

Only respondents that are providing broadband services complete this section.

9. What types of users are using broadband services provided by you? (Tick all applicable)
   Residential
   Business
   Other (Please specify)_____

10. Approximately how many users are you providing services to?

a. Residential

< = 100	301 – 400	601 – 700	901 - 1000
101 - 200	401 – 500	701 – 800	> 1000
201 - 300	501 – 600	801 – 900	

b. Business

< = 10	31 – 40	61 – 70	91 - 100
11 - 20	41 – 50	71 – 80	> 100
21 - 30	51 – 60	81 – 90	

c. Other (As specified in question 9)

< = 10	31 – 40	61 – 70	91 - 100
11 - 20	41 – 50	71 – 80	> 100
21 - 30	51 – 60	81 – 90	

11. Which type of broadband service do most users choose? (Tick one)

a. Residential
   ADSL
   Cable
   Wireless
   Other (Please specify)_____

b. Business
   ADSL
   Cable
   Wireless
   Other (Please specify)_____

c. Other (As specified in question 9)
   ADSL
   Cable
   Wireless
   Other (Please specify)_____

12. Which plan (speed) is the most popular choice for users? (Tick most applicable)

a. Residential

256K	2Mb	5Mb
512K	3Mb	6Mb
1Mb	4Mb	> 6Mb

b. Business

256K	2Mb	5Mb
512K	3Mb	6Mb
1Mb	4Mb	> 6Mb

c. Other (As specified in question 9)

256K	2Mb	5Mb
512K	3Mb	6Mb
1Mb	4Mb	> 6Mb

Section 4: Experiences with Broadband Technology

Only respondents that are providing broadband services complete this section.

13. What issues have you encountered with providing support to users for these broadband services, if any?

14. What issues have you encountered with the network performance and management of broadband services, if any?

15. Any other issues that you are facing now?

16. What are your plans for the future of broadband, if any?

E-Government in Caribbean States: From Rhetoric to Reality

Stewart Bishop, University of the West Indies, Barbados; E-mail: osbishop@uwichill.edu.bb

OVERVIEW

Caribbean States have undertaken E-Government initiatives to streamline administrative processes and to improve customer service. Meanwhile there has predictably been much hype surrounding such moves with lofty promises being made about the "leveling of the playing field". As with current E-Commerce efforts in this region there has not been the ready acceptance and support that might have been expected. This contribution focuses on the E-Government initiatives made by Jamaica, Trinidad and Tobago, and Barbados, perhaps the most developed of the English speaking Caribbean States and represents the initial phase of a larger project aimed at determining the Caribbean reality with respect to E-Government.

BACKGROUND

The three countries chosen for this study have been the leaders among English speaking Caribbean states in terms of their political, economic and developmental status. Jamaica (population of 2.6m) and Barbados (population of 0.25m) have followed very similar paths towards socio-economic development having had an agricultural and, more recently, small manufacturing background. Trinidad and Tobago (population of 1.3m) although having some involvement in those areas has an economy built on oil and gas resources contributing approximately 25% of its GDP. These countries share a common historical, political and cultural tradition and are all members of a regional grouping of English speaking countries called the CARICOM Community.

The removal of trade preferences enjoyed by these States in their trade dealing, mainly with Europe, has seen them gravitating towards a services economy. This international business and financial sector is characterized by fierce global competitiveness with corporations in the developed countries being very demanding in their dealings with their outsourcing partners. Information and Information and Communications Technologies (ICTs) have become critical components for both public and private sector agencies in transacting business.

ICT investments in over three decades have led to some gains in efficiency and effectiveness but much more is required. Indeed these countries have since the Nineties undertaken Public Sector Reform (PSR) to improve administrative capacity and reduce bureaucracy. Such reform has identified the need for better information availability and greater application of information systems in the public sector. Thus while the link between ICT and PSR has definitely been recognized, there has also been the realization that, in at least one of these countries, the public sector information systems might have been haphazard, if not archaic. Stagnation after earlier gains from such systems and failure to undertake evaluation of ICT implementation have been suggested to be major hindrances in the realisation of full benefits from use of these new technologies.

The temptation then might be to leapfrog and fast track the establishment of portals to bring these developing countries into the Information Society. About such thinking and the adoption of E-Government itself, Heeks cautions:

"Simply pulling Northern and/or private sector solutions off the shelf and trying to impose them on public sectors in developing countries will be like driving square pegs into round holes. E-Government solutions must be adapted, not simply adopted, to ensue that the design matches Southern realities."

He further identified two other challenges facing developing countries, namely e-readiness and large design-reality gaps, i.e. differences between design ideas and organizational realities in small States. While E-Government presents outstanding opportunities to effect more efficient and effective service delivery, planning of the transformation to E-Government is perhaps the single most important issue facing most governments today.(Sharma and Gupta 2003)

The introduction of E-Government in small states has also been likened to the creation and sustained development of an organization associated with which there are:

- external fundamentals related to its existence within its environment and community.
- internal and external stimuli contributing to its success and sustainability.

While there are challenges and threats to its eventual development, the opportunities and benefits can be most attractive. Among the critical success factors suggested for successful E-Government transformation are:

- entrepreneurship with risk taking and astute business management in this strategic undertaking. The nurturing role of project champion is very crucial.
- alliances with the private sector, other governments and international agencies.(Bishop and Savoury 2004)

CARIBBEAN E-GOVERNMENT INITIATIVES

Globally the move towards E-Government has been as a result of pressure from citizens groups, the private sector, other governments or even international agencies. Over jealous politicians may even see it as a way to boost their stakes in the eyes of the electorate. Governments have adopted different approaches towards the adoption of E-Government globally in both developed and developing countries.

The participation of Caribbean states in the World Summit of the Information Society and the assistance of the Economic Commission for Latin America (ECLAC) have been of tremendous help in the planning and transformation of their E-Government initiatives.

Sharma and Gupta (2003) have conceptualized a framework for E-Government implementation which will be used to evaluate the initiatives undertaken by the three States. This has been chosen since its building blocks correspond closely to the actual approach taken by the countries. The following phases in the transformation to E-Government are outlined:

i. the creation of a network and technical infrastructure in the form of public data communication network infrastructure and servers, e.g. internet, intranets.
ii. the digitization and data integration process with document management systems, e-mail, data management systems and data warehouses.
iii. the availability of internet and web-enabled E-government service with departmental web sites providing static information as well as two-way communication. The ultimate stage is the provision of a portal facilitating self service applications.
iv. the facilitation of user access to web-enabled services through multiple communication channels and access points, e.g. cell phones and personal digital assistants.

This framework should have a supporting infrastructure which would, inter alia:

v. create E-Government awareness.
vi. build a legal and regulatory infrastructure.
vii. create a critical mass of manpower and skills.

ECLAC conducted a series of surveys of various Caribbean states, including Jamaica, Barbados and Trinidad and Tobago, in 2006 in which progress towards the creation of an Information Society was investigated. The results of those surveys can be evaluated based on the above framework.

Phase 1 – creation of technical infrastructure. All states have completed the liberalization of their telecommunications sectors and there is vibrant competition between service providers. Internet access varies from 40 and 55 % of population in Jamaica and Barbados respectively to 12% in Trinidad and Tobago. Between 60 and 100% of the populations have mobile phones with broadband access estimated at about 10% . Regulatory institutions e.g. Fair Trading Commissions and Telecommunications Units have been set up. Some governments have also removed the import duty on computer equipment.

Phase2 – data integration process. After over 3 decades of computerization the public sector abounds with on-line computer applications e.g. collection of taxes. Customs modernization programmes have been undertaken and initial steps are being made to implement specialized applications such as geographical information systems. Public sector accounting and human resources functions are integrated with the SMARTSTREAM system.

Phase 3 –E-Government and ICT-related portals. Most ministries and several public sector units in the states have established a web presence. These are maintained by computer units within individual units and ministries. There are however central information technology centres in each state which have ultimate responsibility for that state's official Portal. These Portals are expected to be fully functional within 2 years. Currently static information is provided on most web-sites.

Phase 4 – User access. The states are not currently at the stage to tackle this aspect.

Phase 5 –Creation of E-Government awareness. The states have all established E-Government Units as well as E-Commerce Units to coordinate their initiatives. Additionally progress has been made towards the development of National Strategic ICT Plans with coordination by National Committees. To provide a more focused thrust specific responsibility for ICTs has been assigned to a particular ministry. There is in each state a high-powered committee, e.g. *the Fast Forward* Steering Committee in Trinidad and Tobago, comprising Government Ministers and Senior Officials which provides oversight, strategic guidance and sign-off on the matter of a National ICT Strategy.

Phase 6 – Legal and regulatory infrastructure. Both Barbados and Trinidad and Tobago have passed or have under consideration some legislation dealing with electronic and digital crime. Barbados has actual legislation on Electronic Transactions, IT Misuse and Consumer Protection with Data Protection and Freedom of Information Bills under active consideration. In Trinidad and Tobago Computer Misuse, Freedom of Information and Electronic Transfer of Funds Crime Acts have been passed but Data Protection and Digital Signatures Bills have been circulated for comment. Jamaica, on the other hand, has only Freedom of Information legislation.

Phase 7 – Creation of critical mass. E-Learning initiatives have been undertaken in all states at the primary, secondary and tertiary levels with teacher training accorded a high priority. International agencies e.g Inter-American Development Bank have funded several initiatives in the educational sector. Computer literacy programmes are available. In Barbados, for example, there is a government-sponsored Community Technology Programme providing training at the community level in Internet and e-mail usage, word processing and other basic IT skills.

Overall the three states appear to be approaching the transformation to E-Government in a satisfactory manner according to the framework cited. With the accustomed regional consultations between them, they have been able to benefit from each others experiences. Furthermore the involvement of ECLAC has been of considerable assistance in the formulation and development of these E-Government initiatives.

FURTHER WORK

This contribution reports on the initial aspect of the project, namely the preparatory steps taken by the three states towards E-Government. Other aspects would be:

i. Determination of their relative levels of e-readiness. Included herein could be the e-Government acceptance by citizens and stakeholders as well as their active involvement.
ii. Implementation issues being faced by the states.
iii. Possible comparisons with similar developing countries in terms of internet and economic capabilities in Asia to determine differences in approaches.
iv. Possible strategies for other developing countries not yet undertaking E-Government transformation.

Semantic Web Services Approaches: A Comparative Analysis

Umesha Sridharamurthy, Infosys Technologies Limited, India; E-mail: umesha_s@infosys.com
Anubhav Pradhan, Infosys Technologies Limited, India; E-mail: anubhav_pradhan@infosys.com

ABSTRACT

"Hyperlinks are legacy and Web Semantics is the future". This statement truly represents the spirit of future web. Web is the ever growing phenomenon and web services are one of the most important ingredients of the Web recipe. Our work-in-progress primarily focuses on the comparative analysis of various approaches for the Semantic Web Services. We are going to summarize the analysis on the basis of various functional and non functional parameters related to the Web Services. We will be delivering our findings in a ready-to-use comparative matrix which may be used by the semantic web development practitioners and the semantic web researchers alike.

INTRODUCTION

Enterprise application unification and Business process management are the heart and soul to run businesses in the current internet era and Web Services are one of the vital technical components, playing an integral role into it. Existing Web Services standards including UDDI, WSDL are playing a pivotal role in the current web services scenario by providing the syntax for development and implementation of the web service but they lack in providing the semantics. Semantics in the web is the key for the future web. Lots of efforts are being made in this direction and various Web Services approaches like WSMO, OWL-S, and WSDL-S are unfolded in the due process. These approaches have their own pros and cons with respect to fulfilling the expected functional and non functional requirements of any working web service. Few of the semantic web services approaches like WSDL-S are evolutionary and are based on the existing WSDL standards. On the other hand semantic web services approaches like WSMO and OWL-S are absolutely revolutionary.

We have selected four predominant semantic web services approaches for the detailed study with respect to the functional and non functional parameters, as expected from any working web service. We are in the process of comparing the WSMO, WSDL-S, OWL-S and SWSF semantic web services approaches on various functional and non functional parameters. Few of the functional parameters under considerations are web service publication, discovery, selection, composition, mediation, compensation, replacement, invocation, orchestration, choreography etc. Few of the non functional parameters on which we are focusing the comparison are robustness, availability, scalability, security, network-related QoS, transactional, performance, trust, reliability etc.

RESEARCH GOALS

Semantic web industry confronted with various Semantic Web Services approaches in its day to day development and implementation processes. We believe that this area is bit diverged. Our research is targeted to understand all the predominant semantic web services approaches and to compare all of them with respect to functional and non functional parameters. In the process we will come out with a detailed comparison matrix. We believe that our research findings will surely help the semantic web industry to take a big leap into the next generation of the web services.

Criteria to Assess the Adaptability of Software Engineering Approaches

Katja Andresen, University of Potsdam, Germany; E-mail: Katja.Andresen@wi.uni-potsdam.de
Norbert Gronau, University of Potsdam, Germany; E-mail: Norbert.Gronau@wi.uni-potsdam.de

ABSTRACT

Because of the characteristics of contemporary system development and system evolution, it appears necessary to come up with an approach that allows the permanent and evolutionary engineering of software for new and already-existing information and application systems. The requirement is to plan and construct with room for changes, adoptions and enhancements since this will happen in the lifetime of every large software product. This contribution provides first research results to plan for adaptability in software engineering based on the research project IOSEW[1]. For that criteria are explored which promise assessing software engineering approaches for adaptability. The contribution is submitted as research in progress paper.

FOUNDATION

Adaptability applies biologically-inspired methods to enhance the capabilities of the system in focus. Adaptability comprises several qualities. Within this contribution the term adaptability is to be understood as the ability of a system to adapt itself efficiently and fast to changed demands. An adaptive system is an open system that is able to adapt its behaviour according to changes in its environment or in parts of the system itself. Additionally, it recognises the demand for change itself. The structure is determined autonomously on the basis of the systems purpose and information exchange with the environment.

VIEW ON SOFTWARE ENGINEERING APPROACHES

What would adaptability mean for software engineering approaches? The goal is that the software system can be adapted over time by humans to changing conditions (termed as design-adaptability by Oreizy and Gorlick, 1999). Transferring the cybernetic view on systems on engineering approaches, the system elements would comprise the procedure model (e.g. waterfall, v model) and phases, the (human) actors also tools and surrounding conditions as organizational units, pre-set decisions et cetera.

CRITERIA TO ASSESS SOFTWARE ENGINEERING PROCESS MODELS

This section identifies criteria to reveal the adaptive capacity of software engineering procedures. The first set originates from factory planning but has also been successfully applied to assess and design for adaptability in information systems [Andr06]

Scalability

Scalability refers to the permanent state to operate effectively and efficiently at many different scales. A system is supposed to be scalable if it will remain effective when there is a significant increase/decrease in the number of recourses.

For the software development process scalability stands for the seamless addition or reduction of system elements as actors, resources, tools, functions. The process model is scalable if control structures as loops and iterations can be inserted or deleted leading to the above mentioned steps. The evaluation might be based on diagnosis features.

Modularity

Modularity generally means the structuring of a system into small, partly autonomous subsystems [WiPi+97]. A module consists of a module trunk and a module interface. The interface contains a specification on the characteristics to connect and communicate, which are of importance for its surrounding field.

The phases of a procedure model correspond to the idea of modules. Each phase defines a function, e.g. requirements analysis or testing. Within each phase activities and results may be defined. For example, the result of the requirements phase as a set of documentation.

Interoperability

This indicator refers to the ability of resources to place a high measure of compatibility and connectivity. It is commonly realised by deploying interface standards in the domain of information system architectures [HaSt03].

Interoperability in the context of procedure models stands for the transfer of input or output from one phase to another. The results of the requirements phase should be applicable in the next phase.

Independence

Independence raises the question of spatial and temporal unlimited access to subsystems (components). In information systems the criteria independence is interpreted as unlimited access to applications, functions and data by different technologies as web-browser, terminal-server for instance. Within software engineering the criteria adds an organizational aspect. If the phases of the procedure model are independent they can be performed at any location, in any country at any time for instance.

Redundancy

It is a principle in nature that important functions can be taken over by a near-by system if another breaks [Vest02]. Redundancy requires a fall-back strategy, if failure or unforeseen events happen. An engineering approach considering redundancy checks for results by control strategies as feedback loops and provides alternatives to solve process steps. Does the procedure model provide support for the change of organizational units along the development process?

Self-Organization

Self-organization (autopoiesis) marks the ability of a system to determine the systems structure by adjusting and steering mechanisms related to processes within the system in order to ensure the long-term existence of the system [MaVa87]. Thereby the resources and subsystems produce their own order by taking up information about their environment and their reciprocal effect with the environment.

Self-organization in software engineering is a goal oriented process whereby the phases define the main goals. However, the engineering process model does have to ensure the correct result along with the adequate means to (efficiently) deliver the outcome. It requires learning qualities as double-loop learning. Self-organization is one of highest form of behaviour of complex systems.

Knowledge

Knowledge about the engineering model denotes both – the person-bound and the explicit knowledge [GrKo+05]. The latter is presented for example in the form of writing fixed processes, rules, guidelines, responsibilities, communication channels, programming language and more.

Knowledge and information access support the rapid implementation of functional and organisational changes in general or the handling of the software specifically.

NEXT STEPS

A logical next step is the application of the criteria to discuss established process models as the V model, RUP (Rational Unified Process or eXtreme programming).

Research Problem in Distributed Data Warehouse Environment

Karima Tekaya, ISI ARIANA, Tunisia; E-mail: Karima.Tekaya@isi.rnu.tn

We can't ignore the advantages realized during the past in the area of distribution and support for data localization in a geographically dispersed corporate structure. Therefore, many researches to date investigate building distributed data warehouses with particular emphasis placed on distribution design for data warehouse environment. This article presents the state of the art concerning many process of data fragmentation in data warehouse environment and proposes a number of technical issues that we believe are suitable topics for exploratory research.

1. INTRODUCTION

The users of Data Warehouses do not cease increasing. They are divided more and more geographically on several sites. In addition, data warehouse are characterized by their large size and by the complexity of decisional query requiring several operations of joins and aggregation. Consequently, centralized Data Warehouses are not adapted more to this kind of companies and generate an elevated cost of query execution. To answer to this new need, several techniques of fragmentation have been proposed for the decentralization of a data warehouse, and the optimization of the cost of query execution. The following section, presents some works treating the distributed architecture for a data warehouse. In section 3, some data warehouse fragmentation techniques which exist in the state of the art are evoked and in the section 4, a number of technical issues that we believe are suitable topics for exploratory research will be presented.

2. ARCHITECTURE OF DISTRIBUTED DATA WAREHOUSE

In [Noaman, Barker, 1997] and in [Noaman, Barker, 1999], authors proposed an architecture for distributed data warehouse. It is based on the ANSI/SPARC architecture that has three levels of schemas: internal, conceptual, and external. This work is based on TOP/DOWN approach and presents two fundamental issues: fragmentation and allocation of the fragment to various sites. Authors proposed a horizontal fragmentation algorithm for a fact table of a data warehouse. In [TEKAYA, ABDELLATIF, 2004], we have proposed a methodology for relational distributed data warehouse design. For this purpose, we develop a set of matrix: 'Matrix of data partitioning', 'matrix of data allocation' and a 'matrix of data source' and in [TEKAYA, ABDELLATIF, 2005] we adapt the same methodology to the multidimensional environment. In [Noaman, Barker, 1997], [Noaman, Barker, 1999], [TEKAYA, ABDELLATIF, 2004] and in [TEKAYA, ABDELLATIF, 2005], a basic architecture of a distributed data warehouse has been proposed; we suggest the implementation of these works in a distributed data warehouse environment.

3. TECHNIQUES OF FRAGMENTATION IN DATA WAREHOUSES

Several works shows the importance of fragmentation in a context data warehouse, it represents today a more challenging stake that in a relational or objects database context. In addition, several commercial products showed the utility of fragmentation in the process of queries optimization: In [TEKAYA, ABDELLATIF, MCSEAI'04], we proposed a matrix of fragmentation, 'Horizontal Matrix of fragmentation ', making abstraction to the approach of modelling, this matrix permits from a logical table to generate a set of fragments and it has as input: queries and their frequencies of use. Thereafter, we proposed a matrix of allocation permitting to allocate every fragment to the most adequate site. One data can be a table or a fragment of table, this as while taking account of frequencies of data utilization and the priority of sites. In [TEKAYA, ABDELLATIF, ISDM'05] the same solution was adapted in a dimensional environment; we have experiment the solution through an example. In [TEKAYA, ABDELLATIF, AICCSA'05] the problematic of data warehouse fragmentation was presented and some arguments are showed to prove the importance of fragmentation in distributed data warehouses environment. Otherwise, several works of research and the commercial products showed the utility of fragmentation techniques in the process of queries optimization [Sanjay and al., 2004]. Horizontal fragmentation in data warehouses is more challenging compared to that in relational and object databases. This challenge is due to the several choices of partitioning schemas that can be found: [Bellatrech and Boukhalfa, 2005]

1. *Partition only the dimension tables using simple predicates defined on this table, t*his choice is not suitable for OLAP queries for the following reasons: Any partitioning that does not take into account the fact table is discarded. [Bellatrech and Boukhalfa, 2005].
2. *Partition only the fact table using simple predicates defined on this table, t*his choice has been adopted in [Noaman and Barker, 1999]. The proposed work is essentially based on:
   a. the proposition of a distributed architecture of a data warehouse,
   b. the formal definition of the relational modelling of a data warehouse by the application of normalization rules,
   c. the replication of dimensions on the different sites of the enterprise,
   d. regrouping of selection predicates on facts tables. (Criteria of fragmentation),
   e. the application of the horizontal fragmentation algorithm presented in [Özsu and Valduriez, 1991] and [S. Ceri and G. Pelagatti, 1984].

   The algorithm generates a set of horizontal fragment based on the definite applications on the dimension tables in link with the table of facts. Note that a fact relation stores foreign keys and raw data which are usually never contain descriptive (textual) attributes because it is designed to perform arithmetic operations. On the other hand, in a relational data warehouse, most of OLAP queries access dimension tables first and then the fact table. This choice is also discarded.
3. *Partition some/all dimension tables using their predicates, and then partition the fact table based on the fragmentation schemas of dimension tables, t*his choice has been adopted in [Bellatreche, Karlapalem and Mohenia,2000] and in [Bellatreche, Karlapalem and Mohania, 2002]. This work aims essentially to:
   a. Propose an algorithm for partitioning dimension tables and the fact table of a star schema, (b) Fragmenting the fact table based on all predicates given in OLAP queries might be prohibitive.

Therefore, authors showed that dimension tables play a very important role in fragmenting the fact table. They develop a greedy algorithm for selecting the best dimension tables for partitioning the fact table. (c) Develop a cost model for executing the most frequent OLAP queries on partitioned and unpartitioned star schemas, finally to evaluate the partitioning algorithm with some experiments study and show the tradeoffs partioned and unpartitioned data warehouse. This approach is best in applying partitioning in data warehouses. Because it takes into consideration star join queries requirements (these queries impose restrictions on the dimension values that are used for selecting specific facts; these facts are further grouped and aggregated according to the user demands. The major bottleneck in evaluating such queries has been the join of a large fact table with the surrounding dimension tables).

An evolution of the same work has been proposed in [Bellatrech and Boukhalfa, 2005]. The proposed work is essentially based on:

1. The Formalization the problem of the horizontal fragmentation in data warehouse environment using star join diagram,
2. The Developpement of a methodology of fragmentation for the fact table, which is based on the genetic algorithms,
3. The Description a coding process of fragmentation diagrams. In order to measure the quality of the chosen solution and a model of cost (selective function) have been developed,
4. The implementation of the proposed solution, by the development of a genetic motor in Visual C and to validate the achieved survey, they used a Benchmark APB-1 IIS releases [Council, 1998].

Authors proposed the development or the planning of the genetic algorithm to take account of the query evolution (structures and frequencies). They also aimed an auto-evolutionary data warehouse.

4. PROBLEMS AND RESEARCH ISSUES

Few works quantified contributions of fragmentation in a data warehouse context. Several axes of researches are opened and several ideas remain to explore. The main objective is to bring kindness of techniques used in distributed databases to the domain of data warehouses and benefit the implication of distribution especially on the process of queries optimization. Applications only work on subsets of relations. It is therefore preferable to distribute these subsets.

We can distribute the complete relations but it would generate a lot of traffic, either a replication of data with all problems that it causes (problems of updating and problems of storage). The small fragment utilization permits to make turn more process simultaneously, what drags a better utilization of the computer network.

Therefore, a problem puts itself: how a good degree of fragmentation to define? In fact, the objective aimed by researches essentially consists in formalizing the problem of the horizontal fragmentation in a data warehouse environment and to propose an algorithm permitting to solve it. This solution has been developed through the application of a genetic algorithm in [Bellatrech and Boukhalfa, 2005]. The solution admits as input a list of dimension tables, fact tables and a list of queries including a set of aggregations functions; as result the algorithm generate an optimized fragmentation diagram. Some authors appraise that the set of queries can changes (in the level of structure or frequency) and therefore it is interesting to develop an algorithm witch take in account the evolution of queries. It becomes especially very important for the evolutionary information systems like a data warehouses. Queries evolves according to the informational needs of the enterprise, this evolution has two types: frequency and structure. One request can become less frequent or same unused during the time, another one becomes more important but change of structure, (change of attribute or condition of restriction). Aggregations functions are very frequent and changes according to needs. Of this fact, we must answer to new requests (utilization of news tables dimension or of facts) witch can be very important for the information system and answers must be imminent for the decision making. Therefore, the static fragmentation diagram cannot answer to all these new constraints. Consequently, works may be oriented to develop techniques that permit to take in consideration the evolution of queries of a data warehouse and generate dynamic fragmentation diagrams.

5. CONCLUSION

Distributed data bases system is sufficiently complete to unload users of all competition problems, reliability, and optimization of requests or transaction on data managed by different DBMS on several sites. Of this fact, we studied the contribution of distribution in domains of data warehouses characterized by their big volume of data and by a number of users distributed geographically more and more. We noted that fragmentation plays today a more important role in a context of data warehouse that in a relational or object context, we put some problematic and oriented readers toward several axes of researches. We synthesized techniques of fragmentation that have been achieved in data warehouse context; we noted that can works be more developed. The domain remains opened for possible researches.

Introducing Computerized Accounting Information Systems in a Developing Nation: Egyptian International Motors Company (EIM) Case Study

Khaled Dahawy, The American University in Cairo (Auc), Egypt; E-mail: dahawy@aucegypt.edu

The use of computerized accounting information systems has become an integral part of accounting systems world wide. Most of the research and cases that examine issues related to choice and implementation of computerized accounting information systems have focused on developed nations. However, decisions relating to the choice and implementation of computerized accounting systems are very sensitive to cultural and environmental factors. Therefore, such decisions should be studied within the context of their own environments (Ismail and King, 2006). Environmental factors differ dramatically between developed and developing nations. In addition, within the context of developing nations, the cultural, political, and economic realities of each country are often very different. Therefore, it is better not to develop a standard prescription and make recommendations without first analyzing the specificities of each nation. Therefore, it is vital to improve our understanding of the process of choice and implementation of computerized accounting information systems in specific developing nations, such as Egypt.

The developments in both accounting and Information and Communication Technology (ICT) have made it easier for companies to migrate to computerized accounting systems. Accounting, in Egypt, has dramatically changed in the past ten years by the adoption of the international accounting standards (IAS) in 1992 followed by the dependence on the Egyptian accounting standards (EAS) in 1996 (World Bank, 2002). It is important to note that EAS were mainly a translated copy of the international accounting standards, with some differences[1]. This adoption increased the need for timely and accurate financial records, information, and statements. Integrating information communication technology (ICT) was described as one of the main tools to reach this end.

Egypt, as a developing nation faces many challenges in building an information society in order to bridge the digital divides. Egypt must overcome the barriers that constrain the use and spread of the new communications technologies and their applications. In Egypt efforts for ICT development are led by the government, in close partnership with the business community and the civil society (MCIT, 2006). The Egyptian government has focused on the development of ICT as a national priority to contribute to high and sustainable economic growth for the Egyptian economy. The government views the development of information and communications technology as a national priority. (American Chamber of Commerce in Egypt, 2002).

Egypt is trying to modernize itself technologically. There is a low PC penetration rate standing at 1.6 million stations although increasing at 50% growth rate annually (www.mcit.gov.eg). However, the investment and build-up of Egypt's information and communication technology infrastructure has taken massive steps since the early 1990s in different building blocks including human, systems, procedures, and hardware and information infrastructure (IDSC Annual Report, 2000).

The importance of the use of technology in accounting has been recognized by the Egyptian government. As part of a comprehensive e-government initiative, Egypt's Ministry of Communications and Information Technology (MCIT) has licensed a comprehensive range of Oracle technology to ultimately power and link up to 5000 financial units throughout the country. (MCIT, 2005).

This study aims to assess the implementation of accounting information system on a company in a developing nation. To answer this question this manuscript attempts to do the following: (1) identify the reasons for the shift to an automated system and the main goals that the company aim to achieve form this shift, (2) determine the company's strategic decisions like choices between outsourcing versus in-house development, and ready made packages versus tailor made software, (3) describe the steps of implementation, (4) understand the reaction of the employees to the new automated system, (5) study the required changes on the organizational chart and human resources qualifications that are required, (6) recognize the problems that the company met during the process, (6) point the advantages of the shift to the automated system.

The methodology of this case study will be through intensive interviews with the key players of the Egyptian International Motors Company (EIM), which started business in 1978 under the Egyptian corporate law (law 26/1954). EIM has five main sectors of operations: (1) General Equipment Division, (2) Logistic equipment Division, (3) Irrigation and Pumps Division, and (4) Renault Division, and (5) Yamaha Division.

The following table summarizes the financial position of the company on December 2004:

Balance sheet (EIM)
On December 31, 2004

Assets:		**Liabilities:**	
Current assets	288,000,000	Current liabilities	242,000,000
Long term assets	15,000,000	Long term liabilities	52,000,000
		Owner's equity	9,000,000
Total assets	303,000,000	Total liabilities and owner's equity	303,000,000

EIM has represented diverse multinational names over the years. EIM has created a very special position for itself in the market, serving a large number of clients of various sizes, ranging from major local and international contractors to individuals. In order to achieve the company's vision and the mission, in 2001 the company decided to update its manual accounting system and to introduce an electronic accounting system.

The choice of this company as a subject for this research was because it is a large local firm that implements a computerized accounting information system. The fact that the firm is a local firm and does not have an affiliation with an international firm is important to control the effect of any foreign company that might influence the choice and implementation process. If the firm had an affiliation with a foreign company that had implemented a computerized accounting system, it would dramatically affect the choice and implementation process of the computerized accounting system of the company.

I think that the implementation of the computerized accounting system will show that the company has benefited from this implementation but at the same time it will show that there will be some resistance by the employees. At the same time there might be some problems with the choice of company to use a ready made software that may not be flexible enough to meet the demands of the company.

Understanding Context of Electronic Messages Between Diabetes Patients and Physicians

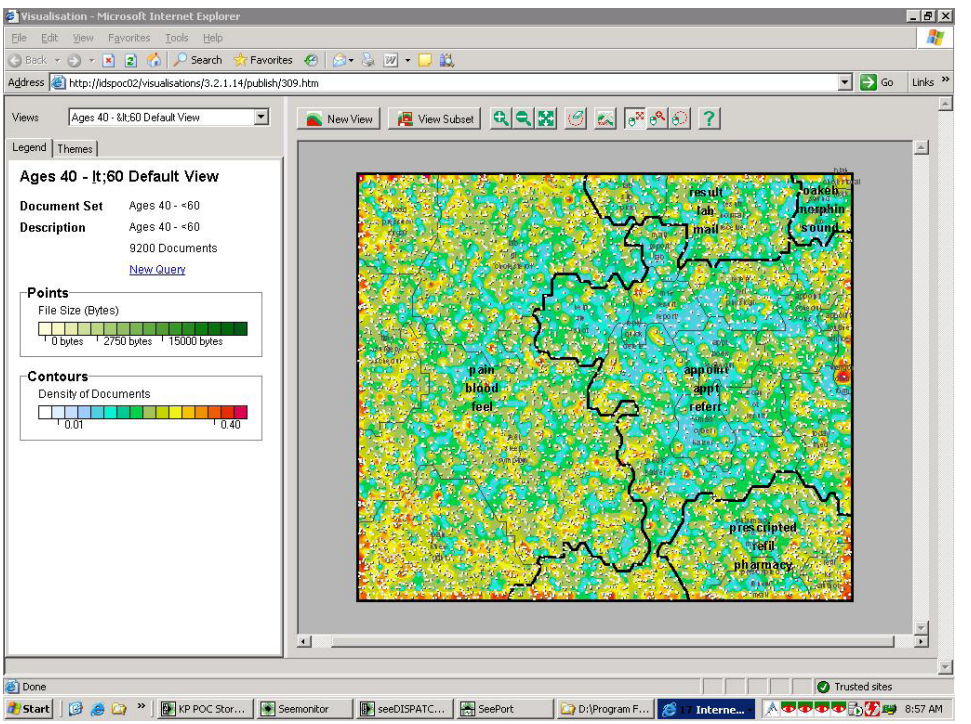
Karita Ilvonen, Stanford Medical Informatics, USA; E-mail: Karita.ilvonen@stanford.edu

One of the first articles to discuss online delivery was Jerome Kassirer's editorial to New England Journal of Medicine in 1995, where he foresaw the internet as next transformation in the delivery of health care. The application of information and communication technology in healthcare has since grown exponentially over the last 15 years and its potential to improve effectiveness and efficiency has been recognized worldwide. Internet use has grown exponentially over the last decade and consumers' searching healthcare information has become a large part of the phenomenon (Baker, Wagner et al.2003; Ferguson 2000). Bundorf et al. (2006) suggested that the emergence of the Internet as a new media for health information provides a new impetus to study the determinants of demand for health information. A study from anadian shows that 10% to 15% of all patient encounters with primary care physicians involve patients who have already consulted sources on the Internet (PriceWaterHouseCoopers 1999). Remote patient management technology will change the way patients are treated, operated on, monitored and counseled. If patients could communicate with physicians or be monitored through the Internet, more than 20% of in-office visits could eliminated, according to respondents the PriceWaterHouseCooper survey (1999). The survey also concluded that more than 30% physicians' time will be spent using web-based tools by 2010.

Patient-physician messaging, email over secure connection is increasingly used to improve communication between patients and physicians. The Institute of Medicine identified email as valuable tool for flexible consulting and speculated that "instead of a $65 office visit and a half-day of work, a 2 minute email communication could meet many patients' needs more respectively and at a lower cost". Chronic patient care requires frequent communication that is often routine in nature. The asynchronous nature of online consultation also renders it more acceptable and efficient from the provider perspective than other remote but synchronous means of communication such as the telephone. Brown (2004) found that patients tend to be much more enthusiastic about messaging than their physicians, particularly for simpler issues. One particular study showed that patients also preferred messaging for more complex issues; perhaps owing to a particularly long waiting list for appointments. This research presents some core findings from an extensive statistical and contextual evaluation of patient-physician messaging on chronic patient care.

This paper is a part of an extensive research, where our overall objective is to understand the implications of messaging service to provider efficiency and use of resources. We wish to map the intervention's effects to patient care processes and use of different communication medias. From earlier results of studying the

Figure 1. Self organizing map (SOM) of the patient messages



same cohort we know that online messaging replaces communication in via other channels such as telephone and visits to the office. The objective of this paper is to analyze the nature of messages sent via the online channel. This study looks at two specific research questions: 1) What types of requests are submitted by the patients 2) how can the requests be categorized.

A study of 350 diabetes patients is conducted at Kaiser Permanente in Oakland, California. The cohort consisted of self-selected patients using the CyberKaiser system. We combined Electronic Health Record Data, messaging free text data and demographic data for our analysis. Diabetics were selected based on ICD-9 codes. We are using Foundation™ software to analyze the unstructured data of the patient messages and are categorizing the messages manually to 12 different categories (e.g. appointment request, medical advice, lab result interpretation etc.) based on the requests made in them. The software used draws Self Organizing Maps (SOM) from the unstructured data and helps us to find major categories and to identify most used terms in the messages.

Figure 1 presents and example graphic of a Self Organizing Map (SOM) used for the context analysis. However, in-depth analysis of the complexity of the messages required categorizing them by hand. We chose first message of each tread send by the patient within the study period of one year for review. Requests and length are categorized and statistical analysis will be performed on the results.

We are hoping to present significant findings on the nature of messages send via the online messaging services. Context analysis findings and categorization of the requests are expected to advance the future development of these services and answer to some concerns on the messaging as an appropriate media for healthcare communication.

Workshop Abstract
The Human Side of IT: A Strategic Approach to Developing Connected Technology Leaders (SM)

Dr. Barbara Trautlein, VP – Research and Associate, Compel Ltd.

WORKSHOP ABSTRACT:
The workshop "The Human Side of IT: A Strategic Approach to Developing Connected Technology Leaders (SM)" will be delivered in an interactive format. This workshop acknowledges that the field of IT and professionals employed in IT are among the most important variables in the future of organizations. However, a growing body of research indicates that the future of IT leadership is increasingly "less about the technology" and "more about empowering people to provide relevant business solutions." The challenge for IT professionals is to develop competencies for navigating social networks, influencing key decision-makers, and building consensus across organizations.

One of the workshop foundations is a research paper presented at the IRMA conference by Dr. Barbara Trautlein, titled: "The Whole World at Work: Managers Around the Globe Describe Their IT Experiences – Suggesting a New Framework for Global IT Leadership." Trautlein, the presenter/facilitator for this workshop, will illustrate why successful 21st century technology leaders will be more connected, communicative, collaborative and consensus-building. The key segments will highlight a holistic leadership development framework called "Connected Technology Leaders(SM)."

SEGMENT ONE: "Changing Expectations" – Dr. Trautlein will share highlights of the global research "The Whole World at Work," involving interviews with managers on five continents that revealed manager frustrations with, aspirations for, and heightened expectations of IT.

SEGMENT TWO: "Shifting Leadership Beliefs and Behaviors" – Successful IT executives and managers develop a high degree of self-awareness, relationship-building acumen, and the ability to think on behalf of the organization as a "whole system." Participants will be exposed to an assessment profile of a winning global IT leadership style for the future.

SEGMENT THREE: "Takeaways? – Defining Next Steps and Getting Connected" –A guided reflection and interactive dialogue will help participants consider the best ways to integrate these findings and approaches into organizations.

A Comprehensive Ontology-Driven Software Development Architecture: An Approach to Developing Romantic Software Products

Nehemiah Mavetera, North West University, South Africa; E-mail: maveteran@uniwest.ac.za

ABSTRACT

Information systems have been criticized for their lack of flexibility and content richness. The problem has been traced back to the developmental stages of these systems. Current ISD approaches are mechanistic, that is, they lack a way of capturing the humanistic element that is inherent in a socio-technical environment such as information systems. To address this anomaly, ontologies can be introduced at the developmental stages to capture the romanticism inherent in these systems, to mediate during the design and development of the software products for these systems and to facilitate easy sharing of information among different information systems. This paper discusses an architecture that positions ontologies at the center of a software development case tool. The ontology drives and coordinates, the requirements analysis, design, and coding of software products that are domain specific. Case based reasoning tools, Bayesian Networks, WordNet, domain specific ontology, conceptual graphs and formal logic are the tools that are incorporated into this software development architecture.

Keywords: Ontology, software development, Architecture, Romantic software products.

1. INTRODUCTION

"There is a reason why computers have not yet become fervent natural language speakers. (It's not a matter of processing power and never will be): we simply are not programming them correctly." ***(El Baze, 2005)***

Current Information systems exhibit a mechanistic character that has curtailed their usability. These systems are very efficient at structuring data to enable and facilitate its interpretation. Mechanistic systems are based on the concept of explicit programming (Agentis International, n.d). Explicit programming produces software products that do not capture semantic and context rich data, a characteristic that is needed in all modern day systems.

The American National Standards Institute (ANSI) proposed a conceptual schema for knowledge encoding in the 1970s (Sowa, 2000). While the schema can coordinate efficiently between the applications, user interface and database of a system, it relied on syntactic coding, and is not evolvable. Other software development paradigms such as the structured approach (Pressman, 2005), object oriented approach (Pressman, 2005, Dennis et al, 2002); software product lines approach (Carnegie Mellon Software Institute, n.d.) software kernels approach (Information Technology University, Denmark, n.d) have been introduced to try and improve the adaptability, evolvability, reusability of software products as well as increase the semantic richness of the resultant information systems. As their eighth basic principle of system development methodologies, Whitten et al (2004), tell systems developers to design their system for growth and change. Pressman(2004), in discussing the nine software myth, raises issues such as evolvability, quality measurement, throughput levels, reusability of software products, management of scope creep during development, and software products documentation as some of the most misunderstood aspects that need to handled carefully during a software development process.

This paper discusses how the ontological approach can incorporate the aspects into information system development. The rest of the paper is as follows. **Section two** discusses the software development problem, **section three** looks at the transition from mechanistic to romantic software products, **section four** briefly discusses the role of ontology in information systems and finally **section five** discusses an ontology driven software development architecture. The conclusion closes the discussion but also summarizes the way forward in the ontology research process in ISD.

2. THE SOFTWARE DEVELOPMENT PROBLEM

The problem in the resultant software products and whose characteristics subsequently emerge in the final information system have been tracked down to the developmental stages of the software product. The software development process is a part of a system development process that includes a set of activities, methods, best practices, deliverables and automated tools that developers use to develop and maintain information systems. Basden (2001), in his article "Christianity Philosophy and Information Systems" decried the continual lack of return of investment from information systems investments. He noted that there is something deeply wrong in the way the "artifact" is developed. This artifact is the software product. He further searches for the problem and the solution. "What is wrong? "and "what do we do about it?" His solution set coupled with other researchers suggestions are herein included as a way to improving the usability of the software product.

2.1 Software Development Issues

Issues considered during the software development process play a vital role in shaping and determining the qualities of the software product. Basden (2001) noted four areas of concern that can be addressed to improve the quality of the product. The areas look at fashioning of technical artefacts for use, development of technology from which we fashion an artefact, the use of the artefact and users' and developers' overall perspective on the use of technology (herein we add the social context of information systems and their situated ness). In addition, other issues require:

- Developers to focus on designing reusable components
- Developers to focus more on the innovative elements of a software product design
- That the innovative elements of a software product represent the domain related additions that make the difference between domain packages.

Managing these issues leads to a gradual change from mechanistic to romantic systems.

3. DEVELOPING ROMANTIC SOFTWARE PRODUCTS

To bridge between the mechanistic development methods and the required romantic methods, we are going to use the ontology artifact. Romantic systems possess a certain degree of humanistic behavior. They are open, non-deterministic and

do not subscribe to mechanistic ideas of representation, formalization, program, order, reason, stability and control like machines. These systems borrow their definition from romanticism (Basden, 2001; John, n.d.; Gregor, n.d; Loflin, n.d) which imitates belief systems that depend on "irrationalism and feelings".

Ontology has enjoyed many definitions in the literature. The section below gives a brief of the common accepted meanings to ontology. This is the definition widely used in information systems development.

3.1 Ontology of a System

Ontology can be viewed as an engineering artifact. In this part, ontology consists of a specific vocabulary used to describe a certain reality (Guarino, 1998). The vocabulary used is accompanied by a set of explicit assumptions, which give people the intended meaning of such a vocabulary.

Studer et al (1998) add that ontology is an explicit formal specification of a shared conceptualization. Formalization looks at machine readability (syntactics) of the ontology. Explicit specification incorporates the clear identification of concepts, properties, relations, functions, constraints and axioms (semantics) within a universe of discourse. If a thing is clear to a subject, that thing should make sense to the said subject(Mavatera, 2004b). The addition of the phrase 'shared conceptualization' denotes ontologies as abstract models of phenomena in the world with implicit knowledge in them. Furthermore, there is some sense of mutual understanding of the concept among people in the same contextual environment (pragmatics).

Neches *et al* (1991) defined ontology as 'the basic terms and relations comprising the vocabulary of a topic area, as well as the rules for combining terms and relations to define extensions to the vocabulary'. Swartout *et al* (1997) describe ontologies as a hierarchically structured set of terms for describing a domain. Gruber (1993) defines ontology as 'a specification of a representational vocabulary for a shared domain of discourse…' He goes on to say that ontology is an 'explicit specification of a conceptualization'. In a more literal way, Ontology consists of a set of concepts and their relationships, forming a conceptual structure that underlies the interpretation of any system model. In short, ontology of a system can be taken as a set of representational terms in the universe of discourse. The ontology is used for 'sharing and reuse of formally represented knowledge'.

4. ONTOLOGY IN INFORMATION SYSTEMS

The purpose of using ontology is to develop software products that capture semantics and social context of information systems through the development of databases of domain ontologies and application packages that capture semantics, context and the situated ness of organizational information systems. It is:

'*…about awareness, connection and meaning, impact versus activity and knowledge versus data'. in-PharmaTechnologist.com (2005)*

The ontology replaces the conceptual schema at the center of an integrated information system as previously stipulated by ANSI (see section 1 above). In this research, we take advantage of ontology characteristics such as easy to use, different formal expressiveness with reasoning support, integrated form generation to acquire instances, ability to build test cases and use the cases to check consistency, ability to be manipulated and reason at run time, ability to drive control logic of a program, ability to be tuned so as to automate the software testing process as well as ability to allow user involvement at any stage of the development to position it at the center of the development of romantic software products.

In short putting ontology at the center of the software development tool allows the resultant software products to be adaptable, evolvable and be context aware.

5. ONTOLOGY DRIVEN SOFTWARE DEVELOPMENT ARCHITECTURE

Figure 1 below shows the architecture of the software development tool that we refer as the OntoSoft case tool. The OntoSoft tool has three major components, the knowledge base repository, the designer engine and the reasoner.

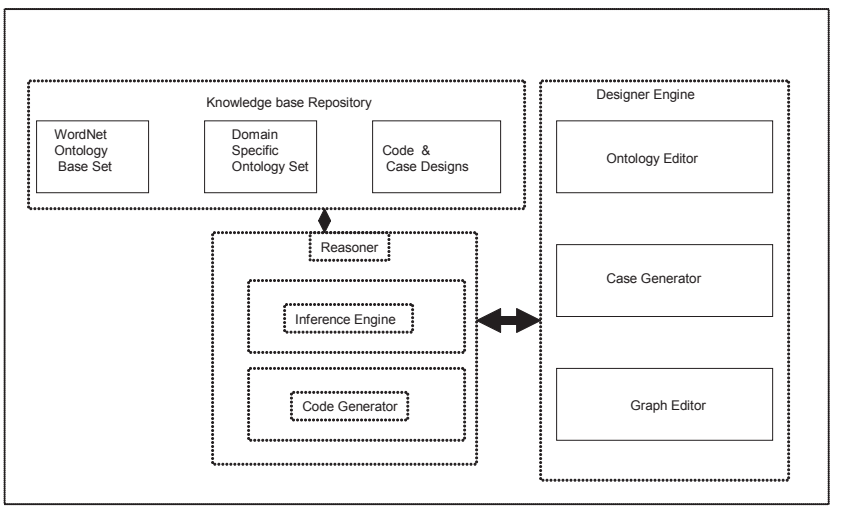
5.1 The Knowledge Base Repository

Unlike the Rebuilder case tool discussed in Gomez,(2004), the OntoSoft knowledge base repository consist of three parts, the WordNet ontology base, the domain specific ontology base(not found in Rebuilder or any other case tool developed so far) and a code and case base set.

The WordNet ontology base is taken and maintained "as is" . WordNet is a type of terminological ontology(Sowa, n.d). It is a lexicon and consists of information about " syntax, spelling, pronunciation and usage of words" In short, it is a natural language knowledge base. It is not updated so as to maintain linguistic consistency in terms of international grammar and general meanings to terms.

The domain specific ontology set is specific to an application software domain and is allowed to change according to the different conceptualizations and ontological commitments(Guarino, 1998) to a certain domain. This is the knowledge base that users' and developers can fine tune to suit their application domains. Finally, the case and code designs base store new and old designs that are relevant to a specific application domain.

Figure 1. Ontology software development case tool architecture



5.2 The Designer Engine

It consists of an ontology editor, case generator and graph editor. The three are used to develop domain specific ontology on the run, cases that capture the differing designs in the application domain and graphs that are used to map related concepts in a domain through their respective conceptual relations.

The designer engine uses the same principles as Rebuilder in terms of case indexing with the only difference being the graph editor. Rebuilder uses UML as case editor. UML as a case editor does not link the cases to the meaning of the cases which are stored in the domain ontology. It is purely syntactic. OntoSoft uses conceptual graphs that are a graphic notation for logic based on existential graphs. The conceptual graphs are augmented with features from linguistics and the semantic networks of artificial intelligence. Conceptual graphs can be used to map to and from natural languages. As a presentation language, they are used for displaying logic in a more human readable form. The conceptual graphs will be linked to the domain specific ontology to beef the knowledge content of the cases and designs.

5.3 The Reasoner

The reasoner consists of the inference engine and a code generator. The inference engine is like the communication engine between the designer engine and the knowledge base repository. It accepts user queries, retrieves old cases, and links new cases to WordNet and domain specific ontologies, links code to the cases and conceptual graphs. In fact, it is the brains behind the OntoSoft case tool.

The code generator automatically develops code specific to a retrieved or adapted case. The reasoner uses Bayesian Networks (BN) techniques to index cases and case based reasoning (CBR) principles which are well covered in Gomez(2004). CBR is based on the reuse of experience. It captures every reasoning instance as an episode that is registered and stored in a case. As each case captures a specific situation and is context related, then the syntactic, semantic and pragmatic aspect of the situation is also captured(Mavetera, 200b). The reader is directed to this article for further explanation on case based reasoning.

6. CONCLUSIONS

This paper discussed problems that currently bedevil our information systems to a proposed development architecture that can solve most of these problems. Of importance is the focus of the paper on the "artifact" during software products development. Unless the artifact is made adaptive, evolvable during the design stage, software developers must not expect the resultant information system to be adaptive and evolvable. The paper positions ontology at the center of romantic software products development process. These products will be reusable, process able, and in addition, they can be adapted and evolved to come up with entirely new software products. The software myths (Pressman, 2005), Software Product Lines(Carnegie Mellon Software Institute, n.d), software kernels (Dittrich & Sestoft, 2005) are all issues that can be solved by positioning ontology at the center of the software development process.

The next stage of the research is to engage industry partners, initially to investigate the software development practices that are in existence, the approaches, the methods, techniques, and the tools they use to come up with a product that give information systems their social situated ness. These findings are a very good tool which can be used to validate and motivate the industry use of the OntoSoft case tool framework. The OntoSoft case tool will also be tested using a prototype.

ABSTRACT

Mobile communication technologies have penetrated consumer markets throughout the world. Traditionally, mobile services mainly facilitate voice communication. Recently, new forms of mobile services have made possible text messaging, web surfing, digital imaging, payments, banking, financial instrument trading, and shopping. These new functions of the mobile services require powerful interface features. These interface features must be easily customizable to fit the taste of an individual user's decision making. Besides, it was predicted that mobile tools, mobile e-services, and wireless Internet protocols will mark the next major sets of development in DSS, thereby expanding the accessibility of the tools to decision-makers wherever they may be. Thus the research studies and compares the user interface features in both the mobile and traditional decision making in order to find the advantages and challenges in user interface deisgn in the two environments. It also dighlights the distinct interface features of mobile device and applications that encourage users' decision to adopt mobile commerce. The study on mobile user interfaces features and their effects on decision making will have singnificant influence on the mobile commerce activities, consumer behaviors, mobile communication markets and also the decision science research.

INTRODUCTION

Mobile communication technologies have penetrated consumer markets throughout the world. According to Universal Mobile Telecommunications System (UMTS) Forum, the global mobile market has grown rapidly to about 1.2 billion subscribers in 2003, with an approximate increase of 20% since 2001. It is also anticipated that there will be more than 2 billion mobile users between 2007 and 2010.

Mobile services have primarily facilitated voice communication. However, recently new forms of mobile services have made text messaging, web surfing, digital imaging, payments, banking, financial instrument trading, and shopping possible. (Mao et. al., 2004) The mobile technology should be low cost with minimal difficulty for implementation. (Zucker et al, 2005). All these requirements of user interface features will have the influence on the individual user's decision making for mobile commerce. According to Daft (1991), a decision is "a choice made from among available alternatives" (p. 180). Choosing from among alternative courses of action lies at the heart of decision making (Payne, 1982). Decision quality is a measure of the goodness of this choice. A user interface supports both the mechanics of the interaction and facilitates the broader notion of a dialogue between human and computer. As used here, a user interface is an "observable two-way exchange of symbols and actions between human and computer".

LITERATURE REVIEW

The rapid growth of mobile telephony has fueled the expansion of the mobile Internet as a foundation for mobile commerce (Lee and Benbasat, 2004). Mobile Commerce or M-commerce is defined as buying and selling of goods and services through wireless handheld devices such as mobile telephones and personal digital assistants (PDA) (Bhuyan, 2005). Mobile Commerce represents the convergence of two technologies – the web and wireless technology. While the former hasradically changed the way business is conducted, the later has added a mobile dimension to e-commerce and mobile computing through mobile devices such as cell phone, PDA, or pager (Coyle 2001). The adoption of electronic commerce has made the significant impact on the organizational formation, decision making, business strategy and other business related issues.

Despite the sanguine expectations of many observers and the enhanced capabilities of mobile systems, few researchers on information systems (IS) have empirically studied interface designs for m-commerce. Human-computer interaction (HCI) researchers have explored interface designs for mobile devices through which users experience a very different environment than with personal computers (Lee and Benbasat, 2004). For many decades, there are large numbers of studies in decision making and decision support systems. Gorry and Morton(1971) developed a framework to help the decision makers to understand the evolution of MIS activities within the organization.

Sauter (1999) defined four types of decision making style: left-brain, right-brain, accommodating and integrated. Todd and Benbasat (1992) presented the importance of cognitive effort in Strategy selection and decision making and pointed out that the cognitive cost perspective is helpful in understanding the influence of DSS on decision making. Decision makers utilize the tools provided in such a way as to limit their overall expenditures of effort. In regard to the cognitive support for decision making, Lerch and Harter (2001) examined how decision makers manage their attentional resources when making a series of interdependent decisions in a real-time environment and indicated that decision strategies for real-time dynamic tasks consist of two main overlapping cognitive activities: monitoring and control.

The proposed model is an extension of Lee and Benbasat (2004) 7C model for mobile commerce interface design and traditional interface design. It compares the user interface features in both the mobile and traditional decision making in order to find the advantages and challenges in user interface deisgn in traditional and mobile environment.

Synthesizing the past literature leads to the following general research model emerges. Description of the individual boxes is given in the following sections. It is clear from the past literature that a pattern of evolution in the user interface can be observed. In 1960s, Scott Morton and others started demonstrating befits of using computer based decision support systems. Decision support concepts and technologies were developed in 1970s. With the introduction of personal computers in 1980s, we can observe a rise in the group decision support systems.

PROPOSED RESEARCH MODEL

On the basis of Lee and Benbasat 7C model for mobile commerce interface design, decision making theory as well as the cognition and intuition characteristics of problem understanding, we propsed following research model. The model shows that the both the mobile decision making and traditional decision making process will lead a better problem understanding which has the influence on the individual user's decision making efficiency and quality.

According to lee and Benbasat (2004), the mobile commerce interface framework is composed of: context, content, community, customization, communication,

Figure 1. Areas of study for comparing user interface features on decision making in traditional and mobile environment

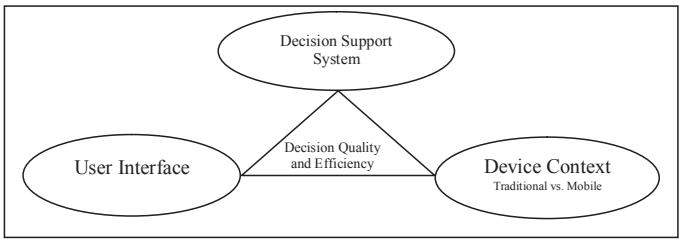

Figure 2. Framework for Information Systems (Gorry and Morton,1971)

	Operational Control	Management Control	Strategic Planning
Structured	Accounts Receivable	Budget Analysis — Engineered Costs	Tanker Fleet Mix
	Order Entry	Short-Term Forecasting	Warehouse and Factory Location
	Inventory Control		
Semi-Structured	Production Scheduling	Variance Analysis — Overall Budget	Mergers and Acquisitions
	Cash Management	Budget Preparation	New Product Planning
Unstructured	PERT/COST Systems	Sales and Production	R&D Planning

connection, and commerce. Context captures how Web sites are developed, consisting of functionality and aesthetics; Content focuses on what a site presents, comprising the offering, appeal, multimedia mix, and content type; Community concerns interaction between users, including interactive and non-interactive communication; Customization refers to a site's ability to tailor itself (tailoring) or to be tailored by users (personalization); Communication is defined as dialogue between sites and users: broadcast, interactive, and hybrid; Connection refers to the extent of formal linkages between sites, consisting of outsourced content, percentage of home site content, and pathways of connections. Commerce is concerned with interfaces related to sales of goods and product services, such as a shopping cart and order tracking.

Several researches have been conducted to study the powerful interface features to meet the users sepcific needs. Albers and Kim (2000) asserted that the small screen would interfere with navigation because information is too fragmented on separate pages to develop an integrated mental model given the user's limited short-term memory. Jones et al.(1999) compared users' navigation activities on small and big screens (640 × 480, 1,074 × 768), and found that navigation activity—the number of scroll up/down and left/right actions.

According to Gallivan and Shen (2005), the introduction of mobile technologies in organizations requires mobile users to have certain new skills, or to increase the level of certain skills they already have. First, mobile workers need to manage distributed objects. Second, mobile users need to maintain a high level self-discipline. Third, mobile users have to deal with high cognitive load. Fourth, employees using mobile technologies face the challenge of balancing work and personal life. Those challenges in user technology interaction in mobile commerce ask for powerful interface design in order to fit the taste of an individual user to faclitate their decision making.

Traditional decision making encompasses three main elements (1) user interface, (2) human computer interaction and (3) decision support systems. This decision making also relies on the development of problem understanding which in turn is developed by intuition and cognition. Decision making is traditionally measured in terms of quality and the efficiency of the decision.

CONCLUSION

Our study has compared the user interface features in both the mobile and traditional decision making in order to find the advantages and challenges in user interface deisgn in traditional and mobile environment and to indicated the distinct interface features of mobile device and applications, hence encouraging users' decision to adopt mobile commerce. Besides, the study on mobile user interfaces features and their effects on decision making will have the singnificant influence on the mobile commerce activities, consumer behaviors, mobile communication markets and also the decision science research.

This research has implications for research on not only mobile device interface design and decision support system but information systems interfaces as well as it addressed the issues of user interfaces in mobile and ubiquitous devices. For practitioners who develop mobile decision support interfaces and applications, this study will serve as a means of understanding user needs effectively.

All research studies have limitations and this one is no exception. The study does not study impact of other features of mobile experience such as connection speed, technologies (2G, 3G), rich diversity of power and specific functionality of devices

ABSTRACT

Business Intelligence (BI) has emerged as one of software solutions that have maximum allocated investments by many organizations for the year 2005. Among various forms and application-based business intelligence, market intelligence (MI) is viewed as a crucial factor for a company to succeed both operationally and strategically in today's' competitive environment. Capturing market intelligence data has apparently become easy, especially with the proliferation of the Web. But, this has made data collection more difficult in reality from the system's point of view, as data sources on the web are voluminous, heterogeneous in terms of structures and semantics, and some part of it may be irrelevant to a specific organizations' marketing decision-making context, which is the primary premises of market intelligence systems. To address these three specific problems, an algorithm based on similarity measures and multi-dimensional scaling (MDS), which produces hierarchical clusters of knowledge maps from a training data-source set for collecting inputs from heterogeneous sources for capturing market intelligence, is proposed in this paper. The paper illustrates that this algorithm can reduce irrelevant or highly similar data sources for inclusion in the selected data-source repository – represented in the form of clusters of knowledge maps. Therefore, it acts as a similarity-based selection and filtering tool also, with the specific purpose of data collection for MI.

Keywords: Market Intelligence, Business Intelligence, Multi-dimensional Scaling

1. INTRODUCTION

1.1 Business Intelligence and Market Intelligence

According to the report of Nucleus, a market research firm on IT, in their research about Top 10 IT predictions for 2005, (Nucleus Report 2005) BI has emerged as the first among the maximum sought-after solutions. Amongst various Business Intelligence elements, Market Intelligence is one of the most significantly and practically applied concept or tool. (Future-Group 1997 and subsequent reports). However, the volume and heterogeneity of information available in the internal and more prevalently external domains (e.g. the Internet), create a huge information overload. (Bowman et.al 1994). In this paper, an algorithm is proposed for collecting market intelligence associated with its three primary problems like relevance, volume and heterogeneity.

The algorithm in specific, and the process, in general, use:

- Knowledge maps for identifying a relevant source of data → addressing the problem of relevance
- Knowledge maps as a selection clustering tool : not for classification or grouping, but for selecting and filtering the data → addressing the problem of volumes
- and then again knowledge maps for transforming all the relevant and filtered data from various heterogeneous systems to a homogenous platform so that various analytical tools can be applied to the resultant data-set → addressing the problem of heterogeneity

1.2 Existing Technologies for Collecting Market Intelligence

In recent years, business intelligence tools have become important for analysis of information on the Web (Fuld et al 2003). Despite recent Improvements in analysis capability there is still a long way to go to assist qualitative analysis effectively. Due to limited analysis capability, existing tools are weak at summarizing a large number of documents collected from the Web, thus handling the problems of relevance, heterogeneity and volume.

1.3 Information Overload- handling techniques

Few algorithms proposed in text/web mining and document clustering find relevant applications here. Lin (1997) identified various display formats for handling multi-dimensional data e.g. scatter displays (Spence 2001) and map displays- to provide a view of the entire collection of items at a distance (Lin 1997). Shneiderman proposed a task by data type taxonomy (TTT) to study the types of data and tasks involved in visual displays of textual information (Shneidermiin 1996), (Wise et al 1995). Most processes of document visualization involve three stages i.e. document analysis, algorithms, and visualization (Spence 2001). He et al. (2001) proposed an unsupervised clustering method that was shown to identify relevant topics effectively. Bharat and Henzinger (1998) augmented a connectivity analysis-based algorithm with content analysis.

1.4 Algorithms

Partitioned clustering, in context of unstructured documents, assigns objects into groups such that objects in a cluster are more similar to each other than to objects in different clusters. Typically, a clustering criterion is adopted to guide the search for optimal grouping. Using this criterion in image segmentation (Shi and Malik 2000) and Web page clustering (He et al 2001) has been shown to achieve high performance. But, heuristics are needed to find good values to the criterion selected.

1.5 Multidimensional Scaling

Multidimensional scaling (MDS) algorithms consist of a family of techniques that portray a data structure in a spatial fashion, where the coordinates of data points x_{ia} are calculated by a dimensionality reduction procedure (Torgerson 1952). The distances (d_{ij}) among data sources can be calculated as follows

$$d_{ij} = [\sum \{x_{ia} - x_{ja}\}^p]^{1/p} \quad (p >= 1),\ x_{ia} <> x_{ja}$$

p is referred to as the Minkowski exponent and may take any value not less than 1. r is the coordinate of point on dimension a, and J is an r-element row vector from the i^{th} row of a/i-by-r matrix containing all *n* points on all r dimensions. The MDS procedure constructs a geometric representation of the data (such as a similarity matrix), usually in a Euclidean space of low dimensionality (i.e.. *p = 2)*.

2. KNOWLEDGE MAPS FOR COLLECTING MARKET INTELLIGENCE

In this section, we present these requirements of an effective market intelligence collection system as shown in Figure 1, which depicts the problems addressed in this paper, namely relevance, volume and heterogeneity of information.

2.1 Collection of Data Sources

From Figure 1, it can be seen that there are two major data sources: internal and external. Both these major sources have mixed type of data elements in them i.e. structured (e.g. from RDBMS, data warehouses, ERP backend databases, MIS, spreadsheets etc,) or unstructured (e.g. text, hypertext, multimedia, binary files and so on). Primary problem therefore is to deal with external data sources that exist in various forms unknown to the organization and in various degrees of unstructured-ness. Techniques like meta-searching and automatic parsing and indexing are commonly used for such data collection problems.

For example, the word-type information can be used in the co-occurrence analysis. Each key word or noun phrase for example can be treated as subject descriptor type. Based on a revised automatic indexing technique (Bowman et.al 1994), the term's level of importance can be measured by term frequency and inverse data-source frequency.

2.2 Co-occurrence Analysis

Co-occurrence analysis can convert data indices and weights obtained from inputs of parameters and various data sources into a matrix that shows the similarity between every pair of such sources. The similarity between every pair of data sources contains its content and structural (connectivity) information. He et al. (2001) designed an algorithm for computing the similarity between every pair of Web documents by a combination of hyperlink structure, textual information, and co-citation. This algorithm has been used in this paper to compute the similarity between data sources, as follows:

Similarity between data source I and data source j is

$$W_{ij} = \alpha \{A_{ij} / |A|_2\} + \beta S_{ij} / |S|_2 + (1 - \alpha - \beta) C_{ij} / |C|_2$$
$$0 < \alpha, \beta < 1,\ 0 <= \alpha + \beta <= 1,$$

where A, S, and C are matrices for A_{ij}, S_{ij}, and C_{ij} respectively. Values for A_{ij} will be 1 if data source I has a direct link to data source j, else 0. S is the asymmetric similarity score between data sources I and j, and is calculated as follows:

$$S_{ij} = sim(D_i, D_j) = [[\sum_{k=1}^{p} d_{ki} d_{kj}] / [\sum_{k=1}^{n} d^2_{di}]] \text{ X } S_{ji} = sim(D_j, D_i)$$

where:

1. n is total number of terms in D_i, m is total number of terms in D_j, p is total number of terms that appear in both D_i, and D_j.
2. d_{ij} = (Number of occurrence of term j in data source i) X $\log((N/d_{fj}))$ X w_j) X (Term type factor)
3. d_{fj} is number of data sources containing term j
4. w_j is number of words in term j
5. Term type factor = 1 + ((10-2 X $type_j$ / 10), where $type_j$ = minm 1 if term j appears in title, 2 if it appears in heading, 3 if it appears in context text etc.)
6. C_{ij} is number of data sources pointing to both source I and source j (cocitation matrix).

3. CREATING THE KNOWLEDGE MAPS

The data sources for Market Intelligence, be it structured or unstructured i.e. text/ binary objects/ documents, can be represented in the form of a graph consisting of nodes as the data sources and edges as the similarities between data sources. Using hierarchical and partitioned clusters simultaneously, a hierarchy of similarity clusters of data sources based on their parameters or properties can be created in

Figure 1. Market intelligence data collection system using knowledge maps

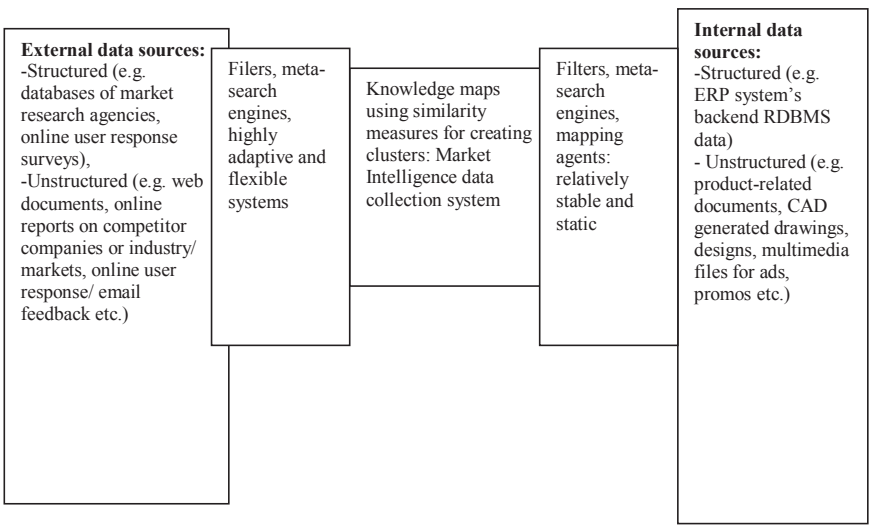

Figure 2. Example of a hierarchical graph of knowledge maps

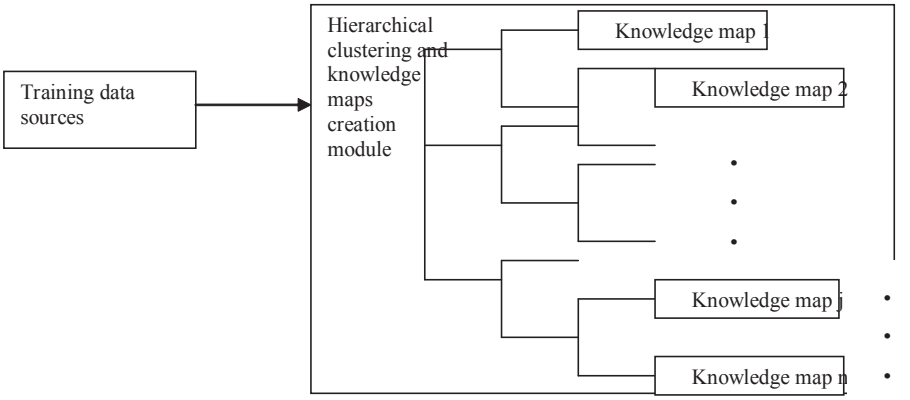

the training phase. Then these clusters can be transformed into two-dimensional knowledge maps using MDS.

Example Run of the Proposed Algorithm:
Let us consider an example where we have n data sources as training data set for training the selection clusters. These training data sets will be used to create a hierarchical graph of clusters transformed into knowledge maps, as shown in Figure 2 below. Partitioning of a graph, say G, can be done in various ways, for example, by using similarity measures as below:

Normalized Cut on graph G = {cut between (A, B)/ assoc(A, V)} + {cut between (A, B)/ assoc (B,V)}

where, Cut between (A,B) = $\sum_{i\in A, j\in B} W_{ij}$, W_{ij} is similarity between nodes i and j of the graph. A cut on a graph G = (V, E) is defined as removal of a set of edges such that the graph is split into disconnected sub-graphs, thereby can be converted into a hierarchy of knowledge map.

Torgerson's classical MDS procedure, (Torgerson 1952), can be used here for it's simplicity and ease of implementation. The MDS procedure can be implemented using the following steps.

First, Similarity matrix is to be converted into a dissimilarity matrix D by subtracting each element by the maximum value in the original matrix. Then matrix B which is a scalar product is to be calculated, by using the cosine law. Each element in B is given by:

$$b_{ij} = -1/2 \left[d_{ij}^2 - 1/n \sum_{k=1}^{n} d_{ik}^2 - 1/n \sum_{k=1}^{n} d_{kj}^2 + 1/n^2 \sum_{g=1}^{n} \sum_{h=1}^{n} d_{gh}^2 \right]$$

where d_{ij} is an element in D, n= number of nodes in the data-source graph

After calculating B, singular value decomposition is performed using the formula as below:

$B = UxVxU'$, $X = U\,X\,V^{1/2}$

(where U has eigenvectors in its columns and V has eigenvectors on its diagonal.)

Therefore, B = X x X'.

The first two column vectors of X thus calculated now can be used to obtain the two-dimensional coordinates of points, which can be used to place the data sources onto knowledge maps.

4. USING KNOWLEDGE MAPS FOR CREATING CLUSTERS OF COLLECTED DATA

Creation of knowledge maps from a graphical representation of various data sources, based on their similarities or, more specifically and logically their degree

Figure 3. Data sources as inputs to the clustering and knowledge maps creation module

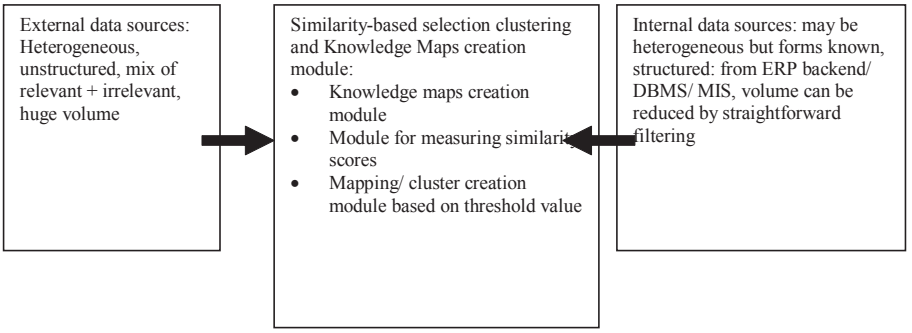

Figure 4. Run-time collection of data sources

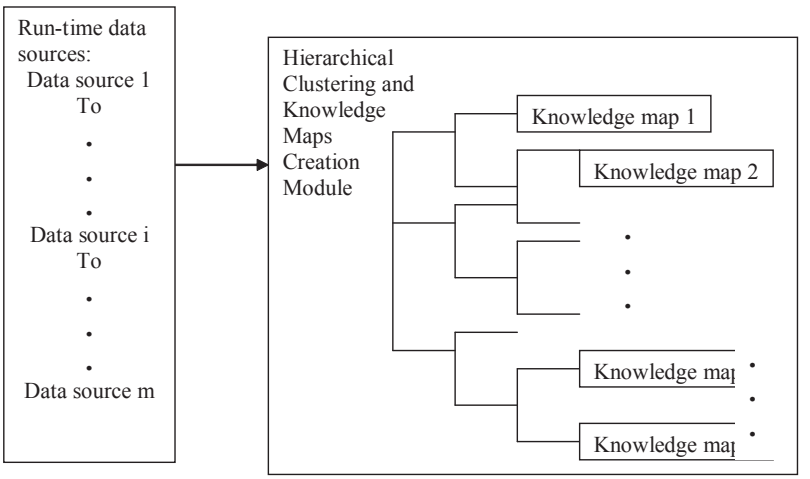

of dissimilarities, is shown earlier. Basically, by segregating the graph representing the data sources, we get a hierarchical cluster of various knowledge maps where these knowledge maps can be seen as representing similar data sources. This is what is to be done in the training phase of the clustering and knowledge maps creation module, as explained in Figure 2 in terms of training the modules with the data sources and Figure 3 in terms of the various data sources themselves in the context of Market Intelligence requirements of an organization.

After the use of training data sources a set of hierarchical clusters with knowledge maps have been created and thereafter the run-time data collection has to start. During the run-time, two events can take place. Say, a data source i is being input to the module as shown in Figure 4 below. Now the similarity score of this data source will be calculated by the appropriate sub-module in respect to the existing Knowledge Maps that are already trained into the module. The thershold value of this score will have to be given by the user. It can be given one-time, or it can be exectuion envrionment/ run-time specific depending on the degree of filerting/ reduction requirements. If the similarity score of data source i is found to be closer(i.e. lesser that the thershold value given) to any of the existing knowldeg maps in the hierarchical cluster, then it is included in that knowledge map. Here a possibility is that the closely-matching knowledge map can be futher fine-tuned with the data-source i input's parameters and properties. In that case, it will be like a fine-tuning training phase going in tandem with the run-time phase. But here the data source colelciton will be more enriched , more representative and inclusive.

The other possibility is that the data source i does not have a close proximity to any of the existing knowledge maps in terms of it's similarity value and the threshold(i. e. the similarity score in terms of all existing knolwdge maps is more than the threshold value). In such situation, a new knowledge map has to be created and put in the approrpasite place in the hierachy of knopwldge map clusters.

As explained above, the steps in Figure 4 can be explained as given below:

Steps:

1. One data source i arrives for feed into the module which has sub-modules like Knowledge Map creation module and similarity scoring module
2. Similarity scoring module measures the similarity score of the data source (for i = 1, $S_{ij} = 0$, during the training phase) and a KM for data source i, say KM_i is created.
3. The similarity score is calculated and compared against all existing KMs, i.e. KM_1 ti KM_n
4. If the similarity score is < threshold value given for data reduction for any existing KM say KM_j, then the KM_i gets mapped or included into KM_j and KM_j learns for similarity patterns from KM_i and refines itself.
5. If similarity score is > threshold value, KM_i creates another cluster of it's own.
6. Go to step 1.

Using this algorithm, the primary three problems that were introduced in the previous sections, gets addressed.

1. First, by using training data sources, the trained Knowledge Map clusters have the patterns identified only for relevant data which has been included in the training data. So the problem of relevance i.e. eliminating/ reducing irrelevant data collection is achieved to a limited scope depending on the choice and exhaustibility of the training data source-sets.
2. Second, the problem of volume is addressed by using Knowledge maps and similarity-based clustering where similar data sources are not repeatedly included in the collected repository of KM-represented data.
3. Third, the problem of heterogeneity is addressed as all the heterogeneous structured or unstructured data sources are finally being represented in the form of Knowledge Maps, which can then be used as a homogenous input to the analytical modules of the MI systems.

CONCLUSION

This proposed algorithm has been shown to handle the three primary problems of data collection for market intelligence in an organization. Further extensions may include exploring various other knowledge map creation mechanisms including the Genetic Algorithm approaches and extrapolating the Knowledge maps into the analytical systems required for analyzing and visualizing the Market intelligence data.

Evolving Stochastic Context-Free Grammars Using Genetic Algorithm

Anupam Shukla, National Institute of Technology, Raipur, India; E-mail: anupamshukla2005@yahoo.com
Devesh Narayan, National Institute of Technology, Raipur, India; E-mail: devesh_nar@yahoo.com

ABSTRACT

The learning of stochastic context-free grammars from corpus using genetic algorithm is explored in this work. Minimum description length principle is used for deriving the fitness function of the genetic algorithm. Stochastic context-free grammars are evolved by optimizing the parameters of the covering grammars. I provide details of my fitness function for grammars and present the results of a number of experiments in learning grammars for a variety of languages.

INTRODUCTION

Stochastic context-free grammars (SCFGs) are perhaps best known as a tool for expressing the syntactic structure of natural languages. Practical techniques for grammar induction have many important applications or a wide range of natural language (NL). In recent years SCFGs have been widely applied to problems in computational biology, such as modeling the secondary structure of RNA families. Other applications include visual recognition of activities and language modeling for speech recognition, robotics. A problem of central importance in each of these applications is inducing SCFGs from data.

Inferring a stochastic grammar from data, as revealed by most previous practice, involves in general two essential sub-tasks, one to infer a set of phrase structure rules (or productions), another to estimate a correspondent set of probabilistic parameters (i.e., production probabilities) The inference can be viewed as a search process for the best grammar allowable in a predefined grammar (or hypothesis) space. There are many sophisticated algorithms exist to facilitate the searching, e.g., genetic algorithm and stimulated annealing algorithm. However, no matter how sophisticated is the search method in use, the goodness criterion to guide the searching remains a critical issue. It is this criterion that tells a search algorithm which grammar is better. In this project we developed a suitable criterion for the estimation of the parameters of the stochastic context-free grammars. It is based on the classic and algorithmic information theory and on the Minimum Description Length (MDL) principle and genetic algorithm.

STOCHASTIC CONTEXT-FREE GRAMMAR (SCFG)

A stochastic context-free grammar (SCFG) is a variant of ordinary context-free grammar in which each grammar rule is associated with a probability, a real number in the range [0,1]. The set of production probabilities will be referred to as the parameters of the SCFG. For a SCFG to be proper, the probabilities associated with all rules that expand the same non-terminal symbol must be one.

The language L(G) generated by a SCFG G comprises the set of all strings of terminal symbols derivable from the start symbol of the grammar. In addition, the parameters define a probability distribution over strings in L(G). For a string $\alpha \in$ L(G), the probability of a parse tree for α is given by the product of the probabilities of all the grammar rules involved in its construction. The probability $P_G(\alpha)$ of the string α is the sum of the probabilities of all of its parses.

S → AB (1.0)
A → a (0.6)
A → CS (0.4)
B → b (1.0)
C → a (1.0)

The above SCFG, with the probability associated with each production is given in parentheses, generates the language $\{ a^n b^n | n \geq 1\}$, where $P_G(ab)=0.6$, $P_G(aabb)=0.24$ and so on.

BIASED WEIGHT GRAMMARS

Biased Weight Grammars are similar to SCFGs in that they associate numerical parameters with the rules of the grammars, a bias and a weight. Any BWG G can be converted to an equivalent SCFG G'. Let Grj denote the set of rules in G that expand the same nonterminal symbol as rule rj. Then each rule rj in G with bias bj and weight wj has a corresponding rule rj' in G' with associated probability pj given by

$$P_j = \frac{b_j w_j}{\sum_{r_k \in Gr_j} b_k w_k} \quad (1)$$

The language generated by a BWG G to be the same as L(G'), the language generated by its equivalent SCFG G', with the same associated probability distribution over its sentences.

CORPUS-BASED GRAMMATICAL INFERENCE

A corpus C for a language L is a finite set of strings drawn from L, where each string $\alpha \in C$ is associated with an integer f_α representing its frequency of occurrence. The size N_c of the corpus is defined as the sum of the frequencies of the individual strings in C. That is

$$N_c = \sum_{\alpha \in C} f_\alpha \quad (2)$$

The relative frequency p_α of a string $\alpha \in C$ is defined as $p_\alpha = f_\alpha / N_c$ Given a corpus C as training data, the inference problem is to identify a SCFG that (a) models the corpus as accurately as possible and (b) generalizes appropriately to the wider language from which the corpus was drawn. This problem is tackled by trying to identify a BWG with these properties taking its associated SCFG as the one learnt by our system.

For any probabilistic language model, natural measure of accuracy is the probability of the corpus data given the model. In this case, the most accurate model in this sense is that grammar G" given by

$$G" = \text{argmax}_G P(C|G) \quad (3)$$

Where P(C|G) (the conditional probability of the language data C given by the grammar G) is defined as

$$P(C|G) = \frac{N_C!}{\prod_{\alpha \in C} f_\alpha!} \prod_{\alpha \in C} P_G(\alpha)^{f_\alpha} \quad (4)$$

On the other hand, simply maximizing the probability of the corpus data will not generally meet the further requirement of generalization. A perfectly accurate model is one which generates exactly the finite corpus and assigns to each string the correct relative frequency. In otherwords, the most accurate grammar will over-fit the training data. What actually require is the grammar that is most probable given the training data. That is, a grammar G" such that

$$G" = \text{argmax } G\ P(G|C) \quad (5)$$

Unfortunately, it is not clear how to calculate P(G|C) directly. From Bayes rule

$$P(G|C) = \frac{P(G)P(C|G)}{P(C)} \quad (6)$$

Ignoring P(C), which is a constant, maximizing P(G|C) just corresponds to maximizing the product of P(C|G) (which can be calculated directly) and P(G), the prior probability of the grammar G. This poses the problem of fixing an appropriate prior probability distribution over grammars. In principle there are many different priors that could be chosen, but it seems reasonable to assume that we should prefer smaller and simpler grammars to larger, more complex ones. Our choice of prior is therefore related to the minimum description length principle of Risannan as well as earlier work on inductive due to Solomanoff.

THE MINIMUM DESCRIPTION LENGTH PRINCIPLE

Given some data D, we should pick that theory T which minimizes:

$$L(T)+L(D/T)$$

Where L(T) is the number of bits needed to minimally encode the theory T, and L(D/T) is the number of bits needed to minimally encode the data D given the theory T.

From Shannon's information theory, we know that if we have a discrete set X of items with a probability distribution P(x) defined over it, then in order to send a message identifying x ε X we need approximately $L(x)= -\log_2 (P(x))$bits. In other words,

$$P(x)= 2^{-L(x)} \quad (7)$$

This enables us to interpret the M D L principle in Bayesian terms. From the equation it can easily be seen that minimizing L(T)+L(D/T) corresponds to maximizing P(T)P(D/T) and hence P(T/D).

It should be noted that for us the most useful feature of the M D L Principle is that it can be used "inverse". Information theory (Shannon 1948) tells us how work out minimum code lengths given prior knowledge of the probability distributes over items in some set of interest. The M D L Principle enables us to assign prior probabilities to items in some set in a meaningful way, even if we do not really have enough prior knowledge. We can do this by attempting to find minimal length encoding for the items and then use equation (4) to work out the probabilities.

THE GENETIC ALGORITHM FOR SCFGS

Given a corpus C as training data, our approach to grammatical inference involves the following steps

1. Construct a covering grammar that generates the corpus as a (proper) subset.
2. Set up a population of individuals encoding parameter settings for the rules of the covering grammar.
3. Repeatedly apply genetic operations (crossover, mutation) to the selected individuals in the population until an optimal set of parameters in found.

The covering grammar is in the Chomsky Normal Form (CNF) and contains every rule of the form A → BC and every rule of the form A→ a.

A member of the population encodes a set of weights for the rules of the covering grammar. Each weight is encoded as a binary integer, using w a fixed length bit string. The bias associated with each rule is determined in advance according to a prior probability distribution p" over grammar rules. Thus, for a rule r in the covering grammar the associated bias is given by p"(r). The prior distribution is chosen to reflect a preference for shorter, simpler rules. This makes it easier for the genetic algorithm to learn grammars of the sort we prefer(simpler and shorter) because changes to the weights of more heavily biased rules have a greater effect on the resulting probabilities of the sentences in the corpus. Consequently the algorithm is far more sensitive to simpler, shorter rules.

The members of the initial population are generated randomly after which the genetic algorithm repeatedly executes the following select-breed-replace cycle.

Select a random member of the population for breeding using roulette selection method.
Breed by applying crossover and mutation to produce two children.
Replace the weakest parent by the fittest child.

In crossover operation, variable size cromosomes are used. In making a chromosome for a set rules, only those rules are included for which the weight is not zero.

THE FITNESS FUNCTION

In practice, it is not convenient to compute the conditional probability P(G|C) directly as a means of evaluating the fitness of grammars. Instead, the genetic algorithm uses an objective function F given by

$$F(G) = \frac{K_C}{L(C|G) + L(G)} \quad (8)$$

Maximizing F(G) corresponds to minimizing the denominator of equation. This in turn just amounts to maximizing P(G|C). The numerator Kc is a problem(corpus) dependent normalization factor that yields fitness values in the range [0,1].

Since $L(C|G)= -\log_2 P(C|G)$ it is given by

$$L(C|G) = -\log_2 \left(\frac{N_C!}{\prod_{\alpha \varepsilon C} f_\alpha!} \right) - \sum_{\alpha \varepsilon C} f_\alpha \log_2 (P_G(\alpha)) \quad (9)$$

The first term is a constant (depending only on the corpus) and therefore can be ignored in minimizing the denominator of equation 5. The second term is Nc times the cross entropy of the corpus C given the model provided by the grammar G. It can be interpreted as the number of bits needed to communicate the corpus (with the frequencies given) using a code guaranteed to minimize message length if the sentences had occurred in the corpus with probabilities as given by the grammar.

In order to compute L(G), the grammar is represented as a code. Different choices of coding scheme give rise to different probability distribution over the set of grammars. In genetic algorithm, a coding scheme is used in which a grammar can be represented in any convenient fashion as a genome, compute its length according to our chosen coding scheme and hence assign it a prior probability.

For BWGs with a fixed determined set of biases, a grammar is completely specified by some set of pairs of the form (r,w), where r is a rule and w its weight. Pairs are omitted if their weight is zero. The length for the whole grammar is given by the

sum of the lengths of the codes for each of its rules, where the length of the code of a rule is given by the length of a code for r plus length of a code for w.

To encode a weight w, one of a family of prefix codes for integers which all form good approximations to the minimal encoding can be used. These codes represent an integer by a code for the integer itself, preceded by a code for its length. The code for the integer w requires

approximately $\log_2(w)$ bits while the code for its length needs roughly $\log_2(\log_2(w))$ bits(using normal binary encoding). However this does not give any way of deciding where the code for the length ends and the code for the integer w itself begins. Therefore a code is used which duplicates every binary digit of the integer representing the length followed by a single 0. This means that an integer w will need approximately $\log_2(w)+2\log_2(\log_2(w))+1$ bits.

To compute the code lengths for r, a probability distribution P"(r) over the rules is defined. A natural way of computing the probabilities of each r_j is to look at the probabilities of the symbols in each position of the set of rules in the covering grammar. In particular, we look at the set of symbols allowed at a given position in the rules given the preceding symbols. If all legal symbols at that position can occur with equal probability, then P"(r) can be computed as follows

Let N be the set of non-terminal symbols in the covering grammar G and let n be the length of right hand side of the longest rule. Now write each rule r_j in the form $S_{j_0} \rightarrow S_{j_1} S_{j_2} \ldots S_{j_n}$ where S_{j_m} is defined to be a special "blank" symbol for all m greater than the length of the right hand side of rule r_j. Define S_{j_k} $(0 \le k \le n)$ to be that set of symbols given by

$$S_{j_k} = \begin{cases} N & \text{if } k=0 \text{ and} \\ \{ Sjk \mid \ni r_i \varepsilon G \text{ such that } S_{i_l} = S_{j_l} \ (0 \le l \le k) \} & \text{otherwise} \end{cases} \quad (10)$$

The probability P"(r_j) of rule r_j is than given by

$$P"(r_j) = \prod_{0 \le k \le n} P_{j_k} \quad (11)$$

Where $Pjk(0 \le k \le n)$ is defined as $1/|S_{j_k}|$

Given the probability distribution P over rules, the number of bits needed to represent a particular weighted grammar is given by

$$\sum_{(r,w)\varepsilon G} (-\log_2(P"(r) + \log_2(w)+2\log_2(\log_2(w))+1 \quad (12)$$

This quantity is of course $L(G) = -\log_2(P(G))$

ALGORITHM FOR EVOLVING STOCHASTIC CONTEXT-FREE GRAMMAR

To identify a Stochastic Context Free Grammar for a given corpus as training data that (a) models the corpus as accurately as possible and (b) generalizes appropriately to the wider language from which the corpus was drawn, the steps involved are as follows

Step 1: Identify a covering grammar for a given corpus as training data using Sequitur algorithm. The grammar must be as small as possible and simple.

Step 2: Generate all parses for all strings in the corpus derivable from the covering grammar using All Parse algorithm.

Step 3: Convert a stochastic context free grammar in to a biased weight grammar. Associate numerical parameters with the rules of the grammar, a bias and a weight

Step 4: Code grammar using prefix coding scheme for integers. This scheme is used to represent a grammar a convenient fashion as a genome. Compute its length according to our chosen coding scheme. The length of the whole grammar is given by the sum of the lengths of the codes for each of each of its rules, where the length of the code of a rule is given by the length of a code for r plus length of a code for w.

Step 5: Determine an objective function for the genetic algorithm to evaluate the fitness of grammars.

Step 6: Apply genetic algorithm for setting the parameters of the stochastic context-free grammar.Genetic algorithm is repeated until a threshold value is achieved for parameters of SCFG or a maximum iteration value is reached. Threshold value is dependent of the type of the language generated by the grammar G.

EXPERIMENTAL RESULTS

We have conducted a number of experiments in learning grammars for a range of formal languages. These languages are representative of those considered in other studies.

1. (a+b)*bb: the language is the set of strings ending with a sequence of at least two **b**s.
2. **EQ**: the language of all strings consisting of equal number of **a**s and **b**s, (ab+ba)(ab+ba)*.
3. The language $a^n b^n$ $(n \ge 1)$.
4. **BRACKET**: The language of balanced brackets.
5. **PAL**: palindromes over {a,b}.

For each experiment, a corpus was first produced automatically using a hand-crafted SCFG for the target language. This involved randomly generating on the order of 1000 strings up to a pre-specified 'maximum sentence length' (typically 6 or 8). For each problem, the population size was fixed to 25.

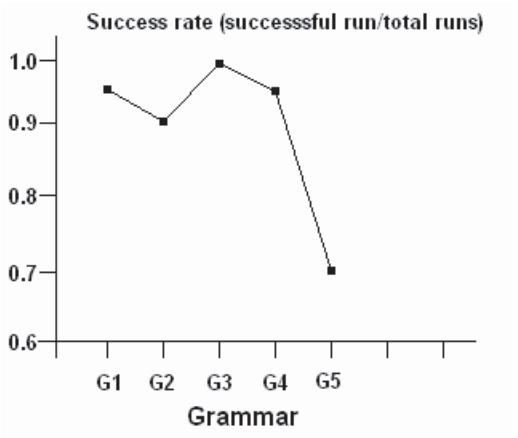
In order to assess the performance of the genetic algorithm, 20 runs were completed on each language learning task. A run of the genetic algorithm was terminated as 'successful' if a SCFG was found with fitness above a threshold value of 0.93. While this figure is somewhat arbitrary, experience has shown that grammars attaining this fitness are usually correct in the sense that they generate the target language exactly, and assign appropriate probabilities to the strings. Runs of the genetic algorithm that failed to attain the threshold value were terminated after a maximum number of select-breed-replace cycles. The number of cycles was set individually for each problem and was high enough to ensure convergence in the population.

The results of the experiments are summarized in the table given above. For each learning task, the table gives the number of non-terminals used in the covering grammar, the number of parameters to be optimized, the success rate (number of runs that attained the threshold fitness value) as well as the maximum fitness value found on the best and the worst runs of the genetic algorithm. As can be seen,

Table 1. Experimental result for different type of grammars

Language	Non-terminals	Parameters	Success rate	Best fitness value	Worst fitness value
G1: (a+b)*bb	3	6	19/20	0.972	0.946
G2: EQ	3	5	18/20	0.970	0.681
G3: BRACKET	3	5	20/20	0.955	0.949
G4: $a^n b^n$	4	5	19/20	0.978	0.866
G5: PAL	5	10	14/20	0.951	0.869

Figure 1. Graph between success rate and grammar given in table 1



the first four tasks ((a+b)*bb, EQ, $a^n b^n$, BRACKET) presented little difficulty. Inspection of the grammars produced on successful runs for these experiments showed that they were indeed correct. For the occasional unsuccessful runs the relatively poor fitness values attained suggest the presence of local maxima around which the population has converged. The palindrome example PAL provided the algorithm with a rather harder test. Here, the success rate fell to around 65% to 70%. On runs where the algorithm failed to find the correct grammar, inspection of the best grammars showed that the population had converged on solutions, which had the correct rules for palindromes starting with any of the available symbols, except for one. Because these grammars covered the palindromes while assigning generally low probability to a range of other sentences they still managed to attain a relatively high fitness.

Figure 1 shows that success rate is generally greater than 90% for the grammars. It depends on the complexity of the grammar.

CONCLUSIONS

The approach to grammatical inference described in this project differs from previous works using genetic algorithms in addressing the problem of corpus-based inference of stochastic context-free grammar. In our approach number of rules in covering grammar is reduced by using sequitur algorithm and convergence rate of genetic algorithm is speedup by using variable crossover over variable length chromosome algorithm. This makes direct comparison our results with those of other algorithms difficult. However, the experiments that we have conducted are typical of those in other studies and the results reported in this project appear promising. The approach also appears to compare well with other (non-genetic) techniques for stochastic grammatical inference.The main limitation of our approach is the cost involved in evaluating the fitness of each candidate solution, which requires parsing every string in the corpus in all possible ways. Success rate of our algorithm depends on the complexity of the grammar. Although inference can be performed very quickly for small covering grammars, the number of parses that must be considered increases exponentially with the number of rules in the grammars. This problem can be solved by including the possibility of a massively parallel implementation of this algorithm.

Intelligent Collaboration: The Paradox of "Ethical Agency" and "Corporate Governance"

Tagelsir Mohamed Gasmelseid, King Faisal University, Saudi Arabia; E-mail: tagelsir.gasmelseid@gmail.com

ABSTRACT

The unprecedented technological developments witnessed in the 21st centuary have been accompanied with a growing importance of "information ethics" due to their far-reaching effects especially for global transactions. Such importance has also moved a wide range of "issues" to the front line agenda of enterprises. The measures used to approach the resulting or potential "ethical dilemma" continued to be oriented towards the minimization of threats and improving privacy through technological and legal measures. Howevere, the use of advanced intelligent technologies such as software agents technology brings the issue of "ethical agency" to the surface and calls for a "redefinition" and paradigm shifts with regards to the way 'information ethics" is conceptualized.

1. INTRODUCTION

The recent technological advancements have significantly redefined the context and domain of data acquisition, processing, and sharing. While new patterns, platforms and architectures are being developed for the maximization of benefits from data, the growing emphasis on "collaborative work", "responsiveness" and "building of alliances" is reshaping the way global enterprises do business. Coupled with their process-oriented "enabling" features, the use of global networks and web based systems has turned enterprises into an archipelago of "integrated" islands of performance. The resulting new digital global economy is becoming increasingly based on global networks of "capital", "information" and "power" and is driven by institutional concepts of "deregulation", "liberalization", and "re-engineering" (Tagelsir, 2006). Within this context, the effort of enterprises is being directed towards process-centered activities that affect corporate functionalities such as:

a. Maintaining operationally-feasible process-technology matrix in a way that sets both the "rationale" and "foundation" for business process reengineering and continuous improvement.
b. Developing data repositories and adopting alternative forms of database creation, tuning and sharing using alternative architectures, platform and software engineering methodologies.
c. Mobilizing resources (including global networks and other related componenets) in pursuit of improving their potential to facilitate the provision and integration of e-services.
d. Managing information-intensive applications by incorporating "security" and "ethical" dimensions into their core processes.

The main focus of this paper will be on understanding the dimensions of "corporate governance" and "ethical promotion" for global enterprises with emphasis on copyright mechanisms and "ethical agency".

2. INFORMATION ETHICS

Information ethics is the field that investigates the ethical and moral issues associated with the development and application of information technologies in different domains. While it has been regarded as the theoretical foundation for "computer ethics", the focus of information ethics tend to be oriented towards addressing information privacy and confidentiality, data and application misuse, content management and web based interactions, online information authorization and verification, confidence building, resource sharing and the life cycle of information especially ownership, copyright and digital divide.

However, the continous organizational, institutional and operational transformations associated with the use of global networks are challenging enterprises to strike a balance between "information-sharing" and "information protection" and to effectively manage the ethical dimensions that govern the dynamics of "confidence" and "control" in pursuit of improving the capcity to develop and use alternative methods of "information distribution" and "information encryption". Building confidence as an ethical virtue, also demands enterprises to create "balanced and flexible" institutional measures and procedures that appropriately make this virtue "the responsibility of all".

The issue of content management and regulation are also becoming intensively ethics-related considerations. This is because the dynamics of "global access" demands enterprises to maintain "long reach" interfaces on the one hand and promote "corporate governance" and conviviality on the other hand. The ethical dimension of universal access originates from the interplay of different "technological" and "situational" change agents that may result into "disorder" and "unethical" practices if not applied properly. The growing amount and multiplicity of data types, diversity of data structures, hetrogenity of information representation architectures, and the growing capacity of web based systems and portals to manipulate, in a way or another, the way information is being accessed and used are generating fundamental information ethics and moral considerations. Some content-management issues like multilingualism, semantic and ontological considerations are introducing additional ethical dimensions and are acting at the same time as determinants for striking a balance between "access" and "sustainability".

The concern for information ethics especially for global enterprises originates from a set of reasons:

1. Competition in the global market is becoming increasingly resource-based, responsive and knowledge-intensive. The critical success factor for global enterprises, in this regard, is to effectively provide clients an integrated interface. Because global competition is dictating new axioms for the diffucion of technology, the question of information ethics emerges because the mechanisms of information use and protection significantly affects the capacity of enterprises to build international alliances.
2. Globalization processes increase the importance of information ethics because they lead to fundamental structural changes offered by the opportunities and threats available in the operating environment of enterprises and the growing importance of increased application and integration of advanced information and communications technologies into core business processes.
3. The emerging multiple formats and uses of information for web based processing and interaction requires continual reconsideration of ethical principles and how these codes are being adopted and applied. This is because information ethics influence personal decisions, professional practice, and public policy (Elrod & Smith, 2005).

3. MANAGING INFORMATION ETHICS

Because the nature and magnitude of "information ethics" is usually viewed within the context of a "networked" intersection of organizational, institutional, technlogical, cultural and political variables (Rafael 2000), alternative approaches and measures are being adopted over time to manage the issues associated with "information ethics".

The development of information and communications infrastructure has been widely used to "safeguard" information ethics by using robust, global, broadband and high-capacity processing platforms including the internet, Integrated Broadband Networks (IBN) and Integrated Services Digital Network (ISDS) (Manuel, 1996). However, the majority of these technology-centered interventions continued to be oriented towards maintaining, improving and promoting ethics by emphasizing on reducing security and ethical threats and to some extent, improving privacy.

A wide range of multiple legal measures are also being used as means for maintaining information ethics in enterprises such as Article 12 of the Universal Declaration of Human Rights, The UN Guidelines for the Regulation of Computerized Personal Data Files (1990) and the guidelines of Fair Information Practices. Howevere, the "sole" use of legal measures is challenged by the difficulty of maintaining acceptable levels of applicability between national laws and international legal frameworks. Such difficutlies have made global enterprises to continuously face difficulties with regards to developing effective customer relations' management systems, building effective international business alliances and meeting the operational requirements of global processing.

As a part of formal protection, intellectual property rights, copyrights, patents and trade marks proved to be effective mechanisms for securing information ethics within the context of collaborative global connectivity. A system of intellectual property rights (IPRs) is necessary to ensure that individuals or companies will carry out innovative activities otherwise imitation will erode the inventor's profit rate, and hence lower the incentive for inventive activities. An IPR, such as a patent, grants the inventor a legal monopoly to the commercial exploitation of the invention (Bekkers, et al 2002).

Through patents, for example, an IPR system enables the monopolization of inventions (for different time periods in different counties) in accordance with their satisfaction to certain country-specific and sometimes international requirements that qualify them for protection. The invention has to be new, involve an inventive step and be capable of industrial application. This means that nobody can carry out the invention claimed in the patent without express permission from the patent owner (Kennedy 2002). Despite the universal applicability of intellectual property rights, emphasis continued to be made on the decisions whether or not to patent using intellectual property rights based on a variety of decision attributes in pursuit of ensuring flexibility through flexible copyright modification and customization (Bulut & Moschini, 2006; Anton & Yao, 2004; Denicolo & Franzoni, 2004).

Despite the considerable benefits of such mechanisms, their efficiency in meeting the challenges posed by globalization tend to be questionable at least if they are not used collectively. While some efforts are done to examine the relationship between the use of copyrights and the process of building global alliances, little have been done to investigate their impact on the capacity of enterprises to benefit from technological developments and use of alternative intelligent (and other) frameworks to implement web based global trasactions especially when software agents' technology is being used and their resulting "moral and ethical" agency dimensions.

4. THE DOMAIN OF MORAL/ETHICAL AGENCY

Information ethics are strongly affecting the management of decentralized operations, building of alliances, enhancing coordination and sharing functionalities among web based applications. In addition, they have also been affecting the way enterprises are developing and using platforms for the "management of complexity" and enhancing "corporate governance".

Howevere, while enterprises are implementing decentralized activities through delegation and empowerment, the growing deployment of e-services and processing has motivated the use of "software agents" as means for supporting or acting on behalf of their "owners" or "users". The use of agent-based systems technology is growing in different domains because of their ability to offer modularity and abstraction necessary for facilitating the management of real, complex, large, and unpredictable problem domains (Tagelsir, 2006). Their deployment in different areas proved their relevance to handle complex, distributed problems involving a multiplicity of interconnected processes whose solutions demand the allocation of fusion of information and expertise from demographically distributed sources (Power 2000; Iglesias, et al, 1998). Especially in distributed environments where decision making data tend to be decentralized and the need for global control of the entire system increases, software agents must be able to interoperate cooperate and coordinate with each other in peer-to-peer fashion to increase their problem-solving scope through the use of multiagent mechanisms. Multiagent systems approach problems through the development of functionally specific, and possibly heterogeneous specialized modular components (agents) to solve particular problems by using their own most appropriate problem solving paradigms and interact in order to reach an overall goal and support different people (using different information sources and communication links), at different times, with different software tools and techniques. They generate approximate solutions by dividing the necessary knowledge into subunits, associating an intelligent independent agent to each subunit, and coordinating the overall agents' activity.

The context of "moral agency" tends to be oriented towards the conceptualization of information ethics of "mobile" multiagent systems by approaching the matter within the domain of "ethical decision making". The ethical principles that govern agent interactions and functionalities greately reflect the patterns and approaches used by their "owners" and "users" to conceptualize and justify their actions as either ethical or not.

However, by generally defining "ethics" as being doing with making a principle-based choice between competing alternatives, the use of multiagent systems provides different characteristics for the resulting "ethical dilemma" and "ethical decision making". The difficult task in this context is to approach the problem "logically" and make decisions based on well-reasoned, defensible "ethical principles", value judgments, and (formal & informal) guidelines. The emphasis on "deontology", articulation of rights, the definition of professional relationships and efficacy as means for maintaining confidentiality and impartiality and the adoption of different types of consequentialism (egoism, utilitarianism, and altruism) may all be necessary for approaching information ethics within the context of intelligent agent interactions.

The context of moral agency tend to be oriented towards examining the "morality" of artificial agents, cross-agent interaction in the infosphere and the problems arising from the life-cycle i.e., creation, collection, recording, distribution, and processing of information especially ownership and copyright, digital divide (Wikipedia website).

The issues of ethical or moral agency takes place clearly in multiagent mobile systems rather than single or limited-agents systems whose functionality is governed by limited boundaries of processing and information sharing and use. Within this context, the potential of ethical dilemma exists in two situations:

a. Because mobile agents interact with other agents outside the entire multiagent organization either to access databases or carry out transactions on other servers, an ethical dilemma may exist when:
    1. The mobile agent, either deleibrately or not, reacts (in a way or another) to the ethic-oriented dimensions of technology that characterize its use in different sirtautions such as amplification, routinization and sublimation. The ethical dimensions associated with such technological attributes stems from their ability to improve the sensory and interception ability of the entire mobile agent through the use of use of zoom lens, listening devices, and heat-detection toolsas well as their ability to "sustain" unethical actions and complicate their detection. All of these concerns increase the potential of an entire mobile agent to find "escape gates for bad unethical behaviour".
    2. The agents "visited", "interacted" or "consulted" by the entire mobile agent bring it into the "trap of unethical domain". These actions range from denying access, wrong-directing, and arresting, among others.
b. Despite the fact that the functionality of the entire mobile agent is governed by the processing and communication models incorporated into its knowledge and inference engines, it became confused about "what to do" when it finds itself faced by critical situations that are not predefined. And this brings to attention the basic question regarding the level of "autonomy" to be provided to the mobile agent and its ability to use its sensing abilities to "adjust its behaviour" in response to the changes taking place in its environment. It also has to do with the type of "ethical decision making" principle adopted by its "owner" or "user" and whether alternative paths of action or decision making models are allowed, whether the agent can "consult" with other agents in its entire multiagent organization, whether it returns back to the owner or user or commit unethical actions and justify them using the egoism principle.

But will the use of intellectual property right systems (including copyrights, trade marks and patents) "relaxes" or "complicates" the resolution of the resulting ethical dilemma? Will the actions committed by the entire mobile agent (irrespective of

their type and magnitude), be regarded as "ethical" or not? While the analysis of such dilemma remains "situational" and "domain-specific", at least providing an "yes" answer to the above mentioned questions remains questionable keeping in mind that the functionality of "mobile" multiagent systems remains governed by a complex cause-effect and reasoning context. However, the "reluctance" to have a "yes" originates from the fact that while the use of "databases and resources" copyrighting, encryption and other forms of information protection may "organize and regulate" the capability of the entire mobile agent to migrate across different servers, but it also encourages the "hosting" agents residing on these servers to bring the "visiting agent" into the ethical dilemma. Because the management of websites these days is becoming increasingly sensitive to breach of information privacy and confidentiality (and even political ones associated with war against terror), the continous change of website addresses or encryption keys may provide a room for unethical actions.

5. INTELLIGENT INTERACTIONS AND ETHICAL AGENCY: DIRECTIONS FOR RESEARCH

Because the use of web based inteligent frameworks are witnessing a growing deployment and infusion in core processes of global enterprises, the emphasis on the context of "information ethics" and the use of alternative mechanisms to regulate information access and use, special attention need to be directed towards some key research issues such as:

1. To avoid the downside risks associated with the use of copyrights and other intellectual property mechanisms and their impact on potential "unethical" agency, a "structrual" paradigm shift is looming very big. The refinement and orchestration of such mechanisms used to expand their focus beyond "lawful thinking" to move a step forward and incorporate "implementation" requierements and benefiting from the outstanding capabilities of the emerging technologies. Without such a shift the "conceptualization" of the domain of "information ethics", ethical agency and accordingly "operationalizing concepts" through acceptable implementation will not go hand-in-hand.
2. While the use of intelligent agents will continue to act as a major "enabling" platform for global interactions, the context of "ethical agency" need to be "mirrored" against threats associated with global collaboration, preception of such threats by decision makers and enterprises, attitudes towards using multiple approaches for the maintainance of "ethical" domains, and most importantly, the ability to couple and decouple mechanisms as the situation changes. Without such integrated thinking our ideas about information ethics in general and "ethical agency" in particular will remain a "cry in the desert", not implemented even if it is heared by someone because, simply, it is "scattered".

6. CONCLUSIONS

The question of information ethics is gaining momentum attention and importance within the context of global trasactions due to the complexities associated with the information-based migration of enterprises to "global trajectories". While such ethics are significantly and directly affecting some industries such as digital products (software, entertainment and libraries), their impact on others is also growing. However, the "isolated" implementation of technological and legal measures has been challenged by a wide range of considerations. The use of "intelligent agents" as a backbone concept for the implementation of global transactions, task coordination and information sharing among enterprises increases the importance of understanding "ethical agency" in a way that allows for an "acceptable" degree of integrated thinking that foucsses not only on "potential threats" and "unethical actions" but also to set the foundation for generating a process-technology matrix to guide implementation.

The Impact of an ICT Project (Health Information Systems Programme) on the Work Practices of Health Workers in Primary Health Sector: A Case Study from India

Zubeeda Banu Quraishy, University of Oslo, Norway; E-mail: zubeedaq@ifi.uio.no

ABSTRACT

Health care sector is very complex and different from other sectors due to the high level of unpredictability in processes. For ex, an epidemic might break out, or emergency situation may suddenly occur and totally change the schedules of trajectories. The available resources in terms of drugs and equipments might also affect the articulation of work. Articulation here refers to collaboration and reaching common understanding(Strauss et al 1985) which is imperative in this field. Hence trajectories are not simple and linear. Introducing computers and implementing health information management systems requires new work routines and practices which are quite challenging(Boulus,2004). As pointed out by Nina Boulus(2004) changing work practices and improving management information systems are not singular elements but rather part of a large heterogeneous socio-technical network that includes arte facts, tools, people and other socio - cultural factors etc. Also she views the transformation process as a mutual, dynamic and reflexive transformation of both information infrastructures and situated practices of use. While the typical focus of training programs during the process of implementation of HIS is their technical content, many practitioners have demonstrated that social factors could be instrumental in the target system's success as the positive outcomes afforded by user training and adoption of the system are improved user attitudes, behavior, and performance. Thus to make the ICT projects sustainable it is essential that social factors along with technical issues are given importance during the process of implementation as ultimately the technology intervention has to get integrated into the existing work practices of the people in the organization thus leading to the establishment of new routines which will support the institutionalization of this technology- induced change. Using narrative method this paper will not only highlight the work culture that existed before the intervention of an ICT project but also how the work practices changed slowly during the process of an ICT intervention, and the different challenges (technical, social, geographical and political) faced both by the implementation team and the users in bringing about a change in the work culture of health workers based at the community level is described.

INTRODUCTION

Information and Communication Technologies, variously called ICT4D, i4D, or ICT, for Development interventions have demonstrated tremendous transformational potential for the developing world in e-government, telemedicine, e-learning, and other grass roots initiatives. (Sood, 2002).

There is enthusiasm in the development community over the great potential for ICTs as it is believed to alleviate the social and economic problems of the developing world (d'Orville, 2000; Allen & Thomas, 2000). A special challenge would be how to reach out to the poor and marginalised particularly women and make sure that they are not excluded from the emerging information society (Ekenberg & Asker, 1999). In order to bring about a realistic ICT profile particular to a rural community this implies that the starting-point for ICT use must be the people needs (d'Orville, 2000; Mansell, 1999) which can be identified by using a participatory approach.

Many approaches to using ICT for development have exposed the failure of top-down, one-way, non-consultative, technology-driven approaches to development communication (O' Farrel, 2000). Thus, developing appropriate ICTs (i.e. a framework) for sustainable development is, therefore, quintessential.

In health sector electronic information systems are revolutionizing health-care practice, research and education. Many health-care professionals realise the need for skills in finding and using information, and in assessing information systems since information is a critical ingredient for development. The more information that the poor and the marginalized possess, the greater their sense of empowerment.

With greater information particularly in health sector the health workers and the other staff based at the grass root level are better able to organize health care and take immediate and appropriate actions to improve the quality of health care services.

In this paper I try to describe how a contextual intervention of an ICT, Health Information Systems Programme (HISP) an action research project for mainstreaming and strengthening health information management at the district level is introduced to bring about changes in the work culture of health workers based at the community level.

Information and communication technology (ICT) continues to have a significant impact on the lives of people as its impact weaves through the cultural, psychological, political, sociological dimensions of human/social existence -- to spiritual and cultural values. The critical influence on people's responsiveness to change probably is its social attitudes, religious beliefs, and culture.

(In the present paper, the empirical data presented has been collected from Kuppam, a small area with nine Primary Health Centres(PHCs) spread over five mandals(administrative divisions) in Chittoor district in Andhra Pradesh, a site where the project was piloted and later was in the process of achieving sustainability).

The case study presented below apart from describing the impact of an ICT project on human behaviour also provides us a deeper understanding of the socio technical aspects of the complexities and challenges that emerge from the implementation of the HISP, an ICT project which is important from an anthropological perspective.

WORK CULTURE THAT EXISTED BEFORE THE INTERVENTION OF HISP

Before the intervention of the HISP it was found that PHCs which were supposed to provide both prevention and out reach services were instead burdened with achieving targets related to performance indicators such as immunizations, Ante Natal Care(ANC) registrations, ANC check ups, institutional deliveries,

sterlisations etc as there was an extreme pressure from the health authorities on health staff particularly on the Multi Purpose Health Assistant(MPHA)based at the grass root level to achieve the numbers fixed by them without taking in to account the ground realities.

Since the MPHA is the main link between the primary health care and the community in the rural areas extreme pressure is exerted at the health worker in fulfilling the targets. So, ultimately the health worker who is required to do outreach services and provide services to the communities instead neglects her duties and gets fully involved in completing the targets 'by hook or by crook'. As a result there is lot of manipulation in the data collected and collated at all levels.

Some of the elder MPHAs reminisces that during seventies and early eighties the focus of PHCs was only on providing services to the community. But in recent years with the focus on targets on important performance indictors the concept of primary health care has changed and the stress is only on figures that is, quantity and not on service.

For years the usual routine of work the MPHAs have been doing is that after performing the outreach services in the community the entries are made against the services provided in the field diary. And on reaching home instead of copying the figures from the diary in to the respective fourteen registers maintained for each service they postpone the above work to the day when review meeting is held in PHCs.

On the review meeting day the figures are entered in to the various registers maintained for each service and then they are culled out again to prepare different reports for different services though it is tedious and monotonous. More over in this pattern of work they find it quite easy to change the figures in the last minute to match the targets given by the medical officer before they can submit those forms to the supervisor on the review meeting day.

But during the intervention of the Health Information Systems Programme (HISP) commonly referred to as computer project among the health workers which was implemented in all the 9 PHCs of Kuppam, jointly done by University of Oslo, Norway and Government of Andhra Pradesh, the implementation team explained how HISP in the long run will benefit the health workers by reducing the work pressure by not entering data in to many registers but only in one or two forms in the DHIS(District Health Information Software) installed in a computer and how the data can be analysed and converted in to information.

INITIATING A CHANGE IN WORK PATTERN THROUGH HISP

Attempts to Mainstream Information Systems in Health Sector

Keeping in view the main objectives of HISP and the work pattern that exists within PHCs in the broader socio political context it became imperative to initiate efforts in changing the work culture of the health staff within PHCs and also to bring about the changes in the district medical and health office at district head quarters.

DATA ELEMENTS AND REPORTS

Before attempting to introduce change in the work practices of health workers initial months were spent in Chittoor district trying to understand the structure and functioning of both district and primary health units, information flows, different arte facts and tools used for data collection, reporting structure and formats. Based on the information attempts were made to develop minimum data sets by removing redundant data elements.

Similar to the redundant data elements was the practice with the reports. After discussing with officers in charge for various programmes and making them see the uselessness and waste of efforts of sending repeated reports containing duplicated data efforts were made by implementation team to reduce the number in the reports sent from district to state.

Simultaneously efforts were made to set up the necessary infrastructure by placing computers in all the 9 PHCs of Kuppam constituency for initiating change through DHIS (District Health Information System),an open source software for improving their routine health information processes since more than 60% of the time of health workers is spent on health information transactions (collection of data, collation of data in various forms and registers, and the transmission of data to upper levels of district and state). It was also considered that improving these processes will then directly have an impact on work, and the health staff can focus more time on providing care to the community as compared to filling

Figure 1. Map showing Kuppam constituency with five mandals and nine primary health centres

up endless forms that ultimately are marginal to their work of providing health care to the community.

So, keeping in view the above perspective 'On-site' and 'Off-site' training strategies were devised in order to build the capacity of health workers to work independently on the HIS software. Initially the trainers and the health staff had many problems on both sides -teaching as well as learning.

After lot of motivation and continuous training from the implementation team and the pressure from the officials at the different levels finally there were quite a number of medical officers and health staff including MPHAs, MPHS, pharmacist and lab technicians from different PHCs who managed to learn the computers, DHIS software and the generation of reports. Slowly this pattern of work became a routine and health staff enjoyed their new work culture as it not only reduced their work load and efforts but they were getting empowered with new skills. Moreover this training helped them to build capacity for dealing with health information, and enabling a culture of "use of information."

Both with peer pressure and through word of mouth the attitudes of their colleagues also changed and all the staff in their respective PHCs dutifully started using computers and DHIS software for entering data, doing analysis and generating reports.

Eight months after the project was initiated in Kuppam it was evaluated by the office of Commissioner of Family Welfare Department(CFWD) who gave instructions to the DM&HO to institutionalize HISP.

We assumed that as in any developing country more so in the rural areas the computers, free software and the free training on the software would be a welcome feature but there were many constraints and resistances which were not obvious initially but were very subtle and strong in nature to overcome them.

DIFFERENT CHALLENGES ENCOUNTERED WHILE INTRODUCING CHANGE IN THE WORK CULTURE OF HEALTH WORKERS

Apart from the different challenges faced by the implementation team such as power dynamics and social politics within PHCs not allowing the grass root workers learn computers and acquire new skills, too many meetings and workshops focused on achieving the targets sapped the time and energy health workers, hardware problems & problems of power supply which hindered the training programmes, gender concerns and the most important issue was that of the refusal of statistical officer in the DM&HO to learn computers and DHIS software thus putting all the efforts of HISP implementation team and the sanction from CFWD to institutionalize HISP at stake.

In spite of all the challenges faced both by the implementation team and the users in adopting the technology there was a positive outcome in terms of users adopting and using the technology in their work practices. The users particularly those based at the primary health centres (MPHAs, MPHS and in some cases medical officers, lab technicians and Pharmacist) started to use computers and DHIS in their daily work. The above case study delineates how new technology affects and interacts with the various actors and vice versa indicating a mutual interaction process.

But whether the impact of an ICT project lasted long enough in their work practice bringing about a change in their work culture is a point for discussion which needs to be discussed separately.

Dynamic Security Scheme for MANET

A. Shajin Nargunam, N.I. College of Engineering, Thuckalay, Tamil Nadu, India; E-mail: ashajins@yahoo.com

ABSTRACT

Secured communication in mobile ad hoc network is a crucial issue due to dynamic nature of the network topology. Due to lack of centralized control, issuing certificates from a centralized certification agent is not possible in ad hoc network. The major problem in providing security services in such infrastructure less networks is how to manage the cryptographic keys that are needed In MANET any node may compromise the packet routing functionality by disrupting the route discovery process.. These unique characteristics of mobile ad hoc networks causes a number of nontrivial challenges to security design such as open network architecture, shared wireless medium, stringent resource constraints and highly dynamic topology. These challenges make a cause for building multi-fence security solution that achieves both extensive protection and desirable network performance. In particular, the absence of a central authorization facility in an open and distributed communication environment is a major challenge, especially due to the need for cooperative network operation. We propose a novel cluster based security scheme to protect mobile ad hoc network link layer and network layer operations of delivering packet over the multihop wireless channel. The dynamic network topology can be managed efficiently by the proposed cluster based architecture. A well-behaving node becomes a cluster member after the initial trust verification process. The membership validity period of a node depends on how long it has stayed and behaved well. Non overlapping clusters are created using the dynamic cluster creation algorithm. The cluster construction is fully distributed so efficiency is not degraded by node mobility.

Keywords: Cluster, Denial of Service, MANET Security.

I. INTRODUCTION

In ad hoc network every node is self-organized and each node can communicate directly with other nodes in the network through broadcast radio transmissions, i.e., transmissions that reach all the terminals within the transmission power range. However, due to radio range limitations, physical broadcasting does not cover all nodes in the network. In multi-hop scenario, packets are relayed by intermediate nodes to reach the destination. Applications of mobile ad hoc networks can range from military field communications, where networks must be deployed immediately without the support of base stations and fixed network infrastructures, to inter-vehicle communications, designed for both traffic safety enhancement and entertainment purposes. The ultimate goal of the security solutions for mobile ad hoc network is to provide security services, such as authentication, confidentially, integrity, anonymity and availability to mobile users. In order to achieve this goal, the security solution should provide complete protection. We seek to protect the network connectivity between mobile nodes over potentially multihop wireless channel, which is the basics to support any network security services. Security never comes for free. When more security features are introduced into the network, it increases the computation, communication and management overhead. In fact, both magnitude of security strength and network performance are equally important, and achieving a good trade-off between two extremes is the basic challenge in security design for mobile ad hoc network. Fully distributed cluster based security scheme provides secure peer to peer communication without compromising the network performance.

The rest of the paper is organized as follows. Section II discusses a review of related work. Section III describes the security issues in MANET. Section IV discusses the fully distributed cluster based security topology. Section V describes the dynamic clustering algorithm. Section VI discusses the performance issues. Section VIII concludes the paper.

II. RELATED WORK

The traditional key distribution protocols rely on infrastructure with online trusted third parties. When the users want to establish secure communication among them, each one of them has to obtain a new session key from the key distribution center. There is also number of schemes extending this approach to ad hoc network. [5] Present a hierarchical framework and key distribution algorithms for dynamic environment, with a focus on how keys and trust relationships are transferred when users move between so-called "areas" in the hierarchy. When distance vector routing protocols such as AODV [4] are used, the attacker may advertise a route with smaller distance metric than its actual distance to the destination or advertise a routing update with a larger sequence number and invalidate all the routing updates from other nodes.

Broadcast can be limited by adjusting the TTL value on each transmission is disused in [1]. The rapid proliferation of wireless networks and mobile computing applications has changed the landscape of network security. The traditional way of protecting networks with firewalls and encryption software is no longer sufficient and effective. The first key pre-distribution scheme is given in [6].

Carmen et al. analyzed a wide variety of approaches for key distribution in sensor network [3]. Study of recent literature reveals that reliable mathematical modeling of ad-hoc networks is gaining increased attention [7]. In [2], they considered the case when each node is its own authority and tries to maximize the benefits it gets from the network. Attackers are mainly outsiders of any security system, and such attackers can be resisted through authentication protocol [9]. Routing protocol intrusion detection has also been studied as a mechanism for detecting misbehaving routers [10]. Mobile agent based mechanism is used in [8] to detect the intruders.

In [10] fully distributed cluster based packet routing architecture is given. The feasible path to a destination is calculated using the QoS information available with each cluster members.

III. SECURITY IN MANET

In contrast to fixed networks a centralized certification authority is not feasible in ad hoc networks. Distributing the functionality of certification authority over number of nodes is a possible solution. This can be achieved creating n shares for a secret key and distributing them to n different node. Key can be generated by combining s shares using threshold cryptography technique.

Current ad-hoc routing protocols are completely insecure. Moreover, existing secure routing mechanisms are either too expensive or have unrealistic requirements. In ad hoc network, security solution should isolate the attackers and compromised nodes in the network. Proactively isolating the attackers ensures that they cannot continue to attack and waste the network resources in future. A security solution should have decreasing overhead over time when the network is in good condition without any attacks. By adopting the cluster based security scheme it cause less overhead as the network is in operation and proactively isolate the attacker as non cluster member.

IV. CLUSTER-BASED TOPOLOGY

We assume that self organized mobile networks are formed by a group of nodes having a valid identity (for example communication between the military officials or disaster recovery team). In our design each node is granted temporary admission into the network using an identity verification process. Each node generates a secret using the equation (1) and forwards it to the neighboring nodes. To verify the secret, neighboring nodes generates the covert using its identification number and compute the difference between the received value and the calcu-

lated covert. If the difference is less than the threshold value Sth, it accepts the sender as a valid member and add the sender node ID to set S. (S is the set of all valid neighbors and dynamic clustering algorithm uses set S to create non-overlapping clusters)

$$y = f(\vec{u}, cur - time) \quad (1)$$

After initial verification all nodes are continuously monitored by the neighboring nodes and credits are calculated based on the behavior of the neighbors. Watch-dog mechanism is used to monitor the neighboring nodes. A node accumulates its credits as it stays and behaves well in the network. The period of validity is propositional to its credits. Miss-behaving nodes credits are decremented; it will be denied network access when it reaches the minimum threshold level.

A. Probabilistic Clustering Model

It is possible to characterize this type of phenomena to which the poisson distribution is possible. T1, T2, T3 … Tn are the non-overlapping intervals, then the number of nodes entering into the cluster boundary in the interval is independent. There exists a constant q such that the probability of one event (exactly one node enters into the cluster boundary or leaves the cluster boundary) occurs in the interval of length dt is approximated to q*dt. The probability of two or more events will occur during an interval is approximately zero. So the experiment can be called as poisson experiment. For such experiment, if X counts the number of events occurs during any given interval, then it can be shown that X posses a poisson distribution. If the three poisson condition do hold and is X counts the number of events occurs during some specific time interval duration t, the X is poisson distributed with $\lambda = qt$.

$$P(X = x) = p(x; \lambda) = e^{-\lambda} \lambda^{x} / x! \quad (2)$$

The probability distribution function is

$$P(X \le x) = \sum_{k=0}^{x} p(x; \lambda) = \sum_{k=0}^{x} e^{-\lambda} \lambda^{k} / k! \quad (3)$$

E(x) is a parameter that carries information regarding the central tendency of the random phenomenon modeled by X. E(x) is often sufficient to give a partial description in terms of moments of the random variable. A moment generating function of a distribution can be employed to find the moments of the random phenomenon. Function of the variable t is defined as the moment of the random phenomenon X with respect to time t. The cluster topology changes can be represented using the random experiment X. The probability of nodes entering into the cluster boundary and nodes leaving a particular boundary can be calculated from the moment generating function.

Figure 1. Security architecture protocol stack

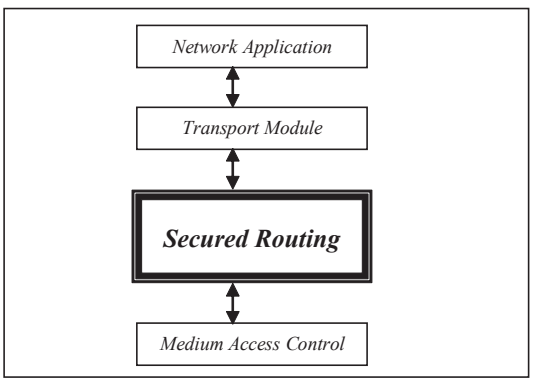

Figure 2. Framework of the network layer security

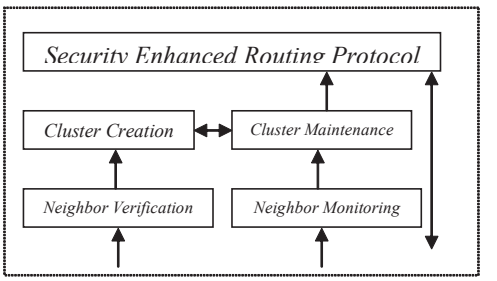

Figure 1 illustrates the protocol stack architecture of our security system. Figure 2 illustrates the composition of our security solution, which consists of five inter-related components.

B. Cluster Gateway Node Selection Process

MANETs can be modeled as an undirected graph with weight, G, G= [V, E] V, is the set of the mobile nodes and the E the set of the bidirectional wireless link. G and V are both dynamic set. An edge dominating set is a split edge dominating set if removal of D splits the graphs G1 and G2 into two sub graphs. The split domination number Dn is the cardinality of the dominating set.

Theorem 1

Let D be a split edge dominating set of G then

$$|E - D| \le \sum_{x \in D} \deg(x) \quad (4)$$

The equality holds if and only if the following conditions (a) and (b) hold.

a. D is independent
b. For each $x \in E - D$ there exits only one edge $y \in D$, such that $N^{I}[x] \cap D = \{y\}$, where $N^{I}[x]$ is the set of edges having exactly one vertex in common with x.

Proof:

Since each edge in $E - D$ is adjacent to at least one edge in D, it contributes at least one to the sum of degrees of the edge of D.

Hence $|E - D| \le \sum_{x \in D} \deg(x)$

Now let $|E - D| = \sum_{x \in D} \deg(x)$

Suppose D is not independent. Let x1 and x2 be any two edges of D having a common vertex. Then x1 is counted twice; once in deg(x1) and once in deg(x2). Then the sum of the degree of edges in D exceeds $|E - D|$ by at least two, a contradiction to the equality (6). Hence, D must be independent.

Now let $|E - D| = \sum_{x \in D} \deg(x)$ and (b) does not hold. Then $N^{I}[z] \cap D = \phi$ or $|N^{I}[z] \cap D| \ge 2$ for some $z \in E - D$. Since D is split dominating set the former case does not arise.

Let *x1* and *x2* belong to $N^{I}[z] \cap D$. Then $\sum_{x \in D} \deg(x)$ exceeds $|E - D|$ by at least one, since z is counted twice; once in deg(x1) and once in deg(x2), a contradiction. Hence if (a) and (b) are true then $|E - D| \le \sum_{x \in D} \deg(x)$.

If D is independent then D represent the set of gateway nodes that interlinks two clusters. So set of gateway nodes connecting two different clusters can be identified using equation (4).

Cluster creation module forms the non-overlapping clusters based on the valid neighbor set data. Gateway nodes are identified by the cluster maintenance module and all members maintain the list of gateway nodes. In dynamic network environment asymmetric keys can be used to encrypt/decrypt the data.

C. Cluster Maintenance

Cluster maintenance module proactively maintains the route information of all cluster members. There are three topology changes that requires cluster updation

Route discovery packets are forwarded only to the gateway nodes if the destination node is not in the same cluster. Our security system can operate in two modes. In normal mode route discovery packets are forwarded in plain text. Source announces its public key. Destination node can encrypts its data using source public key. For further data transfer symmetric keys can be used. In normal mode a passive attacker can view the path information during a data transfer. In fully secured mode in addition to data encryption the network layer packet header is also encrypted using the public key of gateway node along the path. In a shared wireless channel all neighbors hear the signal. But only the corresponding node can decode the coded signal using its private key. So information is never disclosed to unauthorized nodes.

V. IMPLEMENTATION

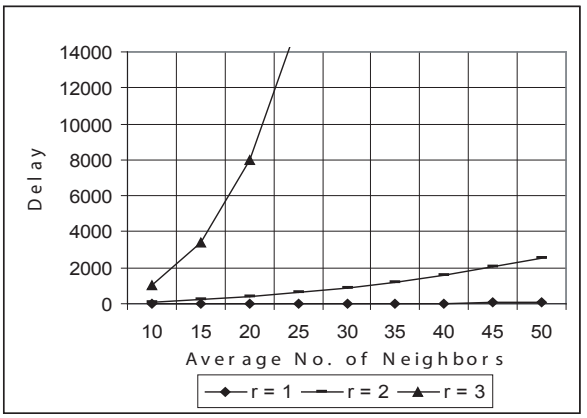
In order to provide scalability and to enhance the availability (by providing the service locally), the network is partitioned into a number of non-overlapping groups called clusters. In the conventional approach, each cluster has exactly one distinguished node, designated as cluster head, which is responsible for organizing and establishing the cluster. Cluster-head election algorithms are used to elect these cluster heads. The main bottleneck in this approach is the single point of failure (if the cluster head crashes, the entire QoS parameter table information will be lost), which forces the above procedure to be repeated for the construction of the QoS parameter table and subsequent election of the cluster head. To overcome the above problems, a fully distributed architecture is proposed. Clusters are created using a cluster creation algorithm and each cluster member maintains a QoS parameter table (about its cluster members) and a gateway table. Gateway nodes manage the communication with adjacent clusters. Routing is typically divided into two types: routing within the cluster (intra-cluster routing) and routing between different clusters (inter-cluster routing).

In this section, we present our algorithm and protocols that implement the localized security services and the self initialization of the mobile ad hoc networks. For the proposed clustering technique each node needs one or more hop connectivity information to execute cluster creation and maintenance algorithm. The cluster boundary or radius is adjusted based on the congestion factor of ad hoc network. The degree of the node is used as the congestion factor cf. If the congestion factor cf is grater than maximum threshold tmax (cf > tmax), it implies ad hoc population is very high consequently the hop count is set to one. If the congestion factor is between tmax and minimum threshold tmin (tmin <= cf <= tmax) it denotes the node is in a medium populated area consequently the hop count is set to two to create a strong connectivity. If the congestion factor cf is less than tmin (cf < tmin) it implies the node is in a sparsely populated area consequently the hop count set to three to maintain the strong connectivity.

Dynamic Clustering Algorithm

1. S: set of ID's of neighbors according to the hop count including the current node ID.
2. if (cur_id == msi(S))
   cluster_id = cur-id;
   forward to all nodes in set S (cur_id, cluster_id, location)
   S = S – {cur_id}
3. while (S != empty)
   on receiving neighbors(id, cid, loc)
   if (id == cid) and (cluster_id == UNKNOWN or cluster_id > cid) and (md == NOTSET or md > diff(cur_loc – loc)
   cluster_id = cid
   md = diff(cur_loc – loc)
   S = S – {id}
   if (cur_id == min(S))
   if (cluster_id == UNKNOWN) cluster_id = cur_id

Figure 3. Delay versus average no. of neighbors



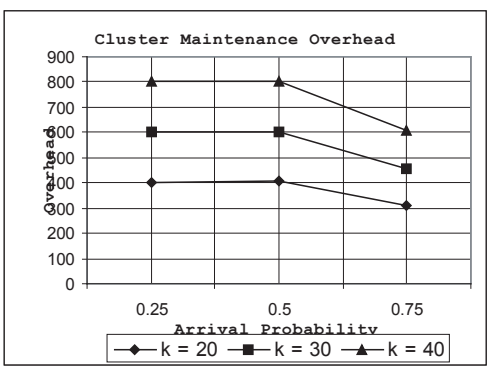
forward to all nodes in set S (cur_id, cluster_id, location)
S=S-{cur_id}

Using the above algorithm the non-overlapping clusters are formed based on the location of mobile nodes. The nodes, which are very close to each other, are grouped together. Each node maintains a route table with the QoS values and public key of all trusted cluster members. The algorithm is self-terminating and it leaves only the far-off isolated nodes as non-cluster members.

Neighbor monitoring is a lightweight process. It does not affect the normal functioning of a mobile node. For calculating the credit it simply listens to the packet forwarded by the nearby nodes. Using the message authentication code it checks whether the packets are relayed correctly by the neighboring nodes. Active attackers can be isolated using this mechanism. But another issue is in the shared wireless channel any node with in the transmission range of another node can receive the signals. So passive attackers can read all transmitted plain text data. To defend such types of attacks we propose a lightweight public key encryption method. The encryption and decryption process is done in the network layer. If network layer receives an encrypted packet, it decrypts the packet using its private key. If current node is the destination node, the data part is given to the upper layer. Otherwise according to the route table information find out the next node along the path to destination. Encrypt the packet using the intermediate node public key and send it. By this way we can protect the data from passive attackers also.

For cluster maintenance idle nodes periodically send a small alive signal to all trusted cluster members. If the update timer expires the corresponding node entry status in the route table is changed to down and it starts a wipe out timer. If the wipe out timer expires the corresponding entry is removed from the routable. If an alive signal or a data packet is received form that node before the timer expires then the status the node is revoked to up state and it restarts the update timer.

Figure 4. Cluster maintenance overhead



VI. PERFORMANCE EVALUATION

As the network topology changes dynamically, we considered a random topology for the analysis.

Let k denotes the average number of neighbors of a node. n is the number of mobile nodes in the network. c is the average number of members per cluster. Total number of messages replicated by a single cluster init message is

$$S_r = 1 + \sum_{i=0}^{r-1} k^i(k-1) \quad (5)$$

Where r denotes the radius of the cluster in number of hops. Rr nodes receive and process the cluster init message.

$$R_r = \sum_{i=0}^{r-1} k^i(k-1) \quad (6)$$

Figure 3 shows that as number of neighbors increases the processing overhead increases which in turn increases the packet transmission delay. Value of Rr is directly proportional to r and k. In ad hoc network topology changes dynamically. So k varies dynamically and it is not possible to control the topology change in ad hoc network. To have strong connectivity the cluster radius has to be increased. If r increases then the transmission delay increases exponentially. So without losing the connectivity we have to reduce the radius r. if number of neighbors' increases then r can be reduced without affecting the connectivity. If r decreases then transmission delay decreases. The cluster radius can be adjusted according to the value of k to maintain the connectivity and to reduce the transmission delay. If k is grater than the maximum threshold (tmax) then r can be set to one. If k is less than the minimum threshold (tmin) then r can be set to three. The maximum and minimum threshold values can set according to the other external parameters. If value of x is between tmax and tmin then rcan be set to two. The cluster initialization overhead can be maintained at an optimum level without losing the connectivity by adjusting the values of k and r.

For cluster maintenance each cluster member needs to forward the new information to all other cluster members. If a cluster member leaves the network, the trusted cluster member who identifies the change must inform this to all other members. A misbehaving node can also send a similar message to all other cluster members. But to prove the identity of the sender the trusted cluster member can encode the data using its private key. All other member maintenance the public keys of other trusted members and the data could be decoded using the corresponding public key. If a new node enters into the cluster boundary, it calculates the congestion factor. Based on the congestion factor it calculates the hop count and it executes the dynamic clustering algorithm. The cluster maintenance traffic overhead varies based on the arrival of new cluster member and departure of existing cluster members. Let Pnew is the new cluster member arrival probability. Let t is the traffic overhead per link. The overhead created by the arrival of new nodes is N.

$$N = Pnew\ [t(1 + 2\ r\ k)\ ] \quad (7)$$

Normally the probability of arrival of new cluster members increases as the node congestion increases. In our approach to maintain the connectivity, the cluster radius r is adjusted according to the congestion factor. So value of r decreased as Pnew increases. Figure 4 show that cluster maintenance overhead due to arrival of new cluster members does not increases as the new cluster member arrival probability increases.

$$c = r\ k \quad (8)$$

The control message traffic overhead for cluster maintenance is in o(c2). Even though the number of nodes in the network increases c remains almost constant because the cluster radius is adjusted according to number of nodes. c dose not increases as n increases. The control message traffic overhead does not increase as the number of nodes in the network increases. So this approach is scalable.

VII. CONCLUSION

Most of the proposed routing solutions are, as yet, incomplete when it comes to security issues. We can trust a routing mechanism only when it guarantees that all transmission will be protected. In this paper we proposed a novel security based routing protocol in which the packets are routed only through the trusted members. The trust factor of a mobile node is verified and monitored by neighbor verification and neighbor monitoring modules. Based on the calculated credits other cluster members maintain their routing table. In fully secured mode all transmissions are protected by encoding the network layer packet header in addition to data encoding. In the sheared wireless channel all neighbors hear the signal but only the corresponding router can decode the packet using its private key. Analysis shows that the secured cluster creation and maintenance overhead does not increase as the network size increases. This scheme is more efficient in terms of the resultant routes establishement, resource reservations, and computational complexity. If multiple malicious nodes collaborate, they in turn will be restricted and isolated by their neighbors, because they monitor and exercise control over forwarding RREQs by nodes. Hence, the scheme successfully prevents Distributed DoS (DDoS) attacks. Future works includes the implementation and testing of the algorithm in real environments.

The Implication of Outsourcing Practices for Knowledge Management

Sardari Ahmad, Shahed University, Tehran, Iran; E-mail: As_ahmad2001@yahoo.com

ABSTRACT

It is the aim of this paper to explore the nature of outsourcing and subcontracting practices and to identify the effects of using such policies for the accumulation and maintenance of knowledge in organizations. using evidence from, a case study research, conducted in three (3) medium size Tools industries, this study examines how outsourcing and subcontracting policies are set in practice and how the formation of such contractual inter-organizational relations affect the organizations as learning and knowledge entities) While it is argued that knowledge sharing between organizations requires mutual collaboration but also the construction of social environment, which promotes communication and sharing of cultures, it is shown in the research that contractors were not actually willing to share their expertise and their know-how. Additionally, the outsourcing of operations has affected the formation of people's identities in the organization and the will and ability of employees and managers to participate to the company's processes. It is therefore argued that outsourcing has reduced the absorptive capacity and the intellectual capital of the organization and has produced secondary negative effects such is organizational dependency from contractors and loss of the organization's ability to control and initiate innovation. The paper summarizes the findings within a model of 'vicious cycle' and suggests that outsourcing eventually leads to the addiction of .the organization to 'buy' expertise and knowledge, in order to fulfill short-term goals, instead of trying to acquire or create new knowledge.

Keywords: knowledge management, outsourcing, communities of practice

INTRODUCTION

The basic aim of the study is to show how the use of outsourcing policies (outsourcing, out tasking, subcontracting) affects the accumulation and circulation of knowledge in organizations and to elaborate a clear view .on how organizations deal with this relationship Although there is growing interest for the transformation of organizations into dynamic networks (Grandori & Soda, 1995) and the rhetoric of virtual enterprising gain attention (Hale & Whitlam, 1997), there is little interest so far for understanding the implications of the structural changes for knowledge management; organizational knowledge is treated in mos1 studies using the perspective of the traditional organizational boundaries despite the fact that· "it is certainly the case today that all organizations are being reformed and they an increasingly dependent on external sources of knowledge" (Quintas, 2002: 7). Despite the fac that some articles are concerned about the connection of outsourcing with organizational knowledge (Misawa & Hattori, 1998; Takeishi, 2002; Hendry, 1995) it can be argued that no much has been said about how outsourcing practices affect organizations, especially in term of knowledge management. The lack of such literature seems to be more important because c the increasing use of outsourcing and subcontracting by many enterprises (Chan, 199.::1 Hendry, 1995: 193; Johnson, 1997).

APPROACHING A DEFINITION FOR KNOWLEDGE MANAGEMENT AND OUTSOURCING POLICIES

Outsourcing

It is true that under the current neo-liberal model, in most capitalistic economies, organizations give a great importance in short-term results and neglect certain aspects of long-term planning (Whitley, 1999; Lazonick & O' Sullivan, 2000). Under this short-terms perspective, which has been often criticized as 'myopic', organizations have been increasingly using outsourcing and organizational networks in the last decade as a mean to manage their operations economically (Jarillo, 1988; 1993). It is actually shown in many studies that the reasons for using outsourcing policies are usually economic (Budros, 1999; Quinn, 1992; Jarillo, 1993) or knowledge oriented (Takeishi, 2002; see Chan, 1994 for a classification of outsourcing reasons).

By the word 'outsourcing', we mean the use of outsiders and contracted work or the use of an external agent's services in order to fulfill operations that should normally take place 'in-house' (Embleton & Wright, 1998; Laabs, 1997). As argued in Johnson (1997:4-6), the term 'outsourcing' can be considered as a big umbrella covering all forms of contracted work provided' by outsiders, although the word 'outsourcing' is usually used for information systems and facilities management projects (Vanson, 2001). Under this perspective, in this study the word outsourcing will be used to imply all forms of assigning work to outsiders such are formal outsourcing, out-tasking and sub-contracting. Summarizing the key elements from literature (Johnson, 1997; Hendry, 1995; Yakhlef, 2002).

Knowledge Management: The Social Dimension

This paper chooses 1£ adopt a social perspective of knowledge management. According to Sardari 2002 Tsoukas (1996), most Knowledge Management approaches are rather formistic. In fact, the streams of functional knowledge management (Nonaka, 1994; Nonaka & Takeuchi, 1995; Choo, 1998) or the supporters of intellectual capital theories (Boudreau & Ramstad, 1997; Bukh et al., 2001; Stewart, 2000; Edvisson & Malone, 1997).

Therefore, organizational knowledge is treated here as a projection of organizational life and as embedded in organizational norms and cultures (Teece, 2001: 126; Weick, 1995; see also Blackler, 1995 about encultured and embedded knowledge).

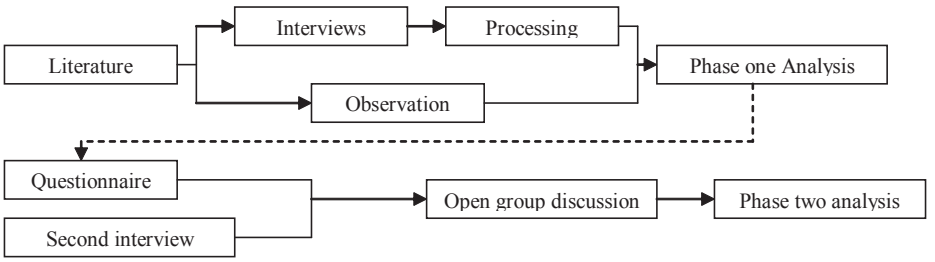
RESEARCH METHODOLOGY AND DESIGN

Our research was conducted following the principles of a 'case study' approach (Yin, 1994), and in fact it is based on a 'multiple case study' analysis (Eisenkhart, 1989). The case study approach has certain advantages, especially for knowledge management research. It provides the researcher great opportunities to explore deeply the organizational realities and to identify the reasons and causes of certain phenomenon (Yin, 1994; Blaikie, 2000:215). Additionally the case study approach allows the researcher to use a mix of qualitative and quantitative data (Yin, 1989; 1994; Stake, 1994), although "qualitative methods are of primary importance" (Gillham, 2000: 10). In practical terms, choosing to do a case study is to choose to search for an explanation of the organizational realities and phenomenon's and requires a process of reasoning. In fact, case study is not a technique but more or less a mode for organizing data and evidence (Goode & Hatt, 1952; Gillham, 2000), a perspective on how to see and explain social facts.

Amaratunga & Bauldry (2001) support the common idea that a complete case study research design should include a variety of research techniques, which could help the researcher, secure the conclusions and generalize the findings. In this research, the aim of the research design was to gather information from the interviewees from all tools companies and to return and cross check their first opinions with questionnaires and second interviews. Then a last open group discussion was designed to provide a final feedback from the organization about the issues that have arisen during the research.

Research has finally included three (3) medium sized tools companies and the sub- contractors. The subjects of research are summarized below:

Figure 1. Research process for all eleven Tools companies



OUTSOURCING PRACTICES IN THREE MEDIUM SIZED TOOLS INDUSTRIES

It has been seen that in all departments where operations are outsourced there has been a lack of effective communication (see Henrikssen, 1999 for similar case) between outsourcing companies' staff and the outsiders. In cases where contractors had to be present to the organization's environment (accounting consultants, software developers), sharing of knowledge was low while in cases where operations were taking completely outside the physical boundaries of the company, knowledge sharing was extremely low (sales and promotions, production). It is argued that geographical issues are also correlated with the low levels of knowledge sharing. It was also generally seen that all collaborations failed to be developed as partnerships of mutual interest and to assimilate a form of alliance (Doz, 1996; Mowery et aI., 1996). On the contrary it has been obvious that relations between staff and outsiders were focused on the contractual obligations; lack of time (McDermott & O'Dell, 2001) and the politics of contractors to protect their role and knowledge (Scarborough, 1995) lead to an important gap in communication. It is definitely the case that there was no will to exchange knowledge while the social environment would not assist such efforts.

A STUDY ON THE EFFECTS OF OUTSOURCING FOR ORGANIZATIONAL IDENTITIES AND KNOWLEDGE MANAGEMENT

Since knowledge management is treated as a social value and the accumulation of intellectual capital is well related with the quality of social capital (Stewart, 1997; Nahapiet & Goshal 1998),. In fact, the following diagram presents the effects that have been observed in the three (3) outsourcing companies.

INDIVIDUALS' IDENTITIES

A primary finding during the research in companies was that the outsourcing of certain activities had a dramatic effect on people and their identity in the organization. EmpJoye~5 and managers' role has become less important and people who were close to the processes ;n the past seemed to take a certain distance from the situation. Most of them expressed the concern that not only did they lose part of their power in the organization but that in a way they have been marginalized and have been unable to understand their role; a form. of alienation has been observed (Wheeler, 1996). It has been seen that the lack of effect communication with contractors caused the alienation of employees (Levinson, 1973)

Disintegration of Communication and Social Capital Pathology

It is arguable then that in PROEL, the traditional groups of people dealing with issues have been dissolved; teams with had the responsibility for doing the job have been replaced by teams from outside the firm (Lin, 2000). As analyzed in previous chapters, communities of practice require a certain degree of cohesion and must be concentrated on certain goals, to have a specific identity (Lave & Wenger, 1991). Previous sections` evidence presented, show that the individuals` identities have been affected and so were the identities of workgroups and items.

Addiction to Outsourcing: Losing the Absorptive Capacity

While outsourcing has affected identities and as a result the formation and the role of communities, it has also produced effects for organizational learning and for the maintenance of knowledge itself. What was found to be very important is that not only companies did lose parts of knowledge but that the disintegration of communities of practice, the lack of observation and experimentation (see Barley,1996; Orr, 1990) combined with the poor social environment created dynamics for further and continuous worsening of the situation. The disintegration of learning processes in the organization took the form of a snow slide.

SECONDARY EFFECTS: EXPLORING THE VICIOUS CYCLE OF KNOWLEDGE DEPENDENCE

The above situation produces secondary negative effects for the organization as a whole and it has been shown in our cases that the loss of absorptive capacity and the disintegration of knowledge in communities lead to further negative results. A main effect is the one of organizational dependence since the three (3) outsourcing companies are now relying on firms and outsiders to maintain their business activities. As argued in Fine (1998) and Takeishi (2002), relying to the knowledge of outsiders creates an expected level of dependence of the company. What was seen from our research was an increased dependence from the outsiders' knowledge and skills. During the research it was possible to identify certain cases where lack of organizational knowledge and the inability of the organization to have access to specific know-how costed a lot of time and money. Most incidents

Table 1. Matrix showing contractual relations of outsourcing among the eleven _ companies-subjects of research

Company/sub-contracts	Accounting & consulting	Promotion operations	Information system	Some Manufacturing Processes
PROEL SA	Thesis Ltd	Independent group of salesman(A)	Q-Logic SA	PH&T Iran
IA Tools Ltd	(In-house)		Infinitum Software Solutions Ltd	An Tools PROEL SA
MEDION Ltd	Large Auditing	Independent group of salesman(B)	(Mostly In-house)	PROEL SA

Figure 2. Pathology of knowledge management when outsourcing operations

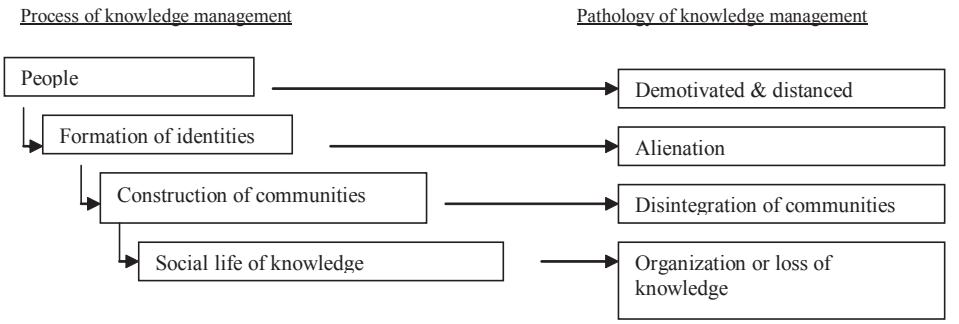


Figure 3. A summary of effects of outsourcing for knowledge management in organizations

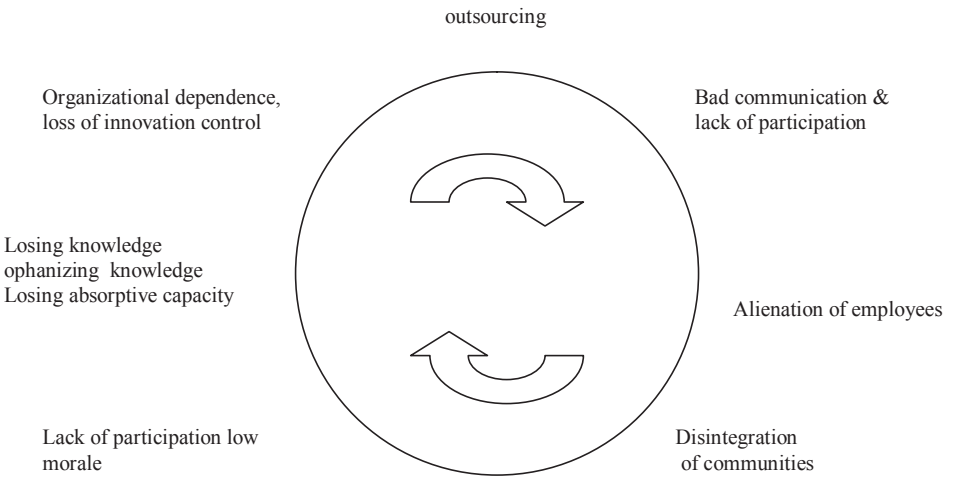

have been presented to the companies in matrix forms. To a certain extent what was also observed, as a result of dependency, was a raising insecurity (Embleton & wright, 1998; Hendry, l995; Takeishi,2002) and a lack of trust in organizational capabilities to face problems; such situation is still creating an increasing dependence from those who know how to do the job. In other words, outsourcing has become a one-way process to import knowledge in the organizational boundaries and solve problems.

The above findings could be described as a `vicious cycle' of effects which have the form of a continuous chain reaction.

So, a main issue is that the use of outsourcing initiates further needs for outsourcing within the same department or even in different operations. Both organizational dependence and innovation outsourcing have created to most managers the impression that the company could not survive without the contractors' knowledge; an interesting issue coming but of the questionnaires is that most of them would approve more outsourcing because "it seems that we do a better job when being in position of control instead of doing things" (Sales Manager of lapharm). This idea of recycled outsourcing, missing from current literature, is very interesting and should be further studied and elaborated.

CONCLUSION

The vicious cycle of outsourcing effects should be considered as the main implication of this research. It has been shown that the use of outsourcing and subcontracting initiates certain social effect which finally produce further changes to the organizational life and to the intellectual capital of the organization. A continuous process of alienation (Erikson, 1990; Wheeler, 1996), disintegration of communities (Lave & Wenger,1991; Wenger, 1998) and organizational de-identification (Dukerich et al., 1998) takes place while the company is transformed from a learning entity (Easterby-Smith, 1999) into an expertise purchaser (Chan, t994) This study takes a negative stand against outsourcing, critically objecting the focus of management and shareholders on downsizing and reducing costs, neglecting important long-term aspects of organizational life (Lazonick & O'sullivan, 2000; Kasey, 1995; Whitley,

1999) and the importance of knowledge management and accumulation. It is argued that before transforming the policy of outsourcing into specific management decisions, a consideration of issues concerning the organizational culture, identities and finally knowledge should take place (Embleton & Wright, 1998; Chan, 1994; Vanson, 2001; Hendry,1995).

I argue that there are three typical approaches which can be followed:

a. Building and supporting inter-organizational mixed teams and communities.
b. Transforming the nature of relationship, several studies argue for a conversion of outsourcing contracts into strategic alliances.
c. Formalizing knowledge in order to achieve conversion of tacit and experience knowledge into typical, codified information flows.

Further research, currently conducted by the authors, focuses on specific organizational or functional mechanisms which would assist the company to preserve and accumulate knowledge while changing the internal structure, while outsourcing or downsizing.

The Effect of Information Quality on Surgery Process Variation

Latif Al-Hakim, University of Southern Queensland, Australia; E-mail: hakim@usq.edu.au

ABSTRACT

This paper discusses the relationship between quality of care and information quality (IQ). The focus of the paper is on surgery process variation. The paper aims to identify the IQ dimensions that considerably affect surgery process variation. The research uses a case study approach and employs gap analysis and Delphi technique. Results indicate that accuracy, accessibility, completeness and timeliness are the most critical IQ dimensions that are affecting process variation.

Keywords: Delphi technique, gap analysis, information quality, process variation.

QUALITY OF CARE AND INFORMATION QUALITY

Quality of care is about meeting the physical, psychological and social expectations of the patients who search for care. According to the American Institute of Medicine, quality of care is "the degree to which health services for individuals and populations increase the likelihood of desired health outcome consistent with current professional knowledge" (Kupersmith 2003). The Advisory Commission on Consumer Protection and Quality in the Health Care Industry notes that there is a continuing pattern of variation in health care services, including regional variations and small-area variations (Advisory Commission, 1998).

Deming, who has developed a profound knowledge of quality, considers 'variation' as "the chief culprit of poor quality" (Evans and Lindsay 2005, p. 94). Deming observes that variation in quality characteristics exists in every process. Variation makes the process unstable and its outcome unpredictable because the variation that exists from one time period to the next is also unpredictable (Miller, 2005). Healthcare service is an information based service (McLaughlin 1996). Understanding the variation in information is the first step in reducing healthcare service variation and then stabilising the healthcare process. There are major variations in the conclusions of clinical observations and their interpretation (James et al. 1994). In fact, most healthcare quality problems can be attributed to variation or what is referred to as 'unwarranted variation" in healthcare delivery (Wennberg 2002). The term 'unwarranted' in relation to variation reflects a lack of necessary or quality information to conduct healthcare processes. This suggests that information quality is a critical factor in decreasing variations in the healthcare industry. Recognition the importance of data and information quality becomes a key area of both strategic and operations management in the healthcare industry (Lorence and Jameson 2002). The Lorence and Jameson study also emphasises that there is a shift from the traditional error-based approach to evidence-based data driven medicine. This allows the measurement of quality of care to be based on data rather than intensive, personal interaction with patients. As such, "the quality of data maintained by organisations becomes a critical factor in the ultimate delivery of care" (Lorence and Jameson 2002).

This paper discusses the information quality (IQ) dimensions and aims to identify the critical and decisive IQ dimensions affecting surgery process variation. The paper employs a case study approach. The paper uses gap analysis and Delphi technique (Linstone and Turoff, 2002) in order to define the critical dimensions affecting the process variation. The following section identifies the dimensions of information quality.

DIMENSIONS OF INFORMATION QUALITY

Evans and Lindsay (2005) stress that quality can be a confusing concept. They provide two main reasons for this assertion; (1) people view quality using different perspectives and dimensions based on their individual roles, and (2) the meaning of quality continues to evolve as the quality profession grows and matures. Similarly to product quality, IQ has no universal definition. To define IQ, it is important to comprehend both the perspective from which IQ is viewed and its dimensions. The Cambridge Dictionaries Online (2005) defines perspective as "a particular way of considering something" and dimension as "a measurement of something".

Individuals have different ways of considering the quality of information as they have different wants and needs and, hence, different quality standards which lead to a user-based quality perspective (Evans & Lindsey, 2005). This perspective is based on the Juran definition of quality which defines quality as 'fitness for intended use' (Juran and Godfrey, 1999). Thus, information and data can be regarded as being of high quality if they are fit for their intended use in operations, decision making and planning (Redman, 2004). Other related IQ perspectives are 'conformance to specifications' and 'meeting and exceeding consumer expectations' (Evans & Lindsay, 2005). While these perspectives capture the essence of IQ, they are very broad definitions and are difficult to use in the measurement of quality. There is a need to identify the dimensions that can be used to measure IQ.

IQ is a multidimensional concept. This means that organisations must use multiple dimensions and measures to evaluate the quality of their information or data. Several researchers have attempted to identify the IQ dimensions. Wang et al. (1995) list twenty six IQ dimensions, which in turn are classified into either internal view (design operation) or external view (use and value). Each of these classifications is divided into two subcategories; data-related and system-related (Wand & Wang, 1996). Wang and Strong (1996) conducted an empirical two-phase sorting study and provide the most comprehensive list of IQ attributes. Their list comprises 118 attributes. The 118 attributes are reduced to 20 dimensions, which in turn are grouped into four categories: accuracy, relevancy, representation and accessibility. Wang and Strong (1996) re-examine their four initial categories and relabelled the first two categories and the four categories become: intrinsic, contextual, representation, and accessibility. It should be noted here that Wang and Strong use the term DQ (rather than IQ) to represent both DQ and IQ. Recently, Lee et. al (2002) developed a two-by-two conceptual model for describing IQ. The model comprises 16 dimensions, which are classified into four categories; sound information, dependable information, useful information and usable information. Table 1 provides definitions of the most common IQ dimensions used in the literature and illustrates their categories.

RESEARCH METHODOLOGY

Case study approach can be used to provide a detailed description of a phenomenon (Yin, 1994). The finding of this research is based on a single case study which is used to explore the role of data quality dimensions in process variation. This case is also revelatory in nature. According to Yin (1994; 1998), the revelatory case approach is a single case study conducted under difficult circumstances not normally open for in-depth study.

The case study is part of a project initiated by the author and has been funded by the Faculty of Business at the University of Southern Queensland, Australia. The project includes two postgraduate students - an Honours Degree student and a Masters Degree student. The selected case is an Australian rural public hospital. The hospital comprises thirteen departments including; Surgical, Anaesthetic, Orthopaedic, Obstetric & Gynaecology, Paediatrics, Emergency, Critical Care, Medical Imaging, Medical, Renal, Public Health, Oncology, and Rehabilitation.

Table 1. Definitions of the common IQ dimensions used in literature and their categories. Adapted from several research works (Al-Hakim, 2006, p xiv-xv)

Dimension	**Definition**	**Category**		
		Wang and Strong (1996)	Wang et al. (1995)	Lee et. al (2002)
Accessibility	The degree to which information is available, easy obtainable or quickly retrievable when needed. Accessibility depends on the customer's circumstances.	Accessibility	Internal + External - Data / system related	Usable
Accuracy	The degree to which information represents real world state.	Intrinsic	Internal -Data related	Sound
Amount of Information	This dimension measures the appropriateness of volume of information to the user or task at hand	Contextual	Internal / External -Data related	Useful
Believability	This dimension measures the user assessment of trueness and credibility of information.	Intrinsic	Internal / External - Data / system related	Usable
Coherency	This measures how information "hangs together" and provides one meaning to different users.	Intrinsic + contextual	Internal -Data related	Sound
Compatibility	The level to which information can be combined with other information to form certain knowledge.	Intrinsic + Contextual	Internal -Data related	Useful
Completeness	The degree to which information is sufficient enough to depict every state of the task at hand or the represented system, that is, assesses the degree of missing information.	Contextual	Internal -Data related	Sound
Conciseness of representation	The compactness of information representation.	Representation	External -Data related	Sound
Consistency of representation	The degree of similarity and compatibility of information representation format.	Representation	Internal -Data related	Sound
Ease of manipulation	The applicability of information to different tasks.	Intrinsic	Internal - Data related	Useful
Ease of understanding	The degree of comprehension of information	Representation	Internal - Data/ system related	Useful
Free-of-error	The degree to which information is correct. This dimension measures the number, percentage or ratio of incorrect or unreliable information.	Intrinsic	Internal- Data / system related	Sound
Interpretability	The appropriateness and clarity of information language and symbols to the user.	Representation	Internal -Data related	Useful
Objectivity	This dimension measures information impartiality including whether information is unbiased and unprejudiced.	Intrinsic	External -Data related	Useful
Relevancy	Relevancy indicates whether information addresses the customer's needs. It reflects the level of appropriateness of information to the task under consideration.	Contextual	External -Data related	Useful
Reputation	The degree of respect and admiration of both information source and information content.	Intrinsic	External - Data related	Usable
Security	It indicates the level of either restriction on access of information or appropriateness of information back-up - protecting information from disasters.	Accessibility	Internal / External - System related	Dependable
Timeliness	This dimension measures how up-to-date information is with respect to customers' needs or the task at hand. It reflects also how fast the information system is updated after the state of the represented real-world system changes.	Contextual	Internal/ External - Data / system related	Dependable

The project is concerned with the surgical department. The department includes an operating theatre suite comprising six operating theatres. Four are used for elective lists that are run for two sessions per day. The two other theatres are dedicated to 24 hour emergency surgery services. There are eight recovery wards catering to the theatre patients.

A Delphi approach is used to collect, amend and reshape information regarding IQ dimensions affecting surgical process variation. The Delphi approach is characterised as a method for structuring a group of communication processes in a way that allows a group of individuals, as a whole, to deal with a complex problem (Linstone and Turoff, 2002). Semi-structured interviews were conducted with hospital officials including a senior registrar, senior nurse and elective surgery coordinator and other related officials and medical professionals. The officials were given an opportunity to provide feedback after initial assessment of the results.

The interviews are based on a questionnaire which aims to rate the expectation of the interviewee in relation to dimensions of IQ affecting process variation and the perceptions of the interviewee about the performance of the dimension. Each

question has two fields named as importance and performance. For the first field, the interviewee is asked to rate the expectation about critically or importance of the dimension on process variation. The second field considers the interviewee's perception of the performance of the dimension. If a dimension is not applicable to the process variation, the interviewee's is asked to tick N/A.

The Likert scale is used in the questionnaires to rate the importance and performance of IQ dimensions because it is the most popular method to measure attitudes and easy to administer (Sekaran, 1992). The Likert scales give the researcher a clearer understanding of the interviewees' perceptions on the key issues in the interviews (Yin, 1998). In this research a 7-point Likert scale is chosen to for two reasons. This scale can provide more accurate comparisons between different respondents as compare to the 5-point scale that is commonly used. Also, the odd scale is to allow the respondents to choose the neutral answer (point 3) if they are not sure of the answers. If the interviewee strongly agrees that a dimension under consideration is critical or performed well, he / she ticks '7'. The interviewee ticks "1" if he / she strongly disagrees.

IMPORTANCE-PERFORMANCE ANALYSIS

Healthcare officers dealing with a healthcare process may have different expectation about various IQ dimensions affecting process variation. The expectation from each dimension may also depend on the employee's performance and behaviour. They can also perceive or interpret the performance of an IQ dimension in their organisation. The expectation from a factor is referred to as "expected importance" and the interpretation of performance forms the "perceived performance" of a factor. A grid similar to the one shown in Figure 1 can be used to evaluate and analyse the importance-performance data (Evans & Lindsay, 2005; Keyt et al., 1994). An organisation should make a great effort to achieve high performance on factors of high importance and not to waste effort on factors of low importance.

Importance-performance analysis was first introduced by Martilla and James (1977). A gap between the perceived performance and the expected importance of a dimension may provide some indication as to whether the dimension is effectively implemented.

A gap between the importance and performance of each dimension is calculated. An IQ dimension is critical when the expectation is that the dimension is very important. However, when a dimension is critical and performed very well, that is, the importance-performance gap is insignificant, the dimension is not decisive.. A dimension is decisive only if it is satisfied the following two conditions:

1. It has a strong importance rate, that is, it is critical.
2. It has a significant importance-performance gap.

If an IQ dimension affecting the process is critical and has a positive value of importance-performance gap (expectation is higher than perception), then we have a potential problem in information flow and then with process variation. A negative value (expectation is less than perception) indicates an overestimation, which may result in wasting effort to increase performance in less critical factors (Al-Hakim and Xu, 2005).

FINDINGS

The initial round of interviews revealed that a considerable number of dimensions are considered critical dimensions with rating equal or higher than six (out of 7). These dimensions are accessibility, accuracy, believability, coherency, compatibility, completeness, free-of-error, interpretability, objectivity, relevancy, and timeliness. The meeting with the officers raised the question of whether the dimensions should be considered before or after the final decision to admit a patient to the operating theatre. The answer is that the research is concerned about process variability after the decision has been made to admit a patient to operating theatre. The officers emphasised the following issues:

- The dimensions accessibility, accuracy, believability, coherency, compatibility, completeness, free-of-error, interpretability, objectivity, relevancy, and timeliness are proposed to be analysed, verified or settled before the decision of admission of a patient to an operating theatre. However, except for the free-of-error dimension, there is no objective viable scale or metric that measures these dimensions. An IQ problem may happen regardless of the depth and level of effort.
- The surgeon who makes the decision to admit a patient is usually the surgeon who performs or supervises the surgery. Surgeons make decisions based on their assessment of trueness and credibility of information. Accordingly, the dimensions believability is not a decisive dimension. This assertion is true when more than one surgeon deals with the decision to admit a patient to the operating theatre.
- A supporting argument was that having doubts about source of information or on the trueness of information may unnecessarily disturb the surgery process and may considerably and unnecessarily increase costs.
- There are several recorded instances of a surgeon asking for information which he/she believed existed but no information actually existed. Such an event considerably affects surgery process variation. This makes the performance of completeness is relatively low.
- The officers emphasises that there are no problem in the performance of interpretability, objectivity and relevancy of information. However, with the high performance of these dimensions, surgeons may provide different meaning to the same information when they added to each others.

Based on the above discussion, the officers revised the importance-performance analysis as shown in Table 2.

Results (Table 2) indicate that accuracy and believability are extremely critical dimensions. Though the gap of importance-performance for accuracy is relatively small (0.43), there is a need to take further measures to ensure the accuracy of information received. The performance gaps for accessibility and timeliness and completeness are relatively high (1.29 and 1.00, respectively). This indicates the necessity to reengineer the information technology system in a way that allows real-time accessibility to the required data and information as well as timely and regularly updating data and information. There is also a considerable need to ensure the completeness of information.

CONCLUSION

The paper discusses the relationships between quality of care and information quality (IQ). It emphasises that the process variation is the main source of poor quality of care. The paper aims to identify the IQ dimensions that affecting the

Objectivity	6.20	*	*
Relevancy	6.20	*	*
Timeliness	6.43	5.43	1.00

** The performance of these measures is considered up to the required standard and the importance-performance gap is insignificant.*

 # Non-critical factor

variation of the surgery process. It employs importance-performance gap and Delphi approach in order to identify the decisive IQ dimensions affecting surgery process variation. A dimension is a decisive dimension where it is critical (with high importance level) and does not perform well, that is, has a significant importance-performance gap. Results indicate that surgeons make decisions based on their assessment of trueness and credibility of information. However, surgeons may provide different meaning to the same information. In addition, there are several recorded instances of a surgeon asking for information which he/she believed existed but no information actually existed. Such events considerably affect surgery process variation. The analysis shows that the following IQ dimensions are decisive dimensions affecting the surgery process variation; accessibility, accuracy, coherency, compatibility, completeness, and timeliness.

AKNOWLEDGMENT

The author wants to acknowledge the support and participation of many professionals and staff of Toowoomba General Hospital. Also the author would like to acknowledge the financial support of University of Southern Queensland.

The Development of a Planning Model for the Content of Small Business Websites

Stephen Burgess, Centre for International Corporate Governance Research, Victoria University, Australia; E-mail: Stephen.Burgess@vu.edu.au

ABSTRACT

This paper reports on the development and refinement of a model that links business planning and analysis tools, such as the SWOT analysis, with the creation and maintenance of the small business website. Initially, a number of existing models are examined. The development of the model is traced through its early implementation as a spreadsheet through to its current incarnation as a handbook. An overview is provided of how the early stages of the model would operate in practice.

Keywords: website; development; planning; study; small business; model

INTRODUCTION

Some of the major issues facing small businesses in relation to their use of information technology (IT) are that they lack basic knowledge of how to use IT effectively, they do not know how to measure the benefits of IT and they lack the skills to plan for its long-term use in the business. These shortcomings typically translate to small business use of the Internet, particularly in relation setting up web sites. This paper reports on the development and refinement of a model that links well known business planning and analysis tools, such as the SWOT analysis, with the creation and maintenance of the small business website. The model, developed in 2002, is updated to take into account recent developments in the usage of Internet technologies and some models highlighted in the international literature that target small business website development.

SOME BACKGROUND

There are many studies that examine the adoption of IT by small businesses. Although they do not necessarily provide a 'forward looking' viewpoint from the standpoint of presenting a means by which small businesses can then effectively adopt a website, they can provide a useful set of antecedents to help small business policy makers, consultants and even owner/managers to put into place those factors that may best assist them. For instance, Mehrtens, Cragg & Mills (2001) developed a model of Internet adoption for small businesses using an innovation theory approach. Lee (2004) examined a number of models related to IT adoption by small businesses, and tested a model of eight antecedents to Internet adoption in small businesses with a survey of 71 US small retail businesses. From studies such as these we know that factors such as the size of the small business (and therefore the resources they have at their disposal), the drive and IT skills of the owner/manager and employees, the existing systems within the business and external factors such as the availability of suitable infrastructure and external pressures (placed by groups such as customers and competitors) can affect the adoption of Internet technologies. In addition to this, small businesses need to have an appreciation of the types of benefits that websites can provide. At this early stage of the paper, the argument is made that a model looking to advise small businesses on the development and maintenance of their websites should consider these factors.

EXISTING MODELS

There are many published models (too many to mention here) that document how a 'typical' small business might build its website over time. Many of these are known as 'staged' website development models. There is a deal of support for the notion that small business website development generally commences with a simple brochure-type web presence and evolves over time to incorporate different levels of sophistication and complexity. In describing staged models of adoption, Alonso Mendo & Fitzgerald (2005) suggest that they represent the early stages of Internet adoption by businesses gaining access via simple technologies (such as email) to dispense and gather information. Later stages refer to the creation of a basic web page, then the business moves onto publishing a wider range of information, marketing of products and possibly some after sales support. This is followed by e-commerce capabilities, where orders can be placed and perhaps paid for by customers. Finally, at the mature stages the business website is fully integrated with 'back office' systems. Levy & Powell (2003) do not necessarily support a 'stages of growth' model for Internet development and suggest that few small businesses even go beyond the early stages of website development. This is supported by Alonso Mendo & Fitzgerald (2005), who suggest that many small business web sites can remain in a 'dormant' state for months or even years. They criticise these 'staged' models on the basis that they are:

- Oversimplified
- Based on a (false) assumption that businesses progress from basic to more advanced use in a 'linear' fashion
- Lack validation
- Do not take into the diverse nature of small businesses
- Do not consider other theories (such as 'evolutionary' models)
- Focus too much at the industry level and not on individual instances.

Martin & Matlay (2001) refer to these types of models as 'linear' models and also argue that they may be too simplistic for the variety of small businesses in existence – suggesting that this variety can come in the form of business size, economic activity, location, resource availability and level of ICT adoption.

There are, however, some different approaches to developing models for website development and use. Alonso Mendo & Fitzgerald (2005) propose a multidimensional framework, that seeks to examine how small businesses change their websites (the process of change), what kind of changes they make (the content of change) and why they change them (the drivers of change) for the general purpose of understanding the evolution of their e-business practices. Fillis, Johannson & Wagner (2004) proposed a conceptual model designed to help understand why some smaller businesses implement and develop e-business activities and others do not. Their model considers a range of internal and external factors that may impinge on attitudes to e-business and the implementation (or not) of an e-business strategy. Initially, the business is affected by factors such as government policy and globalisation, then industry factors. Within this environment, factors such as the size of the business, the types of products or services they offer and the set of business competencies within the business will influence either positive or negative attitudes to e-business and its eventual adoption or non-adoption. The model recognises that an adopter may choose to revert from e-business back to conventional business processes, or a non-adopter may eventually become an adopter of e-business. Again, this is more of an 'explanatory' model, but does identify some useful factors that should be considered.

Chaston & Mangles (2002) propose a model to support and deliver an e-commerce marketing strategy. Decisions in this model are based on a hierarchy, with financial and operational competencies being determined by the strategic positioning options chosen by management.

Once the strategic position is determined, the business must be able to fund the level of investment required to support their online marketing strategy. This includes having appropriate systems, having the resources to update the website, ensuring appropriate integration with existing business systems and ensuring that the website is promoted at a level to attract visitors. When the strategy has been

determined and the finances allocated, Chaston & Mangles (2002) suggest that the business needs to examine new ways of improving their Internet products and processes, ensure that the workforce are skilled to carry out the online activities, ensure that a high level of quality in relation to products and services and customer service and efficiency in relation to logistics is provided (as customers can more easily switch to other suppliers). This model provides an indication of the type of model that the author has in mind, to provide a set of (top down?) steps that a small business can use to properly integrate its website activities with its business strategy.

AN ATTEMPT AT A FULL PLANNING MODEL

In order to address some of these problems facing small businesses that wished to use the Internet to interact with customers, particularly those relating to a lack of proper planning techniques, the conceptual version of a model to guide small businesses (refer to Figure 1) was proposed in 2002 (Burgess & Schauder 2002). The model was based upon the major steps in other IT and e-commerce models. It represented at the time an attempt to address the specific needs of small businesses by guiding them through a proper planning process that was relatively easy for them to comprehend.

As a prelude to developing the model, Burgess & Schauder (2002) identified a number of steps that are common to models that can be used to assist firms to identify strategic IT ideas (such as those identified by Porter & Millar (1985), Barton & Peters (1991), Osterle (1991) and for electronic commerce opportunities by Marchese (1998) and Al-Moumem & Sommerville (1999)). These steps included a need for an initial, thorough business investigation of where the business stood in relation to its own resources and as part of a marketplace involving customers and competitors. This exercise can increase the likelihood that decisions made later in regards to web content are based upon a sound knowledge of business activities. This step involves a SWOT (Strengths, Weaknesses, Opportunities and Threats) analysis, which has traditionally been used for planning in the marketing or economics areas of the business. An analysis is performed on the various areas of the organisation to identify current or potential strengths and weaknesses when compared with other competitive forces. Then, actual or potential opportunities to gain strategic advantage or threats to the organisation's well being are identified (Kotler et al. 1989). This analysis provides the business with a picture of where it currently stands and the basis for making sound business decisions about the proposed website presence.

As part of the SWOT analysis, the firm's internal and (some) external forces the activities of competitors and expectations of customers) were to be examined. Internally, the firm's resources in relation to time, money and expertise were considered, as well as the characteristics of the firm's goods and services. The firm's overall strategy was also examined, as a firm wishing to grow in size may require a more 'aggressive' web strategy than a firm that is satisfied with its existing customer base. Finally, the Internet skill level of employees was determined. Externally, the web sites of competitors were examined, as well as the ability of customers to access the firm's web site and their expectations of the business.

Other steps of the model after the business investigation referred to identification of the firm's overall web site strategy, what web site features they were going to implement (facilitation), what method they used to implement these features, how they promoted the web site and how they evaluated its success.

It is important to note that this model is fundamentally geared towards the support of decisions about website content. Issues such as the selection of Internet Service Providers, security of the business website and design of the website are important considerations and will be included in later versions of the model.

RECENT DEVELOPMENTS AND A NEW MODEL

One shortcoming of the model is that it did not take into account the fact that many small businesses change their websites over time (the reader is referred back to the discussion of 'staged' models). Whilst they may not necessarily do this in the manner that many 'staged' models indicate (from 'brochure' through to full e-business integration) – there are often changes made in the website over time. Additionally, there are now many more options available to a small business when setting up their web presence. Many of these are associated with Web portals. For instance, a small accommodation business may wish to use the booking engine offered by specialised accommodation or regional portals, meaning that they can perhaps reach a wider market and will not need to concern themselves with the technology involved in online booking engines. In the case of small manufacturing firms, such as a winery, there may be attractions in using the online shopping cart features of a regional portal or industry portal. Again, this may provide access to more customers and lead to extra custom without having to be concerned about developing the shopping cart technology. A simpler example of an 'extended web' presence is when a small business provides its basic contact information to regional or industry portals. This can be quite inexpensive and, because the information does not change readily, is relatively easy to maintain. A more specialised example is where a business may wish to attract potential customers to a region, and realises that a regional portal has a listing of all of the tourist attractions and the latest events in the region. Why should they repeat these on their own website? They could rely on customers seeing this information as they link to the business through the regional portal, or perhaps more realistically provide a link back to the specific page on the portal. Let someone else worry about updating the information!

So – how can the model be updated to reflect the need to take into account that small businesses will probably change their website over time, and allow the business to consider what features of the 'extended web' will be used? **Error! Reference source not found.** represents the author's attempt to update the model to take these considerations into account.

The updated version of the model includes:

Figure 1. An initial model to assist small businesses to interact with customers on the Internet

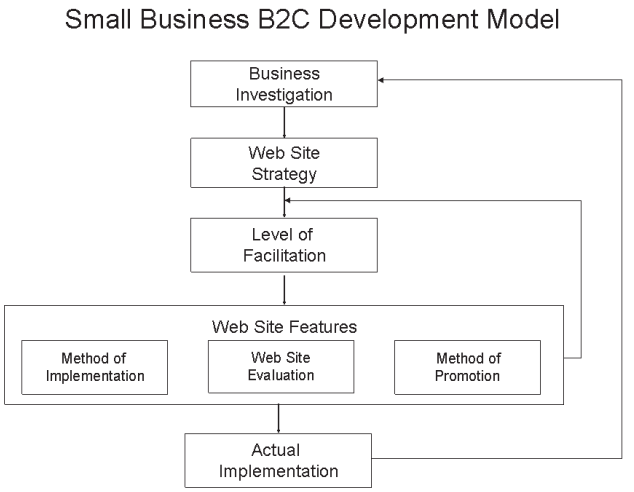

Figure 2. The revised, 'extended' version of the model

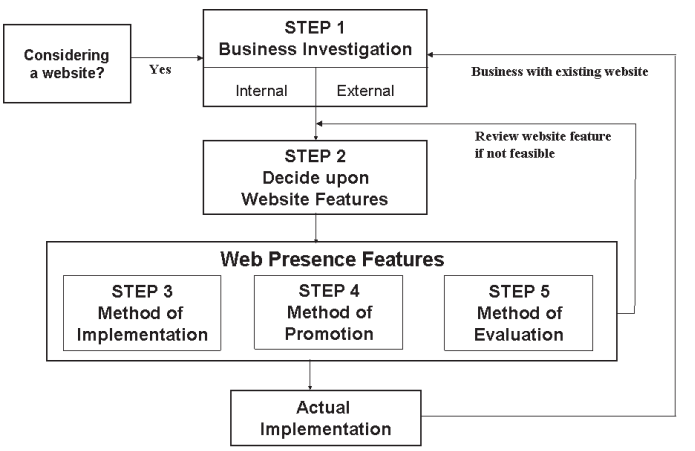

- The removal of the 'strategy' section from the earlier version of the model. This is now incorporated into the business investigation (SWOT).
- There are now two entry points into the business investigation phase. The first is where the business will be setting up a website for the first time. A detailed SWOT analysis will be needed here. The other entry is where the business has already been through the model and has already set up a website.
- The addition of a 'website audit' in the business investigation phase. This takes into account that the business may have already developed a website and may be considering changes to that website.

In the Website features stage, the decision of what features are to be placed on the website is re-evaluated each time the model is applied. The business may decide that it wants a particular feature on its website, but can also decide if it wants it NOW (or perhaps that it might be desirable in the future).

The 'method of implementation' phase has a step that includes consideration of the Extended Web. That way, if a business has decided to implement say, a shopping cart feature, it can use a shopping cart on an external portal if it decides it may not be suitable (or may even be too difficult) to implement on its own website.

MOVING FROM THEORY TO PRACTICE

[For this section of the paper I will move to discuss the development of the model in the first person]

One major problem faced in this project was how to take the theoretical model and turn it into a useful, applied model. The initial idea was to develop a manual or book that small businesses could work through and use to 'record' the results of the analyses that they carried out along the way. This would then lead to recommendations as to what web site features they should implement. There were two major concerns here if I was going to use a solely paper-based manual. The first was that if a small business person wished to go back and alter any of the data entered, he or she would have to use an eraser or liquid paper. The second was how to lead the person to the eventual recommendation at the completion of the analysis. I eventually determined that the spreadsheet package, Microsoft Excel, would provide the solution. Most small businesses that have computers use a spreadsheet package, and the majority of spreadsheet packages in use at the time were Microsoft Excel. The spreadsheet has long been recognised as a tool that can be used to support basic decision-making. It provides users with the capability to alter figures and to see the effects the alterations have on recommendations. In this case, it provided a means by which the path from analysis to recommendation could be handled automatically by the software. The programming language that is part of Microsoft Excel, Visual Basic for Applications, provided the flexibility to alter the software and the interface easily, based upon the suggestions of the micro focus group participants.

However, over time I realised that it was somewhat arrogant on my behalf to presume to make decisions about website content for small businesses, so the process has now been incorporated this into a handbook (the idea I originally shunned). I believe the best way to support small businesses with their decisions about their website presence is to provide them with as much information as possible and then let them make the decisions about content. The handbook contains many changes in the manner I approach the problem when compared with the spreadsheet – but the basic principles still apply – with the analysis carried out according to different website features. The following text is an extract from an early part of the handbook:

This handbook will encourage you to follow five steps in relation to planning and implementing your (or amending an existing) web presence. The analysis commences with a business investigation. If you do not have a web presence you will probably be performing much of this analysis for the first time. If you already have a web presence you may have performed some of this analysis before (perhaps without realising it) and you will certainly need to take an inventory of the website features you have already implemented. Either way, it is a good idea to perform these five steps on a regular basis, perhaps every 6-18 months.

After you perform your business investigation you will need to decide which website features you wish to adopt. After this, you will need to decide how and where you will implement your website features, how you will promote your web presence and how you will evaluate the performance of your web presence. Before you implement your web presence you may decide that some features are not suitable (perhaps due to cost or difficulty of implementation) – you should review all of your analysis to ensure that your proposed web presence fits your business strategy before you go ahead and implement it (or make major changes if you already have a web presence).

At this point it is important to point out that this review is for the purpose of which website features you will wish to add or remove from your web presence. As you will have read in the Introduction it is important that you keep the content of your website up to date. This is something you will need to do continually – MAINTAIN your website. This is why the upcoming analysis will discuss the two aspects of each website feature you adopt. How much effort it takes to SET UP and how much effort it takes to MAINTAIN each website feature.

The handbook then leads the small business owner through the business investigation. One of the main tools used during the analysis is the *Website Content Checklist* (refer Table 1).

This is designed to provide the business owner with a snapshot of the primary information needed to make decisions about website content. The reader is requested to imagine that this chart is printed on A3 paper, mounted on a wall and can be written on with an erasable felt pen. The first column of the checklist represents a particular strategy that the business may wish to adopt in its web presence. The second column lists the particular website features that can help to achieve these strategies. From here on each of the columns are numbered and refer to a different part of the analysis. If the business already has a web presence, the features that are already available can be listed on column 0 of the checklist. Columns 1 and 2 are for information only – and refer to the level of skills or how much effort is needed to setup the feature (column 1) and maintain the feature over time (column 2). In this instance, 'effort' can refer to the amount of employee time that is taken in setting up and/or maintaining the feature. In relation to employee skills, website features range from being quite easy to implement (for instance, just typing in text) to quite complex (requiring advanced programming skills). If a business wishes to implement a particular feature that requires more skills than those available, it may wish to build its own employee skills capacity (perhaps through training), access the skills outside the business (perhaps through a consultant) or host the website feature on an external site where the skills have already been employed (for instance, on a portal). In relation to capital, it is quite inexpensive to host a website with simple features – but some of these features may require more employee time (and thus cost more) to maintain. More complex features will also generally take longer, and be more difficult, to set up. In this instance it is probably easier to provide some examples.

Here is another extract from the handbook:

You may not want to do all of these things with your website. There are two things that you really need to know about each website feature:

- *They can range from being really 'easy' (quick, inexpensive and requiring only basic skills) to quite 'complex' (time consuming, expensive and requiring technical skills) to set up.*
- *Some features can be really easy to maintain over time, some may be quite difficult – perhaps taking up valuable labour hours to keep them up to date.*

So, when you are considering what features to have on your website you need to think about how much effort it will take to implement them and how much effort you will need to put in to maintain them. In some cases a feature that is easier to set up may be harder to maintain. Here are some examples of different website features and how they might differ in relation to setup and maintenance:

- *Business contact details: it is really easy to put these up on a website and, since the business location and contact telephone numbers rarely change, they also require little maintenance.*
- *Product catalogue: on the surface it appears that these are quite easy to put on a web site. You can just enter the product details and price as plain 'text' – which is quite easy to do. The problem occurs if your products and/or their details change regularly. Each time they change you will need to manually change them on the website. However, if you keep a separate products database it is possible to link this with your website. Whilst this can be quite costly and complex to set up, the benefit is that any changes you make are automatically reflected on your website. So – one option is easier to set up but harder to maintain. The other is more difficult to set up but easier to maintain!*

Table 1. Website content checklist

Type of feature	What goes on the website	Exist Web Site Feat	STEP 1 - INTERNAL			STEP 1 - EXTERNAL		STEP 2	STEP 3 – Where will the feature go?			
			Employee skills/ Capital		Product and/or Service	Competitors have?	Cust-omers want?	You want?	Your Web Site	External Website		
			Ease of setup	Ease of mtce						Directory Service?	Industry Portal?	Regional Portal?	Other
		0	1	2	3	4	5	6	7	8	9	10	11
Your Contact details	Physical location (address)		E	E									
	A location map		E	E									
	Telephone/ Fax number		E	E									
	Your Email address		E	E									
	Form for customers to fill in to contact you		E	E M									
Your product and/or service details	General product/ service details		E	E									
	Static product catalogue **OR**		E	E M C									
	Dynamic product catalogue		C	E									
Features for product and/or service support	A separate 'links' page		E	E									
	List local community events		E	E M									
	Frequently asked questions (FAQ)		E	E M									
	Instructions on how to use your product		E	E M									
	Provide a specific email address for direct contact		E	M C									
	Online bulletin board** (moderated?) for queries		C	M C									
	Frequently asked questions (FAQ)		E	E M									
	Instructions on how to use your product		E	E M									
	Special online promotions		E	E									
	Online form to fill in to receive newsletters		M	M									
Build online community	Online bulletin board** (moderated?) for discussion		C	M C									
Allow customers to place orders, pay for them and/or receive digital goods	Allow customers to print orders to then fax in **OR**		E	M									
	Allow customers to order via Online forms **OR**		M	M									
	Orders placed via a form and linked to a database of purchase orders **OR**		C	E									
	Customers can print a credit card payment form to fax in (combined with order form?) **OR**		E	M									
	Automated payment		C	E									
	Direct download		C	E									

Columns 1 and 2 can give a business owner an idea of the resources that they may need to devote to a particular website feature. It should be pointed out that in its published version the table is in code – with 'E' representing 'easy', 'M' representing 'moderate' and 'C' representing 'complex' to set up.

As part of the investigation, businesses are also expected to examine the particular characteristics of their products and services. For instance, do they produce products that can be easily mailed (such as books or CDs)? The business might consider implementing a shopping cart feature to allow customers to order their products online. Do they provide a service that involves digital goods (such as music)? There is already a significant market for online music delivery. Any particular features that the business identified might be suitable because of the products or services that they offer can be recorded on column 3 of the checklist.

Now the analysis moves to outside of the business. The model recommends that businesses examine the web presence of their competitors to see what features they are adopting. These can be recorded in column 4. Similarly, if customers have been requesting certain features to be added to the website (for instance, frequently asked questions) then these can be recorded in column 5.

Businesses are now in a position to make a decision about their website content. They know the basic types of websites features available and what they can do for the business from the first two columns of the spreadsheet. If they already have a web presence they know what features they have already implemented (column 0). They know how much effort they will need to put in to set up (column 1) and maintain (column 2) a particular feature. They know if their products or services are suited to a particular feature (column 3), what their competitors have on their websites (column 4) and what customers may be demanding from the website (column 4). They are now in a position to make up their mind about which features they would like on their web presence (and this can be recorded in column 6).

Although not the focus of this paper, the remainder of the columns (7 to 11) are there so that a business can represent *where* a particular feature is located – on its own website and/or on another website (such as a directory or a portal). Separate parts of the model examine promoting the website and evaluating its success.

Unfortunately the word limitations on this submission mean that the usual discussion about the implications of the model is somewhat curtailed here as the concentration of the latter part of the paper has been predominantly on its operation. The next phase of the development of the model is obviously to test it amongst small businesses – those new to implementing a website and those that have already done so.

CONCLUSION

This paper followed the development of a planning model for small business website development. The planning model, initially developed from models related to planning for effective use of information technology, has been refined after consideration of a number of recent small business website models (centred mainly around website content and adoption). When the antecedents to the successful adoption of Internet technologies in some of these models are combined with the idea that small businesses often change their websites over time and now have more options as to where to 'house' their website features, a newer version of the model has been proposed. A practical example of how the model might operate through a handbook and website content checklist has illustrated how information can be presented to the business owner so that they can make their own decisions about website content.

Software Can Enhance Learning: A Case Study Evaluating the Implementation of an E-Learning Tool in a Multicultural, Tertiary Environment

Tony Richardson, Institute of Information and Mathematical Sciences, Massey University, New Zealand; E-mail: t.s.richardson@massey.ac.nz

ABSTRACT

The past 15 years have seen a major increase in the numbers of full fee paying international students entering the New Zealand tertiary education sector. Accompanying this have been significant government policy shifts which have moved New Zealand Universities from a traditional to a corporate and research oriented model of operation. Both these factors have manifested themselves at the classroom level as opposing forces, those of reduced emphasis on faculty teaching time and, paradoxically, expanded need for teaching time for the increasing numbers of students with poor English skills. This paper evaluates a software-based approach to providing a solution to this teaching-time paradox. The author considers the pros and cons of the proposed solution in principle and also in practice using a specific commercially available software application and proffers some conclusions on the desirability and feasibility of such a project.

Keywords: Multicultural e-learning system, Multimedia and hypermedia, Online learning companion, virtual mentor, Robodemo, Captivate

INTRODUCTION

In 1999 there were just 675 full fee paying students (FFPS) in New Zealand. By 2001 the number had risen to in excess of 52,000. In 2002 over 80,000 international students came to New Zealand from 116 different countries, representing 8.4 % of tertiary enrolments (Asia2000, 2003). This is a phenomenal rate of growth which seems set to continue, despite slowing in 2003 due to market demand, institutional capacity, policy effects, the impact of tightening quality requirements and consumer behaviour.

Before quotas were lifted in 1999 there were very few FFPS from China in New Zealand, for instance the secondary school sector had just 43. In the three years after the quota was lifted following China's endorsement of New Zealand as an acceptable educational destination, the number had risen to 6,476. This ferocious Chinese demand for New Zealand education is driven by the esteem with which a tertiary qualification is held in China (only a small proportion of those applying can get into Chinese universities, thereby creating pent up demand), the easing of travel restrictions and fundamental economic growth. Today, China dominates with 39.6 % of total international students in New Zealand (Asia2000, 2003).

Even these figures, startling though they are, mask the real "on the ground" picture since recent immigrants form a large percentage of those who are not classified as international students. In short, the reality is that in New Zealand today, when walking into a class of undergraduate students one is typically looking at a sea of fresh, eager, young, Asian faces. These students currently face two significant disadvantages:

a. Their pre-tertiary education has been predominantly passive rote-learning, making them inept at raising issues with staff and seeking face-to-face advice during lectures.
b. Their lack of English skills.

Although New Zealand tertiary institutions all require fluent English language competencies for most undergraduate degrees [IELTS] (the universities state specified minimum levels of competence, such as 6.0 in the International English Language Testing System (IELTS) or 550 in the Test of English as a Foreign Language (TOEFL)), this does not appear to translate into actual ability with the English language in the classroom. Most certainly in any typical Information Systems student cohort there would be only a sprinkling of students capable of expressing abstract ideas, outcomes of client interviews, conceptual system designs or user interface justifications. Staff room polling indicates that, while most staff are sympathetic to the plight of these students, there is a significant philosophical debate about the approach which should be taken. There is a great reluctance to change the traditional teaching methods and a not inconsiderable irritation that courses have to be "dumbed down" to compensate for students' lack of comprehension. Lecturers complain of having to translate their lectures on the fly from their "normal" vocabulary into simple English. Such informal indications appear to reinforce Colleen Ward's research (2001) in which she concluded that, in general, educators involved with international students were unlikely to make any changes to teaching methods or course content despite there being need and/or opportunity to do so. In technology courses, which may involve the use of multiple complex software environments, students who are unable to resolve issues using online "help" systems face further disadvantages: shortage of time and lack of assistance. The latter factor due to reducing government funding per student, the resultant increasing financial pressures on Universities and the consequential increase in the student: staff ratio.

This situation is a frustration for staff who expect undergraduates to be more self-sufficient and pro-active, yet must repeatedly answer the same questions and an irritation for students, who are unable to interrogate the advanced and expensive software supplied because of their inadequate English. The students feel they "lose face" in the admission to staff of their language inadequacies and for many, this is a price too high to pay.

It should be emphasised that these students are not below average; in fact many of them achieve higher IELTS scores than the minimum the universities require. Rather, they lack a wide general vocabulary and have only a smattering of technical English. It is worth noting here, that a significant number of students who have English as a first language often suffer from the same incapacitating problem.

There are only a few solutions to this problem and if those which reduce University income are eliminated (raising the English requirements of students, or reducing and limiting the number of students on a course) the question arises how best to increase teaching resources without increasing the time allocated to faculty teaching. The implementation of a software-based solution seems immediately attractive; this paper forms an examination of both the desirability and the feasibility of such an exercise.

MOTIVATION

The motivation for this implementation stems not from a hoped for "silver bullet", nor from a submission to marketing hype, but from positive past experiences automating aspects of University undergraduate instruction and assessment. In 2000 a pilot study was carried out (Richardson, 2000) among students who used a purpose-designed computer-based tutorial and assessment package called SOAP

(Student Online Assessment Program, pre-Microsoft use of the term) developed with the following requirements in mind:

Quality of Testing
- Elimination of plagiarism
- Audit trail verifying student identification and completion of the test
- Automated marking
- Centralised result logging

Quality of Test Management
- Reduction in overall staff time
- More immediate results feedback
- More immediate performance feedback
- Improved student satisfaction
- Elimination of post test disputes

The student reactions to the introduction of the system were interesting and were summarised at the time as follows:

Running the pilot system gave some very valuable insights into the practicalities of system based tutorials and assessment. Overall, the computer literate students embraced the system and gave very positive feedback. They liked the ability to proceed at their own pace which the computer-based tutorial gave them. They were happy with the email help desk and computer-based practice test. The less computer literate students attended University-based tutorials and progressed more slowly, requiring more hand-holding to understand the interface and the principles of the exercise. (Richardson, 2000)

Among the conclusions reached in 2000 were:

Experience with the SOAP system highlighted the inability of students with poor English skills to understand a written query and translate that English sentence into SQL code. It was not use of computer-based learning or the lack of technical SQL skills that limited a significant number of students' performance; rather, it was their poor grasp of English that was their undoing. (Richardson, 2000)

While SOAP was a specific solution to a specific set of course issues, the general goals of a reduction in faculty time allocated to each student, increased student satisfaction and ubiquitous availability were inherited by the 2005 system requirements. In addition, the system evaluated here had a prime goal of circumventing the cultural and English language issues that proved to be the major stumbling block for students in the 2000 pilot study.

An additional motivation for the introduction of e-learning technology and one that is less quantifiable though nevertheless real is the student perception of what "up to date teaching methods and materials" actually means. Students now expect online, 24/7 access to teaching materials such as lecture notes, chat forums, streamed video, reading lists, web links and so on. In the current market-driven tertiary environment, such items are considered desirable features of a course and act as points of differentiation with other tertiary providers. These features are seen by students as pedagogical assets, necessary for the successful completion of a course and not, as is the view of many faculty members, merely technology which is convenient for and panders to lazy students.

TECHNOLOGY PLATFORM

With the 2000 SOAP experience in mind and the 2005 requirements set, several software packages were considered for evaluation. It should be emphasised here that the requirements called for a content generation and manipulation package rather than a delivery system. In fact the University had standardised on WebCT as its e-learning delivery platform and, for delivery of the 2005 e-learning content, would be an option, together with stand-alone web sites linked to individual faculty members. Although there were many generic screen-capture packages, available both for proprietary operating systems and as open source, none offered a feature set commensurate with the proposed system requirements (Table 1), proven stability and adequate support.

Table 1. 2005 system requirements

Features
Text entry boxes
Quizzes and scoring
Storyboard-based editing
URL and email branching
Audio creation and editing
Text and caption manipulation
High resolution video output
Streaming
Small output file size
Smooth mouse movements

After a comparison was made between the myriad of packages available and the proposed system requirements, the actual software options were reduced to two: Macromedia Robodemo and TechSmith Camtasia. Both TechSmith and Macromedia were viewed as well-established companies with proven track records and lists of well-respected corporations in their client base. The two rival products, Robodemo and Camtasia both had similar feature sets, were comparably priced, relatively easy to use considering their complexity and were well supported. A decision was made in favour of Robodemo due to its superior level of integration with Dreamweaver and Flash, both of which formed the chosen platform for web-development. A further consideration was the historic and continued satisfaction with Macromedia as a commercial software development company.

It should be noted here that shortly after this decision was made, Robodemo was re-launched as "Captivate" which included some enhancements to the Robodemo development interface and an improved feature set. For the purpose of this report both "Robodemo" and "Captivate" are synonymous.

Captivate offers a broad scope for experienced developers to generate e-learning systems with interfaces and content in synchronisation with the individual lecturer's style of presentation. It opens the door to the development of e-learning systems that reflect the personality and experience of the lecturer, including anecdotal examples and asides, rather than a clinical set of functional, point and click exercises that marginalise the student. This ability to personalise and link the multimedia tutorial with both the lecture content and the lecturer provides continuity for the student and a point of one-on-one contact. The 2005 system takes a learning-objects approach to its organisation in that, over time, a significant library of video/audio clips should be amassed, each dealing with a specific topic and able to be played and re-played under the students' control. These are significant benefits, being conducive to learning and providing a cross-cultural bridge for students who habitually use repetition as a lever to understanding. Similarly, using the lecturer's voice for audio tracks rather than third-party voice-over further cements an individual relationship with students and encourages them to relax in the presence of a familiar course "leader".

To summarise, the author expected Captivate to provide a flexible and comprehensive video screen capture, editing and manipulation tool, with the ability to record and synchronise audio tracks and produce small output files playable in a ubiquitous browser user interface. From a systems environment point of view, the author observe that this development and evaluation took place in a somewhat "Lone Ranger" atmosphere, where, though e-learning was seen by the University as generally a good thing, there was a dearth of specific goals or coherent strategies in place and no central, standards-based development model. As a result the project was staffed by academics throughout its entire life-cycle, the resultant conclusions therefore were based on real-world usage rather than remote laboratory evaluation by Information Technology technicians.

EVALUATION

Students and Delivery

The 2005 system was implemented initially on a computer graphics course. The students enrolled on this course had a very wide spectrum of English abilities; indeed a significant percentage could be classified as having very poor or negligible English communication skills. However, all students on the course had

similar issues understanding the somewhat arcane software specific terminology. Introducing the Captivate content as the main tutorial method attempted to address this specific issue.

An important difference between the students of 2000 and the students of 2005 is the non-academic work patterns. The pilot system developed in 2000 was laboratory based since students tended to attend University in semester time and be employed during breaks. The 2005 system had to be designed with a changed employment pattern in mind since some students worked part time all year round and required access to teaching materials accordingly. Robodemo addresses this service issue by providing output deliverable via web-browser 24-7. Students are able to benefit from the portability of a Robodemo movie and play the multimedia presentation at home or in a computer laboratory at a time to suit their work schedule. As Robodemo content may be output as Flash movies, the software required to view them is equally ubiquitous and also free to download.

More importantly, Robodemo content may be created for a variety of media. As noted by Tom Green (2005)

We are rapidly moving into a media development market where our work is no longer tethered to the desktop computer. The rise of cell phones, handheld devices and even tablets has expanded the reach of our development efforts.

Robodemo facilitates output to different devices, each device having its own screen size and playback requirement and, since Flash players are available for most handheld devices, content may be output to a plethora of different devices; with the proviso that it is correctly sized for the specific device during capture.

Students who lack English skills may be confronted by tutorial material they don't understand; nor do they have sufficient English conversation skills to appropriately question the tutor or lecturer. Often, afraid of losing face, they will send indecipherable emails to the lecturer rather than raise their hands in class.

Self-conscious about how they [Asians] are perceived by others, their questions and opinions may be geared to building relationships rather than expressing unique ideas. They tend to be reserved with people they do not know well, and they assume a power relationship with the teacher as an authority, so they may avoid the possible offence of even asking questions that they do have (McCarty, 2005)

Robodemo-based tutorials allowed the student to control tuition at their own pace, replaying content that was not understood. Many students schooled in Asian education, have experienced an environment that did not encourage an interactive learning style using Robodemo content. These students were able to watch and listen in their own time to explanations dealing with the use of graphics applications which reduced pressure on them in lectures. Robodemo can incorporate branching to applications and other interactive hypertexting, which leads students through application based upon their responses to questions and quizzes in the tutorial content. In this way the application is somewhat adaptable to the individual's e-learning style.

In Human Computer Interaction (HCI) there are many widely accepted guidelines that must be considered when developing user interfaces (Connolly 1996, Schneiderman 1987, Nielsen & Norman). One of the main guidelines is the need to make users feel in command rather than at the mercy of the system (Connolly, 1996). This can be achieved by keeping the user informed, clarifying each step and providing context sensitive help facilities. Robodemo facilitates this goal by using rollover buttons, dialogue boxes and other interface objects, as well as a fully integrated help generator called RoboHelp. To assist user navigation, Robodemo provides indicators of the points reached. Also, Robodemo-based content may exclude extraneous material, assisting student learning by 'only including what is necessary to the user' (Schneiderman, 1987). The creator of the content may remove or add parts of the screen capture – from mouse movements and keyboard sounds to quizzes and rollover buttons, leaving only the most relevant and useful actions and noises.

Management and Administration

The Computer Graphics course uses various software packages to teach the basics of 3d animation and multimedia production. Packages such as Bryce 3d and Poser are used extensively for landscape and human modelling. Each of these has a steep learning curve that students must surmount in order to gain understanding and confidence using the software package. Until the introduction of the 2005 system, the course had been organised as a series of five, three-hour "lectorials" (a mixture of lectures and tutorials) per week, delivered in a purpose built computer graphics lab. This labour intensive delivery method provided extra impetus for the introduction of an e-learning solution.

Creating Robodemo-based content for each tutorial normally delivered over the semester amassed a significant library of objects, which in turn has facilitated rapid and easy variation of the course structure. Indeed, the course delivery method was to some extent reshaped, as the content previously provided by lecturers as part of a presentation would be delivered instead by Robodemo. The tutorials needed no longer to be presented in a computer lab at set times; instead students could choose to view the tutorials at leisure in any lab or from home.

It was found, in general, that when creating movies, Robodemo helped concentrate the mind of the lecturer/creator such that oversights and sequence errors were mostly eliminated. As a consequence, rework was reduced or similarly eliminated.

From a course management perspective, Robodemo helped overcome the proverbial bus syndrome by providing a library of quality-controlled objects that lecturers could use to educate themselves and provide continuity for students.

Cultural Usability

Del Galdo (1996) comments that there are increasing numbers of products currently available concerning internationalisation, localisation and translation; that these usability issues have been placed at the forefront for many companies who want to move into the foreign market. Macromedia's Robodemo is no exception.

There is a great deal more to culture than just language. We cannot make exceptions about culture based on what is the norm in our own culture (Del Galdo, 1996).

Robodemo helps achieve internationalisation of tutorials with numerous toolbars to help customize the content, storyboarding and overall structure of the movie. This can be as simple as changes to the text in dialogue boxes or adding multicultural audio tracks to frames. Graphical metaphors in the movie can be similarly adjusted so that the use of a culturally unsuitable metaphor is not included. Unfortunately many of the software applications studied in the Graphics course do not also follow the same rigorous usability testing but by using Robodemo students can be educated to recognise the English meaning for a symbol or metaphor that has been used within the software package.

Observations

During the initial development of movies some observations were made regarding Robodemo's usability. There were irritations with certain aspects of the functionality and usability of the Robodemo package. However these were minor and became transparent with increased familiarity.

Adding audio to the movie was found to be one of the more time consuming components of the movie making routine. Whilst using a good microphone was essential, the frame by frame approach of adding a vocal soundtrack was slow going. The use of an additional software package to remedied this. Captivate has since improved this step.

Whilst initially the movies took longer to prepare, now the practiced hand can develop content in a quarter of the time taken to develop a normal lecture & tutorial (Table 2). The number of repetitive emails received regarding course content has significantly dropped as students spend more time using this elearning tool, and less time trying to replicate what they mistakenly saw or heard in class.

IS THERE A DOWNSIDE?

Many students do not have the motivation or skills to sit down and teach themselves by reading a manual or self-study guide. Manuals are usually more effective for reference than for learning. On the other hand, Robodemo attracts the student's interest and can even be enjoyable to use. It also has added benefits of being able to be developed for a diverse body of learners

Table 2. Break down of course work

	Before Robodemo	After Robodemo
Hours of Lectures/Tutorials per semester	5 x 3 hours =15 x 12 weeks = 180	12 x 2 hours = 24
Staff hours developing course	100	50 (first year)
Hours developing one tutorial	18	12 hours (initially), 8 hours now

It is argued that if e-learning is to be driven by the needs of the users, then diversity should be a driving force behind the use of e-learning technology (Minton, Boyle, Dimitrova, 2004).

E-learning has brought proven benefits to the course. It has encouraged students to take responsibility for their own learning and introduced flexible learning so that the tutorials can be taken to suit their circumstances. With e-learning there are options for learning at a place, time, pace and style to meet the student's needs.

E-learning assures standardization of training and content presented. Each student receives a consistent lesson – rather than a repeated version by a lecturer who may accidentally miss vital steps along the way. Students become productive more quickly and require less handholding to achieve results. It has saved time over traditional face-to-face courses as students only study what they need and at their own pace. Robodemo empowers learners with responsibility for their own learning experience.

The e-learning content must be designed and written in a quality manner for the students to keep interest and learn. A poorly designed movie can result in boredom or even confuse the person supposed to learn the material.

CONCLUSION

For the most part in tertiary education, students require lecturers and tutors to drive the instruction process. They are given content, are able to ask questions and are asked to memorize facts and synthesize material. However if their ability to do so is hampered by a lack of English skill or by a reluctance to show their lack of knowledge, students can fail to progress in their understanding.

E-learning refers to a broad range of activities that involve the use of information and communication technologies (ICT) to support and enhance learning. By introducing Robodemo as an e-learning tool, many of the difficulties that lecturers have coordinating and presenting a time intensive course can be dealt with and students benefit from the ever expanding library of interactive resources. Students are able to reinforce their knowledge as needed and at their own pace.

Whilst initially the time spent on developing the course may be significant as one learns the Robodemo system, the time and effort saved in the long term makes the shift to elearning worthwhile. Robodemo has helped support an increasingly large and diverse student population while at the same time reducing teaching time.

The key to improving the effectiveness and quality of student learning and making it worthwhile is to replace existing traditional modes of teaching with more active and engaging learning opportunities, delivered where appropriate by e-learning (Ashford, 2003)

Future work on this project will include quantitative analysis of student use of the Robodemo based system.

ABSTRACT
Knowledge extraction from semi-structured or unstructured documents and texts have become a significant research issue in today's context when knowledge is viewed as the crucial corporate asset and capturing tacit or implicit knowledge and converting them into some reusable form have therefore become necessary. In this paper, a concept called knowledge pre-processing is proposed, to adequately exploit certain latent structured-ness in specific areas of the knowledge sources. The concept uses the basic principles of compilers, namely the lexical and semantic analyzers, parsers and thesaurus.

Keywords: Knowledge, Clustering, Pre-processing, Context Free language

1. INTRODUCTION

Knowledge pre-processing can make knowledge extraction processes faster and more resource-efficient. The basic functions of a pre-compiler can be used as a pre-processing unit, as analogous to the Oracle- pro*C kind of combinations. In case of such pre-compilers like Pro*C with oracle, we see that the pre-compiler primarily acts as a filter and sends the classified inputs to different processing units or modules like a separate c compiler for processing the C programming sections and an SQL compiler for processing the 'exec SQL …" statements. Similarly, if this concept gets applied in pre-processing knowledge elements for creating re-usable knowledge repositories which can store integrated knowledge elements across various sources, types and structures, the knowledge extraction, capture, conversion/ translation(to the format acceptable to the repository) etc. i.e. the later steps become easier and faster.

In fact, many of the knowledge elements which are generally viewed as 'unstructured' or 'free-flowing texts' have some degree of explicit structured information for example embedded in their labels. Unfortunately, these already embedded 'semi-structured' information which can help any extraction module to do some 'level 0' or 'pre-classification', do not get adequately exploited if the whole document along with the semi-structured part also is input at the beginning itself to the extraction modules. For example, there can be limited amount of 'pre-classification' information embedded or available in the document headers, message headings, subject lines of letters or emails and so on. These, if adequately processed by a knowledge preprocessor before entering into the actual extraction phase, some classification information can already be made available through this pre-processing, to the extraction modules.

Therefore, the benefits of a knowledge pre-processing unit to be placed before the actual knowledge extraction and capture modules can be explained as follows:

- It can help the knowledge extraction modules, which are often extremely resource-hungry and slow (due to less availability of such computational resources), more efficient. The knowledge extraction modules tend to become slow because of their unavoidable and extreme logical and processing complexities. A pre-processed input can make the logic simpler to some extent.
- It also helps the knowledge extraction modules to exploit some amount of structured information that remained embedded in part of unstructured documents like headings etc.

In this paper, we propose a generic model for knowledge pre-processor using the concepts of compilers in programming languages.

However, the main difference between the two contexts (i.e. the programming language executable code generation vs. knowledge pre-processing) is essentially the fact that the output of the knowledge pre-processor is not any executable code etc. but some structured information about the knowledge source that is being input to a knowledge extraction module. The other significant difference which is a basic one is the fact that input for a compiler is a source code file with a specific programming language as using regular expressions and regular grammar, whereas in case of a knowledge pre-processor the input will be free flowing text strings for example as constructs in CFL(Context Free language).

There have already been some applications of compiler-related techniques for discovering classification information from unstructured text, like topic searching using lexical analysis, lexical chains etc. Here, our main purpose is NOT to extend any of these techniques or even enter into the searching algorithms, pattern search or thesaurus-based pattern matching algorithms which get applied to the entire body of the messages/ documents i.e. the whole of the unstructured inputs.

On the contrary, in this paper, we are proposing the concept of using a pre-processor based on similar concept like compilers, along with some explanations and examples of its possible use and benefits. Towards this end, we have first discussed some of the approaches for pattern discovery, subject identification, classification and clustering of unstructured/ semi-structured documents. Then we take a clean-slate approach with zero assumptions about the concept of knowledge pre-processing, and develop a new generic model for doing the same. Therefore, the authors' contribution starts from the section under heading "Generic model outline for knowledge pre-processor" which explains the basic framework of the knowledge pre-processor and its generic components, their roles and inter-relations.

2. UNSTRUCTURED TEXT HANDLING APPROACHES

There is various research issues related to unstructured/ free-flowing text. The issues range from highly theoretical, mathematical, logical and analytical dimensions like discovering cohesions and relations between various sections of body texts (e.g. paragraphs), discovering topics, searching for topics. Further issues are related to the practical or implementations-specific side of the problem e.g. storing the discovered/ searched information in a knowledge representation format which is more accessible, understandable, easy to implement, and easily retrievable to achieve the ultimate goal of re-usable knowledge repositories. These issues translate down to specific research questions like: text segmentation, topic tracking, topic detection, link detection, classification and clustering.

The background work for these issues have started since many years, starting from the machine readable dictionary-based approaches by McRoy(1992), Li(1995), then heuristics-based approached by McRoy(1992) etc. Topic segmentation issues have been worked upon by Hearst 1997 (topics boundaries discovered with slighting window-like systems), Kan 1998 (entity repetition-based concepts). Clustering techniques have also evolved over time, for example divisive clustering (Choi 2000), partitional and hierarchical clustering (He 2000). These works have culminated into further research work e.g. topic detection in unrestricted text using lexical cohesion(Chali 2001).

One of the methods for representing documents as networks using partitional and hierarchical clustering techniques is further explained in this section, to compare its strength and applicability with the proposed knowledge pre-processing model here. This section is based on the work of him (2001) and Chen (2001). The original research was aimed at classifying hypertext documents, but the process logic is appealing for applications to any unstructured text domain. The basics of this process are as follows:

- Any knowledge source/ input is treated unstructured documents
- Co-occurrence (He 2001) analysis is used to find the similarities and then consequently the dissimilarities between the documents. This is done as follows:
  Co-occurrence analysis converts data indices and weights obtained from inputs of parameters and various document sources e.g. email/text message bodies, into a matrix that shows the similarity between every pair of such sources.(He et al 2001,He and Hui 2002, Shneidermann 1996)
  When measured between two documents, say Ei and Ej,

$$Sim_{ij} = \alpha \{A ij / |A|2 \} + \beta Sij / |S|2 + (1- \alpha - \beta) Cij / |C|2 \quad (1)$$

  $0< \alpha, \beta$ (parameters) <1, $0 <= \alpha + \beta <=1$,

  where A, S, and C are matrices for A_{ij}, S_{ij}, and C_{ij} respectively. Values for A_{ij} will be 1 if Ei has a direct link/ reference/ hyperlink to Ej, else 0. S is the asymmetric similarity score Ei and Ej, and is calculated as follows:

$$S_{ij} = sim (Ei, Ej) = [[\sum_{k=1}^{p} d_{ki} d_{kj}] / [\sum_{k=1}^{n} d^2 d_{ij}]] \quad (2)$$

  where n is total number of terms in Ei, m is total number of terms in Ej , p is total number of terms that appear in both Ei, and Ej., dij = (Number of occurrence of term j in Ei) X log((N/dfj)Xwj)X(Termtype factor); dfj is number of documents containing term j; wj is number of words in term j; Termtype factor = 1 + ((10-2 X typej / 10), where typej = min 1 if term j appears in subject, 2 if it appears in body, 3 if it appears in 'note' etc.) and Cij is number of Es pointing to both Ei and Ej (co citation/ cross-referencing matrix).
- Document bodies which are very similar in terms of their contents i.e. many of the identified key-terms (i.e. Terms excluding the general terms like pro-nouns, prepositions, conjunctions etc.)are same, can be clubbed up together to form a cluster. Dissimilar document bodies can be created as other clusters.
- These clusters can then form a network using hierarchical and partitional clustering method to form a graph with the nodes as representative knowledge maps for a particular group of documents with high-similarity in their body text.
- Partitioning of a graph, say G, can be done in various ways, for example, by using similarity measures as below: (Rich and Knight 2001,Shi and Malik 2000)

$$\text{Normalized Cut } (x) = \{\text{cut between } (A, B)/ \text{ assoc}(A, V)\} + \{\text{cut between } (A, B)/ \text{ assoc } (B,V) \quad (3)$$

where, Cut between $(A,B) = \sum i \in A, j \in B \, Sim_{ij}$, Simij is similarity between nodes i and j of the graph. Assoc(A,V) and assoc(B,V) shows how on average nodes within a group are connected to each other. A cut on a graph G = (V, E) is defined as removal of a set of edges such that the graph is split into disconnected sub-graphs. (Chen et al 1998,Chen et al 2001)

Now, this approach can work fine when the whole document has no element of structure in it at all i.e. any headers / titles / subject lines etc., or these also are combined together along with the body text and are processed together as well, not separately. This property is the main strength as well as weakness of this approach in specific and these kind of clustering-based approaches in general. The strength is that it can handle the whole document as a whole. The weakness is, in doing so, 1) It fails to exploit whatever little structure-related information that is embedded in some part of the document structure itself e.g. label, headings etc., 2) the complex and repetitive nature of the algorithm makes it extremely resource-intensive and in absence of such intensive or dedicated resources, extremely slow.

Other approaches like lexical chains suffer from similar constraints. Lexical chains arise from concepts of lexical cohesion that may arise from semantic connections between words (Chali 2005). Deriving the cohesion structure of a text is equivalent to retrieving lexical chains like LC = $\{w_1, w_2, \ldots, w_n\}$. These approaches while working fine with entire text as inputs, as is the case of topic discovery, searching or matching, do not again exploit certain default structured properties of text documents.

The concept of LCs however, can be used appropriately within the context of this paper as well, i.e. we can create the first level of document identifiers or classifiers by applying these LC-discovery concepts to the document label information itself e.g. the heading/ subject lines etc. We have actually used the concept similar to that of Roget's thesaurus as explained by Chali 2005, in the lexical analysis equivalence part of our model.

3. GENERIC MODEL OUTLINE FOR KNOWLEDGE PRE-PROCESSOR

The generic model of knowledge pre-processor, as explained in the section above, is shown in Figure 1.

Explanation of the sub-modules of the knowledge-preprocessing module:

- Lexical information extractor: This is designed in line of lexical analyzer in compilers, the main differences being that in case of compilers, the output of a lexical analyzer is a symbol table with tokens, lexemes and patterns. But here the output of a lexical analyzer will be broken-down fragments of the subject sentence into nouns/ verbs/ adjectives/adverbs etc. (the identification of a noun/verb and its subgroups e.g. names/ objects/ functions etc. can be done by using pattern matching and thesaurus). If we represent this analogy as in Figure 3, we get the symbol table equivalent in knowledge pre-processor as shown in table 1 inside Figure 3.

Figure 1. Positioning the knowledge pre-processor in the context of creating a re-usable knowledge base/ repository with unstructured sources

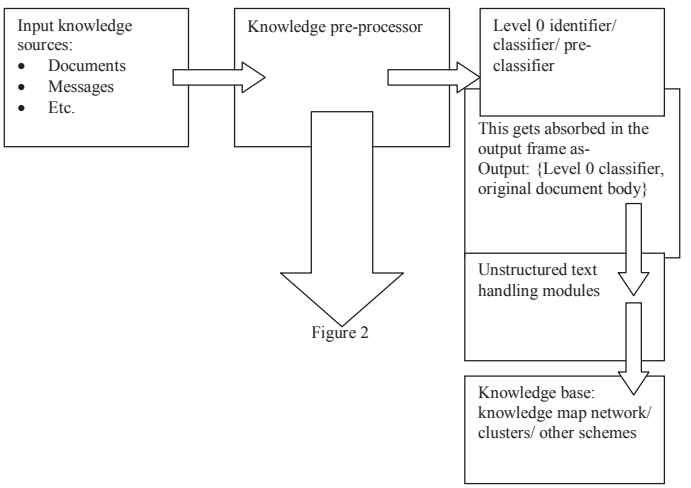

Figure 2. Knowledge pre-processor – basic building blocks and their outputs

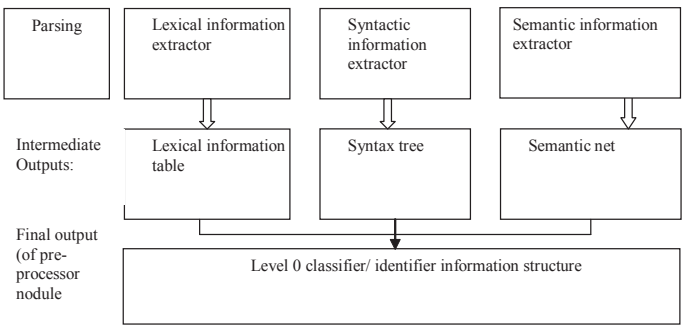

Figure 3. Lexical information extractor as an analogous equivalent of a lexical analyzer in a compiler

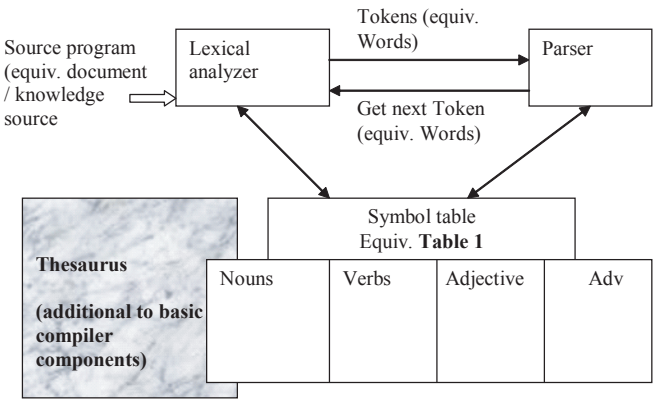
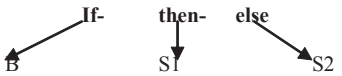


- Syntactic information extractor: The syntax extractor can draw it's equivalence to the syntax directed definitions including the annotated parse trees, dependency graphs, evaluation order-based graphs and syntax trees. A syntax tree can be thought as a condensed form of parse tree useful for representing language constructs. For example a production rule-type knowledge presentation scheme can appear as a syntax tree in the following form:



For a production rule: If B then S1 else S2.

- Semantic information extractor: Can be designed with an equivalence of semantic analyzer. The output can take form of a semantic network.

In the following section, we use a simple example drawn from a practical application situation and take this example through the initial steps in the knowledge preprocessor, basically onto up to the lexical analyzer equivalent part. This example can be further worked upon for generating the syntax trees as explained briefly above. And then it can be taken further to form it's semantic net equivalent.

AN EXAMPLE

Suppose there are two customer e-mail messages about rouble-shooting, to be input to a CRM knowledge base. The email messages have their subject lines in a fairly structured fashion, as they have used the pre-defined form fields of customer feedback forms on the company websites. These subject fields are considered as two inputs strings in this example. They are as follows:

InputString1: {Microwave model no. 2021 purchased in year 2002 not functioning: the table is not rotating}

InputString2: {Microwave model no. 4576 purchased in year 2005 not functioning: heating is not proper}

First level of lexical analysis on these two strings may generate output as follows:

InputString1: [Microwave model no. 2021 purchased in year 2002 not functioning]: (considered as connector) [the table is not rotating]

InputString2:[Microwave model no. 4576 purchased in year 2005 not functioning]: [heating is not proper]

2nd level: nouns (match from dictionary of nouns: can be made restricted to contexts: e.g. names (e.g. in case of customers complaining about service etc. by names), objects (as microwave in this example), place-names, function-names(e.g. 'heating' in the 2nd input string and so on)

InputString1: [[Microwave] [model no. 2021] purchased in [year 2002] not functioning] : [the [table] is not rotating]

InputString2:[[Microwave] [model no. 4576] purchased in [year 2005] not functioning]: [heating is not proper]

3rd level: verbs

InputString1: [[Microwave] [model no. 2021] [purchased] in [year 2002][not functioning]] : [the [table] is [not rotating]]

InputString2:[[Microwave] [model no. 4576] [purchased] in [year 2005] not functioning]: [heating] is not proper]

4th level: qualifiers/ adjectives

InputString1: [[Microwave] [model no. 2021] [purchased] in [year 2002][not functioning]] : [the [table] is [not rotating]]

InputString2:[[Microwave] [model no. 4576] [purchased] in [year 2005] not functioning]: [heating] is [not proper]]

Now, suppose we construct a table to store these strings as analyzed by the lexical extractor we get Table 1.

This table can be further fine-tuned, for example, by using a look-up table with index values for all these word-types and their sequential combinations e.g. 1 for nouns, and then 11 for names, 12 for objects, 13 for verb-type nouns e.g. function-names (like 'heating'), 2 for verbs(21 for auxiliary verbs, 22 for continuous tense …), 3 for adjectives, 4 for binary(yes/ no-not) response and so on. So, a phrase like 'Heating is not proper' can be expressed using this preliminary look-up table would be

Table 1. A minimal view of the lexical extractor output with two example input strings

Type of string component =➔	Noun	Verb	Adjectives	Adverbs
InputString1: substring1	[Microwave] [model no. 2021] [year 2002]	[purchased] [not functioning]		
InputString1: substring2	[table]	[not rotating]]		
InputString2: substring1	[Microwave] [model no. 4576] [year 2005]	[purchased] [not functioning]		
InputString2: substring2	[heating]		[not proper]	

<13>	<21>	<4>	<3>
[Heating]	[is]	[not]	[proper]

This whole string can be stored as an identifier with the numbers as indices for specific values as 13-21-4-3, just to remember the structure of the phrase. This information can be further added as the syntactic information for the phrases which would help in easy reconstruction of the phrases and subsequently easy and highly understandable retrieval. Also, the connectors may give valuable information, e.g. in this example case the symbol ':' depicts a further explanation of the problem, whereas in other cases the same symbol might mean different things e.g. cause-and-effect link between the two constructs. So, the connector along with its semantic role as a connector (e.g. a further explanatory/ a cause-and-effect link) will also have to be stored as part of the semantic extractor's job.

The rest of the example can be worked upon using further concepts on syntax and semantic analysis, as has already been mentioned before. Also, we can combine this model with the LC or co-occurrence analysis models as explained in earlier sections and can make the process more efficient.

4. CONCLUSION

This paper presents a fresh approach for knowledge extraction from unstructured sources using the concept of a pre-processor and the tried and tested concepts of traditional compiler construction in theoretical as well as applied computer sciences domain. The primary advantage of having a knowledge pre-processor, as has been explained in the first section of this paper, is the fact that a pre-processor can perform a level 0 analyzing and discover or present a basic identifier or classifier for an unstructured knowledge source by exploiting some amount of structured string-type information that are usually present in the source headers or document labels or message subjects/headings. This way it can reduce the workload of a knowledge extraction module which can then take the entire body-text of the document/ message/ knowledge source and apply the well-researched approaches of unstructured text handling on them. This way the entire process of knowledge extraction becomes faster and more resource-efficient. Further research possibilities include detailed design and implementation of the sub-modules under the knowledge pre-processor and exploiting the opportunities there again to use the tired and tested concepts of compilers, theory of computer science, theory of languages like regular grammar and CFL etc. With reference to the model presented in this paper, there are research issues in terms of scalability of the model e.g. the volume of unstructured data as well as heterogeneous source support-systems that can be handled by the model. Also there are issues related to the implementation, performance, resource utilization and tuning of any system based on this model which includes questions like which algorithms to choose for unstructured information handling, topic detection, preliminary information extraction, clustering etc., how to optimize the resource utilization for these algorithms, how to improve performance of an actual knowledge preprocessor and so on. Therefore, the model presented in this paper can be extended in multiple dimensions including theoretical aspects like algorithms design and analysis to implementation aspects including scalability and performance issues.

Automating the Business Process Case: Cairo Alexandria Stock Exchange

Sherif Kamel, The American University in Cairo, Egypt; E-mail: skamel@aucegypt.edu

ABSTRACT

Automating the business process in today's organizations is becoming a vehicle for competition and an important tool that helps provide a more effective and efficient service for its customers and employees alike. This paper demonstrates the findings of a market study[1] that was conducted in Egypt that focuses on the automation of the Cairo Alexandria Stock Exchange (CASE) and its implications on the operations of the exchange in terms of services offered, efficiency and effectiveness. The paper focuses on evaluating the trading process for brokers and investors both before and after the automation process of the exchange and identifying the impact of automation on the dissemination of information among the different stakeholders. Finally, the paper reports on a set of recommendations and conclusions that highlight the lessons learnt from the experience of the exchange in Egypt and provide guidelines for future implementations within similar environments.

INTRODUCTION

Stock Exchanges (SE) are the physical place, where stocks are traded, i.e. where they are bought and sold by brokers and dealers for other people's accounts who represent the investors. The stock exchange's main aim is to provide facilities for trade of company stocks and other financial instruments. Stock exchanges are usually found in central locations to keep it easy to record transactions. However, nowadays trade is much less connected by these physical places, as modern exchange stock markets are electronic networks with the evolution of information and communication technology infrastructures, which gives them speedy and less costly transactions (Helen, Hawkins and Sato, 1997). Such organizations are approved and regulated by the Securities and Exchange Commission (SEC). Stock exchanges are also called Bourses in European markets. Examples of famous stock exchanges are New York Stock Exchange (NYSE), which is probably one of the biggest stock exchanges in the world, London Stock Exchange (FTSE), Deutsche Börse (DAX), Tokyo Stock Exchange (TSE), and Cairo Alexandria Stock Exchange (CASE). The role of stock exchanges has been remarkably transformed over the last couple of decades due to the increasing and effective role information and communication technology platforms play.

Historically, stock exchanges first started in the 17th century. During that time, goods were traded and exchanged in central locations and the settlement of payments occurred at the end of the fair. Settlement days became more independent, eventually forming an autonomous market place. In the past, a number of steps as shown in table 1 used to take place in order to execute any transaction on the trading floor of stock exchanges (Helen, Hawkins and Sato, 1997).

However, the process of clearing and settlement became obsolete such that no more physical transfer of securities is required. Nowadays, the process became much easier when the automation of the process started. Figure 1 shows the traditional process of trading on NYSE trading floor.

Information systems have had a major influence on the different aspects of life leading to the integration of many processes and leveraging the performance of different organizations when properly designed and delivered. The capital market was not an exception and benefiting from the advantages that the information and communication technology infrastructure presents was a good opportunity to capitalize upon (American Chamber of Commerce in Egypt, 2004). There were several reasons behind automating the capital market on a global scale. This included a number of conditions such that having a perfect market would entail a strong automated capital market, which does not depend on the exchange of physical goods anymore as the digital transactions are dominating. Moreover, the fact that having an automated system transaction became very standardized made it easier to exchange securities all over the world and rendered the market more capable to compete and more effective in providing its services. Finally, having 24 hours access to information about the capital market became a priority and a necessity to compete in today's global environment and marketplace (Picot and Roehrl, 1995). It is important to note that with the information and communication technology evolution coupled with the growth of the digital environment, trading is becoming easy, accessible and a few clicks away from any potential trader.

The automation of stock exchanges started in the early 1970s, and the transaction of securities became electronically traded through the support of information and communication technology. Automating the capital markets did not only benefit one of the players of the financial trading game, however all the players in this sector gained from such technological breakthrough. After the automation, investors were not entitled to go and deal directly with stock exchanges, they did not have to go to a stock broker's office or deal with the hassles of calling him/her on the phone. As mentioned before, in the past, investors had to compete for the broker's time through regular and continuous access. The application of information technology allowed the investor to reach the information he/she requires any time anywhere. Moreover, investment decisions have become easier for the investor as more information became available around the clock (American Chamber of Commerce in Egypt, 2001). Post the automation process, the operation of the capital market transaction became classified as shown in table 2. The trading process post the automation of its components is demonstrated in figure 2.

As stated, all the players of the capital markets gained from the application of information technology in the stock exchanges. Generally, the automation process achieved a number of positive implications including; reduced interfaces, avoided media disruptions, and allowed disintermediation of middlemen like the agents on stock exchanges. Communication became more effective, efficient, faster, and wider and less costly in accessing information. As a result, transaction costs of trading were reduced. Automation allowed more transparency of information

Table 1. Traditional trading floor steps (Helen, Hawkins and Sato, 1997)

An investors calls a broker and orders the purchase of shares
When the order is noticed, the broker communicates with the relevant trader for order execution
Floor trader receives the order and calls a booth colleague who supplies the order to be executed
Floor trader goes to the pit in the middle of the trading floor where shares are traded and sends the order for execution
Execution is settled when the counterparty is found
Both parties record the transaction in their trading book
Simultaneously, the buyer reports the transaction to the trade reporting system and the trader makes a call to the booth to inform the broker to notify the client about the execution

Figure 1. Traditional process of trading at NYSE (Helen, Hawkins and Sato, 1997)

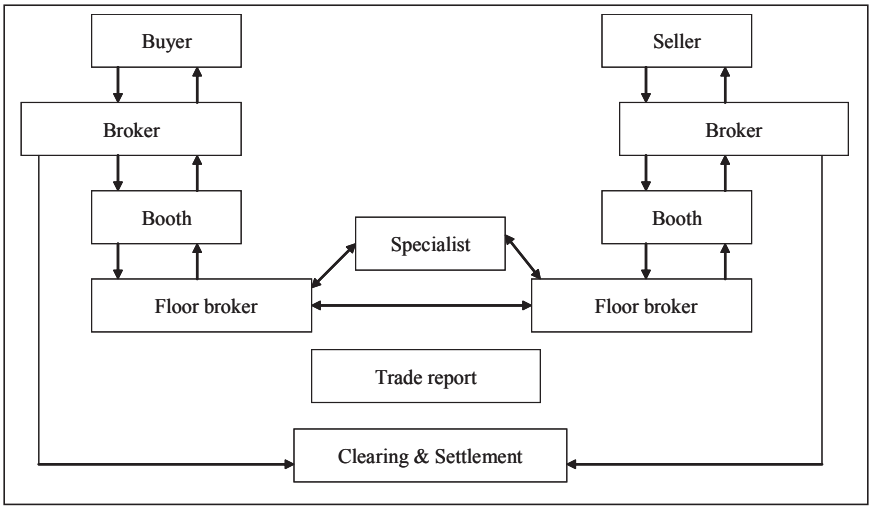

Table 2. Automation of the capital market (American Chamber of Commerce in Egypt, 2001)

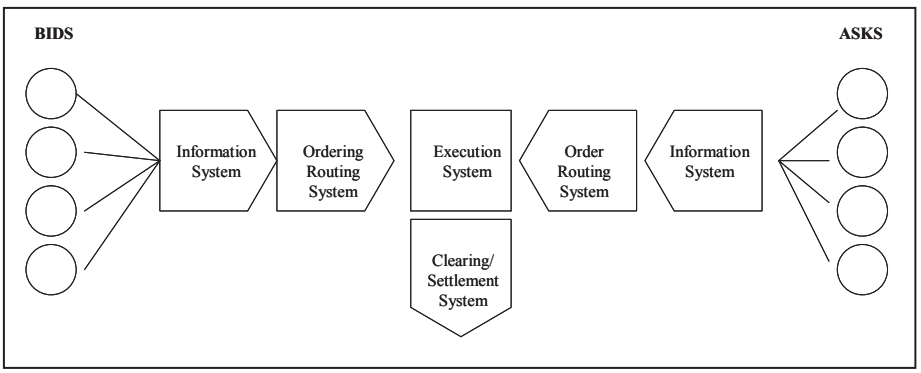
Operational System	Definitions
Information System	Mainly electronic (digital) replacing the traditional "pink sheets" system with information available and accessible around the clock
Order Routing System	Electronic transmission of orders to relevant recipients replacing individuals using hand signals and moving back and forth on the trading platform, currently all transactions are transmitted via electronic networks leading to remarkable increase in the volume of trading
Execution System	Automation facilitated the process and rendered it more effective and more efficient
Clearing and Settlement Systems	Process became easier and faster

Figure 2. Process of trading (American Chamber of Commerce in Egypt, 2001)



and faster reaction time from both the investor and the broker ends. It is worth mentioning, that automation increased the volume of traded stocks in vast amounts and handled more trade faster. Moreover, automation improved and accelerated the decision making process for both investors and brokers. Overall, the operational efficiency of the market climbed after the automation and the transactions rates in terms of efficiency was remarkably improved.

From an investor's point of view, using the Internet is an invaluable advantage that supports the investment decision by getting quotes digitally and real-time from the World Wide Web (Parl and Yun, 2004). Investors can get extensive resources about the latest financial and stock news, search press releases and recognize any company declarations in a timely manner within a globally information-push environment. Investors as well can track the performance of the portfolios they create and continuously calculate the value of their investments and make changes as they see appropriate. Many of them use online brokers and execute their trading activities from home realizing another benefits and implications of the information and communication technology evolution and that is telecom-

muting with more expected to be introduced in the marketplace contributing to the diffusion to smart homes and users alike. Respectively, it became more convenient for investors to access huge amounts of stock market information at any time around the clock. Furthermore, investors are not subject to get outdated news like before from newspapers, radio and even television as financial news are available on the Internet instantly rendering the concept of information dissemination a way of life and helping the concept of information-push to become the way to do business.

The massive penetration of the Internet worldwide allowed investors to send trading orders in a few seconds instead of waiting for stockbrokers. Moreover, analytical tools for stocks are available for investors to evaluate their stocks and assist in the investment decisions on a real-time basis. Examples of such tools include graphs, charts; historical data, technical analysis, and portfolio tracking in addition to the possibility of an automatic execution of sale or purchase orders that are triggered by special events. However, it is important to note that although there were many positive implications for the introduction of automation to the exchanges, which led to the creation of many opportunities, there were a number of challenges faced globally. These challenges include regulating the exchange competition; regulating the costs incurred; regulating across-border trading; and security of the trading process since it became more difficult after the introduction of the automation process to control fraud and manipulative activities. Following is an overview of the research methodology deployed and the study conducted on the Cairo-Alexandria Stock Exchange with a focus on assessing the implications of the deployment of information and communication technology on the performance and productivity of the exchange.

RESEARCH METHODOLOGY

The methodology used was based on empirically testing the research questions through a field study instrumented via the use of a questionnaire and the conduct of a set of interviews. The process started with an in-depth interview with both the current and ex-chairman of CASE to get an understanding of the process of trading. Interviewing the ex-chairman was valuable since the process of automation occurred during his tenure. The questionnaire was distributed among different investors and brokers with an attempt to reach the largest sample of brokers and investors available. It should be noted that it was not easy to find many investors or brokers especially after filtering those who were busy, unwilling to cooperate, or do not have much knowledge about using information dissemination for trading. This is a problem in research in most developing countries; the availability of information and willingness of information holders to share it with others for research purposes.

The research team selected a sample of brokers from CASE itself, as well as sample brokerage firms including EFG-Hermes, Sigma Capital, HC Securities and Okaz brokerage, which are all local and regional firms operating in the financial market in Egypt and the region. Additionally, a number of banks that were involved in brokerage activities including the Commercial International Bank were also part of the study. In terms of investors, a random selection process was used through family, friends, and university professors and via brokers when facilitated. The sample used is not as large as anticipated, but it was sufficient to base the findings upon it and to deduct some insights to the workflow of CASE before and after the automation process. However, it is important to note that looking at the overall volume of individuals investing in CASE; it was an enormous challenge to find investors who are willing to collaborate. The research did not intend to study information dissemination for corporations since there was no single person responsible for the trading of corporations as well as the fact that the researchers believed that corporations are more privileged in attaining information, and might not be so willing to share as much or be as transparent in their feedback. After distributing and collecting all questionnaires and conducting all interviews, the process of analyzing data and coming up with findings, generalizations and conclusions took place. This was followed with a meeting with CASE chair and his senior staff. The purpose of the meetings was to focus on the vision for the future and the proposed recommendations and directions that can help CASE be more efficient and effective in information dissemination for all those stakeholders interested to use its services (www.egidegypt.com). It is important to note that this research represents phase one of a much-extended research that is currently addressing the needs and implications of information and communication technology on the stock exchange and its effects on the economy at large.

RESEARCH FOCUS

The focus of the research could be identified in four major directions and that included the following:

A. To evaluate how the use of information and communication technology allows and assists in the efficient and accurate dissemination of information to brokerage firms as well as to individual investors.
B. To assess the existing trading process at Cairo Alexandria Stock Exchange through in-depth interviews with its different stakeholders
C. To identify the drawbacks and the negative implications of automating CASE
D. To test whether the technology acceptance model (TAM) and theory of diffusion of innovation were applied throughout the process of automating CASE

The above-mentioned issues represented the basis for the research questions addressed through the study and leading to the assessment of the automation of CASE and the deployment of the state-of-the-art technology infrastructure. Following is a demonstration of the history of the Cairo Alexandria Stock Exchange (CASE) and the recent developments that took place in its management and functions with a focus on the deployment of information and communication technology.

OVERVIEW OF THE CAIRO ALEXANDRIA STOCK EXCHANGE (CASE)

During the last few years, the financial sector in Egypt including the capital market, the stock exchange market, the banking and insurance sectors went through a number of structural adjustments and reform programs to improve the overall national performance of the economy including massive investment in its information and communication technology infrastructure. Additionally, the government of Egypt had to stop intervening in the financial sector leaving the market to be determined according to the forces of demand and supply. According to the American Chamber of Commerce in Egypt, the state of the financial sector in Egypt can be summarized as follows; a) the stock market was ranked the 2nd in its size among the African and Middle Eastern stock markets in June 2000; b) the newly automated trading system that was introduced is capable of handling 100,000 transactions per day resulting in increasing the level of the trading volumes and increasing the liquidity; c) more encouragement to additional investments and decreasing the restrictions for the foreign access is underway; d) significant efforts are currently being exerted to boost the privatization process and various bonds were issued to facilitate the growth of the stock market (www.egyptse.com).

Moreover, the market experienced an increase in the activity of mergers and acquisitions during the last four years reflecting the interest of foreign firms in the market in Egypt, which was mainly reflected in the penetration of international banks in the local market. It is also important to note that there has been a remarkable improvement in the number of firms traded in the stock market where the capitalization used was estimated to be around 1.6 billion US dollars and increased dramatically over the last few years to 12.5 billion US dollars reflecting how the stock market is moving on the right direction and excelling in its performance as a result of a number of adjustments including information technology transfer and proper deployment in the financial sector (www.usaid-eg.org).

During the 19th century, Alexandria's futures market was one of the oldest in the world. The first local recorded cotton transaction took place in 1885 in Alexandria's Café de L'Europe where cotton merchants met and cut deals based on supply and demand for long and short staples. The first cotton dealmakers eagerly waited for the weekly arrival of the newssheets from Europe to guide future operations. Reputation counted for everything. From Café de L'Europe cotton dealmakers formulated the Association Cottoniere d'Alexandrie (later the Alexandria General Produce Association-AGPA) for trading in cotton, cottonseeds and cereals in the spot and future markets. In 1899, during the reign of Khedive Abbas Hilmi II, AGPA became the Alexandria Bourse and representing the focal point of the city's financial community.

Historically, the origins of the Cairo Alexandria Stock Exchange (CASE) goes back when Moise Cattaui Pasha, a renowned figure in investment and brokerage chose the old Ottoman Bank as an official headquarter of the newly incorporated Bourse and Banking Company of Egypt Limited on May 21st, 1903 (www.egyptse.com). Later on, an international competition started for the best design of a bourse to be located in the center of Cairo. When the process was completed

and the design was selected it was known as the Cairo Bourse (later became the Cairo Alexandria Stock Exchange-CASE) that was once among the world's top stock exchanges and leading the way in most of the times. During that time, the number of firms trading had reached 299 with a capital of 15.9 million US dollars. In Alexandria, the official stock exchange was established in 1888 indicating that it was even prior to the Cairo Stock Exchange that was established in the 1940s. The Alexandria stock exchange was ranked fifth worldwide in 1903. It is important to note that both exchanges were active and were functioning separately independent from each other. However, the adopted social and political polices in the 1950s led to huge reduction in the performances of both exchanges. This state remained declining from 1961 until 1992, where the stock exchange lost its position and status (www.egyptse.com).

As indicated earlier, both exchanges were working separately; each had its own chair and committees responsible for managing the stock exchange affairs. The chairs were appointed by the general assembly composed of brokerage offices and banks. Both were governed by the same rules and regulations. However, on 6 March 1997, the legal structure was redefined and both Cairo and Alexandria stock exchanges were merged becoming one operating in Cairo and Alexandria, headed by the same chair and governed by one board of directors. The new structure indicates that the chair is appointed by the prime minister for a period of three years. The board of directors includes 60% that are elected from brokerage firms and investment banks and the remaining 40% are chosen from the Central Bank of Egypt (CBE), the Capital Market Authority (CMA) and two additional members from the Bank's Association. CASE is a public person who has no shares that are issued or owned by others. Although the government has the ownership of CASE it is still managed as a private entity. On 14 May 2001, the exchange market started using a software trading system leading to having both exchanges using the same system for trading securities. It is important to note that CASE is the only registered stock exchange market in Egypt with a mission to become the leading stock market in the Middle East and Africa and to expand its role regionally and globally through technology links and cooperation agreements, thus increasing market liquidity and provide the fastest, cheapest and best execution of transactions.

CASE DEPLOYMENT OF INFORMATION TECHNOLOGY

Prior to the automation of CASE, the stock market was an auction, where everyone manually places his/her order, which was normal in the past because there was not so much activity, but later on there were so many transactions so there was a need for a comprehensive process that is efficient and that could be comparable to similar exchanges around the world. Therefore, during the period 1996-1997, CASE set the first basic framework of the vision of the new automated system which was a trading system where everyone places his/her order on the system and it automatically matches the trade. Later on, the system was replaced by a more advanced version with added features and capable of absorbing much higher capacity (up to 50000 transactions per day).

CASE set its plans to apply technology on its trading system and become an automated order-driven system. The process of automation was introduced through two main stages. First, the Capital Market Authority (CMA) was responsible for developing the automated trading system being the market regulator. The process included the regulatory framework, an automated trading system, a surveillance system and upgrading the clearance and settlement systems. The regulatory framework was developed in order to improve the market pace which required crucial amendments in the capital market law. These amendments led to the introduction of new rules and regulations to guarantee transparency, efficiency and fair competition in the capital market. The surveillance system built allowed online trading at CASE and offline surveillance system at CMA. One of the assignments of CMA was to establish a comprehensive database for the companies that are registered on the stock market. The database included; a) companies' statements and information about their status, growth, and activities; b) detailed daily reports on the companies' stock issuance and licensing; c) financial disclosure of registered companies and investment funds; and, d) other information that could benefit investors and brokers (www.mcit.gov.eg).

Additionally, CMA created a system to announce exchange rates and market reports on the exchange markets on daily, weekly and monthly basis. Furthermore, the CMA established for CASE an online presence through their website that provides different stakeholders with information on real-time basis. During the second stage of CASE automation, an agreement was concluded with a Canadian Software Company to handle the design and delivery of the automated trading system and to guarantee conformity to international standards and state-of-art information and communication technology. CASE started using EFA software trading system in 2001 allowing brokers to enter orders from either location or from the offices of licensed brokers. On the Cairo trading floor, there are 123 terminals and 19 more terminals in Alexandria in addition to 65 terminals in the brokers' offices. Orders are queued into the database to be automatically matched by the trading system (www.egyptse.com). The deployment of the new automated system required the establishment of an advanced information and communication technology infrastructure within CASE in addition to the development of state-of-the-art information network, training of staff and also organizes training sessions for brokers and individual investors interested amongst other activities. The system was gradually introduced during the period 1998-2000 through a testing phase with a lot of mocks, trainings to brokers until the first version of the system was installed at the end of this period (www.egyptse.com).

RESEARCH FINDINGS

The initial target sample of questionnaires was 200 for investors and 30 for brokers. However, after filtering out the ones that are not completed and ensuring that the ones used were valid and could be included in the analysis, the sample covered was reduced to 66 investor questionnaires and 20 broker questionnaires representing 33% and 66% respectively of the original plan. It is important to note that the total number of individual registered investors is one million however; the number does not reflect those that are actually active investors, which is around only 20% (200,000 active investors) of the total number of investors.

The demographics of the investors constituting the sample were mainly 85% males and 94% local citizens (Egyptians). The sample comprised of bachelor degree holders (65%), master degree holders (18%), high school degrees (3%) and PhD holders (2%). In terms of satisfaction of the newly installed automated process and its implications on information dissemination, the respondents were almost equally divided. Relating their satisfaction level with their educational achievement, it is observed that the more senior the respondents were and the more they were educated, the more their satisfaction level was confirmed. This can be attributed to being either a coincidence that occurred as a result of not having enough respondents or maybe because those with higher educations achievements have more access or sources of information and appreciate more its value and its contribution in rendering the investment decision making process more effective.

With regard to the actual sources of information that investors mainly relied upon, it was observed that most investors rely on their brokerage firms to provide them with information and updates about market trends and statistics. Investment banks trailed by far as the second most preferred source whilst CASE did not even make it to the fifth spot. This was indicated through the fact that while 70% of the respondents deemed various sources of information to be important, only 2% acknowledged accessing information through CASE due to various reasons. It is also interesting to note that word of mouth proved to play an important role as a source of information for investors which also explains why investors had a problem with the accuracy and reliability of the information. Table 3 demonstrates the sources of information as ranked by the sample examined in the study.

Although it was difficult to find investors who had invested before and after the automation of CASE, from those that were available, it was found that the

Table 3. Sources of information

Source of Information	**Percentage**
Word of Mouth	3.5%
Investment Banks	4.5%
www.yahoo.com	1%
www.gn4me.com	2%
Egypt for Information Dissemination	10%
EFG-Hermes	9%
Cairo Alexandria Stock Exchange	**14%**
Brokerage Firms	12%
Arab Finance Corporation	7%

automation process did not inflict real implications on the process of information dissemination. The culture of using information and communication was not yet well diffused within the marketplace. The findings indicated that those who were unsatisfied with the quality of information provided be it accuracy, speed of diffusion, timeliness or ease of use more or less did hold the same position post the installation of the automation process. Table 4 shows the factors preventing investors from making effective trading decisions as indicated by the responses of the sample. The main problem that was raised by the respondents was the time-lag between the time when events occur and the time when investors actually receive the information.

The responses of the investors showed little but gradual trust in the newly introduced system with 15% not really trusting the newly introduced automated system. This can be the result of a number of factors mainly related to the use of information and communication technology and the human resource capacities trained and prepared to use different automated applications. With respect to the responses of the brokers, the number of brokers has been steadily increasing since the introduction of the automation process due to the relative improvement in the process of information dissemination. The overall response seemed to be favorable of the new automated operation when compared to the traditional system which was confirmed by 90% of the responses. Brokers were more positive with respect to the role of the exchange as a primary and reliable source of information when compared to other sources. The findings of the research indicated that while CASE is not considered by most investors an important source of information, it is the main source of information for brokers who are themselves the main source of information for investors. This in reality implied that while CASE may actually be a good and valid source of information and knowledge about the financial market, investors do not really feel its presence or importance in terms of effectiveness and efficiency. Table 5 demonstrates the importance of information and its level of demand from the brokers and its transformation before and after the automation of the exchange.

With respect to the issue of investors relying mainly on brokers and their sources of information, the results were mainly moderate with no inclination to any major trends. Based on the interviews, the results were slightly different indicating that investors were gradually becoming more mature and less dependent on their brokers for information; alternatively, they seek information themselves and make their own decision. Table 6 shows the average investors relying on brokers for information to take a trading decision.

With respect to the span of time it took information to reach the investors, brokers indicated that in the majority of the cases 1-2 days were needed which may not seem that long. However, from an investor's point of view this duration could be the difference between a profit or a loss and they believed that there is an urgent need to cut down such duration substantially. Table 7 demonstrates the assessment of brokers of the duration it takes information to reach investors.

Table 4. Factors preventing investors from making effective trading decisions

Information Assessment Elements	Number of Respondents
Information not easy to use	26
Information is not useful	17
Unequal opportunity	19
Inaccuracy	28
Time-lag	47

Table 5. Levels of demand for information

Level of Demand	Findings
No demand	2%
Low demand	30%
Medium demand	35%
High demand	30%
Intense demand	3%

Table 6. Average investors relying on brokers for useful trade information

Level of Demand	Findings
Not at all	2%
Partially	28%
Mostly	52%
Entirely	18%

Table 7. Duration it takes information to reach investors

Duration	Findings
1-2 Seconds	0%
1-2 Minutes	12%
1-2 Hours	25%
1-2 Days	55%
1-2 Weeks	8%
1-2 Months	0%

RECOMMENDATIONS

Based on the number of issues discussed and the findings of the research conducted, one of the main debatable issues was the amount of time it was taking for real-time information to reach the investors to be able to take a trading decision. Therefore, the recommendation made relates to the development of a module for brokerage firms to help them overcome the information dissemination problem and at the same time serve both investors and brokers. The wealth of knowledge needed to be shared on a timely basis to capitalize on the benefits of information and communication technology. The model situation usually occurs when a broker gets feedback from a reliable source about any of the company's new decisions that would affect the stock prices and that appears to be important for their investors. Then the decision is to contact all investors at the same time to offer them the best opportunity to buy or sell stocks. It takes a very long time for the investors to be informed about the new changes in the stocks and when they start to react either by a decision to buy or sell, the price of the stock is usually altered. Therefore, investors have to be informed of changes that take place in order for them to be aware of their surroundings and be able to trust the brokerage firm when investing their belongings in the stock market.

The recommendation that was suggested was the development of an information base that can be used by brokerage firms and placed on a high-end server that is updated on a timely basis and linked to news networks that cover and relate to stock news and that can have implications on investors' decisions. News would automatically be updated into the information base which would instantly send electronic mails (email) and short message services (SMS) informing brokers that a change had taken place in the market that would be ultimately be important for investors and might result in them taking appropriate actions. With the diffusion of information and communication technology and media convergence, such inflow of information and knowledge and its timely and real-time access is becoming more of a reality. Respectively, brokers in seconds would inform their investors about all changes taking place through an email or an SMS (based on the investors' choice), giving him/her the opportunity to reply instantly and take an immediate action by either buying or selling. Such process is estimated to take a cycle of around 7-9 minutes taking the process to be as real-time as possible irrespective of time or distance barriers.

CONCLUSION

Based on the findings of the research, it is apparent that the current attitude of investors towards dissemination of information is relatively conservative with not much of a difference before and after the automation process in terms of information dissemination. There was an obvious difference between the impression of CASE senior management and various investors and brokers with opposing views on the role and effectiveness of the newly automated process. One of the major barriers faced was acceptance of technology especially by senior and relatively

older brokers and investors not really accustomed to the use of information and communication technology. The recommended solution should help realize and meet the requirements of the investors and cater for the need for information dissemination that was not addressed by the automation process of CASE. However, it is important to note that according to the findings of the research, the new automated process brought to CASE transparency, fairness, efficiency, higher volumes of transactions, a more user friendly environment, saved time and effort and became more capable of matching global market needs which was translated into having more foreign investors in the exchange.

To conclude, post the automation process of CASE, there has been a number of objectives realized indicating that more improvement of the process could be achieved with regular analysis of the market needs and continuously introducing customized services to the community of customers. Among the direct and indirect implications of the automation of CASE was providing a regulated and transparent market based on efficient and flexible technology and supply investors and brokers with reliable and real-time information services and attracting more investors from both local and international markets to increase the pool of liquidity in the economy. Moreover, it led to developing new products and services as bonds, raising the awareness campaign and introducing new trading practices that match the needs of investors, and aiding in the establishments of privately owned services that provide operational and technical support to registered brokers. Finally, it paved the way to working on creating the most effective and the best membership rules in the Middle East and Africa.

The awareness and diffusion of the use and benefits of information and communication technology led to the proper deployment of technology to serve the purpose and objectives of CASE. This has enforced the concepts based upon which the technology acceptance model is based. The easiness of using the services and the perceived usefulness were both critical elements contributing to the success of the automation process of CASE. The research study findings indicated, based on the sample covered, that with the automation process and the investment in human resource capacities including all stakeholders, information and communication technology tools will permit CASE to provide useful services to different traders while improving technology processes and infrastructure. Moreover, the analysis indicated that consistent with the technology acceptance model both perceived ease of use and perceived usefulness are playing important roles in defining the acceptance level of different CASE introduced technology-based services. It is important to note that this research study represents phase one of a much larger research work assessing the implications of the automation and the diffusion of information and communication technology on CASE, trading and the economy at large.

RFID Adoption: Issues and Challenges

Eric W. T. Ngai, The Hong Kong Polytechnic University, PR China; E-mail: mswtngai@inet.polyu.edu.hk
Angappa Gunasekaran, University of Massachusetts – Dartmouth, USA; E-mail: agunasekaran@umassd.edu

INTRODUCTION

Radio Frequency Identification (RFID) is an emerging technology that has been increasingly used in logistics and supply chain management in recent years, particularly in the US and Europe. World's largest retailers are increasingly requiring their suppliers to be RFID compliant. Although RFID is not a new technology, the term RFID has been popular for the past couple of years. We are seeing an increasing interest in this technology by companies (Prater and Grazier, 2005).

RFID tools can identify, categorize, and manage the flow of goods and information throughout a supply chain (Ngai et al., 2005). Rapid development of RFID combined with a major push coming from mandatory RFID tagging decree by Wal-Mart and the U.S. Department of Defense and others like European companies Metro AG and Tesco, has caused companies to take a hard look at what RFID can do for them and whether they should give further consideration to adopting the technology.

RFID has been around for decades. It is one such technology that we can embed into objects to track location, monitor security, and record the status of events or even environmental conditions (Stanford, 2003). RFID systems have emerged as new forms of inter-organizational systems (IOS) and are used to improve the efficiency of the processes in a supply chain. Because of their capability for use in real-time identification and tracking over long distances, some believe that RFID systems will fundamentally change the way companies do business (Smith and Konsynski, 2003).

The following are some of the current issues and challenges facing the RFID technology adoption in industrial applications.

CURRENT ISSUES FACING RFID ADOPTION

Globally Interoperable Standardization Problem

There is lack of global standards for RFID adoption. It is no doubt that the adoption of official standards, enabling interoperability between applications or devices, can significantly accelerate the adoption of RFID technology. The RFID industry has been mainly using two different standards. One is being developed by the International Standards Organization (ISO), the world's main developer of standards that has developed several standards around RFID which are used in Europe. The other is the Electronic Product Code (EPC) system, which is being commercialized by EPCglobal, a non-profit organization set up by EAN International and the Uniform Code Council. What standard should be used is one of the most frequently asked questions from the users. It is critical that the EPC and ISO standards can co-exist in order to ensure end-to-end interoperability of RFID systems to track goods through the global supply chain Finkenzeller (2003).

Environment

Currently, the most used frequencies for RFID implementations are – 13.56 MHz (i.e. "HF" for High Frequency) and 915 MHz (i.e. "UHF" for Ultra High Frequency). At these frequencies, transmissions are impacted by two environmental factors. The first one is water and other one is liquids which are hindrance to RFID system performance. Liquids can absorb the radio energy/signals and thereby limit range or prevent tag read/write operations altogether. Label media adhesives also can be an unexpected source of liquid. Some types of adhesive or label materials that absorb moisture from the environment, which could cause performance problems. This makes "reading" tags through liquids very difficult, if not impossible. Metals are another hindrance that generally reflect radio frequency signals and deflect the radio waves, thus altering their path. This is essential source of RFID interference and should be avoided if possible. This does not necessarily mean that metals prevent "reading" tags on objects or cartons that contain metal, but the radio waves must have a path into and out of the material.

The second technical problem is that one should watch out for the use of the other equipment of the frequency that is near the one used by the RFID solution. For example, the first generation of GSM phones transmits at 900 MHz, as do some handheld RF barcode scanners. This is near enough to 915 MHz to potentially cause interference. This problem can usually be overcome by shielding the RFID reader.

Security and Privacy

RFID technology has proven to be reliable, especially in supply chains, and is already showing tremendous advantages. But an automated supply chain mandates the necessity for data privacy, identity and non-refutability, and organizations should ensure the RFID technology they adopt supports their security requirements. Companies need to be aware of the security risks, such as profiling, eavesdropping, denial of service attacks and inventory jamming.

Education and training is the best way a business can ensure it understands the limitations and risks associated with RFID adoption. Businesses should not assume that the risks associated with RFID adoption are small because the RF footprint of current generation tags is constrained. Understanding the mean time to crack—access, alter or deny the use of—the tags is a prerequisite to ensure that tag selection embodies the objectives of the company's corporate security policy.

RFID has the potential to threaten consumers through intervention of their informational privacy, their physical privacy and security and their civil liberties (McGinity, 2004). Consumers are concerned the possible abuse of personally identifiable data (such as credit card number, security number) and sensitive data (such as prescription drugs) by the retailers when companies adopt RFID technology. A considerable driver of the fear of RFID to consumers is a lack of understanding about RFID technology. Companies should inform consumers that they use RFID tags on the products, and educating consumers of the true technological limitations of RFID.

Data Management

Many conversations about RFID inevitably end up touching on the presumed high volume of data and resulting data management issues that are expected to arise from tagging individual products. Data management is a key issue for any organization deploying RFID technology, and the robust middleware to handle that onslaught of data and route it to the right database is most concerned. To leverage this enhanced visibility of data captured, enterprises need to establish the right architecture to filter and translate RFID data into business relevant events and then to use these events to create and automate business process for providing quality service and better competitive advantages.

Generally speaking, RFID data management issues fall into several categories: RFID data collection and storage, data integration, data synchronization, data ownership and privacy, data interpretation and analytics, and execution of end-user business processes to sense and respond to RFID data. Companies need to address a couple of questions, for example: what RFID data should be collected and stored? How this RFID data is different from that is currently collected and stored? Who owns the RFID data, and what elements are subject to privacy or security considerations? What is the best way to visualize this RFID data collection and act upon key events? And most important, what business processes need to be changed to enable people to act upon this information?

Tag Failure Rate

As pointed out by the report of Deavours (2005) in the "UHF EPC Tag Performance Evaluation" – "Even tags of the same make and model vary significantly in their performance as this excerpt from the RFID Alliance Lab's report (http://www.rfidjournal.com/labreports). The tests showed that the range of under-or nonperforming tags can range from 0 percent up to 19 percent. Companies should screen out under or nonperforming tags. Even if tag producers will reimburse you for bad tags, you still need to do the screening yourself.

Focus on the worst case performance tags, not average or best case because your system will have to be designed to accommodate the worst performance. Currently, there is a high rate of first pass write failure, anything up to ~10%. Clearly, this failure rate is not the one that one could sensibly sustain in live operations. A Root Cause Analysis has thrown up two probably causes of this high failure rate:

1. A tag was mounted on a plastic base and multiple tags were then mounted on a plastic backing roll. Separating the two quickly set up an electrostatic discharge which damaged the chip.
2. When pulling the tag off the reel for manual application, the operators had a tendency to pull the tag across the centerline thus causing the antenna strip to separate from the chip.

Quality Assurance

An important part of the user's requirement is that the tags on all goods must be intact and readable. Considering the Wal-Mart as an example, pallet tags must be 100% readable at the receiving dock and case tags must be 100% readable on a conveyor moving at the speed of 600 feet per minute with a minimum spacing of 8 inches between cases (Deavours, 2005).

One should ensure that there are sufficient processes, checks and balances in place to guarantee that all RFID tags on pallets and cases have been written correctly and are intact at the point of shipment to the next location, be that a customer location or another distribution center. One should also ensure that all reasonable steps have been taken to prevent the damage or removal of the tag in transit.

RFID Expertise for Deployment

A recent survey by the Computing Technology Industry Association revealed that 80 per cent of the responding companies said there were not sufficient numbers of skilled RFID professionals. Two-thirds of them said training and educating their employees on RFID technology is one of the biggest challenges they face in order to succeed in the RFID market (Morrison, 2005). We believe that the problem is more serious in Asian countries. Like Hong Kong, there is a lack of strong expertise in RFID technology deployment. Local large-scale deployments are usually made by foreign companies. It is difficult to find local experts in the RFID field with large-scale deployment experience. Certainly, education through short course like an RFID certification program and a coordinated crash training program may be the best hope to fill the work force urgently need but for long time, the knowledge and skills related to RFID technology should be education in higher education.

CURRENT CHALLENGES FACING RFID ADOPTION

Along with the potential offered by RFID come the inevitable challenges that must be understood and overcome before companies can reap the benefits.

Management Commitment

Gaining management commitment is one of the biggest challenges in implementing RFID. Despite it can result in savings, it is always difficult to get senior management commitment because it is new to them. Return on investment (ROI) is an important consideration for management consider in assessing RFID investments before RFID project commitment. Gillette is using the RFID tags in one of the biggest EPC project, tagging all pallets and cases of its Venus women's razors that his vice president, Mr. Cantwell championed RFID technology internally at Gillette (Roberti, 2004).

Dual Systems

With RFID, not all partners will use it, and those who do may require it for only their RFID-ready distribution centers. Furthermore, not all the items or packages will be tagged. Another need for dual systems arises when you deal with small and medium businesses that can not afford RFID systems. You should assume that exceptions to the "all or nothing" ideal will always exist and be prepared to deal with this challenge from a technical and operational standpoint.

Cost Challenges

The biggest challenge companies faced with RFID is that it is the high cost of implementation. One of the challenges a company faces with the introduction of RFID technology is whether the business really needs the technology and how to justify the investment in the implementation. Cost-benefit analysis is critical to the successful adoption of an RFID project. At present, the cost of RFID adoption is the major investment in hardware, application software, middleware, tags and the cost of integrating RFID-based system with the legacy systems, consultancy fees and employee training.

Legal and Patent Challenges

Most of the companies overlook the importance of having a legally binding master agreement before adopting RFID. As most of us know that in the end there are no real winners in a trading relationship that ends up in litigation. RFID technology, should carefully discuss with vendor, each trading partner about the liability limitations that pertain to the data contained on tags (because it can mistakenly be overwritten). The intellectual properties (IPs) of some RFID technology is still not clear. Like in 2004, Symbol Technologies has filed a counter patent-infringement lawsuit against Intermec Technologies (http://www.rfidjournal.com/article/articleview/1443/1/58).

We believe that to make sure RFID technologies are widely adopted, RFID needs to be royalty-free. As some vendors are concerned about paying high royalty cost to develop RFID systems which is another barrier for widely development of RFID systems.

Operational Automation

Companies should evaluate their own needs and determine which processes can benefit from automation with the use of RFID and associated technologies. To aid in their operational evaluation, they must study the business operations processes in their company and determine the volume of information exchange. Which if your items are suitable for tagging? What are the types of tags will they need today and how quickly will those needs change in the future. Whether they need to combine that RFID tag with a bar code when they realize that the RFID system fails them too often and leaving them. Evaluate company's operations and determine how, where and when best to apply one or a combination of these technologies to benefit the organization, its customers and the entire supply chain. Those questions are the most frequencies asked questions by the users.

Selection of Hardware and Software

The challenges here include the choice of RFID solution including the hardware and software required. The choice of tag types in terms of read range, read/write capability, reader type, and middleware. The performance of hardware products in the market varies and a lot of efforts need to be devoted to hardware evaluation and testing. Also, the performance of RFID system varies in different environments. The solution is to tightly integrate the hardware equipment with the software system. The software system should be able to correct any problems due to the unreliable data captured via RFID.

Another consideration is whether to use the RFID tag alone or to tag it in addition to a bar code label. The advantage of the dual technology is, of course, that should one fail, and the other can serve as a backup. However, they can be sure about their implementation and maintenance costs will be higher as a result.

Technology Support for Adoption

At present, both RFID hardware and software in Asian markets are mainly from the US. Although RFID solutions are from foreign vendors with support of local distributors, which provide limited technical support, as most of their staff are marketing oriented. We have found that most RFID hardware providers in Asian markets lack technical support staff, and their RFID teams mainly consist of salesmen and marketing staff. This is due to the fact that RFID is just an emerging technology in most Asian countries.

CONCLUSIONS

Besides, the costs and technical challenges, we believe, the value of RFID, and how companies can implement this technology to enhance the quality of service, their production and eventually corporate earnings are crucial in RFID adoption. It is hoped that this paper will provide the readers to have a better understanding of the current issues and challenges facing the RFID adoption and be in a position to further investigate each issue and challenge discussed here best understand it before the implementation.

Technology researchers find out the ways to increase the range of RFID signals and reduce the radio frequency interference, standards organizations like ISO and EPCglobal unravel the standardization problem and make an open and compatible standard while stores determine how to make customers desire RFID in their lives (McGinity, 2004). However, as with other emerging technology, RFID technology is still not fully development. We see that the more research effort and development put into RFID study, the more successful RFID adoption we can see.

The following points out some research topics that are of interest for further research for RFID adoption:

- Social and economic impacts of RFID impacts of RFID adoption;
- Privacy, security, legal and cultural challenges of RFID adoption;
- Antecedents of RFID success adoption;
- Evaluation metrics and implementation of methodologies for RFID adoption;
- Barriers and critical success factors for RFID adoption; and
- Educational requirements and curriculum implications of RFID technology.

Finally, we quote a comment originally made by Mark Roberti, editor of RFID Journal that "Companies will have no choice but to use RFID, just as they have no choice but to use the Internet today".

Issues Affecting the Adoption and Continual Usage of Internet Banking Services in Semi-Rural Areas of South Africa

Nehemiah Mavetera, North West University, Mmabatho, South Africa; E-mail: maveteran@uniwest.ac.za
Maureen Kesimolotse, North West University, Mmabatho, South Africa

ABSTRACT

In modern society, Information communication technology (ICT) diffusion is very rapid. However, ICT infusion is very slow. Several issues contribute to ICT infusion. They range from social, economic, demographic and political reasons. Internet banking is one such ICT contribution that is facing limited acceptance in some parts of South African society. This research looks at issues affecting the adoption and continual usage of Internet banking in a South African semi rural area, Mafikeng region. Although Internet banking has been receiving a lot of interest worldwide, very little methodical study has been done to determine reasons why many people in semi rural areas like Mafikeng do not adopt and make use of Internet banking services. Technology Acceptance Model (TAM) was used to guide the enquiry process into factors affecting Internet banking infusion. Internet Security was found to be a major factor contributing to Internet banking adoption and continual usage in Mafikeng.

Keywords: Internet Banking, Technology Acceptance Model, Internet Security, ICT diffusion, South Africa

1. INTRODUCTION

For banks to serve clients through the Internet can be very risk if security is not improved. The primary services provided through Internet banking are transferring money among one's own accounts, paying bills, checking account balances and sending and receiving confidential information between banks and their clients.

Information about financial institutions, their customers and financial transactions are considered very sensitive. Doing such business via a public network consequently introduces new challenges for information security. Internet banking system must solve issues of authentication, confidentiality, integrity and non-repudiation. The system must ensure that only authorized people can access an Internet banking account, the information viewed remains private and cannot be modified by third parties. Any transactions made should be traceable and verifiable. The behavior of people in a semi rural area of South Africa towards the adoption and usage of Internet banking will be the focus of this paper.

The rest of the paper is as follows: **Section Two** discusses the general Internet issues in South Africa. **Section Three** discusses the theoretical frameworks used to appraise the adoption of information systems in the society. **Section Four** looks at the research approach, **Section Five** discusses the results and **Section Six** concludes the discussion**.**

2. BACKGROUND TO INTERNET USE IN SOUTH AFRICA

South African Internet users have been increasing steadily since 2000 from 2.4 million to 3.6 million in 2005 (Internetworldstats, 2006). This is an average user increase of 50% and an average of 6.7% of users relative to the country's gross population. Table 1 shows the increase in the number of internet users from 2000 to 2005.

The Goldstuck report on "Internet Access in South Africa 2004", mentioned the introduction of high speed or broadband wireless by Sentech, and the good rand to dollar exchange rate as some of the factors that could contribute to increased internet access in South Africa. This is in addition to the introduction and licensing of a Second National Operator (SNO). The introduction of the SNO will remove Telkom monopoly and introduce competition in the fixed line industry. This may eventually lead to decrease in telecommunication costs which are rated highly as one of the factors hindering internet infusion in South Africa. In addition to broadband access from Sentech, introduction of ADSL and ISDN from Telkom will further increase internet speed and will positively contribute to reduction of internet costs.

2.1 Internet Banking Review

For customers, developments taking place in the banking world means cheaper, faster and convenient banking (Chan 2001). Nowadays, banks are installing automated teller machines (ATMs) in a bid to bring services to the people. Banking has been revolutionized (Standard Bank, 2004). Point of sale banking, where people are allowed to use debit and credit cards to pay for goods and services in addition to withdrawing money have also been introduced.

Advances in information technology (IT) have created cell phone banking and Internet banking as serving channels in the banking sector. Internet banking is

Table 1. Internet Users Growth Trends in South Africa, 2000-2005. (Source: Internetworldstats, 2006)

YEAR	Users	Population	% Pen.	Usage Source
2000	2,400,000	43,690,000	5.5 %	ITU
2001	2,750,000	44,409,700	6.2 %	IWS
2002	3,100,000	45,129,400	6.8 %	ITU
2003	3,283,000	45,919,200	7.1 %	Wide World Worx
2004	3,523,000	47,556,900	7.4 %	Wide World Worx
2005	3,600,000	48,861,805	7.4 %	Wide World Worx

"communication with the Bank and/or performance of Transactions through the Internet network"(ING Bank, n.d.). Some people refer to it as online banking. Generally, the two words are used interchangeably and defined as terms " used for performing transactions, payments etc. over the Internet through a bank, credit union or building society's secure website." (Wikipedia, n.d.).

Internet banking has changed the way banking is conducted areas such as, distribution, production, payment and trading (Llevwellyn, 1997). It also created new customer values, in content, infrastructure, and context (Methlie, 1998). Although the number of Internet users has increased significantly over the past decade, only a small number of those users have made actual purchases over the Internet. The failure of the Internet as a retail distribution channel has been attributed to the lack of customer trust in this electronic channel and web merchants (Stewart, 1999) as media of banking.

Customer trust can be related to customer loyalty and hence increased revenues for a firm such as a bank (Reichheld, 1993), High customer trust, low customer turnover and decreased costs can generate new business for a firm via word-of-mouth recommendations (Schlesinger and Heskett, 1991). Studies on factors that determine customer trust and loyalty in Internet banking are becoming extremely important.

2.1.1 Internet Banking in South Africa

According to World Wide Worx (2004), South Africa is one of the richest and economically important countries in Africa. Despite the country's sound economic framework, the apartheid legacy has prohibited South Africa from achieving its full economic potential.

South Africa's four main domestic banks offer Internet banking services. These are Standard bank, First National bank, ABSA bank and Nedbank. According to SA.Internet.com (2001), ABSA had predicted an Internet population of 3.2 million by the end of 2002. On the contrary, online banking only reached the one million mark in South Africa at the end of 2003. This implies ABSA's prediction went off the mark. World Wide Worx (2004)'s report, "Online banking in South Africa", the number of online bank accounts in South Africa grew by 28% in 2003.

However, about half of the country's Internet users have signed up for Internet banking (Webchek, 2002). This has encouraged banks to launch many new online banking offerings. Despite all these positive trends, few questions however remain unanswered. Two of such important questions are:

- Is there a great opportunity for growth amongst semi- rural Internet banking users in South Africa?
- What are the reasons contributing to the slow uptake of Internet banking services in South Africa?

This research paper covers an area that has long been neglected by many researchers in this field. It looks at a section of the society which falls between the urban elite and the seriously disadvantaged rural population, the semi rural society. This section of society has a great potential in adding value to businesses and must be considered as the next generation market niche especially in the banking sector. By its nature, the banking industry has traditionally focused on the urban elite as their revenue base. Market saturation is now forcing many banks to formulate new business strategies that are powered with new information systems strategies such as Internet banking strategies. These strategies can easily be realizable due to the fact that technology costs are ever going down and customers are ever looking for pervasive services.

2.2 Issues facing Internet Banking Customers

Internationally, banking is an information sensitive industry (Hoppe, 2001). There are a number of issues hampering the acceptance of Internet-based banking. These include customer satisfaction with existing service channels, security concerns, and a perceived lack of utility in the Internet channel. For newcomers to the Internet, issues such as security and privacy concerns are still the greatest barriers to entry.

2.3 Trust in Internet Banking

Trust is defined as "a willingness to rely on an exchange partner in whom one has confidence" (Mukherjee et al., 2003). Customer trust is depended upon Internet banking reliability and integrity. Trust plays a vertical role in building long-term exchanges between banks and customers. There exist many factors that contribute to Internet banking acceptance by users. Different models are used to study technology acceptance in organizations and society at large. The next section discusses some of these models.

3. FRAMEWORKS FOR EVALUATING IT ACCEPTANCE IN SOCIETY

Business-to-customer (B2C) commerce in the financial industry depends on the consumers accepting and recognizing online banks the same way they have accepted brick and mortar banks (Mattila, 2001). One of the objectives of this research is to investigate consumer adoption and usage of Internet banking. The research will help South African banks to understand the attitude of customers towards Internet banking. In order for banks to find out the attitudes of their customers towards Internet banking, indirect indicators such as verbal expression or overt behavior should be used to measure hypothetical constructs that show variables that are not directly observable.

3.1 Technology Acceptance Model

Technology Acceptance Model (TAM) proposed by Davis (1989) is derived from the Theory of Reasoned Action (Cho & Cheung, 2003). The goal of TAM is to provide a description of the determinants of technology acceptance that are competent of explaining user behavior across a broad variety of end-user technologies and user populations (Kamel & Hassan, 2003). TAM achieves this goal by recognizing a small number of basic variables suggested by other researchers dealing in the cognitive and sentimental determinants of computer acceptance (Chan, 2001).

TAM assumes that perceived usefulness (PU) and perceived ease of use (PEOU) are the primary significance for computer acceptance behavior. This model hypothesize that actual usage is determined by users' behavioral intension to use, which is influenced by their attitude and belief of perceived usefulness (Cho & Cheung, 2003). Users attitude towards Internet banking is determined jointly by perceived usefulness and perceived ease of use.

- **Perceived Usefulness (PU)** is whereby a potential user believes that his job performance would improve when using a particular system (i.e. Internet banking). How will Internet banking improve the way users do their financial transactions?
- **Perceived Ease of Use (PEOU)** is whereby a potential user believes that using a particular system (i.e. Internet banking) would be hassle free. Issues such as system's user interface design come to the fore.
- **External variables** of the system, such as documentation, and training are also considered here.

3.2 Development of Hypotheses

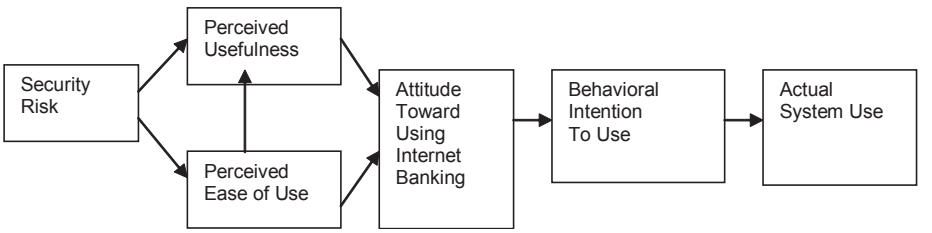
Hypotheses were developed based on the Technology Acceptance Model. According to Cho & Cheung (2003), perceived ease of use is a better predictor of attitude while perceived usefulness is a better predictor of intention of inexperienced users. The research considered the role of Internet banking security as an external variable affecting consumer adoption on Internet banking.

3.2.1 Internet Banking Adoption Model

Figure 1 shows the TAM based Internet banking adoption model. Perceived ease of use (PEOU), perceived usefulness (PU), attitude, intention, and the actual use are directly extracted from the technology acceptance model (TAM).

- **PEOU**: In this research, PEOU means the ease of login to the bank site and perform transactions. PEOU is positively related to attitude towards Internet banking security.
- **Attitude**: The research defines attitude as a person's positive or negative feeling about Internet banking. In TAM, attitude is directly related to intension. Internet banking security risk, PEOU, PU all influence attitude and they in turn affect the intention to use.
- **PU**: Perceived usefulness can be measured using security as a parameter. The perceived usefulness influences attitude towards using Internet banking. If Internet banking security is reliable and there exist Internet banking perceived usefulness, then people will have positive attitude towards using Internet banking.

Figure 1. TAM-based Internet banking adoption model



- **Security risk**: The effect of security risk on the adoption and continual usage of Internet banking was considered as an external variable. Security risk is the uncertainty users have on the fidelity of Internet transactions. This category includes issues pertaining to hackers, crackers, passwords, and the type of security protocols. Security risk may have negative impact on the PEOU and PU. If security risk on Internet banking web sites is reduced, users will be more willing to adopt and use the facility. The less the security risk, the higher PEOU, and PU.

3.2.2 Hypotheses Proposals

The following six hypotheses were proposed:

- H1: Peoples' attitude towards Internet banking is directly related to Perceived ease of use (PEOU)
- H2: Perceived ease of use (PEOU) is directly related to perceived usefulness (PU) of Internet banking
- H3: Perceived usefulness is positively related to users' attitude to use Internet banking
- H4: Users' intention to use is dependent on users' attitude towards Internet banking
- H5: Security risk is negatively related to Perceived ease of use of Internet banking
- H6: Security risk is negatively related to Perceived Usefulness of Internet banking.

4. RESEARCH APPROACH

This is a quantitative type of research. Quantitative research is based on the assumption that natural phenomena can be quantified in numeric terms. The development of metrics (numbers) that can be used to describe phenomena (objects and relationships) under study are the focus of this type of research (Cornford and Smithson, 1996). Because numbers (quantities) are the principal instruments to make a decision, this research becomes also a positivistic type of research.

Positivism is used to describe a philosophical position that can be discerned in research and can also involve crude and superficial data collection (Bryman, 2004). This type of research treats the subject of research as something capable of developing general theories of universal applicability (Cornford and Smithson, 1996). In some cases the theories need to be proposed and tested. The research will focus on a case of Mafikeng region. This case study exhibits particular characteristics that are not common to most of South African regions. It is a sample of participants from a semi rural background. The results that are found here may need to be supported with research from other representative areas of South Africa to make them more conclusive.

4.1 Research Design

A survey was conducted in the region of Mafikeng. The data gathering was done using a questionnaire. All the questions were of closed type. The intention was to collect information on people's perception of Internet banking and Internet banking security. The questionnaire had three parts. Part I dealt with Internet access issues and use of Internet banking. Part II questions looked at respondent's perception towards Internet banking. On a five point Rieckert scale, respondents were asked to indicate what they think about different aspects of Internet banking and security. Part III of the questionnaire included questions that gathered the demographic characteristics of the participants. Issues like age, gender and employment status were asked. Data collection took place between November and December 2005. Hundred questionnaires were distributed, fifty four (54) were completed and returned, and forty six (46) were not returned. All the data collected was analyzed using SPSS 13.1 version for windows.

5. RESULTS AND ANALYSIS

Comparisons were made between people who are using and not using Internet banking. Occupation, gender, access to Internet and Internet banking knowledge were considered. Table 2 shows the profile of the respondents. Of the returned 54 questionnaires, nineteen(19) were users of Internet banking, thirty three (33) were not using Internet banking and there were two missing data. Of these 54, twenty six (26) were males and twenty eight (28) were females.

Table 3 shows the distribution of respondents according to places they access the Internet.

The purpose of this question was to know which place is most used for Internet access. Of 54 observations, 9.3% access Internet from school, 70.4% access Internet from the work place, only 1.9% access it from home and 18.5% were missing data. This shows that from the sample chosen, very few people can pay Internet access at home.

Table 4 shows statistics of people who know about Internet banking. The purpose of this question was to give the researcher a guide of whether people have knowledge about Internet banking.

About 81.5% (44) of participants have knowledge of Internet banking and 16.7% (9) have never heard about Internet banking before. We have 1.9% (1) missing data. Table 5 shows results of people who are using Internet banking. These results will be used to judge Perceived Ease of Use and Perceived Usefulness of Internet banking.

Table 2. Respondent's profiles

Gender	Male	48.1%
	Female	51.9%
Occupation	Employed	81.5%
	Unemployed	18.5%
Age	17-21	7.4%
	22-30	29.6%
	31-40	24.1%
	41-50	25.9%
	51-60	11.1%
	61 and above	1.9%
Experience in using Internet banking	Yes	35.2%
	No	61.1%
	Missing data	3.7%

Table 3. Place of Internet access

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	School	5	9.3	11.4	11.4
	Work	38	70.4	86.4	97.7
	Home	1	1.9	2.3	100.0
	Total	44	81.5	100.0	
Missing	System	10	18.5		
Total		54	100.0		

Table 4. Knowledge of Internet banking

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Yes	44	81.5	83.0	83.0
	No	9	16.7	17.0	100.0
	Total	53	98.1	100.0	
Missing	System	1	1.9		
Total		54	100.0		

Table 5. Internet banking users

Do you have experience using Internet Banking?

					Cumulative
Valid	Yes	19	35.2	36.5	36.5
	No	33	61.1	63.5	100.0
	Total	52	96.3	100.0	
Missing	System	2	3.7		
Total		54	100.0		

Table 6. Security perception

Advances in Internet security technology provide for safer Internet Banking.

					Cumulative
Valid	Disagree	2	10.5	11.1	11.1
	Neither	9	47.4	50.0	61.1
	Agree	6	31.6	33.3	94.4
	Strongly Agree	1	5.3	5.6	100.0
	Total	18	94.7	100.0	
Missing	System	1	5.3		
Total		19	100.0		

About 35.2% (19) of respondents have experience using Internet banking. This implies that out of 54, 61.1% (33) have no experience of Internet banking. There were two (2) missing data. Table 6 shows the Internet banking user's perception of Internet banking security. The Internet banking users are the ones who can give the Perceived Ease of Use and Perceived Usefulness from their experience in using Internet banking. Perceived Ease of Use is a better predictor of attitude and Perceived Usefulness is a better predictor of intention of inexperienced users (Cho & Cheung, 2003).

The respondents gave their answers using a five point Rieckert scale. As discussed in section 4.1, the range was from disagree (scale 1) up to strongly agree (scale 5).

The responses answered the research questions. The questions test our proposed model, where security was used as an external variable. The research questions concerns the most important elements of Perceived Usefulness (PU) and Perceived ease of Use (PEOU) in Internet banking. When respondents asked to provide their perception about security in Internet banking, Perceived Usefulness was considered the most important element of the PU construct.

Respondents were asked to indicate whether they think advances in Internet security technology provide for safer Internet banking. About 10.5% of the 19 who use the service disagree that advances in Internet security technology provide for safer Internet banking, 47.4% observations did not give their perceptions, 31.6% observations agree that advances in Internet security technology provide for safer Internet banking while only 5.3% observations strongly agree. We had 5.3% (1) missing data.

Table 7 indicates the distribution of responses with respect to the user friendliness of Internet banking. This question also was used in our proposed model, where

Table 7. User friendliness of Internet banking

Internet Banking is easy-to-use.

					Cumulative
Valid	Neither	2	10.5	10.5	10.5
	Agree	11	57.9	57.9	68.4
	Strongly Agree	6	31.6	31.6	100.0
	Total	19	100.0	100.0	

Table 8. Advice other to use Internet banking

I will not advice others about to use Internet Banking.

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Disagree	3	15.8	15.8	15.8
	Disagree	4	21.1	21.1	36.8
	Neither	4	21.1	21.1	57.9
	Agree	7	36.8	36.8	94.7
	Strongly Agree	1	5.3	5.3	100.0
	Total	19	100.0	100.0	

security is also an external variable in Technology Acceptance Model (TAM). This research question also concerns an important element of Perceived Usefulness (PU) and Perceived ease of Use (PEOU) in Internet banking. In respondents' perception about ease of Internet banking, Perceived Ease of Use was considered the most important element of the PEOU construct.

About 10.5% (2) observations of 19 strongly disagree that Internet banking is easy-to-use, and 57.9% (11) agree that Internet banking is easy-to-use while 31.6% (6) observations strongly agree.

The focus of the question above was on the direct and indirect effects of PEOU and PU on the intention to choose Internet banking. Attitude construct has a larger direct effect on intention than PEOU and PU. The answer to the question above is that attitude mainly influences intention and behavior directly, but also indirectly through PEOU and PU.

About 15.8% (3) observations of 19 strongly disagree that they will not advice other to use Internet banking, 21.1% (4) observations disagree, 21.1% (4) did not provide their feeling, 36.8 %(7) observations agree that they will not advice others to use Internet banking, 5.3% (1) observations strongly agree.

5.1 Hypotheses Results

Using the analyses made on section 5, Table2 through to Table 7, the following deductions can be made about the proposed hypotheses.

H1: Perceived ease of Use (PEOU) is directly related to peoples' attitude towards Internet banking security.

The results of this hypothesis show that the majority of responses confirmed that attitude towards Internet banking adoption is directly related to Perceived Ease of Use and Perceived Usefulness. Attitude is also indirectly affected by security risks in Internet banking.

H2: Perceived ease of use (PEOU) is directly related to perceived usefulness (PU) of Internet banking.

Perceived ease of Use is directly related to Perceived Usefulness. This hypothesis was tested by the question "is Internet banking ease to use?". This hypothesis has been proven true as the responses where positive about the ease of Internet banking.

H3: Perceived usefulness is positively related to users' attitude to use Internet banking.

The result of the above hypothesis is true because the responses show that if the Perceived Usefulness is positive the user's attitude will also be positive.

H4: Users' attitude has a positive relation to the users' intention towards the adoption of Internet banking.

The result of the above hypothesis is also true because if the response of attitude towards Internet banking is positive, the intention to use will also be positive.

H5: Security risk is negatively related to Perceived Ease of Use of Internet banking

The hypothesis above explains that if the security risk is high in Internet banking, the possibility that user's see it to be Perceived Ease of Use is negative.

H6: Security risk is negatively related to Perceived Usefulness of Internet banking

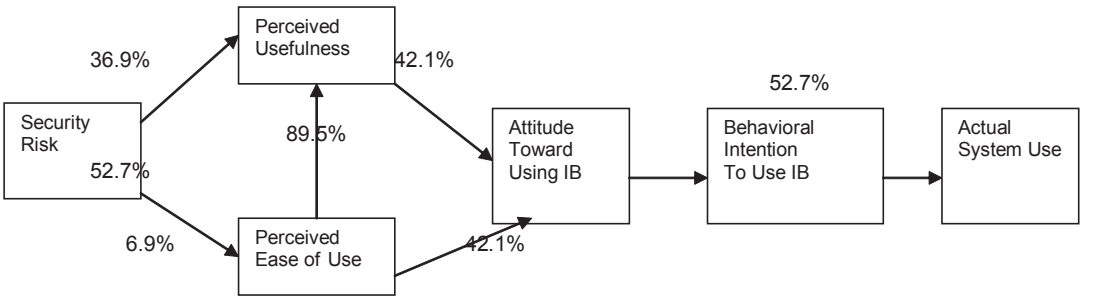
The hypothesis has been proved that it is true that security risk is negatively related to Perceived Usefulness.

Figure 2 shows the percentage distributions of the results obtained that justify the six hypotheses that were developed above.

6. DISCUSSIONS AND CONCLUSIONS

TAM as an appraisal technique for technology acceptance in communities can be applied effectively if other variables are kept constant. By focusing on the security parameter in Internet banking(IB), and ignoring other factors, the research has

Figure 2. Results for TAM-based Internet banking model



managed to show that Internet banking acceptance is directly related to both PU and PEOU but inversely related to the security issue. In other words, security as portrayed herein, is a major factor that reduces the uptake and continual use of Internet banking in Mafikeng.

The study has however shown that apart from security, in semi rural areas like Mafikeng, the following factors play a very important role in the acceptance and usage of Internet banking.

- Economic status of the society. Mafikeng is generally a poor society and prospective Internet banking users have no access to the Internet. Many of those using Internet access it from work places as indicated in Table 2.
- The people have no knowledge of the security systems in place in Internet banking. This has been indicated in the research by the fact that many respondents did not answer the security question, opting to abstain, Table 6.
- Implicitly, costs such as telkom costs, bandwidth and speed may also affect the uptake of a technology such as Internet banking. The research bases this argument on the fact that, if at all, a user has to use an Internet café to access the facility; the costs can be prohibitively very high. All these are a combination of Internet speed, bandwidth and telkom costs.
- The literacy level of a society play a major role in this type of research. Usually technologies such as Internet are associated with the educated, learned elite of the society. This factor was not properly followed in this research but considering that Mafikeng is a semi rural area, many people did not know what to answer on the questionnaire because they are semi literate. Table 2 statistics supports this fact.

The biggest limitation of the research is the fact that the number of respondents was very small. In studies like this, the sample could have been increased to about a thousand (1000) participants. This was not possible because of the financial and time constraints. Also, since this is a case study, the results may not be accepted at face value to be a general representation of all South African semi rural areas. The research intends to spread the investigation throughout South African towns so as to reach a general conclusion.

Building Ensembles Using Decision Tree Metrics Based Meta-Trees

Peter Kokol, University of Maribor, Slovenia; E-mail: kokol@uni-mb.si
Gregor Stiglic, University of Maribor, Slovenia; E-mail: gregor.stiglic@uni-mb.si

ABSTRACT

Ensembles of classifiers have become one of the most popular techniques in machine learning research. The problem of selecting the most appropriate classifier for classification that is known from machine learning is also an important issue in the ensemble building methods. This paper tries to find a method that would select the best performing ensemble building method based on dataset characteristics instead of the most appropriate classifier. The proposed approach captures the characterization of the dataset from the metrics of the tree induced from the dataset. On 15 benchmark datasets, the proposed meta-tree based method discovered some strong and simple rules that could be used in future research in the field of basic ensemble building method selection.

1. INTRODUCTION

Combining multiple classifiers in ensembles is one of the standard and most important techniques for improving classification accuracy in machine learning. This paper compares performance of four different ensemble methods – Bagging [1], Boosting [2], Random Subspacing [3] and Random Forests [4]. There are numerous methods of combining different classifiers into ensembles, but there is no universal method of how to achieve the best accuracy on all datasets using only one ensemble creation method. The results of four above mentioned ensemble building methods are used to build meta-tree which would be capable of selecting the most appropriate ensemble building method based on the characteristics of the given machine learning problem. A variety of data characterization techniques have been developed, however their quality still needs to be improved. In our approach the idea of capturing the characterization from the metrics of the tree induced from the dataset is used [5].

The paper begins with the description of the ensemble building techniques in chapter 2 which is followed by chapter 3 on meta-tree building details. Next section describes our experiments and results of meta-tree learning. Conclusions and proposal of future work are discussed in the final chapter.

2. ENSEMBLE CREATION TECHNIQUES

To create an ensemble of classifiers two components are needed: a set of diversely trained classifiers and a mechanism that composes the single predictions into an overall outcome. This paper compares four most popular methods of combining the classifiers into ensembles which are described in more detail below.

2.1. Bagging

To compose ensemble from base classifiers using bagging, each classifier is trained on a set of n training examples, drawn randomly with replacement from the original training set of size m. Such subset of examples is also called a bootstrap replicate of the original set. Each such subset contains, on average, 63.2% of the original training set [6]. A set of classifiers is then used to classify the example using the majority vote of the ensemble.

The vital element of the bagging technique is the instability of the classifiers. If perturbations in the learning set can cause significant difference in the classifier construction, than bagging can improve accuracy of ensemble.

2.2. Boosting

Boosting is represented by the AdaBoost.M1 algorithm described in [2], which is the most commonly used algorithm for boosting ensembles. To use boosting it is assumed that the base classifier can handle weighted examples. In case where this is not possible we use sampling of the training set examples according to a weight distribution.

In AdaBoost algorithm classifiers are trained sequentially. Each classifier is trained on the dataset based on the misclassification of the previously generated classifier. Weights of the examples are updated according to the classification accuracy of the previous classifier by lowering weights of correctly classified examples and increasing weights of misclassified examples. After the training process is finished the predictions are made using weighted vote of the individual classifiers.

Boosting was tested by many researchers who proved that it can be declared as one of the best ensemble methods [7, 8, 9]. It was also applied to decision trees based ensembles and it can be considered as one of the best classification methods [10].

As each other classification method boosting also contains some drawbacks. One of the most important is overfitting although early literature mentions that boosting would not overfit even when running for a large number of iterations [11]. Recent research clearly shows overfitting effects when boosting is used on datasets with higher noise content [7, 12].

2.3. Random Subspacing

The ensemble method also called Random Subspacing was proposed by Ho in [3] and is based on multiple decision trees constructed systematically by pseudo-randomly chosen features from the training dataset. Each tree is constructed using randomly chosen features which cause higher diversity of ensemble members. Therefore Random Subspacing method can achieve nearly monotonic increase in generalization accuracy while preserving high accuracy on training data, provided that the features are sufficient to distinguish all samples belonging to different classes, or that there is no intrinsic ambiguity in the datasets [13].

2.4. Random Forests

Breiman upgraded the idea of bagging by combining it with the random feature selection for decision trees. This way he created Random Forests, where each member of the ensemble is trained on a bootstrap replicate as in bagging. Decision trees are than grown by selecting the feature to split on at each node from randomly selected number of nodes. Number of chosen features is set to $log_2(k+1)$ as in [4], where k is the total number of features.

Random Forests are the ensemble method that works well even with noisy content in the training dataset and are considered as one of the most competitive methods that can be compared to boosting [14].

3. BUILDING META-TREES

There was a lot of research done in the field of meta-learning methods based on data characterization in the domain of machine learning [5, 15, 16]. Meta-learning is based on set of meta-attributes that usually characterizes the dataset, and search for the optimal correlation between these attributes and the performance of learning algorithms. This paper focuses on research of the correlation between basic decision tree metrics as meta-attributes and performance of different ensemble building methods as learning algorithms.

To build meta-trees one should follow the three basic steps:

- describe the characterization of the dataset by definition of meta-attributes

- learn meta-tree using as much as possible different datasets to estimate the value of meta-attributes and measure the accuracy of different ensemble building techniques
- evaluate the results of built meta-tree

Many techniques extracting the characterization of dataset have been developed, such as data characterisation techniques (DCT) [17] including simple measures (e.g. number of attributes, classes et al.), statistical measures, and information theory-based measures. Inspired by work of Bensusan et al. [16] and Peng et al. [5] we use simple decision tree metrics to define meta-attributes, but two different decision tree algorithms are used – C4.5 [18] and Logistic Model Trees (LMT) [19].

Eight metrics were defined that consist of C4.5 pruned and unpruned number of leaves and number of nodes, LMT number of leaves and nodes and C4.5 leaves and node pruning ratio. Pruning ratio is computed as number of leaves divided by number of nodes in pruned tree by the same value in unpruned tree. Another two attributes that represent number of instances and features were added.

4. EXPERIMENTAL RESULTS

This section describes the experiments that were performed to build and evaluate meta-learning decision tree for ensemble method selection. Most of the experiments were done using WEKA toolkit for machine learning [20]. To train the meta-tree 10 UCI [21] datasets were selected and tested the built tree on 5 UCI datasets which are presented in Table 1.

Instance and feature sampling when learning the meta-tree were used to make learning datasets more diverse. This way each dataset consisted of 100 to 200 sampled instances and $n/2$ to n features for each experiment, where n represents the number of features of the original dataset. Ensemble building methods were run five times with five different settings of forest dimension for 20 times on 10 training set datasets. This way 1000 different datasets were used in the phase of learning the meta-tree.

A part of our experiment was also a classic comparison of four different ensemble methods using different number of decision trees. To observe the accuracy at different number of trees in ensembles five groups of experiments were selected. The first and smallest set of ensembles consisted of 6 trees and each next set consisted of the number in previous experiment multiplied by 2. Following this formula the size of ensembles equals $6 \cdot 2^i$, where $i=[1..5]$. The average accuracy of 10-fold cross-validation on 10 training datasets using different number of decision trees in ensembles is shown in Figure 1.

Table 1. List of datasets and their details

Training Set				
Dataset	Attributes	Continuous	Instances	Classes
cmc	9	2	1473	3
tic-tac-toe	9	0	958	2
segment	19	19	1500	7
balance-scale	4	4	625	3
ecoli	7	7	336	8
vowel	14	10	990	11
vehicle	18	18	846	4
dermatology	34	1	366	6
heart-statlog	13	13	270	2
liver	7	7	345	2
Test Set				
diabetes	8	8	768	2
glass	9	9	214	7
wine	13	13	178	3
hepatitis	19	6	155	2
sonar	60	60	208	2

It can be seen in Fig.1 that Bagging gains less on accuracy comparing to other methods when the number of classifiers increases. While on the other hand Random Forest method still increases significantly from when increasing the number of trees from 24 to 48. The later can be explained with the fact that Random Forest method produces the most diverse sets of classifiers as it is using Bagging and even some kind of Random subspacing when generating classifiers. At around 100 classifiers the accuracy of all methods becomes stable so the ensemble with 96 trees is used in most of experiments.

In the next experiment the first meta-learning tree was built using all 1000 runs of ensemble building on different datasets. Fig. 2 represents the number of wins for each method and number of experiments where two or more methods achieved the best results. Due to 10-fold cross-validation only 33 experiments ended with a tie of two or more methods that produced the same best accuracy. Those 33 experiments were excluded from the meta-learning training set which consisted of 967 examples, each containing 8 decision tree metrics and 2 statistical measures (number of instances and features). After this step the first C45 based meta-learning tree was built using all four ensemble building methods as decisions. The accuracy of this tree was 74.77%.

From Fig. 2 it can be observed that Boosting won in the majority of cases. These results can also be the consequence of the fact that Random Forest, Bagging and Random Subspacing methods share a lot of characteristics in the way they build ensembles of classifiers. Therefore an additional experiment was performed where Boosting method was compared to Non-Boosting methods (Random Forest was used as a representative of this group). The accuracy on training set was 84.4%.

Next experiment compares small (6 trees) and large (96 trees) ensembles and shows how ensemble methods are performing when the number of classifiers increases (Fig. 3).

Figure 1. Average accuracy for different ensemble methods using different number of decision trees

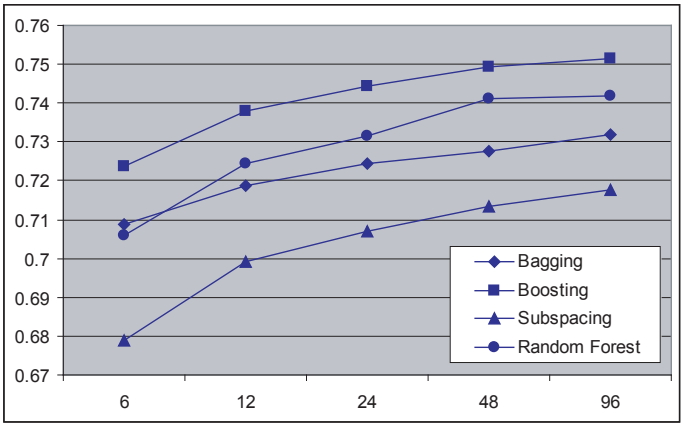

Figure 2. Number of wins and tied situations of four ensemble building techniques

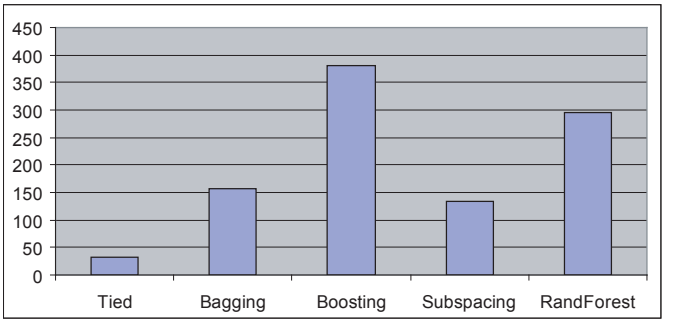

Figure 3. Comparison of four ensemble methods on small and large ensembles

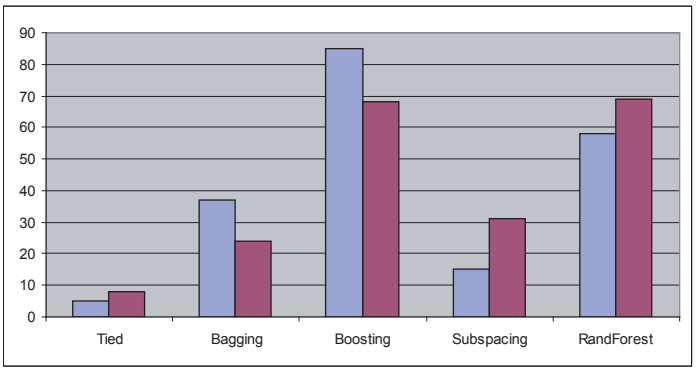

It can be seen that Boosting is not dominant anymore when large number of classifiers is used. It is also interesting to observe a drop in accuracy of Bagging performance and an increase of accuracy at Random Subspacing method. This could again be due to the fact that Random Forest shares a lot of characteristics with Bagging and Random Subspacing. Therefore another observation was done where "Bagging – Random Subspacing" and "Boosting - Random Forest" comparison is done independently (Fig. 4).

Figure 4. Direct comparison of ensemble building methods (large ensembles)

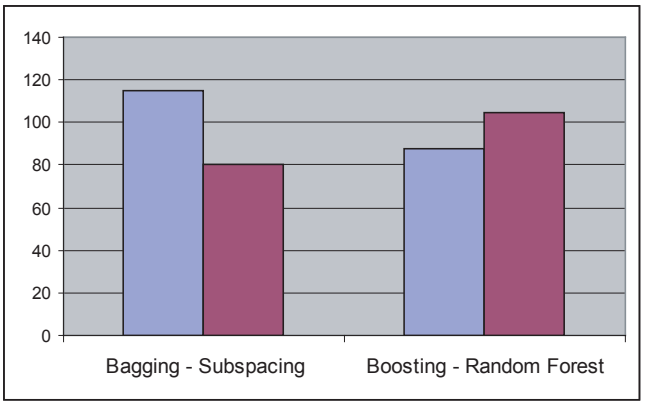

Figure 5. Simplified meta-learning tree (1-Boosting, 4-NonBoosting)

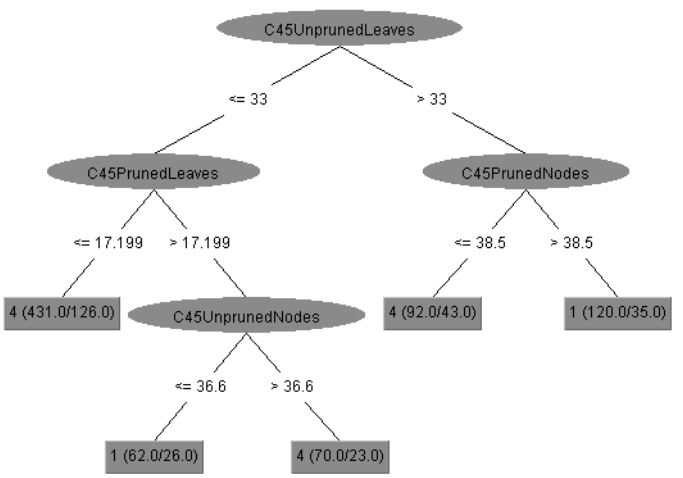

Fig. 4 shows that Random Forests in direct comparison even more evidently outperform Boosting in large ensembles. On the other hand Bagging outperformed Random Subspacing, but this comparison depends on the number of instances and the dimensionality of selected datasets very much. On average our training datasets had 14.2 features which could be to few for the Boosting method to perform better.

To simplify the observation of the large generated C45 meta-tree the number of instances per leaf is set to 60 and generated fairly simple meta-tree with the accuracy of 68%. The simplified tree (Fig. 5) shows two strong rules that characterize the main difference between boosting and non-boosting methods. Left and right most branch of the tree, which include more then 70% of training samples, can be transformed to the following rules:

- IF C45UnprunedLeaves <= 33 AND C45PrunedLeaves <= 17.2 THEN UseNonBoosting
- IF C45UnprunedLeaves > 33 AND C45PrunedNodes > 38.5 THEN UseBoosting

The above rules show that trees with lower complexity dictate use of non-boosting methods while trees with the higher measured complexity suggest using the boosting method of ensemble building.

Based on the observations from Fig. 5 it can be said that C45 metrics contribute the most useful information for the ensemble building method selection.

5. DISCUSSION AND FUTURE WORK

This paper presents the meta-tree approach to selection of the most appropriate ensemble building method for different datasets in machine learning domain. The accuracy of four most popular methods was measured for combination of classifiers into ensembles and were used for building C45 meta-tree based on C45 and LMT based decision tree metrics. This method of selecting the ensemble building technique enables assessment of the dataset complexity through decision tree metrics.

Our experiments show that some very simple rules can be extracted from the generated meta-trees which can help us understand which meta-features are the most important in the selection of ensemble building method problem. From the obtained results it is also obvious that there is no assurance that a single best ensemble building method can be found for all datasets.

There are still several open issues that have not been discussed in this paper. In particular more metrics could be included, especially the metrics of complexity in meta-datasets. In the future we will incorporate some ideas of fractal dimensions that can be used for the measurement of complexity and try to find some common points with the already used metrics. Another important aspect of the research would be the comparison of our proposed method with the similar methods that are in principle used for single classifier selection.

ABSTRACT

There are many situations in service provisioning scenarios that lead to conflicts and impasses. Very often consumers and providers do not share the same perspective about quality of service. These divergences become more pronounced when the involved parties use different vocabularies to show their interests. It has become commonplace since service providers use different ontologies to describe the offered services. In this paper we discuss the inclusion of a middle layer in the Service-Oriented Architecture (SOA), composed by mediators, in order to make closer the involved sides towards a service negotiation. Considering that mediation is a complex task which crosscuts all the service-related tasks (e.g. discovery and composition), it is proposed a formal approach to describe behavioral aspects of the mediator unambiguously.

Keywords: Mediators, Semantic Web Services, Service Discovery, Service Composition, Formal Methods.

1. INTRODUCTION

Service-oriented applications are potentially source of conflict, since there are two opposite parties: the *service requester* and the *service provider*. Divergences around the maximization of satisfaction with minimal cost (by the *service requester*), against the minimization of resource usage (by the *service provider*) may create impasses that require some external help. Mediators usually play that role bringing together these parties towards an agreement that explicitly considers individual needs but possibly admit reconsiderations. The development of such complex applications commonly requires the adoption of some structured guidelines to be observed.

The Service-Oriented Architecture (SOA) and Web Services technologies (Booth, 2004) have been largely used by developers of Web applications, which functionality is divided into self-contained units, the *services*. This architecture is made up by three entities. Besides the client and the provider, the *registry* is a fundamental part of this architecture. The basic dynamic tasks of SOA entities include: (i) the publication of the service inside the registry by the provider; (ii) the subsequent search for a specific services by the client; and (iii) the consequent execution of a web service and its corresponding result handling during the invocation phase. Eventually, a composition of services can occur when there is not a single service that can fully satisfy the client needs. An opposite situation can also occur, when many services fulfill the client requirements. In this case, it is critical to decide what service actually is the best, considering the client's viewpoint.

Situations like service composition and selection naturally encompass negotiation, although SOA does not explicitly treat this aspect. Indeed, mediators are generally treated as operational elements implemented by the applications (Wiederhold, 2004). However, considering the importance of mediation activity in a service scenario, it is reasonable to put mediators in the first-level of service-oriented architectures. It is precisely what this paper deals with.

Besides specific techniques for reconciliation, the mediator needs information in order to be efficient. It includes information about client and provider requirements, as well as information about the service itself. Although the use of mediators is not new (Wiederhold, 1992), (Wiederhold & Genesereth, 1997), (Mocan et. al, 2005), there is a gap to be fulfilled in the formalization of the mediator's behavior and the precise description of information treated by the mediator. The described proposal presents an architecture that extends SOA by the inclusion of the mediator as the fourth entity at the first-level. An important characteristic of the proposed architecture is the use of ontologies (Gómez-Perez et. al, 2005) that serve as a basis for meaningful information and context-aware activities related to the mediator.

This paper is organized as follows: Section 2 briefly surveys the state of the art in mediators and semantic web services technologies, mainly ontology and its use by mediators. Section 3 depicts the elements of the proposed architecture. Sections 4 and 5 present the translation of the proposed model into a formal specification, relating its static and dynamic aspects, respectively. Finally, Section 6 presents some conclusions and an outlook on our future work.

2. MEDIATORS AND SEMANTIC WEB SERVICES

In the Semantic Web, the information is given with a well-defined meaning through ontologies, which represent formal and explicit specification of a shared conceptualization of some knowledge domain (Berners-Lee, 2001). However, it is unrealistic to expect a global consensus between people and organizations onto a common, shared ontology.

Semantic heterogeneity represents a typical case in which mediation can be applied. In order to reconcile ontologies, it is necessary to analyze the mismatches between them (Sheth et. al, 2003). Mismatches might be present at a conceptual level, as well as at the terminological, taxonomical or purely syntactic levels (Hameed et. al, 2003). Different applications have different ontologies, different semantics, and different knowledge and data stores (Laskey et al., 2006). It is necessary to detect and resolve such discrepancies among them. Correspondences may have to be established among the source ontologies, and overlapping concepts need to be identified.

In the context of SOA, intelligent and active use of information requires a class of software modules that mediate between the service requester and service provider. Mediation simplifies, abstracts, reduces, merges and explains data (Wiederhold, 2004). Interoperability problems inevitably emerge from highly heterogeneous Web service descriptions (Paolucci et. al, 2004). For example, Web services functionalities may be described by different ontologies (e.g. WSMO or OWL-S), can use different protocols or they may have been designed with different goals in mind (Paolucci et. al, 2002). Semantic mediators identify implicit similarities, by the use of ontology reconciliation techniques, such as merging, alignment or integration (Hameed et. al, 2003). Therefore, mediators form a distinct middle layer, making the service requester queries independent of the service description semantics from registries. The translations needed in such layer and what form will have the modules supporting this layer are somehow interrelated.

Since there will eventually be a great variety of mediators, service requesters have to be able to choose among them. Alternate metamediators will have to exist that merely provide access to ontologies that describe available mediators and its properties. Since mediation occurs in different contexts and levels, metamediators synthesize intermediary mediations in order to compose a global mediation. Moreover, the use of ontologies to describe knowledge related to mediators themselves can improve the reuse of mediation functions. Applications may compose their subtasks as much as possible by acquiring information from the set of available mediators. Additionally, unavailable information may motivate the creation of new mediators (Wiederhold & Genesereth, 2004).

A lot of work has been done on mediation systems (Mocan et. al, 2005), (Garcia-Molina et. al, 1997), (Yan et al., 1997), (Tomasic et al., 1998). However, a proper conceptual setting for this task is largely missing. Formal methods, based upon elementary mathematics, can be used to create precise, unambiguous architectural descriptions, in which information is structured and presented at an appropriate level of abstraction. Hence, reasoning about a specification and attempting to construct proofs about its properties can help to detect problems at an early stage of system development. The process of constructing proofs leads to a better understanding about the requirements upon a system, and can assist in identifying any hidden assumptions.

3. AN ONTOLOGY-BASED ARCHITECTURE FOR MEDIATION

The conceptual elements of the extended SOA architecture proposal can be observed in Figure 1.

The first-level entities, i.e. *Service Requester*, *Service Provider*, *Mediator* and *Registry* are highlighted. The majority of other concepts are grouped into contexts. In the service requester context, the desired *functional requirements* are represented by the goal concept, while the user's subjective notion of quality is defined by *QoS Preferences* (what "includes" the service), *QoS Constraints* (what "excludes" undesirable services), and *QoS Priorities* (what "distinguishes" similar services). On the other hand, in the service provider context, the *capability* concept represents the provided functionality, while *QoS offered* abstracts a subset of *non-functional requirements* related to the service provisioning. It is important noting that the same service may be offered in different levels of quality, which causes an impact over resource allocation.

In a typical SOA scenario, the service requester accesses the registry in a direct manner, in order to discover potential services that accomplish the desired functionality. In this case, the mediator represents the entity that makes easy this search. This reconciliation process is made on the ontological level. Considering that ontologies are composed basically by related classes and properties, the role of mediator comprises an automatic verification of intersections in the concepts associated with these elements.

Mediators, as considered in this work, adopt a win-win approach to reach some agreement between the involved parties. Thus, in order to remain neutrality, mediators could be placed apart, in a namely semantic web server (Ribeiro et al., 2004), (Ribeiro et al., 2006), avoiding possible tendentious decisions that could possibly beneficiate either clients or providers. Another aspect to be considered is the fact that the whole mediation may be actually a composition of minor mediation processes. Hence, the concept of mediation in the proposed architecture abstracts several intermediary conflict resolutions, in different levels of complexity.

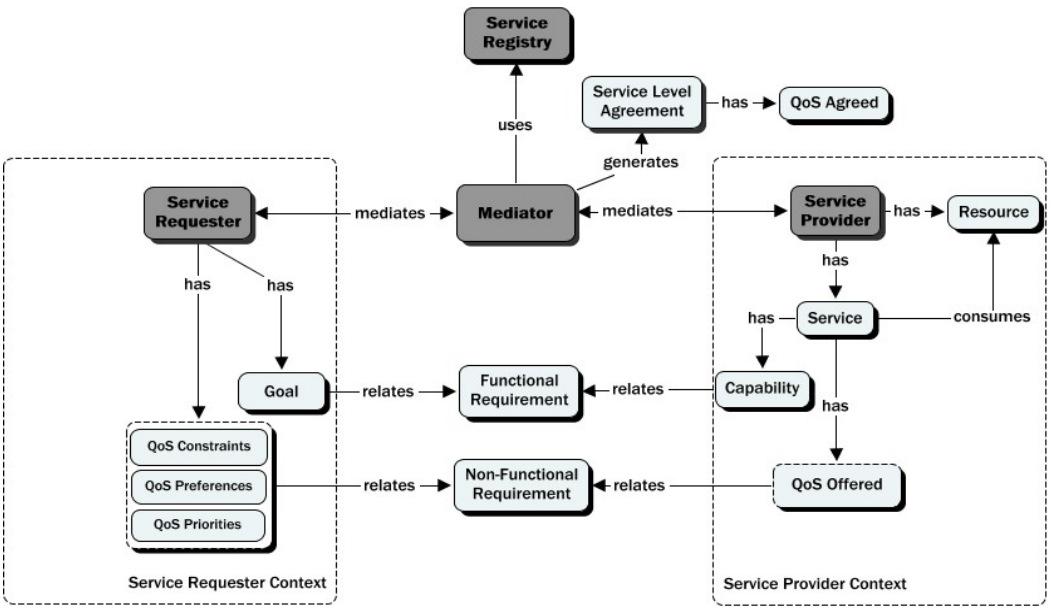
Despite knowing the importance of the role of discussions around implementation issues, this paper focuses on some universal aspects of mediators. For instance, mediators make use well-defined reconciliation laws, valid in some context or jurisdiction, in order to approximate different perspectives and possibly generating a contract that consolidates the conditions related to service provisioning. Hence, any mechanism that makes use of semantics (e.g. semantic web services, intelligent agents or matchmakers) could be used to implement mediators.

4. TRANSLATING THE CONCEPTUAL MODEL INTO A FORMAL SPECIFICATION

The use of formal methods in describing and verifying properties and behavior of systems is not new (Dong et al., 2002), (Dong et al., 2004). The Z notation (Spivey, 2004), for example, is a specification language based on set theory and predicate calculus. Some basic characteristics of Z notation guided its choice as the formalism in this work. The first one is related to its maturity level, recently conveyed into ISO standard (ISO, 2002). The second one refers to the availability of tools to support formal activities, such as type checking, theorem proving and animation of formal specification (Saaltink, 1997).

The fundamentals of Z notation and types are sets defined at the beginning of specification. A *given set* is a powerful abstract element of Z, represented by names inside brackets, from which a formal specification begins. *Enumerated* sets are also permitted in Z notation. In the following, some of the main given sets used to describe the related architectural elements are presented.

Figure 1. The extended service oriented architecture proposal



[Class, Instance, DataType, Parameter, Protocol, Resource, Registry, Preconditions, Postconditions]

Level ::= High | Medium | Low

OperationMode ::= Notification | OneWay | SolicitResponse | RequestResponse

OntologyReconciliationType ::= Alignment | Merging | Integration

ReconciliationResultType ::= ExactMatch | PluginMatch | SubsumesMatch | IntersectionMatch | Impasse

Other key element of Z specification is the *schema*. In analogous way, schema can be considered as class inside object-oriented paradigm. Like a class in OO paradigm, the schema includes a declarative part to encompass variables and a second part dedicated to the manipulation of variables, the predicate.

Schema

Variables

Predicate

Schemas in Z are used to describe both static and dynamic aspects of a system. The static aspects concern the global state of the system and the relationships between its components, namely the invariant. A rigid control over state integrity is accomplished by the invariant during any operation that changes the state. Dynamic aspects include all operations that manipulate the elements of the state (Spivey, 2004).

The *Ontology* type was composed by other types including power sets (P) of *Class*, *DatatypeProperties* (a partial function of *Class* in *DataType*), *ObjectProperties* (a relation between two classes) and *Individuals* (a function of *Class* in *Instance*). The *Mediator* is represented as a schema made up by *Description*, which is typed as an *Ontology* for mediators; a power set of *Techniques* and a *Context*, which represents a relation between two ontologies, i.e. the conceptualizations of involved partners.

Ontologies are built layer on layer. Since the proposed model relies upon them, it is necessary checking and validating its axioms, through the definition of Z semantics for the ontology language. This semantic model serves as a reasoning environment for verification using Z/EVES (Saaltink, 1997), which offers some powerful commands for theorem (e.g. *prove*, *rewrite* or *reduce*). In this section, only the static properties of ontologies are checked (Figure 2), which can be well captured by axiomatic definitions. Dynamic properties (e.g. *discovery* and *composition* phases) are detailed in Section 5. For the sake of space and simplicity, several ontology properties from the proposed axiomatic model were shortened.

5. GENERATING OPERATION SPECIFICATIONS

5.1 Mediation and Service Discovery

In general, service discovery comprises the matchmaking between *goals* (from the service requester context) and service *capabilities* (from the service provider context). The semantics of *goal* element, as well as Web service *capabilities* can be represented by a set of concepts described in a *functional requirement ontology*. The semantic mediator verifies possible similarities on the conceptual level. In order to consider goals and capabilities to match on the semantic level, these elements have to be interrelated somehow. Precisely spoken, we expect that some set-theoretic relationship between them has to exist. The most basic set-theoretic relationships that one might consider are the following:

- Exact match: goal = capability
- Subsumes match: goal c capability
- Plugin match: capability c goal
- Intersection match: goal I capability ë 0
- Non-match: goal I capability = 0

These set-theoretic relationships basically provide the basic means for formalizing an intuitive understanding of a match between goals and Web services in the real world. For this reason, they have been extracted from some extent already in the literature (Paolucci et al., 2002), (Paolucci et. al., 2004). The ideal situation can be represented when an *exact match* between requester desires and provider offerings occurs. Here the semantic mediator identifies that the offered service functionality coincides perfectly with the service requester goals (see Figure 3.a).

Subsumes match (Figure 3.b) occurs when the capabilities that are advertised by the service provider form a superset of relevant objects for the requester as specified in the goals. In other words, the service might be able to fulfill the desired

functionality. However it is possible that the service delivers objects that are irrelevant for the requester. When the service capabilities form a subset of requester goals, as illustrated in Figure 3.c, then a *plugin match* occurs. In other words, the service in general is not able to provide all the desired functionality, but there is a guarantee that no irrelevant objects will be delivered by the service.

There is a case when the set of service capabilities and the set of requester goals have an *intersection match* (Figure 3.d). Thus, the service is not able to deliver all the objects that are relevant for the requester, but at least one such element can be delivered. In this case a composition of services may be an alternative in order to achieve the desired functionality. Figure 3.e illustrates the case when the service capabilities description and requester goals are disjoint. That means there is no semantic link. Therefore, in the context of ontology reconciliation, it is also considered an *impasse* situation.

As mentioned before, semantic mediation is directly associated with ontology reconciliation techniques. This process involves the alignment of the two basic ontology structures: *classes* and *properties*. All the matching cases were formalized by two operation schemas, respectively *Goal2ServiceClassAlignment* (between classes), and *Goal2ServicePropertyAlignment* (between properties). Since these

$$

operations are very similar, only the class alignment is showed in Figure 4. The symbol (Δ) means that this operation changes the global state of the system. The predicate section instantiates some local variables, including ontological structures such as *DatatypeProperties* and *ObjectProperties*. The functional requirements are assigned to distinct ontologies followed by a logical concatenation of reconciliation preconditions.

The schema closes with a state change, by the inclusion of a new local mediator that was created to deal with the service discovery context, according to the *DatatypeProperties* and *ObjectProperties*. Considering these formal statements, the entire discovery phase could be represented by a sequential composition of the two before mentioned operation schemas. The following statement summarizes this aspect.

DiscoveryPhase ; *Goal2ServiceClassAlignment* ; *Goal2ServicePropertyAlignment*

5.2 Mediation and Service Composition

The partial response to the required functionality justifies the use of composite services. Composing Web services requires the description of each service, so that other services can understand its features and learn how to interact with.

A generalized model for Web service description is described with more details in (Medjahed et al., 2003). Figure 5 illustrates that, basically, the service description includes: *domain* information, represented by domain ontologies; a set of *operations,* which include aspects related to the message interchange; *bindings,* that defines message format and protocol details for service invocation; and *capability*, that describes the business functionalities offered by the service operations. Each element in the service purpose refers to the business functionality offered by a specific operation. In order to serve as a basis for workflow models that determine the behavior of composite services, other elements such as *inputs, outputs, preconditions* and *postconditions* are defined. Finally, the provider's notion of quality of service is represented by *QoSOffered* (a function of a set of non-functional requirements in a level of quality).

Service composition can also occur in different levels, from the binding level to the QoS level. A major issue when defining a composite service is whether its component services are *composable* (Medjahed et al., 2003). For example, it would be difficult to invoke an operation if there were no mapping between the parameters requested by this operation (e.g., data types, number of parameters) and those transmitted by the service requester. Hence the service composition is a complex task that involves both syntactic (e.g. binding) and semantic features (QoS Offered).

The proposed formal model aggregates the composition preconditions in two phases: *OperationCompositionPhase* and *ServiceCompositionPhase* (see Figure 5). The first one relates the mediation process in the reconciliation of the syntactic features (e.g. mode and message composability). The second one relates semantic features, in which an instance of a mediator verifies possible intersections in binding and domain aspects of the services, according to the context and reconciliation laws (e.g. *EquivalentClass* and *SameAs* axioms)

The entire *CompositionPhase* is defined by a schema that aggregates a sequential composition between *OperationCompositionPhase* and *ServiceCompositionPhase*.

CompositionPhase ; *OperationCompositionPhase* ; *ServiceCompositionPhase*

6. CONCLUSION AND FUTURE WORK

This paper presents an extended SOA proposal that explicitly includes the mediator as first-level entity. The main purpose of the architecture is to argue and reason about conceptual aspects related to the role of the mediator in service discovery and composition. It was investigated the use of ontological reconciliation techniques which serves as a basis for meaningful mediation. A formal set-based approach to describe the mediator behavior and related concepts was presented.

In particular, we investigate and analyze what kind of statements need to be formally checked and proven about relations between mediation and other service related tasks. These formal statements are called *proof obligations*. At the design stage, a proof can show not only that a design is correct, but also *why* it is correct. The additional insight that this affords can be invaluable: as requirements evolve and the design is modified, the consequences are easier to investigate. At the implementation stage, a proof can help to ensure that a piece of code behaves according to the specification. The practice of proof leads to better specifications.

In terms of future work, we intend to investigate and analyze what kind of statements need to be formally checked and proven in order to relate the mediation activity to the other service related tasks, including service selection, negotiation, agreement and monitoring. More specifically, we intend to extend the proposed formal model towards proof obligations in which QoS information can be used by the mediator to improve the process of reconciliation in the ontological level. These proof obligations, that basically comprise the formulation of theorems and automatic reasoning and simulation of the proposed architectural properties, will

Taking a Back Seat? Integrating Trust in E-Government Service Delivery in South Africa

ABSTRACT

The problem of citizen distrust for government is a growing phenomenon across Africa. The decline in citizen trust has major implications for e-government development in South Africa. Yet trust is considered a key ingredient for building quality e-services and citizen customer loyalty to e-government initiatives. The paper aims to examine trust in e-government service delivery, highlights key considerations in building "trust-based" e-government service delivery model for South Africa and recommends measures to promote a sustainable e-government service delivery. The paper is based on experiences, lessons and observations made from the Cape Gateway Project, a leading e-government initiative in South Africa. The study offers insights into our understanding of citizen trust, and how to investigate it in relation to e-government service delivery in an African context.

1. INTRODUCTION

The development of e-government process in its many guises is attracting increased attention from government, business and civil society in South Africa. Governments, businesses and increasing sections of civil society are now advocating that e-service delivery must be considered as a more viable, quick and efficient method for conducting transactions with the public sector and elected representatives Early efforts in e-government development in South Africa were driven by concerns to close the digital divide through the provision of the necessary back-bone infrastructure/hardware, (i.e. computers, internet, service provider infrastructure etc.), and the human capacity to mediate the new service delivery format (DPSA, 2001). Realizing that the gains made in the modernization of the technology infrastructure were necessary, but not sufficient, citizens have started to demand better quality services from their governments (Taylor, et. al. 2006). Fueling the new thinking globally is the "growing culture of rights," which attributes access to information as a basic human right (Parent, et. al, 2005).

The continent of Africa trails the rest of the world in e-government development with 14 percent of the global population, 2 percent of global internet users, or only 6 million out of more than 800 million people owning personal computers (Gebremichael, and Jackson, 2006). Even as South Africa adopts e-government, (Detolly, 2006) questions are emerging about its potential benefits and degree of sustainability of the e-service delivery revolution (Alexander et. al, 2006) . Additional questions linger around issues of how to promote equitable e-service delivery to citizen customers and generate long-term trust and loyalty to the new service delivery mechanism (Frazer-Moleketi, 2006). It stands to reason that to build the long term loyalty and customer base that is necessary for governments to achieve economies of scale in service provision, users need to trust not only the humans in charge, but the technology infrastructure that drives e-government in Africa.

Unlike in e-business, the question of trust in e-government in South Africa seems to have taken a back seat. Partly to blame is the fact that the "development of trust-based relationships" has been overshadowed by problems of pervasive government corruption across Africa (Sunday Times, 2006; City Press, 2006: Mail and Guardian, 2006). The incapacity or unwillingness to prosecute high crimes tends to betray citizen trust in government. In South Africa, the rising poverty levels and growing HIV and AIDs epidemic (UNAIDS, 2005) are oftentimes perceived as indicators of government inefficiency and failure. It is therefore not surprising that some ordinary citizens in Africa hold the perception that government is synonymous with "corruption," "poor service delivery" "uncaring attitudes" and "culture of empty promises" (Sunday Times, 2006). In contrast, governments in developed nations serve the civil society better, are held to account, and play a pivotal role in the delivery of quality services to citizens. Despite the fact that accountability in government remains somewhat an illusion, and information and communication technology (ICT) infrastructure remains appalling, some African organizations (e.g. African Information Society Initiative (AISI), NEPAD, etc.) are working tirelessly to promote ICT use, good governance credentials and trust.

Eliminating the "trust deficit" in Africa requires governments to "strategically integrate trust" in e-government transformation and e-value creation. Of concern to citizens around the world is the fear that "information security risks" could further erode any semblance of trust in e-service delivery. This paper therefore aims to examine the issue of trust in e-government service delivery, highlight key considerations in building a "trust-based" e-government service delivery model for South Africa, and recommend guidelines to deliver sustainable e-government trust. The study is based on our experiences, lessons and observations from the Cape Gateway Project, a leading e-government initiative in the Western Cape Province in South Africa.

The rest of the paper is organized as follows: the next section provides a brief background on trust and e-government service delivery in South Africa. This is followed by a framework for the development and integration of trust in e-government service delivery in South Africa. The third section reviews the literature on the role of trust in e-government development. In section 4, we conclude with insights on key considerations for integrating trust into e-value creation in e-government service delivery.

1.1 Background: Trust and E-Government Service Delivery in South Africa

In South Africa, the notion of *Ubuntu* and the principles of *Batho Pele* are the most significant attempts to build a "people-centered" culture in government service delivery. The term "*ubuntu*" embraces human values such as compassion, respect, kindness, inclusivity and the ideals of human life. It is a Zulu term that describes the fact that "a person is what he or she is because of other people in society." The *Batho Pele* principles are about customers expressing their rights. The term *Batho Pele* means "people first" and is a Government of South Africa (GSA) program that aims to re-brand service delivery in ways that promote the needs of the individuals in South Africa (DPSA, 2001). Government can show trust in its services when it demonstrates *Ubuntu* and *Batho Pele* in its operations and its relationship with citizens.

Trust can be perceived in the context of the socio-economic/political context facing a newly democratic South Africa. Recent press reports on demonstrations against poor service delivery by municipalities in South Africa indicates both rising levels of frustration, and the decline in trust about government's capability to deliver basic services to the people . Also, the claims by some religious constituencies that South Africa has lost her "moral bearings" are a further indication about growing frustrations with government conduct (Tutu, 2006). The effect of such negative perceptions not only lowers investor confidence, but locally it leads to a severe dissolution of trust between citizens and their government. In some countries,

distrust from citizens has slowed the erection of e-government structures and its deployment (Evans and Yen, 2006).

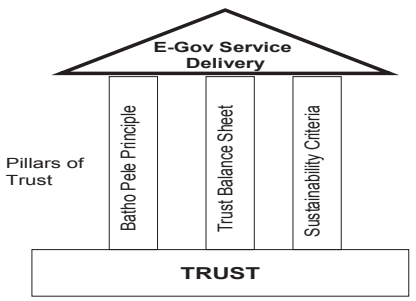
To what extent the adoption of the *Batho Pele* principles and "*Ubuntu*" ideology has succeeded in making service delivery customer focused in South Africa remains unclear. There are obvious signs of citizen disaffection with service delivery despite the on-going public service delivery transformation. This leads us to the argument that trust-based e-government solutions provide an alternative means to improve not only quality of service delivery, but also enlist the e-loyalty that is expected from satisfied citizen customers. If trust continues to take a back-seat, there are fears that the same problems (i.e., lack of trust, digital divide, etc.) that beset e-business could beset e-government (Mullen and Horner, 2004) in South Africa.

The e-government transformation in Western Cape Province is being driven by the Cape Gateway Project (DeTolly, 2006). To operationalize the Provincial Government of the Western Cape's vision, a multi-lingual and multi-channel e-government program was developed by the Center for e-Innovation. Despite its initial success, the moral basis for developing sophisticated e- government services amidst growing poverty is now being questioned (Alexander, et. al., 2006). To avoid the erosion of trust in this project, this issue needs to be addressed.

2. FRAMEWORK FOR THE DEVELOPMENT OF TRUST IN E-GOVERNMENT IN AFRICA

Trust is increasingly perceived as a significant barrier to the development of e-government services globally (Mullen and Horner, 2004; Tassabehji and Elliman, 2006). It is not different in South Africa. Because of its history of discrimination and apartheid, strenuous and purposeful efforts have been made by the GSA to engender trust in e-government services. From an analysis and examination of the different efforts, we have constructed the framework for engendering government e-service delivery in South Africa (see Figure 1).

Figure 1. Framework for engendering trust in e-government in South Africa, 2007



According to the framework in Figure 1, e-government service delivery in South Africa rests on a foundation of trust by citizens and organizations. Specifically, e-service delivery by the GSA is supported on three pillars (the Batho Pele Principle, a trust "balance sheet" and a set of sustainability criteria). These pillars, in turn, rest on the trust foundation. As can be deduced from the figure, e-government services are liable to be shaky and ineffective if one or more of these pillars are destroyed. In the rest of this section, we discuss these supporting pillars.

2.1. Batho Pele Principles: Conceptualizing Trust in the Public Sector in South Africa

Trust is the glue that binds the GSA to its citizens and organizations. This tie is fashioned from and cemented by the value-based aspects stipulated in the *Batho Pele Principle*.

The GSA adopted the *Batho Pele* principles in 1997, and this provides a good starting point to understand how South Africa has approached the question of trust in public service delivery. The *Batho Pele* principles cover eight key human valued-based areas (See Figure 2). The aim is to ensure that public service delivery provides all citizens an opportunity for effective consultation, technology solutions that promote broad-based access to services, the treatment of citizens with respect (i.e. courtesy), maintenance of service standards at all government levels (i.e. including security apparatus), transparency, complaint handling (i.e. redress) and value for money to all tax payers (White Paper, 1997). The *Batho Pele* principles are expected to be the first port of call to engender codes of trust in both citizens and businesses in their interaction with government.

As shown in Figure 2, it is important to note that trust is reciprocal, and is not a one but two way interaction (Schmid, 1987). Whilst civil society and business demand trust from government it should be a reciprocal process. The citizens experience trust when they encounter elements such as reliability, dependence and positive utility (Josang et. al, 2005) in their interaction with government. When trust prevails, policing costs are reduced (Schmid, 1987). The ability of GSA to "track" and "measure" the evolution of trust in e-service delivery depends on the extent to which its clients (businesses, civil society and other government departments) clearly demonstrate behavioral changes that are based on mutual trust-based relationships or reciprocity.

2.2 Building an e-Government Trust "Balance Sheet" for South Africa

In order to monitor the evolution of trust in e-government, we propose a" balance sheet approach" that tries to integrate the elusive concept of trust into

Figure 2. Batho Pele principles-setting government trust in motion in South Africa, 2007

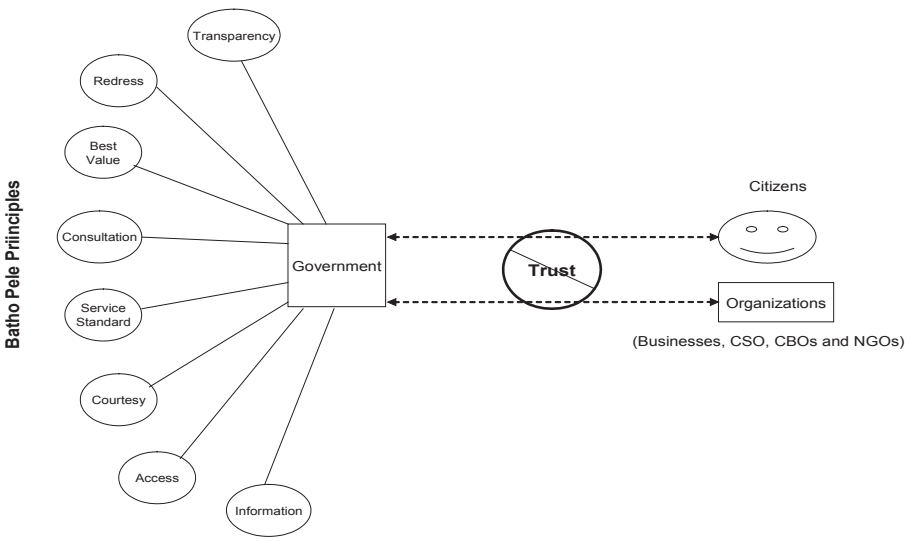


Figure 3. Proposed e-government trust "balance sheet" for South Africa, 2007

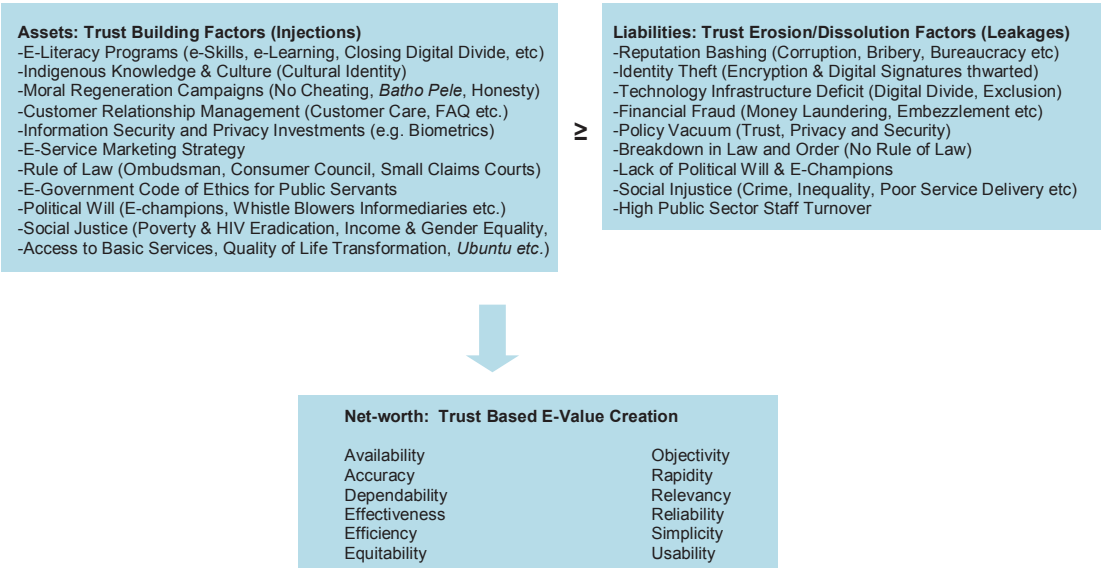


e-government program implementation. We perceive e-government trust as a form of socio-economic or political capital or asset. The challenge is to identify methodical ways in which trust can contribute to the "net-worth" of e-service delivery. Conceptually, the GSA should aim for a positive trust "balance sheet," one that consistently adds value to e-service delivery. This requires understanding clearly the difference between "trust building" and "trust dissolution" factors in e-government deployment. The "trust building factors" are what are traditionally referred to as the "assets" or "injections" while the "trust dissolution factors" are the "liabilities" or the "leakages" on an e-government trust balance sheet. The development of "trust building" initiatives ought to be treated as a key focal area driven by, and is largely part of, an overall e-government strategy.

As illustrated in Figure 3, trust building initiatives in South Africa can cover critical aspects such as (i) raising the confidence levels of citizens through e-literacy programs (ii) integration of indigenous knowledge and culture in e-government development, (iii) promotion of "moral regeneration" campaigns, (iv) innovative adoption of customer relationship management in the public sector, (v) investments in information security and privacy, and (vi) exercising the rule of law. For instance, the public may gain trust and confidence when they perceive their governments as serious in upgrading their e-skills base, expressing sensitivity to citizen-customer needs, and more importantly, demonstrating a commitment to prosecute high crimes perpetrated by public officials. The widespread problem of the break-down of the rule of law that characterizes many African countries unfortunately, is a recipe that "extinguishes any residual hope" that may be required to build trust-based relationships between government and civil society.

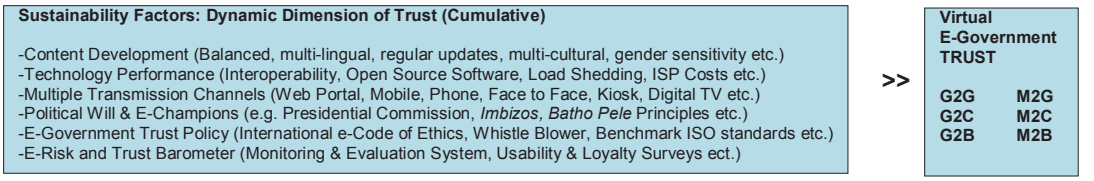
Likewise, it is important that GSA consistently monitor those factors that can be identified to cause "leakages" in trust between government, civil society and the business sector in both the first and second economies.. We identify among others (i) government image related characteristics, (ii) poor integrity of public officials (i.e., due to rampart corruption, financial embezzlement etc), (iii) lack of robust trust and privacy policy framework, (iv) weak technology infrastructure (i.e. urban-rural biases, class biases, etc.), (v) e-risks (e.g. identity theft, hacking, viruses, etc.) and (vi) high staff turnover rates of public officials as some of the key contributing factors to the dissolution of e-government trust in South Africa. The identification of "leakage issues" such as these in civil societal trust in government service delivery is a necessary first step in addressing the matters under discussion here. However, progressing the issue of building trust between the government and civil society, the GSA will need to take further steps to monitor any negative developments or liabilities in trust and should strive to promote "trust building" initiatives or "trust assets" that are related to e-government deployment as already mentioned above.

2.3 Building Sustainable Trust-based E-government Model for South Africa

The need to deliver on the opportunity to develop a "trust-driven e-government development model" requires policy makers to view trust not as a short-term gain, but as a long-term strategy for public service transformation. Unless the GSA realizes that trust gained in the short term can easily be lost, it will be difficult to grow the "trust dividend" in a sustainable way. To achieve longer term trust through a partnership based approach to participative governance there is need to identify issues that contribute towards building sustainable civil society trust for e-government which has extra dimensions in a 'virtual world' that are not evident in traditional service delivery approaches. In appreciating the "rainbow nation status" that South Africa prides itself on, it should promote a balanced e-government comprising (i) broad-based e-government content development (i.e. multi-lingual, multicultural, regularly updated, balanced in its coverage, etc.), (ii) the promotion of the widespread use of open software and multiple channels to make e-government accessible to majority poor (e.g. in remote rural locations, poor urban locations/townships, etc.) over time, (iii) the development and nurturing and retention of political will and e-champions, (iv) the crafting of an e-government trust, privacy and confidence strategy, and (vi) regular monitoring of trust and privacy issues to ensure an acceptable level of use of e-government services by critical mass of civil society.

The intrinsic value of "trust-building" assets must always exceed "trust eroding" liabilities in order to generate a desired positive "trust net-worth", considered a key part of the "e-value index" for a government web portal (Maumbe et., al., 2006). We envisage that improvements in e-government service delivery contribute to the "trust net-worth", and can be evaluated at three levels: (i) nature of the information (e.g. static web pages), (ii) transmission methods or communication channels and (iii) nature and sophistication of transactions (Evangelidis, 2004). Maumbe et. al., (2006), identify key internal, external and technical prime movers that contribute individually and collectively (i.e. through interactive mode) towards "e-value creation". The proposed e-value creation framework embeds, trust in the external environment (i.e. based on the cumulative interaction between intra-governmental agencies and strategic stakeholders, including business community and civil society). We expect that e-government information and service quality criterion such as (i) availability, (ii) accuracy, (iii) dependability, (iv) relevance, (v) rapidity and (vi) simplicity among others (see Figure 2), are key indicators that should represent an integral part of "trust-based" e-service delivery evaluation platform in South Africa. The effective development and tracking of such key performance indicators should help in taking the "pulse rate" of the e-government trust net-worth needed to generate the ultimate e-value-induced loyalty expected from satisfied citizen customers in a developing global information society.

Figure 4. Sustainable e-government trust: The dynamic nature of trust in South Africa, 2007



Furthermore, it is important for policy makers to realize that trust is a dynamic and not a static phenomenon (Figure 4). If the attainment of "virtual trust-based e-government sustainability" is the goal, it is crucial for the government to deploy multiple transmission channels that affords citizens and businesses, the opportunity to explore various e-service options offered via mobile technologies, especially in remote and poor regions where there is not sufficient 'back-bone' infrastructure to roll out Internet based online services. We therefore suggest the need for the development of some kind of "early warning system" that periodically gauges the status of an e- government trust factor. Without such a tool, inevitable break-down of trust between various service interaction mediums; Government to Government (G2G), Government to Consumer (G2C), Government to Business (G2B) and mobile-Government to Government (mG2G), mobile-Government to Consumer (mG2C), mobile Government to Business (mG2B), and mobile-Government to Business (mG2B) will result, and that will effectively undermine the goal of achieving trust-based e-value creation in the long term.

Currently, the GSA is undergoing an African Union and NEPAD Peer Review Mechanism that ranks African governments according to their economic sustainability, transparency, state of democracy and investment climate (www.aprm.org.za). Such a report is a barometer that could be used as a signal for and by the citizens to assess corruption and gauge their trust for the government. South Africa has passed the Access to Information Act and Protected Disclosures Act (i.e. also known as "Whistle Blowing Act" of 2000) (Camerer, 2001; www.pcaw.co.uk). The former Act aims to provide unhindered, equal access to government information to all the citizens while the later aims to promote whistle blowing on corrupt activities. Toll free lines are used to report serious crime in government and other sectors. Although, these mechanisms do not measure trust directly, they act as indicators for its monitoring. Examples of civil society organizations that advocate for public interest disclosure include Freedom of Expression Institute, Institute for Democracy in South Africa, Human Rights Commission, Black Sash and Office for Serious Economic Offenses.

3. TRUST AND E-VALUE CREATION IN E-GOVERNMENT SERVICE DELIVERY: LITERATURE REVIEW

Governments across the world confront the problem of eroding trust from their citizens (Evans and Yen, 2006; Parent et. al., 2005). The advent of e-government has fundamentally transformed relationships between government and citizens. A recent study revealed that citizens who regularly transact online with their governments reported significant positive changes in trust levels for the government (Parent, et al, 2005). Such findings provide a rationale for most e-government programs to become "citizen-centered" or "citizen-centric" in their e-service delivery approaches (Richter, 2004).

Nonetheless, the problems of technical implementation (i.e. system design), weak user participation (implementation), and lack of cooperation between different government departments still hinder numerous e-government programs (Stahl, 2005), and that calibrates the entry point for the need to cultivate trust. The effective integration of trust into e-government development demands public policies that reflect the thinking that e-service delivery is more than modern technology or systems design, but it is about putting people first (Richter, 2004).

Like any other technological activity, e-government development entails risks and uncertainties which require systematic assessment (Evangelidis, 2004). Trust influences the successful up-take of e-government information and services. A number of e-commerce adoption studies have identified the "trust element" as a significant factor in the uptake of e-services by citizens (Tassabehji, and Ellimann, 2006). Without a willing citizenship, e-government implementation can be problematic (Evans and Yen, 200). Trust is viewed as dynamic in nature and is not a static phenomenon. This argument suggests that trust can be cumulative, implying that it could rise or fall to new levels (i.e. just like investor confidence) depending on the presence/absence of trust-building or trust dissolving factors.

In an effort to preserve trust in e-government service delivery, questions are being raised about what is an acceptable moral behavior in electronic environments (Mullen and Horner, 2004). The authors argue that failure to establish coordinates about ethical behavior in cyberspace could undermine trust in e-government services. Others argue that in debating ethical problem in e-government, it is illogical to perceive citizens as customers as that assertion is more appropriate for commercial or e-commerce applications (Stahl, 2005).

The government's desire to forge close connections with civil society and its citizens, understand their unique preferences, and ultimately secure their trust provides a basis for customer relationship management (CRM) in the public sector arena (Pan et. al, 2006). The authors argue that CRM approach assumes that a customer relationship already exists, yet the creation of that customer relationship is as important as its management. Therefore, building e-government trust requires bridging the digital divide through e-literacy programs and raising ICT awareness. This of course recognizes the fundamental issue that many governments now confront and that is that the provision of access in and of itself is simply not enough. The technology needs to be socially appropriated in ways that not only understands civil society needs but provides a communication channel for structuration (Giddens, 1984) of service delivery systems to better meet civil society needs and elected government desires for participative governance that values social cohesion (Mbeki, 2006). Embedded in efforts to establish robust trust alliances between government and citizens in e-service delivery is the need to uncover the ethical problems of such technology deployment (Palm and Hansson, 2005). Attempts to ignore the ethical implications of technology (e.g. disability, ethnic minorities, gender issues, etc.) will undoubtedly introduce adverse consequences that will lead to a depletion of citizen trust across civil society, and will slow down the pace of e-government adoption in society.

4. CONCLUSION

South Africa has already embarked on the journey to transform its public service delivery to make it citizen-centered (DPSA, 2006). The deployment of e-government services has changed the nature of the relationship between GSA and its citizens (Detolly, et al, 2006, Alexander et. al, 2006). Civil society and citizens, like private sector customers, are keen to make informed decisions about e-government services. As concerns that government service delivery and capacity to manage the so called 'wicked issues' are getting worse emerge, the GSA needs to strategically integrate "trust-building" mechanisms in its e-government service delivery to the citizens. Trust in the new ICT enabled world i.e. the information society is the glue that holds government e-service channels and citizen customers together.

The adoption of the *Batho Pele* principles and the notion of *Ubuntu* by South Africa in 1997 triggered the first attempt to infuse trust traits in society through its "people first" approaches in service delivery. These issues have been strongly reinforced by government programs such as the Accelerated Shared Growth Initiative (ASGISA), the Strategic Plans of many Government Departments, ANC policy demands and the pronouncements of President Mbeki (2006). This paper attempted to provide a holistic view of the concept of e-government trust. To achieve that, we presented a framework that maps out key factors that contribute towards e-government "trust-building," "trust-dissolving," and "trust sustainability". We recommend the need for the GSA to regularly audit and strategically integrate citizen trust in e-government development, in order to meet the rising

"e-value expectations" from citizens who are utilizing e-services. Armed with such a tool, GSA will have an "early warning system" that will help send key signals to policy makers to make necessary and timely adjustments to advance e-government service delivery.

Although the paper does not advocate that e-government trust is a panacea for the implied deterioration in citizen trust, that it will play an increasingly important role is unquestionable. Therefore, trust can no longer afford to take a back seat in e-government development policy in South Africa. If awareness about need to curb government and private sector graft is raised, trust for GSA is bound to increase as more cases of corruption and unlawful activities will be exposed. Trust-based e-government has the potential to improve communication, enhance citizen participation, lower transaction costs and increase social cohesion (Taylor, et. al., 2006). Most importantly, it will promote a positive trust dividend (i.e. net-worth analogy) between civil society, citizens and their governments which is a crucial aspect for the emerging participatory democracy in South Africa. Finally, as this matter is of prime importance in the policy and delivery frameworks in South Africa, there is a critical need to develop a coherent research and evaluation agenda to bring out the relationship between civil society and citizen trust, building social cohesion and e-government service development and deployment in South Africa.

The Impact of Culture on the Adoption and Use of IT in the UAE: A Study Towards Bridging the Digital Divide Between the UAE and the Developed Countries

George Ditsa, United Arab Emirates University, Al Ain, UAE; E-mail: georged@uaeu.ac.ae
Saleh Alwahaishi, United Arab Emirates University, Al Ain, UAE

ABSTRACT

Culture is thought to be probably the most difficult to isolate, define and measure in the adoption and use of IT. Consequently the impact culture on the adoption and use of IT does not feature prominently in the literature. As cultural factors may be important to the success of IT adoption and use, this research project was aimed at a focused study of its impact on the adoption and use of IT in the United Arab Emirates (UAE). The results of the study was compared along eight cultural dimensions and contrasted with a study (Hasan & Ditsa, 1997, 1999) on the adoption and use of IT in developing and developed countries. The results of this study were also used to identify issues of concern with the relationship of culture and IT and their implications for IT adoption and use in the UAE. The study results were further used to suggest ways of bridging the digital divide between the UAE and developed countries.

INTRODUCTION

Technology is believed to be culturally neutral and that the process of development, adoption and use of technology is uniform across countries, once basic economic and political conditions are satisfied (Review of the World Bank 1994). The review observed that many technology projects, including IT, in developing countries fail because the designs were not sufficiently tailored to those countries' history and industrial traditions. There are problems that cannot be attributed to the technology process, but rather the cultural differences between designers of the technology and the recipients. It is true culture may not be the only factor which influences the adoption and use of IT. Other such as economy, politics, social factors, education and skill levels may be deciding factors.

Hasan and Ditsa (1997, 1999) studied the adoption and use of IT in three regions of widely diverse cultures. They concluded that culture is an important ingredient in the identity of the IT products themselves and influences the impact of IT adoption and use in different cultures.

Following from the studies of Hasan & Ditsa (1997, 1999) and Ditsa (2005), this research carried out a focused study on the impact of culture on the adoption and use of IT in the UAE. The results were compared along eight cultural dimensions and contrasted with the studies of Hasan & Ditsa, (1997, 1999). The results of the study were also used to identify issues of concern for the relationship of culture and IT and their implications for IT adoption and use in the UAE. The study results were further used to suggest ways of bridging the digital divide between the UAE and the developed countries.

DEFINITIONS

Culture

Culture can be thought of as the beliefs, philosophy, shared values, attitudes, customs, norms, rituals, common practices, and traditions which govern the ways of living of a group of people. Macquarie Dictionary defines the culture of a society as:

"The sum total of ways of living built up by a group of human beings, which is transmitted from one generation to another."

Hofstede (1991, p.5) defines culture as: "the collective programming of the mind which distinguishes the members of one group or category of people from another". More simply, culture is shared values of a particular group of people (Erez & Early, 1993) and culture reflects the core values and beliefs of individuals, which are formed during childhood and reinforced throughout life (Shore and Vankatachalam, 1996). This implies that culture is all pervasive and has a strong influence on all our undertakings. It is not however easy to measure and hence is a difficult variable to use in a rigorous research.

Hofstede (1991) further looks at the manifestation of cultures as symbols, heroes, rituals and values, which he illustrates as the concentric skins of an onion, with the symbols forming the outer skin, followed by heroes, rituals and values in that order. Symbols are the most visible attributes of a culture, whereas values form its innermost and deepest manifestations and are difficult to change. Values, according to Hofstede, are broad tendencies to prefer certain states of affairs over others. That is, they are what make a group or a category of people distinguish between good and evil, clean and dirty, beautiful and ugly, natural and unnatural, normal and abnormal, logical and paradoxical and rational and irrational. According to psychologists these values are acquired unconsciously at an early age by the individual in a cultural group.

The Eight Cultural Dimensions

For the purpose of our study we adopted the eight cultural dimensions from Hasan and Ditsa (1999). Definitions of the eight dimensions are as follows:

- **Power Distance:** *The extent to which the members of a society accept that the power in institutions and organizations is distributed unequally.*
- **Uncertainty Avoidance:** *The degree to which members of a society feel uncomfortable with uncertainty and ambiguity.*
- **Individualism:** *Preference for a loosely knit social framework in which individuals take care of themselves and their immediate family as opposed to* ***collectivism*** *which is preference for a tightly knit social framework in which individuals expect their relatives or others in their group to look after them in exchange for unquestioning loyalty.*
- **Masculinity:** *Preference for achievement, heroism, assertiveness and material success as opposed to* ***feminism*** *which is preference for relationships, caring and quality of life.*

- **Time Orientation:** *A measure of people's consideration of the future.* Long-term orientation is characterized by people who persevere methodically toward results and save for the future whereas short-term orientation is characterized by people who expect quick results.
- **Monochrony and Polychrony:** *Cultural dimensions describing attitudes towards the use of time in performing tasks.* In Monchronous societies people focus on issues one at a time and emphasize schedules and procedures for task completion. In Polychronous societies people perform activities in parallel and focus on task completion rather than adherence to procedures.
- **Context:** *The amount of information that surrounds an event, inextricably bound up with the meaning of that event.* In a high context culture the information surrounding an event is already in the person, and very little is in the coded, explicit, transmitted part of any communication between participants. In low context cultures the mass of information is vested in the explicit code.
- **Polymorphic and Monomorphic:** *Cultural dimensions which relate to the influence of opinion leaders.* In polymorphic cultures, such as traditional villages and farming communities, the expertise of leaders or managers is assumed to span a wide range of issues, whereas in monomorphic cultures, such as modern industrialized societies, a manager's scope is limited to his or her explicit areas of expertise.

Digital Divide

There is growing disparity in the use of IT between the developed and developing countries. While developed countries are harnessing IT to revolutionize their operations of their industries, developing countries, on the other hand, appeared not to have the capabilities or the urge to do so. The disparity which exists in access to and use of IT between countries and between groups within countries is what is referred to today as the "digital divide". The growing disparity in the adoption and use of IT also results from the culture of a people (Ditsa, 2005).

THE STUDY

Methodology

The methodology used for this research is both qualitative and interpretive following the model proposed by Miles and Huberman (1984), which incorporates the four phases of: data collection; data reduction; data display; and the verification and drawing of conclusions. The data for analysis was collected from a set of organizations in each cultural region which were chosen to be as diverse as possible in size and industry type. The researchers took particularly care to select, where possible, representatives of the local IT community rather than foreign advisers or members of multinational corporations.

All the data was text-based and comprised of organizational documents and transcripts of semi-structured interviews with IT staff at both managerial and operational levels. In these interviews the researchers recorded answers to specific questions on: the history and use IT in the organizations; the method of acquisition and development of information systems; and the attitudes of operation and management staff involved in IT. The researchers also recorded any informal discussions that followed. As soon as possible after each interview, a full report was written based on the notes taken. Follow up interviews were conducted as soon as possible when we felt the need for further explanation for the data collected.

These reports and documents were then analyzed by using a process of data reduction with the selection and arrangement of relevant items. We extracted only that data which relates to culture as defined in this paper. The data was arranged along those dimensions and is displayed in Table 2 of this report. An interpretation of this data into generalized issues was then made and presented in the concluding sections of the paper.

Data Collection Methods

The data used for this study is descriptive in nature and the method of collection of the data is as follows. Interviews were conducted and observations made on the adoption and use of IT in two organizations in Al Ain, and one each in Abu Dhabi and Dubai. Before the data collection visits, preliminary contacts were made with these organizations. The organizations and interviewees were appropriately informed about our study. For obvious reasons, we agreed to guarantee the anonymity to some extent of all the organizations involved in this study.

In each organization, at least one interviewee was selected who had been involved in IT since its first introduction into the organizations. Evidence was also taken from the scarce literature of other case studies on the adoption and use of IT in the chosen organizations. Comparisons were then made with the wealth of data on IT in a Western developed country, Australia.

The Three Chosen Cultural Regions for the Study

Based on the studies of Hofstede (1983a, 1983b, 1984, 1991) and Hofstede et al. (1990), we have identified two distinct cultural regions in addition to the **UAE**, which is the focus of this study. The two are West Africa, which is in the developing world, and Australia, which is a developed country with Western culture.

Australia is one of the developed or industrialized nations which form about 25% of the world population but produce and consume about 12 times more per capita than the Third World countries (ABS, 1998). Australian companies play in specialized areas of IT. Most Australian organizations rely on IT for daily operations and strategic decision making.

Australian culture is very egalitarian resulting in an extremely low PD and a monomorphic structure where people are only respected for their own area of expertise. Australia culture is also individualistic and masculine and, perhaps being predominantly a nation of immigrants, Australians are generally venturesome and innovative. Per capita, Australia is a world leader in the use of new technology.

In contrast with Australia, the **UAE** represents the old and even ancient world, although the country can be considered as young. The UAE, like other countries in the Middle East, has some commonalities of culture, language and religion with countries of Northern Africa, and the other Islamic countries of the Levant and the Arabian peninsular. The use of IT in the UAE has grown tremendously in the last few years. Government IT initiatives appear to be towards making the UAE the technology capital of the region. These can be seen in establishment of educational institutions, the Knowledge Village, Dubai Silicon Valley, annual fairs such GITEX and Global Village to promote IT. The use of IT is widely encouraged in both public and private sectors. Examples are eGovernment initiatives in Dubai and Al Ain, and the police force. The presence in the country of giants in the IT industry (such as Oracle, Dell, IBM, Cisco, and Microsoft) attests to this. This is also evident in the use IT in the financial and other sectors.

Hofstede's (1991) cultural study in the **West African** region included Ghana, Nigeria and Sierra Leone and our study in this region focused on one country, Ghana. Apart from Liberia, which was created after the abolition of the slave trade, all other West African countries were once colonized. Ghana was at one time or another colonized by the Portuguese, the Spaniards, the Danes, the Dutch, the Germans, the French and, lastly, the British. The colonial legacies left in these countries are very obvious in their national and organizational administrative structures, languages and educational systems. For example, the official language of Ghana is English, as is that of Nigeria and Sierra Leone, whereas that of Burkina Faso, Cote d'Ivoire and Togo, is French.

According to Hofstede's (1991) study, the cultures of this region are very similar and despite the colonial rules which brought with them foreign cultures, the cultural identities of these countries still remain unique. Traditional cultures still permeate organizational cultures. The basic family values with extended family systems still dominate in this region.

DATA REDUCTION AND DISPLAY

Comparative Cultural Indices

Values of the eight cultural indices for each of the three cultures chosen were estimated from the literature. These values were also verified by representatives from the cultures used in the study and are shown in Table 1.

Summary Cultural Comparison of the Three Regions on the Eight Cultural Dimensions

From the analysis of the data collected in the study, a summary was made of instances where the value of each of the eight cultural indices was related to IT issues in each of the three cultures. These results were then verified with a representative from each of the three cultures and are presented below with a tabular summary in Table 2.

Table 1. Values of the three cultures along the eight cultural dimensions

	AUS	WA	UAE
Power Distance	Low	High	High
Uncertainty Avoidance	Moderately Low	Low	High
Individualist vs Collectivist	Highly Individualistic	Highly Collective	Collective
Masculinity vs Feminism	Masculine	Feminine	Masculine
Time Orientation	Long-term	Short-term	Short-term
Monochrony vs Polychrony	Poly	Mono	Mono
Context	Low	High	High
Polymorphic v Monomorphic	Mono	Poly	Poly

APPLICATION OF THE RESULTS TO THREE ISSUES OF CULTURE AND IT

From the results of this study we deduced three issues (Cultural identity of IT, Cultural Values of IT, and Impact of IT on Culture) that the eight cultural dimensions can be broken down into as summarized in Table 3.

It should be noted that most of the cultural indices of West Africa and the **UAE** are similar and in opposition to most of the values embedded in IT by Western culture, particularly along the dimensions of Power Distance, Individualist/Collectivist, Time Orientation, Context and Monochrony / Polychrony. The latter two dimensions are particularly interesting in regard to modern, interactive, windows-based systems which are becoming popular all over the world. These would seem to suit high context cultures and be at odds with the Monochronous nature of the work of a traditionally trained analyst-programmer concerned with structured algorithms and abstract data types.

IMPLICATIONS FOR THE IT INDUSTRY

The key area of concern for the relationship of culture and IT is the realization that many aspects of IT are not culturally neutral. Most of the popular commercially available hardware and software emanates from the US and similar Western cultures. Our study has focused on many of the issues that arise when people in different cultures use IT.

Of the eight dimensions of culture that we have used in this study, at least three could be thought of as inherent in the currently available technology, most probably because of its Western origin. These three are power difference, uncertainty avoidance and time orientation. Most IT products and projects suit cultures with low PD, low UA and long-term time orientation in the following ways:

- **PD** - Those in power in cultures with high PD are often fearful of the open nature of modern IT.
- **UA** - Adopting any form of IT is risky but there may be a greater risk of not joining the global IT community.

Table 2. Summary of the cultural comparison of the three regions on the eight cultural dimensions

	AUS	WA	UAE
Power Distance	IT has flourished in this low PD culture as networked organizations develop flatter management structures.	In this high PD culture, IT is often an imposition on organizations from the top without taking advice from IT staff.	In this high PD culture governments want to control IT and are concerned with its power to democratize society.
Uncertainty Avoidance	People here are prepared to take risks and ready to adopt new IT, resulting in successful innovation.	Also prepared to take risks but many unwise and risky projects are undertaken and a lot of incomplete IT projects are observed.	In this high UA culture there is almost no R&D. They accept only well established IT products from the developed world.
Individualist vs Collectivist	The individualist characteristic of this culture is exemplified in the typical solitary image of a dedicated computer programmer.	Here there is a collective attitude towards solving IT problems by teams of IT professionals. This has the potential to produce good IT solutions.	Most IT projects are initiated by people trained in the west who have individualist skills, whereas locals usually prefer to work in teams. This is a source of conflict in joint projects.
Masculinity vs Femininism	IT development has been predominantly technical and male oriented. Women are becoming more prominent as the number of less technical positions grows.	Both males and females vie for top jobs in the IT industry and people are more interested in what the technology can do rather than technical details.	Most jobs in IT are held by men but IT is providing jobs for women. This is welcomed by those trying to raise the position of women but is seen as a threat in conservative circles.
Time Orientation	Most organizations have a three to five year IT strategies and think reasonably long term.	Short-term planning is prevalent, so that only the results of today determine success and are rewarded	Management want quick results and do not appreciate the time value of money. Many organizations retain inefficient manual systems.
Monochrony vs Polychrony	Modern interactive, multi-tasking systems encourage polychronous work and are popular.	IT professionals prefer completing one job before taking another: a display of monochronous culture.	Batch systems were readily adopted and many have not been upgraded. This is indicative of a monochronous culture.
Context	System developers are good at low level development which requires detail and abstraction.	Interested in getting a system in place without much attention to details.	Seems to prefer modern high level end-user development tools which suit a high context culture better than traditional programming.
Polymorphic vs Monomorphic	IT management is separated from core business resulting in problems of communication: a display of a monomorphic culture.	IT managers are expected to have knowledge of every aspect of IT and the organization: a display of a polymorphic culture.	Managers are expected to deal with IT issues without being trained in IT: a display of polymorphic culture.

Table 3. Three aspects of IT and culture for each of the eight cultural dimensions

	Cultural identity of IT	Cultural Values and IT	Impact of IT
Power Distance	IT implies and supports a low PD culture.	IT can change the power base of organizations in high PD cultures giving skilled IT workers equity with managers.	IT can lower PD or be used to reinforce control.
Uncertainty Avoidance	IT is risky and has flourished in low UA. In today's world it is also risky not to adopt IT which poses a dilemma for high UA cultures.	High UA cultures may only adopt "safe" older IT and be less competitive in the global arena.	The global economic imperative of IT may have the effect of lowering UA as business are force to take the IT challenge.
Individualist vs Collectivist	Traditional IT suits Individualists but modern systems such as GSS and the Internet suit Collectivists.	IT can suit the individual or the group. It can support individual or cooperative work practices.	IT empowers individuals in collective cultures. It also creates groups across time and space.
Masculinity vs Femininism	IT has been male dominated, with a focus on the technology for its own sake. A Feminine attitude is people oriented and focuses on the end-user of IT.	Whereas the older IT systems fitted into masculine societies, feminist cultures feel more comfortable with modern user-friendly systems.	Older IT systems enforce a technological masculine way of working whereas the more modern usable systems promote feminine cooperative work practices.
Time Orientation	The changing nature of IT makes long-term planning difficult but critical. There is a need to plan long-term but also be flexible.	The need for long-term planning in a rapid changing environment can cause problems in cultures with short-term time orientation	The current climate of constant change is making people more flexible but also put more effort into anticipating future requirements.
Monochrony vs Polychrony	IT exhibits both these time aspects of work (eg Monochronous batch processing and Polychronous interactive multi-processing).	The popularity of modern windows systems in the West is in part because they support Polychronous work.	Older IT forced many into monotonous Monochronous jobs. Modern systems support Polychronous work and increase job satisfaction.
Context	IT has traditionally required explicit analysis and abstraction consistent with a low context culture.	The object oriented development approach may suit more high context cultures as it is more oriented to objects in the real world and integrates data and process.	Traditional IT has imposed its language and mode of operation on all users. It teaches problem solving skills and data abstraction with low context.
Polymorphic vs Monomorphic	IT works best when organizations combine technical and business knowledge. This is compatible with a Polymorphic culture.	Leaders in polymorphic cultures have problems with IT because it is such a specialized area of which they know little, yet they are expected to show leadership in IT adoption.	In the past IT has been run by IT specialists, however modern organizations are successful if the CIO has both business and IT expertise.

- **Time Orientation -** Some forward thinking and long-term strategy is needed to choose the best IT path for any country or organization.

Across the remaining five dimensions of culture, it is possible to choose appropriate technology for particular cultures. These could be:

- using groupware techniques in collective cultures, as opposed to single user systems which are more appropriate in individualistic cultures;
- more technical approaches to development in masculine cultures and more people oriented approaches in feminine cultures;
- using modern visual and object-oriented programming package for more high context cultures and more traditional algorithmic methods for low context cultures;
- highly interactive systems are easily accepted in polychronous cultures whereas linear systems suit monochronous cultures;
- monomorphic cultures readily accept specialists whereas in polymorphic cultures managers must have broader more generalist training, as they are expected to be experts in everything.

LIMITATIONS OF THE STUDY

More data is always desirable. It would have been useful to increase the number of organizations in the study and across the seven Emirate of the UAE. These would have required more time and resources, which in the current study were very limited.

CONCLUSION AND SUGGESTIONS FOR FURTHER RESEARCH

This study suggests that cultural impact on IT adoption and use cannot be ignored. Culture is an important ingredient in the identity of the IT products themselves and influences its adoption and use. Problems will arise when there are differences between the culture of an IT product and the culture of its user. We discussed this under the heading of three issues: the Cultural Identity of IT, Cultural Values and IT and the Cultural Impact of IT.

As the use of IT expands globally, there is need for further research into cultural aspects and implications of IT. A greater understanding of the various dimensions of culture, as applied to IT and the people who use it, will lead to more globally acceptable IT products and better choices for IT.

From the results discussed, suggestions can be made to the **UAE** government and the private sectors to encourage more use of IT in order to bridge the digital divide between the country and the developed countries. This may mean more provision of resources, education towards modernizing aspects of culture that inhibit the successful us of IT, providing tele-cottages to educate that section of the population that is computer illiterate. There will also be the need to encourage more use of IT at all levels of the educational sector. Teaching of IT at these levels should highlight the cultural aspects that inhibit the successful use of the technology.

ACKNOWLEDGMENT

The authors would like to express his sincere appreciation to the Research Affairs at the United Arab Emirates University for the financial support of the project under fund grant # 01-04-9-11/05 which yielded this paper.

The Role of Cybercafé in Bridging the Digital Divide

Muhammed A. Badamas, Morgan State University, Baltimore, MD, USA; E-mail: badanmas@hotmail.com

ABSTRACT

Digital divide exists for those who do not have access and use Internet to fight the war against world poverty. Despite the remarkable advances in technology, more than 80% of the world population does not have access to telephone or Internet (Family Care, 2006). There are many international projects and efforts aimed at bringing the Internet to people in developing countries. Most of these projects are initiated and sponsored by international and governmental institutions. In this paper, we examine one way of bridging the digital divide based on private initiatives and yet yielding greater results and benefits to those who use it, to narrow the digital gap. There are over 100, 000 cybercafés in Nigeria. We examine the technology deployed and its advantage; discuss the operations of cybercafés in Nigeria and how they are helping to bridge the digital divide. The study involves a survey of cybercafés and the users of cybercafés. The result of the survey provides insight into what users of Internet in a developing economy use the Internet for.

Keywords: *digital divide, cybercafé, Internet, Nigeria, VSAT, economy*,

INTRODUCTION

The World Summit on Information Society in its declaration of principles, expressed its "desire to build a people-centered, inclusive and development-oriented Information Society, where everyone can create, access, utilize and share information and knowledge", and is "fully aware that the benefits of information technology revolution are today unevenly distributed between the developed and the developing countries" (WSIS, 2003).

Digital Divide is the term used for the unequal access to information and communication technologies by various communities. The digital divide exists at various levels between developed and developing nations. The implications of digital divide are very serious, because information and communication technologies propel economies of the rich countries.

In emerging economies, numerous projects have been launched to set up community access centers. Various strategies, actions and initiatives are being taken at all levels to bridge the digital divide. There are many international projects and efforts aimed at bringing the Internet to people in developing countries. Most of these projects are initiated and sponsored by international and governmental institutions. Despite all efforts, the digital divide persists, because of poor infrastructure among other factors resulting in inadequate access to affordable telephones, broadcasting, computers and Internet. (NEPAD, 2003)

The most overlooked solution to bridge the digital divide is the cybercafé phenomenon in the developing nations. The use of cybercafés to provide Internet access and connectivity to the populace is increasing and helping to close the digital divide. This study examines the cybercafé phenomenon, the technology deployed and its advantages, and how it is used to bridge the digital gap.

LITERATURE REVIEW

The implications of the digital divide has been documented in several reports (ITU, 2001, USIC, 2000, Bridges.org, 2001, OECD, 2001, Flor, 2003). Internationally, ICT is concentrated in the industrialized countries with little ICT in Africa. It is estimated that USA alone has over 183 million telephone lines while the continent of Africa has about 20 million telephone lines (ITU, 2001). In terms of the Internet, in 2000, there were about 137 million people with access to the Internet in USA and Canada (USIC, 2000). Africa has an estimated 274,742 Internet hosts with PCs shares of 7,558,000, representing 1.53% of the world total (Ya'u, 2002). By mid-2002, there were 1.7 million dial-up Internet subscribers in Africa with 1.2 million in North and South Africa, and the rest of Africa having about 500,000 subscribers (Jensen, 2003). In 2004, less than 3 out of every 100 Africans use the Internet compared with an average of 1 out of every 2 people in G8 countries. (ITU, 2004). In 2002, Nigeria has a 1,030,000 Internet hosts with 420,000 Internet users and a total of 853,000 PCs, with a population of about 125,000,000 (ITU, 2004).

Problems faced by Internet users in Africa are many. These include the cost of telephone connection to the Internet service provider, poor line quality slowing connection speed, frequent line drops, significant infrastructure problems and trained computers operators (Kenny, 2000). In his paper, Kenny (2000) discusses at length, the costs of Internet provision and access in Africa. Ya'u (2002) identifies four dimensions that affect the digital divide in Africa. Theses are the international dimension, the African's isolation from the cyberspace, the uneven distribution of telephone lines among African countries, the unequal access of ICTs between urban and rural people.

Schilderman (2001) believes that the establishment of sustainable ICT in developing countries is likely to take time and considerable efforts. The high cost of international bandwidth is a major constraint, with developing countries often having to pay the full cost of link to a hub in a developed country. Many developing countries have less than 10 Mbps of international Internet bandwidth (ITU, 2004). One of the challenges facing service providers in Africa is how to provide broadband connectivity in an unfriendly environment and make Internet connection affordable to the people. In most of the countries, the cost of one hour of Internet access can wipe out a day's wage.

There are many recent technological innovations that make ICT cheaper to the people. One of them is the VSAT technology, used for interactive voice and data broadcasting (Hudson, 1999). However, the reduction in the cost of Internet connection is not enough to reduce the digital gap. A new public access regime is needed. A Cybercafé provides a regime that provides both cheaper connection and easy access to Internet.

There is little research on what cybercafés are used for and who use them. (Callon, 1987). Since the early 1990, a number of people have undertaken researches on cybercafés (Wakeford, 1999). Stewart (2000) addresses the role of cybercafés in the general development of use and knowledge about multimedia and concludes that cybercafés are for technical access, for consumption of multimedia and serve as community and cultural spaces. Internet cafes are located world-wide and people use them to access web mail because it is more affordable than personal ownership of equipment.

The concept and name of Cybercafé was invented in 1994 by Ivan Pope in a proposal outlining the concept of a café with internet access from the tables. Inspired by this proposal, a cybercafé called Cyberia was opened on September 1, 1994 in London, England. In 1995, the first cybercafé was opened in East Village, New York City. (Sonia *et al*, 2003). There are over 100, 000 cybercafés in Nigeria. (The Guardian, 2006). Adomi (2005) did study the effects of a price increase on cybercafés in Abraka, Nigeria. But there is no reported study of the extent of the contribution of cybercafé in bridging the digital divide in a developing country.

THE STUDY AND METHODOLOGY

The study objectives are to determine the contribution of cybercafé in making Internet accessible to many people in a developing economy and to examine the patronage of cybercafés. The study also examines the various types of users of

cybercafés in terms of their professions and what they use internet for, while in the cybercafés. The study covers the surveys of cybercafés in Ibadan and Lagos, and a survey of users of cybercafés in the two cities. The two cities are selected because of their prominence in terms of Internet diffusion. Lagos is the commercial capital of the country with all major commercial activities. The population of Lagos Metropolitan is about 12 million. (Census, 2005). Ibadan is the major educational center with the first university in Nigeria, a prominent Polytechnic and a large student population.

The study also investigates the type of users of cybercafés and what they use the Internet connections in the cybercafés for. A questionnaire was designed and administered at about twenty cybercafés. Each user-client was given a questionnaire to complete as he/she comes into the cybercafé. Seven hundred questionnaires were distributed. Five hundred and forty-eight users were completed and returned the questionnaires. This represented about 78 percent that can be considered good for analysis (Babbie, 1979).

Part of the survey is for the users to rank reasons for using cybercafés and to rate the reasons. A rating between 1 and 5 indicates the nearness to most important or least important a reason is to the user. A questionnaire on rating important reasons is the traditional data collection tool which does not force respondents to confront the relationships between the reasons (Margado, *et al,* 1999). Rating method is used because important reasons could be termed to be homogenous considering the level of economic, political development and the environments within which the cybercafés operate. Rating is also used because it allows the evaluation of one reason at a time rather considering all reasons simultaneously. Simple descriptive statistics such as means are used to determine the ratings of the important reasons (Pinsonneault, *et al*, 1993).

RESULTS

The first observation of the cybercafés is the fact that no beverage is served in any of them. This is contrary to what is available in a typical cybercafé in Europe, Canada or U.S.A. A cybercafé in this study is purely an Internet center where a user can connect to the Internet. The center is also used to send and receive fax messages and to make telephone calls, especially, international long distance calls. Another observation is the fact that high tariff of dial-up connection for long distance and international calls makes it not feasible to use telephone dial-up facilities for Internet connections. It is also discovered that all the cybercafés surveyed use the same technology, VSAT, because it provides access to Internet at a cheaper rate to the users. VSAT technology is used for interactive voice and data broadcasting (Hudson, 1999).

VSAT (Very Small Aperture Terminal) is a device used to receive satellite transmissions. The "very small" component of VSAT refers to the size of the dish antenna mounted on a roof or wall or placed on the ground. The first component of a VSAT is the outdoor unit made up of the antenna, the low-noise blocker (LNB) which receives the satellite signal and the transmitter which sends signals. The second component is the indoor unit which is a PC containing receiver and transmitter boards and an interface for communicating with the existing in-house equipment – LANs, servers, and PCs. Connecting the indoor unit to the outdoor unit is a pair of cables.

VSAT is not limited by the reach of the cable since it can be placed anywhere that is the view of the satellite. VSAT is capable of sending and receiving all sorts of video, data and audio content at the same speed no matter the distance from the switching offices and infrastructure. VSAT technology is cost effective and provides quick implementation. Maintaining VSAT is limited to yearly maintenance.

A typical VSAT in a cybercafé has the following equipments;

- A 1.8 or 2.4 meter dish with 4W BUC and a satellite receiver mode for C-Band or KU-Band.
- A wireless access point and bridges
- 128/256 or 256/512 kbps bandwidth
- A server with appropriate operating system and other softwares for network administration and administration. Examples of the softwares are Windows NT, LINUX, Mikrotik, and Cyberclock

The cost of a VSAT start-up package, as revealed by the investigation, is shown in Table 1 in U.S. dollars.

The minimum computers available in a cybercafé surveyed are 10. While most of them have about 20 systems, one in particular has 30 computers connected to the VSAT. The connection fee is one hundred naira for an hour payable by a user (about $1.00). It is less than $1.00 if the user comes in after 10.00 p.m. The average number of clients in a cybercafé is 200 per day. If we considered that the number of Cybercafés across the country is 100,000, (The Guardian, 2006) then we have about 20 million people connecting to Internet daily. This represent about 16% of the population.

Table 1. Cost of VSAT installation

Purchase Options	Personal	Professional	Corporate	Commercial
Lease Purchase – 8 Months	1,800.00	2,500.00	4,500.00	9,100.00
Lease Purchase – 12 Months	2,000.00	3,000.00	5,200.00	10,000.00
Full Purchase	5,000.00	5,500.00	8,000.00	10,500.00
Bandwidth	32/128	64/256	128/256	128/512
# of Terminals Supported (Max)	5	10	20	30+
# of Voice Parts	1	1	1	1

Note: All start up packs include: Complete Indoor and Outdoor Equipment, 4 months bandwidth, quarterly software and maintenance installation charges. (Koochi Communications, 2004)

Table 2. Type of users by age-group

Age-group (Years)	Businessmen	Workers	High Sch Student	Univ./Poly Student	Professionals	Total
10-18	0	0	35	0	0	**35**
19-25	15 (4.3%)	92 (26.1%)	0	245(69.6%)	0	**352**
26-30	52 (58.4%)	2 (2.2%)	0	15 (16.9%)	20 (22.5%)	**89**
Above 30	0	0	0	0	72	**72**
Total	**67**	**94**	**35**	**260**	**92**	**548**

Table 3. Internet applications

Internet Applications	Percentage of Users
Chatting	74.8
E-mail	89.2
File Transfer	33.4
Research	53.5
Shopping	7.5
Information	69.3
Education	20.3
Others (entertainment, etc)	8.8

Table 4. Time connected to Internet

Age-Group	Average Time (Hrs)
10-18	**2.19**
19-25	**2.50**
26-30	**2.66**
Above 30	**2.04**

Table 5. ICT equipment usage

ICT Equipment	Percentage of Users
Telephone service	62.2
Mobile/Cell phone	80.7
Text/SMS Usage	63.7

Table 6. Reasons for using cybercafés

Reasons for using Cybercafés	Mean	STDV
Ease of using cybercafé	1.74	0.834
Cost of ISP Services	1.78	1.042
High Telephone charges	1.90	1.004
Affordable Cybercafé Services	1.93	0.872
Cost of Computers – expensive	2.14	0.924
Unreliable telephone services	2.33	1.380
Unreliable Power Supply	2.54	1.318
Lack of Computer Technicians	2.82	1.450

The study finds that 64.2% of the users of cybercafés are in the age-group 19-25 years, 16.2 % are in the age-group of 26-30 years, 13.1% are above 30 years old. Only few, 6.4% are in the age-group of 10-18 years. In the terms of the types of work the users do Table 2 shows the age-group by job types.

Eighty-seven percent of the respondents use computers at least once a week, with about ninety-two percent of the respondents use the Internet at least once a week. Of those connecting to the Internet, about eighty-six percent are connected for at least two hours at a time. Most of the users, 89.2% use the Internet for e-mail. Table 3 shows application areas of the respondents.

On the length of time connected to the Internet, the average connecting time by a user is 2.89 hours. Table 4 shows the average time connected to the Internet at a sitting by age-groups.

If the uses of other ICT (information and communication technology) equipments are considered, Table 5 shows the percentage of the respondents who owe or use the specific equipment and/or application.

Table 6 shows the ranking of the reasons why people use the cybercafé, from the most important using mean ratings and their standard deviations. The lower the mean of a reason the more important is it to the users. The higher the mean of a reason, the least important is the reason for using cybercafé. The standard deviations indicate the variability of the means – the higher the standard deviation of a given reason, the lower the level of agreement among the respondents on the issue

DISCUSSION

In discussing the results of this study, the following interrelated factors, adapted from Peters (2003), are applied to determine the effective utilization of Internet by the people:

1. Physical Access: The VSAT technology has made Internet available and accessible to many people
2. Appropriate technology: VSAT technology is appropriate to the local needs and conditions. There is little dependence on infrastructure, especially, power supply.
3. Affordability: Internet through VSAT technology is affordable to the people. The rate of one hundred naira (less than US$1.00) per hour makes it very affordable to the people. This rate is far less than the hourly rate of $5.40 for Nigeria in 2004 (Daub, 2004). Affordability is important in increasing the number of customers of cybercafé. A change in price regime usually exhibits this fact. (Adomi, 2005)
4. Socio-cultural factors: People are not limited in their use of Internet based on gender and religion. However, one noticeable factor is the paucity of the number of females using the cybercafés. Women have not taken advantages of opportunities available on the Internet.
5. Trust: It is not possible to determine the confidence of the people in the technology in terms of privacy, security or cyber crime. This is because few users use the Internet for any financial transaction
6. Legal and regulatory framework. There are no laws and regulations limiting the use of Internet.
7. Local economic environment: There is presently no local economic environment favorable to the use of Internet. But most institutions that required one kind of registration or other are now encouraging people to online or to make available information about their organizations.

This study reveals several things regarding the cybercafé phenomena. It shows that many people, hitherto, unrecorded, use the facilities in the cybercafés. While efforts are being made by institutions to close the digital divide, greater efforts are currently being undertaken by private individuals to close the divide. It is not uncommon to hear people who have no access to Internet to talk about receiving "mails" through Internet.

The age-group of users of cybercafés indicates that the youth of the country are now conversant with the Internet. This point to the fact that in the very near future, this group will continue to use the Internet

CONCLUSION

If the digital divide is to be bridged, efforts such as the establishments of cybercafés by the private entrepreneur should be encourage by the governments. This study reveals that the private can do more to bridge the gap than the public sector. The operations of cybercafés indicate sufficient understandings of local needs and conditions and attempts to satisfy theses needs through market forces. More people are connected to the Internet than before because of the operations of cybercafés. More people are now empowered in developing countries to overcome development obstacles.

This study is an initial effort to investigate the cybercafé phenomena and the VSAT technology to bridge the digital divide. In the near future, the results of the study shall be compared with similar study in other developing nations so as to understand the differences among the needs of Internet users. In addition, future researches can examine the economic impact of cybercafé in the local economy, and cybercafé and knowledge management in a developing economy.

ABSTRACT

The MySpace phenomenon and the increased use of virtual communities (VC) by large international organisations such as IBM and Procter and Gamble (P&G) confirms the importance of VC in today's society and the global economy. The holistic approach of using modern Internet tools and technologies with social networks presents both opportunity and challenges in the modern era. This paper addresses both the challenges and opportunities presented to communities wishing to establish a virtual cyber-presence. The research outputs are based on a review of academic literature in the area of VC. The research objective of this paper is to review current practices and success strategies as proposed in academic publications and studies.

INTRODUCTION

A virtual community is a community of people with a common interest but not necessarily a common geographic location (Sands, 2003). In their most basic form, virtual communities are websites that allow their users to interact with each other using tools such as discussion forums, 'Blog Spaces', real-time chat and trading areas.

Virtual communities allow companies to build stronger, more cost-effective connections between themselves, their partners and their customers (Roberts, 2006). If planned and executed correctly, VCs can benefit businesses by improving resource allocation, customer service and revenues, as well as lowering operating costs. Furthermore, virtual communities can act as bridges between companies and their customers by fostering product awareness, providing forums for questions and concerns and serving as conduits for feedback to improve future company products.

Virtual communities effectively allow the exchange of vast amounts of information between users scattered globally. Amazon.com, for example, utilises a virtual community to ensure that purchasing customers share information and opinions on their products, and this information can then be used to promote additional sales from other potential customers. This ensures that customers come back to Amazon for this free service that allows them to review what other customers have thought about products there.

The research objective of this paper is to review the challenges of virtual communities as highlighted in academic literature, and then look at suggested solutions to these. The paper will then summarise the findings and propose solutions to the challenges associated with virtual community implementations.

The research methodology employed in this paper will involve reviewing academic literature on the subject of virtual communities with a focus on problems associated with their implementation and uptake.

RESEARCH METHODOLOGY

A literature review was undertaken to obtain an in-depth understanding of the VC research area.

The methodology adopted in this paper is to firstly identify what virtual communities are from the extensive published academic literature. The paper shall continue by summarising the academic literature on the following topics:

- Why virtual communities are needed
- The various types of virtual communities
- Technologies for virtual communities
- Community member roles
- Virtual community life cycle

The paper will then discuss the various problems and challenges associated with virtual communities before outlining several success strategies from the academic literature that need to be followed in order to create a successful virtual community.

VIRTUAL COMMUNITIES

There are many definitions of virtual communities. Sands (2003) describes virtual communities as "*a community of people with a common interest but not necessarily a common geographic location*" that interact over the Internet.

Barnatt (1998) uses a similar definition, describing virtual communities as "*...any group of people who share a common bond, yet who are not dependent on physical interaction and a common geographic location in order to sustain their group affinity*".

Case et al (2001) describe the term 'community' in a traditional sense - i.e. a location where people with similar interests can share experiences, ask questions and collaborate. Members of a given profession can join a community bringing with them a large amount of critical information, knowledge and experience, which they share only occasionally at events such as conferences. Virtual communities, on the other hand, overcome this minimal interaction by connecting geographically disparate groups in real time, through an online environment. This allows them to share knowledge and information with speed, but with little expense. Like traditional communities, virtual communities also act as a repository of information for their members, but they can store a much larger amount of important data (Case et al, 2001). Another advantage for virtual community members is access to opinion leaders and industry experts with a mouseclick with whom they would otherwise never have contact.

One of the most widely used definition of VC is Communities of Practice (CoPs). These link together cross-functional teams that are focused on the same set of business processes (Hagel and Armstrong, 1997). A CoPs is a group of people that share a passion for something they specialise in and who interact on a regular basis in order to learn how to do it better (Wenger, 2004). Each one of us belongs to a number of CoPs (at work, at school, in our hobbies etc.) - we are core members of some communities and in others we are more peripheral (Wenger, 1998). CoPs improve the performance of their members, by allowing them to share the experience or advice of other members (Wenger, 2004).

According to Hagel and Armstrong (1997) the main types of Virtual Community are:

1. Customer-Focused Communities
   - **Geographic Community** - formed around a physical location of common interest, e.g. Amsterdam, South Africa, New York.
   - **Demographic Community** - focused on gender, life stage or ethnic origin. These communities may stimulate a good volume of high-value transactions from members such as teens, single parents, senior citizens etc.

- **Topical Community** - centred on topics of interest such as hobbies, pastimes, sport, politics, culture, etc. An example of this type is the Liverpool football club community.

2. Business-to-Business Communities
   - **Vertical industry Community** – these are widespread forms of early business communities, particularly in high-tech industries (e.g. forming software user groups). For example source forge is a community of open source developers contributing free software components.
   - **Functional Community** – these communities serve the needs of people in specific business functions, (e.g. marketing) and are useful for mutual support and access to information.
   - **Geographic Community** - similar to consumer-focused geographic communities described earlier, in that they are formed around a physical location of common interest. Small businesses may benefit from the ability to exchange information about their concerns and needs with similar companies.
   - **Business Category Community** – members of these communities include SMEs, franchises, and exporters, all of which have a similar need for information, and again a similar benefit from regular interaction with similar businesses. An example of this VC includes the Department of Technology and Industry (DTi) knowledge network.

VIRTUAL COMMUNITIES AND TECHNOLOGIES

Technology plays an important role in the life of many communities (Wenger et al, 2005). The technologies mentioned in this paper are regularly used not only by virtual communities, but also by communities of people that are able to meet face-to-face.

A community implies an experience of togetherness that extends through time and space (Wenger et al, 2005). Therefore recreating this behaviour of personal interaction through technology is vital for a VC to operate successfully.

In acquiesce Hagel and Armstrong (1997) also stress that members are the most important factor in the success of virtual communities - technology is merely the enabler that facilitates the delivery of value to end users.

Wenger et al (2005) state that there is no "perfect" technology configuration – it changes from community to community over time.

The technologies most relevant to virtual communities can be split into:

- Synchronous technologies - allow members of a virtual community to communicate and collaborate in 'real-time'. Instant messaging, video conferencing and whiteboard applications are good examples.
- Asynchronous technologies – allow members to communicate when there is a time difference involved. Examples include discussion boards and E-mail.
- Publishing technologies – allow members to collaborate through information exchange. Blogs, RSS feeds, newsletters, document repositories (including version control) and calendars are used to facilitate publishing.
- Transaction technologies – payment technologies allow members to securely purchase goods and services through the virtual community as well as identifying the parties involved in the transaction. (e.g. Paypal).
- Data Collection and Interpretation Software – allow community organisers to analyse member profiles and participation statistics, in order for them to continually re-engineer the community in order to meet the users' needs.

COMMUNITY MEMBER ROLES

Flavian and Guinaliu (2005) suggest that there are 5 types of roles required in

Table 1. Community member roles

Role Name	Role Function
Coordinators	• Understands the community's business area / industry / interest • Understands which members should talk to each other • Orchestrates community activities • Connects community members • Nurtures the community • Establishes new sub-communities • Optimises the community's structure and design
Moderators	• Respected members of the community • Channels debates in a suitable direction • Manages member-generated content (. bulletin boards, chat areas) and ensures it is suitable for the community • Manages member profiles • Builds up a library of member-generated content. Moderators work with Instigators to decide what content is kept and what is not from bulletin boards and chat areas
Instigators	• Evaluates and searches for useful resources for the community • Voluntarily and respectfully proposes conversational topics to encourage participation • Utilises member profiles from Moderators in order to understand which information is important to the users • Searches for new resources of interest to them
Support Team	• Understands the technical requirements of the community • Provides training for community members • Manages the technology infrastructure - ensures that community members have enough server capacity to store both content and profiles • Ensures that the community is secure • Liaises between the community members and the executive sponsor to ensure that the community delivers its goals • Responds to community's questions effectively without large expenses • Evaluates feedback from a number of sources (such as bulletin boards) in order to keep service levels high • Ensures that community transactions are secure
Executive Sponsor	• Responsible for staffing of the community • Gives investment, guidance and legitimacy to the community • Maximises the community's revenues from advertising and transactions and ensures that the products and services offered to community members are relevant to the their needs

Table 2: Development Stages of a VC (Adapted from Hagel and Armstrong, 1997)

Stage of Evolution Description Key Features
1 Virtual Villages Communities are highly fragmented but profitable businesses, each containing multiple, small sub communities. • Low barriers to entry • Many entrants • Companies participate across multiple communities • Network users sample across multiple communities • May become profitable niche businesses
2 Concentrated Constellations Concentration of core communities, and development of affiliate relationships with niche communities.. • Increasing returns lead to concentration within "core" topics, such as travel, teenage interests, the legal profession etc. • Niche communities benefit from affiliating with core communities
3 Cosmic Coalitions Core communities aggregate across complementary core topic areas (such as sports or music). They do so either because of the proactive efforts of one community organiser or because all see benefits in becoming a wider "co-operative". • Members find value in formation of coalitions, a common user interface and billing, for example
4 Integrated Infomediaries Communities and coalitions evolve into agents for members, managing their integrated profiles to maximise value to members. • Members themselves represent the most efficient location for capture of profiles • Members assert ownership over their profiles (and understand their value) • Specialised infomediaries can organise and maximise value of member profiles

order to keep a VC successful. Wenger et al (2005) believe that there are 3, whilst Hagel and Armstrong (1997) believe there are 9.

This paper builds on the assumption that there are 5 roles, summarised in Table 1.

VIRTUAL COMMUNITY LIFECYCLE

Hagel and Armstrong (1997) believe that in order to create a successful VC the organisers need to understand the possible evolution of both the structure of the community business and the relationships between communities themselves. As such Hagel and Armstrong (1997) proposed an evolutionary route for VCs (Table 2).

Wenger (1998) takes another view to the development stages of a virtual community, described in Figure 1.

BENEFITS FROM VIRTUAL COMMUNITY USE

There are several benefits for all parties using VCs. The main benefit is that VCs allow fast and inexpensive dissemination of knowledge and information between members whilst controlling information overload (Case et al, 2001). Members receive far more information than they would typically be able to access conveniently and cost-effectively in the past. Member's opinions and previous experiences are also disseminated throughout the entire community so benefiting all members (Hagel and Armstrong, 1997).

Benefits to Customers

VCs enable customers to exchange "word-of-mouth" experiences with each other, allowing other potential customers access to a critical evaluation of products or services they are interested in. Companies like Amazon.com have recognised this and built on it using a feedback system with customer comments. The company benefits from satisfied customers' comments to other members of the community. This gives customers the purchasing confidence and encourages return visits to the company. This feedback system works perfectly in a VC rather than in the offline world (Hagel and Armstrong, 1997).

Every new member of a VC increases the value of the community to both the new and existing members. The more members a virtual community has, the more attractive it will become to future members therefore creating a self-feeding cycle.

It is important to stress that the benefits of virtual communities are not related solely to financial transactions and commodities. They allow vital exchange of knowledge between experienced and inexperienced people that would otherwise be difficult to attain.

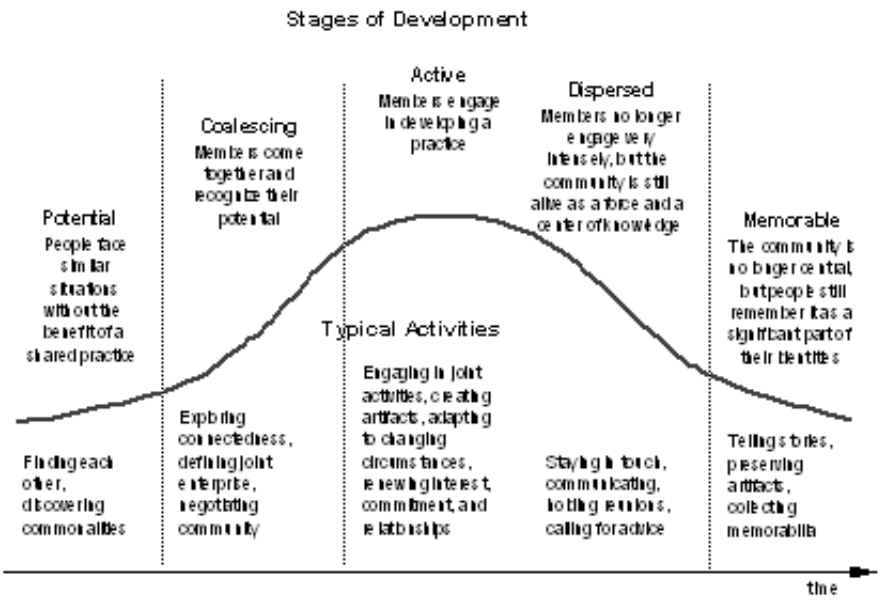
Benefits for Companies

Virtual communities' effectiveness at bringing companies and customers together enables small producers to have a national marketing capability for the price of an online advertisement. The customer feedback obtained from VCs is not only accurate and easy to obtain, it is extremely cost effective, with very little investment required. Companies could easily sponsor a VC in their area of business and converse with members in there to raise their awareness of their products (Hagel and Armstrong, 1997). These factors are all incredibly beneficial to Small to Medium Enterprises (SMEs) where it is vital that production mistakes are kept to a minimum.

Benefits for Individual Members

VCs create benefits for users at an individual level by enabling them to complete their job faster, more effectively, cheaper or even more enjoyably (Roberts, 2006). For example, an employee at a car manufacturer that works on the assembly line

Figure 1. Virtual communities development stages (Wenger,2005)



may have difficulty in one aspect of their job, but when they share this problem on the virtual community, other members can post suggestions to them for new ways of counteracting that problem.

CHALLENGES OF VIRTUAL COMMUNITIES

Despite the benefits there are numerous challenges that stand to impede the success of each virtual community. There is a critical short-term problem for all VC pioneers – the time it takes to establish the critical mass of members (Barnatt, 1998). It is unlikely that the virtual community will show anything but a financial loss in its early years, and attempts to raise short-term income from the new virtual community (such as subscription fees or the selling of members' information on to marketing organisations) are likely to fail.

Another challenge is that virtual communities have very low barriers for exit, meaning that it is difficult to keep that critical mass of members for long periods of time.

Hagel and Armstrong (1997) describe the threat that VC pose to larger organisations as the "piranha" effect. Just as piranhas reverse the principle that bigger fish eat the smaller fish, so too VCs become a threat to big corporations if they flourish in numbers. If more than a handful of these communities survive the first two or three years and are successful in wooing proportions of the customer base, they pose a long-term threat to larger organisations.

VCs will also not be eligible for every business application (particularly when the producer is also the distributor). For example, it is unlikely that many people will want to regularly visit a financial services virtual community. There is a challenge to this type of virtual community, as people are generally interested in each other (in areas such as gossip, news and sports), and not in the latest financial offerings or payment plans (Barnatt, 1998).

Maclaran and Catterall (2002) also raise the point that the discussion traffic on a VC is not evenly spread over 24 hours seven days a week. There may be long periods of inactivity followed by a surge of messages over a shorter time period. Different groups may also be active at different times, so there is a tendency for information overload.

Roberts (2006) highlights the fact that building VCs poses major challenges and risks to the organisers as well as the staff responsible for their design, launch and operation. The corporate landscape has become littered with VCs initiatives that failed to deliver tangible value. Poor preparation, unrealistic expectations and no clear sense of how the virtual community will support organisational goals are cited as reasons why virtual communities fail.

One of the greatest challenges is convincing both potential members and associated companies that participating in VCs is worthwhile. Hagel and Armstrong (1997) believe that the greatest challenge for management is converting traditional wasy of working to the innovative way that virtual communities operate. The company's business model changes from a "push" strategy (whereby companies push products or services onto potential customers) to a "pull" strategy whereby the newly empowered customers dictate the products stocked by the company. This shift in power (from companies to customers) is described as a "reverse market". Hagel and Armstrong (1997) also believe that failing to embrace VCs will result in a loss of opportunity and they will risk becoming squeezed by new players that understand this new phenomenon.

Technology can also be a challenge. Community technology is designed for communities, but is experienced by individual members (Wenger et al, 2005). Therefore, having to take into consideration so many users' needs, designing the appropriate technology is difficult. In fact this challenge is one of the reasons why large companies may avoid launching their own virtual community (Hagel and Armstrong, 1997).

Another issue is the return on investment is generally long term. Those who expect an immediate return on investment may become frustrated. Significant revenues are unlikely to be forthcoming until certain thresholds have been reached, and therefore, initial investments are generally made in an environment of uncertainty and risk. Revenue streams such as member fees are likely to slow the growth of membership substantially and other competing virtual communities may offer the same / similar service for free. Advertising and transaction commission is unlikely in the early years of the virtual community - companies are likely to wait until a critical mass of members has materialised (and usage profiles can be reviewed), which takes time (Hagel and Armstrong, 1997).

SUCCESS STRATEGIES FOR VIRTUAL COMMUNITIES

Despite these challenges, several strategies are proposed by academic researchers to maximise virtual community success. They are as follows.

1. Analyse User Needs

Successful VCs depend on accurate analysis of members needs. The community should be created according to its members' needs and not those of the company promoting it, their advertisers or any other group outside the community (Cothrel and Williams, 1999). The needs of the community members need to be constantly reviewed and refined to ensure that the community is fulfilling its purpose (Flavian and Guinaliu, 2005). Community organisers cannot assume that all their members have the same levels of commitment and therefore the same needs (Wenger et al, 2005). Roberts (2006) states that the following questions ensure the virtual community delivers its goals:

- Who are the intended users?
- How will they be introduced to your community?
- What is the "critical mass" required for the community to be cost-effective?
- How web-savvy is your intended audience?
- What do your intended users really think about the introduction of a virtual community? (Roberts, 2006)

Roberts (2006) cites the example of Mary Kay skin-care, who's IT department invested months of analysis of the company's sales force and back-office needs from every stakeholders' points of view before considering the solutions to meet those needs online. User surveys, industry newsletters and user discussions were all used to allow the organisation to explore what was important in their users' work lives.

Another idea is to review competitors' sites periodically in order to keep abreast of new developments as they occur (Hagel and Armstrong, 1997).

2. Get Members Involved and Strengthen Community Feeling

The key to becoming a successful community organiser over time is their ability to aggregate members, retain them and even encourages them to transact (Hagel and Armstrong, 1997). Flavian and Guinaliu (2005) suggest that the VC should be formed around individuals who are highly motivated and willing to participate in the group - creating a higher commitment to the community. Members should also be able to locate or be directed to relevant people and stored information (Case et al, 2000) therefore fostering a community spirit and so improving members' loyalty to the VC.

The VC which fails to provide immediate, tangible benefits, will fail to impress users. Successful VCs empower users with the ability to perform their current job more effectively (Roberts, 2006).

Hagel and Armstrong (1997) believe that aggregating members, as well as aggregating relevant resources are vital for success. From these, member profiles can be analysed enabling organisers to better understand the needs of their members.

3. Don't Control Members

Freedom to choose the topics of discussion will allow the community to grow freely as will leaving members to resolve their disputes wherever possible. (Flavian and Guinaliu, 2005). A moderator interfering will only result in limiting the amount of information discussed, and eventually drive members away.

Marketers need to create discussion boards and risk allowing members discussing freely not only the company's products but those of its competitors. The results can then be analysed objectively and result in increased trust (Hagel and Armstrong, 1997).

4. Use Suitable Technologies and User Interface

Hagel and Armstrong (1997) propose 4 key guidelines to create a successful technology strategy:

- Use proven technologies
- Use robust technology for information capture and analysis
- Avoid developing any technology in-house, and
- Use a modular technology architecture.

Flavian and Guinaliu (2005) suggest systems that can transmit complex messages (e.g. combining text with images and sounds), in a simple way similar to the way in which members interact offline. Members should be able to locate or be directed to relevant people and stored information with ease (Case et al, 2001). Members should also have access to all the information they require without feeling overwhelmed - the amount of communication and information flow should be intelligently regulated so that the burdens of membership do not outweigh its benefits.

Roberts (2006) suggests starting with a small functional system to deliver results and quickly create a critical following which can then be built upon. The more effective the VC becomes, the more it will impact on its members. Therefore, scale and capacity to perform at the promised level should be considered (Roberts, 2006).

In a community that depends on technologies for interaction, tending to the technology becomes an important role. Wenger et al (2005) state that organisers must keep abreast of the latest technologies - they must then decide which new technologies would apply to the evolving needs of their members.

5. Assign Roles

As described earlier, different roles within the community allow for an increased level of dynamism (Flavian and Guinaliu, 2005). The roles allow the members to concentrate solely on their area, thus promoting a high level of focus within the community.

6. Community maturity

Management of the virtual community is essential. Timely, accurate and relevant content will attract users and make them return (Roberts, 2006). Interesting, provocative material is vital to maintain the conversations. Successful virtual communities require regular monitoring for problems and modifying for the evolving needs of their members (Snyder, 2000). Even the most successful virtual communities are works-in-progress, and user feedback should be used to redesign the web interface (Roberts, 2006).

CONCLUSIONS

This paper has demonstrated that although there are many benefits to adopting virtual communities, there are also several challenges involved that may deter potential community managers from VC implementations. Getting the critical mass of members remains the biggest challenge, due to the low barriers for exit that virtual communities operate within. Without this critical mass, it is difficult to attract members and investment for the community. Other challenges include selecting the correct technology, ensuring continual participation from members, convincing business managers that virtual communities are worthwhile and the fact that virtual communities are not applicable to every type of business application.

The challenges can be overcome, however, by using the success strategies mentioned in this paper. Analysing user's needs (both before development and throughout the lifetime of the virtual community) is a must if the virtual community is to deliver value to the end-user. Encouraging participation, selecting appropriate technologies, allowing members to contribute freely, and assigning roles to community members all aid in making the virtual community a success.

A future research area would be to measure the challenges (and their respective impacts) for each type of virtual community and also classify the importance of each of the success strategies for each type.

The Web Service-Based Combination of Data and Logic Integration in Federated ERP Systems

Nico Brehm, Carl von Ossietzky University Oldenburg, Germany; E-mail: nico.brehm@uni-oldenburg.de
Jorge Marx Gómez, Carl von Ossietzky University Oldenburg, Germany; E-mail: jorge.marx.gomez@uni-oldenburg.de

ABSTRACT

ERP systems become more complex and financial expenditures that are connected to the application of such systems increase. ERP systems consist of many software components which provide specific functionality. However, these ERP systems are designed as an all-in-one solution, often implementing functionality not needed. The paper presents the reference architecture of a federated ERP system which allows the distribution of ERP system components on the basis of Web Services. This architecture draws upon a hierarchical standardization model of data and service types. The model advances the reusability of data types and reduces the necessity of data transformation functions in business process descriptions.

Keywords: ERP, FERP, Web Services, Web Service Standardization, WSDL, SOA

1. INTRODUCTION AND MOTIVATION

An *ERP system* is a standard software system which provides functionality to integrate and automate the business practices associated with the operations or production aspects of a company. The integration is based on a common data model for all system components and extents to more than one enterprise sectors [1, 2, 3, 5].

Modern ERP systems consist of many software components which are related to each other. Currently these components are administered on a central application server. In connection to the ERP system complexity several problems appear:

- Not all installed components are needed.
- High-end computer hardware is required.
- Customizing is expensive.

Due to the expensive proceedings of installation and maintenance only large enterprises can afford such complex ERP systems. One solution to face these problems is to develop a distributed ERP system where the system components are reachable over a network (e.g. internet). This component ensemble (federated system) still appears as single ERP system to the user, however it consists of different independent elements which exist on different computers. Based on this construction it is possible for an enterprise to access on-demand functionality (components) as services[1] of other network members over a P2P network. This approach solves the mentioned problems as follows:

- Due to the separation of local and remote functions, no local resources are wasted for unnecessary components.
- Single components are executable on small computers.
- Due to decreasing complexity of the local system also installation and maintenance costs subside.

A *federated ERP system* (FERP system) is an ERP system which consists of system components that are distributed within a computer network. The overall functionality is provided by an ensemble of allied network nodes that all together appear as a single ERP system to the user. Different ERP system components can be developed by different vendors [1, 4].

Figure 1. Architecture of a conventional ERP system

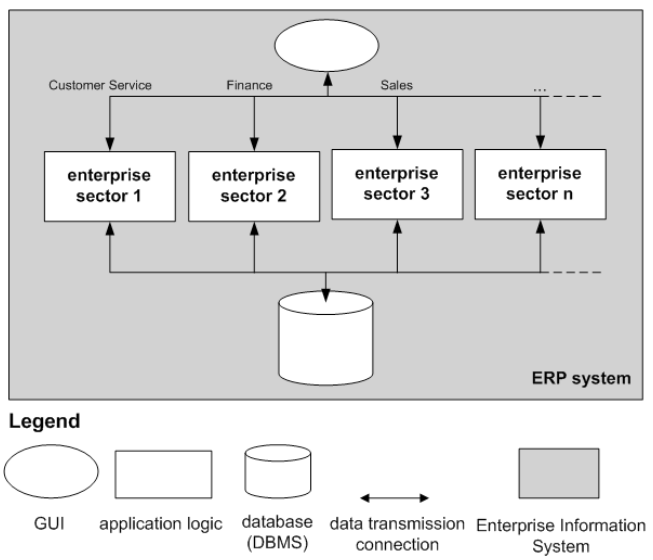

Figure 2. Vision of a Federated ERP system

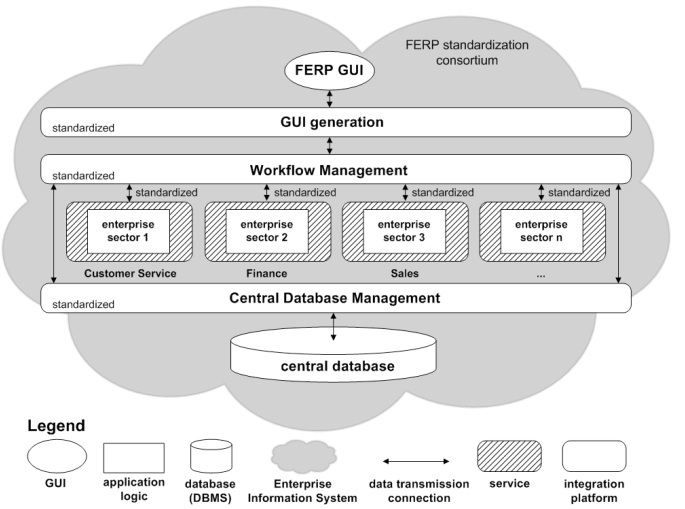


In this paper we present an FERP system based on Web Services. The main idea follows the multi-layer paradigm of modern information systems which aims at the separation of the application logic from the presentation layer and the database layer. In our approach the application logic of ERP systems is encapsulated in a multiplicity of Web Services which can be provided either locally or remotely. The vision of this approach is to allow the application of business logic components in a distributed manner. In order to facilitate a vendor-independent development and provision of those components the approach considers the standardization of Web Services as well as GUI descriptions and database interactions. The standardization process is supposed to be advanced by a consortium of ERP vendors, utilizing enterprises and scientific institutions (*FERP standardization consortium*). Figure 2 shows the abstract architecture of the presented approach.

2. REFERENCE ARCHITECTURE

Figure 3 gives a survey of the reference architecture of a Web Service-based FERP system. The architecture consists of several subsystems which are interconnected. Because one of the main objective of an FERP system is to integrate business components of different vendors, all components have to comply with standards. In this approach these standards are described as XML schema documents. In order to separate the three different layers of a typical layered architecture of conventional ERP systems each layer is assigned to its own standard.

The subsystems of the proposed architecture are the following:

FERP Workflow System (FWfS)
The FWfS coordinates all business processes which have to be described in an appropriate XML-based workflow language. A workflow in this context is a plan of sequentially or in parallel chained functions as working steps in the meaning of activities which lead to the creation or utilization of business benefits. Workflows implicitly contain the business logic of the overall system. The function types a workflow in FERP systems can consist are the following:

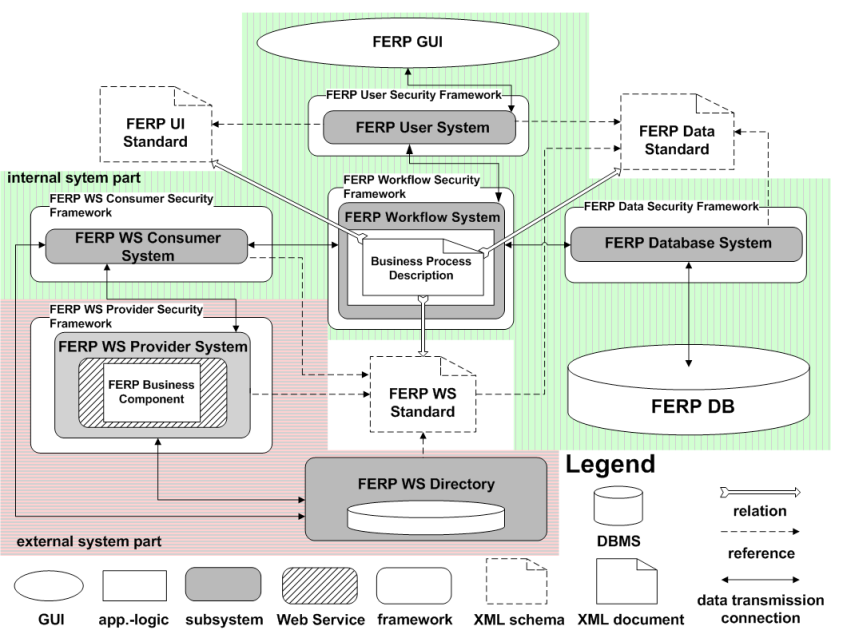
- model based user interface functions, e.g. show, edit, select, control
- database access functions, e.g. read, update
- application tasks which are connected to Web Service calls

FERP User System (FUS)
The FUS is the subsystem which implements functions for the visualization of graphical elements and coordinates interactions with end users. This subsystem is able to generate user screens at runtime. Screen descriptions which have to comply with the *FERP UI standard* are transformed to an end device-readable format, e.g. HTML in case of web browsers.

FERP Database System (FDS)
The FDS is the subsystem which implements functions for the communication with the FERP database. This subsystem is able to interpret XML structures which comply with the *FERP data standard*. The interface differentiates between two kinds of requests. Database update requests contain object oriented representations of business entities as XML trees. Database read requests contain X-Path or X-Query expressions specifying portions of data to be extracted. In both cases the request parameters have to be transformed into different types of request statements that vary depending on the type of database management system (DBMS) which is used. Assumed that a relational DBMS (RDBMS) is used the underlying data model also has to comply with the FERP data standard which means that the corresponding table structure has to reflect the XML-Schema specifications respectively. The java.net project *hyperjaxb2*[2] provides a solution to generate SQL statements on the basis of XML schema definitions. Another solution is the application of native XML databases or XML-enabled RDBMS.

FERP Web Service Consumer System (FWCS)
The business logic of FERP systems is encapsulated in so called FERP business components which are wrapped by a Web Service. The FWCS is the subsystem which provides functions for the invocation of Web Services. All possible types of FERP Web Services are specified by the *FERP WS standard*. This standard contains XML schema definitions which describe Web Service operations as well as input and output messages. A Web Service references these types in its description which is expressed in the Web Service Description Language (WSDL) which is the common standard for the description of Web Services and is already well supported by tools. Furthermore this subsystem is able to search for Web Services which are defined by a unique identifier. By this it is possible that different Web Service providers implement the same business component type as Web Service. Beside the implementation of Web Service invocation and search functions this subsystem is responsible for the interpretation and consideration of non-functional parameters. Examples for those parameters are: security policies, payment polices or Quality of Service (QoS) requirements on the part of Web Service consumers.

Figure 3. Reference architecture of an FERP system



FERP Web Service Provider System (FWPS)
The FWPS is the subsystem which implements functions for the provision of Web Services which comply with the FERP WS Standard. The subsystem includes a Web Server which is responsible for the interpretation of incoming and outgoing HTTP requests which in turn encapsulate SOAP requests. The subsystem provides business components of the FERP system as Web Services. A connection to the *FERP Web Service Directory* allows the publication of Web Services. Furthermore this subsystem is responsible for the negotiation of common communication policies such as e.g. security protocols or usage fees with the requesting client.

FERP Web Service Directory (FWD)
The FWD provides an interface for the publication and the searching of FERP Web Services based on the UDDI standard. The structure of this registry leans on the FERP WS standard. In this standard Web Services are assigned to categories mirroring the predetermined functional organization of enterprises.

3. HIERARCHICAL XML SCHEMA STRUCTURE

The proposed architecture is dependent on the specification of different standards. The next two paragraphs focus on the standardization of FERP data types and Web Service operations in the context of FERP systems. Because of the complexity of enterprise data models and the difficulty to standardize a completed data model we propose a hierarchical standardization model which allows different abstraction levels. This model uses XML namespaces for the representation of hierarchical levels and XML schema documents for the definition of data types and their relationships. The reason for the usage of XML schema documents is

Figure 4. Extract of the hierarchical Easy Access® menu of an SAP/R3® system[3]

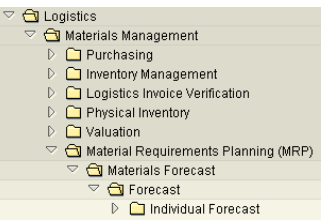


Figure 5. Hierarchical XML schema structure of an FERP system

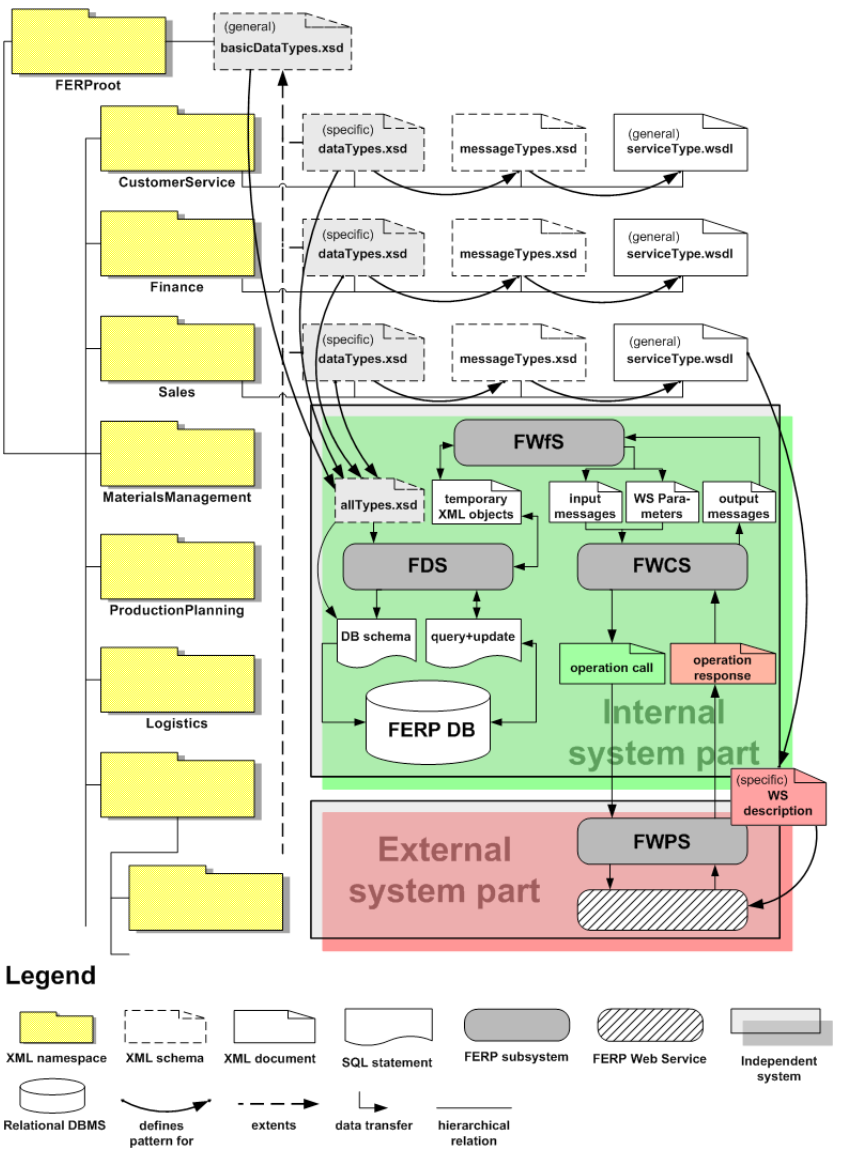


their compatibility with WSDL. The interoperability between FERP Web Services and the FDS is achieved by a transformation of XML schema-based data model descriptions to SQL-based data model descriptions. Web Service Descriptions in WSDL reference the FERP data standard by including the appropriate XML schema documents of the standard. In order to standardize the input and output messages of FERP Web Services we propose the usage of XML schema documents as well.

Figure 5 shows the hierarchical XML schema structure of an FERP system and shows the influence on the systems activities. The left hand side represents different enterprise sectors which are assigned to XML namespaces. This hierarchy can be compared to the internal structure of the application logic of conventional ERP systems which is often mirrored to the navigation structure of their GUI. Figure 4 shows the function hierarchy of the Easy Access® menu of an SAP®/ R3® system.

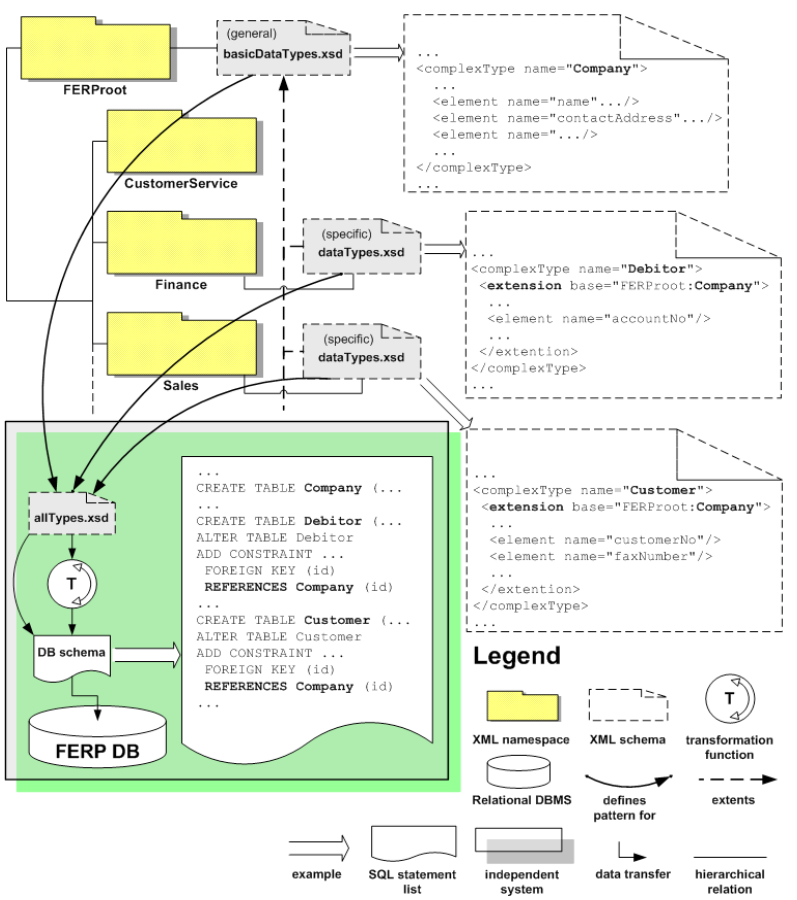
The upper half of figure 5 shows the relationships between XML schema documents and concrete Web Service descriptions. Standardized Web Service input and output messages (defined in *messageTypes.xsd*) build the basis for the standardization of Web Service types (described in *serviceTypes.wsdl*). The lower half of figure 5 shows the interactions between the different subsystems of the FERP system. The system internally creates a new XML schema document (*allTypes.xsd*) which includes a copy of all standardized data types that are used in process definitions. The system has a connection to the server of the FERP standardization consortium and will be notified in the case that the standard changed. Those changes are only allowed in terms of extensions. Thereby old versions will be supported during the whole lifetime of the standard. The hierarchical structure provides a useful foundation for this requirement because it is already field-proved in the context of object oriented programming paradigms like polymorphism, generalization and specialization. The local XML schema representation will be transformed to a relational representation of the data model as SQL statement list (see the example in figure 5 in the next paragraph). In addition to the schema transformation the FDS is able to transform SQL result sets to XML documents that comply with the FERP data standard in the case of *DATABASE_LOAD requests*. On the other hand XML documents will be transformed to SQL INSERT or UPDATE statements in the case of *DATABASE_STORE requests*. Both LOAD and STORE functions are provided by the FDS and can be used by the FWfS.

Web Service calls are initiated by the FWfS as well (see figure 5). Therefore the FWfS sends a standardized XML representation of the appropriate input message to the FWCS. A second XML document contains configuration parameters which specify the concrete Web Service provider to be chosen by the FWCS. Those parameters include either a URL for a static Web Service call or requirements for a dynamic call like e.g. a maximum price. An alternative way for the specification of requirements for dynamic calls is a centralized mapping between Web Service types and requirements. Once the FWCS chose an appropriate Web Service provider it will repack this message to a *SOAP operation request* which includes the standardized name of the Web Service operation to be invoked. This request will be sent to the FWPS. After having finished the processing of the business logic the FWPS will return a SOAP operation response which includes a standardized response message. Figure 5 shows how this response message is going to be sent back to the FWfS that primarily initiated the Web Service call.

4. DATA INTEGRATION OF DIFFERENT ENTERPRISE SECTORS

One of the main reasons why ERP systems have been achieving success in the past is their data-driven view towards the integration of different enterprise sectors. As defined above "*this integration is based on a common data model for all system*

Figure 6. Example for the hierarchical enterprise data integration



components and extents to more than one enterprise sectors" (see paragraph 1). The presented architecture of a Web Service-based FERP system reaches this integration by the hierarchical XML schema structure which is mirrored to the relational data model. Figure 6 shows an example for this hierarchical XML schema structure. In this example the general type *Company* has two specialized representations, *Debitor* and *Customer* which define additional elements. These elements can be seen as individual properties of the assigned enterprise sector. Because the FERP DB uses separate database tables for the management of these records, updates will also influence related enterprise sectors which share the same table for all general elements. We tested this functionality by the application of the *hyperjaxb2*[4] framework which draws upon *JAXB*[5] and *Hibernate*[6].

5. RELATED WORKS

The intra-enterprise integration of business application systems is commonly abbreviated as EAI[7]. According to the 3-tier architecture of business application systems today's EAI platforms support the integration over all three tiers. Enterprise portals mainly provide a basis of the consolidation of existing software systems on the user interface level which means that portals feature a user-centric orientation [8]. The Web Services paradigm implements a Service-oriented architecture which presupposes a middleware for the management of services. Search and publication requests are processed by this middleware. Business Process Management (BPM) platforms support the orchestration of such services. Thus it is possible to centralize Web Service accesses in business process definitions. In some cases EAI platforms support both a portal functionality and a BPM platform in combination with each other.

Disadvantages of domain-independent BPM platforms as foundation for the implementation of Web Service-based ERP systems are the following:

- XML object representations have to be transformed to different data models (XML schemas) when independent Web Services are used in one process because in most cases no common standard[8] is referenced in independent Web Service descriptions.
- XML object representations of Web Service return values have to be transformed to SQL statements[9] in the case that return values have to be stored in an external database. This transformation has to be part of the business process definition. Because of this problem Web Services often are assigned to their own database which is directly accessed by the business logic of a Web Service. The problem of this solution is that Web Services cannot be exchanged if they are provided externally[10] because the connected database will be not available anymore. Another problem is that such a solution would not comply with the definition of an ERP system (see paragraph 1) where the integration of different enterprise sectors is achieved by the usage of a common data model. Therefore conventional ERP systems use a central DBMS whereby also the management of database transactions is simplified.
- Input values for Web Services which have been extracted from the enterprise database have to be transformed from a database result set representation to an XML object representation which complies with the respective Web Service description.

The presented approach of a Web Service-based FERP system offers the following advantages that all together address actual challenges of business process modelling approaches[11]:

- Output values of Web Services can be directly used as input values for other Web Services because all Web Service definitions reference the same standard.
- Output values of Web Services can be transmitted to the FDS directly because both implement the same data model.
- XML object representations which have been extracted from the FDS can be used straightforward as input values of Web Services because both, the data model of the FDS and the parameter description of each Web Service comply with the same standard.

Another neighbouring working area is represented by Federated Database Systems [9] which are a type of Meta-DBMS. Those systems integrate multiple autonomous DBMS to a single system. This integration is achieved by schema mapping techniques. One solution for the data integration in Web Service-based ERP systems could be the utilization of a Federated Database System in order to consolidate independent DBMS which are directly assigned to Web Services. The Federated Database System would represent a central entry point to a decentralized DBMS structure which in turn would comply with the definition of an ERP system. This solution has the following disadvantages in comparison to the presented approach:

- Enterprises are dependent to Web Service providers who also provide one part of the database federation. In the case that different providers offer the same Web Service type a migration from one provider to another implicitly necessitates data migration.
- A global schema[12] indeed can define a normalized data model but redundancies in the overall network of independent DBMS are possible anyway. Because Web Services would directly access their local DBMS duplicate entries in the DBMS federation could lead to complications when a process or another Web Service accesses the central Federated Database System.

In comparison this approach, an FERP-system has the following advantages:

- A migration from one Web Service provider to another does not influence the data view because all data is stored in a central database which can only be accessed by a local[13] process. Web Services have no direct database connection.
- Because the hierarchical FERP standard considers the combination of Web Services' duties and affected data each level in the hierarchy is assigned to unique operation and data types. Furthermore the inheritance support allows a reutilization of general data types. Thereby redundancies in the database can be avoided because on the one hand existing data type definitions can be reused for new Web Service definitions and on the other hand standardized Web Services which use existing data types will create redundancy-free[14] data.

6. CONCLUSIONS AND OUTLOOK

Comparing distributed ERP systems and ERP systems running on only one computer, the distributed systems offer a lot of advantages. Particularly small- and medium sized Enterprises (SMB) benefit from using shared resources. However, the design of distributed system architectures is subject to a number of problems. The paper addresses the problem of redundant data in business application systems of independent vendors presents a basis for the standardization of ERP system components that are provided as Web Services. A standardized data model builds the basis for message and service standardization. The hierarchical structure of the presented standard advances the reuse of existing data types. Furthermore we presented a reference architecture of FERP systems which reduces the necessity of data transformation functions in business process descriptions.

The standardization of the syntactic level is only the first step. Behaviour, synchronization and quality of Web Services must flow into the definition of an overall ERP system standard. The future work must pick up these problems to realize the vision of a loosely coupled ERP system which allows the dynamic outsourcing of applications [5, 7] and the combination of software components of different providers.

ACKNOWLEDGMENTS

This paper has drawn upon opinions and views of many colleagues. In particular we acknowledge the review of Lars Gersmann who defined his practical position as an experienced software engineer and highlighted practical advantages of our approach which even influenced the title of this paper. Furthermore we thank Inty Saez for his review which gave us more ideas for the prototypical implementation of the presented reference architecture which is still in progress. Last but not least, also a special thanks in this order to the students of the University of Oldenburg who jointly performed lots of test implementations which delivered the foundation for many architectural design decisions. At the moment we are testing YAWL[15] as basis for the prototypical implementation of an FWfS.

Study on Factors Underlying Students' Ethical Decision Making in Music File Sharing

"John" J. H. Im, Sacred Heart University, 5151 Park Avenue, Fairfield, CT 06825, USA; E-mail: imj@sacredheart.edu

ABSTRACT

Business ethics is at a high stake in view of a rash of recent unethical business scandals. Business schools are defensive in a barrage of blames for not teaching business ethics effectively to their students. The college of business at SHU is particularly sensitive to this issue since it has been proud of its Catholic intellectual tradition and has been doing its best to comply the requirements by AACSB for the accreditation. This study will help us to understand factors underlying in our business students' ethical decision making and to address those factors effectively in the business curriculum so that they will behave more ethically by respecting others' intellectual properties. One limitation of this study is that we measure our students' ethical behavior based on only one matter, music file sharing.

INTRODUCTION

Concerns on business ethics are raised very high nowadays in a wake of a series of recent business scandals caused by high-profile executives in well known companies such as Enron, Anderson, Tyco, ImClone, Boeing. Some of those misconducts are often attributed to the excessive compensation structure with stock options that tempts top executives to manipulate business results for option holders' short-term interests at the cost of everyone else. Desire for high achievements in today's hyper-competitive business environment may also pressure profit-obsessed top managers to make unethical decisions to maximize economic benefits. As a way of remedy, there are various discussions on corporate-governance reforms (Hannafey, 2003; Tipgos, 2002; Watkins, 2003). For instance, top executives' compensation may be linked to a company's long-term achievements to alleviate the pressure for short-term profits. New York Stock Exchange would require companies to have a majority of independent directors as a better way to supervise top executives. Certainly, those governance reforms may help thwart some fraudulent conducts. However, many of misconducts are rooted in the socio-cultural and behavioral factors such as greedy personality, lapse of business ethics, unhealthy organizational culture.

Can managers learn how to behave ethically? If possible, who can teach them? For decades, business schools have taught business ethics in various ways to their students. Also, accreditation bodies like the Association to Advance Collegiate Schools of Business (AACSB) require an ethical component in their curricula. However, recent ethical lapses in business circles put business schools under close scrutiny. Media put blames on lax ethics education in business schools that are busy teaching core and tangible materials (Etzioni, 2002; Merritt, 2003; Wall Street Journal, 12/30/2003). There are several researchers who studied business students' perception of ethics. Elm, et al (2001) claims that "business students have lower moral reasoning levels than students in other fields." Angelidis and Ibrahim (2002) reported that there was no significant difference between business students at secular and non-secular uniervities. Richards, et al (2002) urges business schools to assess ethics education needs in their own MBA programs, particularly if they have not added significant ethical content to their curricula. Sankaran and Bui (2003) measured ethical attitude among accounting majors and compared with other business majors and non-business majors. While reviewing the trends in ethics education, Farnsworth and Kleiner (2003) assert "Ethics should be a required course in US colleges and universities because the study can initiate the process to address these challenges." Procario-Foley and McLaughlin (2003) and Stablein (2003) agreed that business students should be more exposed to ethics in their business education.

ETHICS EDUCATION

In 2003, the college of business at the Sacred Heart University (SHU) its core curriculum for undergraduate students to properly address the AACSB guidelines as part of its self-study for the long-awaited accreditation. One of the focal issues was whether a business ethics course should be required as a core course for all business undergraduate students like the MBA curriculum. A majority of the undergraduate curriculum committee members voted not to do, but to ask instructors to teach the concept of business ethics in their courses since each disciplinary area such as accounting, marketing, finance, human resource management, sport management may better address its own ethical decision making cases. However, the faculty voted to require a business ethics course for all business students when the dean insisted to do as a way to show the college's strong commitment to ethics particularly in compliance with the SHU's Catholic intellectual tradition, which is reflected in the college's newly drafted mission statement, as follows:

"Our values are within the Catholic intellectual tradition: …We stress ethical decision making … We strive to develop professionals who will act ethically, morally, and responsibly." (Mission Draft, 2004, p. 1).

Learning business ethics is one thing and doing ethical decision making is another thing. The lingering question is how positively a business ethics course affects a business student's ethical decision making. As a way to answer this question, we decide to see any difference in business students' ethical decision making before and after taking a business ethics course. Rather than developing some ethical decision making scenarios, we pick a real issue, music file sharing, which many college students have been participating in though they know that it's illegal and unethical. It is reported that at least two SHU students have been named for inclusion in an RIAA (Recording Industry Association of America) lawsuit brought against computer users who download and share copyrighted materials. If students knowingly participate in this kind of unethical behavior, how can we expect them to respect intellectual properties when they become managers later? We want to know what excuses they have so that we can better address those in our business ethics education.

Business ethics is at a high stake in view of a rash of recent unethical business scandals. Business schools are defensive in a barrage of blames for not teaching business ethics effectively to their students. The college of business at SHU is particularly sensitive to this issue since it has been proud of its Catholic intellectual tradition and has been doing its best to comply the requirements by AACSB for the accreditation. This study will help us to understand factors underlying in our business students' ethical decision making and to address those factors effectively in the business curriculum so that they will behave more ethically by respecting others' intellectual properties. One limitation of this study is that we measure our students' ethical behavior based on only one matter, music file sharing.

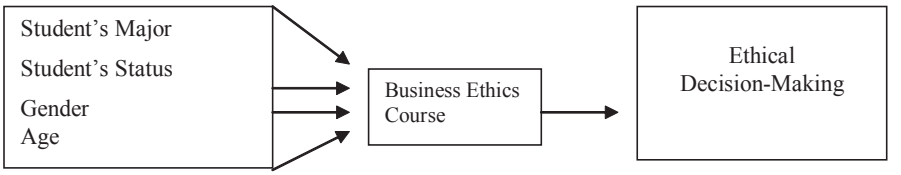
RESEARCH METHOD

The conceptual framework of the study is shown in Figure 1.

There are five research questions, as follows:

- Research Question 1: Ethical decision making of business students becomes different after taking a business ethics course.

Figure 1



- Research Question 2: Ethical decision making of business students is different by major.
- Research Question 3: Ethical decision making of MBA students is different from that of business undergraduate students.
- Research Question 4: Ethical decision making of female students is different from that of male students.
- Research Question 5: Ethical decision making of old students is different from that of young students.

To find answers to those questions, we developed a questionnaire as shown in the appendix 1. The section 1 is to collect demographic data and the section 2 is for a respondent's perception on the issue. In the section 3, we listed two questions for each of the six ethical principles explained in an MIS textbook: (1) The Golden Rule, (2) Immanuel Kant's Categorical Imperative, (3) Descartes' rule of change, (4) Utilitarian Principle, (5) Risk Aversion Principle and (6) Ethical "no free lunch" rule (Laudon & Laudon). Data has been collected form SHU students who are business school undergraduates and MBA students. Computer science major students are included in order to compare the effect of their major (business management vs. computer science). Since the registering of the survey is included by selection rather than by manipulation, it is not an experimental research design. Therefore no causal relationships can be inferred. Instead, descriptive statistical analysis will be reported. According to the research questions 1 through 5, there are four independent variables in the study: students' major, status (undergraduate vs. graduate), gender and age.

Reliability is defined in practice in terms of internal consistency of the responses from the participants. Internal consistency is the extent to which the individual items in the questionnaire correlate with one another or with the instrument as a whole. To demonstrate the reliability of the instrument, Cronbach's alpha will be calculated. Construct validity of the questionnaire will be demonstrated by factor analysis. For the research question 1 through 4, Chi Square test of Independence will be performed based on data for section 2 in the survey, and t-test based on data for the section 3. Qualitative data for the section 4 in the survey will be gathered and analyzed. For the research question 5, One-way Analysis of Variance (ANOVA) — treating the dichotomous criterion variable (yes or no) as dummy variable — will be performed based on data for the section 2 in the survey. One-way ANOVA with one-between groups design will be performed based on data for the section 3.

DATA ANALYSIS AND DISCUSSION

(Will be done later)

SUMMARY AND RECOMMENDATIONS

(Will be done later)

ABSTRACT

Throughout the last few decades, the state of North Carolina has voted to put both Republicans and Democrats in elected positions. The election of 2004 was no exception. North Carolina voted for a Republican president and a Democratic governor. This research seeks to understand the reasons for this voting pattern by focusing on one the largest counties in North Carolina, Guilford County. Guilford County was used for this study since it was one of the few counties in North Carolina that votes democratic. This research is an attempt to discover pattern and insight on voting habits based on the demographics of homeowners, house values and the age of property. This research will be beneficial not only to political parties but also to the citizens of Guilford County who want to see the data and unique comparisons between voting records and housing information

INTRODUCTION

Throughout the last few decades, the state of North Carolina has voted to put both Republicans and Democrats in elected positions. The election of 2004 was no exception. North Carolina voted for a Republican president and a Democratic governor. Since 1964, North Carolina has only given its electoral votes to the Democratic Party twice – 1964 (Johnson) and 1976 (Carter). 2004 continued this same voting behavior from previous elections. George W. Bush (R) garnered 1.96 million votes while Mike Easley (D) won nearly as many votes as the president with 1.94 million. Guilford County is one of few counties in North Carolina that voted Democratic in both the presidential and gubernatorial 2004 elections. Overall exit polls for North Carolina indicated that income and demographics played a strong role.

A County-by-County election return data from *USA Today* (Vanderibei, 2004) together with County boundary data from the US Census' Tiger database. Blue for Democratic, red for Republican, and green is for all other. Each county's color is a mix of these three-color components in proportion to the results for that county (Vanderbei, 2004). Clearly this map indicates that there are pockets of voters who are more likely to vote one way of the other solely based on their locations. It is also interesting to see that the density of voter participation is also closely related to what is shown in Figure 1. In Figure 2, the voter density of most urban areas shows a distinct propensity to vote democratic. It is interesting to note that the concentration of minority voters in urban areas is much higher than that of rural area and as seen in both figures 1 and 2, these voters tend to vote democratic.

This research, we were interested in understanding the voting patterns for a specific southeastern county in the United States and to see whether the broader presented reached earlier holds for this county as well.

Specifically we were interested in:

- Map and validate the North Carolina exit poll data to Guilford County for the 2004 election

Figure 1. County-by-county election returns in Presidential Election of 2004

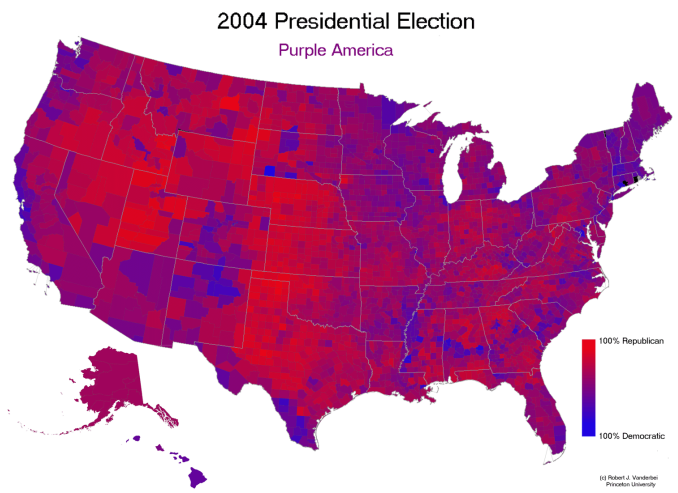

Figure 2. Voter density in 2004 Presidential Election

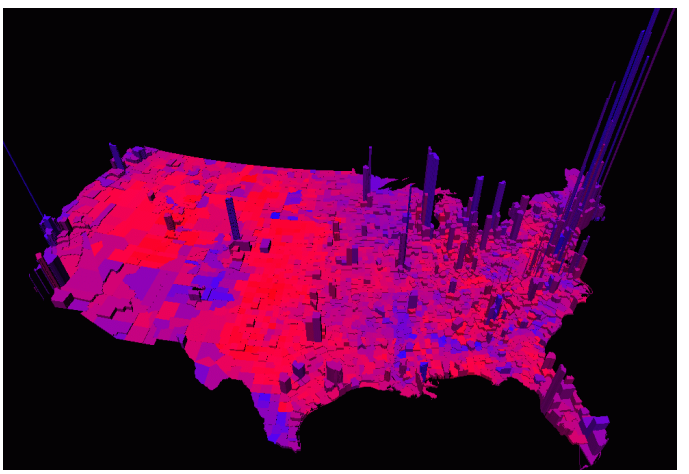

- Determine presidential and gubernatorial voting behaviors for precincts in Guilford County
- Map home values in precincts to voting behaviors
- Map age of the home to voting behaviors

In 2004, Guilford County broke from the "North Carolina pattern" in a slim fashion to vote for John Kerry, the Democratic challenger. Guilford County was one of a minority of counties in the state to vote for Kerry over George W. Bush. In addition, Guilford County was one of the 14 counties that made up 50% of the presidential vote in 2004. In addition to Guilford County, Orange County and Durham County were three of these fourteen counties that voted for Kerry (Guillory, April 2005). It has been widely held that Guilford County tends to lean democratic due to the combination of several factors Paul Shumaker, a political consultant for the Republican Party, states "Large urban counties and counties with a large public university presence provided the best results for Democrats." (Shumaker, April 2005). It can certainly be argued that Guilford Country has a strong educational infrastructure with schools such as UNC-G, NC A&T, Guilford College and Greensboro College. In addition, an argument can be made that this county has an active Democratic contingent and did an excellent job of promoting early voting. Most importantly, Guilford County has a sizable minority population. But what are other factors that impact this pattern of voting. According to 2004 exit polls conducted by Edison/Mitofsky, it appears that in general, suburbs in North Carolina vote strongly Republican while urban areas tend to vote evenly for both sides. In addition, voting by income reveals that incomes under 30K vote democratic versus incomes over 30K that vote republican (*Southnow*, April 2005). Is there a relationship between the value of a house and the voting behavior of the homeowner? Are there correlations between the voting behaviors of precincts and the value of the homes in those precincts?

Focusing on present housing statistics, voter demographics and votes cast in Guilford County in the 2004 election, this research project will seek to validate the exit poll results from Edison/Mitofsky as they pertain to Guilford County? Our research group intends to validate these findings in Guilford County by matching home value to income through a 40% rule of mortgage to income as well as define precincts as being in the city of Greensboro – urban – or outside of Greensboro but within Guilford County - rural. We anticipate that while most of the results match this exit polling, our research will also support the data that "In terms of electoral politics, the attitudes of both groups of voters (Republicans and Democrats) reflect the divided nature of an electorate in which neither major party commands a majority of popular support" (*Southnow*, April 2004).

This research is an attempt to discover pattern and insight on voting habits based on the demographics of homeowners, house values and the age of property. This research will be beneficial not only to political parties but also to the citizens of Guilford County who want to see the data and unique comparisons between voting records and housing information

DETAILED DATA MINING USING GIS DATA

In order to validate that North Carolina exit poll data (Edison/Mitofsky 2004) applies to Guilford County, this research project will focus on the following data points:

- present housing statistics
- voter demographics
- votes cast in Guilford County in the 2004 election

In addition the data mining of the GIS data would allow us to have a better understanding to the following questions:

- Do higher home values translate to Republican votes?
- Do lower home values translate to Democratic votes?
- Do precincts that are considered urban or metro vote democratic? Are there strong levels of home ownership in these districts and do they vote democratic as well?
- Do the "rural" precincts in Guilford County – outside of Greensboro city limits – vote republican?
- Do residents of identically valued houses in different neighborhoods vote the same or different?
- Are there particular precincts that split their votes or vote straight ticket?
- Are there particular home values that split their votes or vote straight ticket?
- Is there a correlation between home values and presidential and gubernatorial election results?
- How should precincts with lower numbers of homes for sale be scrutinized for other forms of housing such as rental apartments?

Our research intends to validate these findings in Guilford County by matching home value to income through a 40% rule of mortgage to income as well as define precincts as being in the city of Greensboro – urban – or outside of Greensboro but within Guilford County - rural. We anticipate that while most of the results match this exit polling, our research will also support the data that "In terms of electoral politics, the attitudes of both groups of voters (Republicans and Democrats) reflect the divided nature of an electorate in which neither major party commands a majority of popular support" (*Southnow*, April 2004).

Through this analysis, we intend to prove that in addition to the more widely understood, race and as predictor of voting preference, home value also plays somewhat of an indicating role in how precincts vote. Certain home value ranges will prove to be a wash. Precincts with lower home values will prove to vote democratic. Precincts with higher home values will prove to vote republican.

There are several assumptions that need to be considered in this project. We assume that:

- 40% of the combined income of individual or family translates to the assumable mortgage of a home
- The value of a house translates roughly to a home mortgage financed at 90%
- The value of a home is a close indication of the income of the owner
- Cities with universities tend to vote Democratic
- Precincts within the city limits of Greensboro will be considered urban
- Precincts within Guilford County but outside of the city limits of Greensboro will be considered rural

We were interested in studying whether using the age of the house, the tax value of the house and demographics of the homeowner can be used to predict the voting behavior of the homeowners.

We used the following commonly understood relationship between the value of the house and the income of the occupants. Based on the formula:

Value of house = 40% of (combined) income

Using this formula, we construct the following propositions:

- **< $30,000 income translates to $75,000 home and these voters tend to vote Democratic**
- **$30,000 – $50,000 = $75,000 - $125,000 home with no differentiation between parties**
- **$50,000 –$ 75,000 = $125,000 - $187,500 home with no differentiation between parties**
- **$75,000 – $100,000 = $187,500 - $250,000 home with no differentiation between parties**
- **> $100,000 translates to $250,000+ house and these voters tend to vote Republican**

IMPLEMENTATION

The data was analyzed and mined to determine the validity of the conventional wisdom. In addition to using Microsoft Excel, the project team also used mining tools provided by Microsoft Analysis Services in the SQL 2005 suite. In combination with these analysis tools, the project team also relied on data visualization tools through the use of GIS – geographic information system.

A data warehouse was developed using dimensional modeling approach to be the feeder for our data mining tools. This data warehouse is used to store:

- Precinct data including precinct ID, city, county, and precinct name,
- Voter registration statistics including voter registration, sex and ethnic background
- Presidential and gubernatorial voting data from 2000 and 2004
- Housing data including the average home value in the precinct, average value per square foot, age of home, and average year built.

Figure 3. Dimensional model used for data warehouse

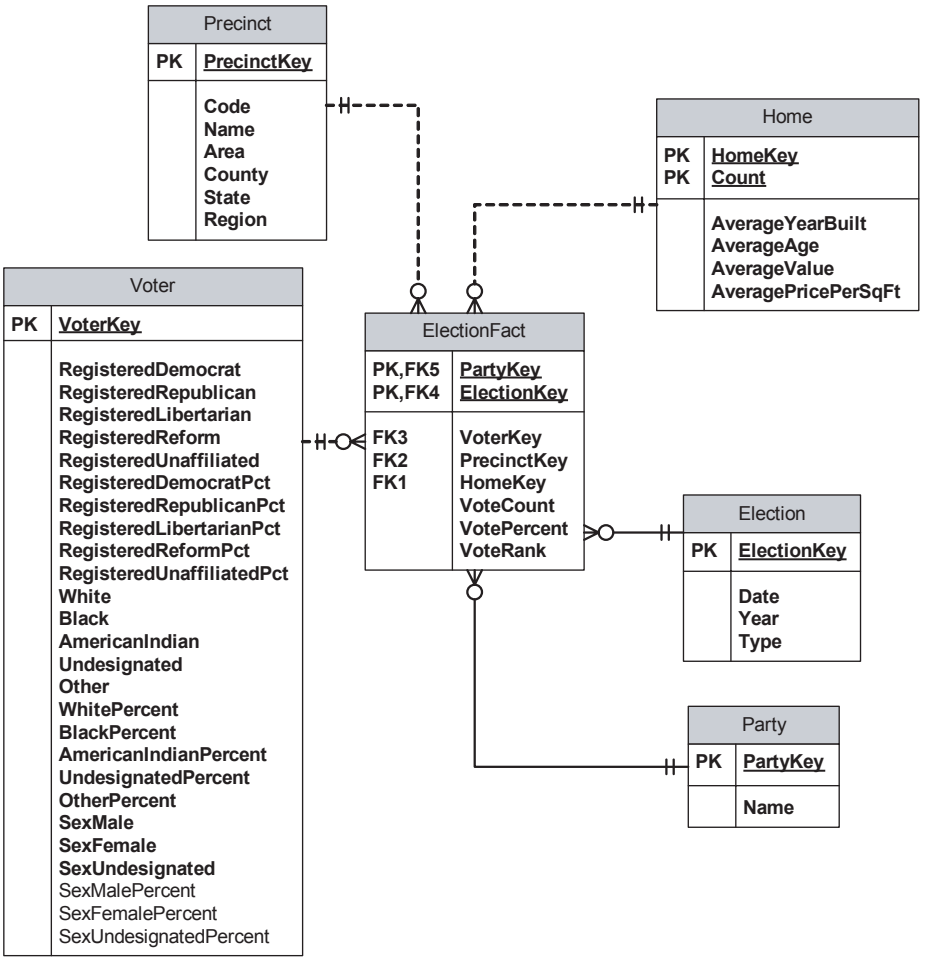

Figure 3 depicts the dimensional model used for this data warehouse.

To populate this data warehouse, the data was collected from various sources including:

- Triad Multiple Listing Service (MLS) – This is a powerful real estate listing site that provides detailed data on the local housing market
- Guilford County Taxation Department
- U.S Census Bureau
- Guilford County Board of Elections
- North Carolina State Board of Elections
- Triad MLS – A detailed report containing the fields in the previous section was created. A search was performed on active and pending houses in Guilford County for all areas of the county. Approximately 3692 records were created and displayed in the report. The report was exported from the site as a tab-delimited text file.

Data on the 2004 General Election Results were obtained from the Guilford County Board of elections. This data was in the form of a spreadsheet. Unfortunately, the 6 precincts were split into two precincts after the Precinct TIGER shapefile was created. Data for these two precincts was manually combined prior to further processing. A VBA routine was created to copy the appropriate data from the results into the database. This routine also generated and populated calculated data such as percent of vote. Data on Precinct Voter Registration was obtained from the Guilford County Board of elections. Finally a routine was developed to move the data to the data warehouse. This routine generated and populated calculated results such as translating counts into percentages. Data on Home Values was imported into the data warehouse. This method generated and populated the average home price, the average price per square foot, number of homes in the sample for the precinct, average age, and average year built.

GEOGRAPHICAL INFORMATION SYSTEMS

Data visualization provides a graphical interpretation of a data so that it can be analyzed from different perspectives. This study will combine data warehousing analysis techniques with spatial analysis to generate visual ads to assist in data visualization. Spatial data is data describes a location (point), line, or a shape (polygon) such as. A point object could represent a poll location, a line object could represent a street segment and a polygon could represent an area such as an election precinct. Spatial Analysis allows for the analysis based on the spatial feature as well as the relationship between two or more objects. For example what is the greatest distance from a polling location to the edge of the precinct.

The primary software package used for this phase was ESRI's ArcGIS ArcMap function. This application enabled the project team to:

- Load and view spatial data stored in a variety of formats.
- Manipulate and modify spatial objects and their attributes.
- Manipulate display graphics by symbolizing, classifying, and labeling spatial objects.
- Identifying, selecting, and finding features by attributes or location.
- Preparing data for analysis by removing unwanted features and combining others.
- Analyze spatial data by buffering and overlaying features.
- Generating the final output Maps

Figure 4. Guilford County 2004 Presidential Election results

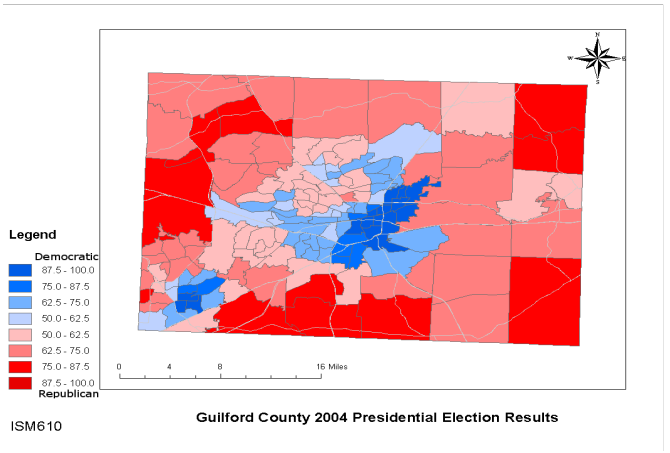

Figure 5. Guilford County registered minority (2004)

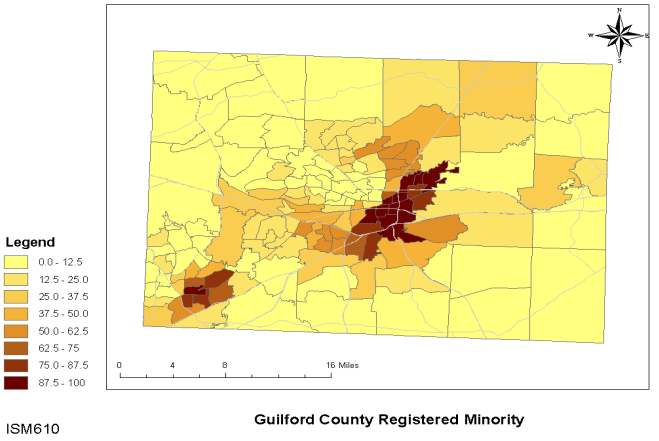

Figure 4 shows Guilford County 2004 presidential election results and Figure 5 shows Guilford County Registered Minority in year 2004. This Figure depicts the percentage of minority voters in each precinct based on voter registration information obtained from the Guilford County Board of Elections for 2004. Precincts rendered with darker values have a higher percentage of voters identifying themselves as being of minority background. As one can clearly see, the two figures are almost identical, indicating a high correlation between the two.

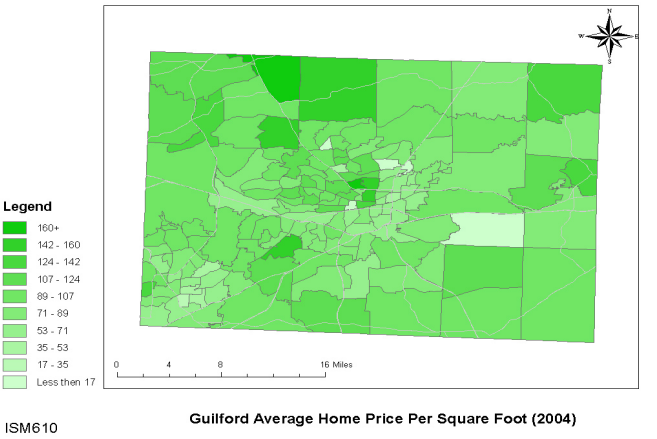
On the other hand, Figure 6 features the average value per square foot of the homes sold in the precinct during the study period. This information was imported into the data warehouse and rendered in ArcGIS application and the resulting map generated. Precincts with lighter shades of green experienced home sales of lower average value per square feet compared to those areas with darker shades of green. In this case, the relationship between the voting pattern and home prices per square foot is not clear.

Home Values

The group also analyzed housing data from MLS by grouping listings and data into the corresponding precincts. The group could not collect housing data for 4 of the 151 precincts. These precincts are Greensboro 28, Greensboro 45, Greensboro 8 and Jefferson 4.

Figure 6. Guilford average home prices per square foot (2004)



Average home value for the county from the sample was $140,583.89. We gathered housing information on 1,353 homes in Guilford County. Removing the four precincts where we did not have information, the average number of homes to precincts was 9.2.

Average age – 35 years.

Average $ / sqft - $91

No precinct that voted democratic had an average home value more than 211,200. The following graph represents how precincts with various average home values voted in the 2004 presidential campaign. The y-axis represents average home value per precinct. Each blue dot is a precinct. 0 represents a precinct that voted republican and 1 represents democratic ones.

NAÏVE BAYES DATA MINING BASED ANALYSIS

In analyzing the GIS data, we used the Naïve Bayes approach for data mining. Naïve Bayes is a classification and prediction algorithm that calculates probabilities for each possible state of the input attribute, given each state of the predictable attribute. This can then be used to predict an outcome of the predicted attribute based on the known input attributes. In order to better understand how precinct housing price data plays an indicating role in how precincts vote, our group needed to analysis the available data from several vantage points.

In combination with the voting data and voter demographic data, we looked to combine housing data from MLS. Through this analysis, we intended to prove that home value plays somewhat of an indicating role in how precincts vote. Although certain home value ranges would prove to be a wash, the group sought to prove that precincts with lower home values would prove to vote democratic while precincts with higher home values would prove to vote republican.

Based on the formula: *Value of house = 40% of (combined) income*

We analyzed the data within the following parameters. The analysis is included with each part.

< $30,000 income translates to $75,000 home and these voters tend to vote Democratic

40 precincts fell in this category. 34 of the 40 precincts voted democratic (85%) in the 2004 presidential campaign. The data strongly supported this position.

$30,000 – $50,000 = $75,000 - $125,000 home with no differentiation between parties

39 precincts qualified in this category. 23 of these precincts (59%) voted democratic. There did not appear to be a significant differentiation between this income range and voter outcome.

$50,000 –$ 75,000 = $125,000 - $187,500 home with no differentiation between parties

32 precincts composed this category. 6 of these precincts (19%) voted democratic. It appears that our data disproved this part. 4 out of 5 precincts with incomes in this range voted republican.

$75,000 – $100,000 = $187,500 - $250,000 home with no differentiation between parties

19 precincts fall in this category. 3 of these precincts (16%) voted democratic. Similar to the previous income range, the data that we collected disproved our initial thought that this range would be a wash. In fact, this income range strongly supported the republican candidates.

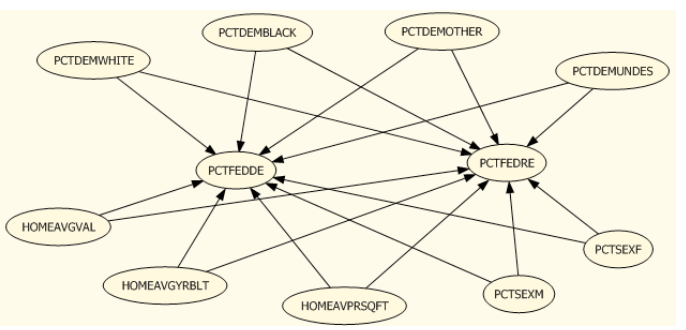
> $100,000 translates to $250,000+ house and these voters tend to vote Republican

17 precincts fall this category. Every one of these precincts voted republican. In this range, the data clearly supported the initial premise.

The Naïve Bayes algorithm was used to analyze the relationships between various voter attributes and the percentage of votes for each political party. The collected input variables included:

- Ethnic Background
  - o PCTDEMWHITE - percentage of registered voters identified as White.
  - o PCTDEMBLACK - percentage of registered voters identified as African-American.
  - o PCTDEMUNDES - percentage of registered voters undesignated.
  - o PCTDEMOTHER - percentage of registered voters identified as other.
- Male/Female
  - o PCTSEXM - percentage of registered voters designated as Male.
  - o PCTSEXF - percentage of registered voters designated as Female.
- Housing Information
  - o HOMVAVPRSQFT – Average home value per square foot.
  - o HOMEAVGVAL – Average home value.
  - o HOMEAVGYBUILT – Average year that home was constructed

The following diagram series of figures represents the dependencies between input values and output values that were used in the algorithm.



IMPORTANCE OF EACH DATA ELEMENT:

Each of the following graphics depicts the critical relationship between each of the attributes and the precinct percentage of votes for the democratic presidential candidate. These graphics are presented in order of significance from most to least. Based on analysis the importance of each input data type ranks as follows:

1. Percentage of registered voters identified as African-American.
2. Percentage of registered voters identified as White.
3. Percentage of registered voters identified as Female.
4. Percentage of registered voters identified as Male.
5. Average Home Value
6. Percentage of registered voters identified as other.
7. Average Home Value per Square Foot
8. Percentage of registered voters of unidentified Ethnic Groups
9. Average Age of Home.

The Naïve Bayes analysis closely follows the general analysis above in terms of the strong influence the race and gender have on precinct voting. Housing data does not play as strong a role with average home value being a stronger attribute than home value per square foot or average age of home.

ATTRIBUTE DISCRIMINATION VALUES

Attribute Discrimination indicates the importance of a particular attribute category in determining the output values. The following charts show how the most important data attributes play a part in the final output values – the percentage votes for the republican and democratic parties.

The attributes favoring *high* democratic vote results in a precinct include:

- Home average value less then 95,000
- Percent of white voters in precinct of less then 17%
- Percent black voters greater then 85%
- Average home value per square foot of less then $67

The attributes favoring *low* democratic vote results in a precinct include:

- Percent African-American voters of less then 13%
- Percent White voters greater then 85%
- Registered male voters greater then 47%

Because there are only two major parties, the factors that favor one party tend to be ones that work against the other as indicated in the Attribute Discrimination chart for the Republican Party. The following graphics depict the information in the preceding bulleted lists:

CONCLUSION

As stated in the introduction, Guilford County was one of a minority of counties that voted not only for the Democratic candidate for governor but also the democratic candidate for president. The intent of this paper was to answer the question – why? In order to tackle this question, we needed to gather not only the basic information such as the voting data from 2004, but we also wanted to gather housing data to determine if there was a significant correlation between housing data and voting data.

The data supports one of the group's premises that higher home values translate to republican votes. Conversely, lower home values translate to democratic votes. In addition, there appears to be a strong correlation between home values and the presidential election results. Gubernatorial results are not as clear as the presidential results.

In terms of gender and racial demographics, our analysis supported the traditional thoughts around Guilford County. Race and gender play a critical role in determining voting trends in precincts. Housing played a complementary role in determine democratic and republican voting behaviors. Voters from precincts with an average home value of less than $70,000 strongly supported democratic candidates. Voters from precincts with an average home value of more than $125,000 voted more republican. All precincts with an average home value of $250,000 voted republican. In fact, no precinct that voted democratic had an average home value of more than $211,200.

In conclusion, our project team successful merged two sets of seemingly disparate data to reveal intriguing connections between voter demographics, voting results and housing statistics. While race and gender were the strongest attributes in the overall study, Naïve Bayes analysis revealed some strong connections between housing and voting results.

Internet Commerce Adoption in the GCC Countries

Zeinab Karake Shalhoub, American University of Sharjah (AUS), P.O. Box 26666, Sharjah, UAE; E-mail: Zeinab.karake-shalhoub@insead.edu

ABSTRACT

The purpose of this study is to determine the status of Internet and e-commerce adoption by the countries of the Gulf Cooperation Council (GCC). The research is designed to help local governments and the corporate sector formulate more effective strategies and make efficient resource allocation decisions. Surveying 189 companies' Web sites, the study uses the three-level model of Internet commerce adoption (MICA) to assess Internet adoption rates for firms in the various industries and shows variability in adoption rates among the different industries in the region. Many industries are lagging with the adoption of the Internet indicating a need for education and training. According to Burgess, Cooper and Alcock (2001), the central tenet of the MICA model is that in developing commercial web sites, organizations start with the establishment of a simple presence on the web and these sites get more functionally complex as the expertise of these organizations in the use of Internet technology increases and they incorporate more modules to these sites.

Keywords: Internet Adoption, MICA, GCC, Website Maturity, Developing Countries

INTRODUCTION

Over the past 15 years, countries of the Gulf Cooperation Council (GCC) have taken quantum leaps in the direction of liberalizing their economies and diversifying them away from the oil-based sector. Leaders in the six countries have realized that in the Internet era, it is important to effectively move in the direction of e-commerce and e-government in order to create competitive advantage. In order to assess their success/failures rates, both governments and firms need to learn the status of e-commerce adoption, especially when establishing policies and devising strategies. The results benchmark the internet adoption status of the GCC countries will yield statistics to support policy formulation for future industry development.

Internet technology has changed the world's supply chain by enhancing cooperation and adoption efficiency as well as adding value to products and enterprises. In recent years, electronic commerce has increased the sharing of business information, has built business relationships, and has enhanced business transactions by means of telecommunications networks (Zwass, 1997). According to recent studies, internet-based e-commerce provides a fast and efficient way of obtaining comprehensive market information, feedback from industry and supplier performance (Soliman and Youssef, 2003).

Many research projects are being conducted to document successful e-commerce processes. One such study finds that there are many processes critical to the success of e-commerce including order fulfillment, revenue generation, financial control, web management, monitoring, order generation, call center integration, and consumer behavior (Duffy and Dale, 2002). New business models are needed to conform to the electronic commerce of today's economy. Defining the customer's expectation in e-business is important as well as the need to invest adequately in the improvement of services (Rotondaro, 2002). The critical dimensions such as finance, legal issues, logistics, marketing, operations, security and technology, as well as strategy must be considered when planning new e-commerce ventures (Kao and Decou, 2003). Regardless of the benefits that can be gained from e-commerce, or the critical issues solved, the first thing for modern enterprise should do is to go online and adopt the Internet.

GCC AND THE INFORMATION/KNOWLEDGE SOCIETY

The Gulf Cooperation Council (GCC) was established in accordance with an agreement concluded in 1981 in Riyadh, Saudi Arabia between: Bahrain, Kuwait, Oman, Qatar, Saudi Arabia and UAE. These countries declared that the GCC is established in view of the special relations between them, their similar political regimes and geographic proximity (Karake-Shalhoub, 2006). The author evaluated the countries individually and collectively using three international indicators and standards developed by multinational organizations: The Economic Freedom Index, The Information Society Index, and Digital Access Index. The findings revealed that the GCC countries display the highest penetration rates in mobile phones, fixed lines and Internet users. Mobile phone penetration in the GCC stands at 26.16 percent while average Arab world penetration stands at 7.92 percent. GCC mobile phone penetration is also well above the world average, at 17 percent. While fixed line penetration in the Arab world stands at 7.95 percent and Internet penetration at 2.69 percent, the GCC enjoys a much higher fixed line penetration of 16.52 percent and Internet penetration of 9.48 percent (Karake-Shalhoub, 2006). Further, the study found that some of the GCC countries have emerged as forerunners and are among the 50 top information technology (IT) users in the world. In terms of the Digital Access Index (DAI), which includes variables, such as education and affordability, four of the GCC countries (UAE, Bahrain, Qatar and Kuwait, were classified in upper access category, and the remaining two (Saudi Arabia and Oman) were classified in medium access category (Karake-Shalhoub, 2006).

All indicators, then, point to the fact that the GCC countries are ready to engage in e-commerce transactions. Based on a study done by Ernest and Young, in 2002 it was estimated that the current total B2B trade in the region was between $3.5-4.2 billion, of which the automotive industry, the oil industry and IT industry accounted for the bulk of the online transactions. They also estimate that considering the ongoing initiatives in various other segments, particularly in the Oil, Petrochemical and Government sectors, it is likely that the B2B trade in the region could grow to $7.25-9.15 billion in 2005. Overall, eCommerce trade (B2C and B2B) in the GCC region can consequently be expected to amount to between $8 -10 billion in 2005.

A main indicator of the level of diffusion of electronic commerce is the rate of credit card penetration in a country/region (Karake-Shalhoub et al, 2006). According to the latest statistics of Visa International, daily use of debit and credit cards in the GCC countries continue to grow strongly. According to this report, for the 12 month period ended March 2005, an average of 730,000 purchases were made per day on Visa debit and credit cards in the GCC, or more than eight transactions every second, representing a 30 per cent growth over the previous 12-month period (Credit Cards News, 2005).

This year, shopping spending increased by 32 per cent to $10.5 billion from last year. While the rise in volume and value of card payments is pleasing, what is perhaps more significant is that the majority of purchases being made by Visa cardholders in the GCC are everyday, small value purchases. This indicates that these societies are moving away form the cash-based format, and that credit and debit cards are starting to challenge cash in societies of the GCC as the preferred way to pay.

Based on analysis of spending by geographic region, it is stated that more than a third of the shopping spend in the GCC was generated by Saudi cardholders. In addition, markets such as the UAE are already showing clear signs of cards replacing cash, with the numbers of purchase transactions by UAE cardholders being higher than the number of ATM cash withdrawals.

INTERNET COMMERCE ADOPTION MODEL

The rapid adoption of the Internet as a commercial medium has motivated firms in the Gulf Cooperation Countries (GCC) to experiment with innovative ways of marketing to consumers in cyberspace. Previous research has shown that that innovation, organization and external factors can influence a firm's decision to adopt e-commerce as a marketing and selling strategy (Lin et al, 1998). Using a survey of 162 SMEs, the authors found that the drivers of firm Internet adoption are different from those of traditional information system adoption, and the degree of internet adoption by firms in the study was strongly related to the owner's perception of the relative advantages of using information technology. Another study found that the degree of information system adoption can be related to the firm's previous innovation experience (Lee and Runge, 2001). Previous research has evaluated e-commerce adoption by firms from different perspectives. Wen et al (2003) employed a data envelopment analysis (DEA) model evaluates e-commerce adoption, diffusion and performance of firms using various measures such as financial and operational. A study by Davidson (2002), though a search of the literature, shows Web sites are classified in different ways: Web Typology, Scoring System, and Stages of Development.

THE SAMPLE

This study, and for the first time, covers a sample of Web sites in a group of developing economies in the Middle East, namely the six countries of the Gulf Cooperation Council. The author evaluated 183 popular commercial Web sites. These Web sites were identified and classified based on the Standard Industrial Classification (SIC)/North American Industry Classification System (NAICS), as classified by the AMEinfo Business directory. AMEinfo adopted the SIC/NAICS classification because it is the most comprehensive overall industry classification system found when AMEinfo restructured its database of more than 200,000 companies in January 2005. Table 1 contains the distribution of the sample by country.

As can be seen from Table 1, Saudi Arabia and the UAE comprise close to 75 percent of the websites examined. This is consistent with the fact that the two countries have the largest numbers of registered Internet hosts (ITU, 2003).

The distribution of websites per industry is depicted in Table 2. The classification was based on the 1997 North American Industry Classification System (NAICS), which was updates of the original Standard Industrial Classification (SIC) (OMB, 1997). The industry classifications "Finance and Insurance" and Retail Trade" account for more than 53 percent of the total companies in the sample.

Based on the above Table and assessing the viability of the sample size within each industry, it was deemed appropriate to concentrate our research on industries represented by more than 10 firms reducing our sample size to 157; hence, the following sample (Table 3) will be analyzed.

This paper utilizes the model of Internet commerce adoption (MICA). The Model of Internet Commerce Adoption (MICA) advocates that in developing commercial web sites, private and public sector entities normally start by creating a 'presence' on the Web and add more and more functions and applications over time. As such, the sophistication and comprehensiveness of the sites will expand as the site provides more applications (Burgess and Cooper, 2000). This staged approach to the development of web sites that is embraced by MICA is well recognized within the Information Systems (IS) history that acknowledges that growth and development is caused by adding more functions (Burgess and Cooper, 2000).

According to the MICA model, a website goes through three stages of development, from infancy to maturity; these are promotion, provision, and processing (Table 4). During the promotion stage, companies start simply by establishing a "presence" on the Web; the main objectives here is to establish websites which make customers acquainted with their products and services. In doing so, they provide basic information covering business scope and post news relevant to their operations; some use animation and multimedia to draw visitors' attention toward an important promotion offered. Users, however, users cannot send anything to the site and can only receive information from promotion web sites. The second stage of website development is the provision stage; here the web site offers users the functionality of sending and receiving information. Users of a "provision" website receive information, access to search engines, and even choices of languages. The hope here is that these value-added applications will help maintain existing customers and cultivate new ones. More complex applications are also embedded as integral components of interactive Web sites. Users can search for information and use functionalities such as e-mail; they can also register online and take part of message boards. Interactive websites encourage and entice visitors to inquire, request, complain, challenge, or make recommendations; they also help companies adopt a sense and respond strategy, however, an imperfect one.

In the processing stage, customers play the most influential role. One of the main utilities here is customer relationship management, from initiation to maintenance. Other electronic services such as online orders or inquiries are all completed

Table 4. Web site classification scheme

Item Name	Description
Promotion Stage	
1. enterprise information	background and business scope
2. product information	product catalog and names
3. news of enterprise	important news such as new product releases
4. animation and multimedia	attract user's attention; focus on major targets
Provision Stage	
5. recruitment info.	list of open jobs and job requirements
6. technical info.	detailed info on existing product/services or advanced info on new product or services
7. email hyperlink	users' interaction
8. search functionality	assist users in finding info. quickly
9. language choice	provides service to an international audience
Processing Stage	
10. online resume	functionality to fill in relative information
11. e-service	ability to query, analyze, or download technical information
12. online order or inquiry	functionality of making purchases or inquiring about products and services.

online through the website. For example, a CV can be filled out using a template provided by the site and then submitted by an applicant; users and visitors are able to download technical information, and complete their orders online. More mature transaction sites incorporate ordering, purchasing, and delivering functionalities. Developing these web sites requires high levels of sophistication in programming.

DESIGN OF THE RESEARCH

Previous research has demonstrated that larger companies are more likely to adopt e-commerce and to implement e-business applications (Macher et al, 2002). In terms of diffusion in the industry, the service sector shows greater internet commerce adoption and greater e-commerce maturity than other sectors, largely due to lower capital and manpower investment.

In our research the Burgess and Cooper MICA model (2000, 2001 and 2002) is used to assess the stage of e-commerce adoption by each of the 159 GCC websites identified in the previous section. Each website was evaluated and assessed using the MICA 12-code scheme (Table 4). Following previous research, if a MICA item was found, it was assigned the code "1" on the MICA sheet, and "0" if the item was not present. As in previous research, if a website had items including online resume, e-service, and online order or inquiry, it is categorized as belonging to the processing stage. A website is categorized in the processing stage, if any code "1" could be found from item 10 to item 12 (Peng et al, 2005). If the website does not qualify to be in the processing stage category, then it is checked for appropriateness to the provision stage. If there was any code "1" found for item 5 to item 9, then the website was classified into the provision stage. Finally, we would confirm that a web site was in the promotion stage if any code "1" was found from item 1 to 4, but not having any in item 5 to 12. To measure the maturity of website design, the ratio of items coded one to the total number of

Table 5. Classification of Websites according to MICA stages of development

Stage	No. of Sites	Percentage
Promotion	0	0.00%
Provision	98	0.62%
Processing	61	0.38%

• Processing	5	0.28
Total	18	1.00

items in each stage was computed. For example, the processing stage has three items (items 10 thru 12), if only one item was coded "1" then the relative maturity of the site within each stage would be computer as 1/3 or 0.33.

ANALYSIS AND RESULTS

A content analysis was performed on the 159 websites included in our sample. Based on the MICA 12-code scheme, all the websites were classified into one the three stages. Table 5 presents the classification of the sites by stage of development; as it is indicated, no site was classified in the "promotion" stage; this is not surprising since the countries of the Gulf region were early adopters of e-commerce and digital technologies. The majority of the sites, or 62 percent, were classified in the "Provision" category, and 38 percent were classified in the "Processing" stage.

Table 6 shows the MICA classification of the sites by industry type. The results show that the Finance and Insurance and Public Administration industries have the lion share of 'processing' websites, and 56 percent and 81 percent respectively. These were followed by the Information industry (37 percent), Health care and Social Assistance (36 percent), Utilities (28 percent), Retail Trade 927 percent), and Manufacturing (19 percent). These results are not surprising since the Financial and Insurance sector is dominated by global, well established firms such as Citigroup, HSBC, Bank of Canada, and bank of America, among others. In addition, the Local banks in the region are at a very advanced stage, and compete head to head with their foreign counterparts. Results of the Public Administration are explained by the fact that at least three of the six GCC countries (UAE, Bahrain and Qatar) have well established and well developed e-government programs supported by top political leaderships that encourage, and in some instance mandate (as is the case of the UAE and Bahrain), e-services, e-payments, and e-solutions.

The study also revealed several additional findings: (1) none of the websites offered chatrooms or discussion forums; (2) only fifteen (15) of the websites featured online resume functionality; (3) none of the website had a currency converter; and (4) sixty-one sites had language options (mainly Arabic and English). These findings are surprising, especially since these websites are geared toward promoting international and global orientation of the businesses.

CONCLUSION AND RECOMMENDATIONS

This benchmark study provides a framework for evaluating the status of Internet and e-commerce adoption by the countries of the Gulf Cooperation Council (GCC). The twelve items of MICA were used to evaluate the development stage of the seven main industries with Web presence in the region; namely, Finance and Insurance, Health care and Social Assistance, Information, Manufacturing, Public Administration, Retail Trade, and Utilities. The research shows that none of the 159 websites under examination are in the 'promotion' stage, sixty-two (62) percent are in the 'provision' stage and thirty-eight (38) percent are in the 'processing' stage.

The results reveal that two industries had a large dominate the 'processing' stage; these are Finance and Insurance and Public Administration; these results are not surprising and might be justified by the fact that the Finance and Insurance sector is dominated by large, global companies which have the knowledge, resources and expertise in website development; and that the Public Administration sector is supported by successful e-government initiatives in the region.

The results for the other remaining industries can be explained by the fact that online ordering is currently not very popular, but will hopefully increase dramatically in the near future as awareness among providers and clients increase. The current strategic direction for the governments in the GCC region is very promising and is that of encouraging the use of e-commerce.

Definitely, more awareness programs are needed; and more education and training is needed to encourage the internet adoption. Further, the government should help enterprises become familiar with the use of the internet and research is needed to measure the impact of incentives and training on adoption.

Education Portal Strategy

Henrik Hanke, University of Duisburg-Essen, Germany; E-mail: henrik.hanke@uni-duisburg.de
Alf Neumann, University of Duisburg-Essen, Germany; E-mail: alf.neumann@cemsmail.org

ABSTRACT

Education portals promise to be an integrated point of entry that provides all stakeholders of an education body, frequently referred to as campus or university, with a single, personalized, web interface to all information and application resources in a secure, consistent and customizable way. They also promise to be the means by which multiple devices and multiple access methods can be utilized to retrieve all appropriate information and learning resources anytime, anywhere, with anything. Therefore, developing an education portal can be a key strategic technology decision since it can impact the entire campus community in the way it learns, teaches, communicates and interacts. This paper presents the major issues for portal strategists in the preparation and implementation of education portals, and looks at the development approaches, lessons, comments and concerns from concrete projects. A generic approach towards portal strategy is being derived from the international portal experience which implies four subseqent stages that determine the way portals can be embedded in an institutional context: emerging, applying, infusing, transforming.

INTRODUCTION

Education portals promise to be an integrated point of entry that provides all stakeholders of an education body, frequently referred to as campus or university, with a single, personalized web interface to all information and application resources in a secure, consistent and customizable way (Kavavik, 2002) through multiple devices and multiple access methods can be utilized to retrieve all appropriate information and learning resources anytime, anywhere, with anything. Hence, they allow more interaction and collaboration among students, faculty, staff, and alumni (Barratt, 2003). Properly implemented, portals can be a strategic asset for the institution. In that sense, they do far more than a traditional web site of static information ever could (Strauss, 2002).

The promising opportunities notwithstanding, developing an education portal can be a key strategic technology decision since it can impact the entire campus community in the way it learns, teaches, communicates, and interacts. Therefore, the primary challenge for educational institutions in prior to the implementation of a portal solution is to develop a deliberate *portal strategy* based on a careful analysis of long term and short term needs, and a clear vision with concrete strategic goals (Katz, 2000, 2002).

However, the international portal experience in the educational sector over the past decade shows that various strategies have been pursued in very different institutional environments and with very different objectives (Perraton, 2000). This has been driven to some extent by the fact that the portal concept as other technologies in open and distance learning (ODL) has been first applied and adapted to higher education and professional training environments, but establishes gradually also in primary and secondary education institutions (Owston, 1997; UNESCO, 2000).

Therefore, looking at the development approaches, lessons, comments and concerns from concrete projects, it is primarily the diversity that stands out. This article sheds light on those aspects that can serve as a common basis for an integrated, generic approach towards portal strategy. It understands the four directions of impacts on *learning*, *teaching*, *communication* and *interaction* of education portals as strategic dimensions along which strategic goals are set and embedded in an institutional context.

The generic approach may guide portal strategists in governing bodies of education portals through the delineation of strategic success factors and development priorities at different stages of portal development independent from the educational sector. Therefore, the terminology of this article refers in a common sense to teachers and students instead of differentiating these broader categories into professors, faculty staff, trainers or pupils. Educational institutions such as universities, colleges, schools are collectively termed campus.

FOUNDATIONS OF EDUCATION PORTAL STRATEGY

Portals in the field of education are a widely discussed, but nonetheless often misunderstood term. Therefore, the view on education portal strategy should not lack a brief explanation of the conceptual foundations and the terminology. The general portal concept is based on three essential features: personalization, customization and standardization. The main purpose of personalization is to provide information tailored to the needs of a visitor such as given through the different teacher and student roles these visitors might have in the portal environment. The individual must be able to customize, thus, have complete control over the information displayed on the portal pages. Standardization refers to the user interface as single sign-on (SSO) access point to a variety of tools and resources (Kavavik, 2002).

Portal related initiatives exist at many campuses, but formal strategies for a portal, its use, and its benefits have not been created. Most of the development has occurred in the form of small, targeted projects designed to enhance the functionality of existing web sites. These projects have been prompted by specific educational or administrative needs (Gleason, 2001). An essential contribution to make the education portal concept more consistent throughout the variety of different institutional and educational specificities is the pyramid model of Oblinger and Kidwell (2000). Based on this approach, success factors for the implementation of education portals can be classified at three levels: *governance*, *services* and *infrastructure*.

In this sense the designation of leadership and a concentration of decision-making responsibility are keys to the development and implementation of a portal, providing confidence to campus that it can place the responsibility and trust in the hands of a knowledgeable individual or an informed and dedicated group of individuals. This governing body must be capable to conceptualize the entire portal organization and processes, and to control the technical, policy and financial portal infrastructure. Community involvement and input can play an important role in finding a deliberate balance of necessary competencies.

The service level presents the educational core of the portal. It addresses all aspects of learning, teaching, administration that a campus intends to capture by electronic means. The service orientation can be both teacher-centred and student-centred according to different teaching and learning models, types of learning content and applications. Hence, such models and different types of education portals, in a gradual implementation process also referred to as different stages of portal implementation, are duals of one another (UNESCO, 2002a).

At the infrastructure level, the technology architecture, the financial endowment and the policy framework delineate the vital environment of education portals. The choice of the appropriate overall technological infrastructure is a make-or-buy decision. On the one hand this depends on resource constraints in terms of in-house development capacity and financial resources. On the other hand, regarding the expediency and the uniqueness of existing file systems and the risk to lock the campus into a single proprietary vendor, the decision must be based on clear requirements on flexibility and adaptability of purchased solutions and legacy systems (Looney & Lyman, 2000). Efficiently, an education portal implementation must consider all requirements at the infrastructure level in order to assure its accurate, long-term operation (Gleason, 2001).

STRATEGIC SPACE OF EDUCATION PORTALS

Looking at the factors classified by Oblinger and Kidwell (2000), the prerequisites for a successful education portal implementation and the global portal environment of campus-specific variables may very well differ from institution to institution and may shape the educational opportunities of portals in very different ways. Whereas, governance and infrastructure appear to play more of a role as determinants of the institutional environment in which a portal strategy is embedded. Thus, the greatest source of strategic development opportunities of education portals is the service level.

The focus on services realigns the discussion of education portal strategies to the core of education portals - open and distance learning (ODL). Katz (2000, 2002) specifies four dimensions that capture the strategically most significant aspects in this field: teaching, learning, communication and interaction.

TEACHING AND LEARNING

Teaching and *learning* are best thought of as interconnected and interrelated. However, the subject falls into two dimensions when it is regarded in the context of portal strategies and concrete strategic decisions on the design of e-learning systems (ELS), organizational and processes-related issues. The primary interest here is how far and how consistent a campus intends the portal to support and enhance teaching, learning and related administrative processes (Oblinger, 2001).

The distinct dimensions differentiate the common terms *e-learning* and ODL towards a strategically meaningful view, and put the ELS concept in the focus of education portal strategies. This is key to create a beneficial learning environment with a positive impact on both effectiveness and efficiency of the teaching and learning process. Whereas, effect refers to qualitative educational objectives on certain competencies or knowledge. Efficiency relates to the time or effort needed to achieve this objective. The wide ELS spectrum can roughly be divided into the areas learning management systems (LMS) to administrate learning and teaching processes, and learning content systems (LCS) to provide adequate support in the acquisition of knowledge or competencies (Becker & Knackstedt, 2004).

Courses and curricula define the educational profile of a campus as well as a portal. Therefore, content development and the implementation of appropriate applications to deliver this content are crucial issues in LCS. Comprehensive, well designed resources may stimulate students' self-directed learning. Whereas, to achieve an optimal online resource pool it is essential to recognize that existing conventional content cannot be transferred directly into technology supported courses (UNESCO, 2002b). Therefore, the quality, scale and scope of the portal resources is at least to some extent a question of the design and development capabilities of teachers who are often considered as the content producers (Alpar, Grob, Weimann & Winter, 2002). Another important aspect of ELS relates to the administrative support of students and teachers. LMS may replace formerly separate staff functions so that teachers or students themselves can perform administrative tasks with little effort and parts of the original campus administration become obsolete (Hawkins, Rudy & Nicolich, 2005).

COMMUNICATION AND INTERACTION

Education portals provide an enhanced platform for communication and interaction as facilitators and enablers for teaching and learning processes (Oblinger, 2001). Both areas represent target dimensions of portal strategies.

A central principle of learning, *communication* in an education portal environment involves teachers, students and supporting administrative staff. The portal can provide its users with easier access to information as well as with information that is more relevant to them. In so doing, it manages the application framework which distributes information resources in multiple forms and media. Such resources can be communicated either synchronously or asynchronously, pushed by broadcasting or accessed on demand. As these applications change, so the quality and nature of the resources and the impetus on the learning process will change (Pickett & Hamre, 2002). Thus, the sophistication of communication channels of a portal controls the quality of the information, and the resource flow and exchange.

Another key principle of learning, the emphasize of *interaction* underlines that in the education portal concept learning is not just about covering content, and it is not technology alone. The purpose of technology is to effectively support good pedagogy (Dede, 2005). Interaction means connected, collaborative generation of knowledge and acquisition of skills between students and teachers and among students and students (Oblinger, 2001).

The education portal creates an interaction space, on the one hand, for larger numbers of students to share a common learning experience, or on the other, to enable an individual student to have a unique, personal interaction with a teacher or with another student, no matter where located. More importantly, these learning experiences can be of much higher quality than they would be possible without an advanced, virtual communication and interaction platform (Collins, 2003).

INTERDEPENDENCIES

While learning content is the central resource, applications supporting communication and interaction in practices, experimentation, simulation and project work facilitate the transfer of content into knowledge and capabilities. A portal may cover a broad range of corresponding features that all imply different levels of sophistication of the ELS which embeds the entire teaching and learning process and related administrative activities. Furthermore, as teaching and learning techniques will change along with more interactive, self-directed approaches of student involvement in the education process, so the fundamental roles and the relationship of teachers and students will do (Oblinger, 2003).

The connections between these subjects show the way for a strategy concept that must understand all dimensions from teaching and learning to communication and interaction as interdependent aspects of digital education services. The strategic goals along these dimensions must reflect the interdependence.

In a straight forward approach towards more advanced education concepts on ELS, interaction becomes more and more an integral aspect of portal applications and the teaching and learning process. Students will not only benefit from the unified interface to courseware and required information about courses, easier communication with teaching and administrative staff, but also access to communities of interest and community services, and enhanced learning opportunities tailored to specific learning needs and preferences, following an increasingly student-centred view (Oblinger & Oblinger, 2005).

Hence, also ELS features require gradual or continuous adjustments in order to meet educational standards based on learning behaviour, and preferred communication and interaction processes. In this context reference models on such behavioural aspects may be helpful (Becker, Delfmann & Knackstedt, 2004). In terms of curriculum and application development, they may be obtained from integrated just-in-time student assessments and program planning in order to better understand the learning effect of different courseware (Olds, Moskal & Miller, 2005).

Furthermore, a corollary of changing patterns of teaching, learning, communication and interaction, the redefinition of ELS roles in furthering and adapting the education process present a strategic issue in portals since it is based on the three features personalization, customization and standardization, and closely linked to clear and distinct role schemes. The strategy must acknowledge that depending on the focus of the education concept teachers may act as architect, consultant, expert, guide, lecturer, resource, reviewer. A student may be apprentice, builder, listener, mentor, peer teacher, publisher, team member, writer (Oblinger & Oblinger, 2005).

Eventually, the technological opportunities to adapt an ELS to concrete needs according to different principles of learning and role models appear to be unlimited (Dede, 2005). The great opportunities notwithstanding, an education portal strategy will hardly succeed without the consideration of capabilities of both teachers and learners to make use of the technology (UNESCO, 2002a).

STRATEGIC APPROACHES

The four dimensions teaching, learning, interaction and communication constitute the strategic space in which the education portal strategy pursues objectives, determines the scale and scope of a portal solution, educational services and features. The remaining question is the strategy formation itself.

UNESCO (2002a) identifies four broad approaches through which educational institutions adopt and use information and communication technology (ICT), termed emerging, applying, infusing, and transforming. These categories reflect the specificities of campus environments with different institutional determinants for the adoption process.

On the application of the strategic dimensions outlined above, it is possible to derive a compatible concept of equivalent approaches that all imply a certain strategic posture of education portals. Thus, the approach a campus pursues towards

Table 1. Generic approaches towards education portal strategy

Strategy appraoch	Emerging	Applying	Infusing	Transform-ing	Virtual campus
Interaction			collaborative learning, learning content systems adopted to teaching practice, integration with non-ICT content, increasing student responsibility	strong leadership, clear governance models, ICT is integral to overall curriculum development, web-based learning, interaction spaces	if upon education concept implementation no transformation is needed but rather an ad-hoc concept of an entirely virtual organization and corresponding processes
Communi-cation	didactic pedagogy, focus on learning management systems, basic communication	Factual knowledge-based learning, learning management systems, learning content systems developed by specialists, content applied in discrete subjects			
Education concept	**Teacher-centred**			**Student-centred**	

education portal strategy can be understood as generic. However, the institutional preconditions, technological opportunities and capabilities, and education concepts present the starting point of a campus-adequate strategy.

The *emerging approach* is firmly grounded in traditional, teacher-centred practice. The curriculum reflects an increase in basic communication functionality. This way the campus community develops an awareness of the benefits of portal technology. The vision reflects individual benefits so that interactive pedagogy is rather a minor aspect in the portal concept than a part of an integrated e-learning program. Teaching and learning processes follow conventional didactic patterns.

The *applying approach* replaces offline tasks formerly carried out in the campus administration and in the curriculum through online portal applications. Whereas, the development of applications and features is driven by ICT specialists. Teachers largely dominate the learning environment that is mainly designed for factual and knowledge-based learning. Direct interaction between students and teachers takes still place offline.

The *infusing approach* involves integrating and embedding the curriculum in the portal, and is seen at those campuses that already employ a broad range of computer-based technologies in laboratories, classrooms, and administrative offices. Teachers explore new ways in which the portal can change and optimize their professional practice, and the effectiveness and efficiency of learning processes. Driven by subject specialists the curriculum begins to merge resources with comprehensive ELS functionality. The student focus increases along with the availability of more collaborative applications.

The *transforming approach* is appropriate for campuses that use technology to rethink, modernize and innovate their entire organization. The education portal becomes an integral part of daily personal productivity, teaching and learning practice. The focus of the curriculum is student-centred and integrates a variety of resources in sophisticated applications that support multi-sensory, experiential learning and different preferred learning styles. The ELS incorporates all areas of teaching and learning, and related administrative activities. Collaboration and mentoring concepts play a key role. The governing body demonstrates strong leadership and requires an advanced level of community involvement. Through a consistent transformation, a campus can become a completely virtual education centre.

The international experience shows that the adoption of ICT and the transition of conventional campus environments is usually a gradual process (UNESCO, 2002a). Therefore, the generic approaches can be seen either as a continuum of stages for the implementation of portal technology or as ad-hoc concept to guide a portal strategy in the definition of a deliberate balance of strategic goals in order to leapfrog certain stages. Whereas, necessary resource commitments at the portal service and infrastructure level will increase the greater the step is from an existing institutional framework, its educational objectives and its technological readiness towards a more *virtual campus* approach (UNESCO, 2003).

CONCLUSIONS

Eventually, it is obvious that the challenge of an education portal strategy is no less than the challenge of bringing a campus into a wave of technology. The generic approaches can assist the delineation of strategic success factors and development priorities for portal development. They provide a framework to further the teaching, learning, communication and interaction capacity of existing portal solutions in systematic way, adapted to the specificities of a campus. Table 1 illustrates the multi-dimensional picture outlined above and its interdependencies.

MIS Recruitment and Retention Factors: Some Preliminary Cross-Cultural Comparisons

Rodney Turner, Victoria University, Melbourne, Victoria, Australia; E-mail: rod.turner@vu.edu.au

ABSTRACT

With the growing internationalization of businesses, and the increasing mobility of IS/IT professionals there is a need to understand the aspects of the work environment and the job that motivates these professionals. As more and more organization employ professionals from a range of different cultural backgrounds, the question arises as to whether or not the incentives structure, work features and motivators are the same for different cultural groups. This paper reports the results of a pilot study comparing attitudes of computing professionals from three countries (Australia, China and the Philippines) into those work environmental factors and motivators that act as incentives to join a company, and to remain. Exploratory factor analysis identified eight factors that attracted individuals to join and stay with a company. These factors when converted to composite variables results compared for the three countries. The similarities and differences are compared suggesting that a "one size fits" all approach to recruitment in IS may not be justified.

Keywords: Motivators, Incentives, Information Systems, Cross-cultural, International Comparisons

INTRODUCTION

During the late 90s and early 2000, the worldwide shortage of IS/IT professionals caused serious concern in economies around the world. This shortage seems to have abated, maybe temporarily. With the growing internationalization of businesses, the interdependencies of the world economies, and the increasing mobility of IS/IT professionals there is a need to understand the aspects of the work environment and the job that motivates IS professionals. As more and more organization employ professionals from a range of different cultural backgrounds, the question arises as to whether or not the reward structure and motivators are the same for different cultural groups.

The study reported in this paper explores the features of the working environment that firstly attracts an IS/IT professional to join an organization and secondly whether the views have changed since joining. This will be of benefit to employers of IS/IT professionals recruiting from widely differing cultures in understanding in some way what may motivate their staff.

OTHER STUDIES

Gill and Pidduck (2001) showed that work challenge and work environment were far more important to IS professionals than issues of compensation. The Gartner Group (Morello, Zidar, McNee & Smith 1998) predicted that enterprises relying on financial compensation alone were likely to have a high staff turnover. Goles (2001) reporting on student perceptions of IS/IT job attributes, suggests that financial and other benefits are not used to select jobs but rather to eliminate them. Goles further suggests that the learning of new skills in the job is of significant interest amongst students. Smits, Tanner & McLean (1995) found that salary was only an indicator of career progress and was not a significant indicator of job satisfaction of organizational commitment. Lee (2002) provided some interesting insights regarding career strategies, job and career plateauing, and job satisfaction among IT professionals. Paré, Tremblay & Lalonde (2000) presented a model to explain turnover intentions of IT staff and identified several factors covering HR practices, remuneration and organizational behavior & commitment that influence turnover intentions. A slightly more recent study by Horwitz, Chan and Quazi (2003) addressed the issues of attracting then motivating and retaining qualified knowledge workers. They separated the approach into three separate strategies. The most popular motivation and retention strategies had some common overlap covering challenging work, management support, work freedoms and bonuses which also were the more effective strategies for retention whereas strategies such as flexible work practices and funding for studies and conferences were the least effective. More recently King, Xia, Quick & Sethi (2005) demonstrated there were complex mediating relationships involving socialization tactics, role adjustment and organizational attachment which made IT professionals different from other professionals.

Several authors have suggested that training was an important factor in both the hiring and retention of IT professional staff (Gjestland, Blanton, Will & Collins 2001; Paré, Tremblay & Lalonde 2001; Acton & Golden 2002). Paré et al. in particular noted that IT employees are sensitive to the importance of skill development when it comes to deciding whether to leave an organization. They also noted that training is too often regarded by employers as a perk rather than an investment in intellectual capital. Lash & Sein (1995) presented a theoretical framework where organizations and IT professionals are motivated by different expectations. Organization, they suggest, have specific needs leading to jobs that must be filled whereas IT professionals are concerned with career anchors. Thatcher *et al*. (Thatcher, Liu & Stepina 2002) developed a path model examining that showed intrinsic motivation that was positively related with job attitudes and found hygiene factors were important in motivating IT workers.

A study of new information systems professionals King & Xia (2001) found that socialization of new employees was an important factor in retaining newly hired IT employees. They proposed that organizations make a special effort to assist new IT employees adjust via socialization processes to help them change from "outsiders" to "insiders" including mentoring schemes. Lee (2002) found that social support is significantly associated with job satisfaction and turnover intentions.

Little has been reported concerning the issue of cultural differences involving MIS professionals' career anchors. Wormley and Igbaria (1991) reported on differences experienced by Afro-American MIS employees, found less job discretion, and career support than their white counterparts. Further they found less career satisfaction, lower performance ratings and earlier career plateaus than whites. Igbaria and McClosky (1996) surveyed 90 MIS employees in Taiwan. They found that job security, service and challenge were rated highest whilst technical competence and autonomy were rated lowest. They noted a number of differences towards entrepreneurship, challenge and autonomy between Taiwanese and American MIS employees with Taiwanese MIS employees exhibiting a lower career orientation.

METHOD

Based on a review of the literature a questionnaire was prepared addressing issues relating to features of the job, working envirnment and surrounding matters which might initially attract someone to join a company and which might provide incentives to stay. Participants were asked to indicate what attracted them to join their company and if these efatures motivated them to stay after they had joined. Given the concerns often expressed anecdotally by employers over the

churn of highly skilled personnel these are important questions needing answers. Demographic details were also requested including age, gender, years employed in the present position.

Both paper based and web-based survey distribution were used. Mehta and Sivadas (1995) demonstrated that e-mail based surveys generated response rates comparable to those of postal surveys but significantly faster, at lower cost and of a higher quality. On the other hand, Tse, Tse, Yin, Yi, Yee & Hong (1995) in an internal survey of Hong Kong University staff experienced a much lower return rate for e-mail surveys (6%) compared with conventional mail (27%) that they attribute to the possibility of participant identification with e-mail. Comley (1996) found comparable response rates from the two methods. Comley also indicated that electronic data collection methods are often self-selecting due to recipients irregularly checking email messages and consequently have the potential to introduce bias. He points out however that although this is a problem for representative samples it is less of a problem for targeted groups as in the case of the present research. Electronic surveys, by their nature are accessible only by those with access to the appropriate technologies and we would expect that this problem would be lower amongst IS/IT professionals than in the general population because of the nature of the work they do.

The questionnaire was set up using Microsoft FrontPage 2000. Data were captured using Microsoft Access 2000. Electronic surveys have the advantage being pre-coded and free of ambiguity of response in that only one response per item can be selected. They have the disadvantage that they risk missing those who do not have access to computers and the web, although this was not seen to be a problem for the group being surveyed. During the first half of 2003, invitations to participate were sent by email to 365 IS professionals throughout Australia. A total of 40 usable replies were received from Australian participants representing an overall response rate of 11 percent – acceptable for unsolicited surveys of this type but lower than was hoped. In China and the Philippines paper based surveys were distributed by local contacts and distributed numbers are not available. However the selection was based on convenience sampling. Analysis of the data was carried out using SPSS R14.

The survey was sent to IT workers seeking their views on those aspects of the job or organization that appealed to them. Respondents were those who were actually working in an IT environment in a professional capacity. It specifically excluded contractors, self-employed people or those in managerial roles as the study was expressly aimed at IS professionals who are employees.

Participants were asked to rate the importance of incentives offered by employers to IT career professionals. They were asked to rate the importance of 31 items using a Likert scale of 1-5 (where was 1 irrelevant to 5 essential). The incentives considered included opportunity for promotion, travel, a friendly work environment, challenging work assignments, ongoing training provided by the employer, an industry competitive salary, flexible working conditions, reliable internal communications, supportive superiors, scope for individual skills development, and economic fringe benefits such as company vehicles and shares.

RESULTS

As can be seen from Table 1, in each country the majority of IS professionals were male, accounting for nearly 73 percent of respondents from Australia, 80 percent from China and just over 55 percent for the Philippines.

Table 1. Gender distribution

Country (P14)		Frequency	Percent
Australia	Female	11	27.5
	Male	29	72.5
China	Female	6	20.7
	Male	23	79.3
Philippines	Female	21	44.7
	Male	26	55.3

Table 2. Age distribution of respondents

Country (P14)	Age Group	Frequency	Percent
Australia	20-29	18	45.0
	30-39	11	27.5
	40-49	10	25.0
	50-59	1	2.5
China	20-29	18	62.1
	30-39	5	17.2
	40-49	5	17.2
	50-59	1	3.4
Philippines	30-39	43	91.5
	40-49	4	8.5

Table 2 shows the age distribution of respondents. Over 62 percent of the Australian respondents are below 40 years of age, from China 79 percent and from the Philippines nearly 92 percent. As might be expected, fewer respondents were in the above 40 age group presumably because older respondents are more likely to be in senior positions.

Respondents were asked how long they had been employed in their present position. Two people did not answer this question. Of those who did answer the average was 2.7 years, the shortest two months and the longest 10.7 was years. The majority had held their position between 3 months and five years.

Results from the questionnaire containing 31 questions relating to employment aspects are presented in Table 3. Cronbach's α was used to test the reliability of the questions. For pooled results, the Cronbach value was 0.91 for responses concerning "joining" the organization and 0.92 for "staying" with the organization. These each comfortably exceed the benchmark value of 0.7 normally chosen for item reliability. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy and Bartlett's test of sphericity were used for testing the suitability for applying factor analysis. The value for KMO was 0.83 and Bartlett's test indicated a significant result indicating the questions were suitable for factor analysis. Principle Components Analysis using a Varimax rotation was applied. Those questions that returned a loading of less than 0.5 and which load on more than one factor were excluded. The final factors with low loadings suppressed for clarity are presented in Table 3.

Eight latent factors were isolated that accounted for just over 70 percent of the variance. The eight factors isolated relate as follows Factor 1 – Job Challenges, Factor 2 – Recognition of self, Factor 3 Non-financial rewards, Factor 4 – Financial rewards, Factor 5 – Company reputation, Factor 6 –Support culture, Factor 7 – Risk aspects and Factor 8 - People related. Composite factors created from these groupings were according to the methods outlined in Hair, Black, Babin, Anderson & Tatham (2006). As the number of component variables was different in each case, an average score was computed from the component variables for each composite factor. The same factors were also applied to responses concerning the reasons for staying with a company. Questions relating to on-going training were confounding variables and loaded onto more than one latent factor. Treated separately they showed no significant differences regarding joining and staying but there were significant differences for the provision of on-going training. This feature was substantially less important for Chinese worker; Australian and Philippine workers were similar in their responses.

Joining Factor Comparisons

The results for desirable features joining the company are presented in Table 4. The composite variables were compared for the three countries using the Kruskall-Wallis test. All but one factor displayed significant differences at the 0.01 level or better. Rewards and company status are much more important to the Philippine group than for either the Chinese or Australian group. The Australian group appears more influenced by stability concerns that do either the Chinese or Philippine groups. Job challenges are slightly more important to Australian IS workers than the Philippine group and much more than the Chinese group.

Table 3. Final rotated factor scores (joining)

	Component							
	1	2	3	4	5	6	7	8
J20 Variety of challenging work projects	.730							
J4 Challenging work assignments	.714							
J5 Provision for on-going training to gain new skills	.702							
J16 The company IT/IS culture	.656							
J10 Opportunities to expand personal skills	.630							
J21 Opportunities for job mobility within the company	.539							
J24 Recognition of my skills by my superiors		.859						
J25 Acknowledgment of effort by superiors		.823						
J23 Recognition of my skills by my co-workers or peers		.789						
J2 Opportunities for sponsored travel			.819					
J28 Opportunities for international work			.767					
J1 Good promotional prospects within the company			.550					
J11 Fringe benefits (eg company shares, car etc)				.796				
J31 Good bonuses based on performance				.715				
J6 A high salary for the industry				.546				
J13 Company reputation nationally					.822			
J14 Company reputation internationally					.716			
J8 Reliable internal communications						.874		
J9 Supportive superiors						.646		
J29 Proximity of company to my home							.782	
J27 There are few opportunities in IT at present							.739	
J17 Company size								.768
J30 Organization is socially active								.646

Extraction Method: PCA.
Rotation Method: Varimax with Kaiser Normalization.
a Rotation converged in 9 iterations.

Staying Factor Comparisons

The results for staying with the company are presented in Table 5. All factors exhibited significant differences across the three samples with the Chinese group clearly rating their views much lower than the others. Rewards, reputation and recognition factors are more important to the Philippine group but risk factor are more important to the Australian group.

Differences

Table 6 summarizes the differences in composite responses for joining and staying with a company. In all cases the z-scores are negative suggesting a lessening of attitude towards their employing company. However there are no significant differences for the Australian group for any of the factors at the 0.05 or 0.1 levels. For the Chinese, "people issues" are significantly different with an increase in the positive ranks. For the other groups there was also an increase but the results were not significant. For the Philippine group the situation is quite different with four factors showing a significant difference between the joining and staying responses covering job challenges, recognition of self, financial rewards and risk factors. Non-financial rewards, company reputation and the support culture factors are not significant for the Philippine group at the 0.05 level but are at the 0.1 level. Only the people factor is not from significant at these levels. However these results display a lessening in the reasons for staying compared with those for joining with the exception of company reputation.

DISCUSSION

These preliminary indicators show that there are some differences in expectations of IS/IT professionals based on cultural origins. It appears from the results that remuneration are less important to both Chinese and Australian IS workers than for Philippine IS workers and similarly for non-monetary rewards. Company reputation is more of an attraction for Philippine staff. Australian staff appear to favor broad recognition of to motivate them to join a company. Australian IS workers also indicate factor such as job availability and proximity to home as important and this may indicate a concern for the current job market in Australia

The differences when asked whether the same items that attracted them to join a company also were important in their staying with the company displayed interesting cultural differences. The responses from Australian participants did not show significant changes. People issues were less and significant for the Chinese group but the remaining factor bore no significant differences. For the Philippine IS workers there were several factors that were significantly different at the 0.05

Table 4. Composite factor mean ranks for each country (joining company) (significant for p<0.01; # not significant p>0.05)*

	country	N	Mean Rank
job challenges *	Australia	40	68.61
	China	29	42.03
	Philippines	47	60.05

	Philippines	47	60.56
people stay	Australia	40	60.84
	China	29	41.60
	Philippines	47	66.94
	Total (all)	116	

level or better. Factors that became more important included Challenges, Recognition, Rewards ($p<0.1$), Remuneration, Support ($p<0.1$) and Risks; Company reputation was less important ($p<0.1$).

The study has its limitations. Firstly, the number of respondents is quite small and this limits the ability to generalize the results. The differences in responses concerning reasons for joining and reasons for staying with a company were obtained at the same time. This of course relies on the ability of the respondent to remember what aspects were the attractions to join the company and this is problematic for those with a longer service. The data were collected in the respondent's home country. The same outcomes may not be present if collected from people working in a foreign country.

The research reported here is preliminary in nature but does suggest that cultural differences may affect IS/IT staff preferences when it comes to rewards and incentives. With the growing internationalization of companies, the increased mobility of staff, and a growing number of staff from different cultures, it should not be assumed that a homogeneous reward/incentive structure is going to satisfy all. More research into this appears warranted.

The instrument used is available on request.

ABSTRACT

The division Concepts of the Assistant Chief of Staff Evaluation (ACOS Eval) of the Belgian Ministry of Defence is making a study on the subject of "management by costs" based on an approach of capabilities. The original idea was based on the generation of future capabilities (investments and planning) and later extended to the operational use of the existing capabilities. In this paper an intelligent agents framework is proposed to simulate the possible scenarios of capabilities. Central to this subject is the ontology issue, where the Ontology Negotiation Protocol, as explained by Bailin and Truszkowski [Bailin 2001], is one of the solutions that should be further developed to resolve the problems related to the ontologies.

Keywords: Intelligent agent, strategy, capabilities, resources planning, ontologies, ONP (Ontolgy Negotiation Protocol), Military

1. INTRODUCTION

The division Concepts of the Assistant Chief of Staff Evaluation (ACOS Eval) of the Belgian Ministry of Defence is making a study on the subject of "management by costs". The purpose of the study is not only to develop a system to manage the costs, but also to provide a decision support system (DSS) to the leaders and managers, based on information about costs.

The original idea was based on the generation of future capabilities (investments and planning) and later extended to the operational use of the existing capabilities. The challenge is that the political (and social) environment is changing fast, which has a considerable influence on the (political) way of using Defence in such a fast moving world.

Flexibility and quick adaptability to new situations are very important in the planning and acquisition of resources for military capabilities. Therefore a system to support the process of acquisition and operational use of capabilities should be dynamic and agile. Scenarios must be quickly and thoroughly evaluated without ignoring the impacts on existing programs and performances.

The study has three phases. The first one is to define an ideal system where different kind of techniques are used like operational research, commercial-of-the-shelf software, benchmarking and intelligent agents. The latter is the subject of this paper. The second phase is to distillate the necessary conditions of "the management by costs" and confront them in a third phase with the existing (dispersed but not integrated) systems to propose the change management, which implies the implementation of the new system.

This paper will treat a conceptual model of "management by costs" to plan the acquisition of future resources and to follow up the operational use of the actual resources, by using intelligent agents (pieces of software which can determine their own strategy to obtain their given objectives). In the following paragraph, the global context of capability approach is described. Paragraph three discusses the framework of intelligent agents for the configuration of future capabilities and the issues around ontologies. The operational use of capabilities is described in paragraph four. This paper ends with possible extensions of this framework, further research and conclusions.

2. CAPABILITY APPROACH

The political leaders would like to have some effects on the society (outcomes) by using the military power, which will then perform actions (output) to obtain these effects. The wanted effects will be described in a number of scenarios ([Bernard 1978], [Géré 2000]) . Therefore the Military Command will configure capabilities to perform actions for all scenarios. However due to budgetary and operational reasons, not all scenarios can be covered at the same moment. The political leaders have to express which will be the maximum deployment of forces (capabilities) at the same time. Military Command can propose different configurations, each with the costs. Or the political leaders can decide a maximum budget, for which the Military Command can optimise the configuration of capabilities. Rabaey et al. [Rabaey 2006b] describe a model of the capability approach based on semantic web technologies, however this model uses only web services and concerns more the business processes necessary in a framework of capability approach.

Modules deliver the necessary capabilities, where one module can serve multiple capabilities. These modules are composed of resources. In the process area of capabilities generation, modules and/or resources are acquired following investment and recruiting plans (acquisition function). So we have a schema of outcomes – outputs – capabilities – modules – resources [Rabaey 2006a].

3. DYNAMIC SYSTEM WITH INTELLIGENT AGENTS

3.1. General Description

As already mentioned, the environment of a country or allied countries is changing very fast. A 'stable' future cannot be foreseen and the enemies of the democratic countries and the operation theatres are all over the world and are quite unpredictable. Therefore a dynamic system to determine the most optimal configuration is necessary.

Rabaey et al. described the concept of Business Intelligent Agents (BIA) to construct dynamic processes [Rabaey 2003]. The BIA asks for services at web services or other BIA. The correct communications through the different ontologies are therefore very important. In this paper we present a framework that goes deeper into the processes and services, namely the resources which use the processes.

So, we are studying a model where intelligent agents (IA) represent the items of some levels. Intelligent Agents are software entities that carry out some set of operations on behalf of a user or another program with some degree of independence or autonomy, and in so doing, employ some knowledge or representation of the user's goals or desires.

They get their information out of a Knowledge Base (KnB) by appealing to the KnB's IA and its ontology. Citing Gruber, an ontology is "a specification of a conceptualization" [Gruber 1993]. It describes the terms with their attributes and relationships in a specific domain. When ontologies were introduced in computer science, they were designed for artificial intelligence purposes since they pertain to knowledge sharing and reuse [Gruber 1991]. More recently, they are also used in the fields of information retrieval and the like [Fensel 2004]. The introduction of ontologies in information retrieval improved the search results in a repository or knowledge base. Contrary to a traditional keywords search, only information relevant to the request or query is shown due to the shared understanding. Not

only a shared vocabulary is available, but also axioms for specifying the relationships between the different terms [Decker 1999]. Therefore, the information of the KnB is categorized on the basis of an ontology.

3.2. Dynamic and Complex System

The idea of IA's came from concepts of quantum medicine and quantum healing. Some forms of quantum medicine tell us amongst other things that the whole body keeps memories of events and emotions and that organs, molecules and so on have knowledge or intelligence of what has to be done in the body (through some sort of 'communication channels'). This implies that the brains control not everything, but that intelligence and communication capabilities are spread all over the body [Chopra 1989].

So the model of the armed forces is the quantum model of the body and the mind, and each part, represented by an IA, can communicate to bring and to keep the body and the mind (Defence-model) in balance and optimise its functioning. However, it is not the purpose to develop a "Quantum Defence" where everything is leaded and managed by software pieces. The purpose of the quantum medicine is to construct a model of the mind/body to better understand the complex set of mind and body of a human being. Our purpose is to give the military leaders a model/tool to help them better understand the complex organisation, which Defence is. Nothing can replace the military genius.

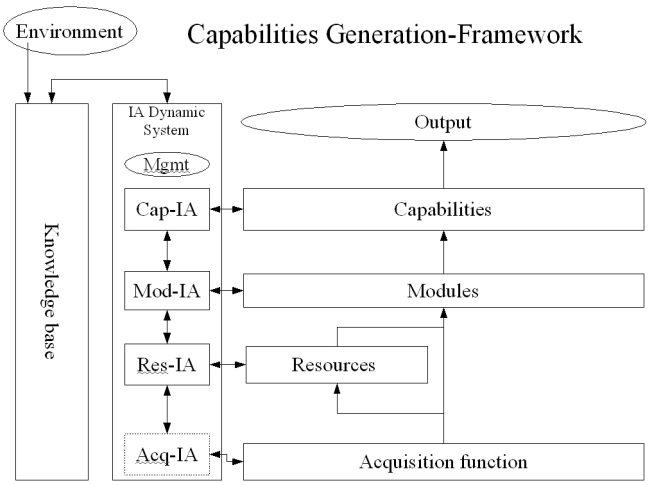
An intelligent agent (IA) or group of IA's represents each item of every level. Each IA is having its own domain ontology. In other words, an ontology is specific related to the agent's world ([Tamma 2006], [Rabaey 2006b]).

The IA's are however working under the guidance of a management cell (Mgmt), which defines the environment, given in a container, that the IA's have to use. This means that the environment or the domain the IA's have to use is described by the ontology of the container. Each IA will receive its ontology or environment by the management cell.

The first semantic problem which poses a problem is when the IA has to formulate a strategy by consulting the information available in the KnB. This implies that the IA needs to understand the ontology employed for categorizing the information in this KnB.

The communication with other IA's is a second ontology conflict which poses a threat. They have to communicate with other IA's of the same or other levels in order to reach its (acceptable) optimised configuration (taking into account the set of constraints and the expected output). At this point, all costs of the resources to acquire (humans, material, infrastructure, etc.) and the costs of existing resources and the maintenance of both can be calculated for a certain period. Of course, the Military Command and/or political leaders will decide themselves, which will be the final solution. The dynamic system is only a decision support system. Therefore, some kind of shared understanding for enabling communication between IA's is imperative [Fensel 2004]

Figure 1. The capabilities generation-framework



Since each IA is using its own private ontology, a mechanism for bridging this ontology heterogeneity is essential [Tamma 2006].

3.3. Ontology Negotiation

Li Ding et al distinguish in their work [Ding 2006] five different kinds of solutions for tackling this problem: one centralized global ontology, merging ontologies, mapping ontologies, ontology translation and runtime ontology resolution. By creating one centralized global ontology, ontology heterogeneity is excluded, but its creation and maintenance is very time-consuming and consequently very expensive. In case different ontologies are having domain similarities, it is interesting to merge them into one ontology. This has as drawback that the merging procedures have to be retaken each time something has changed to one of the initial ontologies. The process where relations between similar words are mapped is called mapping ontologies [Ding 2006]. This technique is very valuable for understanding each IA's view on the world or to visualize their boundary objects [Mika 2003]. A boundary object was first coined by [Star 1989] and can be defined as an object which is used as a kind of interface between boundaries of the domain knowledge of each IA Ontology translation is another solution for ontology heterogeneity. It translates two ontologies into a target ontology. The last kind of solution – runtime ontology resolution – takes place during the real time IA interaction [Ding 2006].

The ontology negotiation protocol (ONP) explained by Bailin and Truszkowski [Bailin 2001] belongs to this latter category. This protocol is focused on information retrieval tasks and is occurring automatically and without a human intervention [Bailin 2001]. The following paragraph summarizes the ONP of Bailin and Truszkowski since we deem that the implementation (with the necessary adaptation) of this protocol in our framework is quite valuable. This ONP distinguishes four parts: interpretation, clarification, relevance analysis and ontology evolution [Bailin 2001].

IA(a) sends a query message (which contains a sequence of keywords) to IA(b). IA(b) tries to interpret each word of the message by looking at its own terminology. In case the word is not retrieved in its terminology, it searches for synonyms at a semantic lexicon such as Wordnet (online available at http://wordnet.princeton.edu). Then, it compares the synonyms with the ones in its own lexicon and when there is a match, IA(b) sends a confirmation to IA(a). In case IA(b) does not find any of the synonyms in its repository, a clarification request is sent to IA(a). After a clarification and/or confirmation, the results of the query are analysed and compared with the query itself in order to determine how well the results (documents) are corresponding with the initial query. The relevance is computed by performing some tests. In the last phase of this negotiation, the possibility of expanding the ontology with new concepts is examined and depending on the results one of the ontologies is adjusted. [Bailin 2001].

3.4. The Working of the Dynamic System

In order to come to an optimised configuration, the ontology problems have to be resolved in order of appearance: interpretation of the KnB's ontology by each IA and the communication between the IA's of the different and equal levels. The paragraphs below describe how these conflicts can be resolved and they are mainly based on the ONP of Bailin and Truszkowski [Bailin 2001].

1. When the IA(a) receives its environment, it can start to collect relevant information in the KnB. It is important for the IA(a) receiving the most appropriate information for establishing its strategy. Based on its received ontology, the IA(a) can formulate and send a query to the IA(b) of the KnB. This query contains a set of keywords collected from the IA(a)'s ontology. Each keyword is being checked whether the IA(b) can understand the keyword. This check is performed by searching for it in its ontology. When the element is not retrieved, a semantic lexicon such as Wordnet should be consulted as is proposed in the ONP of Bailin and Truszkowski. It aims at locating synonyms in the IA(b). These synonyms can enable a semantic translation bridge between both IA's ontologies. In case the intervention of such a lexicon is not sufficient, a clarification should be asked at the IA(a). When a clarification and/or confirmation are obtained, the quality of the query results sent to IA(a) are examined. During the last phase, it should be determined whether the ontology of IA(a) or IA(b) has to be extended with a new concept.
   When this process is executed for every IA, all the IA's have to start formulating their own strategy. How this strategy is built will not be tackled in this paper.

2. After the strategy creation, all the IA's have to communicate with each other in order to come to its optimised configuration. The desired effects and the strategy to obtain these are communicated from top to bottom. The horizontal negotiation or collaborative model is an approach which enables achieving these effects and strategy.
   In this model the IA's are collaborating or negotiating horizontally to get a global optimum (at their level i). This global optimum is based on defining the optimum use of services of a lower level, level i+1. Therefore downwards negotiation for obtaining information on the lower existing services is necessary. The information will then be communicated upwards, to the level i. This means that ontology negotiation is respectively needed in two directions: horizontally and one level downwards. The horizontally ontology heterogeneity can be solved by merging the ontologies of all the IA's of the same level into one ontology X_i. In that way the IA's of the same level can collaborate and negotiate with each other. Consequently, an information query concerning the optimum use of services of the lower level (i+1) is sent to level i. The ontology X_i tries to interpret all the keywords of this query as described in the ONP of Bailin and Truszkowski. With this information the IA's of level i can create a global optimum at level i. This process is repeated until the highest level is reached.

4. OPERATIONAL USE

Derived from the first framework, we can also build a framework where the existing capabilities and its underlying components are trained and used. The main purpose in our study is to get an estimation of the operational costs (operations and training).

Combined with the objectives of the operations (or training), we can define the degrees of effectiveness, efficiency and transmittance. Transmittance is the ratio that determines the allocation of ALL resources of an organisation regarding ALL the objectives of the organisation.

However other aims than management by costs can be obtained. Heraclitus said once: "You could not step twice into the same river; for other waters are ever flowing on to you." If not only the generic characteristics of resources and modules are registered but also others, registered from earlier operations and training (p.e. Moral strength), then we can have the evolution of those items, so that we can differentiate modules and in this way gather the most ideal modules for one use of a specific capability.

Therefore a whole system of evaluation and/or lessons learned can be put in place to register and treat the performance of the different resources and modules. As a consequence, besides getting information about the operational and professional value of the elements of Defence, feedback for the KnB of the Capability Generation Framework will be obtained, so that more accurate information can be taken into account for a better DSS in that domain (See figure 2).

5. EXTENSIONS

Units of the Armed Forces can be in one of the different states (rest, action, and so on). After a period of rest, the resources could be put back for conditioning, forming, then reassigned into modules ready for training in capability scenarios. For a structure of Resources – Modules – Capabilities, this implies that for each level a different kind of management can be designed. If territorial capabilities are demanded, like helping the population during and after disasters, then the capability manager can train the military unites (modules) together with civilian units of the government. This can be done by extending the system to other parts of government departments.

If the military units are deployed with other units of allied nations, then a standardised system can be designed , or the interfaces with the respective systems can be standardised.

In both cases of collaboration with others, the security of the Knowledge Base and of the intelligence must be assured.

The next logical step is to make simulations. Therefore the environment should be modelled. Other systems may represent enemies, terrorist groups, population and so on.

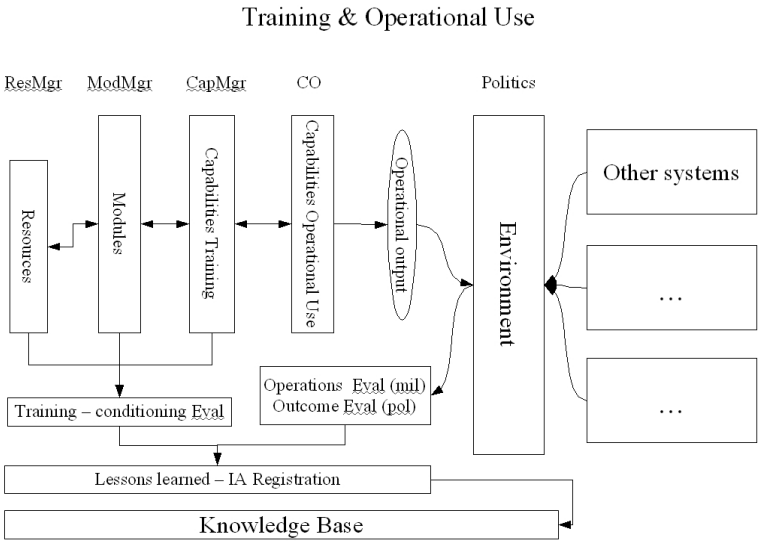
6. FURTHER RESEARCH

Intelligent agents are communicating with each other in so called containers. In the beginning IA could only determine its strategy regarding the environment, if this environment was explicitly defined in its set of parameters. Now IA technology has evolved, IA can now react differently according the rules of the container in which the IA has to undertake actions. Flexibility and adaptability are some of the advantages of specific containers. In the Capability Generation framework, the same system of IA can be used in different countries, each with its own set of acquisition rules, represented by their respective country IA-container.

A second point is the formal way of representing the characteristics of the resources, modules and capabilities, so that they can be interpreted by the IA.

A third point is the refinement of the Ontology Negotiation Protocol of Bailin and Truszkowski [Bailin 2001]. Since a collaboration with other countries and agencies

Figure 2. Training and operational use



is necessary, we may have to consider the incorporation of boundary objects for solving the multi-linguistic ontologies and differences in culture and reasoning. This means that ontology mapping should be embedded in this ONP in order to come to ontology mapping negotiation protocol. This will be the challenge, if no global, universal semantic system will exist.

The system of capabilities and resources planning can also be used in a civilian context (business and/or government), so that synergies with civilian parties can be found.

7. CONCLUSIONS

The dynamic systems of resources and capabilities planning and of capabilities generation are still in a conceptual stage, where further research is still needed. It was originally conceived to calculate the costs of the capabilities generation. We have also seen that the derived operational use model can not only be used to calculate the operational use of existing capabilities, but also to build a global evaluation system, where lessons learned can be established, and that can give feedback to the capabilities generation framework. The possible integration of an "environmental" context could give the opportunity to simulate scenarios and to hold computer aided military exercises.

In this paper an intelligent agents framework is proposed to simulate the possible scenario's of capabilities. Central to this subject is the ontology issue, where the Ontology Negotiation Protocol, as explained by Bailin and Truszkowski [Bailin 2001], is one of the solutions that should be further developed to resolve the problems related to the ontologies.

IT Frauds and Audit Risks: Evidence of Improvements

Saeed Askary, Deakin University, Australia; E-mail: saskary@deakin.edu.au

ABSTRACT

This study examines whether frauds in Information Technology (IT) environment affects audit risk and quality. Information system technology dominates over almost every type of business and auditors should have enough knowledge and skills about those systems as part of their responsibilities to ensure about their client's internal control systems. Auditors should be able to examine the reliability of financial reporting process of those systems and provide audit opinion at the end. Thus, information systems audit, although integrated with the overall audit process and objectives, should finally facilitate for good corporate governance through providing quality audit report. This study uses data from Computer Crime and Security Survey (CCSS) 2006 to investigate the effects of IT risks on audit risks. Interestingly, the study find that the average improvements in audit of control risks is 49 percent, detection risk 46 percent, and inherent risk for as less as 25 percent. An overall improvement for auditor's risk is 41 percent in which it shows a considerable improvement.

Keywords: Audit Risks, IT Crimes, Frauds, Sarbanes-Oxley Act, Internal Control, IS Audit.

"Organizations are reporting a rise in fraud, responding with expanded fraud measures both reactive and preemptive, and planning further actions for the future." Richard H. Girgenti, National Partner in Charge KPMG Forensic (2003)

INTRODUCTION

The purpose of this study is to examine those information technology (IT) risks related to IT's attacks, crimes and frauds on the audit risk from 1999 until 2006. IT risks are key issues for auditors nowadays because of the vast impact of IT as well as the importance of information systems (I.Ss) on producing reliable data and valuable business information to various internal and external users. The impact of IT risk in form of IT crimes, frauds, misuse, attacks on audit risk is important in regard to audit quality and the credibility of financial reports. Moreover, it is important for corporate governance feat the auditor's opinion about how is the design and performance of the I.Ss in which are their direct responsibilities to be monitored and reviewed.

The reliability of information system is significantly depend on the design of the computerised internal controls systems and very critical for companies in achieving to their strategic goals, planning, as well as greater performance in term of high profitability. Information technology prevail over entities of all sizes and integrated with the internal control systems in many ways (Fukukawa, Mock, and Wright, 2006), and thus auditors should consider their due care and skill for understanding the internal control to perform during their audit engagements (ISA 315). Therefore, it is vital for auditors to understand those I.S. risks, frauds, crimes and IT attacks that causes many financial and non-financial damages to their clients. Then they should ensure designing those appropriate tests to ensure detecting the frauds, crimes, errors, and misstatements. A *priori* of the detrimental effects of the IT risks is that the diminishing quality of the I.Ss to generate relevant, reliable and timely reporting and increasing the audit risk. This implies that the IT threats must be identified and documented by auditors at one stage, and then the auditor's role is to analyse the threats along with test the other elements of the internal control system to find out the weakness or shortages to report them to managers in order to be improved and fixed.

The rest of the paper is organised in five sections. First, a discussion is provided about the audit risk and defines the auditors' responsibilities to understand and have enough knowledge and skills of their client IT environment and I.Ss. Then, IS risks are identified following up the methodology and results of the study. Conclusion section is presented at last.

IT AND AUDIT RISKS

According to O'Donnell and Moore (2005) "The pervasive use of systems in organisations and the increased emphasis on assurance of Information Technology (IT) processes has increased the need for accounting professionals with IT control knowledge and skills" (p.64). In addition, auditor should have enough competence including IT knowledge and skills, as required by Section 2 of the IES 8 to become a member of audit profession. This standard identifies two types of competence in form of *general* and *knowledge* contents. Paragraph 40 of the knowledge content requires "the knowledge content of the information technology subjects area should include, first, information technology systems for financial accounting and reporting, including relevant current issues and developments" and second, "frameworks for evaluating controls and assessing risks in accounting and reporting systems as appropriate for the audit of historical financial information" (p.11).

The latest Exposure Draft (ED) of the International Accounting Education Standards Board proposed as the International Education Practice Statement 2.1, *Information Technology for Professional Accountants.* In scope section of the practice statement, audit profession is categorised as "the accountant as assurance provider and evaluator". Paragraph 28 to 31 of the ED details all responsibilities of assurance provider and evaluator role in an IT environment and those required skills as depicted by the Appendix 4 of the ED. The appendix lists various IT tasks and related competence that IT auditors should have in three different areas. These are planning systems evaluation, evaluate systems and communicate results of evaluation and follow-up tasks. In plan systems evaluation, auditors are required to identify, analyse and evaluate risk factors and business issues affecting the IT assurance engagement or project and their implications.

In addition, auditors should also define level/frequency of systems errors, flaws and failures that are deemed significant or material in terms of audit risks. Gallegos (2002) by refer to well-know organisations such as the American Institute of Certified Public Accountants (AICPA), the US General Accounting Office (GAO), the Information Systems Audit and Control Association (ISACA)[1] and the Institute of Internal Auditors (IIA) also defined and listed twelve characters of the due professional care for IT auditors. They are peer review, audit conduct, communication, technical competence, judgment, business knowledge, training, certification, standards independence, continuous reassessment and high ethical standards. Therefore, authors are expected to comply with the characteristics and in case of any failure to detect any IT frauds, errors, misstatements, then this may be considered as an audit negligent, and may bear a legal action against the auditors.

According to Allen *et al.* (2006) strategic risk approach use "industry specialists appears to effectively promote understanding of a client's business risk" and they consider fraud risk as a "a particularly challenging task for auditors to perform" (p.161) . Traditional audit risk model, in which consist of inherent, control and detection risk, underpin the audits of financial statements (Blockdijk, 2004) and should be in the lowest acceptable level to increase the credibility of financial reports through lower level risk or risk free auditor's opinion. Thus, the lower audit risk, then the quality of audit opinion would be higher.

Many research have shown that inherent risk assessment has been interested on actual audit function (e.g. see Waller 1993, Mock and Wright 1993 and Elder and Allen 2003). Inherent risk related those susceptible account balances or transactions in which continued with different level of material misstatement, errors and frauds. Control risk is squarely related to internal control systems design and performance. Detection is the auditors' risk when they fail to detect any misstatement, errors, or fraud that affects fairness and truthfulness of financial statement reports in all material aspect. One exogenous factor influence audit risk is materiality and *a prior* in regard to risk evaluation is, those undetected immaterial risky balances or transactions would not affect the true and fairness of financial reports.

INFORMATION SYSTEMS' AUDIT

The ISACA extensively detailed the IS auditors' responsibilities and issued many comprehensive standards, guidelines and recommendations for this filed of auditing[2]. Based on ISACA, the purpose of IS audit is to review and provide feedback, assurance and suggestions and classifies major elements of IS audit into five broad areas such as physical and environmental review, system administration review, application software review, network security review, business continuity review, and data integrity review.

Notwithstanding I.S audit or general audit function, auditors should assess the integrity and robustness of internal control systems. The importance of internal controls generally is highlighted by the Sarbanes-Oxley Act in section 404, in which the Act requires organizations to select and implement a suitable internal control framework to strong corporate governance and reducing risk management by the accuracy, reliability, and integrity of an organization's transactional data. However, the significant role that information technology plays in design, efficiency and applicability of the internal controls need more attentions from auditors' perspectives to reduce IS audit risk as a point of quality audit opinion. Many IT environments' internal control framework such as COSO's *Internal Control—Integrated Framework* has become commonly used framework by many companies claim that the framework complies with Sarbanes-Oxley. However, according to Ernst & Young March 2005 survey of US listed foreign private issuers, almost half of the companies did not plan to conduct a separate and distinct fraud risk assessment of their internal controls in which required by SOX 404 to accomplished by 15 July 2006.

As a result of continuing efforts to define, assess, report on, and improve internal control systems recently five guidelines have been published by recognized professional bodies. These are the Information Systems Audit and Control Foundation issued COBIT (Control Objectives for Information and related Technology), the Institute of Internal Auditors Research Foundation by Systems Auditability and Control (SAC), the Committee of Sponsoring Organizations of the Treadway Commission's Internal Control - Integrated Framework (COSO), and the American Institute of Certified Public Accountants issued the Consideration of the Internal Control Structure in a Financial Statement Audit (SAS 55), as amended by Consideration of Internal Control in a Financial Statement Audit: An Amendment to SAS 55 (SAS 78) (Janet L. Colbert, and Paul L. Bowen). Those reports reveal the importance of internal controls in an I.S audit environment particularly for risk assessment and internal controls structure.

Majority of professional accountants bodies (i.e. Big 4) provide the following services under Systems and Process Assurance (SPA) services[3] such as financial and operation applications, business process controls reviews, database security controls reviews, IT general controls reviews, infrastructure security reviews, third party assurance and opinion services, Sarbanes-Oxley readiness, process improvement and sustainability services, compliance with other regulatory requirements (e.g., Turnbull, Basel II, King), due diligence on systems and controls, pre and post-implementation systems reviews, project assurance services, data services (e.g., CAATs, data quality reviews), and computer security reviews.

DATA AND METHODOLOGY AND RESEARCH QUESTION

The study used the findings of Computer Crime and Security Survey (CCSS) 2006 due to the uniqueness of the survey in US. Respondents from corporations, government agencies, financial institutions, medical, and universities consist of 616 computer security practitioners. The survey measured the U.S dollar amount of losses by type of the computer crimes, security and frauds. Total losses for 2006 is US $52,494,290 mainly consisted of unauthorized access to information ($10,617,000), laptop or mobile hardware theft ($6,642,660), theft of proprietary information ($6,034,000), and financial fraud ($2,556,900) and other losses due to I.S risks are about $26,643,000. The main concentration has been devoted to CCSS's types and trends of the attacks, crimes, misuses, and fraud from 1999 to 2006 to answer this question:

Table 1. IT risks associated with the audit risk components

IT Frauds	Audit Risk Relevance
Theft of proprietary information	Control Risk
Insider abuse of net access	Control Risk
System penetration	Control Risk
Unauthorised access to information	Control Risk
Laptop/mobile theft	Control Risk
Telecom fraud	Detection Risk
Financial fraud	Detection Risk
Misuse of public web application	Inherent Risk
Virus	Inherent Risk
Abuse of Wireless network	Inherent Risk

Research Question : If audit risk is affected by IT risks, misuses and attacks and internal control systems, which is a great source for auditor to assess about control risks, are affected by the IT risk, then have improvements been taken places by the corporate entities since year 1999 to prevent those frauds?

In order to evaluate the effect of the IT risks, first a relationship between those IT risks should be established with audit risk components; that is, inherent risks, control risks, and detection risks. In order to have this relationship, Table 1 developed to summarise the IT risks which is adopted from figure 14 (p. 13) of the CCSS survey. For classification purpose of the IT risks, then theft of proprietary information, insider abuse of net access, system penetration, unauthorised access to information, and laptop mobile thefts are associated with the control risks and telecom and financial frauds are associated with the detection risk or auditor's risk. Misuse of public web application and virus and abuse of wireless network are considered to be inherent risks.

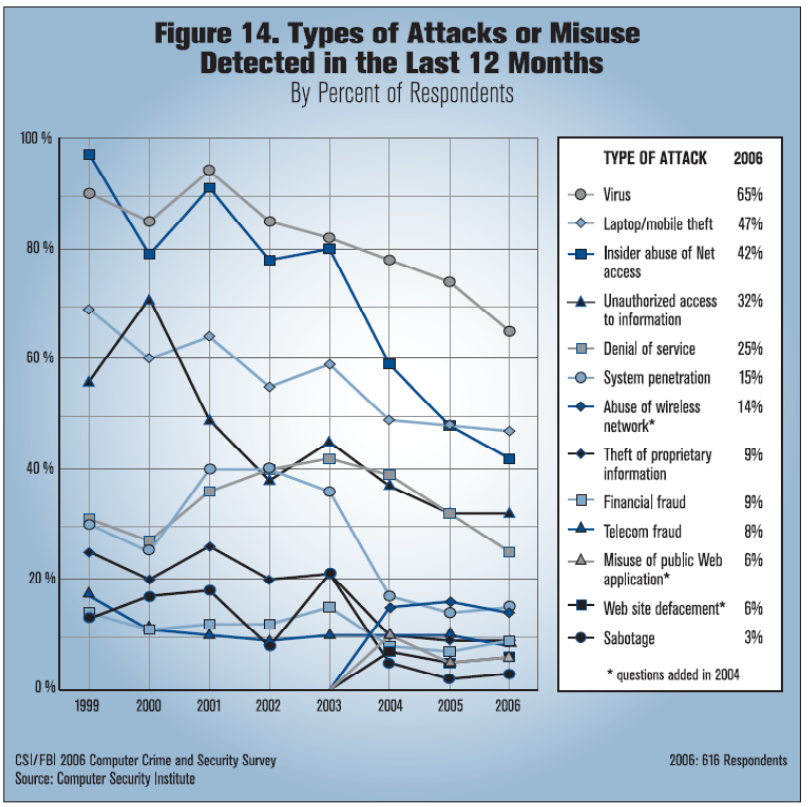
A trend analysis of the IS risks close to audit risks have been performed by looking at the data from 1999 till 2006. Then improved or declined percentages are measured to evidence of decrease or increase in overall audit risks.

RESULTS

Descriptive results of the CCSS survey shows that 21 percent[4] of respondents declared the experience of IT attacks, crimes and fraud risks that harmed the confidentiality, integrity or availability of network data and systems from as less as once to more than ten times. Various kinds of technologies used for the security purposes mainly were the anti-virus softwares (98 percent), Firewalls (95 percent) and Access Controls (93 percent). More interestingly, the respondents also used largely the computer security policies and procedures such system audit policy (51 percent), external network access control policies (75 percent), user access management(95 percent), media backup procedures (94 percent) and documented standard operating procedures(79 percent). Figure 1 graphically shows general improvements in IT risks as follows.

The figure generally demonstrates that a steady decrease in almost all of IT types of risks detected since 1999. Table 2 quantified all IT risks and their percentage of changes from the CCSS survey. There were, however, three areas in which average losses *increased.* Losses from laptop or mobile hardware theft increased from $19,562 per respondent in 2005 to $30,057 per respondent in 2006. Losses

Figure 1. Types of IT risks and their trends since year 1999



from telecommunication fraud increased dramatically from $2,750 per respondent in 2005 to $12,377 per respondent in 2006. The third category in which average losses increased was Web site defacement. While the average losses for this category increased from $1,494 per respondent to $1,806 per respondent, less than one-third of a percent of total losses reported were due to Web site defacement (CSI/FBI 2006).

The results, as derived from the table, represents that the lowest improvement is related to abuse of wireless network and the highest improvement correlated with theft of proprietary information. Average improvement in audit control risks is 49 percent, detection risk 46 percent and inherent risk only 25 percent. An overall improvement for auditor's risk is about 41 percent which is a considerable

Table 2. Changes in improvement of Audit Risk in terms of IT risks

IT Frauds	Audit Risk Relevance	1999 %	2006 %	Δ % (Improvement)
Theft of proprietary information	Control Risk	0.25	0.09	-64%
Insider abuse of net access	Control Risk	0.97	0.42	-57%
Telecom fraud	Detection Risk	0.18	0.08	-56%
System penetration	Control Risk	0.30	0.15	-50%
Unauthorised access to information	Control Risk	0.56	0.32	-43%
Misuse of public web application*	Inherent Risk	0.10	0.06	-40%
Financial fraud	Detection Risk	0.14	0.09	-36%
Laptop/mobile theft	Control Risk	0.70	0.47	-33%
Virus	Inherent Risk	0.90	0.65	-28%
Abuse of Wireless network*	Inherent Risk	0.15	0.14	-7%
Total Average				41%

*Since 2004

improvement in IS audit risks and require more investigations to establish why and under which circumstances these issues have came about.

The report also implied that "the impact of the Sarbanes–Oxley Act on information security continues to be substantial" (CCSS, 2006, p. 2). Also, the respondents replied that regulatory compliance related to information security is one of the most critical security issues they face (Ibid). The role of the Sarbanes–Oxley Act of 2002 on security activities considered to be of the critical issues for the next two years by 63 precent of the respondents.

This survey also addressed several emerging security issues that were first searched only with the survey. All of the following issues relate to the economic decisions organizations make regarding computer security and the way they manage the risk associated with security violations. These are those techniques organizations should evaluate the performance of their computer security investments; security training needs of organizations; organizational spending on security investments; the impact of outsourcing on computer security activities; the use of security audits and external insurance also revealed that over 80 percent of the organization conduct security audit, and the portion of the information technology (IT) budget organizations devote to computer security.

CONCLUSION

An information system audit is part of the overall audit assessment process by auditors, if the assessment is conducted to reduce to the low level, then it is one of the facilitators for good corporate governance via reporting quality earnings and information. This study reveals through the CSI/FBI survey 2006 the evidence of improvements in form of reduced I.S risks within I.S environments including IT crimes, frauds, and misuse. The results show that a considerable improvement of 41 percent in audit risks had been achieved by U.S corporations. Initial cause for this improvement may related to conduct security audits, that the survey shows over 80 percent of the organisations conduct security audits, and the impact of the Sarbanes-Oxley Act on information security continues, as this is confirmed to be substantial by the survey.

ENDNOTES

1. The ISACA is one of the Professional associations in information systems (IS) audit, control, security and governance. ISACA has a global membership of more than 35,000 in 100 countries in Asia, Central America, South America, Europe, Africa, North America and Oceania. Founded in 1969 as the EDP Auditors Association, ISACA is a global leader in IT governance, security, control and assurance. It is the single leading international source for information technology controls. ISACA is dedicated to serving the needs of its members, who are internal and external auditors, CEOs, CFOs, CIOs, educators, information security and control professionals, students and IT consultants (http://www.isaca.com).
2. So far, fourteen standards for IS Auditing has been published. See the web link: http://www.isaca.org/Template.cfm?Section=Downloads5&Template=/ContentManagement/ContentDisplay.cfm&ContentID=18248

4. 48 out of 341 respondents (Table 1 of the CCSS report) experienced 1-5 times, 15 respondents declare 6-10 times, and 9 declared more 10 times.

Dynamic Distributed Data Warehouse Design

Karima Tekaya, ISI ARIANA, Tunisia; E-mail: Karima.Tekaya@isi.rnu.tn

ABSTRACT

The fragmentation of a data warehouse into multiple data mart makes the task of the administrator very difficult. He must manage all operations of insertion, update and delete at the level of sources, Extraction, Transformation and Load (ETL) operations, logical Models, fragmentation and allocation. While nearly touching all levels of the architecture of a data warehouse, the administrator's task is going to become especially as difficult as the level of fragmentation is raised. Of this fact, it will be interesting to develop an auto-evolutionary system permitting to maintain a data warehouse up to date without interrupting its working and while keeping all the time one same level of performance. This article presents a dynamic distributed data warehouse design, proposes some basic concepts, develops a formulation of the problem and integrates an automatic system of administration based on intelligent agents.

Keywords: data warehouse, dynamic, fragmentation, ETL, Replication and design.

1. INTRODUCTION

A data warehouse is generally characterized by a very big volume of data; it is used, contrary to the transactional data bases, exclusively in consultation, all operations of up dating are taken in charge by the administrator. A data warehouse can be centralized or distributed. Many researches to date investigate building distributed data warehouses with particular emphasis placed on distribution design for data warehouse environment and the dynamic aspect is the current subject of work in the autonomic data management area.

The following section, presents in more details the problematic. The section 3 summarizes the state of art concerning data warehouse fragmentation techniques and dynamic data bases. The section 4, presents the contribution of this article and in the section 5, a dynamic distributed data warehouse design solution will be developed.

2. PROBLEMATIC

The problem of data warehouse fragmentation was carefully developed in [7], [8] and in [9]. But, the realized works always gave a static fragmentation that requires to be updated every time there is a change.

All operations of up dating are taken in charge by the administrator; the partitioning of data into multiple data mart is going to make very difficult his task. He must manage all operations of insertion, updating and deleting, at the level of sources, Extraction, Transformation and Load (ETL) operations, logical Models, fragments and allocation. While nearly touching all levels of the architecture of a data warehouse, the administrator's task is going to become especially as difficult as the level of fragmentation is raised.

3. STATE OF THE ART

Distributed Data Warehouse and Fragmentation Techniques

In [4] and in [5], authors proposed an architecture for distributed data warehouse. It is based on the ANSI/SPARC architecture that has three levels of schemas: internal, conceptual, and external. This work is based on TOP/DOWN approach and presents two fundamental issues: fragmentation and allocation of the fragment to various sites. Authors proposed a horizontal fragmentation algorithm for a fact table of a data warehouse. In [1], we have proposed a methodology for relational distributed data warehouse design. For this purpose, we develop a set of matrix: 'Matrix of data partitioning', 'matrix of data allocation' and a 'matrix of data source and in [2] we adapt the same methodology to the multidimensional environment. In [5], [4], [1] and in [2], a basic architecture of a distributed data warehouse has been proposed; we suggest the implementation of these works in a distributed environment.

Several works shows the importance of fragmentation in a data warehouse context, it represents today a more challenging stake that in a relational or objects database context. [6],[7],[8],[9],[10],[11],[12],[13]. In addition, several commercial products showed the utility of fragmentation in the process of queries optimization: In [1], we proposed a matrix of fragmentation, 'Horizontal Matrix of fragmentation ', making abstraction to the approach of modeling, this matrix permits from a logical table to generate a set of fragments and it has as input: queries and their frequencies of utilization. Thereafter, we proposed a matrix of allocation permitting to allocate every fragment to the most adequate site. One data can be a table or a fragment of table. In [2] the same solution was adapted in a dimensional environment; we have experiment the solution through an example. In [3] the same problematic was presented and some arguments are showed to prove the importance of fragmentation in distributed data warehouses environment. Otherwise, several works of research and the commercial products showed the utility of fragmentation techniques in the process of queries optimization [13]. Horizontal fragmentation in data warehouses is more challenging compared to that in relational and object databases. This challenge is due to the several choices of partitioning schemas that can be found in [8]

Dynamic Data Warehouse

We are not aware of any research work addressing the dynamic data warehouse. Some works developed the idea of a incremental design of a data warehouse [14], and other works are focused on dynamic operational data bases [15] , [16].

4. CONTRIBUTIONS

The contribution brought by this article consists in proposing a methodology for a dynamic distributed data warehouse design. This solution is essentially based on the extension of the classic solution of a centralized data warehouse. Some basic concepts are added, a formalism of presentation is developed and the integration of an automated administration system is done to maintain the data warehouse continuously up to date. The proposed solution can be adapted to centralized and so to distributed data warehouse.

5. DYNAMIC DISTRIBUTED DATA WAREHOUSE DESIGN (FIGURE 1)

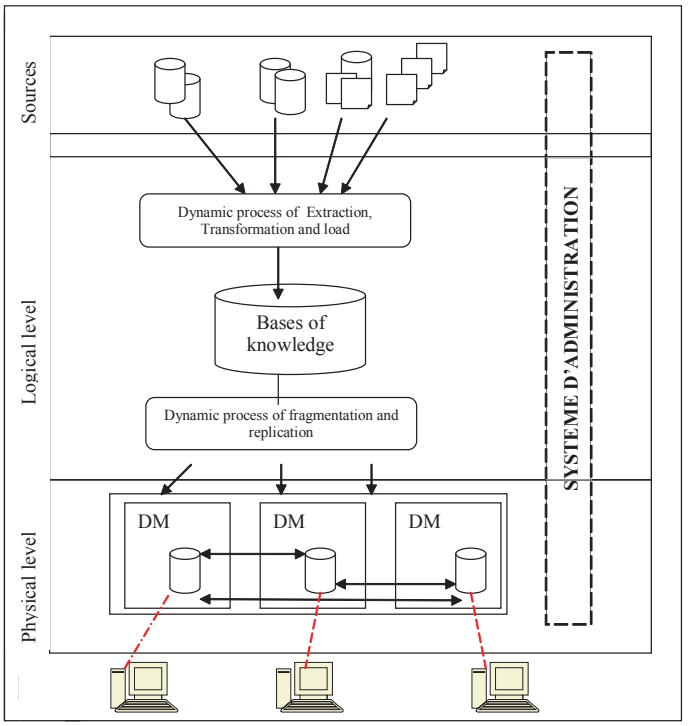
5.1 Basic Concepts

The proposed solution is an extension of work achieved in [2], this work is essentially based on the integration of a process of fragmentation and replication into the design level.

We propose the following basic concepts:

- *Dynamic process of extraction, transformation and load*: We add the term dynamic because this system is activated each time there is a change in data sources, function of transformation and load operations.
- *Bases of knowledge*: describes each data in the data warehouse. A data is characterized by a source, function of transformations and the allocation.

Figure 1. Architecture of a dynamic distributed data warehouse



- *Dynamic process of fragmentation and replication*: added to generate the derived horizontal fragmentation to the different tables and to found the best allocation for each data or fragment. We add the term dynamic because this system is activated each time there is a change in query frequency or structure.

- *System of administration*: integrate all functionalities to maintain a data warehouse up to date. The system of administration is touching all levels of the architecture of a distributed data warehouse (Figure 1). It's role is
  - o (1) to detect needs of refreshment of each data in every data mart,
  - o (2) to detect changes in function of transformation in every data mart,
  - o (3) to detect needs of updating in the bases of knowledge
  - o (4) to detect changes in query structure or frequency

5.2 Formalism

We are going to formalize the different concepts proposed through computational multi-dimensional matrixes.

a) The Matrix of Data Sources Integration (Table 1)

The d*ynamic process of extraction, transformation and load* can be simplified with the Matrix of Data Sources Integration MDSI (Table1), for each attribute A_{jL} ((1<=j=k), (1<=L=m); k the number of dimension or fact table (Ti) and m the number of attribute in Ti from dimensional model. We put for each data (1) *the source* (from which Logical Model LMr (1<=r<=s; s the number of source used for the integration process. (2) for each data A_{rz}((1<=r<=s, 1<=z<=x ; x the number of attribute for each LMr) the transformation function applied into data source to make an attribute A_{jL} adapted to the specification of the integrated data warehouse.

A transformation can be elementary or composite.

An elementary transformation is gotten while calculating the function $f_{tc(}\mathbf{A}_{rz),}$ it gives as result an attribute $\mathbf{a}_{j\,L}$ that will be integrated in the data warehouse.

A transformation can be composite (CT), that means, calculated according to several attributes sources. The result will be gotten while applying the function $f_{tc(}\mathbf{A}_{r1},...,\mathbf{A}_{rx),}$ This matrix has been implemented in [2].

b) Matrix of Primary and Derived Horizontal Fragmentation (Table2)

The dynamic process of fragmentation can be simplified by the Matrix of Primary and Derived Horizontal Fragmentation (MPDHF). The MPDHF consists to the definition of the uses of data by the treatments t_{ipi} (1<=i<=n, 1<=pi<=qi ; n numbers it of site, q numbers it of treatment by site. A treatment t_{ipi} can use one or several tables DTj dimension DTj (1<=j<=k; k number of dimension table from the star

Table 1. The matrix of data sources integration

Table 2. Matrix of primary and derived horizontal fragmentation

		Treatments	DIMENSION TABLES		
			$DT_1(a_{1,1}, \ldots a_{1,L1}, \ldots a_{1,m1})$	$DT_j(a_{j,1}, \ldots a_{jLj}, \ldots a_{j,mj})$	$DT_k(a_{k,1}, \ldots, a_{k,Lk}, \ldots a_{k,mk})$
SITES	S_1	$t_{1,1}$ ... $t_{1,p1}$ .... $t_{1,q1}$	$Fhp_{11}=f_p(DT_1, \{a_{1,l1,..,} a_{1,Ll}\},CF)$ $Fhd_{11}=f_d(FT, Fhp_{11,} CJ)$	…	…
	…				
	S_i	$t_{i,1}$ ... $t_{i,pi}$ ... $t_{i,qi}$	$Fhp_{1i}=f_p(DT_1, \{a_{1,l1,..,} a_{1,Ll}\},CF)$ $Fhd_{11}=f_d(FT, Fhp_{11,} CJ)$	$Fhp_{ji}=f_p(DT_j, \{a_{j,1,..,} a_{j,Lj}\},CF)$ $Fhd_{ji}=f_d(FT, Fhp_{ji,} CJ)$	…
	…				
	S_n	$t_{n,1}$ ... $t_{n,pn}$ ... $t_{n,qn}$	…	…	$Fhp_{nk}=f_p(DT_k, \{a_{k,1,..,} a_{k,Lk}\},CF)$ $Fhd_{nk}=f_d(FT, Fhp_{nk,} CJ)$

model) and/or one or several attributes a_{jLj} (1<=L<=m; m number of attribute of a dimension table DTj. For example, a fragment horizontal primary Fhp_{11} is generated following the use of one or several attributes $a_{j,Lj}$ of the dimension table DT1 and by the treatment $t_{1,1}$.

The list of the primary horizontal fragments results from the application of the function f_p that takes in entry the dimension table to fragment DT_j, the list of the attributes concerned by fragmentation $\{a_{1,l1,..,} a_{1,Ll}\}$ and the criteria of fragmentation CF. It returns as result a fragment of the dimension table DT_j.

The list of the derived fragments results from the application of the function f_d that takes in entry the concerned FT, the primary horizontal fragment Fhp and join condition. It return's as result a derived fragment from the fact table.

c) Allocation Matrix (Table3)

The primary and derivative fragmentation matrix generates a set of data used by the different DM. Let Du be a generated data by the MPDHF (1<=u<=t ; t the number of data generated by the fragmentation process) Du can be a fact table, a dimension table a derived fragment or a primary fragment. If Du is used by Si then it will be automatically allocated to Si. And it will be called Persistent Data (PD). The persistence of one data in a DM depends on its use frequency (Fu). If Fu is equal to 0 it will be suppressed from the site and pass in the absent data (AD) state. The function f_a permits to determine for a data D_u to an instant t and according to the frequency of use Fu if it is PD or AD in a data mart DMi.

d) Matrix of knowledge bases (Table 4)

It gives for every allocated data: the source, transformations and allocation information. A transformation can be elementary $\boldsymbol{f_{tel}(A_{rz})}$ using only one source attribute $\mathbf{A_{rz}}$ or composite $\boldsymbol{f_{tcf}(A_{1z}, A_{1x}, A_{r1}, A_{s1})}$ while using several source attributes.

6. SYSTEM OF ADMINISTRATION (FIGURE 2)

(1) Agent of Refreshment

A data can be a table or a fragment of a table. This one is in evolution; changes can touch its structure (change of source, suppression of one or several attributes, additions of news data on the system…etc.) or the content. All operations of refreshment, updating or suppression on data are activated by the ADR. The ADR is activated by changes witch can occur in data source.

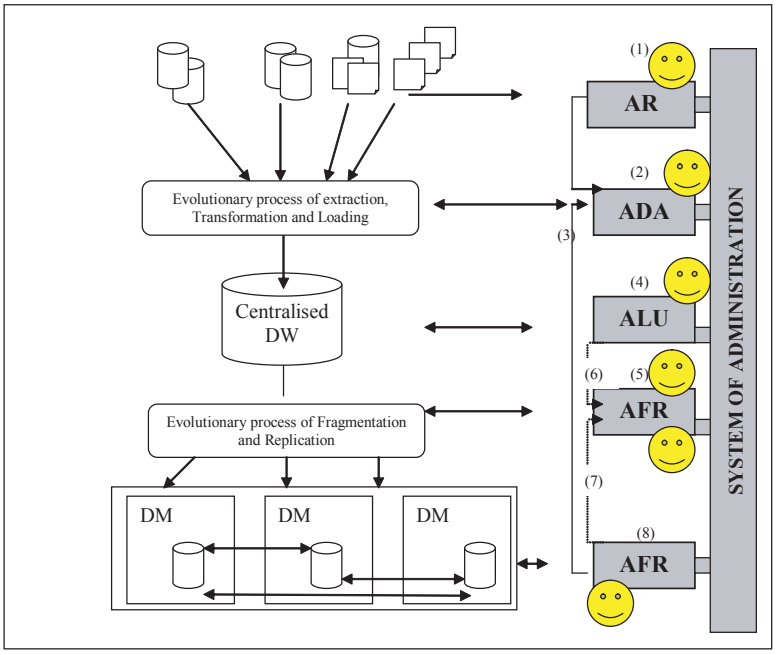
Figure 2. Integration of intelligent agent



(2) Agent of Data Adaptation: (ADA)
Data mart are placed on the different sites, they can have different DBMS, different OS and can have some different features. Data must be adapted to specifications of every site. Then the applied transformation operations on data coming from different sources can undergo changes that vary according to data Marts, and it can also evolve in the time what requires a Refreshment of the corresponding data base. Therefore, the system of administration must take account of all changes concerning the applied transformation operations. The new needs of transformation are detected by the Agent of Data Mart Administration (ADMA) and thereafter communicated to the ADA **(3)**.

(4) Agent of Logical Updating of the Global Data Warehouse Model (ALU):
Its role consists in bringing stakes to necessary updating to the global model of data warehouse if there is a detected change in (1) or in (2).

(5) Agent of Fragmentation and Replication of the Logical Data (AFR)
If we detect one or some modifications at the level of the global logical model of the warehouse **(6)**, it is necessary to regenerate the Evolutionary process of Fragmentation and Replication and to see the impact on the physical models of different data mart. The Criteria of fragmentation essentially are based on decisional queries, these evolve according to the informational needs of the enterprise, this evolution has two types: query frequency and query structure, if there is detection of change (7), The system must verify the impact of this one on the already made fragmentation and so necessary to regenerate the Evolutionary process of Fragmentation and Replication, It will have as consequences the modification of one or some physical models (or data mart).

(7) Agent of Data Mart Administration (ADMA)
The role of this agent is to detect changes in the operation of transformation done by the ADA. It communicates changes to ADA so that it regenerates the evolutionary Process of extraction, transformation and loading. It can also detect changes in decisional queries, these changes can touch their frequencies as well that their structures. It sends an order thereafter to the AFR so that it regenerates the process of fragmentation and replication of the logical data warehouse.

7. CONCLUSION

A data warehouse includes a set of information for the decisional system. It can be centralized or distributed. A data warehouse is dynamic; it can face several evolutions. All operations of refreshment are taken in account by the administrator. The administrator's task becomes difficult if the data warehouse is distributed. To face this problem, we proposed, a methodology of a distributed and dynamic data warehouse design, we proposed a set of basic concepts and a set of matrixes permitting the formalization of the dynamic ETL process, basis of the knowledge, dynamic process of fragmentation and the dynamic process of replication. As perspectives we propose the implementation of the solution.

A Framework for Continuous Monitoring and Assessment of Landline Telecommunication Sectors Based on Standard Indicators

Ali Azadeh, University of Tehran, Iran; E-mail: aazadeh@ut.ac.ir

ABSTRACT

This paper proposes a DEA-PCA based methodology for assessment and ranking of landline telecommunication sectors based on standard indicators identified by the International Telecommunication Union (ITU). A total of 16 indicators were identified from the ITU database. The case study is based on randomly selected 8 indicators. To present the usability of the proposed methodology, data for 18 countries with respect to 3 inputs and 5 outputs were collected through the ITU. The results show weak and strong points of each country identifying, inputs or outputs having major impact on Performance. This is the first study to present an integrated standard model for technical performance analysis of telecommunication landline sectors.

Keywords: DEA, Telecommunication, Landline Sector, PCA, Standard Indicators

1. INTRODUCTION

Major factors influencing the overall productivity of an industrial organization are identified as technology, machinery, management, personnel and rules and procedures ([2], [3], [29]). Technical factors play an important role in the overall performance of a particular industrial sector. In fact, technical productivity is correlated with the overall performance. Furthermore, the overall performance of an industrial organization is often assessed by technical productivity.

The need for an integrated approach for continuous assessment and improvement of telecommunication sectors based on technical performance has become essential. Continuous assessment requires manufacturing classifications and taxonomy to be introduced to enhance knowledge and understanding about the behavior of manufacturing systems ([9], [11], [18], [25], [28]). Consequently, it will enable predictions to be made about organizational system behavior.

2. PROPOSED FRAMEWORK

To achieve the objectives of this study, all technical indicators (inputs and outputs), which influence overall technical performance of telecommunication landline sectors are defined by the ITU [19]. These indicators are related to technical productivity, efficiency, effectiveness and profitability. A generalized classification of standard indicators proposed by the ITU for technical purposes contains of seven groups namely, 1) Telephone network size and dimension, 2) Other services (telex, leased circuits, ISDN subscribers, etc, 3) Quality of service, 4) Traffic, 5) Broadcasting, 6) Mobile services and 7) Information Technology.

Amongst these 7 categories there are standard indicators specified by the International Telecommunication Union (ITU) for performance assessment of landline sectors such as international incoming telephone traffic, telephone faults per 100 lines and telephone faults cleared by next working day. Classified list of standard indicators for telecommunication landline sectors as per International Telecommunication Union (ITU) is given as follows:

Outputs:

1. % of telephone faults cleared by next working day
2. Connection capacity of local exchanges (no. of subscribers connected at one time)
3. International telephone circuits (no. of circuits)
4. % digital main lines
5. Number of local telephone (calls)
6. Number of local telephone (minutes)
7. Number of national long distance telephone (calls)
8. Number of national long distance telephone (minutes)
9. Total national telephone traffic (calls)
10. Total national telephone traffic (minutes)
11. International outgoing telephone traffic (calls)
12. International outgoing telephone traffic (minutes)

Inputs:

1. Telephone faults per 100 main lines (no. of faults)
2. International incoming telephone traffic (calls)
3. International incoming telephone traffic (minutes)
4. Waiting list for main lines (no. of main lines pending to be installed)

The framework of this study utilizes a set of standard indicators, a robust mathematical approach (DEA) and PCA and Spearman correlation technique all used for ranking, assessment and optimization of LTUs being studied. This will aid managers to foresee various economics and technical issues with respect to their LTUs. The steps for implementing the framework of this study are shown as follows:

Step 1: Identify landline technical units (LTUs) or target markets to be studied, ranked and analyzed.

Step 2: Collect standard indicators of the study.

Step 3: Design Preliminary matrix for DEA and conduct DEA analysis, rank LTUs and identify most important inputs and outputs for each LTU. Suppose we have **n** DMUs, where each DMUj (j = 1,…,n) produces 12 output y_{rj} (r = 1,…,5) by utilizing 4 inputs x_{ij} (i =1,…,3). The CRS input-oriented model uses the following measure of performance for DMUj:

$$h_o^* = \underset{v_i,u_r}{Max}\, \mathrm{h}_o \quad \text{S.T.}$$

$$h_j \le 1,\ \mathrm{j} = 1,...,\mathrm{n}$$

$$v_i, u_r \ge 0, \qquad (1)$$

Where $h_o = \frac{\sum_{r=1}^{5} u_r y_o}{\sum_{i=1}^{3} v_i x_o}$ represents the ratio of aggregated outputs to aggregated inputs for one of the **n** DMUs, denoted as $DMU_o, o \in \{1,...,n\}$. x_o and y_o

are respectively the i[th] input and r[th] output of DMUo. By varying **o** over {1,…, n}, we obtain all the DEA scores, h_j^*, with **n** sets of optimal weights. It is clear that larger the h_j^*, the better the performance of DMUj, since DMUj produces more aggregated output or uses less aggregated inputs. However, the highest possible value of h_j^* is one, because of the constraints of Equation (1). If h_j^* = 1, then DMUj is relatively efficient.

The above-mentioned model can lead to a large number of DMUs having DEA scores of unity. We may use the following linear programming problem which is equivalent to Equation (1) by duality:

$$J_o^* = \underset{J_o, l_j}{Min}\ J_o$$

Such that:

$$\sum_{j \neq o} l_j x_j \leq J_o x_o \qquad i = 1,\ldots,4$$
$$\sum_{j \neq o} l_j y_r \geq y_o \qquad r = 1,\ldots,12 \qquad (2)$$
$$l_j \geq 0,\ j \neq o$$

Where J_o is a scalar and λ is a n× 1 vector of constants. The estimated value of J_o is the efficiency score for each of the n DMUs. The linear programming problem must be solved n times, once for each LTU. Equation (1) is known as a constant return to scale (CRS). The CRS assumption is only appropriate when all LTUs are operating at an optimal scale. The optimal values J_o^* can be less than, equal to, or greater than one. Now we are capable to rank the DMUs according to their aggregated output to aggregated to input ratios by J_o^*.

Step 4: Develop Preliminary raw table for PCA analysis. There are 48 indicators to be used in PCA because there are 12 outputs and 4 inputs. Therefore, there are 48 variables and n DMUs and suppose $X = (x_1 \ldots x_p)_{n\times 48}$ is an n× 48 matrix composed by x_{ij}'s defined as the value of jth index for ith DMU and therefore $x_m = (x_{1m} \ldots x_{nm})^T (m = 1,\ldots,48)$. Furthermore, suppose $\hat{X} = (\hat{x}_1 \ldots \hat{x}_p)_{n\times 48}$ is the standardized matrix of $X = (x_1 \ldots x_{48})_{n\times 48}$ with $\hat{x}_{ij}$'s defined as the value of jth standardized index for ith DMU and therefore $\hat{x}_m = (\hat{x}_{1m} \ldots \hat{x}_{nm})^T$. PCA is performed to identify new independent variables or principal components (defined as Y_j for $j=1 \ldots p$), which are respectively different linear combination of $\hat{x}_1 \ldots \hat{x}_{48}$. As mentioned, this is achieved by identifying Eigen structure of the covariance of the original data. The principal components are defined by an n ×48 matrix $Y = (y_1 \ldots y_{48})_{n\times 48}$ composed by y_{ij}'s : The following formulae are used to find out the principal components Y_i, the weights (w_i) of the principal components and PCA scores (z_i of each DMU ($i = 1 \ldots n$).

$$Y_m = \sum_{j=1}^{48} l_{jm} \hat{x}_j \quad \text{for } m = 1 \ldots 48 \text{ and } i = 1 \ldots n \qquad \ldots \quad (4)$$

$$w_j = l_j / \sum_{j=1}^{48} l_j = l_j / 48 \qquad j = 1 \ldots 48 \qquad \ldots \quad (5)$$

$$z_i = \sum_{j=1}^{48} w_j Y_j \qquad i = 1 \ldots n \qquad \ldots \quad (6)$$

Step 5: Verify and validate DEA by PCA by Spearman and Kendal Tau non-parametric correlation analysis methods.

Step 6: Check if the model is validated or not, if validated move on to Step 7, otherwise jump back to Step 2.

Step 7: Utilize the surplus and slack results of DEA for optimization purpose.

Step 8: Assess weak and strong points, take corrective actions and continuously perform DEA, monitor and improve performance.

3. THE CASE STUDY

Landline telephony is one of the most basic needs of today's world. Hence, there is a great need to develop models that assist in determining the efficiency of the sector. The case study works in this direction to present a comprehensive methodology for the assessment of telecommunication landline sector. In order to show the applicability of the proposed methodology a group of 8 indicators comprising of 3 inputs and 5 outputs were collected with respect to 18 countries in 2002 from ITU (Table 1). The following subsections discuss the DEA method used to determine the efficiency of the LTUs, and the PCA method used for verification.

Table 1. The selected technical inputs and outputs

Inputs	x_1	International incoming telephone traffic (minutes)
	x_2	Telephone faults per 100 main lines
	x_3	Waiting list for main lines
Outputs	y_1	% digital main lines
	y_2	% of telephone faults cleared by next working day
	y_3	Connection capacity of local exchanges
	y_4	International outgoing telephone traffic (minutes)
	y_5	International telephone circuits

3.1 DEA for Efficiency Analysis

Table 2 shows the standardized matrix used to perform the DEA analysis. The data presented in the matrix is taken from the International Telecommunications Union (ITU) for year 2002 [19], Landline technical units (LTUs) are listed along with the respective data in the matrix, these values can be obtained online from the ITU website, http://www.itu.int/ITU-D/ict/publications/world/world.html .

As per the generalized equations (1) and (2) for DEA analysis, we can find the efficiency of DMU1 as shown in model 3. The values for the model have been taken from standard DEA matrix shown in Table 2.

$$J_1^* = Min\ J_1$$

$$\sum_{j \neq 1} l_j x_j \leq J_1 x_{i1} \qquad i = 1,\ldots,3$$
$$\sum_{j \neq 1} l_j y_j \geq y_{r1} \qquad r = 1,\ldots,5 \qquad (7)$$
$$l_j \geq 0,\ j \neq 1,\ j = 2,3,\ldots,18$$

Where J_1 is a scalar and λ is a 18× 1 vector of constants. The estimated value of J_1 is the efficiency score for each of the n LTUs. The linear programming problem must be solved n times, once for each LTU. Equation (3) shows the solutions for LTU1. The CRS assumption is only appropriate when all LTUs are operating at an optimal scale. The optimal values of J_1^* can be less than, equal to, or greater than one. Now we are capable to rank the LTUs according to their aggregated output to aggregated to input ratios by J_o^* .After performing DEA analysis it was easy to rank the countries from the range 1 to 18 with respect to their efficiency measures. Table 3 presents the DEA rankings and efficiences of the 18 countries with respect to Model 7. Table 4 shows the results of slack and surplus for the DEA model which may be used for optimization purpose. After performing DEA analysis it was easy to rank the countries from the range 1 to 18 with respect to their efficiency measures.

3.2 Verification and Validation

A comparative study is conducted through PCA by considering the 3 input and 5 output indicators. Furthermore, PCA ranks the countries as per their performance

Table 2. Standardized matrix for 18 countries for DEA (2002)

based on 15 indicators (outputs divided by inputs). This in turn shows which country is either weak or strong in terms of the telecommunication landline sectors. Furthermore, PCA identifies which technical indicators has the major impact on the performance of these countries. In order to verify the finding of the DEA analysis we use the PCA analysis approach and the steps required to do so are mentioned as follows:

Step 1: Normalize and standardize the indicators' vectors. The fifteen indicators must be normalized and have same order to be used in PCA. In this study the outputs were normalized with respect to each input (Table 5).

Step 2: Evaluate the correlation matrix.

Step 3: Eigenvalues, eigenvectors and proportion of the sample variance are calculated for all the twelve principal components (new variables) (Table 6).

Step 4: The principal components and aggregated weights are computed. PCA then provides us with the ranks of the countries as per their performance, the comparision between the DEA results and the PCA results is shown in Table 7.

To verify the results of the integrated DEA model, the PCA rankings are compared with that of the DEA through Spearman correlation experiment. The Spearman correlation is computed by the following formula:

$$r_s = 1 - \frac{6\sum d_i^2}{N(N^2-1)}$$

Where N = 18 and $\Sigma d_i^2 = 198$, substituting values in the equation we find the sperman correlation to be 79.56%. Therefore, we may further analyze and implement the PCA and DEA results. Moreover, the DEA surpluses and slacks may be used for optimization of LTUs as shown in Table 4. PCA may also be used to identify the importance of each of the 15 indicators. It should be noted that the 15 aggregated weights ($\widetilde{w}_m$) for $m = 1 \ldots 15$ show the importance of each indicator computed as follows:

Table 3. The DEA rankings and efficiencies of the LTUs of the 18 countries

LTU	Efficiency	Ranks

4. CONCLUSION

In summary, a unique integrated framework is presented to assess technical performance of the telecommunication landline sectors. Managers on the technical front may use this type of modeling approach to assess the performance of various telecommunication landline services with respect to the technical indicators. In turn, the selected LTUs or target markets would be ranked based on an integrated scientific approach, which reveals the standing of each LTU with respect to a series of standard technical indicators. This would enable managers of telecommunication landline sector to continuously monitor and improve technical performance. In addition, they may want to compare technical performance of a particular LTU or all LTUs with that of similar organizations or competitors. This would bring about further insights and knowledge of their standings with respect to competitors. The case study shows that Taiwan is ranked first and Micronesia is second amongst the 18 countries selected. This is the first study to present an integrated standard model for technical performance of telecommunication landline sectors.

ABSTRACT

This paper shows how to evaluate service quality, improve service deficiency and understanding the needs of customers are the most important issues in mobile value-added service market these days. This study identifies gaps between customers and service providers by a conceptual "Gap model". Based on this study, service providers could obtain higher revenue of mobile value-added service by reducing these perceptive discrepancies.

Keyword: Service; Service quality; Mobile value-added service; Expected service; Perceived service.

1. INTRODUCTION

1.1 Study Background

The market of mobile communication in Taiwan is almost full. Therefore the mobile value-added service will become one of the most competitive facilities for mobile service providers. Unhealthy competition in the mobile service industry has compelled many service providers to initiate quality programs. Achieving high quality standards along with high profitability and great market share is now an important part of strategic planning. The literatures of marketing are also reflecting an awareness of quality. Some of the recent studies have provided the theoretical frameworks of customer expectation of service quality, and some of them have already developed quantitative models to measure service quality.

1.2 Study Motivation

In today's mobile value-added service market, each firm has to provide high quality services to appeal to their customers. Hence how to evaluate service quality, improve service deficiency and understand the needs of customers are the most important issues. For example, with the fast growth of the mobile communication market, people already have more intention to have more services and applications which they can choose from. Among the mobile communication services, text message, voicemail and answering ringing are most popular and widely used today. To ensure the quality of mobile communication service, service providers have to provide convenient, enjoyable and novel services for users. Since more subscribers will create more profits, advertisers will be more willing to cooperate with service providers.

1.3 Study Objectives

This study will discuss the relationship of expectations and perceptions between customers and service providers. Furthermore, it can be applied in the mobile value-added services market.

2. LITERATURE REVIEWS

2.1 Service Quality

2.1.1 Service

Service is identifiable, but essentially intangible activities which are offered by people as products such as delivery and repair. Based on a review of previous research and an exploratory study, Zeithaml(1988, p4) suggested that "perceived value is the customer's overall assessment of the utility of product base on perceptions of what is received and what is given." If perceived service value is similar to the concept of perceived product value, which can be considered to involve a trade-off between a customer's expectation of benefits of using a service and the expectation of cost of using the service. Customers' assessments of service value are hypothesized to influence purchase intentions and behaviors.

2.1.2 Characteristics of Service

There are three well documented characteristics of services as follows:

1. Intangibility: Most services cannot be counted, measured, stored, tested, and verified before selling to customers. Because of intangibility, the firm may find it is difficult to understand how consumers perceive their services and evaluate service quality. (Zeithaml, 1981)
2. Indivisibility: As a consequence, the quality of services cannot be engineered at the manufacturing plant and then delivered to the consumers. That is, quality occurs during services are delivered, usually in an interaction of the customer and the employee of the service providers. (Lehtinen & Lehtinen,1982)
3. Heterogeneity: The performance of services often varies from frim to firm, from customer to customer, and from day to day. Consistency of behavior of service personnel is difficult to assure (Booms & Bitner, 1981). What the firm intends to deliver may be entirely different from what the consumer receives, so the services are heterogeneous.

2.1.3 Service Quality

Service quality is a measurement of the level of how well the service matches the customer expectation. (Lewis & Booms, 1983)

Recent marketing researches, such regarding customers' attitudes toward service, have been focused on perceived service quality. Perceived service quality is defined as the customer's assessment of overall performance of service. (Zeithaml, 1988)

Parasuraman et al.(1985,1988) considers the customer's assessment of overall service quality depends on the gap between customer expectation and perception of actual performance of service.

2.1.4 Dimensions of Service Quality

Consumers' expectations are based on verbal information, personal needs, experience and commercial information. Parasuraman et al. (1985) identified a number of discrepancies in the relationship between the clients and the service providers. During interviews in focus groups, they established ten dimensions of service quality as follows:

1. Tangible features: physical facilities, equipment, and front-line employees.
2. Reliability: ability to perform the promised service dependably and accurately.
3. Responsiveness: willingness and readiness to help clients and provide them services.
4. Communication: providing information in words that clients understand.
5. Credibility: honesty and truthfulness.
6. Security: ensuring clients from physical and financial risks.
7. Competence: adequately trained and skilled employees.
8. Courtesy: helpfulness, respect and a friendly attitude to clients.
9. Knowing: understanding customers and their needs.
10. Access: openness and interaction with clients.

2.2 Gap Model

Research (Thompson, DeSouza & Gale, 1985) and company experience (Rudie & Wansley, 1985) revealed that performing high service quality will result in measurable profits, cost saving, and market share growth. Therefore, knowledge of service quality and how it is achieved in organizations have become the important points for research. Parasuraman, Zeithaml and Ben brry (1985) previously developed service quality model to indicate that consumers' perceptions of service quality are influenced by a series of five distinct gaps occurring in organizations (as figure 1 illustrated). These gaps on the service provider's side may impede high quality performance of services that consumers perceive.

Gap 1: Difference between Expected Service and Management Perceptions of Consumer Expectations.

Service provider executives may not always connote the high quality features to consumers, which attributes what a service must have in order to meet consumers' needs, and the levels of performance on those features are necessary to deliver high quality service. (Langeard et al., 1981; Parasuraman & Zeithaml, 1983)

Gap 2: Difference between Management Perceptions of Consumer Expectations and Service Quality Specification.

Managers may not always have the ability to establish the standard of service quality that can conform to consumer expectation and transfer the standard into the realized ones.

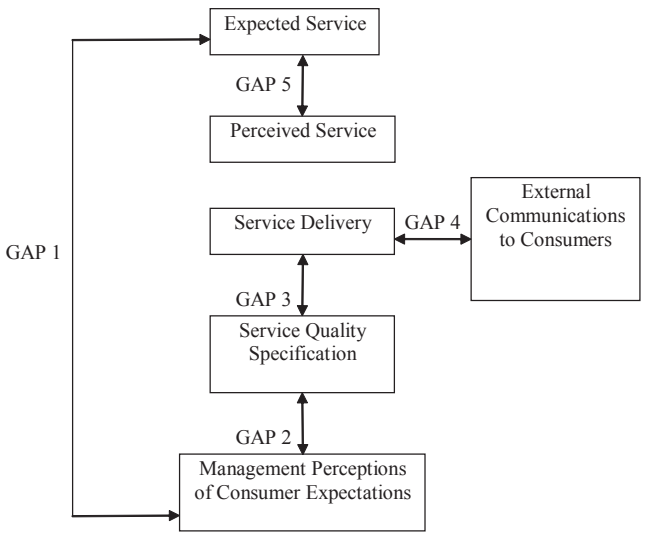
Gap3: Difference between Service Quality Specifications and Service Delivery

There is discrepancy between the specifications of service and the actual delivery of the service. It can be referred to as the "service performance gap". That is, it is the extent which service providers do not perform service at the level consumers expected. The service performance gap occurs when employees are unable or unwilling to perform the service at the desired level. (Zeithaml, Berry & Parasuraman, 1985)

Gap 4: Difference between Service Delivery and External Communications to Consumers

The discrepancy between service delivery and external communications means exaggeratory promises or the absence of information about service delivery. It may affect consumer perception of service quality.

Figure 1. Conceptual model of service quality



Gap5: Difference between Expected Service and Perceived Service

This gap is defined by the PZB model which suggested consumers feel the difference between expected service and perceived service. Hence, gap5 is a function of gap1 to gap4.

3. RESEARCH HYPOTHESES

A set of key discrepancies or gaps exists regarding executive perceptions of service quality and the tasks associate with service delivery to consumers. These gaps can be major hurdles in attempting to deliver a high quality service which consumers expected. The connection between expected service and perceived service is impossible to completely match. In other words, the exaggeration of marketing will influence the difference.

We suggest that the activity of reducing the gaps between expectations, perceptions and the practical actions, is to understand the customers' needs and then service providers will provide the services for matching the needs. Since the higher levels of service quality are related to higher levels of customer satisfaction.

Based on the results of the difference, we have formulated the following hypotheses.

H-1: There are significant discrepancies in customers' expectations of mobile value-added service and management perceptions of these expectations.

H-2: There are significant discrepancies in customers' expectations of mobile value-added service and the service delivered.

H-3: There are significant discrepancies between managers and service providers of the perceptions of customers' expectations of mobile value-added service.

H-4a: Discrepancies between customers' expectations of mobile value-added service quality and management perceptions of such expectations will have negative impact on the quality of mobile value-added service.

H-4b: Discrepancies between customers' expectations of mobile value-added service quality and the service delivered will have negative impact on the quality of mobile value-added service

H-4c: Discrepancies between managers and service providers of the perceptions of customers' expectations of mobile value-added service will have negative impact on the quality of mobile value-added service.

CONCLUSION

The number of users of mobile communication market in Taiwan is very large, but the revenue of mobile value-added service is still insignificant. In other words, there is still potential growth in the mobile value-added service market. By the development of communication technology, it is possible to develop more variety of mobile value-added service today. For developing successful new services, it is important to match the users' needs. We have identified the gaps between customers and service providers above. Based on this study, service providers could obtain higher revenue of mobile value-add service by reducing these perceptive discrepancies.

ABSTRACT

Steganography is the science of hiding information in media based data. We present random numbers logic based steganographic methods and layout management schemes for hiding data/image into image(s). These methods and schemes can be customized according to the requirements of the users and the characteristics of data/images. These methods are secure enough to meet the requirements of the users and user can play significant role in selection and development of these methods. Methods can be chosen randomly and implemented dynamically based on inputs, user choices as well as outputs. Experimental results are given to demonstrate the performance of the proposed methods.

Keywords: Steganography, Cryptography, Random numbers logic etc.

1. INTRODUCTION

Steganography is the art and science of hiding information in ways that prevent the detection of hidden messages. Steganography, derived from Greek, literally means "Covered writing." It includes a vast array of secret communications methods that conceal the message's very existence. These methods include invisible inks, microdots, character arrangement, digital signatures, covert channels, and spread spectrum communications. Steganography and cryptography are cousins in the spy craft family. Cryptography scrambles a message, so that it cannot be understood. Steganography hides the message, so it cannot be seen. A message in cipher text, for instance, might arouse suspicion on the part of the recipient while an "invisible" message created with steganographic methods will not. Modern steganography's goal is to keep hidden message's mere presence undetectable, but steganographic systems because of their invasive nature, leave behind detectable traces in the cover medium. Even if secret content is not revealed, the existence of it can be guessed because modifying the cover medium changes its statistical properties, so eavesdroppers can detect the distortions in the resulting stego medium's statistical properties. The process of finding these distortions is called statistical steganalysis.

In this paper we focus on the developing the techniques that can help hiding messages on the basis of random numbers logic. Present work concentrates upon using Least Significant Bit conversion but is not limited to it. It can involve other methods for steganography discussed in paper. Random numbers based steganographic study is implemented at small scale, but power of random numbers to hide the data/image is not fully exploited and unexplored yet. This paper is an effort to explore the real power of random numbers to hide the messages in secure and customized way.

This paper is organized as follows: Section 2 includes the study of related work. In section 3 we introduce the concept of steganography in more detail, followed by detailed discussion about image processing. In section 4 we discuss about different methods used for steganography. In section 5 includes the proposed methods for steganography based on random numbers logic. In section 6 we discuss few layout management schemes for using methods discussed in section 5. In section 7 we include experimental results to check the strength of proposed methods. Section 8 includes conclusion and future directions for the related research work. Last, but not the least section 9 includes bibliography.

2. RELATED WORK

Steganography is the art of secret communication. Its purpose is to hide the very presence of communication as opposed to cryptography, which aims to make communication unintelligible to those who do not posses the right keys Andersen et al.[1]. The traditional approach to image encoding consists in the source coding, encryption and channel coding Gonzalez et al.[2]. The source coding is used to compress data and match it with the band-width of communication channel. However, the obtained data are sensitive to the communication noise and not protected against unauthorized use. To overcome these disadvantages the next two stages are to be used. To protect data against unauthorized access the encryption is accomplished. The encryption stage is performed separately from source coding. To reduce nuisance of the communication channel noise the channel coding is used which is based on the specialized error correction codes able to detect and correct errors directly during data transmission. Both encryption and channel coding require the introduction of the redundant information in initial data that leads to the increase of data size and corresponded time of transmission. Now a day, we can use digital images, videos, sound files, and other computer files that contain perceptually irrelevant or redundant information as "covers" or carriers to hide secret messages. After embedding a secret message into the cover-image, we obtain a so-called stego-image. It is important that the stego-image does not contain any detectable artifacts due to message embedding. A third party could use such artifacts as an indication that a secret message is present. Once a third party can reliably identify which images contain secret messages, the steganographic tool becomes useless. Obviously, the less information we embed into the cover-image, the smaller the probability of introducing detectable artifacts by the embedding process. Another important factor is the choice of the cover-image. The selection is at the discretion of the person who sends the message. Images with a low number of colors, computer art, images with a unique semantic content, such as fonts, should be avoided as cover images. Some steganographic experts e.g. Aura [3] recommend grayscale images as the best cover images. They recommend uncompressed scans of photographs or images obtained with a digital camera containing a high number of colors and consider them safe for steganography. Pfitzmann and Westfeld [4] introduced a method based on statistical analysis of Pairs of Values (PoVs) that are exchanged during message embedding. Pairs of Values that differ in the LSB only, for example, could form these PoVs. This method provides very reliable results when we know the message placement (such as sequential). However, we can only detect randomly scattered messages with this method when the message length becomes comparable with the number of pixels in the image. Johnson et al. [5, 6] pointed out that steganographic methods for palette images that preprocess the palette before embedding are very vulnerable. Existing cryptographic and steganographic mediums suffer from a myriad of attacks. Johnson [7] has studied such attacks on image steganography while Pal et al. [8] has studied similar attacks in the context of audio steganography. Even though cryptography and steganography are exposed to so many probable attacks, very few people have given a thought to find alternate ways to transmit information. The goal of steganalysis is to defeat steganography methods by identifying the presence of hidden information. This may be done using detection-theoretic methods if the distributions of the cover-image and stego-image are known to the steganalyzer as defined by Cachin [9], and various creative techniques as given by Fridrich et al. [10] etc. Fisk et al. [11] point out the weaknesses of TCP/IP

protocol suite and discuss how those weaknesses could be used as covert channels for secret communication, whereas Bao et al. [12] focus on using communication accessories like email headers etc for secret communication. . Avcibas et al. [13] proposed a stegoanalysis technique based on image quality metrics. Fard et al.[18] proposed a novel (Genetic Algorithm) GA evolutionary process to make a secure steganographic encoding on JPEG images. Martín et al. [19] experimentally investigated if stego-images, bearing a secret message were statistically "natural". Koval et al. [20] discussed the problem of performance improvement of non-blind statistical steganalysis of additive steganography in real images. Luo et al. [21] presented a secure LSB steganography system against sample pair analysis, such as RS, SPA and DIH method by adopting chaotic technique and dynamic compensation skill.

3. A CLOSE LOOK OF STEGANOGRAPHY AND IMAGE PROCESSING

3.1 Steganography

There are many forms of steganography including audio, video and image media. These forms of steganography often are used in conjunction with cryptography, so that the information is doubly protected; first it is encrypted and then hidden so that an adversary has to first find the information (an often difficult task in and of itself) and *then* decrypt it. The following formula provides a very generic description of the pieces of the steganographic process:

Cover Medium + Hidden Data + Stego Key = Stego Medium

In this context, the *cover medium* is the file in which we will hide the *hidden data*, which may also be encrypted using the *stego key*. The resultant file is the *stego medium* (which will, of course be the same type of file as the cover medium). The cover medium (and thus, the stego medium) are typically image or audio files. In this article, we have focused on image files and therefore, refer to the *cover image* and *stego image*.

3.2 Image Processing

An image file is merely a binary file containing a binary representation of the color or light intensity of each picture element (pixel) comprising the image.

The simplest approach to hiding data within an image file is called *Least Significant Bit (LSB) insertion*. In this method, we can take the binary representation of the hidden data and overwrite the LSB of each byte within the cover image. If we are using 24-bit color, the amount of change will be minimal and indiscernible to the human eye. As an example, suppose that we have three adjacent pixels (nine bytes) with the following RGB encoding:

10010101 00001101 11001001
10010110 00001111 11001010
10011111 00010000 11001011

Now suppose we want to "hide" the following 9 bits of data (the hidden data is usually compressed prior to being hidden): 101101101. If we overlay these 9 bits over the LSB of the 9 bytes above, we get the following (where bits in **bold** have been changed):

10010101 00001100 11001001
10010111 00001110 11001011
10011111 00010000 11001011

Note that we have hidden 9 bits successfully, but at a cost of only changing 4, or roughly 50%, of the LSBs.

This description is meant only as a high-level overview. Similar methods can be applied to 8-bit color but the changes, as the reader might imagine, are more dramatic. Gray-scale images, too, are very useful for steganographic purposes. One potential problem with any of these methods is that an adversary who is looking can find them. In addition, there are other methods besides LSB insertion with which to insert hidden information. These methods based on random numbers logic are the subject matter for present paper.

4. IMAGE STEGANOGRAPHY METHODS

Image steganography has been widely studied by researchers. There are a variety of methods used in which information can be hidden in images. Some of them are described here given by Lee et al. [14], Chan et al. [15], Chang et al. [16], and Hsu et al. [17].

4.1 Replacing Least Significant Bit

In image steganography almost all data hiding techniques try to alter insignificant information in the cover image. For instance, a simple scheme proposed by Lee et al. [14], is to place the embedding data at the least significant bit (LSB) of each pixel in the cover image. The altered image is called stego-image. Altering LSB doesn't change the quality of image to human perception but this scheme is sensitive a variety of image processing attacks like compression, cropping etc.

4.2 Replacing Moderate Significant Bit

Chan et al. [15] showed how to use the moderate significant bits of each pixel in the cover image to embed the secret message. This method improves sensitivity to modification, but it degrades the quality of stego-image.

4.3 Transformation Domain Techniques

Other familiar data hiding techniques use the transformation domain of digital media to hide information discussed by Chang et al. [16] and Hsu et al. [17]. Functions such as the discrete cosine transform (DCT) and the discrete wavelet transform (DWT) are widely applied by Chang et al. [16], and Hsu et al. [17]. These methods hide the messages in the significant areas of the cover image, which makes them robust against compression, cropping and other image processing attacks.

Figure 1. General image steganography system

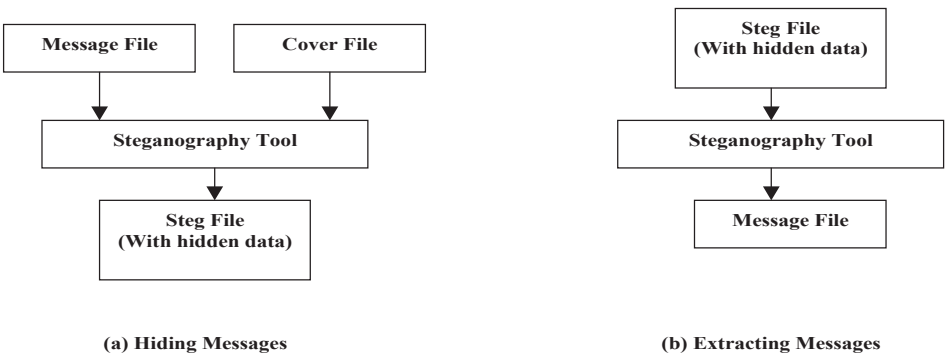

Figure 2. Proposed system based on random number logic

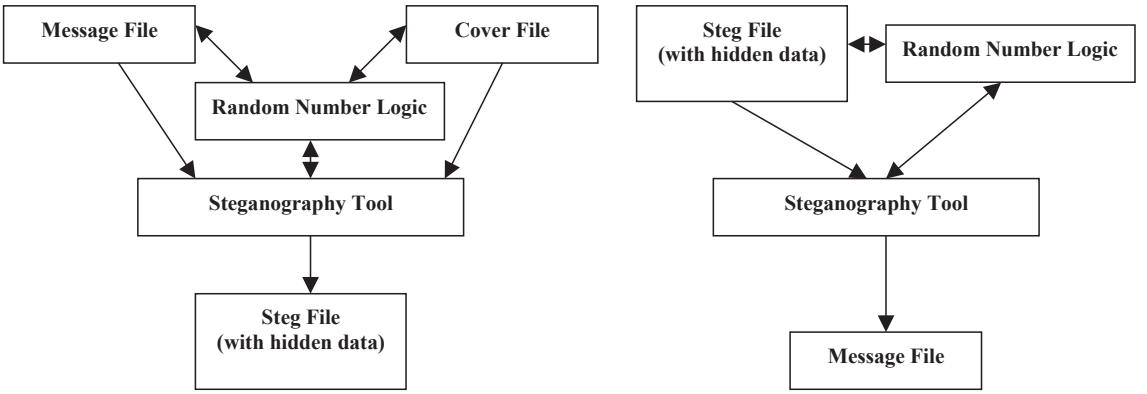


(a) Hiding Messages **(b) Extracting Messages**

5. PROPOSED METHODS

In proposed system random numbers logic play an important role in Customization and secure implementation of staganography (figure 2). As type of different methods progress more complexity is added to the implementation.

5.1 Type I Methods (Simple Methods)

An obvious method that can be constructed from combination of random numbers generator and least significant bit method (Other methods may also be employed on same tracks, but current paper include only Least Significant Bit based method).

Following general congruential method may be used to generate the location of next bit to be replaced i.e. after x_{i+1} bytes from current byte may be used as target byte to replace the least significant bit.

$$x_{i+1} = f(x_i, x_{i-1}, ..., x_{i-n+1}) (\text{mod}\, m) = (a_1 x_i + a_2 x_{i-1} + ... + a_n x_{i-n+1} + c) \ (\text{mod}\, m)$$

In above Formula all m, n, a, c and x are non-negative integers. Given that the previous random number was x_i, the next random number x_{i+1} can be generated. The numbers generated by a congruential method are between 0 and m-1. e.g. suppose that we have three adjacent pixels (nine bytes) with the following RGB encoding:

10010101 00001101 11001001
10010110 00001111 11001010
10011111 00010000 11001011

Now suppose we want to "hide" the following 4 bits of data (the hidden data is usually compressed prior to being hidden): 1011.Random number generator used for hiding data is

$$x_{i+1} = a x_i + c \ (\text{mod}\, m)$$

e. g. x_0=a=c=7 and m=3 have list of random numbers (called psuedo random numbers) as 2, 0, 1, 2, 0, 1… bits stored for hiding in above data is marked by bold bits in following data, whereas underlined bit represents modified bits.

10010101 00001101 11001001
10010110 00001111 11001011
10011111 00010000 11001011

The number of successively generated pseudo-random numbers after which the sequence starts repeating itself is called the *period*. Setting up the values of the constants may be divided into two categories of full period or partial period. If the period is equal to m, then the generator is said to have a full period, otherwise partial period. Kelton et al.[22] may be referred for the detailed discussion over setting up the values of these constants. Here we can say that full period methods are observed to be lesser complex and secure as compared to partial period methods.

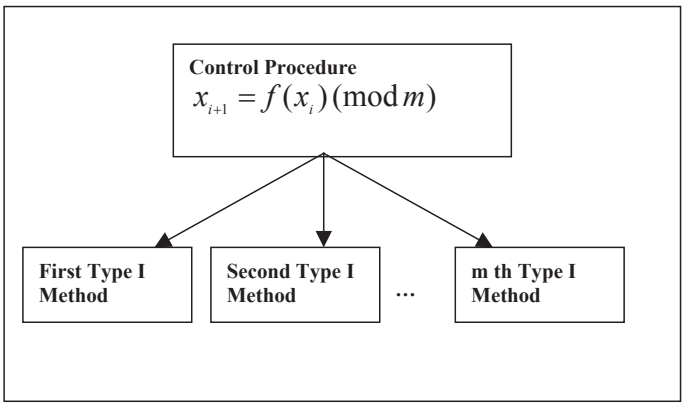
This method will include the hidden data at random places of different byte in the image. This method will inversely affect the density of bits to be stored in cover media by a factor m/2 (divisor/2). So there is a need to keep a fit between the divisor m and number of bits in hidden data. Increasing the size of cover media may create suspicion to steganalyst about hidden data in image. So there is a need to check the characteristics of cover image and hidden image to formulate the random number generator variables. Second issue about this method is its security aspect. Different combinations of least significant bits may be analyzed very easily and repetition of same sequence will make the steganalysts' job much easier. So this method is not secure enough to meet the requirement of steganography, this method is very easy and may be customized without much effort. Thousands of combinations of functions and values of variables are available to implement it. So, this method can be customized easily and give initial level of security to data.

5.2 Type II Methods (Low Complexity Methods)

These methods are based on the combinations of two or more type I methods to hide the data. There is a control procedure attached to these methods that controls the sequence of these methods randomly. This randomness is based on the output generated by earlier sequence. Figure 3 will illustrate the procedure of implementing the randomness.

Control procedure decides the method to be used for steganography. The programmer initializes initial values of the variables, whereas later values of variables are generated from the output received from earlier implementation, e.g. Sequence of 100 bytes is used to hide a sequence of 20 bits in it. First 10 bits are stored in first 50 bytes of cover media o the basis of initial values supplied to control procedure. A sequence of methods without repetition is involved for the purpose. Output generated is taken as the source of selecting values for variables. If we need only one value for function f, last few bytes of output may be used for the

Figure 3. Type II low complexity methods



purpose and remaining data is processed on the basis of altered sequence of Type I methods. Implementing the procedure in reverse direction, predefined initial sequence of methods is guided by input data for further iterations, as value of variables is stored in input file. In this way data hiding may be performed in a customized and secure way as functions are decided by users whereas altering sequence of storage can provide security in a well manner.

5.3 Type III Method (Moderately complex methods)

In this type of methods different encryption algorithms are attached to type II methods. Encrypted hidden image is stored in the cover image through type II methods. Key for encryption is generated through random procedures or is decided by the user and prefixed to hidden data/image.

5.4 Type IV Method (Highly Complex Methods)

In this type of methods one set of type III methods is used as one block of stego tool. Two or more such blocks (different from each other) may be combined together in parallel, in series or a combination of both as follows:

5.4.1 Parallel Combination

In this method different block of type II or type III method may be combined together to hide the data. This kind of scheme is suitable for large images. Cover image and hidden image are divided into small parts (blocks) and each block is applied to hide the data. Distribution of data for different blocks is implemented on random numbers logic.

Figure 4. Type III moderate complexity methods

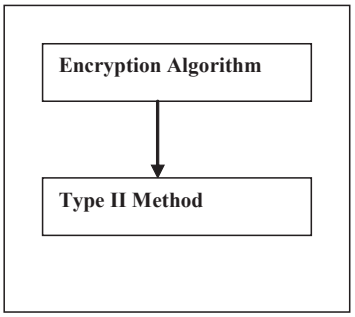


Figure 5. Parallel combination of type III methods

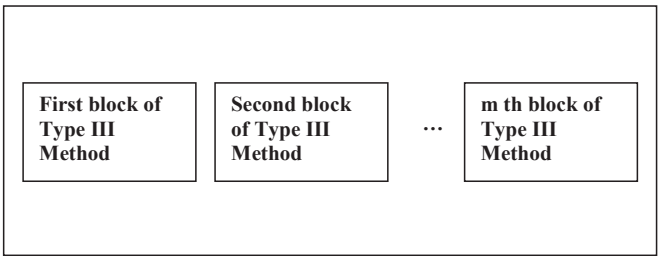

Figure 6. Serial combination of type III methods

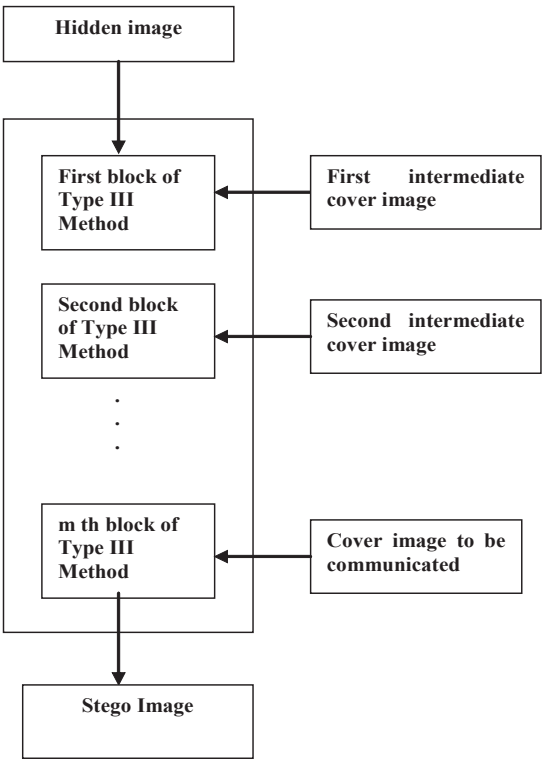


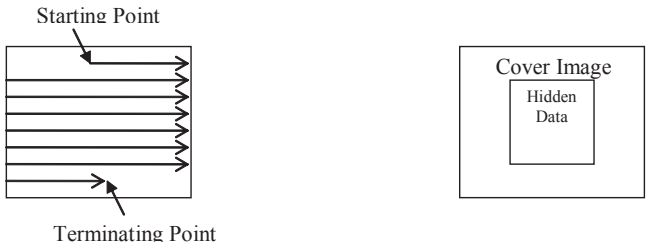
5.4.2 Serial Combination

In this method different block of type II or type III method may be combined together to hide the data. This kind of scheme is suitable for relatively small hidden image/data, but security is the major concern. In this method cover image, intermediate cover images and hidden image are used for the purpose as shown in figure 6. Initial hidden image is hidden in intermediate cover image, which is further hide into cover image and to generate stego image to be communicated. Such a combination is secure enough to be analyzed, but density of data that one can hide will be very less in quantity.

5.4.3 Hybrid Combination

In this method parallel and serial combinations are combined together to hide the data. Different layers of parallel combinations are combined together to hide the data. One parallel combination is called a layer, two or more such layers may be combined together to generate the stego image using intermediate cover images.

Figure 7. Two variations of level 1 schemes



6. LAYOUT MANAGEMENT SCHEMES

Methods discussed in previous section can contribute a lot in hiding information in images. These methods can be made more sophisticated with the help of layout planning. Here layout planning comprises of three basic components i.e. starting point, flow of data and termination point. Starting point is the initial point from where to start hiding information with the help of methods discussed in previous section. Flow of data comprises of the pixel by pixel flow of data hiding in cover image. Termination point is somewhat obvious from the layout i.e. the pixel at which the process of hiding data will terminate. One other component may be the visual sense. By the help of visual senses of eyes, we can decide the part of images, where data can be hidden without being noticed by the stegoanalysis evaluators. Using human eyes may contribute in deciding the part of image, but affects the artificial intelligence of the system, so becomes discretion of user to use it or not. Different Layout Management Schemes are divided under different levels as follows:

6.1 Level 0 (Simple Layout Scheme)

At this level different types of methods are selected from section 5 and are implemented from the starting point of the cover image and continued pixel by pixel from first pixel to last pixel of the image.

6.2 Level 1 (Plain/Garbage Data Insertion)

In this scheme before starting point original(from cover image) plain text or garbage data is placed into cover image followed by the hidden data according to the selection of methods from section 5.

In figure 7 first diagram indicate to leave few pixels before starting and after terminating point, whereas other diagram includes original cover image pixels all around the hidden data. Second diagram is only possible, when hidden data is small as compared to the space available for hidden data in cover image.

6.3 Level 2 (Image Processing Operations Based Scheme)

Before placing hidden data in cover image, cover image pixels may be inverted, rotated or flipped and then hidden data may be placed according to the combinations of methods selected from section 5 and low level layout schemes.

7. EXPERIMENTAL RESULTS

Experiments are performed to check the performance of different methods using variety of random number generators with varying values of variables and constants. Least Significant Bit transformation was the major way to implement the methods but other techniques like moderate significant bit transformation and transformation domain technique were also tried on similar lines, but here we produce the results based on least significant bit transformation based technique. Four hundred such combinations are tried on all four types of methods and results are combined together as follows:

Figure 8. Density chart: Bits hidden per byte vs. value of divisor

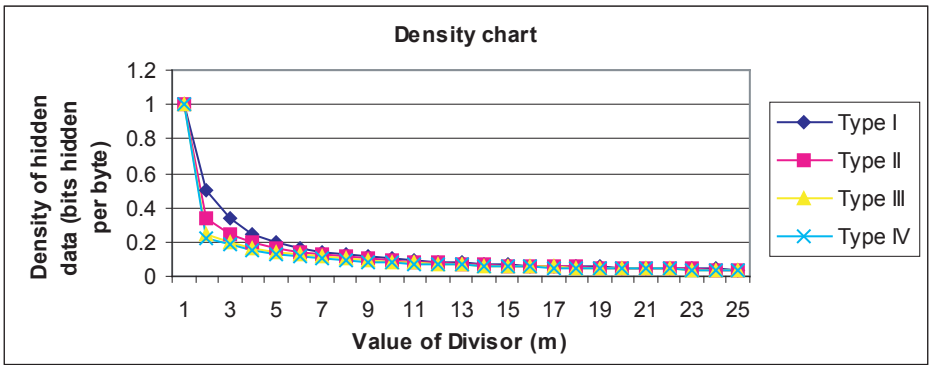


Figure 9. Mean square error comparison: Mean square error vs. Type(s) of method.

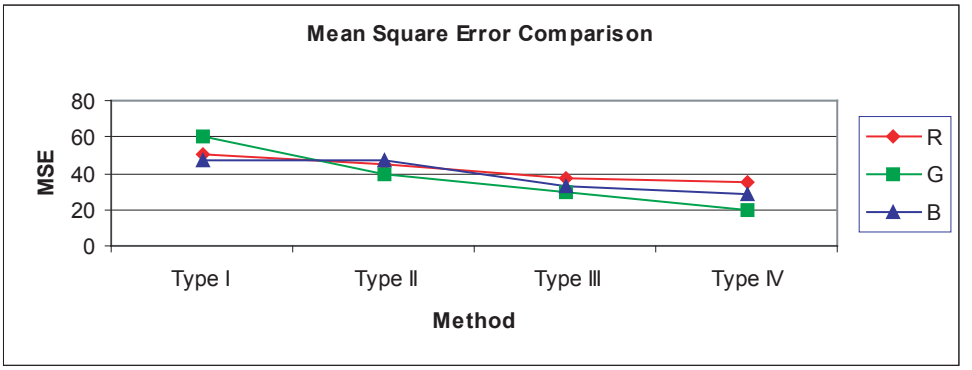

7.1 Density of Hidden Data

First of all one of the most important issue is that how much data can be stored in cover image and selection of suitable divisor. A simple Least Significant Bit method requires n bytes for hiding n bits. This density is decreased m times of total storage capacity for type I method and it is further degraded for other methods as shown in the figure.

It is obvious to receive more densely placed hidden data for smaller value of divisor 'm' as compared to a larger one and it is being indicated in figure 8 as well.

7.2 Quality of Cover image

There are many metrics to quantify the quality of two or more images. To compare these methods objectively, we adopt Mean Square Error (MSE) as our quality metrics. The MSE between the original image $I_o(x,y)$ and the stego image $I_r(x,y)$ for each color channel is defined as :

$$MSE = \frac{\sum_{x=1}^{m}\sum_{y=1}^{n}[I_o(x,y) - I_r(x,y)]^2}{m \cdot n}$$

where m x n is the size of the image

Results indicate that type I methods hides more data so these affect the color combination of different image it, but less for other methods.

7.3 Security of Hidden Image

Different tools available in market like s-tools, EzStego, Stegdetect, Stego suite etc. are tried on different methods and it is being observed that these tools are well conversant with type I methods, but are unable to detect the presence of hidden data of other complex combinations.

Experiments performed on all four types of methods through different tools available for stegoanalysis indicate that complex combination of methods are very secure as compared to the simpler one and figure 10 confirms it as well.

7.4 Complexity of Algorithms for Different Methods

Numbers of lines used executed for hiding data increases rapidly as we use more complex methods. As type I is simple method, it is less complex. Complexity increases as we use further much more complex methods.

Figure 11 indicates that complexity of algorithms increases as we move from simple to complex methods. Following images are included to show that image 'a' and 'c' can't be distinguished by human eyes, but these are significantly different from each other.

8. CONCLUSION AND FUTURE DIRECTIONS

In current paper we have applied random numbers based methods on least significant bit transformation for steganography. We formulated thousands of variants based on users' choices and calculated the results of around four hundred such combinations. Results cover the security, complexity, density and quality aspects of these methods. Authors are working upon more complex layout management schemes in a combination with these methods. In future, research work will be continued on

ABSTRACT

Personalized information seeking and retrieval is regarded as the solution to the problem of information overload. Personalization algorithms and techniques are maturing, but their centralized implementation solutions are becoming less efficient for dealing with ever changing user information needs in data intensive, dynamic and distributed environments. In this paper, we present a conceptual design for personalized, situation-aware information seeking and retrieval services, which offers a new way of thinking about the retrieval of personalized information for time critical applications.

Keywords: *personalization, information seeking and retrieval, situation awareness, service-oriented architecture*

1. INTRODUCTION

Today information is distributed globally. Organizations and information seekers can now access information anywhere anytime via wired or wireless networks. The coordination of organizational processes distributed over various independent locations has improved significantly. However, this increase in information availability cannot guarantee that users are able to retrieve and access all the information that specifically meets their needs. Organizations have to operate in increasingly complex environments, where, dynamically changing information structures, and distributed heterogeneous data resources make it increasing difficult to find the 'right information' at the 'right level of details' in the 'right format' , and at the 'right time'. The problem is amplified in domains such as crisis response networks, medical and healthcare networks, where the accuracy of the retrieved information and obtaining it in a time critical manner are extremely important.

Personalized information seeking and retrieval is regarded as the remedy when it comes to relieving the problem of information overload. Research in the field mainly focuses on developing models, methods and tools that can be used to adapt information content and its presentation to the individual user's information search goals and preferences. Today, personalized techniques are able to provide feasible solutions to the problem of inappropriate information overload at technological level ranging from simple user-controlled information personalization to autonomous system-controlled adaptation [Mizzaro & Tasso, 2002]. Many academic and commercial off-the-shelf information search services and tools are available to filter out irrelevant information effectively, and to rank and present information in a user preferred way.

Although these personalization techniques and algorithms are maturing, their centralized implementation solutions are becoming less efficient for supporting the rapidly changing information needs in dynamic and distributed environments. Changes in organizational or personal information needs may lead to a need to redesign a complete application. Therefore, it is necessary to design personalized information seeking and retrieval application in an agile and flexible way, to provide personalized information in a time critical manner, which can be adapted easily to meet changing information needs. Our increasing understanding of component-based design principles, service-oriented architectures and other aspects of complex information retrieval achievements provide the possibility to achieve this objective. The modularization of complex systems into components, or services that interoperate primarily via exchanging standardized messages at interfaces has become IT technology evolution. All these advances in IT have stimulated a new requirement concerning on modeling and designing personalized information search services in a dynamic and distributed environment to satisfy high-level functional requirements for personalization flexibly in one hand, and to use the specific personalization techniques, algorithms and available technology infrastructure to realize these requirements on the other. Building on the advantages of a service-oriented approach, we propose a new conceptual design for personalized, situation-aware information seeking and retrieval services. We believe this approach provides a new way of thinking about the retrieval of time critical, personalized, situation-aware information in data intensive domains.

Our conceptual design is presented in section 2. We tested and evaluated our conceptual design by applying it in a real-life case. The results are presented in section 3. Our conclusions and an outline for future work are presented in section 4

2. CONCEPTUAL DESIGN

2.1 The Concept of Information Seeking and Retrieval

Information seeking and retrieval is a human-IT system interaction activity in the sense of an IT supported environment. According to research into user information behavior, users' information needs are stimulated when they lack the information required to solve a problem [Wilson, 1998]. Problem solving occupies an important place in the research on information seeking and retrieval [Gaslikova, 1998]. [Gaslikova, 1998] summarizes problem solving in the context of information seeking and retrieval in three stages: problem identification, query formulation, and validation of received information. She claims that any information seeking and retrieval system has to provide suitable software tools for realizing each stage of a problem-solving process. Taking this into account, we regard information seeking and retrieval as a user-system interaction process. It comprises three sub-processes shown below.

- *The information seeking process*: This is the process used, generally or precisely, to identify the problem that initializes a user's information acquisition activity. This covers the question: what is the problem?
- *The information searching process:* This is the process used to identify and structure the specific information required to solve the problem, and to find the locations of required information. It concerns on the questions what information is required? Where to find the required information? And how to access to it?
- *The information obtaining process:* This is the process used to obtain the required information from the various resources and to return the information back to the user.

Users validate the received information during the interaction process with the system.

2.2 Personalized Information Needs

Personalized information needs play an essential role in determining the relevance of any delivered information. The literature shows a deepening understanding of the concept information needs and its role in the information seeking and retrieval. [Taylor, 1968] and [Belkin, 1982] argue that users' characteristics, e.g. users' personality, knowledge, personal interest and preferences etc., determine their information needs. [Wilson, 1994] and [Niedźwiedzka, 2003] shows that social placement or a professional role, e.g. users' professional roles connected with their occupied positions, are the most important determinants of users' information needs. [Wilson, 1999]'s problem solving model abstracts the process of problem solving from context.

Since our research is confined to domains such as crisis response and management networks, healthcare and medical networks, etc., we argue that individuals' personal interests and preferences may not strongly influence their information needs. Although different users in these contexts may have different knowledge levels about their professional role, we consider that their knowledge will be inherent to the professional role they play within their work situations. Therefore, we regard the professional roles users adopt in the society to be one of the most important factors influencing their specific information needs although their personalities and/or knowledge may influence their search strategies.

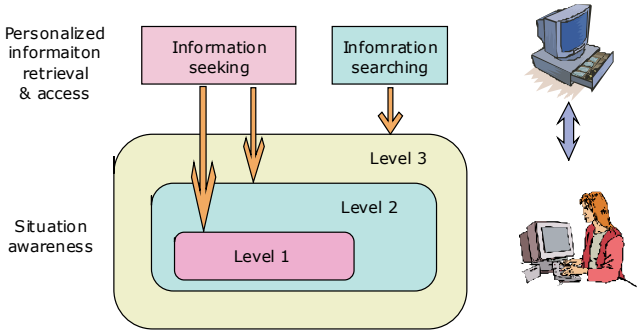
However, users' roles are not sufficient to reflect their actual needs. Information needs change as the users' situation changes, and this directly influences users' judgment regarding information relevance. Role-based information needs are relatively stable and predictable, while an ongoing situation may change these information needs. When users are able to be aware of their situation, in which they are involved, the users are able to identify their problem, and to formulate their information needs. Based on our previous arguments, we believe that personalized information seeking and retrieval is triggered by users' role-based perceptions of a problem they need to solve. We therefore define personalized information seeking and retrieval as an information acquisition process, aimed at providing users, with their role relevant personalized information based on dynamically and automatically perceiving and responding to the users' situations.

2.3 Situation Awareness

2.3.1 Situation Awareness in the Context of Information Seeking and Retrieval

The concept situation awareness (SA) is usually applied to operational situations, especially in the fields of artificial intelligence, agent-based systems, crisis response and management, military planning, etc. [Endsley, Bolte & Jones 2003]. Research in the field of SA focuses mainly on helping persons to be aware of their situations so that they can make informed decision about future actions [Endsley, Bolte & Jones 2003]. [Endsley & Rodgers, 1998] formally defines SA as "the perception of elements in the environment along with a comprehension of their meaning and along with a projection of their status in the near future" [Endsley & Rodgers, 1998]. This definition breaks down into three separate levels [Endsley, Bolte & Jones 2003].

Figure 1. Information seeking and retrieval to support SA process



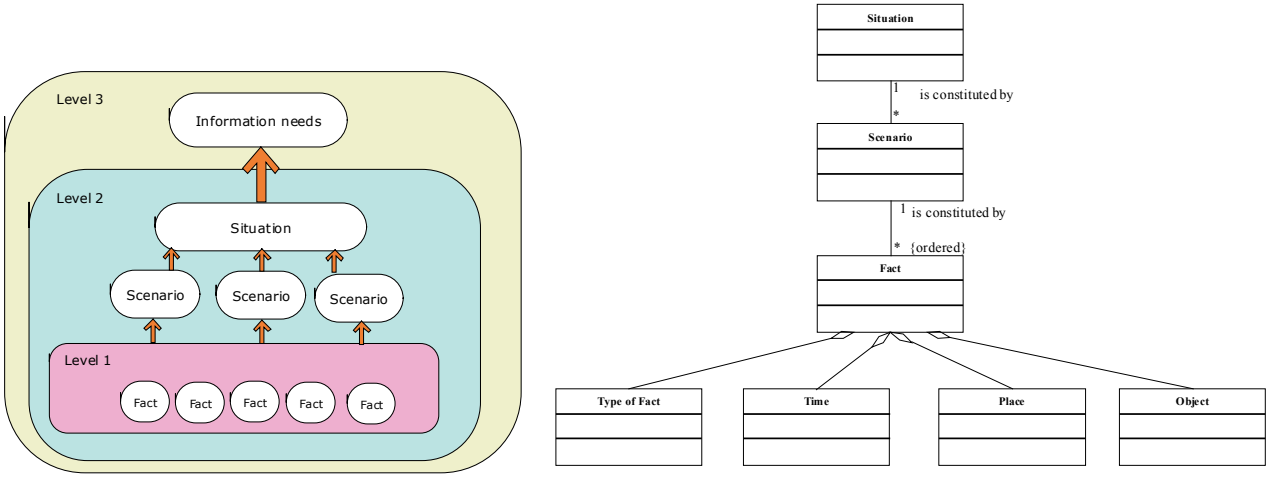
- Level 1—perception of the elements in the environment
- Level 2—comprehension of the current situation, and
- Level 3—projection of future status.

These three levels reflect the process of how people are aware of their situations mentally. Although today's advanced IT technology can replace a huge amount of information processing work, until now, it cannot replace a human's mental information processing process. We regard the information seeking and retrieval provided in our approach as a means to provide support for the users' SA process. We claim that our definition of information seeking and retrieval can be used to provide suitable support for all three steps of SA defined by [Endsley, Bolte & Jones 2003] shown in Figure 1. Levels 1 and 2 of [Endsley, Bolte & Jones 2003] are supported by the information seeking process, aimed at identifying the problem. Level 3 is supported by the information searching process, aiming at defining what information is needed.

2.3.2 Situation Model

Users perceive the problem they need to solve when their situation is described clearly. We choose to use the term situation since it can imply dynamic changes in users' surroundings, the influence of changes on the users, and the users' stable or permanent surroundings. Situation is defined in the [Merriam-Webster] as "the relative position or combination of circumstances at a certain moment". In the [Dictionary], situation is defined as "the combination of circumstances at a given

Figure 2. SA process



moment; a state of affairs". From these definitions, we can see that, a situation consists of a concrete story describing where what happened, when, who are involved, and their relationships.

It is not feasible to specify all possible situations in the context of information seeking and retrieval for any domain. Historical usage data is required to detect situations. This argument is also used in [Endsley, Bolte & Jones 2003]'s three levels of SA model, where an unknown situation is derived from known information. The question, what historical data or information is required to be collected at different level of the SA processes for the users to realize their situation, becomes important; and can be reformulated as what information can be used to describe and model the situation. Based on the [Endsley, Bolte & Jones 2003] 's three levels of SA model, we need to perceive the elements in the environment (Level 1 in the SA) as the information that can be used to comprehend current situation (Level 2 in the SA), in order to project future status (Level 3 in the SA).

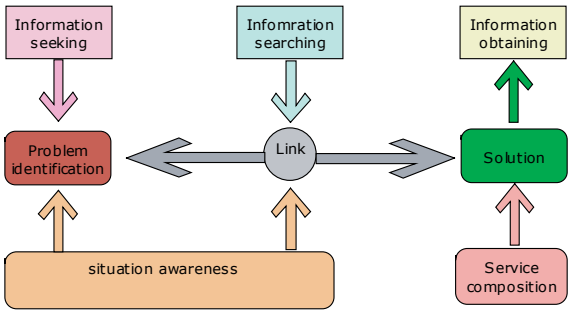
The first step in the SA process is to perceive the elements in an environment. The information elements that can be directly perceived describe the things that are known to have happened or to exist, i.e. the concept fact. Therefore, the information describing those things that have happened or existing things can be abstracted and conceptualized as a combination of 'type of fact', 'time', 'place' and 'involved objects'. The description of a fact can be made by combining 'type of fact' and any or all other three concepts.

Perceived facts are only direct observations made in the environment. They cannot provide narrative descriptions of users' situation. Therefore, facts do not supply sufficient information to understand a situation fully. To support the second level of the users' SA, we use the concept scenario in our research. We define *scenario* as a *short story reflecting a situation*. In this scenario, known outcomes are described, in conjunction with the casual relationships of a group of detected facts. Unknown scenarios can be derived by combining known facts, or from known scenarios. The SA process in our research is presented in Figure 2 (a), and the situation model is presented in Figure 2 (b).

2.4 Service-Oriented Approach for Personalized Information Seeking and Retrieval

A service-oriented approach provides a design principle for the handling of complex, dynamic and distributed information systems. Personalization can be provided by composing existing services, which are implemented on the basis of well-defined service behaviors and interfaces. This design principle is suitable for a distributed, dynamic and heterogeneous environment. According to the service-oriented system design principle, we assume that a solution for the detected information needs in users' specific situations can be quickly reconfigured by using a composition of encapsulated, replaceable and reusable services [Stojanovic, Dahanayake & Sol, 2004]. Based on sub-sections 2.2 and 2.3, we can now formulate the complete framework for personalized, situation-aware information seeking and retrieval, as shown below in Figure 3.

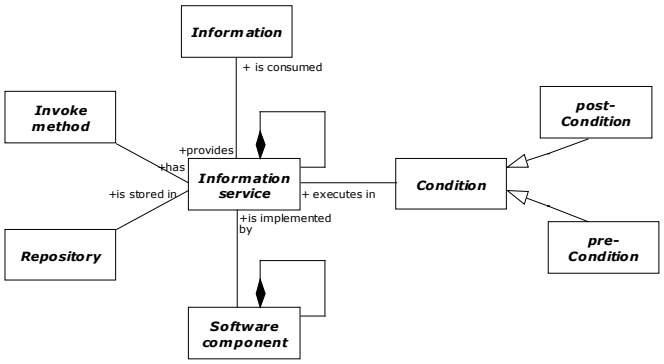
Figure 3: A framework of personalized situation-aware information seeking and retrieval



2.4.1 The Concept Service

According to the literature [Papazoglou, 2003, Stojanovic, Dahanayake & Sol, 2004, Douglas, 2003. etc], in the initial phase of our research, we informally defined the term *service* as "*A service is planned and designed in such a way that it has a specific functionality and it is very simple, but together they perform relatively complex tasks*". This informal definition gives the basic requirements for defining a service in the service-oriented approach. A service must have a specific functionality. As mentioned before, the solution for a detected problem is constituted of a service or a combination of services. Therefore, the specific functionality a service must have in our design is that it provides information. As a result, we simply define the services that consume information and provide information as information services. We assume that the solution to satisfy user's information needs is constituted by an information service or a group of information services. The information provided by a group of services is the collective outcome of all involved information services instead of a simple combination of outcomes of each service. Information services can be assembled and composed by smaller information services. At the level of a simple information service, its required operation and output is realized by grouping a specific collection of information search software components. We present the concept of service in Figure 4.

Figure 4. The concept of information service



2.4.2 Task Model

After the appearance of task-oriented information seek and retrieval in the 1990s [Vakkari, 2003], the concept task has been diligently used in the context of information search as [Byström & Hansen, 2005]. The concept task has gained increasing attention as it provides an important cue to help us to understand why people seek information, what type of information they need, and how they are going to use the information [Byström & Hansen, 2005; Taylor, 1991]. Our definition of a task is mainly based on the research of [Vakkari, 2003; Byström & Hansen, 2005; Vakkari, 2003]. We regard *a task to be a specific piece of work, in which a person or a group of persons undertakes a series of actions in a situation*. Defining a task as a piece of work indicates that it has a performer, a meaningful purpose, and an undertaken context [Hackman, 1969; Byström & Hansen, 2005]. This is a definition, which emphasizes the conceptualizing of tasks more from the point of view of the actors and the social context of the task performance [Checkland & Holwell, 1998, Suchman, 1995].

We define *the organizations or organizational units as actors*. Each actor has a list of professional roles. A role is defined in [Merriam-Webster] as "a function or part performed especially in a particular operation or process". Obviously, role is a function relevant concept. *The professional roles of an actor are defined in terms of functions an actor must provide.* Therefore, actors are exclusive, and based on the functions they provide, i.e. their professional roles. A task is performed when an actor adopts one of its professional roles. A task can be composed of smaller tasks. At the level of a simple task, it is constituted of a series of interconnected actions. A task is undertaken in a context, i.e. the situation, where an actor is required to adopt one of its professional roles. According to the definition of task in our research, tasks are required to be identified from an actor's professional roles, i.e. from the functions an actor can provide. However situation is a dynamic concept, as perceived by the SA process defined in section 2.3.2. It s not feasible to define all tasks corresponding to a specific situation. Instead, the tasks can be defined in facts, which are more concrete and tangible. Since a task can be composed of smaller tasks, required tasks in a detected situation can be composed of sub-tasks identified using the relevant facts. Tasks are undertaken in a process to formulate the solution for an existing fact.

Based on the concepts defined in the previous subsections, we formulate a meta-model of personalized information seeking and retrieval on the basis of service-oriented system design principle. The meta-model is shown in Appendix 1.

3. CASE STUDY

We tested the conceptual design by applying it in a real life case. The case study presented in this section was taken from an ongoing EU research project. The harbor described in this case study is one of the largest and most important harbor infrastructures in the world. Global collaborations for natural disasters recovery and anti-terrorism cooperation have encouraged management at this harbor to take put in global information networking, designed to share information with other crisis experts and professionals. The harbor management intends to build a more flexible and extendable information platform to provide all authorized and involved actors with access to their role-based personalized, situation-aware information to facilitate the performance of their tasks during a crisis response.

Since the development of a complete system is not yet feasible, due to the difficulty of building trust between the various crisis relief/response organizations, and getting them to share their information, we built an early prototype demonstration to show that it would be possible to build such a service-oriented platform to provide personalized, situation-aware information seeking and retrieval services for crisis response situation.

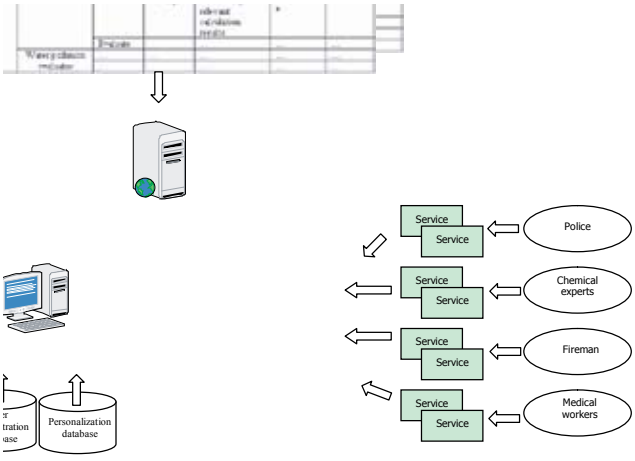
We utilized three computers in our prototype implementation shown in Figure 5, representing the service consumer, service provider, and service broker in a SOA respectively. The information provided by the actors involved was encapsulated as information services. We believe there are four main actors in crisis response: police, medical experts, fireman, and chemical experts. We implemented several information services for these 4 actors as jini services in our prototype. These jini services were required to be registered on a jini lookup server. The requested registration information is shown in the table in Figure 5. We used a simple example from a chemical expert to show what, and how, the required information on information services is registered in the jini lookup server. In the client PC, we use Liferay 4.0[1] as the portal software, and embedded Tomcat 5.0[2] as the web server to build the 'crisis response and management portal'. We built two databases, a user administration database and a personalization database, which were used to support personalized information seeking and retrieval applications running on this portal. User's role-based profiles, stored in the user administration database, were used to control their information access. The personalization database was built based on the meta-model presented in Appendix 1. Previous existing crisis situations, their constituting scenarios, scenarios' constituting facts, facts' solutions, etc, were stored in the tables of situations, scenarios, facts, solutions and tasks as the historical information in the personalization database. The personalization database was implemented in MySQL[3].

Tasks are keys that are used to search for the required information services provided by the different organizations. When a task is selected, it generates a service search template, which is constituted of three attributes, actor, role and task. A selected task generates this service search template by filling in the actor name, role name and task name. The service search template will then be sent to the jini lookup server to look for the relevant information services. All the information services of a selected task are returned to the user. Information service name, information service description, service status and location are also returned to the user. It is the users' work to figure out their required information services based on the returned service information.

4. CONCLUSION & FUTURE WORK

In this paper, we presented a new way of thinking of retrieving personalized information based on service-oriented design principle. Our situation model is capable of reflecting and inferring the unpredictable and dynamic situation users are facing. Our task model is capable of personalizing users' information needs in a dynamic situation according to their professional role(s). The combination of the situation model and task model allows users' role-based personalized, situation-aware information needs to be sufficiently inferred, and well structured in a meaningful way. Simultaneously, applying service-oriented design principle in our conceptual design allows us to realize independent service implementation and service modeling, and quickly to configure information acquisition applications

Figure 5. Prototype architecture



to satisfy users' dynamic information needs by choosing the required services. We believe that our conceptual design provides a possible solution to building a bridge between high-level functional requirements and low-level technology availability.

The next step of our research is to focus on how to reduce the time to action in a time critical situation using an effective information coordination service for situation aware process orchestration [González-Rivera, 2006].

E-Collaboration Tools for Government Funded Projects: NHLBI-PEN Approach and Solution

Gianluca De Leo, Medical Lab & Radiation Services, Virginia Modeling, Analysis and Simulation Center (VMASC), Old Dominion University, 2118 Health Sciences Building, Norfolk, VA 23529, USA; E-mail: gdeleo@odu.edu

Karen L. Wooley, Washington University in St. Louis, St. Louis, MO, USA

ABSTRACT

In this paper, we present the E-collaboration system that has been designed and developed during the first year of the NHLBI-PEN Government Funded Project. We start by presenting the design phase that led to the implementation of the E-collaboration tools of the project. Then, we describe the function of each e-tool, we discuss the impact on the project that they have produced and we present open issues for further implementations of the system. Even if a specific information technology expertise was needed in order to make our system operational, we believe that it can be easily replicated and used by investigators of other government funded projects who do not already have access to an E-collaboration system.

INTRODUCTION

In order to successfully manage a research project, keep it on track and fulfill its goals, it is essential for the team to frequently discuss plans, objectives, achievements and challenges. It is also important to have the ability to share large data sets while maintaining a high level of security and privacy. Meeting and exchanging results regularly are also essential for the success of the project.

Face-to-face communications have been considered as the most appropriate medium to share ideas, comments, and opinions and to reduce misunderstanding [1]. However, large government funded projects often involve researchers from different institutions and/or departments. Therefore it is not always possible to implement this direct mode of communication due to the challenges of distance and the increasing needs of time and cost savings.

Recent developments in information and communication technologies have enabled and facilitated new forms of inter-organizational collaboration [2]. The use of E-collaboration tools introduces a new concept of time and distance, modifies human interactions, creates a novel environment for decision making and changes the classic network of face-to-face relationships into a network of virtual relationships.

E-collaboration has been defined in many ways. For the purposes of this article, we adopt the definition proposed by the guest editors of the first special issue on E-collaboration, published in 2001 in the *Journal of Systems and Information Technology by Kock et al.* They describe E-collaboration as "collaboration among individuals engaged in a common task using electronic technologies" [3]. Our system includes not only computer based technologies but also simple telecommunication devices such as the telephone. We agree with Kock [4] and we believe our system should still be considered an E-collaboration system.

In the following sections we briefly introduce the NHLBI-PEN project and describe the context that brought us to the implementation of a set of E-collaboration tools. Then, we present the hardware and software platform, a detailed description of the function of each E-collaboration tool, and the reasons for their development. We discuss the issues and challenges we experienced during development and implementation along with the limitations of our study, results achieved, and concluding comments.

THE NHLBI-PEN PROJECT

The central mission of the NHLBI-PEN project is to develop a group of well-characterized and versatile nanoscale agents that can be assembled, labeled, targeted, filled, and activated as needed for the diagnosis and treatment of various diseases of relevance to the National Heart Lung and Blood Institute (NHLBI). The project started in May 2005 and it has been funded for five years. The research activities of this project are carried out at three different institutions: Washington University in Saint Louis, University of California - Santa Barbara, and University of California – Berkeley. The teams include researchers from different cultures and scientific backgrounds where about 80% are chemists.

NEEDS ANALYSIS

Remote collaboration initiatives are not common in chemistry departments where Information Technology resources are often limited. The departments usually provide only emails as form of communication, common Internet access and occasionally the possibility to share central equipments.

E-Collaboration requires a synergistic framework based on four components: strategy, organization, process and technology [5]. We believe that a system embodying this synergy is advisable and necessary in order to be successful. Following this assumption, the senior investigators of the NHLBI-PEN project designed a roadmap with the goal of developing a set of E-collaboration tools that could overcome the potential barriers to collaboration and information sharing created by the physical separation and schedule differences between the three Universities.

The road map was based on four stages: 1) requirement gathering, to understand and identify the needs of the users, 2) requirement specifications, to identify any system requirements and user goals that must be met for the system to be successful, 3) design prototype in stages, and 4) evaluating the design to assess the system, test the software and perform usability testing.

Research has shown that it is much more economical to consider user needs in the early stages of the design [6]. In our road map, the needs and limitations of the end users were first inquired and analyzed, and then assumptions were transferred into the prototypes. This approach is well recognized as an effective strategy in designing ease-of-use products and systems [7],

The senior investigators of the NHLBI-PEN project identified four inter-organizational set of tools: information, communication, coordination and collaboration (see Table 1). For each of them, they defined a list of needs that had to be fulfilled by a specific E-collaboration tool. A time frame for implementation, based on months from the starting date of the project, was defined as well. The collaborative tools were selected among the ones presented here [8].

Given monetary constraints and the need to personalize software with specific routines, proprietary software was not a feasible option. In order to increase flexibility, independence from a third party provider was required. The system had to be highly reliable yet easy to maintain, administer and update, once fully operational. Synchronous and asynchronous tools had to be designed with the goals of increasing the communications and the sharing of data and results among the researchers. Easy access to and operation of the E-tools had to be addressed since most of the researchers in the project did not have an information technology background. Focusing on ease of use has been used to advance the product's release date [9].

In summary, the E-collaboration system had to be cost-effective (low cost of implementation), independent to industry and software/hardware vendors (open),

Table 1. Classes of inter-organizational information systems

Information	Communication	Coordination	Collaboration
WEB portal for sharing progress and general information about the project (available after 2 months). WEB portal for storing/remember events and meetings (available after 3 months). WEB site for storing goals and achievements of the researchers during skill development visits to other laboratories (available after 6 months).	Affordable conferencing system (available after 1 month). Research groups mailing list (available after 1 month). WEB site for facilitating the exchange of chemical samples between laboratories (available after 6 months).	Electronic document interchange tool (available after 4 months). System for monitoring the budget (available after 6 months).	Collaborative Planning (available after 10 months).

easy to integrate with the existing procedure/process and fast to deploy on a simple technology. [5]

NHLBI-PEN E-COLLABORATION SYSTEM

Following the plan provided in the road map, an E-collaboration system was designed and implemented. Initial use of the E-collaboration system was restricted to peripheral or uncritical activities and then implemented in full scale. This approach had many advantages: users learned to handle the new E-collaboration approach gradually without detracting from efficiency in their daily activities; technical implementation investment risks were minimized while the possibility of standardization was increased; and the E-collaboration system was tested adequately before going to full scale production.

HARDWARE AND SOFTWARE

The hardware and software platform used for providing the E-collaboration tools described in this paper, is based on a 2U rack Pentium III server class A by Ironsystems [10]. It runs Linux Debian with Apache as web server [11], PHP as scripting language [12], MySql as relational database [13], Webalizer for web statistics [14], and Postfix [15] as SMTP server. Telnet, FTP, DNS and other services have been uninstalled for security reasons. High levels of stability, fault tolerance, and availability are addressed by the use of RAID (Level 1) technology, daily backup policy on different supports (tape, external USB drive, and data storage devices), and redundant and uninterruptible power supply. Security policies are addressed by disabling physical and remote access to the server. Only a secret username has the privilege to log-in through a SSH connection from a subnet inside the Washington University in Saint Louis network. The SMTP server uses a mail relay provided by the department for spam filtering and virus protection. Specific firewall policies, directly controlled and managed by the IT office of the department of Chemistry at Washington University in Saint Louis, block access to the server except for port 80 (HTTP) and port 25 (SMTP). A daily report of the Internet traffic through these two ports is automatically created and checked regularly.

E-CONFERENCE TOOLS

The meetings of the NHLBI-PEN project are usually held in a conference room located at the School of Medicine of Washington University in Saint Louis. In order to reach a high level of participation and to increase the effectiveness of the meeting, a hybrid system, composed by an audio and a virtual office component, was developed. The audio component is based on a SoundStation VTX 1000™ Polycom system that allows communication, *via* telephone line, with the researchers in California. The two extra microphones and the speakers included in the Polycom system allow the circulation of comments, questions, and answers between all the participants (usually twenty in Saint Louis and seven in the two sites in California). The telephone service is provided by the university telephone department. The virtual office component uses a desktop sharing utility, based on VNC [16] that allows each site to be engaged in the meeting by following the PowerPoint presentations in real time. While one site actively initiates and controls their presentations, the other site can passively view. This virtual office component overcomes the limitation in following a distant presentation where the slide under discussion and the highlighted area of the slides by the presenter's laser pointer are unknown. The movements of the laser pointer are subsequently replaced by the movements of the mouse. This desktop sharing utility uses TCP/IP and it is available through a web site that works as proxy. A dedicated computer with Windows 2000 and VNC has port TCP 5900 open through the firewall. Two levels of password authentication are required to have access to the utility: one provided by VNC and the other by Windows.

E-DOCUMENTS TOOL

The E-Documents Tool is based upon PHP Advanced Transfer Manager [17], a free web content management software. It allows the researchers involved in the project to collaboratively create, publish, share and retrieve data when needed. The main features available are: upload, download, delete or modify (users can only manipulate their own files). A super-user creates folders, has full control over all the files, and manages user accounts. In order to fulfill the requirements and the needs of the researchers, the main software package was upgraded. Specific routines were designed, developed, tested and finally added to the basic package in order to have an E-Documents Tool that can provide each user with 300 Mbytes of restricted space (Personal folder) and each research unit (identified as a senior investigator plus his/her researchers) with 2 Gbytes of restricted space. The new version also has a shared folder accessible by everyone that is used for transferring files among units. Finally, a special area has been created for the exclusive use of the Internal Operating Committee members. At the end of July 2006, the E-Documents Tool had 304 files uploaded, 270 Mbyte of data stored, and 44 active users (Figure 1).

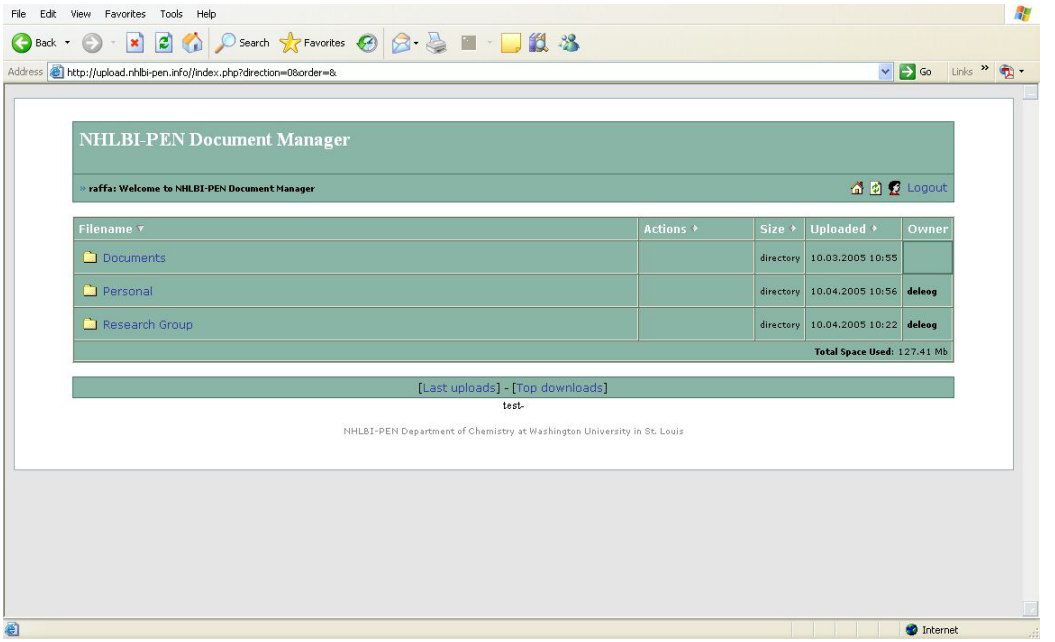
MAILING LIST TOOL

The researchers of the NHLBI-PEN project can utilize several mailing lists for easily contacting the members of each team. The mailing lists are both horizontal (for each of the 12 research teams) and vertical (for each of the 4 component: Materials Synthesis, Imaging, Animal Models, and Skills Development). The Internal Operating Committee has its own mailing list. In addition, a global mailing list that contains all the members is available.

E-RESEARCHER VISITS TOOL

The researchers of three universities are encouraged to schedule frequent short visits to other laboratories involved in the project. Throughout the year, postdoc and graduate students spend a few intensive days in other research groups to learn about additional procedures and methodologies that they have not yet experienced. The E-Researcher Visits Tool stores the researcher's name and

Figure 1. The e-document tool (home folder view)

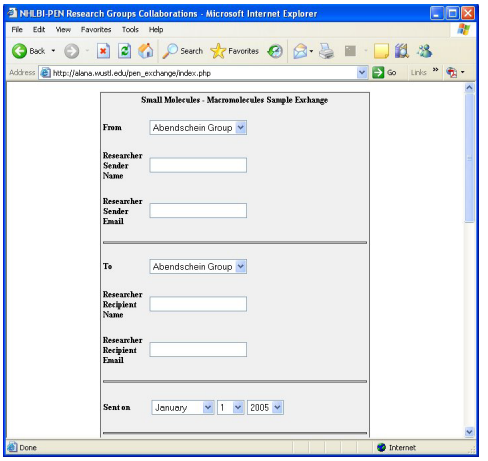


about the research group where he/she belongs, the group that he/she is visiting, and the goals and accomplishments of the visit. At the end of July 2006, the E-Researcher Visits Tool had 17 visits stored. A web site, password protected through the Apache htaccess policy, allows anyone in the project to have access to the E-Researcher Visits Tool.

E-SAMPLE EXCHANGE TOOL

The E-Sample Exchange Tool stores the information and the data of the chemical samples that have been transferred between research groups. There are two different sample exchange tools: one for Small Molecules-Macromolecules and one for Nanoparticles. A user-friendly web interface was developed in order to

Figure 2. E-sample exchange tool (insert a new record view)



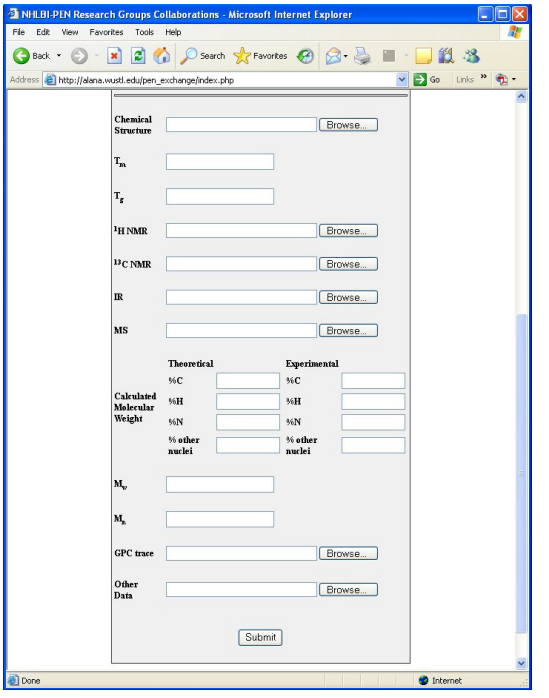


Figure 3. E-budget tool (monthly progress view)

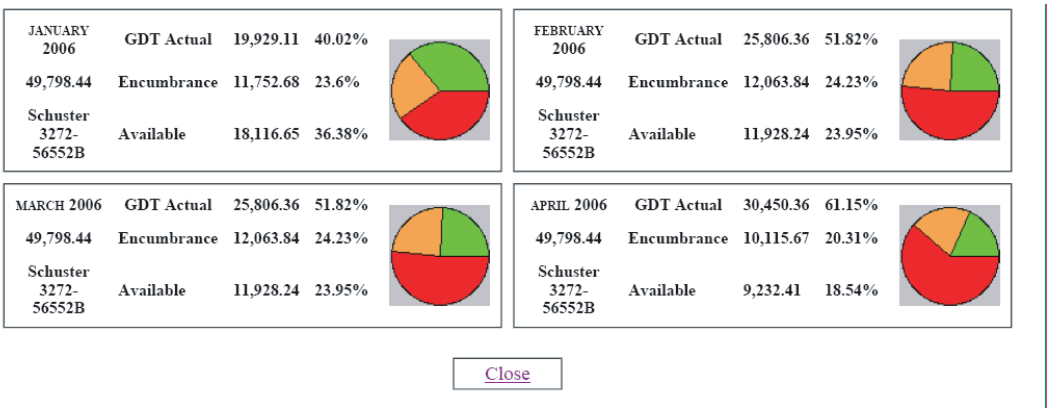
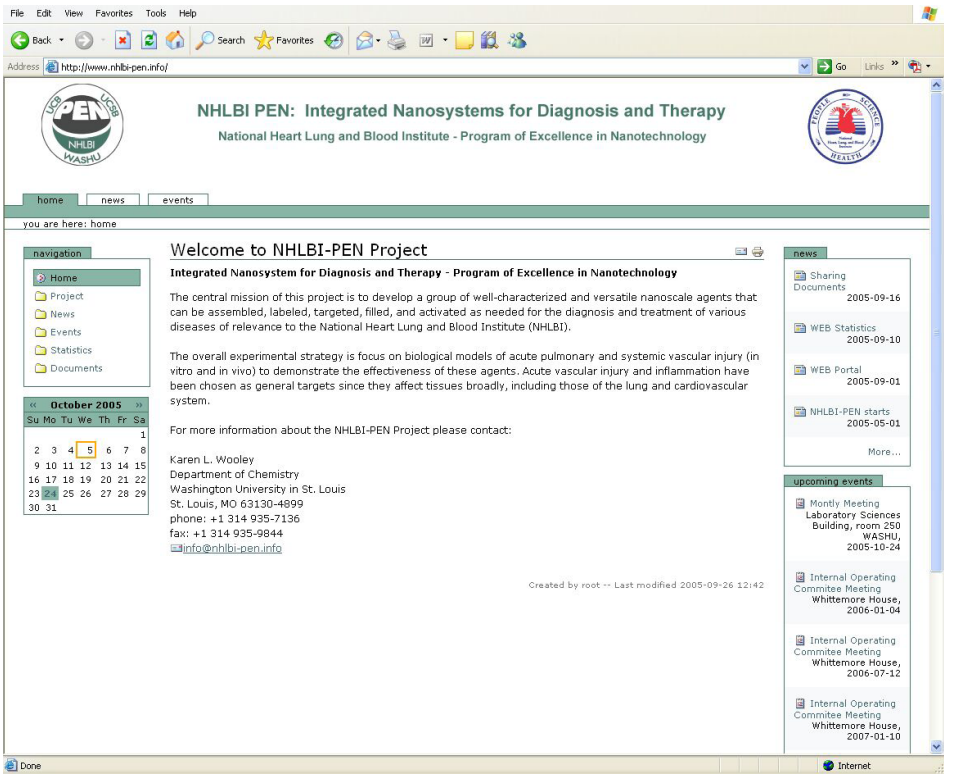


guide the researchers in creating a new record that contains general information and detailed data about the sample. General information includes the names and email addresses of the researchers who sent and received the sample, the date of sending, and an identification code. Detailed data consists of the chemical structure, the calculated molecular weight, the GPC trace, and other chemical properties. As in the case of the E-Researcher Visits tool, a web site allows anyone in the project to have access to the data. At the end of July 2006, the Sample Exchange E-Database contained 19 entries for Small Molecules – Macromolecules and 14 entries for Nanoparticles (Figure 2).

E-BUDGET TOOL

The E-Budget Tool keeps track of all the expenditures of each research group. This tool is available only to the Principal Investigator and her administration office. The budget of each research group is updated on a monthly basis and it shows the spent, the encumbrance and the available amounts. A color pie chart simplifies the visualization of the status of the budget and it is available in two formats. The first chart visualizes the research group budget situation by months, and it is used for monitoring the expenses over a long period of time. The second format gives an overview of all research groups by a selected month (Figure 3).

Figure 4. Web portal (home page view)



WEB PORTAL

The NHLBI-PEN web portal is available at http://www.nhlbi-pen.info (see Figure 4). Since the beginning of the project, the NHLBI-PEN team has been using the web portal for informing the community on new events and news. The status of the project, its progress and future plans are updated regularly. The web portal was developed using Zope [18] and Plone [19] and it provides a common interface and a single entry point to the other NHLBI-PEN E-Collaboration tools and services. The web portal contents can be easily updated by anyone, even without training in Hyper Text Markup Language (HTML).

DISCUSSION

The roadmap described in this paper is related to the first year of the NHLBI-PEN project. All the E-collaboration tools, except the collaborative planning, have been implemented and are fully operational.

The need for developing the E-collaboration tools presented in this article comes from the absence of collaborative systems at the three universities involved in the project. It is true that a teleconference system was available at each site but it was not free of charge, was difficult to reserve and the telecommunication standards used were not the same. Moreover the cost of using such systems cannot be billed directly to the grant and is not usually covered by the indirect costs of the departments. The possibility that the government agency that provides the grant would provide such E-collaboration tools free of charge does not seem realistic too.

Moreover, specific budgets for supporting IT personnel are not usually included in grant proposals. Thus, costs related to the initial investment in hardware should be considered when E-collaboration tools are planned. However, these costs would be a small percentage of the total budget of the project.

We believe the interface to our E-collaborations tools is easy to use. The researchers of the NHLBI-PEN project only need an e-mail account and a browser to have access to all the tools. Our monthly meetings have been attended often by researchers traveling in other countries or away from their offices. A wireless access point was enough for giving them the opportunity to participate. However, in order to increase the user-friendliness of our entire system, we are planning to develop a central log-in management system that stores the user's information. This would allow the user to log into each tool with the same id and password.

Bulletin boards for extended conversation and chat, where real-time text messages appear on both users screens, have not been implemented because they were not considered beneficial to the project. However, the development of a web based task list including a set of actions to be performed, pending activities, and unresolved problems is in progress. The E-Sample Exchange tools will have a "store room" section where researchers can look at the samples that are available in each group, place an order and receive the chemical at their labs. The implementation of a web based free educational tool to fulfill the skills developments component goals has been planned. Initial investigations suggested the use of Moodle [8].

Linux has been preferred to Windows as the operative system platform because more open source software is available under Linux. It is also easier to maintain once installed. We believe that the knowledge required to run a Linux server is equivalent to the one needed to administer a Windows 2000 Server.

Although the system is easy to maintain, we believe that a maintenance service (hardware and software) should be in place in order to guarantee availability of the E-tools to the researchers.

CONCLUSION

With the development of new technologies, and information communication technologies, in particular, teams have evolved to encompass new forms of interaction and collaboration. This paper demonstrates that E-collaboration tools can be used in a research funded project and that the implementation is not difficult to achieve.

The NHLBI-PEN E-collaboration system brings geographically dispersed research partners together, and supports the communication, coordination, cooperation, and sharing of data between the distant locations. We have described a system that allows the researchers of government funded projects to adopt the use of low-cost E-collaboration tools for increasing productivity and team work.

This study does not present any data about user's evaluation of the E-tools because a survey for collecting user feedbacks has not yet been developed. We only know that each E-tool has been extensively used. We are also aware that the number of the users in the NHLBI-PEN project would not have been enough statistically to make any definitive statements about the quality of our E-collaboration system.

However, we have acknowledged a transformation process from traditional (offline) communications toward hybrid services that combine elements of traditional collaboration and E-collaboration. Our E-collaboration solution is presented to improve the existing processes and provide the vehicle to establish new forms of collaboration.

Finally, we believe that a set of E-collaboration tools such the ones described, should be provided by the Universities using indirect cost budgets.

Panels

Disruptive Innovation: Leadership and Organizational Dimensions

Moderator: Dr. Gerry Gingrich, Professor, Information Resources Management College, National Defense University, Fort McNair, Washington DC, USA; E-mail: gingrich@ndu.edu

Panelists: Dr. Robert D. Childs, Director, Information Resources Management College, National Defense University, Fort McNair, Washington DC, USA; E-mail: childs@ndu.edu

Dr. Gerry Gingrich, Professor, Information Resources Management College, National Defense University, Fort McNair, Washington DC, USA; E-mail: gingrich@ndu.edu

Today's interconnected and dynamic global environment presents challenges that were anticipated or even conceived just ten years ago. For example, the competitive pressure from growing economies such as India and China; the sensitivity of US markets to events around the world; the technological advances in virtual communications and collaboration; the decline in American scientific and engineering excellence; and security threats to our critical infrastructure and national power – all of these are acknowledged and accepted today.

These global challenges are beginning to outpace the progress in our organizational processes, architectures, and technology applications. Continuous process improvement moves business processes forward but at an incremental pace; architectures are somewhat but not fully integrated and thus continue to impede information sharing and collaboration; and existing technologies are still slow to enter mid to high levels of management and government, while younger generations have already thoroughly integrated them into their lives.

Having spent the last decade learning how to conduct process improvement and incremental change, our organizations now need to learn more about innovation, creativity, and large-scale transformation. Building on successes and lesson learned from the experiences of the 1990's, they need to increase their rate of learning. In many cases, this increase in learning will be experienced as disruptive to the organization. And, yet it is necessary and critical, for without disruptive innovation and learning, our organizations cannot achieve the desired characteristics of the 21st century organization: partnership-based, metric-oriented, integrated, and externally focused.

It has been said that disruptive innovation is the ability to see change as an opportunity, not a threat. In this panel, leadership and organizational strategies for achieving that perspective will be examined. For the first sixty minutes, two panelists will give presentations focusing on the leadership, organizational, and cognitive variables that mediate the success of disruptive innovation and learning. Dr. Robert Childs will examine key leadership variables such as vision, strategy, and flexible positioning and Dr. Gerry Gingrich will examine the organizational variables of culture, organizational behavior, and cognitive growth. The presentations will focus on two organizational-wide examples of disruptive innovation at the presenters' college – the development of international partnerships and the creation of a robust distance learning program.

For the last thirty minutes of the panel, there will be a forum involving both the panelists and the audience. The forum is intended to integrate the presentations with the audience members' experience. For example, how useful are the best practices to audience members' organizations? Are the lessons learned more useful in the private sector than in the public sector? Should they be modified for one sector or the other? If so, how? The panelists will facilitate the discussion.

Knowledge Development Innovation

Panel Chair: Mohammed Dadashzadeh, PhD, Professor of MIS and Director of Applied Technology in Business Program, Oakland University, Rochester, MI, USA; E-mail: dadashza@oakland.edu

Panelists: Mohammed Dadashzadeh, PhD, Professor of MIS and Director of Applied Technology in Business Program, Oakland University, Rochester, MI, USA; E-mail: dadashza@oakland.edu

Al Saber, PhD, Professor of MIS and Dean of Graduate Programs, Friends University, Wichita, KS, USA; E-mail: asaber@friends.edu

INTRODUCTION

In his 2006 book, ***Knowledge Development Innovation: How To Rescue America's Advantage***, Dr. Boulton Miller concludes as follows:

"Knowledge Development Innovation will provide this nation with the ability to demonstrate a global leadership role in education, making use of the latest improvements in information technology, with faculty technically qualified to fulfill their role as guides or coaches, with students as active learners and synthesizers of

knowledge. It is impossible at this time to predict the outcomes of the information technology developments; however, our education system must remain flexible and be ready to implement whatever new developments become available."

OBJECTIVES

The objectives of this panel are threefold:

A. To discuss what Knowledge Development is and why it is a different objective than Knowledge Management making it worthy of national planning and implementation.
B. To consider Dr. Miller's recommendations for the formation and funding of a Knowledge Development Agency charged with goals that include the development of a Personal Knowledge Development (PKD) system.
C. To present the architecture of a national information technology based solution to the implementation of the PKD idea.

Issues and Trends in IT Capital Planning and Investment Management for the Public Sector

Panel Chair: Dr. John T. Christian, Information Resources Management College, National Defense University, Fort McNair, Washington, DC, USA; E-mail: christianjt@ndu.edu

Governmental agency Chief Information Officers are in a constant struggle faced with the need to provide great information technology (IT) support to a diverse customer base, while operating with few human resources and decreasing funding levels. As IT has moved from being a key component of back office support systems to being a key component of front office mission critical systems, CIOs are finding that they are under greater pressure from their agency colleagues to deliver the IT component of a "business solution" that performs as advertised and is delivered on-time and within-budget. Attempts by IT departments to meet their diverse customers' expectations with the limited resources available may result in the inappropriate allocation of resources to the "squeaky wheel projects" rather than projects that may have strategic impact.

To better manage the expectations of their customers and stakeholders, IT departments should implement an inclusive IT Capital Planning and Investment Management process that is transparent. One approach that may improve the quality of decision-making and the allocation of scarce IT resources is based on the application of financial investment portfolio concepts and techniques to selection, control, and evaluation of agency IT business cases.

The IT investment portfolio approach provides a governance framework that ensures that all IT business cases are rigorously assessed by all of an agency's line of business leaders for business value and business risk. A portfolio approach allows agency leaders to create a portfolio of IT investments that balance business value and business risk. In addition, each IT business case may be rigorously assessed by independent analysts to validate the value benefits and the costs associated with the investment. IT technical experts may validate the technical solution proposed by the business case to ensure that it is aligned with the agency's enterprise architecture. This governance framework can provide significant oversight of each IT investment during its acquisition life-cycle. The IT investment portfolio approach provides sufficient visibility into all of an agency's IT investments so that agency leaders can maintain a clear understanding of the relationship between each of their IT investments.

The first segment of this panel will be devoted to a very brief overview of an IT Capital Planning and Investment Management approach, which has been developed by employing many of the ideas that underpin a financial investment portfolio approach. The purpose of this overview is to ensure that those attending the panel have a clear understanding of the basic concepts of IT Capital Planning and Investment Management using an investment portfolio approach. The balance of the time allotted will be used by the panel members and those attending the panel to discuss current issues and trends in IT Capital Planning and Investment Management in the Public Sector. The panel will be conducted as a conversation between the panel members and the audience.

Philosophical Conversations in Information Management

Panel Chair: Dr. M. E. Burke, Information Systems Institute, University of Salford, UK; E-mail: M.E.Burke@salford.ac.uk

OBJECTIVES

This panel will build on the "Philosophical Conversations" which took place at the Philosophy track at IRMA 2006 in Washington DC. The panel will initially address themes which attempt to identify the major philosophical underpinnings within the field of information management. There are many documented philosophical viewpoints concerning epistemologies such as rationalism and empiricism as well as research paradigms such as positivism and interpretism which have their roots in social theory. However, as information management develops as a profession it

is important that the philosophical underpinning of how information management is perceived through a philosophical lens is addressed. Philosophical viewpoints in information management is a live, continuously developing area that needs to be aired and discussed in an international arena. The following are recommended topics but papers which address related areas will also be considered.

SUGGESTED ISSUES TO BE COVERED

- Finding roots, looking back: taking a historical philosophical perspective and exploring relevance to today's needs.
- Current Philosophical Perspectives
- Discipline boundaries: the differences between information science and information management.
- A framework for design science research activities
- Web Ontologies and Philosophical Aspects of Knowledge Management
- Philosophical Foundations of Information Modelling

Abstracts/Workshops

Web Portfolio Design for Teachers and Professors

John DiMarco, Assistant Professor, Division of Mass Communications, Journalism, Television and Film, St. John's University, NY, USA;
E-mail: dimarcoj@stjohns.edu

DESCRIPTION

This workshop provides the k-12 and college educator with a creative opportunity to develop a multimedia based electronic portfolio that can be uploaded and viewable from the World Wide Web. Instruction includes conceptualization and categorization of assets and artifacts for portfolio development and technology lab tutorials in the use of digital imaging, MS Office output to web pages, and tutorials in industry standard web development software including Adobe Acrobat, Adobe Photoshop, Adobe Fireworks, and Adobe Dreamweaver. The Instructor will develop a complete web portfolio site during the workshop. Participants with laptops and required software (MS Office and Adobe Web Suite) can follow along. Downloadable assets used in class demonstrations will be available before the event from Professor DiMarco's FTP site.

OBJECTIVES

Upon successful completion of this workshop, particpants will be able to:

- Understand why the web portfolio is an important tool for lifelong learning and communication of scholarship.
- Conceptualize and plan a web based electronic portfolio.
- Evaluate and execute artifact content collection decisions and processes.
- Develop assets and thematic content.
- Use industry standard software packages for design, content development, web authoring, and multimedia.
- Critically review and evaluate web portfolios to insure they meet specific disciplinary criteria.
- Perform reflective writing for the web portfolio

RATIONALE

The Web Portfolio as a Standards Based Assessment Tool

Creating a web portfolio prepares educators to embrace technology and to perform analysis, inquiry, and design. Project based learning is an effective approach to web portfolio development. The portfolio acts as a "personal information system and professional cyber identity". In college as well as k-12, these skills are brought back into the classroom so that teachers can help teach their students how to create personal, professional web portfolios. Web development skills will be important to students in any occupation or field in the future due to the increase of mediated electronic communication devices.

In this workshop, professors, teachers, and information professionals will engage in analysis of their professional content, perform personal inquiry during content development, and sample digital design skills while creating an electronic portfolio that will be posted to the World Wide Web.

Creating a personal electronic/web portfolio makes you a lifelong learner and allows you perform self assessment throughout your career. Teachers and professors can use the electronic/web portfolio for student assessments and for themselves to provide evidence of professional growth applicable in tenure and promotion scenarios.

WORKSHOP OUTLINE

Learning Modules	TOPIC
	Electronic Portfolio Definitions
One	*web Portfolio Definitions* *Defining the web portfolio within your discipline and context.* Describe how the electronic portfolio fits into your academic discipline and career goals. Answer the question: This web portfolio defines me as a _____.
Two	**Conceptualize/Brainstorm the web portfolio.** *Defining the audience.* *Explain how the web portfolio will be used to persuade the audience.*
Three	**Web portfolio Content** *Content Evaluation Methods* *Writing the Content List* *Writing project/work/artifact descriptions*
Four	**Information Design** *Navigation issues* *Developing a Flowchart* *Page counts and scope* *Combining the scope documents(concept statement, content list, content outline, and flowchart)*

	Visual Design
Five	*Developing storyboards* *Content development and digital capture techniques* *Screen resolution and graphical sizing issues* *web Resumes* *HTML and Graphical text issues*
Six	**Web Page and Graphic Design** *Developing web graphics* *Developing web screens* *Developing navigation* *Digital Artifact Production (MS Office)* *Using Adobe Photoshop*
Seven	**Slicing and Exporting (GIF or JPG?)** *Setting up the folder structure properly and where to put your artifacts* *Understanding the root directory of the web portfolio* *Using Fireworks to slice*
Eight	**Web Authoring** *web page functionality issues* *web page development demonstrations and tutorials* *Using Dreamweaver to author the web site* *Using Word to create web pages* *Using PowerPoint for Web pages*
Nine	**Uploading the web portfolio using FTP** *Testing the web portfolio* *Checking download time* *Checking links and popups* *Testing Usability* *Final Critique and Assessments*

INSTRUCTOR BIO

John DiMarco is a professor, trainer, consultant, writer, and digital media expert with over 10 years experience in training, communication design, and educational technology. Professor DiMarco has helped hundreds of students create web portfolios. As an Assistant Professor at St. John's University in New York City, John teaches courses in mass communications, media graphics, video, and 2d & 3d animation. He also holds adjunct professorships at NYIT, Nassau Community College, Molloy College, and LIU. From 2001-2003, he held the position of Assistant Professor of Digital Art and Design and Interactive Multimedia at Long Island University, C.W. Post in New York. He is the founder of www.portfoliovillage.com, a website that provides web portfolio space and educational content. His latest book: Web Portfolio Design and Applications was published in 2006. In 2004, John published an edited book titled "Computer Graphics and Multimedia, Applications, Problems, and Solutions" for Idea Group Publishing. John DiMarco is the final stages of completing a PhD in Information Studies (Technical Communication and Communication Education) at Long Island University. His educational background includes a Master's Degree in Communication Design from Long Island University-C.W. Post, and a Bachelor's Degree in Communication & Public Relations from the University at Buffalo.

ALICE Tea Party: An Alternative or Supplementary Approach to Traditional Introductory Programming Courses

W. Brett McKenzie, Associate Professor, Computer Information Systems, Roger Williams University, Bristol, RI, USA; E-mail: wmckenzie@rwu.edu

OBJECTIVE

To introduce ALICE as an alternative or supplement to traditional introductory programming courses.

DESCRIPTION

ALICE is a 3D programming environment developed at Carnegie Mellon University and funded by the National Science Foundation. ALICE is designed to facilitate learning object-oriented, event-driven programming by drawing on our student's immersion in graphically rich media through animation and games. Evaluations have demonstrated that subsequent to studying ALICE

- students chances of succeeding in programming courses increases
- attraction and retention of women and minorities increases
- student enthusiasm for computing as a major increases.

ALICE has been built upon two premises. First, visualization of abstract concepts aids understanding. Second, syntax errors are a major barrier for novice programmers. To address these issues, ALICE programming uses figures, real or fantasy such as Alice Liddell or a white rabbit, that interact with objects, such as tables, chairs, or place settings, in environments that may contain trees, ponds, or buildings. Programming is achieved through dragging and dropping tiles with commands into an editor. Typing is reserved for assigning values to variables.

ALICE facilitates different approaches to programming, some of which are particularly appealing to underserved groups, such as women and minorities. ALICE programs may be either animations, which tend to tell stories, or interactive worlds, which tend towards games. Storytelling seems to have particular importance for the underserved groups. For example, Hawaiian islanders have used ALICE to preserve Hawaiian cultural heritage by creating animations of traditional stories. Similarly, young women, frequently excluded from programming, have been motivated by the chance to create and tell stories through their ALICE programs. The ability to create interactive worlds in ALICE allows an easy path to game programming and accounting for dynamic environments.

Fundamental computing constructs and logic are introduced through either storytelling or games. For example, to make a character walk, a simple step method – raise right leg, move forward, raise left leg, move forward – can be extended by using a loop. A logical structure, such as an "If…else" can be used to ensure that character avoids walking into an object. Similarly, ALICE allows more complex object-oriented activities, such as creating, exporting, and importing new classes built upon base classes, or invoking events through key presses or mouse actions.

The ALICE environment is an open source JAVA based suite and includes an object tree, event editor, program editor, and visualization area. While ALICE comes with a rich set of models, it is possible to import additional models as well as to import and play back audio tracks. ALICE is currently at Version 2. The

next version may be released by the time of the conference and it will include better models and rendering in collaboration with Electronic Arts. Additionally, the new version will have the ability to dump the JAVA code and to interact with external data sources.

TUTORIAL/WORKSHOP ACTIVITIES

In the course of the workshop, participants will build ALICE Worlds (as ALICE programs are called) that demonstrate fundamental aspects of OO programming. The target audiences are instructors from introductory programming and computer fluency courses; however, the workshop does not presuppose knowledge of OO programming. Participants who bring their own laptop computers will get the latest version of ALICE and all workshop materials to install on their computers.

The workshop will also include discussions of integrating ALICE in the curriculum from stand-alone to brief courses, as well as the latest model being developed "the blended course", which combines ALICE and JAVA instruction. ALICE has been adopted at over 100 colleges and universities ranging from the liberal arts schools, such as Haverford College, Pennsylvania to state research universities, such as University of Texas.

TUTORIAL/WORKSHOP LEADER

Dr. W. Brett McKenzie introduced ALICE at Roger Williams University and has presented at NSF Workshops on ALICE at Haverford College, PA and Duke University, NC. More information about ALICE is available at www.alice.org

Educational Applications of Social Software and Collaborative Technologies

P. Candace Deans, Robins School of Business, University of Richmond, Richmond, VA, USA; E-mail: cdeans@richmond.edu

INTRODUCTION

Social software and collaborative technology applications are becoming prevalent across all dimensions of society including business, education, government and individuals. The shift to Web 2.0 applications and trends toward open source have provided the impetus for an explosion of new applications. Instant messaging, blogs, podcasts and wikis represent the most common forms of social software that promise to have widespread influence in the future. The community aspects of these technologies is a common defining characteristic of emerging social software applications. Social software is built on the concept of collaboration and community involvement. Businesses are beginning to see the benefits of blogs and podcasts as a means to reach a diverse customer base and keep a pulse on the "buzz" in the marketplace. These technologies are becoming an essential component of public relations in many companies. Social software is also being used as a communication tool to reach employees and business partners. Educational institutions are also jumping on board to provide additional options for students that meet specific curriculum needs. The potential for these technologies is huge and current trends indicate that competition for products and business applications will be global in scale.

This workshop will address ways in which software and collaborative technology applications are being integrated into the classroom. Podcasts, blogs, and wikis are being used extensively as tools to enhance the learning process. Implementation of collaborative technologies such as electronic meeting software will also be examined. Pros and cons of implementation and some of the lessons learned will be discussed. Examples of how schools are using these technologies and future trends will be examined. Participation from those attending the workshop who have experience with these technologies in the classroom will be encouraged.

WORKSHOP OBJECTIVES

1. To provide participants with an understanding of the various social software and collaborative technology applications and ways in which they are currently being used in the classroom.
2. To provide a forum by which to discuss the pros and cons of using these technologies in the classroom and how they may impact the learning process.
3. To evaluate undergraduate versus graduate level applications and how these technologies should best be integrated into curriculum design.
4. To discuss business applications of these technologies and the responsibility of academic institutions to prepare students with these skills.

SOCIAL SOFTWARE

Blogs, podcasts and wikis are the most common social software applications being used in academic institutions today. The use of these technologies and some of the success factors in various academic settings will be provided. These software applications are currently in the experimental stages in business school settings. The verdict is still out as to whether podcasts, for example, will be become main stream academic tools for providing learning opportunities and alternatives to the current written text. On-line classes took some time to establish credibility and recognized value. Will social software applications provide value add in the academic environment and what role will they play in the future of curriculum design? These questions will be addressed in the context of current experiences and future trends.

COLLABORATION TECHNOLOGY

Collaboration software has become more prevalent in recent years for business applications supporting team projects and electronic meetings. In addition, collaboration software can be used to support managerial meetings with employees who may be in different places all over the world. Project teams can effectively share documents and observe power point presentations simultaneously. Participants can use whiteboard features to draw diagrams, list discussion items or emphasize points on another document or image. It is important for students to gain experience with these technologies and develop skills that will be beneficial and increasingly necessary for the job market. These skills may give students a competitive advantage in the marketplace. In this workshop the implementation of one of the prevalent business collaboration software tools (Breeze) will be discussed. This software was incorporated into the introductory IT courses at both the undergraduate and graduate levels.

CONCLUSION

This workshop will provide a forum from which to discuss these emerging social software and collaborative technologies as tools in the design of business school

curriculum. As the business community continues to embrace these technologies it is imperative that business schools determine the role of these tools and applications in the classroom. In preparing students for the future it has become necessary to evaluate new technologies and their role in educating students who will be competitive in the global marketplace.

Symposiums

Technology and Globalization: A Critical Teaching and Learning Initiative for Business and the MBA

James L. Perotti, PhD, Rochester Institute of Technology, NY, USA; E-mail: jperotti@cob.rit.edu
Valerie S. Perotti, PhD, Rochester Institute of Technology, NY, USA; E-mail: vsperotti@cob.rit.edu

"No new business is worth starting in these times unless it can go global." - Richard Branson, Virgin Empire

"The world is being turned into a digital representation. Distance means nothing if you have a digital infrastructure. Anything digital is borderless. You cannot put obstacles in the way of digital technology flowing everywhere." Andy Grove, Intel Corp. Chairman.

"Globalization 3.0 is shrinking the world from a size small to a size tiny and flattening the playing field at the same time. ... the thing that gives it its unique character – is the newfound power for individuals to collaborate and compete globally" – The World is Flat, Thomas L. Friedman, pg 10

The "common body of knowledge" which widely characterizes curricula of Schools and Colleges of Business today dates back to the 1930s—a functional grouping of courses attempting to mirror the major functions of the enterprise: finance, operations, marketing, accounting. Coupled with the obligatory Organizational Behavior and Strategy courses, these subject areas remain the focus of MBA programs across the country today (Kurhana et al, 2005).

Even a casual review of other professional curricula (medicine, law, for example) suggests that maintaining the same theoretical perspective for almost 80 years would be a dereliction. Changes in medical and surgical practices, revolutionary court decisions and precedents—no patient or legal client would accept professional services from an individual whose understanding of his or her profession dated back 80 years! No medical or law school would take pride in offering such a program of study.

Similarly, few business leaders would agree that the practices (and indeed, the very functions) of business are the same as they were in 1930. Occasionally, an institution has the insight to identify emergent areas which—though outside the traditional functional areas—have an impact so profound as to demand curricular attention. In that light, the E. Phillip Saunders College of Business at Rochester Institute of Technology, having adopted a mission statement focused on globalization and technology, invited the authors to develop an innovative (and collaborative) seminar titled "Technology and Globalization."

At RIT, the seminar is offered in a team-based, fully integrated, action-learning approach. This means that faculty serve as designers and developers of the learners' experience and the students learn through active engagement with a series of progressively more complex projects or problems.

WHY AN INTEGRATED APPROACH?

In a (1994) *Harvard Business Review* dialogue, management theorists and business educators express the need for integration of functional disciplines: "Certainly we must continue teaching the basic functions of business, but in a context that produces an understanding of the interdependencies of organizational functions" (Louis Lataif, Dean of the School of Management at Boston University, p. 128). "Let's stop pretending to train non-managers to be managers through detached case studies and disconnected theories" (Henry Mintzberg, Professor of Management, McGill University, Montreal, p. 129).

HOW DOES IT WORK INSTRUCTIONALLY?

Underlying theory. Pedagogically, the model springs from theoretical literature on problem-based learning which emerges from a Constructivist philosophical view of how one comes to understand. Savery and Duffy (1994, pp. 1-2) characterize the view in terms of three propositions:

1. Understanding is in our interactions with the environment. (We cannot talk about what is learned separately from how it is learned).
2. Cognitive conflict or puzzlement is the stimulus for learning and determines the organization and nature of what is learned. (The learner has a purpose for being here.)
3. Knowledge evolves through social negotiation and through the evaluation of the viability of individual understandings. (Other people are the greatest source of alternative views to challenge our current views and hence to serve as the source of puzzlement that stimulates new learning.)

Savery and Duffy also offer a set of relevant instructional principles:

1. Anchor all learning activities to a larger task or problem.
2. Support the learner in developing ownership for the overall problem or task.
3. Design an authentic task.
4. Design the task and the learning environment to reflect the complexity of the environment they should be able to function in at the end of the learning.
5. Give the learner ownership of the process used to develop a solution.

6. Design the learning environment to support and challenge the learner's thinking.
7. Encourage testing ideas against alternative views and alternative contexts.
8. Provide opportunity for and support reflection on both the content learned and the learning process.

The co-developers of the course felt strongly that the incredible speed of change in the two fields under examination required such an approach for many reasons, but, perhaps most importantly, helping learners to master not the facts of technology or international business, but rather, the capacity to continuously learn and update competence in these areas.

WHAT WILL HAPPEN AT THE SYMPOSIUM?

Symposium presenters consist of the co-authors of this seminar who have offered it a total of six times to date. After a brief introduction to the symposium's approach, participants will be invited to generate timely topics and concerns related to the two subject areas. A facilitated discussion will encourage participants to explore existing and potential synergies between the two most powerful forces in business today. Based on their research with business and industry and on their teaching experiences, the co-presenters will offer suggestions for learning challenges that participants will be able to apply in academic or training and development settings. Participants who request them will receive course materials and a summary of the symposium's key points.

This symposium is uniquely suited to IRMA's topic this year. Practical, timely, and appropriate for information managers and academicians as well, its outcomes should help participants to crystallize related issues for their home organizations.

Experiences in Implementing a Network Engineering Technology Curricula

Lance Hassan, Purdue University, West Lafayette, IN, USA; E-mail: lchassan@purdue.edu
Anthony Smith, Purdue University, West Lafayette, IN, USA; E-mail: ahsmith@purdue.edu
Phillip Rawles, Purdue University, West Lafayette, IN, USA; E-mail: ptrawles@purdue.edu

ABSTRACT

The purpose of this symposium is to share faculty experiences in the successful development of a laboratory-based Network Engineering Technology (NET) program. The symposium will include information on individual courses, the curricula as a whole, facilities required, and experiences in working toward accreditation from CAC/ABET. The symposium will present the individual elements of the lab-based curriculum architected around a network overview diagram that illustrates the infrastructure used to facilitate lab integration amongst the courses.

INTRODUCTION

The focus of the Network Engineering Technology (NET) program is to create highly competent network engineers and administrators. Course materials are reinforced with tightly integrated lecture content and laboratory experiences. Supporting lecture material with laboratory exercises produces an active learning environment where "students must engage in such higher-order thinking tasks as analysis, synthesis, and evaluation", which aids in retention and understanding of material (Bonwell 1991). The NET program further reinforces the relationship between lecture and laboratory at the curriculum-level by utilizing course-based laboratory projects as pieces of the overarching network infrastructure. Collectively, these course-based lab projects combine to provide students with an education and hands-on experience in every aspect of network design, implementation, administration, security, and management.

Figure 1 illustrates the network architecture deployed by the students in the NET curriculum each semester. This diagram provides a basis for understanding how the individual course components collectively contribute to a holistic student learning experience. This architecture is critical to enabling cross-course collaboration among students with disparate technologies.

All course materials are designed with actual industry experiences in mind. Designing exercises in this manner ensures that the students gain knowledge of technologies and practices currently utilized in industry, and they will understand the processes for implementing and troubleshooting networks containing these components. As suggested by Qazi and Ishaq (Qazi 1998), students should be offered interdisciplinary projects that provide a seamless connection between the academic sphere and the professional world. This approach to education provides students with the desired learning experience, preparing them for future work in corporate environments as required by CAC/ABET for accreditation.

The NET program is currently undergoing an accreditation review as an IT program by CAC/ABET and should be complete by the date of the symposium. The presenters will also be prepared to share their fresh experiences gained through the accreditation process.

CORE CURRICULUM

NET students will pursue a wide variety of endeavors within the networking and digital telecommunications field upon graduation. The NET program breaks these responsibilities into the logical groups that include network design, administration, security, and management. The following list identifies the courses that compose the core of the NET curriculum:

- C&IT 330 – Local Area Networking and Systems Administration
- C&IT 343 – Advanced Systems Administration
- C&IT 346 – Wireless Networks
- ECET 374 – Digital Telecommunications
- C&IT 430 – Internetwork Design and Implementation
- C&IT 443 – Enterprise Network Management
- C&IT 455 – Network Security

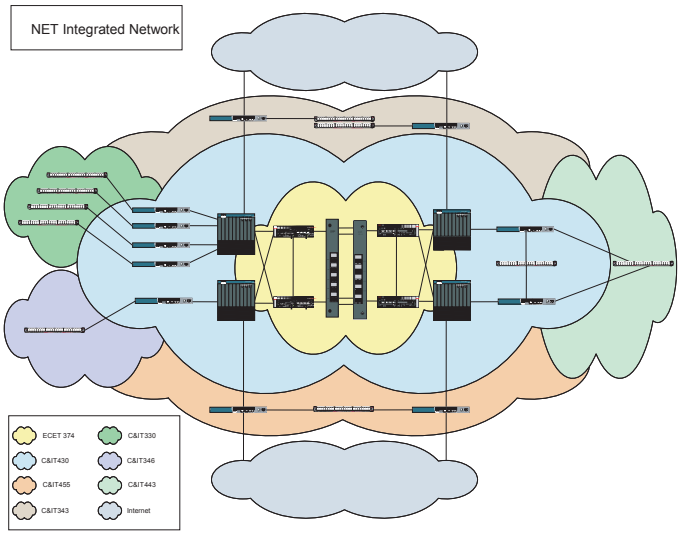
C&IT 330: Local Area Networking and Systems Administration

C&IT 330 introduces students to local area networks, system and network administration. Emphasis is placed on fundamental concepts and best practices. This course also provides students with their first hands-on laboratory experience in the NET curriculum and emphasizes problem-solving and troubleshooting skills through network implementation.

C&IT 343: Advanced Systems Administration

C&IT 343 expands upon the administration concepts learned in C&IT 330 and introduces extended network services. C&IT 343 laboratories focus on solving given business scenarios. Students must research and implement various technologies to address the business cases given, and must support their work with

Figure 1. NET network overview



a structured analysis and report using the Top-down model as a reference. This laboratory gives students exposure to a wide array of administration tools and software packages that will be found in industry.

C&IT 346: Wireless Networking
C&IT 346 introduces wireless and cellular technologies and their impact upon the telecommunications world. In lecture, students learn about wireless-specific protocols and modulation techniques, as well as the architecture needed to support this communication. In laboratory, students implement wireless solutions and integrate them into wired LAN environments.

ECET 374: Digital Telecommunications
ECET 374 provides a broad overview of digital communication methods and systems emphasizing telecommunication fundamentals. Students explore the Public Switched Telephone System (PSTN) backbone and local loop transmission infrastructure, including physical layer concepts such as analog and digital signals, noise, power, errors and modulation. Telecommunication concepts such as T and E carrier transmission and framing are examined and further developed through higher order multiplexing schemes including SONET/SDH. Additional telecommunication technologies such as ISDN, Frame Relay, and ATM are also discussed.

C&IT 430 – Internetwork Design and Implementation
Students design and construct a routed IP-based wide area network capable of simultaneously transporting packet-switched voice, multi-protocol data, and video. Emphasis will be placed on the design and internetworking of diverse telecommunications systems, while considering the effect of engineering decisions on business performance. Organization and management of large scale telecommunications projects are investigated.

C&IT 443: Enterprise Network Management
C&IT 443 explores various aspects of enterprise network management with an emphasis on managing faults and optimizing performance to ensure high service availability. Concepts introduced include basic management functions, standards-based management technologies, and the business impact of network management.

C&IT 455: Network Security
C&IT 455 covers conceptual and technological aspects of network security for voice and data networks. The course deals with the analysis, design, implementation, and management issues surrounding effective network security. Students must research a variety of solutions to current security issues, and implement their findings in the laboratory environment.

Tutorial

Connecting Requirements and Object-Oriented Modeling

Instructor: Hermann Kaindl, Vienna University of Technology, Institute of Computer Technology, Vienna, Austria;
E-mail: kaindl@ict.tuwien.ac.at

Prof. Hermann Kaindl *joined the Institute of Computer Technology at the Vienna University of Technology in Vienna, Austria, in early 2003. Prior to moving to academia, he was a senior consultant with the division of program and systems engineering at Siemens AG Austria. There he has gained more than 24 years of industrial experience in software development. His current research interests include software engineering with a focus on requirements engineering, and human-computer interaction as it relates to scenario-based design. He has published four books and more than ninety papers in refereed journals, books and conference proceedings. He is a senior member of the IEEE, a member of the ACM, the INCOSE and the IRMA, and is on the executive board of the Austrian Society for Artificial Intelligence.*

OBJECTIVES

The participants will understand several key problems with current OO methods and how they can be resolved by "clean" OO thinking. In particular, they will

be able to distinguish between domain objects and software objects. They will experience UML as a language for representing OO models, but also the need to be clear about what kind of objects are represented. In addition, participants will see how scenarios and use cases can be utilized for requirements engineering. But they will also see the additional need to specify the functional requirements for the system to be built.

The purpose of this proposed tutorial is to connect requirements engineering with object-oriented modeling, so that practitioners can apply the best from both "worlds" together.

SUMMARY OF MATERIAL TO BE COVERED

- How do scenarios / use cases fit together with functional requirements?
- How can OO (object-oriented) principles like classification help organizing a huge number of requirements?
- How can the application domain be better understood using OO modeling?

This tutorial addresses these questions because they are relevant for industrial software development but too many misunderstandings still exist with regard to OO processes and methods as related to requirements engineering. It shows how each requirement given in natural language can be modeled as an object, which facilitates a clean organization and association. While scenarios / use cases can somehow illustrate the overall functionality, additionally functional requirements for the system to be built should be formulated and related to them appropriately. In order to better understand scenarios, the goals to be achieved by them should be explicitly defined and linked to them as well. All kinds of requirements typically make statements about the application domain, which should be represented in an OO Domain Model of conceptual classes, in order to make the requirements better understandable.

PRESENTATION FORMAT

This tutorial will consist of lectures and group discussions. The technical points made will be illustrated with a running example throughout.

For the lectures, the instructor will use a computer screen projector connected with his laptop computer.

Assumed Background of Attendees

The assumed attendee background is some familiarity with scenarios / use cases and basic object-oriented concepts, as well as interest in requirements.

The target audience is requirements engineers, software engineers, project managers, anyone supposed to work on the requirements in the context of object-oriented development.

HISTORY, PREVIOUS EXPERIENCE OF THE TUTORIAL PROPOSER AND ADDITIONAL REMARKS

A half-day version of this tutorial was presented at INCOSE 2004 (26 attendees in a conference of about 850). It received very positive feedback (on tutorial evaluation sheets filled in by attendees) and I will embrace the ideas suggested for improvement. Other versions:

- "Modeling Business and Requirements Using UML" at HICSS'38 (35 attendees in a conference of about 600)
- "Reconciling Requirements, Use Cases and Object-Oriented Modeling" at RE'02 (17 attendees in a conference of about 200)
- "Reconciling Business Modeling and Requirements with Object-Oriented Software Development" at HICSS'36 (38 attendees in a conference of about 600)
- "Reconciling Requirements, Use Cases and Object-Oriented Modeling for Systems Engineering" at INCOSE 2003 (37 attendees in a conference of about 1000).

In addition, this proposer has previously held tutorials on the reuse of requirements at CAiSE'00, RE'01, RE'03, INCOSE 2004, RE'04 and INCOSE 2005.

Among other things, this tutorial proposes solutions to issues discussed in a panel organized by this proposer at OOPSLA 2001 "How do Requirements Relate to Objects?" and another panel with the same title at INCOSE 2004. It includes also material on real-world experience from the approach developed by this proposer as presented in an invited State-of the-Practice Talk at RE'01:

H. Kaindl, Adoption of Requirements Engineering: Conditions for Success, *Fifth IEEE International Symposium on Requirements Engineering (RE'01)*, Toronto, Canada, August 2001.

The proposed tutorial is also is based on an in-house course at Siemens, a teaching course at the Vienna University of Technology, research and consulting experience of its proposer and, e.g., on the following selection of articles and papers:

Kaindl, H., Object-Oriented Approaches in Software Engineering and Artificial Intelligence, *Journal of Object-Oriented Programming* 6, 8, 1994, pp. 38–45.

Kaindl, H. A Practical Approach to Combining Requirements Definition and Object-Oriented Analysis, *Annals of Software Engineering*, Vol. 3, 1997, pp. 319-343.

Kaindl, H., Kramer, S., and Kacsich, R., A Case Study of Decomposing Functional Requirements, in *Proc. Third International Conference on Requirements Engineering (ICRE '98)*, Colorado Springs, Colorado, April 1998, pp. 156-163, IEEE.

Kaindl, H., Difficulties in the transition from OO analysis to design, *IEEE Software*, Sept./Oct. 1999, pp. 94–102.

Kaindl, H., A Design Process Based on a Model Combining Scenarios with Goals and Functions, *IEEE Transactions on Systems, Man, and Cybernetics (SMC)* Part A 30(5), 2000, pp. 537-551.

Kaindl, H., Is object-oriented requirements engineering of interest?, *Requirements Engineering*, Vol. 10, 2005, pp. 81–84.

Doctoral Symposiums

Target Population and Behavior Change: Hypertextual Discourse Analysis of Prevention Information on HIV/AIDS Websites

Jing Chong, College of Information Sciences and Technology, The Penn State University, University Park, PA, USA; E-mail: Jchong@ist.psu.edu

1. INTRODUCTION

HIV/AIDS has been around for more than 20 years, during which the lives of over 20 million people have been claimed in the world. Since there are still no effective cures or vaccines available, prevention is the key to promote behavior change and put this epidemic under control. What is essential in prevention efforts is to inform people of information on HIV/AIDS, especially risk behaviors (Goldstein, Usdin, Scheepers & Japhet, 2005; Kalichman & Belcher, 1997). What information is communicated is important since it should be varied according to the stages of behavior change the target populations are in. However, there is a controversy in health communication about whether health information should be targeted to underserved populations or the larger population. The above two issues of information content and target populations are not restricted to interpersonal and traditional mass media communication. It also extends to the Internet due to the ever increasing popularity of e-health among not only healthcare providers but also consumers, especially those who seek for HIV/AIDS prevention information.

The purpose of this study is to examine the target population and stages of behavior change being addressed in prevention information on HIV/AIDS websites by means of hypertextual discourse analysis. Organizational properties and interests of the website sponsors/designers as well as health policies in public health regarding HIV/AIDS will also be examined to find out their influences on the prevention information provided. The current study is formative in the sense that it is the basis for future empirical studies with the users and the sponsors/ designers of those HIV/AIDS websites. The ultimate research goal is to provide insights or concrete suggestions to the sponsors/designers of HIV/AIDS websites as well as policy makers in public health on how to improve the prevention information and public policies in a way that could do more good to the users and to the public health.

2. RESEARCH QUESTIONS

- What populations are targeted in HIV/AIDS prevention information on the selected websites?
- What stages of behavior change does the prevention information address?
- What impacts do website sponsors/designers' interests and health policies in public health have on the findings of the first two questions?

3. LITERATURE REVIEW

3.1 Health Belief Model and Stages of Change Model

The ultimate purpose and function of health communication is to promote behavior change by means of conveying relevant information to the target populations. In order to design the most effective information, there are two aspects needed to be considered. One is what factors or variables can influence behavior change in general. The other is how to tailor messages to different populations in specific. Health Belief Model (HBM) and Stages of Change Model (SOC) are theories dealing with those two aspects respectively.

HBM identifies five factors that could influence preventive health behaviors. They are: perceived barriers to performing the recommended response; perceived benefits of performing the recommended response; perceived susceptibility to a health threat; perceived severity of a health threat; and cues to action. When people try to make decisions whether to take suggested actions with regards to health, they evaluate the severity of the threat and their risks, and weigh potential benefits against barriers/costs. Cues of action act as prompts which could increase the perceived degrees of threats and risks thus encourage people to think and act (Rosenstock, 1974; Witte, 2001).

The factors identified in HBM are not necessarily addressed all together and with the same level of emphasis in the health messages. It is important to tailor the messages according to individual differences, one of which is the stages of change individuals are in. According to SOC, there are five stages: precontemplation, contemplation, preparation, action and maintenance (DeJong, Wolf & Austin, 2001), ranging from complete unawareness of a health problem at one end to relapse into old behaviors after performance of new behaviors for some time at the other (Maibach & Cotton, 1995; Witte, 2001). People in different stages have different behavioral characteristics, therefore need different information to help them move from one stages to the next (Prochaska et al., 1994; Weinstein, 1988). For example, to move them from precontemplation to contemplation stage, what needs to be focused on is information on the health threat, including susceptibility and severity, and the recommended response, so as to increase their awareness (DeJong, Wolf & Austin, 2001; Witte, 2001).

3.2 Target Populations: Universal vs. Selected Intervention

There is a debate going on concerning whether the target populations should be groups of at-risk people differentiated by their identities, or the general public without drawing any line of identity. By borrowing the two terms in *World report on violence and health*, this controversy can be called a dilemma between "universal intervention" and "selected intervention" (Krug et al, 2002).

On one hand, if only the underserved populations or populations at risk are targeted in health communication, they can easily perceive the relevance and give the information more thoughts. However, such communication efforts only deal with inequalities in healthcare without addressing the more fundamental structural factors which are the roots of those inequalities. On the other hand, if the large segments of the population is the target, even small changes in behaviors could possibly result in big transformations in the overall health conditions of the general public. It is also more cost-effective if limited resources could be invested to reach the maximum amount of people. However, individuals or small groups' special needs are ignored (Guttman, 1997).

If this debate is positioned in the HIV/AIDS scenario, there are more social and ethical implications. There has always been a stigmatized label attached to it (Herek & Glunt, 1989). Whatever the label is, it is generally perceived as a disease of "the other", who get infected due to behaviors outside of the mainstream beliefs

held by normative citizens and spread the deadly disease to the innocent, thus pose a significant threat to the general public (Watney, 1987).

Therefore, if those at-risk populations are targeted in HIV/AIDS prevention communication by making their identities salient, the "enacted sigma" by the public would be mentally experienced by them as the "felt stigma" (Green, 1995). They may feel offended and then are resistant to such communication efforts. What's more, the existing negative attitudes among the public towards them would be even worse, which in turn continues to do damage to their self-esteem and self-efficacy (Green, 1995), two important factors in initiating behavior change. Another fault with this strategy is that such communication sends the wrong message to those non-target populations that they are immune to HIV/AIDS since their identities are not included in the prevention information. As a result, they may not even bother to read or listen to the information. Before long, HIV/AIDS crossed the line of sex orientation, race and gender, spreading to virtually every population and putting almost everybody at risk (Kinsella, 1989). In short, the goal of HIV/AIDS prevention communication could never be achieved if both the target and non-target populations ignore whatever information that is conveyed.

Since HIV/AIDS prevention should practically be everybody's concern, would it be better to target HIV/AIDS prevention information to the larger population without drawing any stigmatized line? However, if "everyone" is stated to be at risk in prevention information, everybody would tend to think the information is targeted to others instead of him/herself. What is more, those who are really at risk will neither be aware of their particular risk nor have the motivation to change behaviors (DeJong, Wolf & Austin, 2001). In fact, there are truly populations who are at much greater risk. Statistics show that HIV/AIDS infections are in fact not evenly distributed among different populations in the U.S. with minority people and women being disproportionally infected (CDC, 2003; 2005; US Census Bureau). Other at-risk groups are characterized not just by identities but also by behaviors, such as IDUs (Injecting Drug Users), sex workers, and homosexuals

Although health communication by means of traditional media is not unimportant, the focus of this study is online communication. Considering that more and more people are relying on the Internet for health information, especially those interested in such stigmatized diseases as HIV/AIDS, it is worthwhile to extend the exploration of this issue to the cyberspace.

3.3 eHealth

eHealth is an area where information and communication technologies (ICTs) are applied in medicine and public health, by either healthcare providers to improve their service, or by healthcare consumers to better their health conditions (Eng, 2002). On the healthcare consumers' side, the Internet is perhaps the most popular tool among all the ICTs.

According to Internet World Stats (2004), 68.6% of the U.S. population--more than 201 million individuals, has access to the Internet now. The percentage of adult Internet users in the U.S. who went to the Internet for healthcare information was 80%, a total of 93 million (Fox & Fallows, 2003). The unique features of the Internet, especially the privacy, anonymity and confidentiality it can provide, are particularly attracted to users who are in need of HIV/AIDS information, who want to be empowered, but don't want to be judged and scrutinized (Cotton & Gupta, 2004). In fact, HIV/AIDS patients are among the healthcare consumers with chronic medical conditions who increasingly take the Internet as a major source of information (Kalichman, Weinhardt, Benotsch & Cherry, 2002).

3.4 Political Economy of Media

What populations are targeted and what information is provided to them in HIV/AIDS prevention communication on media are not determined in vacuum. Decisions are always made in certain social context. According to the theory of political economy of media, media are under the control of the economic and political interests of those powerful, upon whom the operations of media have to depend (Jakubowicz & Goodall, 1994). Therefore, the information provided on media reflects what the dominant groups want to say or write, not necessarily what needs to be heard or read (Teo, 2000).

The Internet as a new form of medium can not escape from the influences of the dominant groups who can easily extend their power to this new realm (Hall et al, 1978; Hall, 1982). In other words, the power dynamics in online information is, to some degree, reproducing that in the traditional media (Brock, 2005). For HIV/AIDS prevention information online, it is justifiable to believe that the reasons for its particular design could be explained at least partially by the dominant entities---namely the sponsors/designers and policy makers in public health.

4. METHOD

Only HIV/AIDS prevention information on websites will be examined since websites are considered to be more comprehensive, formal, organized and thus credible than other online formats. The websites collected will be categorized according their URL domain names, including .com, .edu, .gov, .net, and .org., which stand for different ownership of websites (Mohammed & Thombre, 2005). Cross-sectional and within-sectional comparisons can be made so as to better reveal the relationships between the nature of the sponsors/designers and the information content provided by them. *Google* advanced search will be used to collect the websites whose titles have either HIV or AIDS or both. The top 5 hits in each category of domain names will be selected since rankings can represent the level of popularity and credibility to a certain degree. Besides, the websites should be oriented towards not just one population and have a decent amount of prevention information. They will also be checked whether they are outdated and links are working, etc. The selection will be a purposeful process in terms of what and how many websites will be collected, in order to ensure that the cases "offer both typicality and variety" (Pollach, 2003, p280), and only data that can serve research goals and contribute to the solving of research questions be selected (Mushi, 2004). Sampling will be not used due to the impossibility of knowing the population size and having a complete list of all the relevant websites (Mohammed & Thombre, 2005). Other reliable search engines, such as *Yahoo!* and *MSN*, could also be used to double check the popularity and credibility of the selected websites since they have different ranking algorisms. Adjustment to the data set may be made if necessary.

There are two types of data on prevention information that are needed to be collected on selected websites: hypertext and organizational information of the website sponsors/designers. There are two reasons for using the hypertext as the approach to examine the research questions, instead of the information content linked to by the hypertext,. Firstly, hypertext is one of the defining characteristics (Rafaeli & Newhagen, 1996) of the web, while the information contents can be, and often times really are, just the online versions of those from non-electronic media. Secondly, hypertext can be the cue of the topics of the information contents, while structure of hypertext can be the cue of the importance of the contents attached by the sponsors/designers which reflects their interests. Hypertext will be structured in the form of table composed of nodes and links to depict an overview of the website. The homepages will be the starting point and nodes will be followed step by step from there from the higher level of links to the lower level. For organizational information of the website sponsors, usually they can be found on the homepage under such tabs as "about us". The information linked to by those tabs often includes histories, missions, goals, target audience, etc.

Discourse analysis will be used for both the hypertext and the organizational information based on the three functions of texts (Halliday & Hasan, 1976). The topics of prevention information represented by the texts of linked nodes will be analyzed and classified and which stages of behavior they address will be identified. The organizational information will be viewed beyond what is stated by the website sponsors/designers themselves. Rather, what is unspoken and what is assumed will be the focused on (Thompson, 2004). Self-reference and personal address will also be analyzed, i.e. which perspective is used---the more subjective first-person or the more neutral third-person; and which stakeholders are emphasized (Pollach, 2003). In order to relate the interests of website sponsors/designers to the way prevention information is designed, what will be examined are the existence of linked nodes on the homepage and the existence of separate menus for certain topics, since they can indicate what priorities website sponsors/designed assign to certain information and audiences (Killoran, 2005). In addition, how linked nodes are laid out on web pages is also an important index, thus will be subjects of analysis too.

After the analysis of each selected website, cross-sectional and within-sectional comparisons will be made to see their similarities and differences.

5. EXPECTED OUTCOMES

It is expected that the selected websites would be largely uniform in the content of their prevention information and in the populations they target. In other words, little difference could be found among the websites sponsored by different orga-

nizational entities, whether it is commercial, educational or governmental. There is a dominant voice in the discourses on the web concerning what prevention information should be provided and what populations should be targeted.

Jing Chong *is a PhD candidate in the College of Information Sciences and Technology, The Penn State University. Her research areas are health communication on websites and digital divide. The length of her research program is 4 years on a full-time basis. The current stage of her thesis research is in literature review and data collection. Her expected date of completion of the Ph.D program is August, 2008*

Virtual Project Risk vs. Traditional Project Risk in Software Projects

April H. Reed, DePaul University, School of Computer Science, Telecommunications and Information Systems, Chicago, IL, USA;
E-mail: areed7@cti.depaul.edu

INTRODUCTION

This research is designed to distinguish virtual and traditional project risks and specifically to identify the critical risks in virtual software projects. The resulting list of critical risks will provide guidance on managing risks for project leaders working in a virtual team environment. Three areas are important to the discussion of virtual software project risk: virtual software project teams, project failure and project risk.

Virtual software project teams are a growing phenomenon. They are called virtual because team members are not co-located. "Virtual teams are groups of geographically, organizationally and/or time dispersed workers brought together by information and telecommunication technologies to accomplish one or more organizational tasks (Powell *et al.*, 2004)". Many driving forces are causing increased dependence on these teams, including offshoring, outsourcing, reduced business travel due to security concerns, and improvements in collaborative tools. A task force study on globalization and offshoring indicated information technology (IT) has essentially become "a global field, business, and industry"(ACM, 2006). Therefore, there is a need to study how the unique aspects of virtual projects relate to their success.

The Standish Group over the years has measured the incidence of software project failure in corporations with their well known CHAOS reports. They conduct surveys with industry practitioners in the United States and Europe. The 2000 CHAOS report indicated 23% of projects failed while 49% were challenged (Standish Group International, 2001). The 2004 CHAOS report for the third quarter indicated 18% of projects failed and 53% of projects were challenged (Standish Group International, 2004). A one percent decrease in the number of troubled projects shows little improvement over a four year period. These numbers reinforce the need to investigate causes of project failure and identify the most critical project risks. This need is not just for projects in general, but particularly for the rapidly growing case of virtual projects.

Critical project risks are those factors that will have the greatest impact on the success or failure of a project. Boehm indicates critical risks should be the main focus of a project manager, instead of the entire pool of identified risks (Boehm, 1991). Some risk management advocates are proponents of identifying and analyzing "threats to success", which allows appropriate actions to be taken to "reduce the chance of failure" (Wallace et al., 2004).

RESEARCH PROBLEM

The research problem is:

What are the significant differences between risks in virtual and traditional software development projects? Which of these risks are critical to successful project completion of virtual software projects?

Prior research on project risk has been performed predominately on different types of traditional software projects. A review of prior research, a series of interviews and focus groups, and my own experiences as a professional project manager, have led me to the following hypotheses:

- Some risk factors in virtual and traditional software projects are similar
- Critical risk factors in virtual software projects are different from critical risk factors in traditional software projects.
- Resource issues are critical to virtual software projects.
  Reasoning: Resource issues have an impact on project success (Beise, 2004; Fairley, 1994; PMI, 2004) and are likely to be intensified when resources are not co-located
- Communication issues are critical on virtual software projects
  Reasoning: Virtual projects are often dependent on other, less common, forms of communication because traditional face-to-face communication is usually not an option. (Igbaria *et al.*, 1999)
- Virtual team dynamics are different from traditional team dynamics
  Reasoning: Virtual teams are more likely to be diversified since team members are not co-located and they may never meet face-to-face (Ewusi-Mensah, 2003; Powell et al., 2004)

OBJECTIVES

The main objective of this study is to identify a set of comprehensive yet concise *critical* risk factors for virtual software projects, by conducting a survey of industry practitioners. The list is essential to developing effective risk management for virtual software projects. Risk management, "a collection of methods aimed at minimizing or reducing the effects of project failure" (Addison & Vallabh, 2002), can then be used by organizations to increase the likelihood of project success. Thus, the importance of this study lies in its ability to enable virtual software project managers to avoid major risks and achieve greater rates of project success. The 2004 CHAOS report indicated companies in the United States and Europe spent $255 billion on software projects while the cost of failed projects was $55 billion (SoftwareMag.com, 2004).

LITERATURE REVIEW

Several researchers have identified the important risks in traditional software projects. Boehm, conducted a survey of experienced IT project managers who worked with him at TRW in the early 1990's. The result was his "Top ten software risk items" which is contained in the first column in Table 1(Boehm, 1991). One of the limitations of this study was the sample which consisted of a small number of project managers from the same company.

Barki, Rivard et al. sent their 144 item questionnaire to the largest 100 companies across a variety of industries in Quebec and surveyed 120 software development projects. The result was a list of software project risks grouped in five categories of risk factors/risk dimensions: technological newness, application size, lack of expertise, application complexity and organizational environment. The purpose

of the survey was to improve management of software development projects by measuring their risk (Barki *et al.*, 1993). Barki's results are shown in the second column of Table 1.

Wallace, in her dissertation, conducted interviews with software project managers to identify risks and mass distribution of a survey to the Project Management Institute Information Systems Special Interest Group (ISSIG). The result was six risk categories or dimensions: team, organizational environment, requirements, planning and control, user, and project complexity. The purpose of her study was to improve risk management by determining the specific types of risks encountered on different types of software projects. One of the limitations of this study was the sample consisting of members from one group which were very likely to have knowledge of standard risk management practices (Wallace, 1999). Wallace's results are shown in the third column of Table 1. Thus, the three seminal studies conducted to date on the subject of project risk factors have yielded overlapping and not entirely consistent results, as shown in Table 1.

METHODOLOGY

First, a literature review of seminal work was conducted to create an initial list of project risk factors. A survey instrument was created and approved by the university Internal Review Board (IRB), then tested in face-to-face interviews with project managers, to add risks factors from a practitioner's point of view to the list. This was followed by an electronic focus group session to validate and enrich the existing risk factor list. A large volume of rich data was collected then sorted and categorized several times. This data will be compared to the seminal

Table 1

Boehm, Barry (Boehm, 1991) *Risk Factors*	Barki, Henri(Barki et al., 1993) *Uncertainty Factors*	Wallace, Linda and Keil, Mark(Wallace & Keil, 2004) *Risk Dimensions*
Personnel Shortfalls • Personnel availability • Mix of software disciplines represented • Team' expertise • Management's approach	**Lack of Expertise** • Lack of team general expertise • Lack of development expertise in team • Team's lack of expertise with task • Team's lack of expertise with appl • Lack of user experience & support	**Team** • Team member turnover • Staffing buildup • Insufficient knowledge among team members • Cooperation • Motivation • Team communication issues
	Organizational Environment • Extent of changes • Intensity of conflicts • Lack of clarity of role definitions • Resource insufficiency • Task complexity	**Organizational Environment** • Organizational politics • Stability of organizational environment • Organizational support for a project
Developing the wrong functions & properties • Size & complexity of requirements • Level of hardware imposed constraints • Number of system interdependencies • New technology or application • Requirements stability **Gold-plating** • Lack of quality in requirements & product **Continuing stream of requirements changes** • Changing requirements		**Requirements** • Uncertainty surrounding system requirements • Changing requirements • Incorrect, unclear, inadequate, ambiguous or unusable requirements
Unrealistic schedules & budgets • Unrealistic schedules • Unrealistic budgets		**Planning & Control** • Unrealistic schedules • Unrealistic budges • Lack of visible milestones to assess production of intended deliverables • Inaccurate estimates leading to inaccurate resource forecast
Developing the wrong user interface • Poor quality user interface		**User** • Lack of user involvement in development • Unfavorable user attitude toward project
Straining computer-science capabilities • Complex technology	**Technological Newness** • Need for new software • Number of software suppliers • Need for new hardware • Number of hardware suppliers • Number of users outside organization **Application Complexity** • Number of links to future systems • Number of links to existing systems • Technical complexity	**Complexity** • New technology • Complex processes being automated • Large number of links to existing systems • Large number of links to external entities
	Application size • Team diversity • Number of people on team • Number of users in organization • Relative project size • Number of hierarchical levels occupied by users	
Shortfalls in externally performed tasks • Poor quality work from external resources **Real-time performance shortfalls** • Lack of performance quality **Shortfalls in externally furnished components** • Lack of quality in external components		

literature to create a comprehensive yet concise list of risk factors for ranking in the questionnaire: A purchased mailing list of 5,000 names from a project management magazine will provide for mass distribution of the questionnaire to IT project leaders, managers and analysts.

OUTCOMES AND EXPECTED SIGNIFICANCE

The occurrence of virtual software projects will continue to increase as society becomes more global. Virtual software projects will not escape risk; therefore, project failures will occur. Researching and identifying those risk factors most critical to virtual software projects can improve risk management in this new arena. This research seeks to create a validated list of critical risks for virtual software projects that can be used by project leaders to reduce or eliminate risks.

How are the Impacts of End-User Application Development Managed? A Case Study of End-Users and Their Managers

Sandra Barker, School of Management, University of South Australia, Australia; E-mail: sandra.barker@unisa.edu.au

PROBLEM STATEMENT

End User Computing (EUC) has now become prolific throughout business due to the decreased cost of the available PCs and the introduction of "easy-to-use" software application generators. The most often used definition of EUC is one which incorporates the facts that end user computing involves the interaction of managers, professionals and operational level users with application software within their own working departments (Torkzadeh & Doll, 1993).

The research undertaken over the past 25 years has been particularly in the areas of end-user satisfaction with information systems, end-user computing in general, end user application development, and the identification of who end-users are and the organisational areas which are affected by end-users (Rockart & Flannery, 1983; Brancheau & Brown, 1993; Powell & Moore, 2002) together with issues that impact on end-user development but little regarding how this can be addressed in the current technological environment.

Over this period there has been a significant change in the available technology (hardware and software), the introduction of technology into pre-tertiary education and a change in the information technology culture within organisations (Rockart & Flannery, 1983; Brancheau & Brown, 1993; McBride & Wood-Harper, 2002). The review of literature has shown that there is a need for continued research into these areas.

The research question to be investigated is: *How are the impacts of end-user application development managed?* The research to be undertaken will explore the changes in technology, use of technology and its impact on organisations. The specific questions that will be addressed are:

1. What are the impacts of end user application development on:
   - the end users;
   - the managers?
2. How are these impacts managed by
   - the end users;
   - the managers?

LITERATURE SUPPORTING THE RESEARCH

In the 1970s computing was identified with mainframe computers however the introduction of PCs in the early 1980s lead to EUC being reported as '…a rapidly growing and irreversible phenomenon' (Alavi & Weiss, 1985, p6). Rockart and Flannery (1983, p777-778) identified six classifications of end-users dependent upon their function within the organisation. These classifications were:

- Non-programming end-user
- Command level end-user
- End-user programmers

- Functional support personnel
- End-user computing support personnel
- Data processing programmers.

These classifications expanded upon those defined by the Codasyl report (1979, cited in Cotterman & Kumar, 1989) by being more prescriptive with their definition of how the end-users interacted with the technology. Early researchers (eg Rockart & Flannery, 1983) reported on a producer/consumer dichotomy when it came to describing end-users whilst other researchers (Wetherbe & Leithseier, 1985 as cited in Cotterman & Kumar, 1989) reported on the comparison between the end-user operator and the end-user developer.

Leithseier and Wetherbe (1986) amended their research to include a third component, that of the amount of control that the manager or user has over the computer resources. Cotterman and Kumar (1989) developed taxonomy of end-users based upon this research. It was already apparent at this early stage in the research into end-user computing that some end-users (ie non-IS trained users) were undertaking some application development. It was identified in their paper that it is imperative to understand who the users to ensure that each class of user is treated appropriately and that the relevant training, education and management approaches are used to assist them in their daily tasks.

In the early 1990s, Brancheau and Brown (1993, p439) defined end-user computing as the 'adoption and use of information technology by personnel outside the information systems department to develop software applications in support of organisational tasks.' Their paper concentrated on the research into the management issues related to end-user computing and uses the Rockart and Flannery (1983) classification of users as a basis for the research.

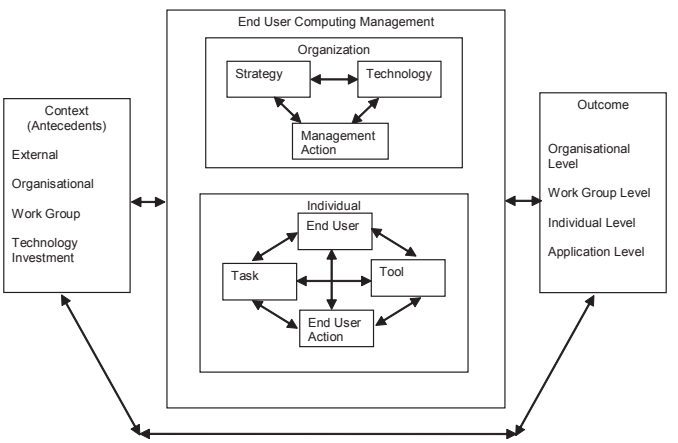
Brancheau and Brown (1993) summarised papers published on the issues related to management of end-user computing and mapped then into the model shown in Figure 1. Their findings outlined two possible areas that required future research: EUC as a component of organisational computing; and EUC as a social learning phenomenon. They identified that 'failure to build on prior EUC research and failure to rely on theoretical knowledge accumulated in key reference disciplines have been major obstacles to furthering our understanding of EUC management' (Brancheau & Brown, 1993, p 477).

Chan and Storey (1996, p119) identified that EUC is an 'important part of organizational computing today' and stated that 'end-user computing was the autonomous use of information technology by knowledge workers outside the IS department'.

During the mid to late 1990s as much of the literature published dealt with similar issues that had previously been reported. Research into this area is, however, very much back on the agenda with many reviews of past research appearing in the last couple of years (eg Powell & Moore, 2002;

Govindarajulu, 2003) and the introduction of research into end-user use and development of applications using new technologies becoming apparent.

Figure 1. Model of the management of end-user computing (Brancheau & Brown, 1993, p441)



Anecdotally, the increased availability of PCs within organisations together with the increased level of computer literacy being taught during the primary and secondary education programs leads the candidate to believe that there are more 'end-users' in employment. The personal productivity tools (like Microsoft Office, Lotus Office, etc) are being marketed as being more user friendly leading end-users to become creative within their everyday working requirements. The, so-called, wizards are giving end-users more confidence with the software without having to understand the programming language on which the spreadsheet, database, web page or presentation is based.

Other key authors in this field have looked into managerial techniques (Gerrity & Rockart, 1986), EUC success (Doll & Torkzadeh, 1989), structured design approaches to reducing errors (Janvrin & Morrison, 2000), user control of EUC (McBride & Wood-Harper, 2002), and EUC quality issues (McGill, 2002).

Gerrity and Rockart (1986, p25) identified that the 'dramatic increase in end-user computing…offers major opportunities for businesses'. They also outlined that, although this 'phenomenon' was bringing some major advantages for the organisation, senior management need to avoid a technology-based management approach and adopt of business-driven management strategy which they describe as a 'Managed-Free Economy' approach.

The literature investigated by Brancheau and Brown (1993) and continued by Powell and Moore (2002) identified numerous areas where there are gaps in the current knowledge base of end-user computing. The research of Powell and Moore (2002, p15) provided a valuable view into these areas given the 'more recent organizational and technological developments (such as advancements in communications technology, outsourcing of EUC support functions, and the globalisation of companies)'. The areas from the Brancheau and Brown model that have been identified as future research areas are:

- cultural antecedents;
- organisational strategy;
- effective and ineffective organisational management strategies,
- organisational technology issues relating to new technologies and the interconnectedness of applications;
- end-user environment relating to skills, tools used and tasks; and
- the outcome based relationship between end-user computing and organisational performance.

RESEARCH QUESTIONS

It is obviously above the scope of this thesis to investigate all of the above areas however the researcher will introduce new knowledge into the field of end-user computing by answering the questions identified earlier:

What are the impacts of end user application development on the end users and their managers?

The information obtained in response to this question will give insight into the outcomes of end-user computing relating to the relationship between end-user computing and organisational performance. It is important to understand this relationship as management strategies employed by an organisation have been influenced by the introduction of end-user computing and end-user application development (Gerrity & Rockart, 1986). By understanding the impacts of EUAD, organizations can be better equipped to control the issues and develop policies to work more efficiently and effectively within this end-user environment.

How are the impacts managed by the end users and their managers?

By investigating the issue of "what managers are doing" the knowledge area of organisational strategy and technology issues can be enhanced and updated as Powell and Moore (2002, p15) identified '…research needs to continue to examine how these factors relate to the practice and management of EUC in today's environment'. The responses and information gathered here will help to determine the management approaches being undertaken and the success or failure of adopting such an approach. The personal experience of the researcher suggests that managers are utilising a Laissez-Faire approach to the management of the end-user developers and as such applications are being developed which are poor quality,

take significant time from the end-user's daily tasks and occasionally duplicate software applications already in use elsewhere in the organisation.

As part of the research some underlying issues will be identified. The main concentration will be on determining who the end users are in the organisation, what they do as part of the daily roles and what training, if any, they have been subjected to in order to enhance their end-user computing and end-user development skills.

It is important to note that all of this can be investigated but, as identified clearly by Cotterman and Kumar (1989), it is an essential part of any study into EUC that the users be clearly defined. To this end a thorough investigation of the Cotterman and Kumar model in terms of today's technology and user skill must be undertaken.

Many researchers have briefly looked at the strategies required to improve the end-user development of applications but to this point no researcher has investigated the implementation of these strategies and their impact on the individual and the organisation. The answer to this question will not only identify who the end-user developers are in the case organisations but also the tasks they are undertaking and the applications they are developing. By identifying issues such as cultural background and end-user environment it is expected that the researcher will develop an identification model to assist in the early detection of end-user developers giving direct line managers the capacity to implement management strategies more effectively.

TYPE OF STUDY

This study will be undertaken using an exploratory approach to investigate the questions posed by utilising a case study format. Qualitative research techniques of interview and focus group will be utilised in conjunction with an initial questionnaire to determine demographic and end-user classification information. The results of the qualitative and quantitative methods used will be analysed through an interpretive viewpoint. Interpretivism is 'concerned with approaches to the understanding of reality and asserting that all such knowledge is necessarily a social construction and thus subjective' (Walsham, 1993, p5). The interpretive approach can potentially 'produce deep insights into information systems phenomena' as it assists researchers in understanding 'human thought and action in social and organizational contexts' (Klein & Myers, 1999, p67).

Walsham (1993, p4-5) stated that interpretive methods of research are 'aimed at producing an understanding of the *context* of the information system, and the *process* whereby the information system influences and is influenced by its context'. The major criteria for being a case organisation in this study are that end-user application development happens to some extent within the organisation by at least two employees and that these employees report to a direct line manager. To analyse the impact of this development the most obvious approach will be to investigate the *process* of the application development within the *context* of both the organisation and the end-user developer.

Brancheau and Brown (1993, p472) identified case studies would play an important part in the future research into EUC stating 'they are uniquely suited to open-ended, detailed investigation of EUC phenomena'. The case study approach has been identified as being one of the most appropriate methods for conducting Information Systems empirical research in the tradition of interpretation and generally involves the use of more than one case study in order to allow for comparison (Walsham, 1993). This approach will allow the researcher to investigate the impacts of end-user developed applications on the organisation by interviewing the users and their direct managers and thus developing a case based view of different organisations.

"...Some People Achieve Greatness...": A Study Correlating Early Vocational Behaviour with Ultimate Vocational Achievement

Tony Richardson, Massey University Albany Campus, Auckland, New Zealand; E-mail: t.s.richardson@massey.ac.nz

EXECUTIVE SUMMARY

Discovering the right people for the job, any job, is a complex, frustrating and often fruitless activity. In recruiting graduates, employers are not simply looking for someone to do a job, they are more likely seeking to take on candidates who have the potential to rise to the highest ranks within organisations. They are seeking those candidates who, a decade hence, will be seen as high-achievers, but identifying such potential in fresh graduates has proven to be elusive. While the decision support role of Information Systems should be considerable

within this domain, in fact an IS framework founded on actual vocational data is entirely lacking.

The crux of this research is to generate and analyse that data in order to determine whether known high-achieving employees exhibited signature behaviour when they were raw recruits almost a decade earlier. It is proposed that the results from this research be used as enabling knowledge for the development of sophisticated assessment simulation Information Systems, whereby signature behaviour may be potentially stimulated and evaluated. In particular the research seeks to establish:

1. Can future vocational outcomes be accurately predicted by initial vocational behaviour?
2. How does initial vocational behaviour relate to an individual's ultimate potential?
3. How may an understanding of vocational behaviour be integrated into a design framework for predictive assessment Information Systems?

If successful, the outcomes of this PhD project could provide a model upon which future candidate assessment information systems are predicated.

BACKGROUND

In his 1979 book (Wolfe, 1979) describing America's National Aeronautical and Space Administration's (NASA's) recruitment process to find the early astronauts, the author is reduced to describing successful applicants as having the "right stuff". Wolfe makes it clear that a mixture of abilities, background and "correctness" were prescribed as selection criteria, even though this filter eliminated arguably the finest test pilot of the day, Chuck Yeager. In the absence of more definitive data, this vague and overarching evaluation adjective "right-stuff" is still used today to retrospectively describe individuals who rise to become high-potential industry achievers.

In an attempt to specify their ideal graduate profiles to either recruitment agencies or internal human resource departments, corporate directors and managers often bemoan the time, complexity, obtuseness, cost and effective failure of the entire recruitment process. When pressed, they say "I know this is important for us, that's why I put the time in. But I really just want them to find me another two grads like him." As they say this they will often point through frosted glass to a bright-eyed staff member whom they employed the previous year and who has proven to be everything they expected of a new graduate, in fact a "golden employee".

Is it possible to predict such high-potential employees at a very early stage? Would such candidates exhibit particular key behaviour if placed in a work-based scenario, such that an accurate prediction of their vocational potential could be made? In part, the research goal of this project aims to answer the question, does such signature behaviour exist?

METHODOLOGY

A quantitative approach was determined to be most appropriate for this research, data mining and statistical techniques were utilised to generate and assess correlations between variables in the data. The instrument designed to generate and gather the data is briefly outlined here.

Earlier valuable research in this area has been based upon retrospective survey data using content and factor analysis e.g. (Lombardo & Eichinger, 2000) in an effort to verify a "hunch" that a particular factor was key signature behaviour (in the case of Lomabrdo & Eichenger the postulated key behaviour was post-appointment learning ability.).

For reasons of real-world validation and because this research will bootstrap and is key to proposed further work on simulator development, the author of this research sought to determine if actual vocational data could be accessed and if so, what would be its optimum form and how could the data be obtained. Several assumptions guided the course of actions culminating in the data gathering instrument.

Assumption 1: Signature behaviour may be observed over a relatively short period of time due to an individual's particular reaction to a particular set of vocational circumstances. This assumption led to the conclusion that, if an average "golden employee" takes 6 to 10 years to establish ultimate vocational success within a large New Zealand company (this condition based on anecdotal evidence), then vocational behaviour data collected over a 3 – 4 month period should prove sufficient to generate evidence of signature behaviour.

Assumption 2: That signature behaviour is more likely to be observed within data of relatively fine granularity. It is simply more plausible that the greater the number of recorded time periods in a single working day the more accurate will be the picture of individual behaviours rather than a set of behaviours all classified together under a daily collective code.

Assumption 3: That an employer of substance would be required for this research project, one which annually employed a significant number of graduates and which could be easily and logically subdivided into hierarchically organised departments.

Assumption 4: That the data collected would be of a highly sensitive nature both internally and commercially and that simply approaching a company and asking to see their employees timesheets records for the past 3 months would not be a reasonable course of action. This assumption led to the formulation of an 8 year association with one of the leading accounting practices in New Zealand and the design and development of a nationwide practice management system.

Assumption 5: That in order for the data to be valid it would need to be verified as correct, internal to the employers organisation. This assumption led to a major increase in scope of the practice management system and to the decision that customer billing data would be generated from the employee behaviour data.

Assumption 6: That, despite the passage of 8 years, the employer would remain willing and able to provide data on the vocational progress of the employees involved in the study. Happily, this assumption proved correct despite a significant change in personnel. This final batch of data was collected in 2006.

STAGE OF THE RESEARCH

The author is two years into a part-time PhD research program. To date it has been a voyage of discovery in an attempt to narrow the conceptual scope and discover the true focus of the project. Initially, a deconstructionist model was adopted, which asked why a particular human being behaved in a particular way. It was felt that if the behaviour of hi-potential candidates/employees could be accurately analysed in this way the knowledge learnt could be applied to compare prospective employees. There is a great deal of literature which adopts this deconstructionist approach to analyse an individual's behaviour particularly in terms of facets of personality. Conceptually, the research model for this project is shown in figure 1, with each contributing body of knowledge appearing as a node, providing input to the central trunk.

As the work has progressed, so the nodes have increased in number until, during a recent re-evaluation a further significant factor was identified as being absent from the study and "fitted" to the original model. This produced the concept model shown in figure 2, which bought into question the validity of the original concept.

Figure 1

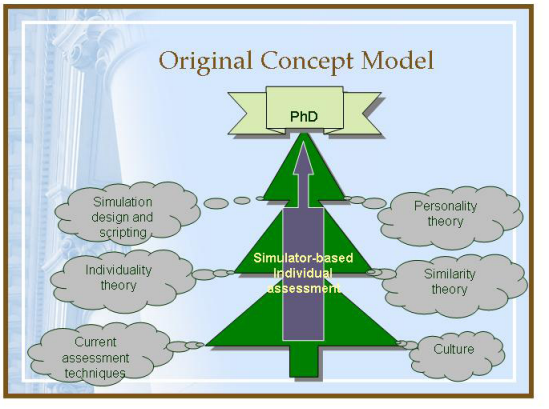

Figure 2

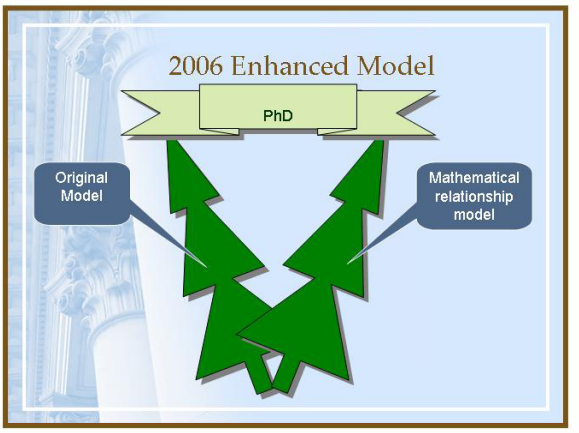

Figure 3

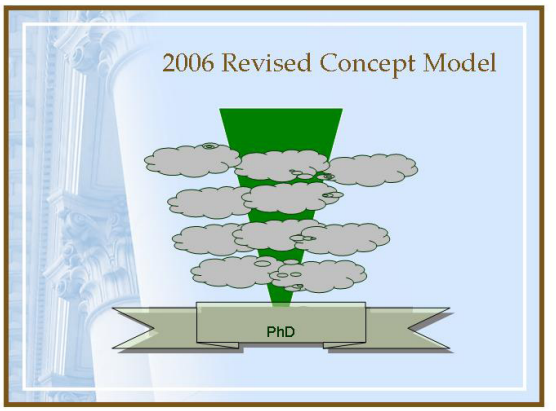

It was felt that this model lacked elegance, clarity and a discernable timetable for completion, indeed feedback from academic advisors declared this concept to contain not one but ten PhDs. A rethink was in order and by re-examining the contributing nodes and loosely applying input/output relationships to them a new concept model was developed, as shown in figure 3.

This model placed the PhD study not at the top but at the bottom, examining the node representing the enabling body of knowledge upon which all other aspects of the initial project were predicated. The research problem at the heart of this project and covered by this bottom-line node of knowledge considers whether, in a group of employees, vocational behaviour at the start of their careers can be correlated with their vocational achievement over a prolonged period of time.

The bibliography generated is included below for reference; the data has been gathered and is awaiting analysis via data-mining and statistical techniques. The current timeline sets completion of the PhD study to June/July 2008.

ABSTRACT

The accessibility to important healthcare resources and the costs of healthcare services are serious challenges facing the rural communities of most developing countries. In order to address these problems, we are pursuing rigorous experimental investigations for the development of an information utility infrastructure, which takes advantages of emerging Utility Grid Computing (UGC) and Body Area Network (BAN) for ubiquitous e-Healthcare service provisioning. In this paper, we derive the system requirements from enterprise models and delineate the general framework guiding the development of the infrastructure.

Keywords: Healthcare Management, Body Area Network, Grid Computing, Enterprise Model

1. INTRODUCTION

Most rural communities in developing countries are facing debilitating situations regarding accessibility to quality healthcare services. There is high demand for increased accessibility to important healthcare resources, increased efficiency and quality-oriented healthcare services with limited financial resources. Rural communities are characterized by prevailing issues such as low health level, low literacy level, limited resources and professional isolation.

In a modern information society, patient care increasingly requires healthcare practitioners to access accurate and complete health information so as to effectively manage the safe and efficient delivery of complex and knowledge intensive healthcare. There is also the need to share this information within and between care teams. On the other hand, patients require access to their own health information in

order to allow them play significant role in their health management. These essential requirements are becoming more urgent as focus of healthcare management shifts progressively from reactive to proactive care, which requires the involvement of patient's personal environment to provide quality healthcare services.

However, much of the fine-grained healthcare information upon which future care depends is still captured into paper archives or at best in isolated hospital databases and managed by proprietary applications. These applications are developed using different technologies and to seamlessly interoperate them is a difficult task. The problem being investigated is how to practically use Information and Communication Technology (ICT) to provide quality and cost-effective healthcare services to rural communities. A simple solution is to adopt the existing remote monitoring systems that have been used in developed countries like America and Europe. However, these technologies have not been widely used in Africa because of their (i) expensiveness and inflexibility for new services and applications, (ii) service provider dependency and (iii) possibility for communication delay during patient-healthcare practitioner interactivity.

The BAN-UGC integration has exceptional potential to improve the quality of healthcare services whilst simultaneously cutting costs by aggregating multiple heterogeneous resources. The technology will support the mobility of people and increase service availability through pervasiveness, home care support and point-of-care treatment. The rest of the paper is summarized as follows. Section 2 describes the BAN-UGC integration. Section 3 describes an Enterprise model for rural healthcare service provisioning. Section 4 gives the requirements for a healthcare utility service infrastructure and the paper is concluded in section 5.

2. INTEGRATION OF BODY AREA NETWORK AND UTILITY GRID COMPUTING

The MobiHealth [1] introduced innovative value-added mobile healthcare services based on public broadband 2.5G (GPRS) and 3G (UMTS) wireless networks for continuous monitoring and transmission of vital signals. This was achieved with the integration of smart sensors to a wireless generic BAN [2]. The BAN is a wireless health monitoring system that consists of sensors, actuators, communication and processing facilities and integrates wearable devices for connecting different sensors. The BAN sensors are responsible for data acquisition, measurement and transmission processes ensuring that a physical phenomenon, such as patient movement, muscle activity or blood flow is converted to an electrical signal. The signal is amplified and internally communicated within the BAN through intra-BAN communication process. The gateway that facilitates extra-BAN communication of vital signals to healthcare providers or brokers is the Mobile Base Unit (MBU) [3]. This way the network facilitates time and location independent monitoring of a patient's health conditions.

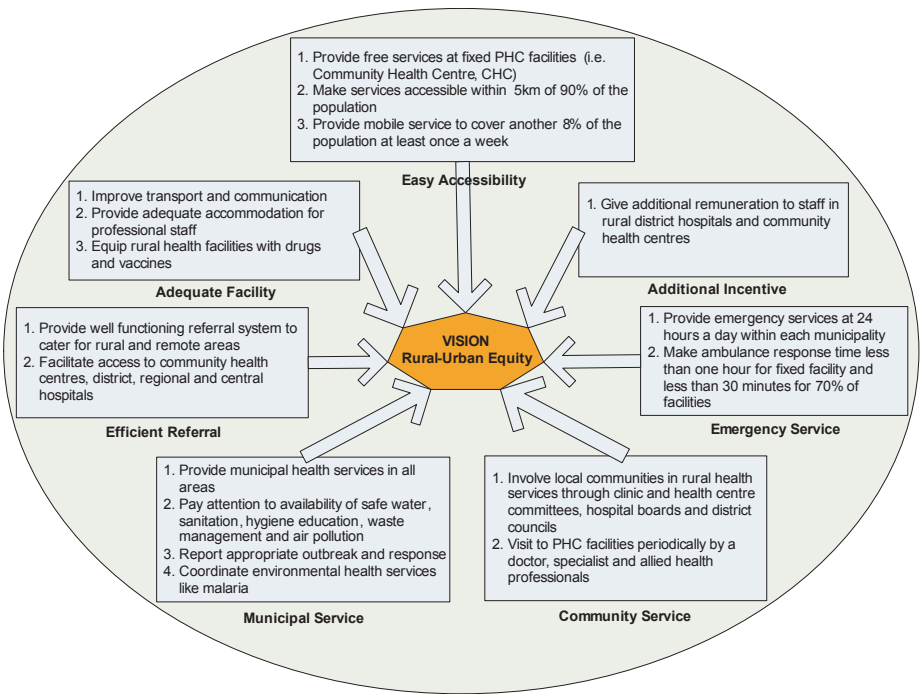
A utility grid [4] is a distributed enterprise grid that provides resources on-demand and supports a pool of computers to be assigned as needed to take-up extra demand that can defy the potential of human expertise. The BAN-UGC integration gives rise to new healthcare services and applications that can provide remote diagnosis and treatment capabilities. Using this integrated technology, healthcare practitioners and patients will have access to resources that can not be provided by BAN only. For example, a patient health records could be moved around and a healthcare practitioner would be able to collaborate with colleagues from other locations and make informed decisions anytime by sharing resources. The vital signals that are measured and transmitted to a software broker could be adequately analyzed using the discovered grid resources. The result of the analysis would be effectively delivered to the user in a real-time. Thus, enabling remote management of patient conditions and quick detection of health emergencies whilst maximizing patient mobility and minimizing healthcare costs.

3. AN ENTERPRISE MODEL FOR RURAL HEALTHCARE PROVISIONING

This section summarizes the Enterprise model for rural healthcare service provisioning in the developing country context, using the Republic of South Africa (RSA) healthcare service provisioning strategy scenario. This strategy is based on the adoption of mobile clinics, efficient referral and Primary HealthCare (PHC) systems. The healthcare service provisioning process was analyzed to align with the established ways of practice and to capture the basic invariant structure of the service provisioning tasks. The refined Enterprise model [5], which includes entities related to BAN, was extended to incorporate UGC concepts. This was used to derive the computational and engineering level requirements for the healthcare utility service infrastructure.

A rural healthcare provisioning process is a workflow of vision-driven tasks aimed at achieving rural-urban equity in healthcare service provisioning, so as to improve the health status of every citizen. From an enterprise modeling perspective, a task typically contains several subtasks, each of which represents several activities.

Figure 1. A vision-driven rural healthcare service provisioning model



A task therefore, is an embodiment of healthcare activities [6]. In this context, a task identifies the vision, goal or objective to accomplish, a subtask states what service is required and activities state how to implement the subtasks to achieve the intended vision. Figure 1 depicts the summary of the refined task activities of the rural healthcare service provisioning practice in RSA.

4. REQUIREMENTS FOR HEALTHCARE UTILITY SERVICE INFRASTRUCTURE

The Enterprise model was directly used for deriving the requirements for the infrastructure support of healthcare service provisioning processes. These can be grouped amongst others into control-plane and usage-plane requirements.

4.1 Control-Plane Requirements

These are the requirements associated to the setup of the bindings of the agent to agent communication, remote monitoring of vital signals, diagnosis and treatment. Some of the requirements include (i) addressing; the MBU needs to be addressable in the wireless environment. The devices attached to the BAN must have unique addresses to be individually addressed. The data acquisition front-end of the devices must be uniquely addressed within a centrally controlled BAN, (ii) plug-and-play; the BAN becomes unknown in the environment whenever the MBU is powered off. The MBU start-up should therefore, contain a push mechanism to enable its discovery in the augmented reality environment. Quality of Service (QoS) mechanisms should be included to enable capacity alignment within the networked and in inline with the application's QoS requirements and (iii) adaptable communication; the amount, quality and coherence of the data to be exchanged have to match with the limitations of the communication channel capability. Adaptable services are typically required in these environments to better cope with bandwidth limitations and variations in communication errors such as data loss and channel dropouts. Data buffering, data prioritization, synchronization mechanisms and data acknowledgements are important requirements. Resource control policy such as computational economy, resource prioritization and reservation are required for effective management and scheduling of resources in the highly distributed environment.

4.2 Usage-Plane Requirements

These are the requirements in respect of data transfer and they are basically the upstream push and downstream messaging mechanisms. The data transfer mechanisms should be implemented such that transfer delays do not exceed the boundaries given by human factor studies. Another important requirement is the communication costs, continuous monitoring of signals and resource consumption must be regulated for effective management purpose. A different cost model for continuous transmission applications such as flat rate charge for unlimited data and usage is desirable.

4.3 e-Healthcare utility-Service Broker

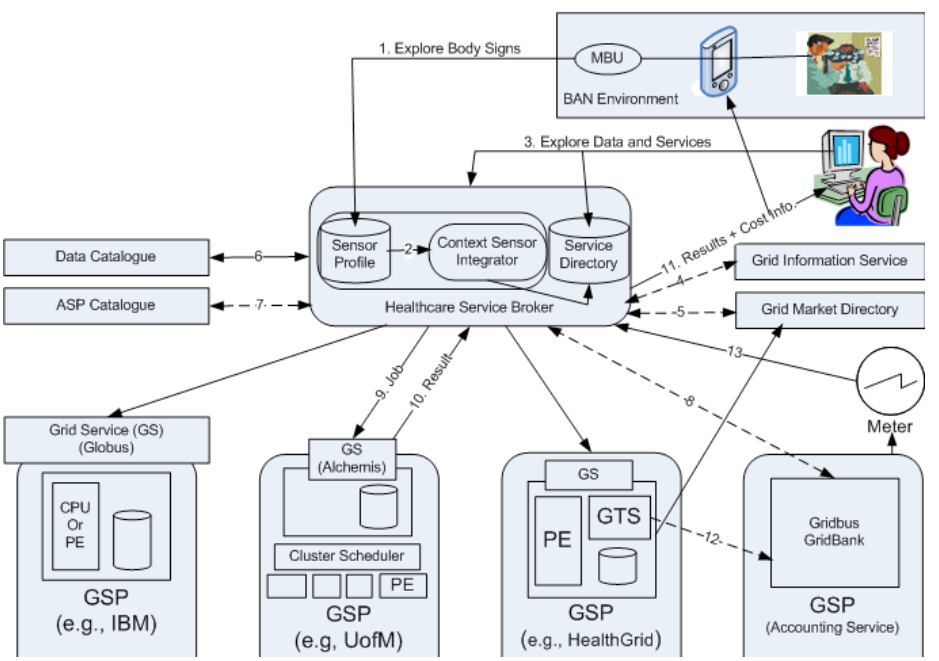
The BAN-UGC integration raises some entirely new requirements for service infrastructures. These requirements can be met by a new type of Grid Resource Broker (GRB), a Healthcare utility-Service Broker (HSB). The HSB acts as a mediator between the user and the network resources to perform various tasks such as patient's health status monitoring, diagnosis and treatment, using sensors and grid services. Figure 2 depicts the on-demand assemblage of healthcare services using the HSB technology.

The BAN collects and transmits vital signs to the sensor profile (Step 1). Context Sensor Integrator (CSI) converts sensor data to a service request specification and store in the service directory (Step 2). User requests can in two forms (i) a service retailer registers services to offer to end-consumers as free social services or on charge basis and (ii) a user subscribes for a service using proximate selection (Step 3). The broker performs service discovery based on request using web services-based Grid Information Service (GIS) and Grid Market Directory (GMD) (Steps 4 and 5). The broker identifies the list of data sources or replicas and selects the optimal ones (Step 6). The broker also identifies the list of computational resources that provides the required services using Application Service Provider (ASP) catalogue (Step 7). The broker ensures that the user has the necessary credit or authorized share to utilize resources (Step 8). The broker scheduler assigns and deploys jobs to grid services that meet QoS requirement (Step 9). The broker agent on the grid resource at the Grid Service Provider (GSP) then executes the job and returns the result (Step 10). The broker collects the results plus cost information and passes them to the user (Step 11). The metering system charges the user by passing the resource usage information to the accounting service (Step 12). The accounting service reports the remaining resource share allocation and credit available to the user via the broker's Local Billing System (LBS) (Step 13).

5. CONCLUSION

This paper gives the infrastructure requirements for BAN-UGC integration that incorporates smart sensors and grid services to support and improve distributed

Figure 2. On-demand service provisioning in utility grid



healthcare service provisioning. These requirements were derived from Enterprise models capturing the community invariants of the healthcare service provisioning processes. The proposed approach has the benefit of making ubiquitous quality healthcare services available and helps in addressing the rural-urban healthcare service provisioning inequality.

Community-Based Performance Management in Local Government

Peter Demediuk, Victoria Graduate School of Business, Victoria University, Australia; E-mail: peter.demediuk@vu.edu.au

NOTES:

I have finished all progam coursework and am enrolled part-time in the doctoral program. I am in the process of constructing the proposal. I would expect to have the proposal ready in May for comment and discussion, and plan to have the thesis completed in 18-24 months after that.

SUMMARY

Performance management occurs where performance measurement intersects with organizational action - and the ambit of accounting has extended to cover significant parts of this cycle. The best value reforms to local government in the UK and Australia valorize performance measurement and community engagement as necessities for effective governance, and so we must now cope with the interaction of action, performance measurement and community engagement. This research will investigate current practice in community engagement within service delivery areas of Australian local governments. In particular the research will explore the gap in the literature about how the engagement impacts on decision-making.

COMMUNITY ENGAGEMENT AND PERFORMANCE MANAGEMENT

"Citizen participation in the decisions that affect their lives is an imperative of contemporary society", and since the latter part of the twentieth century we are witnessing a shift away from reliance on public officials and administrators to frame objectives and action (Roberts 2004, p. 369). The trend towards public involvement in decision-making should "… grow as democratic societies become more decentralised, interdependent, networked, linked with new information technologies, and challenged by wicked problems" (Roberts 2004, p. 316).

Kathi and Cooper (2005, p. 559) categorise the central arguments for citizen participation in governance under moral and instrumental normative grounds. The moral normative argument is that citizen participation in the work of government is a basic right in a democracy. The three instrumental normative arguments hold that community participation: promotes efficiency and effectiveness; is a vehicle for community empowerment and change; and bolsters political stability.

The 'Best Value' performance management framework in Victoria requires local governments to provide, and continuously improve, 'value for money' services that are relevant to community needs. This requirement has three important implications for performance management in government. Firstly it calls for rational decision-making by local government politicians and managers, where action must be driven by good performance information. Secondly, it calls for robust accountability mechanisms, where good performance information needs to capture the results of action. Thirdly, because the nature and impact of services must reflect community needs, the performance information which drives action and captures results must be the subject of community input. So Best Value in Victoria, and similar reforms in Sweden, the UK and New Zealand have challenged traditional practice by requiring a three-way linkage between institutional action, performance measurement, and community engagement. In the midst of such initiatives by governments to increase the level of community engagement, there is a gap in our understanding about the impact of community engagement on decision-making (Kathi & Cooper 2005) (Department of Justice Canada 2001).

AIM AND OBJECTIVES OF THE THESIS

The aim of this study is to investigate the nature of community engagement in local government and its impact on performance measurement and organizational learning. This study seeks to identify: the forces that shape community engagement; the levels and mechanisms of engagement; and how engagement drives changes in performance measurement and management. From the research results, we should gain a better understanding about the effect of community engagement on decision-making and specify critical success factors for sustainable and effective community-centered corporate governance in local government.

OBJECTIVES

- identify: the forces that shape community engagement; the levels and mechanisms of engagement; and how engagement drives changes in performance measurement and management
- gain a better understanding about the effect of community engagement on decision-making and specify community informatics success factors and other CSFs for sustainable and effective community-centered corporate governance in local government

Note: community informatics is the design & application of information and communication technologies to enable community processes and the achievement of community development objectives (Denison et al. 2003).

This study will examine and contrast the perceptions of local government managers and politicians in Victoria and Sweden about the interaction between community

engagement and the five key decision-making elements in performance management: identifying and measuring objectives; determining and measuring actions to meet these objectives; setting targets; determining accountability and reward mechanisms; and adopting information flows and learning processes. The findings will highlight commonalities and differences that managers and politicians have experienced with the interaction of community engagement, performance measurement and action – and highlight critical success factors. The study will inform policy and implementation initiatives by governments and community stakeholders by examining how and why engagement has occurred, and its impact on current decision-making and organizational learning. The study may be extended to UK and New Zealand depending on access and resourcing.

A MODEL FOR EXPLORING COMMUNITY-BASED PERFORMANCE MANAGEMENT

Performance measurement can improve the civic discourse through more specificity and facts, and also stimulate public interest and participation in matters of service quality, which can in turn encourage the work of government employees (HM-Treasury 2001). In normative literature performance measurement provides a mechanism to reconnect the community and services (Talbot 2002, p. 3) and the performance information is a catalyst for adaptation and innovation and thus the 'cornerstone' of government modernization activities (HM-Treasury 2001) but there is a gap in understanding about how it can be operationalised as 'performance management' with the necessary community emphasis.

Otley (1999) proposes a model of performance management that addresses five key elements:

1. What are the key objectives that are central to overall future success, and how does the organisation evaluate their achievement. How does the organisation determine key objectives and methods for evaluating the results achieved?
2. What strategies and plans has the organisation adopted to achieve key objectives, and what activities are necessary for plans to deliver expected results. How does the organisation assess and measure the performance of these activities?
3. What performance standards are required to achieve success with key objectives (Q1) and activities (Q2), and how are performance targets set?
4. What rewards – in the widest possible sense – or penalties will accrue to managers from success or failure in reaching performance targets.
5. What formal and informal information flows (feedforward and feedback) and learning processes are necessary for the organisation to adapt?

Otley contends that each issue is not new and has been addressed in the management control and wider management literature. However the integration of the five areas to provide a description of the overall performance management systems of an organisation is relatively novel as it provides a way of redressing the dearth of information on current practice through "…a structure for examining extant practice in a more holistic way than has previously been the case…" (Otley 1999, p. 377). The framework provides a vehicle within which the "..features of an overall control system can be assessed and evaluated" (Otley 1999, p. 369).

Whilst Otley's (1999)model gives us a less grainy view of the important decision elements facing management, the notion of how to measure the level of engagement for each of these five elements must be operationalised. Here the International Association for Public Participation provides a useful model for categories of community engagement. Community engagement varies along a spectrum of increasing public impact ranging from 'informing' to 'consulting' to 'involving' to 'collaborating' to 'empowering' (IPAA 2003). Informing provides the public with balanced and objective information to assist understanding of problems, alternatives, or solutions. Consulting gains public feedback. Involving ensures that community concerns are consistently understood and considered. Collaborating partners with the public in decision-making. Empowering places final decision-making in the hands of the community.

So to explore the effect of community engagement on decision making, we can combine Otley's (1999) five major elements of performance management system with the five IPAA categories of community engagement to provide the sort of matrix recommended by Miles and Huberman (1994) that facilitates in-depth research studies. We have developed this matrix (Figure 1) as tool for further research into the nuances of community-based performance management.

This model will form a point of departure in exploring how community engagement impacts of the different facets of decision-making that occurs within performance management. The matrix lists Otley's (1999)five key decision issues vertically down the left column. For each decision element, the matrix considers: the levels of community engagement; the mechanisms by which the engagement takes place, the forces (barriers and enablers) for engagement; and the outcomes of that engagement. In particular , we will highlight the mix between community informatics and other factors at play.

RESEARCH STAGES

A review of relevant literature has comprised the first phase of the project, and study will proceed in two stages using mixed methods. These stages involve the

Figure 1. A matrix for exploring community-based performance management

Performance management/ engagement	Level of engagement: Inform	Consult	Involve	Collaborate	Empower	Engagement: Mechanisms	Forces	Outcomes
Determining key objectives & their measurement								
Identifying activities & their measurement								
Setting performance standards								
Determining rewards (implications) for success or failure								
Adopting information flows and learning processes								

collection and analysis of quantitative and qualitative data from government managers and politicians by interview and questionnaire. Stage 1 is about identifying themes and variations around the experiences of managers and politicians with community engagement and its affect on decision-making. These perceptions will be explored using the case study method and operationalised by applying semi-structured interviews as the data collection technique. The themes and variations uncovered in Stage 1 will form the basis for Stage 2, which will further explore findings from the case research. Stage 2 will employ the survey research method, and utilise a questionnaire of closed and open questions as the data collection technique. Data analysis of variables will be in terms of frequency of states and relationships between variables.

The study uses what(Creswell 2003) terms a sequential exploratory design - where quantitative data and results assist in the interpretation of qualitative findings. Here the primary focus is to explore a nascent phenomenon. This design is appropriate to: test elements of an emergent theory; generalize the qualitative findings to different samples; and determine the distribution of a phenomenon within a chosen population.

CASE STUDY RESEARCH USING INTERVIEWS (STAGE 1):

The Interview participants will be politicians and senior government managers recruited from Australian and Swedish entities as a convenience sample (Maylor & Blackmon 2005). The convenience sample may be extended to UK and New Zealand depending on access and resourcing. Prior studies have shown the utility in benchmarking public sector management experiences in Australia against countries with similar reform agendas (Solli, Demediuk & Sims 2002; Solli, Demediuk & Sims 2005). Participants will be interviewed in order to gain their perceptions as professionals, and not as spokespersons for their organization. Only potential participants from Sweden who state that they are comfortable to be interviewed in English will proceed into the Stage 1 of the study, but these participants will also receive a copy of the semi-structured questions in Swedish and English. Protocols for qualitative research using in-depth semi-structured interviews as outlined in (Miles & Huberman 1994) and (Maylor & Blackmon 2005) will be strictly adhered to. These protocols involve issues such as: invitation to participate informed consent; permission to record the interview; confidentiality; avoidance of bias; and security of recorded and transcribed data. A list of semi-structured questions has been derived from the literature. Semi-structured questions provide an opportunity to compare perceptions about common issues across the subjects interviewed. In the course of the interview the researcher also has the opportunity to probe responses to get clarification or more detail, or to examine new relevant issues brought up by participants.

SURVEY RESEARCH USING A QUESTIONNAIRE (STAGE 2):

The in-depth semi-structured interviews (Stage 1) will be followed by a survey to further investigate the generalisability, distribution, and inter-relationships of phenomenon that are identified in the fieldwork. The survey questions will be developed with reference to the themes and variations found in the interviews from Stage 1. Final survey questions will be robustly pre-tested. Potential subjects for the survey will be politicians and senior mangers from a sample of entities with active engagement policies from Sweden and Victoria in Australia. An e-mail survey will be employed, and it is expected that the subjects would have ready access to technology. Participants can alternatively request a printed copy of the questionnaire to complete. Protocols for survey research outlined in (de Vaus 2005) will be followed. Potential participants will receive an invitation letter to participate in the survey by E-mail with the electronic questionnaire file. Participants from Sweden will receive E-mail attachments of the survey in Swedish and English.

NUMBER, TYPE AND AGE RANGE OF PARTICIPANTS:

Stage 1 interviews: The group in each location will comprise of 20 to 30 senior managers and politicians in public sector entities from Victoria (Australia) and Sweden with an age range above 21 years. Depending of progress with this data collection, resourcing, and access issues, interviews may be extended to such participants in the UK and New Zealand The proportions from each country will be an artefact of the opportunities presented through professional contacts and networks.

Stage 2 surveys: 250 individuals who are senior managers and politicians in Victorian and Swedish public sector entities with an age range above 21 years.

SOURCE OF PARTICIPANTS, AND MEANS BY WHICH PARTICIPANTS ARE TO BE RECRUITED:

Interview participants (Stage 1) will be recruited as a convenience sample from local governments in Sweden and equivalent institutions in Victoria (and possibly New Zealand and the UK) using publicly available listings of politicians and senior managers. Experience has shown a high level of interest by politicians and senior managers in Australian, Swedish, UK and New Zealand local governments to be voluntarily involved in research around performance management (Solli, Sims & Demediuk 2000). All research participants in Stages 1 will be informed at the outset about the voluntary nature of their participation, and that they may opt to back out at any time to wish to. A list of possible questions for these semi-structured interviews are:

RESEARCH QUESTIONS – STAGE 1

What happens with community engagement?

Scenario: Think about a typical program (project, function, service etc) with which you are involved – and what happens with community engagement.

Questions:

1. For each performance management element (see figure below):
2. What is the level of engagement?
3. What are the engagement mechanisms that you use?
4. What enablers/barriers have been at play in reaching these levels?
5. What are the outcomes (costs & benefits) from the engagement

STAGE 2

For Stage 2, a sample of managers and politicians will be drawn from local governments in Victoria and Sweden using publicly available databases. Letters of support for the survey will be sought from influential bodies such as the Goteborg Research Institute in Sweden and FinPro and VLGA (Victorian Local Governance Association) in Victoria. This stage will explore themes and variations uncovered in Stage 1.

Collaboration Models or What Does It Take for Collaboration to Become a Common Asset?

Barbara Flügge, Otto-von-Guericke University Magdeburg, Germany; E-mail: bfluegge@sap.com

1. INTRODUCTION

The UN E-Government Author team has been assessing the readiness of the 191 UN Member States with respect to their E-Government readiness (Nation, 2005). The analysis of more than 50.000 features on their website has been used as a first indication how ready and serious a country is applying E-Government, including E-Government related procedures and processes. It also focuses in the second part on the interaction of information technology and the role of governmental and industrial institutions with the human being, the citizen itself.

This range of the study expresses the desperate need of more advanced E-Government applications and as a consequence the ability, accessibility and ease of use of advanced technology from a Governmental perspective. (Nation, 2005), see page 16. The fifth recommendation is expressing the need of the *formulation of a development strategy based on effective and indigenously appropriate utilization of the information and communication technologies (ICTs) in each sector is required so that the market, the government and the citizen have a mutually beneficial and equitable role to play.*

It is also pointing the value-add eGovernment should provide to the entire community.

2. RESEARCH AREAS

Traditionally academic research in collaborative topics started with a specific focus on the individual elements of collaboration. The relevant elements that have been investigated are Enterprise Architecture Frameworks, Business Process Management and Modelling Techniques and eCommerce, namely B2B and eGovernment standardization initiatives.

The dissertation will explore the shift from the traditional context of eCommerce towards collaboration. Collaboration takes place in areas where business and governmental institutions meet. Historically, collaboration research analysed the nature of networks (internal and external networks), business as well as cultural relationships. Through the introduction of local networks like the *keiretsu* phenomenon in Japan (Satoshi Hamaya, 2004) eCommerce and collaboration moved towards IT enabled collaborative scenarios for many to many relationships and away from the one to one focus in eCommerce. As *keiretsu* is specifically linked and limited to the Japanese cultural and business environment, the dissertation will introduce the term ecosystem. The ecosystem illustrates participants and contributors in a pre-defined business environment such as the trade environment and their interactions.

The research is linked to ITAIDE (ITAIDE, 2006) and further activities in Europe focusing on facilitation global trade across business partners and governmental institutions. ITAIDE is an integrated project funded by the IST 6th Framework Programme of the EU which started January 2006 to address some of the key issues related to cross-border trade. Further activities are related to the standardization initiatives at UN/CEFACT where I will be a team member of a steering group for customs specific process, data and form standardization.

3. RESEARCH PROBLEM

What Subject Am I Discussing?

The topic that will be subject to the dissertation is the standardization and interoperability of Enterprise Architecture Frameworks with respect to cross-border and cross-country trade in selected EU member states. The topic fits into the EU wide initiative of the European Commission to implement electronic customs. The expected outcome is the reduction of the administrative burden for governmental authorities and business partners, the compliance of logical, data and product flows as well as assuring secure trade lanes.

The question I am discussing and answering is the following: Why is electronic collaboration still not a common asset to support daily business operations? A hypothetical answer might be that semantically correct, interpretation free contractual and negotiation agreements are not covered yet in the area of information exchange and information standardization.

4. RESEARCH METHODOLOGY

4.1. Indicators of Relevance

Why are still substantial efforts being made in spending time, money and resources to analyze the effects of eGovernment – when will they pay forward?

Accompanied by literature review, the research will use business-oriented indicators of the relevance of eGovernment such as the analysis of Lévy (Lévy, 2005), and the case of Denmark (NIELS BJØRN-ANDERSEN, 2004). These indicators will be empirically extended and categorized along my participation in the ITAIDE project.

There is a number of studies such as the e-Business Watch (Commission, 2005) and UN Report on E-Government and E-Inclusion (Nation, 2005) that point out the need of focusing on the core roles of eGovernment. The current focus goes beyond publishing web sites and providing electronic media to download documents.

Modern business-oriented research is always urged to address the need of providing financial or any other measurable evidence to get an open ear in the commercial and governmental community. The need is to proof that a concept works in real life environments. As one part of the research will be an academic driven research on governmental business cases and applying eGovernment applications within companies and legal authorities, this will be taken into account.

The expected outcome hereby is the definition and the concept of cost and process implications on transformation from customs to eCustoms as well as the definition

of the key elements for transforming another region into an eCustoms region. In this context, I will be assessing the evolvement of process and value drivers that are used in the area of performance measurement research.

4.2. Current Academic Status-Quo

In literature there has been a variety of procedure models and analysis that add to my research field.

The literature I will be assessing is on the one hand reflecting the dimensions of procedure models. Those are related to the technical understanding of collaboration (Thomas Theling, 2005), applicability of applications and the key concepts of interoperability.

In the context of process driven models there will be a brief analysis of models we find in product development (W Hesse, 1992), object oriented models (J Noack, 1999), component based modeling (Schwickert, 1998) (C Heidrich, 1998) and Business Process Management models.

In the area of collaboration research, there is a variety of collaboration related definitions and different meanings. Those need to be clarified and aligned along the research area of global trade. I will focus on inter-organizational business processes, business process management and the way of analyzing collaboration readiness. The cases studies conducted in Denmark, New Zealand and other areas provide empirical data. They indicate what has been useful so far in collaboration research and what not.

Another dimension adding to inter-organizational process analysis is the dimension of the so called ecosystem. Deriving from the ecological context, the term ecosystem got introduced by researchers to refer to the complex and mostly complete picture of a real-life environment in research. At ITAIDE the ecosystem is being represented in a research environment called the Living Laboratory (Living Lab).

A third component to the literature review is the concept of standardization. There is a limited number of analysis on real standardization concepts like RosettaNet and EDI and their contribution to the next generation of eCommerce Frameworks (T. Janner, 2006). I will refer to the UN/CEFACT approach in my research work[1]. The UN/CEFACT approach is providing a framework for standardized data models that did not reach the dissemination level yet to be applied in the software development arena (Flügge, Janner, & Schroth, 2006). ITAIDE itself is providing a collaboration ground itself. I will undertake research in the aspect of collaboration from a business-oriented, process driven and from a technical dimension.

4.3. Evaluation of Current Academic Status-Quo

Concluding the research activities as outlined before, the first milestone of the research activities will be the conclusion which components are relevant to the definition of a collaboration framework for electronic customs.

The evaluation activity will also point out the key roles that are required to move forward with the concept of electronic customs. It will equal electronic customs with the concept of collaborative living scenarios. Different roles like key initiators or early movers might be found in the governmental, academic, commercial or technical world. Wherever they are found, they are definitely required to proceed with this concept (NIELS BJØRN-ANDERSEN, 2004). The evaluation will also include the question of need of organizational adaptability, innovation and flexibility (NIELS BJØRN-ANDERSEN, 2004).

A second milestone will focus on determining common denominators of the procedure models and key differentiators relevant to all business and governmental partners in an ecosystem focusing on global trade.

The evaluation will conclude in the question how new research techniques such as the Living Lab approach support research in the area of collaboration.

4.4 Business Partner Analysis and the Ecosystem Applying Electronic Customs

This section will focus on the relationships of the distinct business partners in the way of trading and doing business. It will also explore the key elements of customs procedures within the EU and the common denominators for the participating countries. As there is no European Customs Office is in place, research might include the World Customs Office and its expectations on electronic customs and its relevance to key elements of collaboration.

From the EU 20.000 foot level it will be key to take a closer look onto the next levels such as regional and industry specific levels, the ecosystem of companies, their business partners in the supply chain for example and a pre-selected user community. Business experts and technical experts complete the assessment of the ecosystem.

The business partner analysis might also focus on political, economical, strategy and infrastructure related influencers. Those might lead to certain behaviour of accepting or denying electronic applications. Still, a detailed analysis of policy and strategic influencers is beyond the scope of the dissertation.

4.5 Process and Data Modelling

Based upon the findings above I will decide upon additional data and analysis I like to add to the research field for the technical process related research on collaboration. The research approach will be case study based.

Within my research I will use business scenarios that have been collected in the living labs of ITAIDE. Each of the business partners is applying different tools and methods to structure and describe the business process scenarios. Such tools are RosettaNet[2] and AIN[3] for example. The scenarios will focus on the interaction of the industry leaders with the legal authorities, namely the tax and custom institutions and describe the logistics, invoicing, trade and reporting processes. I will then transform the scenarios into data models by applying the UN/CEFACT data modelling approach.

4.6 Business Oriented Collaboration in Technology, Industry and Government

This chapter will focus on mapping the traditional and novel collaboration approaches to get an overview on business oriented collaboration.

Figure 1 summarizes the individual steps in the research approach.

The research will be carried out applying qualitative research methods, such as structured and unstructured interviews, questionnaires and case studies.

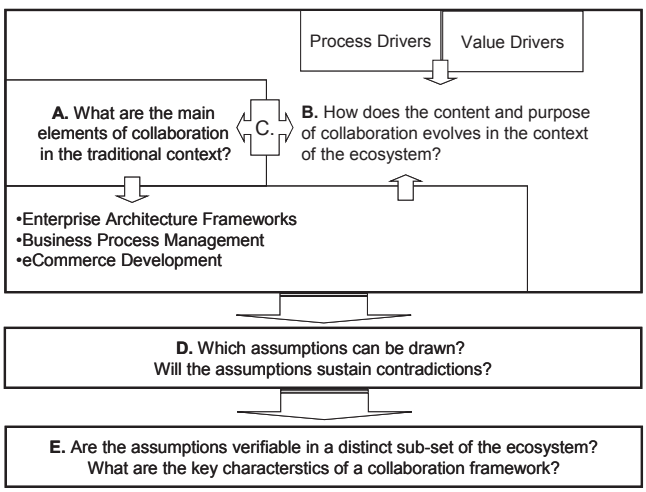
5. EXPECTED OUTCOME

The expected outcome of my research is expressed in the need of a standardization methodology to overcome any effort that is needed to transform collaboration into a common (accessible, understandable and available) asset.

The methodology should provide guidelines to add collaboration as an out-of-the-box or better built-in characteristic of any software solution that is offered in the market.

The methodology should provide in addition a framework with procedures suitable for any company regardless its size, its industry focus, its technical competence or

Figure 1. Research approach



its cultural background. Companies should not worry anymore about the following: How can we invite technically, content and document wise a new business partner to join a trade ecosystem? Which standards would the business partner need to apply or adopt to do business? Does the business partner need to adopt or enhance its information technology to join another ecosystem?
